Administering using the REST API

ALW Queue manager commands

A table of queue manager commands, showing the PCF command, MQSC command, and control command equivalents. The REST API resource and HTTP method equivalents, and IBM MQ Explorer equivalents, are included if available.

Table 1. Queue manager commands

Description	PCF command	MQSC command	Control command	REST API resource and HTTP method	IBM MQ Explorer equivalent?
Change Queue Manager	Change Queue Manager	ALTER QMGR	No equivalent		Yes
Create Queue Manager	No equivalent	No equivalent	**crtmqm**		Yes
Delete Queue Manager	No equivalent	No equivalent	**dltmqm**		Yes
Inquire Queue Manager	Inquire Queue Manager	DISPLAY QMGR	No equivalent		Yes
Inquire Queue Manager Status	Inquire Queue Manager Status	DISPLAY QMSTATUS	**dspmq**	`GET /admin/installation` `GET /admin/qmgr`	Yes
Ping Queue Manager	Ping Queue Manager	PING QMGR	No equivalent		No
Refresh Queue Manager	Refresh Queue Manager	REFRESH QMGR	No equivalent		Yes
Reset Queue Manager	Reset Queue Manager	RESET QMGR	No equivalent		No
Start Queue Manager	No equivalent	No equivalent	**strmqm**		Yes
Stop Queue Manager	No equivalent	No equivalent	**endmqm**		Yes

Related tasks

ALW Command server commands

A table of command server commands, showing the PCF command, MQSC command, and control command equivalents. The REST API resource and HTTP method equivalents, and IBM MQ Explorer equivalents, are included if available.

Table 2. Commands for command server administration

Description	PCF command	MQSC command	Control command	REST API resource and HTTP method	IBM MQ Explorer equivalent?
Display command server	Inquire Queue Manager Status	DISPLAY QMSTATUS	**dspmqcsv**		Yes
Start command server	Change Queue Manager	ALTER QMGR	**strmqcsv**		Yes
Stop command server	No equivalent	No equivalent	**endmqcsv**		Yes

ALW Authority commands

A table of authority commands, showing the PCF command, MQSC command, and control command equivalents. The REST API resource and HTTP method equivalents, and IBM MQ Explorer equivalents, are included if available.

Table 3. Commands for authority administration

PCF command	MQSC command	Control command	REST API resource and HTTP method	IBM MQ Explorer equivalent?
Delete authority record	DELETE AUTHREC	**setmqaut**		Yes
Inquire authority records	DISPLAY AUTHREC	**dmpmqaut**		Yes
Inquire entity authority	DISPLAY ENTAUTH	**dspmqaut**		Yes
Refresh Security	REFRESH SECURITY	No equivalent		Yes
Set authority record	SET AUTHREC	**setmqaut**		Yes

ALW Cluster commands

A table of cluster commands, showing the PCF command, MQSC command, and control command equivalents. The REST API resource and HTTP method equivalents, and IBM MQ Explorer equivalents, are included if available.

Table 4. Cluster commands

PCF command	MQSC command	Control command	REST API resource and HTTP method	IBM MQ Explorer equivalent?
Inquire Cluster Queue Manager	DISPLAY CLUSQMGR	No equivalent		Yes
Refresh Cluster	REFRESH CLUSTER	No equivalent		Yes
Reset Cluster	RESET CLUSTER	No equivalent		No

Table 4. Cluster commands (continued)				
PCF command	**MQSC command**	**Control command**	**REST API resource and HTTP method**	**IBM MQ Explorer equivalent?**
Resume Queue Manager Cluster	RESUME QMGR	No equivalent		Yes
Suspend Queue Manager Cluster	SUSPEND QMGR	No equivalent		Yes

ALW Authentication information commands

A table of authentication information commands, showing the PCF command, MQSC command, and control command equivalents. The REST API resource and HTTP method equivalents, and IBM MQ Explorer equivalents, are included if available.

Table 5. Authentication information commands				
PCF command	**MQSC command**	**Control command**	**REST API resource and HTTP method**	**IBM MQ Explorer equivalent?**
Change Authentication Information Object	ALTER AUTHINFO	No equivalent		Yes
Copy Authentication Information Object	DEFINE AUTHINFO(x) LIKE(y)	No equivalent		Yes
Create Authentication Information Object	DEFINE AUTHINFO	No equivalent		Yes
Delete Authentication Information Object	DELETE AUTHINFO	No equivalent		Yes
Inquire Authentication Information Object	DISPLAY AUTHINFO	No equivalent		Yes

ALW Channel commands

A table of channel commands, showing the PCF command, MQSC command, and control command equivalents. The REST API resource and HTTP method equivalents, and IBM MQ Explorer equivalents, are included if available.

Table 6. Channel commands				
PCF command	**MQSC command**	**Control command**	**REST API resource and HTTP method**	**IBM MQ Explorer equivalent?**
Change Channel	ALTER CHANNEL	No equivalent		Yes
Copy Channel	DEFINE CHANNEL(x) LIKE(y)	No equivalent		Yes
Create Channel	DEFINE CHANNEL	No equivalent		Yes
Delete Channel	DELETE CHANNEL	No equivalent		Yes

Table 6. Channel commands (continued)				
PCF command	**MQSC command**	**Control command**	**REST API resource and HTTP method**	**IBM MQ Explorer equivalent?**
Inquire Channel	DISPLAY CHANNEL	No equivalent	`GET /admin/qmgr/{qmgrName}/channel`	Yes
Inquire Channel Names	DISPLAY CHANNEL	No equivalent	`GET /admin/qmgr/{qmgrName}/channel`	Yes
Inquire Channel Status	DISPLAY CHSTATUS	No equivalent	`GET /admin/qmgr/{qmgrName}/channel`	Yes
Ping Channel	PING CHANNEL	No equivalent		Yes
Purge Channel	PURGE CHANNEL	No equivalent		Yes
Reset Channel	RESET CHANNEL	No equivalent		Yes
Resolve Channel	RESOLVE CHANNEL	No equivalent		Yes
Start Channel	START CHANNEL	**runmqchl**		Yes
Start Channel Initiator	START CHINIT	**runmqchi**		No
Stop Channel	STOP CHANNEL	No equivalent		Yes

ALW Listener commands

A table of listener commands, showing the PCF command, MQSC command, and control command equivalents. The REST API resource and HTTP method equivalents, and IBM MQ Explorer equivalents, are included if available.

Table 7. Listener commands				
PCF command	**MQSC command**	**Control command**	**REST API resource and HTTP method**	**IBM MQ Explorer equivalent?**
Change Listener	ALTER LISTENER	No equivalent		Yes
Copy Listener	DEFINE LISTENER(x) LIKE(y)	No equivalent		Yes
Create Listener	DEFINE LISTENER	No equivalent		Yes
Delete Listener	DELETE LISTENER	No equivalent		Yes
Inquire Listener	DISPLAY LISTENER	No equivalent		Yes
Inquire Listener Status	DISPLAY LSSTATUS	No equivalent		Yes
Start Channel Listener	START LISTENER "1" on page 10	**runmqlsr**		Yes
Stop Listener	STOP LISTENER	**endmqlsr** "2" on page 10		Yes

Table 7. Listener commands (continued)				
PCF command	**MQSC command**	**Control command**	**REST API resource and HTTP method**	**IBM MQ Explorer equivalent?**
Notes: 1. Used with listener objects only 2. Stops all active listeners				

ALW Namelist commands

A table of namelist commands, showing the PCF command, MQSC command, and control command equivalents. The REST API resource and HTTP method equivalents, and IBM MQ Explorer equivalents, are included if available.

Table 8. Namelist commands				
PCF command	**MQSC command**	**Control command**	**REST API resource and HTTP method**	**IBM MQ Explorer equivalent?**
Change Namelist	ALTER NAMELIST	No equivalent		Yes
Copy Namelist	DEFINE NAMELIST(x) LIKE(y)	No equivalent		Yes
Create Namelist	DEFINE NAMELIST	No equivalent		Yes
Delete Namelist	DELETE NAMELIST	No equivalent		Yes
Inquire Namelist	DISPLAY NAMELIST	No equivalent		Yes
Inquire Namelist Names	DISPLAY NAMELIST	No equivalent		Yes

ALW Process commands

A table of process commands, showing the PCF command, MQSC command, and control command equivalents. The REST API resource and HTTP method equivalents, and IBM MQ Explorer equivalents, are included if available.

Table 9. Process commands				
PCF command	**MQSC command**	**Control command**	**REST API resource and HTTP method**	**IBM MQ Explorer equivalent?**
Change Process	ALTER PROCESS	No equivalent		Yes
Copy Process	DEFINE PROCESS(x) LIKE(y)	No equivalent		Yes
Create Process	DEFINE PROCESS	No equivalent		Yes
Delete Process	DELETE PROCESS	No equivalent		Yes
Inquire Process	DISPLAY PROCESS	No equivalent		Yes
Inquire Process Names	DISPLAY PROCESS	No equivalent		Yes

ALW Queue commands

A table of queue commands, showing the PCF command, MQSC command, and control command equivalents. The REST API resource and HTTP method equivalents, and IBM MQ Explorer equivalents, are included if available.

Table 10. Queue commands

PCF command	MQSC command	Control command	REST API resource and HTTP method	IBM MQ Explorer equivalent?
Change Queue	ALTER QLOCAL ALTER QALIAS ALTER QMODEL ALTER QREMOTE	No equivalent	`PATCH /admin/qmgr/{qmgrName}/queue`	Yes
Clear Queue	CLEAR QLOCAL	No equivalent		Yes
Copy Queue	DEFINE QLOCAL(x) LIKE(y) DEFINE QALIAS(x) LIKE(y) DEFINE QMODEL(x) LIKE(y) DEFINE QREMOTE(x) LIKE(y)	No equivalent		Yes
Create Queue	DEFINE QLOCAL DEFINE QALIAS DEFINE QMODEL DEFINE QREMOTE	No equivalent	`POST /admin/qmgr/{qmgrName}/queue`	Yes
Delete Queue	DELETE QLOCAL DELETE QALIAS DELETE QMODEL DELETE QREMOTE	No equivalent	`DELETE /admin/qmgr/{qmgrName}/queue`	Yes
Inquire Queue	DISPLAY QUEUE	No equivalent	`GET /admin/qmgr/{qmgrName}/queue`	Yes
Inquire Queue Names	DISPLAY QUEUE	No equivalent		Yes
Inquire Queue Status	DISPLAY QSTATUS	No equivalent	`GET /admin/qmgr/{qmgrName}/queue`	Yes
Reset Queue Statistics	No equivalent	No equivalent		No

ALW Service commands

A table of service commands, showing the PCF command, MQSC command, and control command equivalents. The REST API resource and HTTP method equivalents, and IBM MQ Explorer equivalents, are included if available.

Table 11. Service commands

PCF command	MQSC command	Control command	REST API resource and HTTP method	IBM MQ Explorer equivalent?
Change Service	ALTER SERVICE	No equivalent		Yes
Copy Service	DEFINE SERVICE(x) LIKE(y)	No equivalent		Yes
Create Service	DEFINE SERVICE	No equivalent		Yes
Delete Service	DELETE SERVICE	No equivalent		Yes
Inquire Service	DISPLAY SERVICE	No equivalent		Yes
Inquire Service Status	DISPLAY SVSTATUS	No equivalent		Yes
Start Service	START SERVICE	No equivalent		Yes
Stop Service	STOP SERVICE	No equivalent		Yes

ALW Other commands

A table of other commands, showing the command description, and its PCF command, MQSC command, and control command equivalents. The REST API resource and HTTP method equivalents, and IBM MQ Explorer equivalents, are included if available.

Table 12. Other commands

Description	PCF command	MQSC command	Control command	REST API resource and HTTP method	IBM MQ Explorer equivalent?
Create conversion exit	No equivalent	No equivalent	**crtmqcvx**		No
Display files used by objects	No equivalent	No equivalent	**dspmqfls**		No
Display formatted trace	No equivalent	No equivalent	**dspmqtrc** "1" on page 13		No
Display version information	No equivalent	No equivalent	**dspmqver**		No
Display transactions	No equivalent	No equivalent	**dspmqtrn**		No
Dump log	No equivalent	No equivalent	**dmpmqlog**		No
Dump MQ Configuration	No equivalent	No equivalent	**dmpmqcfg**		No
End trace	No equivalent	No equivalent	**endmqtrc**		Yes

Table 12. Other commands (continued)

Description	PCF command	MQSC command	Control command	REST API resource and HTTP method	IBM MQ Explorer equivalent?
Escape	Escape	No equivalent	No equivalent	`POST /admin/action/qmgr/{qmgrName}/mqsc`	No
Record media image	No equivalent	No equivalent	**rcdmqimg**		No
Re-create media object	No equivalent	No equivalent	**rcrmqobj**		No
Resolve transactions	No equivalent	No equivalent	**rsvmqtrn**		No
Run client trigger monitor	No equivalent	No equivalent	**runmqtmc**		No
Run dead-letter queue handler	No equivalent	No equivalent	**runmqdlq**		No
Run MQSC commands	No equivalent	No equivalent	**runmqsc**		No
Run trigger monitor	No equivalent	No equivalent	**runmqtrm**		No
Set service connection points	No equivalent	No equivalent	**setmqscp** "2" on page 13		No
Start IBM MQ trace	No equivalent	No equivalent	**strmqtrc**		Yes
IBM MQ Services control	No equivalent	No equivalent	**amqmdain** "2" on page 13		No

Notes:

1. Not supported on IBM MQ for Windows.
2. Supported by IBM MQ for Windows only.

IBM MQ control commands reference

Reference information about the IBM MQ control commands.

For information about running these commands, see Administration using the control commands.

ALW addmqinf (add configuration information)

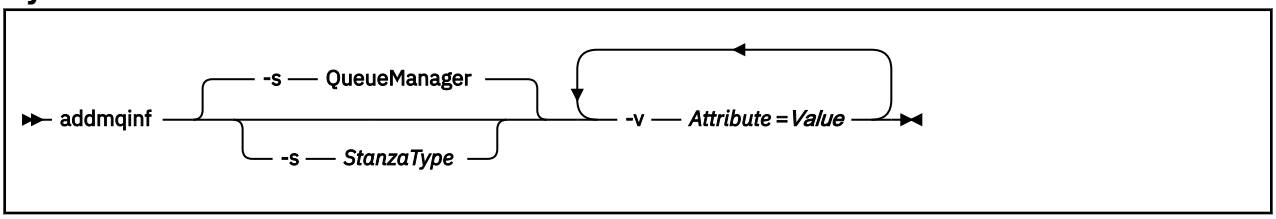
Add IBM MQ configuration information on AIX, Linux, and Windows only.

Purpose

Use the **addmqinf** command to add information to the IBM MQ configuration data.

For example, use **dspmqinf** to display and **addmqinf** to copy configuration data from the system where a queue manager was created, to other systems where the same multi-instance queue manager is also to be started.

Syntax



Required parameters

-v *Attribute* = *Value*

The name and value of the stanza attributes to be placed in the stanza specified in the command.

Table 13 on page 14 lists the QueueManager stanza attribute values. The queue manager stanza is the only stanza that is currently supported.

Table 13. QueueManager stanza attributes

Attribute	***Value***	**Required or optional**
Name	The name of the queue manager. You must provide a different name from any other queue manager stanza on the system.	Required
Prefix	The directory path under which this queue manager data directory is stored by default. You can use **Prefix** to modify the location of the queue manager data directories. The value of **Directory** is automatically appended to this path.	Required
Directory	The name of the queue manager data directory. Sometimes the name must be provided (as in "Example" on page 15), because it is different from the queue manager name. Copy the directory name from the value returned by **dspmqinf**. The rules for transforming queue manager names into directory names are described in Understanding IBM MQ file names.	Required
DataPath	The directory path where the queue manager data files are placed. The value of **Directory** is not automatically appended to this path and you must provide the transformed queue manager name as part of **DataPath**. Linux AIX If the **DataPath** attribute is omitted on AIX and Linux, the queue manager data directory path is defined as ***Prefix*** / ***Directory*** .	Linux AIX On AIX and Linux: Optional Windows On Windows: Required
V 9.2.0 **EphemeralPrefix**	Specifies the path to the directory, within which the queue manager ephemeral data is kept, such as IPC sockets. If the **EphemeralPrefix** attribute is omitted, the queue manager ephemeral prefix is defined as `Prefix`.	Optional

Optional parameters

-s *StanzaType*

A stanza of the type *StanzaType* is added to the IBM MQ configuration.

The default value of *StanzaType* is `QueueManager`.

The only supported value of *StanzaType* is `QueueManager`.

Return codes

Table 14. Return code identifiers and descriptions

Return code	Description
0	Successful operation
1	Queue manager location is invalid (either **Prefix** or **DataPath**)
39	Bad command-line parameters
45	Stanza already exists
46	Required configuration attribute is missing
58	Inconsistent use of installations detected
69	Storage is not available
71	Unexpected error
72	Queue manager name error
100	Log location is invalid

Example

```
addmqinf -v DataPath=/MQHA/qmgrs/QM!NAME +
  -v Prefix=/var/mqm  +
  -v Directory=QM!NAME  +
  -v Name=QM.NAME
```

Creates the following stanza in mqs.ini:

```
QueueManager:
   Name=QM.NAME
   Prefix=/var/mqm
   Directory=QM!NAME
   DataPath=/MQHA/qmgrs/QM!NAME
```

Usage notes

Use **dspmqinf** with **addmqinf** to create an instance of a multi-instance queue manager on a different server.

To use this command you must be an IBM MQ administrator and a member of the `mqm` group.

Related commands

Table 15. Related commands and their descriptions

Command	Description
“dspmqinf (display configuration information)” on page 76	Display IBM MQ configuration information

Table 15. Related commands and their descriptions (continued)

Command	Description
"rmvmqinf (remove configuration information)" on page 135	Remove IBM MQ configuration information

Windows amqmdain (services control)

amqmdain is used to configure or control some Windows specific administrative tasks.

Purpose

The **amqmdain** command applies to IBM MQ for Windows only.

You can usse **amqmdain** to perform some Windows specific administrative tasks.

Starting a queue manager with **amqmdain** is equivalent to using the **strmqm** command with the option `-ss`. **amqmdain** makes the queue manager run in a non-interactive session under a different user account. However, to ensure that all queue manager startup feedback is returned to the command line, use the `strmqm -ss` command rather than **amqmdain**.

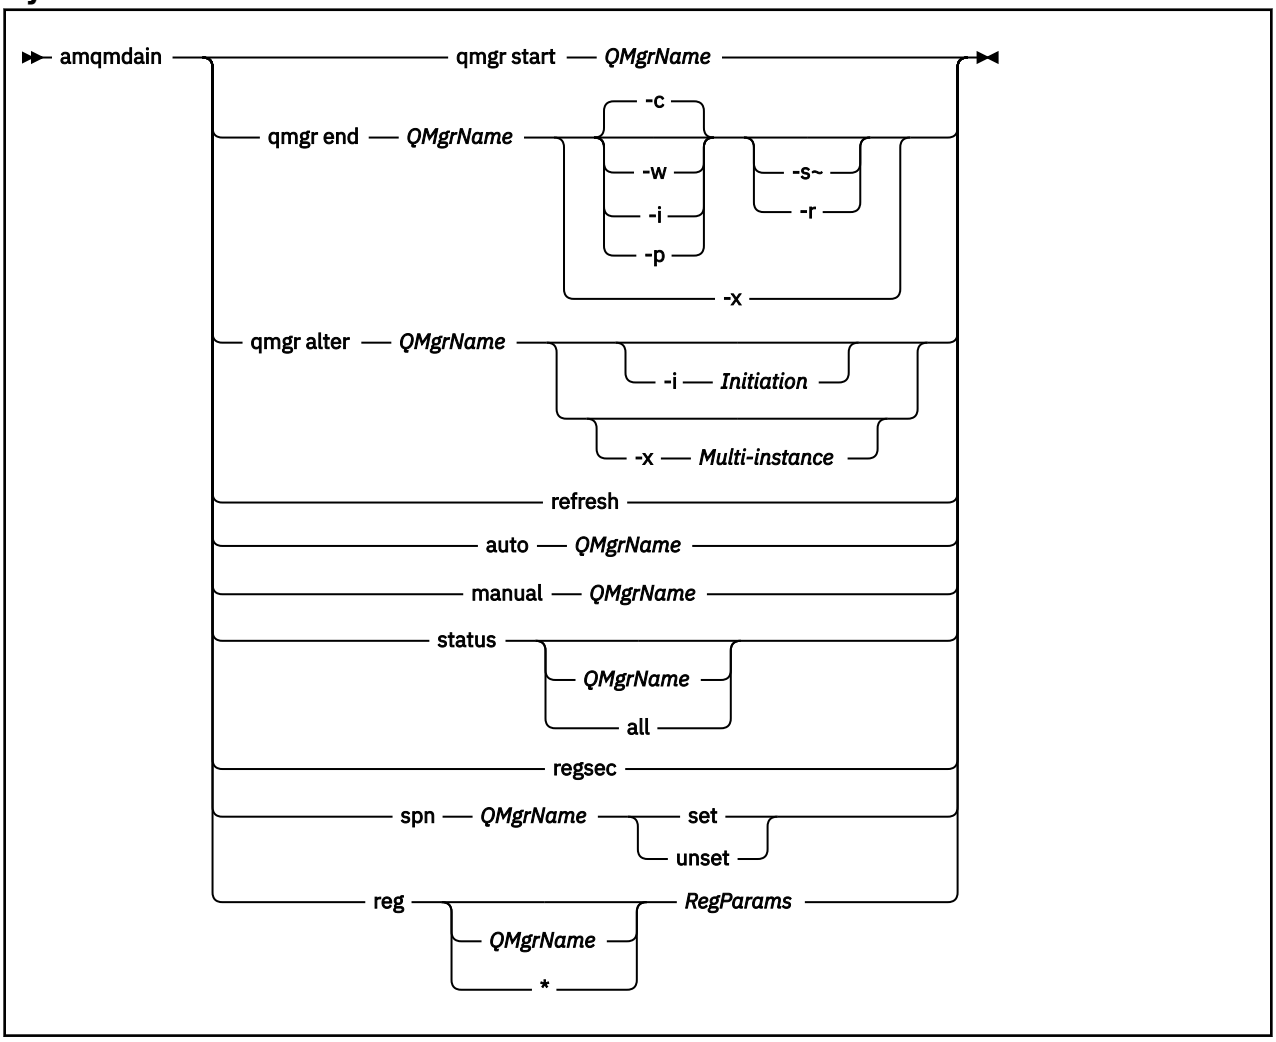
You must use the **amqmdain** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the **dspmq** command as follows:

```
dspmq -o installation
```

To administer and define IBM MQ service and listener objects, use MQSC commands, PCF commands, or the IBM MQ Explorer.

The **amqmdain** command has been updated to modify either the `.ini` files or the registry as appropriate.

Syntax



Keywords and parameters

All parameters are required unless the description states they are optional.

In every case, *QMgrName* is the name of the queue manager to which the command applies.

qmgr start *QMgrName*
Starts a queue manager.

This parameter can also be written in the form *start QMgrName*.

If you start your queue manager as a service and need the queue manager to continue to run after logoff, use `strmqm -ss qmgr` instead of `amqmdain start qmgr`.

qmgr end *QMgrName*
Ends a queue manager.

This parameter can also be written in the form **end QMgrName**.

For consistency across platforms, use `endmqm qmgr` instead of `amqmdain end qmgr`.

For fuller descriptions of the options, see “endmqm (end queue manager)” on page 105.

-c
Controlled (or quiesced) shutdown.

-w
Wait shutdown.

-i
Immediate shut down.

-p
Pre-emptive shut down.

-r
Reconnect clients.

-s
Switch over to a standby queue manager instance.

-x
End the standby instance of the queue manager without ending the active instance.

qmgr alter *QMgrName*
Alters a queue manager.

-i *Initiation*
Specifies the initiation type. Possible values are:

Table 16. Initiation command parameters.

Value	Description
`auto`	Sets the queue manager to automatic startup (when the machine starts, or more precisely when the IBM MQ service starts). The syntax is: `amqmdain qmgr alter QmgrName -i auto`
`interactive`	Sets the queue manager to manual startup that then runs under the logged on (interactive) user. The syntax is: `amqmdain qmgr alter QmgrName -i interactive`
`service`	Sets the queue manager to manual startup that then runs as a service. The syntax is: `amqmdain qmgr alter QmgrName -i service`

-x *Multi-instance*
Specifies if `auto` queue manager start by the IBM MQ service permits multiple instances. Equivalent to the `-sax` option on the **crtmqm** command. Also specifies if the **amqmdain start** `qmgr` command permits standby instances. Possible values are:

Table 17. Multi-instance command parameters.

Value	Description
`set`	Sets automatic queue manager startup to permit multiple instances. Issues **strmqm -x** . The `set` option is ignored for queue managers that are initiated interactively or as a manual service startup. The syntax of the command is: `amqmdain qmgr alter QmgrName -x set`

Table 17. Multi-instance command parameters. (continued)	
Value	**Description**
`unset`	Sets automatic queue manager startup to single instance. Issues **strmqm**. The `unset` option is ignored for queue managers that are initiated interactively or as a manual service startup. The syntax of the command is: `amqmdain qmgr alter QmgrName -x unset`

refresh
Refreshes or checks the status of a queue manager. You will not see anything returned on the screen after executing this command.

auto *QMgrName*
Sets a queue manager to automatic startup.

manual *QMgrName*
Sets a queue manager to manual startup.

status *QMgrName*| all
These parameters are optional.

Table 18. Status command parameters.	
Header	**Header**
If no parameter is supplied:	Displays the status of the IBM MQ services.
If a *QMgrName* is supplied:	Displays the status of the named queue manager.
If the parameter *all* is supplied:	Displays the status of the IBM MQ services and all queue managers.

regsec
Ensures that the security permissions assigned to the Registry keys containing installation information are correct.

spn *QMgrName* set | unset
You can set or unset the service principal name for a queue manager.

reg *QMgrName*| * *RegParams*
Parameters *QMgrName*, and * are optional.

Table 19. Reg command parameters.	
Value	**Description**
If *RegParams* is specified alone:	Modifies queue manager configuration information related to the default queue manager.
If *QMgrName* and *RegParams* are specified:	Modifies queue manager configuration information related to the queue manager specified by *QMgrName*.
If * and *RegParams* are specified:	Modifies IBM MQ configuration information.

The parameter, *RegParams*, specifies the stanzas to change, and the changes that are to be made. *RegParams* takes one of the following forms:

- `-c add -s stanza -v attribute= value`
- `-c remove -s stanza -v [attribute|*]`
- `-c display -s stanza -v [attribute|*]`

If you are specifying queue manager configuration information, the valid values for *stanza* are:

```
XAResourceManager\name
ApiExitLocal\name
Channels
ExitPath
InstanceData
Log
QueueManagerStartup
TCP
LU62
SPX
NetBios
Connection
QMErrorLog
Broker

ExitPropertiesLocal
SSL
```

If you are modifying IBM MQ configuration information, the valid values for *stanza* are:

```
ApiExitCommon\name
ApiExitTemplate\name
ACPI
AllQueueManagers
Channels
DefaultQueueManager
LogDefaults
ExitProperties
```

Note the following usage considerations:

- **amqmdain** does not validate the values you specify for *name*, *attribute*, or *value*.
- When you specify add, and an attribute exists, it is modified.
- If a stanza does not exist, **amqmdain** creates it.
- When you specify remove, you can use the value * to remove all attributes.
- When you specify display, you can use the value * to display all attributes which have been defined. This value only displays the attributes which have been defined and not the complete list of valid attributes.
- If you use remove to delete the only attribute in a stanza, the stanza itself is deleted.
- Any modification you make to the Registry re-secures all IBM MQ Registry entries.

Examples

The following example adds an XAResourceManager to queue manager TEST. The commands issued are:

```
amqmdain reg TEST -c add -s XAResourceManager\Sample -v SwitchFile=sf1
amqmdain reg TEST -c add -s XAResourceManager\Sample -v ThreadOfControl=THREAD
amqmdain reg TEST -c add -s XAResourceManager\Sample -v XAOpenString=openit
amqmdain reg TEST -c add -s XAResourceManager\Sample -v XACloseString=closeit
```

To display the values set by the commands, use:

```
amqmdain reg TEST -c display -s XAResourceManager\Sample -v *
```

The display would look something like the following:

```
0784726, 5639-B43 (C) Copyright IBM Corp. 1994, 2025. ALL RIGHTS RESERVED.
Displaying registry value for Queue Manager 'TEST'
        Attribute = Name, Value = Sample
        Attribute = SwitchFile, Value = sf1
        Attribute = ThreadOfControl, Value = THREAD
        Attribute = XAOpenString, Value = openit
        Attribute = XACloseString, Value = closeit
```

To remove the XAResourceManager from queue manager TEST, use:

```
amqmdain reg TEST -c remove -s XAResourceManager\Sample -v *
```

Return codes

Table 20. Return code identifiers and descriptions

Return code	Description
0	Command completed normally
-2	Syntax error
-3	Failed to initialize MFC
-6	Feature no longer supported
-7	Configuration failed
-9	Unexpected Registry error
-16	Failed to configure service principal name
-29	Inconsistent use of installations detected
62	The queue manager is associated with a different installation
71	Unexpected error
Windows 119	Permission denied (Windows only)

Note:

1. If the **qmgr start QMgrName** command is issued, all return codes that can be returned with **strmqm**, can be returned here also. For a list of these return codes, see “strmqm (start queue manager)” on page 220.
2. If the **qmgr end QMgrName** command is issued, all return codes that can be returned with **endmqm**, can be returned here also. For a list of these return codes, see “endmqm (end queue manager)” on page 105.

End the IBM MQ service on Windows.

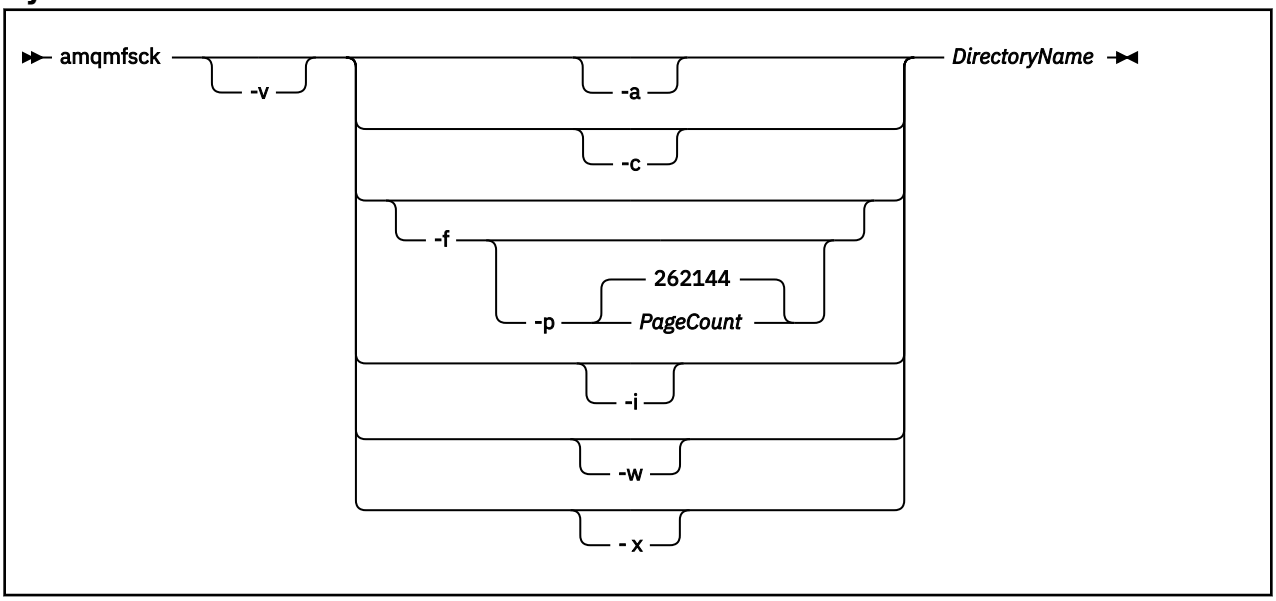
Linux IBM i AIX amqmfsck (file system check)

amqmfsck checks whether a shared file system on IBM i, AIX and Linux systems meets the requirements for storing the queue manager data of a multi-instance queue manager.

Purpose

The **amqmfsck** command applies only to IBM i, AIX and Linux systems. You do not need to check the network drive on Windows. **amqmfsck** tests that a file system correctly handles concurrent writes to a file and the waiting for and releasing of locks.

Syntax



Required parameters

DirectoryName
The name of the directory to check.

Optional parameters

-a
Perform the second phase of the data integrity test.

Run this on two machines at the same time. You must have formatted the test file using the `-f` option previously

-c
Test writing to a file in the directory concurrently.

-f
Perform the first phase of the data integrity test.

Formats a file in the directory in preparation for data integrity testing.

-i
Perform the third phase of the data integrity test.

Checks the integrity of the file after the failure to discover whether the test worked.

-p
Specifies the size of the test file used in the data integrity test in pages. .

The size is rounded up to the nearest multiple of 16 pages. The file is formatted with *PageCount* pages of 4 KB.
The optimum size of the file depends on the speed of the filesystem and the nature of the test you perform. If this parameter is omitted, the test file is 262144 pages, or 1 GB.
The size is automatically reduced so that the formatting completes in about 60 seconds even on a very slow filesystem.

-v
Verbose output.

-w
Test waiting for and releasing locks.

-x

Deletes any files created by **amqmfsck** during the testing of the directory.

Do not use this option until you have completed the testing, or if you need to change the number of pages used in the integrity test.

Usage

You must be an IBM MQ Administrator to run the command. You must have read/write access to the directory being checked.

IBM i On IBM i, use QSH to run the program. There is no CL command.

The command returns an exit code of zero if the tests complete successfully.

The task, Verifying shared file system behavior, describes how to use **amqmfsck** to check the whether of a file system is suitable for multi-instance queue managers.

Interpreting your results

If the check fails, the file system is not capable of being used by IBM MQ queue managers. If the tests fail, choose verbose mode to help you to interpret the errors. The output from the `verbose` option helps you understand why the command failed, and if the problem can be solved by reconfiguring the file system.

Sometimes the failure might be an access control problem that can be fixed by changing directory ownership or permissions. Sometimes the failure can be fixed by reconfiguring the file system to behave in a different way. For example, some file systems have performance options that might need to be changed. It is also possible that the file system protocol does not support concurrency sufficiently robustly, and you must use a different file system. For example, you must use NFSv4 rather than NFSv3.

If the check succeeds, the command reports `The tests on the directory completed successfully`. If your environment is not listed as supported in the Testing statement for IBM MQ multi-instance queue manager file systems, this result does not necessarily mean that you can run IBM MQ multi-instance queue managers successfully.

You must plan and run a variety of tests to satisfy yourself that you have covered all foreseeable circumstances. Some failures are intermittent, and there is a better chance of discovering them if you run the tests more than once.

Related tasks

Verifying shared file system behavior

crtmqcvx (create data conversion code)

Create data conversion code from data type structures.

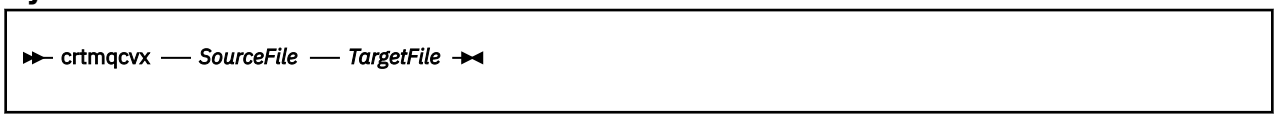
Purpose

Use the **crtmqcvx** command to create a fragment of code that performs data conversion on data type structures. The command generates a C function that can be used in an exit to convert C structures.

The command reads an input file containing structures to be converted, and writes an output file containing code fragments to convert those structures.

For information about using this command, see Utility for creating conversion-exit code.

Syntax



Required parameters

SourceFile
The input file containing the C structures to convert.

TargetFile
The output file containing the code fragments generated to convert the structures.

Return codes

Table 21. Return code identifiers and descriptions

Return code	Description
0	Command completed normally
10	Command completed with unexpected results
20	An error occurred during processing

Examples

The following example shows the results of using the data conversion command against a source C structure. The command issued is:

```
crtmqcvx source.tmp target.c
```

The input file, `source.tmp`, looks like this:

```
/* This is a test C structure which can be converted by the */
/* crtmqcvx utility                                         */

struct my_structure
{
    int    code;
    MQLONG value;
};
```

The output file, `target.c`, produced by the command, looks like this:

```
MQLONG Convertmy_structure(
             PMQDXP  pExitParms,
             PMQBYTE *in_cursor,
             PMQBYTE *out_cursor,
             PMQBYTE in_lastbyte,
             PMQBYTE out_lastbyte,
             MQHCONN hConn,
             MQLONG  opts,
             MQLONG  MsgEncoding,
             MQLONG  ReqEncoding,
             MQLONG  MsgCCSID,
             MQLONG  ReqCCSID,
             MQLONG  CompCode,
             MQLONG  Reason)
{
    MQLONG ReturnCode = MQRC_NONE;

    ConvertLong(1); /* code */

    AlignLong();
    ConvertLong(1); /* value */

Fail:
    return(ReturnCode);
}
```

You can use these code fragments in your applications to convert data structures. However, if you do so, the fragment uses macros supplied in the header file `amqsvmha.h`.

ALW crtmqdir (create IBM MQ directories)

Create, check, and correct IBM MQ directories and files.

Purpose

Use the **crtmqdir** command to check that the necessary directories and files used by IBM MQ exist and have the appropriate ownership and permissions. The command can optionally create any missing directories or files, and correct any inconsistent ownership or permissions.

Attention: The scope of this command is MQ_DATA_PATH which, for example, is `/var/mqm` on Linux. This command does not affect MQ_INSTALLATION_PATH, which is `/opt/mqm` on Linux.

The system-wide directories and files are created as part of the IBM MQ installation procedure. The tool can subsequently be run to check or ensure that the necessary IBM MQ directories and files continue to have appropriate ownership and permissions.

Important:

1. You must have sufficient permission to determine whether the configuration is correct and, optionally, correct that configuration.
2. When you use the **-a** parameter, no queue managers can be running.
3. When you use the **-m** parameter, the queue manager you specified must be stopped.
4. You must not create, delete, or start any queue managers while **crtmqdir** is running.

Linux AIX On AIX and Linux, this typically means that you are the `mqm` user. This is necessary when using the **-a** or **-m** parameters, together with the **-f** parameter.

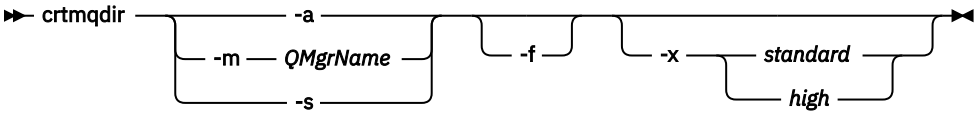
Depending on the configuration, the **crtmqdir** command might require you to be an operating system administrator, or superuser.

Note: Linux AIX The security of *data path*`/log/`*qm*, on AIX and Linux, is set to 2770.

Windows On Windows, this typically means that you are a member of the IBM MQ administration group. This is necessary when using the **-a** or **-m** parameters.

IBM i On IBM i, you must run the command as a member of the IBM MQ administrative group. This is necessary when using the **-a** or **-m** parameters, together with the **-f** parameter.

Syntax



Required parameters

Specify one of the following parameters only:

-a
Check all directories; that is, system-wide directories and all the queue managers.

Attention: The queue manager must be associated with the current installation.

-m
Check directories for the specified queue manager name.

Attention: The queue manager must be associated with the current installation.

-s
Check the system-wide directories; that is, directories that are not queue manager specific.

Optional parameters

-f
This option causes directories or files to be created if they are missing, and on AIX and Linux only, ownership or permissions to be corrected if they are inappropriately set.

If **-a** or **-m** is specified on AIX and Linux, as a minimum, the program attempts to correct ownership or permissions on files that were created at the time of queue manager creation.

-x *level of permissions*
Specify one of the following values only:

standard
By default, directories and files get a standard set of permissions, but a high level of permissions can be requested.

high
This option applies to the following platforms:

- AIX AIX
- Linux Linux

It ensures that files in the following directories can be deleted only by the owner:

- errors
- trace
- webui

Return codes

Table 22. Return code identifiers and descriptions

Return code	Description
0	Successful completion
10	A warning occurred
20	An error occurred

Examples

- The following command checks and fixes the system-wide directories:

```
crtmqdir -s -f
```

- The following command checks (but does not fix) queue manager QM1:

```
crtmqdir -m Qm1
```

ALW crtmqenv (create IBM MQ environment)

Create a list of environment variables for an installation of IBM MQ, on AIX, Linux, and Windows.

Purpose

You can use the **crtmqenv** command to create a list of environment variables with the appropriate values for an installation of IBM MQ. The list of environment variables is displayed on the command line, and any variables that exist on the system have the IBM MQ values added to them. This command does not set the environment variables for you, but gives you the appropriate strings to set the variables yourself, for example, within your own scripts.

If you want the environment variables set for you in a shell environment, you can use the **setmqenv** command instead of using the **crtmqenv** command.

You can specify which installation the environment is created for by specifying a queue manager name, an installation name, or an installation path. You can also create the environment for the installation that issues the **crtmqenv** command by issuing the command with the **-s** parameter.

This command lists the following environment variables, and their values, appropriate to your system:

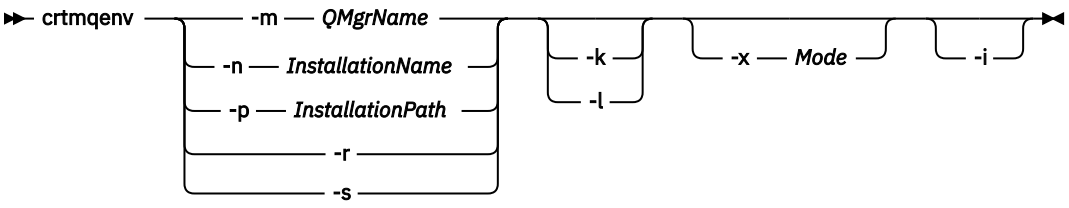
- CLASSPATH
- INCLUDE
- LIB
- MANPATH
- MQ_DATA_PATH
- MQ_ENV_MODE
- MQ_FILE_PATH
- MQ_INSTALLATION_NAME
- MQ_INSTALLATION_PATH
- MQ_JAVA_INSTALL_PATH
- MQ_JAVA_DATA_PATH
- MQ_JAVA_LIB_PATH
- MQ_JAVA_JVM_FLAG
- MQ_JRE_PATH

- PATH

Usage notes

The **crtmqenv** command removes all directories for all IBM MQ installations from the environment variables before adding new references to the installation for which you are setting up the environment. Therefore, if you want to set any additional environment variables that reference IBM MQ, set the variables after issuing the **crtmqenv** command. For example, if you want to add *MQ_INSTALLATION_PATH*/java/lib to *LD_LIBRARY_PATH*, you must do so after running **crtmqenv**.

Syntax



Required Parameters

-m *QMgrName*
Create the environment for the installation associated with the queue manager *QMgrName*.

-n *InstallationName*
Create the environment for the installation named *InstallationName*.

-p *InstallationPath*
Create the environment for the installation in the path *InstallationPath*.

-r
Remove all installations from the environment.

-s
Create the environment for the installation that issued the command.

Optional Parameters

Linux AIX **-k**
Applies to AIX and Linux only. If the **-k** flag is specified:

- AIX On AIX, the *LIBPATH* environment variable is set.
- Linux On Linux, the *LD_LIBRARY_PATH* environment variable is set.

Include the *LD_LIBRARY_PATH*, or *LIBPATH*, environment variable in the environment, adding the path to the IBM MQ libraries at the start of the current *LD_LIBRARY_PATH*, or *LIBPATH*, variable.

Linux AIX **-l**
Applies to AIX and Linux only. If the **-l** flag is specified:

- AIX On AIX, the *LIBPATH* environment variable is set.
- Linux On Linux, the *LD_LIBRARY_PATH* environment variable is set.

Include the *LD_LIBRARY_PATH*, or *LIBPATH*, environment variable in the environment, adding the path to the IBM MQ libraries at the end of the current *LD_LIBRARY_PATH*, or *LIBPATH*, variable.

-x *Mode*
Mode can take the value 32, or 64.

Create a 32-bit or 64-bit environment:

- If you specify -x 32, the PATH environment variable is changed to add a prefix to the binary path for 32 bit executables.
- If you specify -x 64, the PATH environment variable is changed to add a prefix to the binary path for 64 bit executables.

If this parameter is not specified, the environment matches that of the queue manager or installation specified in the command.

Any attempt to display a 64-bit environment with a 32-bit installation fails.

-i

List only the additions to the environment.

When this parameter is specified, the environment variables set for previous installations remain in the environment variable path and must be manually removed.

Return codes

Table 23. Return code identifiers and descriptions

Return code	Description
0	Command completed normally.
10	Command completed with unexpected results.
20	An error occurred during processing.

Examples

The following examples assume that a copy of IBM MQ is installed in `/opt/mqm` on an AIX or Linux system.

1. This command creates a list of environment variables for an installation installed in `/opt/mqm`:

```
/opt/mqm/bin/crtmqenv -s
```

2. This command creates a list of environment variables for an installation installed in `/opt/mqm2`, and includes the path to the installation at the end of the current value of the *LD_LIBRARY_PATH* variable:

```
/opt/mqm/bin/crtmqenv -p /opt/mqm2 -l
```

3. This command creates a list of environment variables for the queue manager `QM1`, in a 32-bit environment:

```
/opt/mqm/bin/crtmqenv -m QM1 -x 32
```

The following example assumes that a copy of IBM MQ is installed in `C:\Program Files\IBM\MQ` on a Windows system.

1. This command creates a list of environment variables for an installation called `installation1`:

```
"C:\Program Files\IBM\MQ\crtmqenv" -n installation1
```

Related concepts

Multiple installations

Related tasks

Choosing a primary installation

Related reference

“setmqenv (set IBM MQ environment)” on page 191

Use the **setmqenv** command to set up the IBM MQ environment on AIX, Linux, and Windows.

Linux AIX crtmqinst (create IBM MQ installation)

Create installation entries in `mqinst.ini` on AIX and Linux systems.

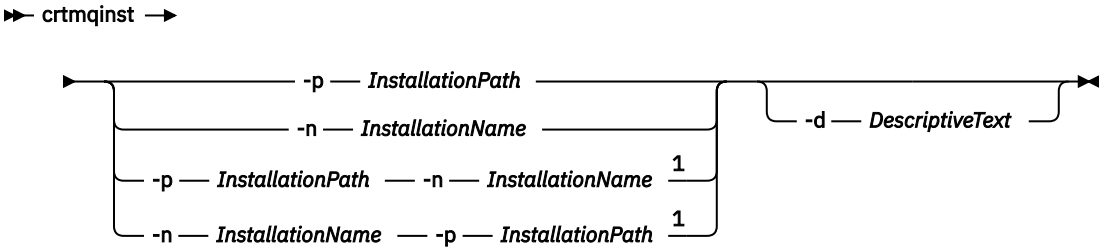
Purpose

File `mqinst.ini` contains information about all IBM MQ installations on a system. For more information about `mqinst.ini`, see Installation configuration file, mqinst.ini.

Attention: Only the user `root` can run this command.

The first IBM MQ installation is automatically given an installation name of `Installation1` because the **crtmqinst** command is not available until an installation of IBM MQ is on the system. Subsequent installations can have an installation name set before installation occurs, by using the **crtmqinst** command. The installation name cannot be changed after installation. For more information about installation names, see Choosing an installation name.

Syntax



Notes:

[1] When specified together, the installation name and installation path must refer to the same installation.

Parameters

-d
Text that describes the installation.

The text can be up to 64 single-byte characters, or 32 double-byte characters. The default value is all blanks. You must use quotation marks around the text if it contains spaces.

-n *InstallationName*
The name of the installation.

The name can contain up to 16 single-byte characters and must be a combination of alphabetic and numeric characters in the ranges a-z, A-Z, and 0-9. The installation name must be unique, regardless of whether uppercase or lowercase characters are used. For example, the names `INSTALLATIONNAME` and `InstallationName` are not unique.

If you do not supply the installation name, the next available name in the series Installation1, Installation2... is used.

-p *InstallationPath*
The installation path. If you do not supply the installation path, `/opt/mqm` is used on AIX and Linux systems, and `/usr/mqm` is used on AIX.

Return codes

Table 24. Return code identifiers and descriptions

Return code	Description
0	Entry created without error
10	Invalid installation level
36	Invalid arguments supplied
37	Descriptive text was in error
45	Entry already exists
59	Invalid installation specified
71	Unexpected error
89	.ini file error
96	Could not lock .ini file
98	Insufficient authority to access .ini file
131	Resource problem

Example

1. This command creates an entry with an installation name of `myInstallation`, an installation path of `/opt/myInstallation`, and a description "My IBM MQ installation":

```
crtmqinst -n MyInstallation -p /opt/myInstallation -d "My IBM MQ installation"
```

Quotation marks are needed because the descriptive text contains spaces.

Note: On AIX and Linux, the **crtmqinst** command must be run by the root user because full access permissions are required to write to the mqinst.ini configuration file.

crtmqm (create queue manager)

Create a queue manager.

Purpose

Use the **crtmqm** command to create a queue manager and define the default and system objects. The objects created by the **crtmqm** command are listed in System and default objects. When you have created a queue manager, use the **strmqm** command to start it.

The queue manager is automatically associated with the installation from which the **crtmqm** command was issued. To change the associated installation, use the **setmqm** command.

Windows Note that the Windows installer does not automatically add the user that performs the installation to the `mqm` group. For more details, see Authority to administer IBM MQ on AIX, Linux, and Windows systems.

Usage notes

Linux

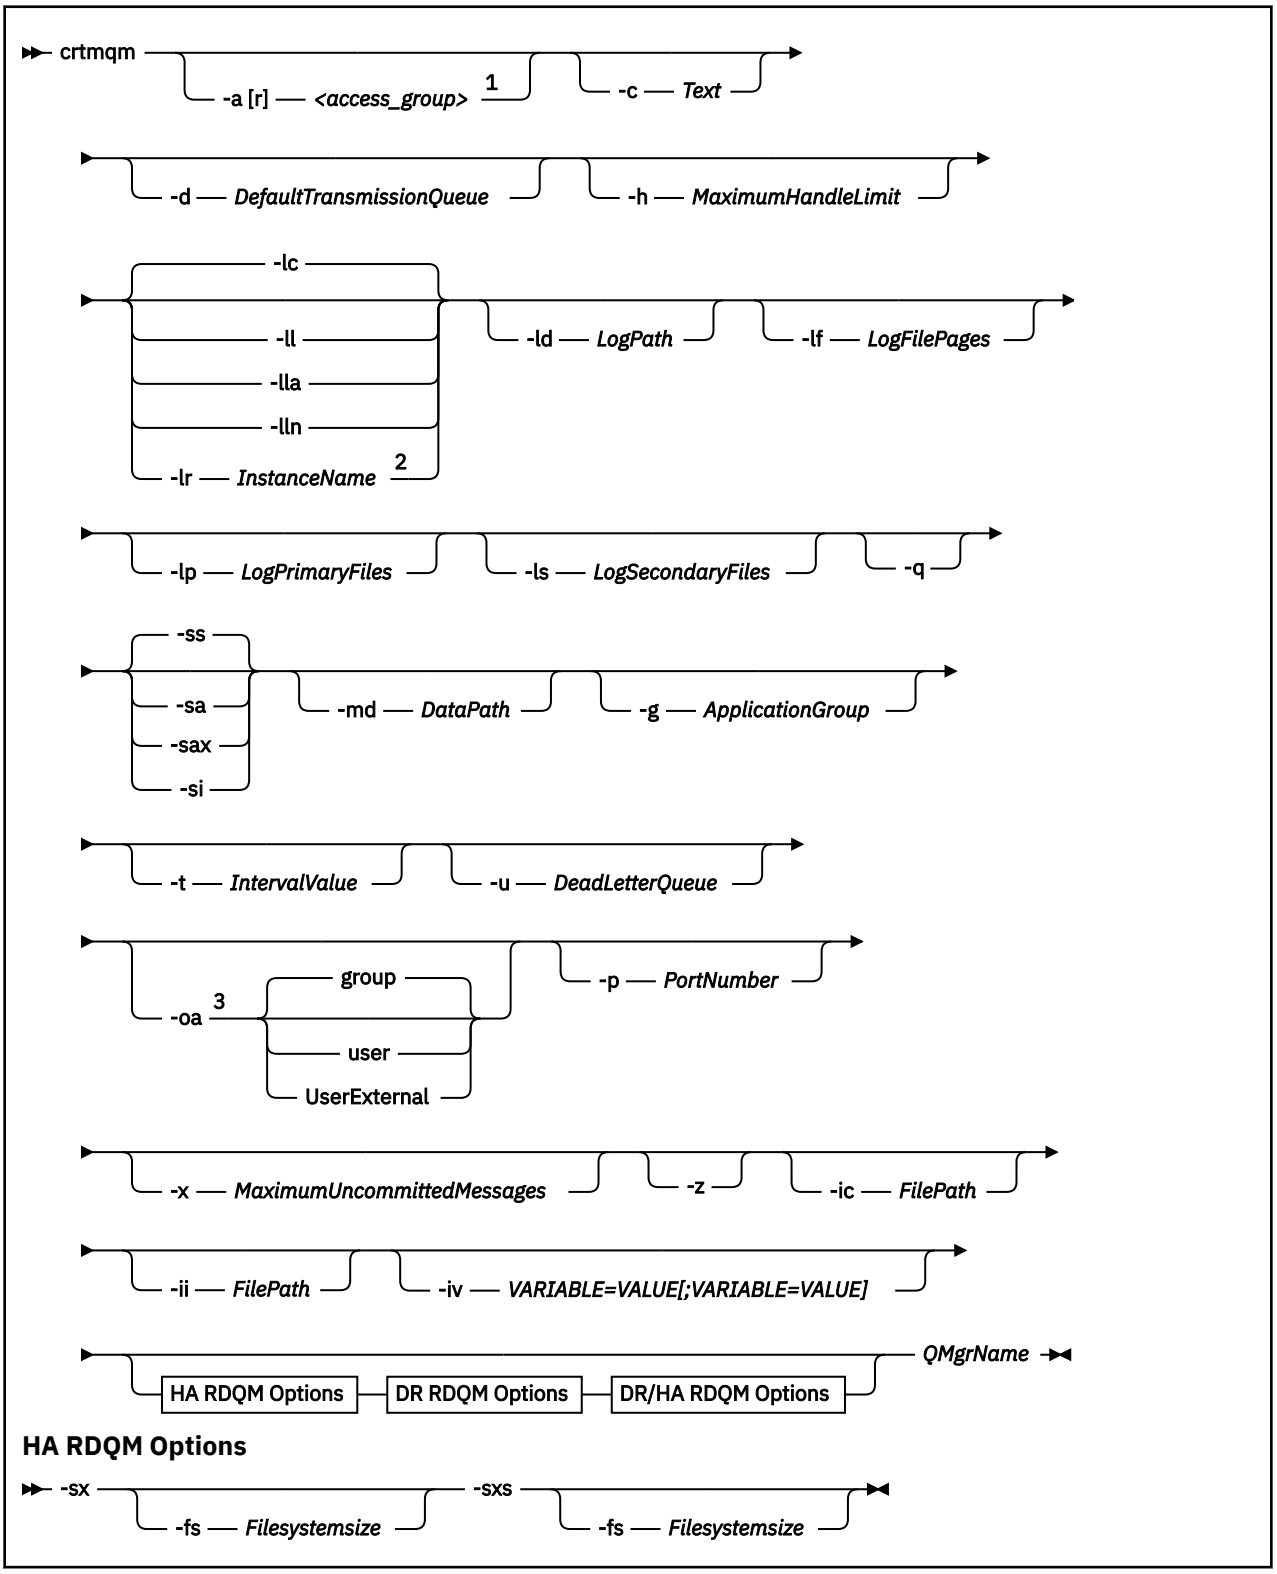
V 9.2.0 Linux From IBM MQ 9.2.0, you can use the environment variable **MQLICENSE** to accept or view the license.

The options you can set the **MQLICENSE** environment variable to are '`accept`' or '`view`'. Other values are treated as if the environment variable is not set.

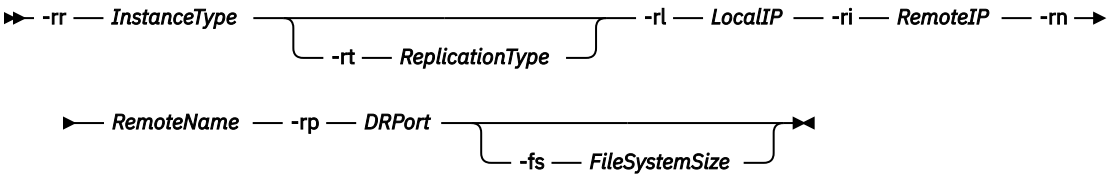
You can also set the **MQLICENSE** environment variable on the **addmqinf** and **dspmqinf** commands. However, you cannot set this environment variable directly on the **setmqprd** command.

Note: You can use this environment variable only when the licence has not already been accepted in the normal way (that is, by running **mqlicense**). If the license has already been accepted, this environment variable is ignored regardless of the value.

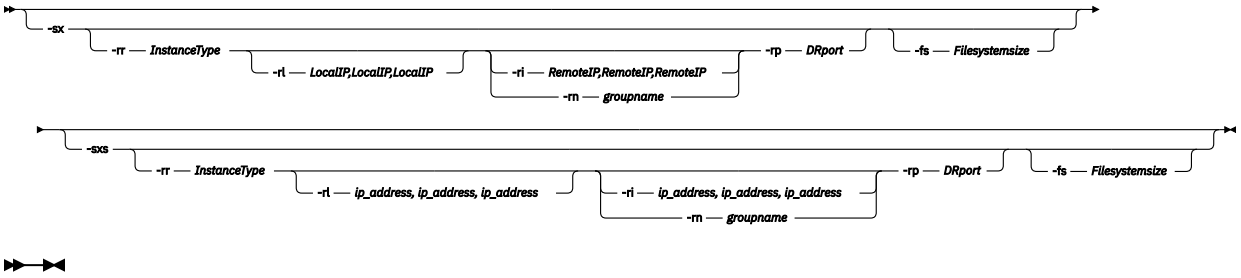
Syntax



DR RDQM Options



DR/HA RDQM Options



Notes:

[1] Windows only
[2] Specify one only of lc, ll, lla, lln, or lr
[3] AIX and Linux only

Required parameters

QMgrName

The name of the queue manager that you want to create. The name can contain up to 48 characters. This parameter must be the last item in the command.

Note: The *QMgrName* is used by IBM MQ applications, other IBM MQ queue managers, and IBM MQ control commands to identify this queue manager.

No other queue manager with the same name can exist on this machine. Where this queue manager is going to connect to other queue managers you must ensure that queue manager names are unique within that group of queue managers.

The *QMgrName* is also used to name the directories created on disk for the queue manager. Due to filesystem limitations the name of the directories created might not be identical to the *QMgrName* supplied on the **crtmqm** command.

In these cases the directories created will be based upon the supplied *QMgrName*, but might be modified, or have a suffix such as `.000` or `.001`, and so on, added to the queue manager name.

Optional parameters

Windows **-a[r] *access_group***

Use the access group parameter to specify a Windows security group, members of which will be granted full access to all queue manager data files. The group can either be a local or global group, depending on the syntax used.

Valid syntax for the group name is as follows:

LocalGroup
Domain name\GlobalGroup name
GlobalGroup name @ Domain name

You must define the additional access group before running the **crtmqm** command with the **-a [r]** option.

If you specify the group using **-ar** instead of **-a**, the local mqm group is not granted access to the queue manager data files. Use this option if the file system hosting the queue manager data files does not support access control entries for locally defined groups.

The group is typically a global security group, which is used to provide multi-instance queue managers with access to a shared queue manager data and logs folder. Use the additional security access group to set read and write permissions on the folder or to share containing queue manager data and log files.

The additional security access group is an alternative to using the local group named mqm to set permissions on the folder containing queue manager data and logs. Unlike the local group mqm, you can make the additional security access group a local or a global group. It must be a global group to set permissions on the shared folders that contain the data and log files used by multi-instance queue managers.

The Windows operating system checks the access permissions to read and write queue manager data and log files. It checks the permissions of the user ID that is running queue manager processes. The user ID that is checked depends on whether you started the queue manager as a service or you started it interactively. If you started the queue manager as a service, the user ID checked by the Windows system is the user ID you configured with the **Prepare** IBM MQ wizard. If you started the queue manager interactively, the user ID checked by the Windows system is the user ID that ran the **strmqm** command.

The user ID must be a member of the local mqm group to start the queue manager. If the user ID is a member of the additional security access group, the queue manager can read and write files that are given permissions by using the group.

Restriction: You can specify an additional security access group only on Windows operating system. If you specify an additional security access group on other operating systems, the **crtmqm** command returns an error.

-c *Text*
Descriptive text for this queue manager. You can use up to 64 characters; the default is all blanks.

If you include special characters, enclose the description in single quotation marks. The maximum number of characters is reduced if the system is using a double-byte character set (DBCS).

-d *DefaultTransmissionQueue*
The name of the local transmission queue where remote messages are put if a transmission queue is not explicitly defined for their destination. There is no default.

Linux AIX **-g *ApplicationGroup***
On AIX and Linux, the name of the group that contains members that are allowed to perform the following actions:

- Run MQI applications
- Update all IPCC resources
- Change the contents of some queue manager directories

The default value is **-g all**, which allows unrestricted access.

The **-g** *ApplicationGroup* value is recorded in the queue manager configuration file, qm.ini.

The mqm user ID and the user running the command must belong to the specified Application Group. For further details of the operation of restricted mode, see Restricted mode.

-h *MaximumHandleLimit*
The maximum number of handles that an application can open at the same time.

Specify a value in the range 1 - 999999999. The default value is 256.

V 9.2.0 Multi **-ic *FilePath***
Automatic configuration of MQSC attributes.

Specify the location containing MQSC commands to be automatically applied to the queue manager on every queue manager restart. This can be a filename, or a directory where each file `*.mqsc` is automatically processed. See automatic configuration from an MQSC script at startup for more details.

V 9.2.0 Multi **-ii *FilePath***

Automatic configuration of `qm.ini` file attributes.

Specify a configuration to be automatically applied to the qm.ini file on every queue manager restart. This can be a filename containing INI format information, or a directory where `*.ini` is automatically processed. See automatic configuration from an INI script at startup for more details.

V 9.2.0 Multi **-iv *VARIABLE=VALUE[;VARIABLE=VALUE]***

Configuration variable for use with automatic uniform clusters.

Specify a name and associated value for use as an insert during MQSC definitions. This parameter is only used for CONNAME fields in defining cluster receivers for automatic uniform clusters. For example:

```
-iv CONNAME=QMA.host.name(1414)
```

The next set of parameter descriptions relate to logging, which is described in Using the log for recovery.

Note: Choose the logging arrangements with care, because some cannot be changed after they are committed. The defaults for the logging options to **crtmqm** can be overridden by attributes in the mqs.ini file.

If you specify the logging attributes in the mqs.ini file, those attributes override the default values of the logging command line parameters to **crtmqm**.

-lc

Use circular logging. This method is the default logging method.

-ld *LogPath*

The directory used to store log files. The default directory to store log paths is defined when you install IBM MQ.

If the volume containing the log file directory supports file security, the log file directory must have access permissions. The permissions allow the user IDs, under whose authority the queue manager runs, read and write access to the directory and its subdirectories. When you install IBM MQ, you grant permissions to the user IDs and to the `mqm` group on the default log directory. If you set the *LogPath* parameter to write the log file to a different directory, you must grant the user IDs permission to read and write to the directory. The user ID and permissions for AIX and Linux are different from those for the Windows system:

Linux AIX **AIX and Linux**

The directory and its subdirectories must be owned by the user `mqm` in the group `mqm`.

If the log file is shared between different instances of the queue manager, the security identifiers (sid) that are used must be the same for the different instances. You must have set the user `mqm` to the same `sid` on the different servers running instances of the queue manager. Likewise for the group `mqm`.

Windows **Windows**

If the directory is accessed by only one instance of the queue manager, you must give read and write access permission to the directory for the following groups and users:

- The local group `mqm`
- The local group `Administrators`
- The SYSTEM user ID

To give different instances of a queue manager access to the shared log directory, the queue manager must access the log directory using a global user. Give the global group, which contains the global user, read and write access permission to the log directory. The global group is the additional security access group specified in the **-a** parameter.

Windows In IBM MQ for Windows systems, the default directory is `C:\ProgramData\IBM\MQ\log` (assuming that `C:` is your data drive). If the volume supports file security, the SYSTEM ID, Administrators, and `mqm` group must be granted read/write access to the directory.

Linux AIX In IBM MQ for AIX or Linux systems, the default directory is `/var/mqm/log`. User ID `mqm` and group `mqm` must have full authorities to the log files.

If you change the locations of these files, you must give these authorities yourself. If these authorities are set automatically, then the log files are in their default locations.

-lf *LogFilePages*

The log data is held in a series of files called log files. The log file size is specified in units of 4 KB pages.

Linux AIX In IBM MQ for AIX or Linux systems, the default number of log file pages is 4096, giving a log file size of 16 MB. The minimum number of log file pages is 64 and the maximum is 65535.

Windows In IBM MQ for Windows systems, the default number of log file pages is 4096, giving a log file size of 16 MB. The minimum number of log file pages is 32 and the maximum is 65535.

Note: The size of the log files for a queue manager specified during creation of that queue manager cannot be changed.

-ll *LinearLogging*

Use linear logging.

Multi On Multiplatforms, if you create a queue manager using the existing **-ll** option, you need to carry out manual management of log extents as previously (**LogManagement**=Manual).

Multi **-lla**

Use linear logging with automatic management of log extents (**LogManagement**=Automatic).

Multi **-lln**

Use linear logging with archive management of log extents (**LogManagement**=Archive).

CP4I **-lr *InstanceName***

Use log replication. Specify this option when configuring a Native HA group. The *InstanceName* provided is used by Native HA to identify this copy of log data and must be unique. The *InstanceName* can contain up to 48 characters. Valid characters in an *InstanceName* are:

- Uppercase or lowercase alphabetics (A-Z, a-z)
- Numeric characters (0-9)
- Dash (-), the leading character is not permitted to be a dash
- Period (.)
- Underscore (_)

Leading or embedded blanks are not permitted.

-lp *LogPrimaryFiles*

The log files allocated when the queue manager is created.

Windows On a Windows system:

- The minimum number of primary log files that you can have is 2 and the maximum is 254.
- The total number of primary and secondary log files must not exceed 255 and must not be less than 3.

Linux AIX On AIX and Linux systems:

- The minimum number of primary log files you can have is 2 and the maximum is 510. The default is 3.
- The total number of primary and secondary log files must not exceed 511 and must not be less than 3.

Operating system limits can reduce the maximum log size.

The value is examined when the queue manager is created or started. You can change it after the queue manager has been created. However, a change in the value is not effective until the queue manager is restarted, and the effect might not be immediate.

For more information about primary log files, see What logs look like.

To calculate the size of the primary log files, see Calculating the size of the log.

-ls *LogSecondaryFiles*

The log files allocated when the primary files are exhausted.

On a Windows system:

- The minimum number of secondary log files that you can have is 1 and the maximum is 253.
- The total number of primary and secondary log files must not exceed 255 and must not be less than 3.

On AIX and Linux systems:

- The minimum number of secondary log files that you can have is 2 and the maximum is 509. The default is 2.
- The total number of primary and secondary log files must not exceed 511 and must not be less than 3.

Operating system limits can reduce the maximum log size.

The value is examined when the queue manager is started. You can change this value, but changes do not become effective until the queue manager is restarted, and even then the effect might not be immediate.

For more information about the use of secondary log files, see What logs look like.

To calculate the size of the secondary log files, see Calculating the size of the log.

-md *DataPath*

The directory used to hold the data files for a queue manager.

In IBM MQ for Windows systems, the default is `C:\ProgramData\IBM\MQ\qmgrs` (assuming that `C:` is your data drive). If the volume supports file security, the SYSTEM ID, Administrators, and `mqm` group must be granted read/write access to the directory.

In IBM MQ for AIX or Linux systems, the default is `/var/mqm/qmgrs`. User ID `mqm` and group `mqm` must have full authorities to the log files.

For RDQM on Linux systems, the default is `/var/mqm/vols/`*`qmgrname`*`/qmgr/`.

The **DataPath** parameter is provided to assist in the configuration of multi-instance queue managers. For example, on AIX and Linux systems: if the `/var/mqm` directory is located on a local file system, use the **DataPath** parameter and the **LogPath** parameter to point to the shared file systems accessible to multiple queue managers.

Note: A queue manager created using **DataPath** parameter runs on versions of the product earlier than IBM WebSphere® MQ 7.0.1, but the queue manager must be reconfigured to remove the **DataPath** parameter. You have two options to restore the queue manager to a pre-IBM WebSphere MQ 7.0.1 configuration and run without the **DataPath** parameter: If you are confident about editing queue manager configurations, you can manually configure the queue manager using the `Prefix` queue manager configuration parameter. Alternatively, complete the following steps to edit the queue manager:

1. Stop the queue manager.
2. Save the queue manager data and log directories.
3. Delete the queue manager.
4. Backout IBM WebSphere MQ to the pre-IBM WebSphere MQ 7.0.1 fix level.
5. Create the queue manager with the same name.
6. Replace the new queue manager data and log directories with the ones you saved.

-oa group|user|UserExternal

Linux AIX On AIX and Linux systems, you can specify whether group or user authorization is to be used. If you do not set this parameter, group authorization is used. You can change the authorization model later by setting the **SecurityPolicy** parameter in the Service stanza of the `qm.ini` file (see Service stanza of the qm.ini file).

V 9.2.1 From IBM MQ 9.2.1, you can use the additional option of `UserExternal` when creating new queue managers. If you select this option, you can create a non-operating system user name, with a maximum of 12 characters, that:

- Must conform to the Rules for naming IBM MQ objects
- Is not known to the system
- Can be used both for checking and setting authorizations

V 9.2.1 If you create a non-operating system user name, that user is considered to belong to no groups, except the `nobody` group. See Principals and groups on AIX, Linux, and Windows for more information.

For further information, see Object authority manager (OAM).

-p *PortNumber*

Create a managed TCP listener on the specified port.

Specify a valid port value in the range 1-65535, to create a TCP listener object that uses the specified port. The new listener is called SYSTEM.LISTENER.TCP.1. This listener is under queue manager control, and is started and stopped along with the queue manager.

-q

Makes this queue manager the default queue manager. The new queue manager replaces any existing default queue manager.

If you accidentally use this flag and you want to revert to an existing queue manager as the default queue manager, change the default queue manager as described in Making an existing queue manager the default.

Linux **-rr *InstanceType***

Create a disaster recovery replicated data queue manager (DR RDQM). Specify **`-rr p`** to create the primary instance of the queue manager or specify **`-rr s`** to create the secondary instance. You must be `root` or a user in the `mqm` group with `sudo` privileges to use this command.

V 9.2.0 Use **`-rr`** with the **`-sx`** or the **`-sxs`** parameter to create a DR/HA RDQM.

Linux **-rt *ReplicationType***

Optionally specify whether your DR RDQM configuration uses synchronous or asynchronous replication. Specify **`-rt s`** for synchronous and **`-rt a`** for asynchronous. Asynchronous is the default.

Linux **-rl *LocalIP***

Specify the local IP address used for replication of data between primary and secondary instances of a DR RDQM.

V 9.2.0 Use **`-rl`** *LocalIP,LocalIP,LocalIP* with the **`-sx`** or the **`-sxs`** parameter to create a DR/HA RDQM and specify the three IP addresses used for DR replication on the local HA group.

Linux **-ri *RemoteIP***

Specify the remote IP address used for replication of data between primary and secondary instances of a DR RDQM.

V 9.2.0 Use **-ri** *RemoteIP,RemoteIP,RemoteIP* with the **-sx** or the **-sxs** parameter to create a DR/HA RDQM and specify the three IP addresses used for DR replication on the remote HA group. You must specify either the **-ri** or the **-rn** parameter when creating a DR/HA RDQM.

Linux **-rn *RemoteName***

Specifies the name of the system that is hosting the other instance of the queue manager. The name is the-+ value that is returned if you run `uname -n` on that server.

V 9.2.0 Use **-rn** *GroupName* with the **-sx** or the **-sxs** parameter to create a DR/HA RDQM and specify name of the remote HA group. The *GroupName* refers to the group defined in the DRGroup stanza in the `rdqm.ini` file. You must specify either the **-rn** or the **-ri** parameter when creating a DR/HA RDQM.

Linux **-rp *DRPort***

Specifies the port to use for DR replication.

Windows **-sa**

Automatic queue manager startup. For Windows systems only.

The queue manager is configured to start automatically when the IBM MQ Service starts.

This is the default option if you create a queue manager from IBM MQ Explorer.

Queue managers created in releases earlier than IBM WebSphere MQ 7 retain their existing startup type.

Windows **-sax**

Automatic queue manager startup, permitting multiple instances. For Windows systems only.

The queue manager is configured to start automatically when the IBM MQ Service starts.

If an instance of the queue manager is not already running the queue manager starts, the instance becomes active, and standby instances are permitted elsewhere. If a queue manager instance that permits standbys is already active on a different server, the new instance becomes a standby instance.

Only one instance of a queue manager can run on a server.

Queue managers created in versions of the product earlier than IBM WebSphere MQ 7.0.1 retain their existing startup type.

-si

Interactive (manual) queue manager startup.

The queue manager is configured to start only when you manually request startup by using the **strmqm** command. The queue manager runs under the (interactive) user when that user is logged-on. Queue managers configured with interactive startup end when the user who started them logs off.

-ss

Service (manual) queue manager startup.

A queue manager configured to start only when manually requested by using the **strmqm** command. The queue manager then runs as a child process of the service when the IBM MQ Service starts. Queue managers configured with service startup continue to run even after the interactive user has logged off.

This is the default option if you create a queue manager from the command line.

V 9.2.0 Linux **-sx [*DR parameters*][-fs *FilesystemSize*]**

Create a high availability replicated data queue manager (HA RDQM) on the primary node for that queue manager (do not specify DR parameters). RDQM is a high availability solution that is available on Linux only. See Creating an HA RDQM for more details about creating an RDQM. You must be `root` or a user in the `mqm` group with `sudo` privileges to use this command. The default size for file system

size is 3 GB. You can specify a different file system size using the `-fs` option. The default unit is GB (so `-fs 8` creates an 8 GB file system size). You can specify a different unit, for example, specify `-fs 1024M` to create a 1024 MB file system size. The queue manager is started automatically.

Specify DR parameters to create a DR/HA RDQM on the primary node for that queue manager. See Creating DR/HA RDQMs for details. The DR parameters are **-rr**, **-ri**, **-rl**, **-rn**, **-rp**.

-sxs [*DR parameters*][-fs *FilesystemSize*]

Create a replicated data queue manager (RDQM) on a secondary node (do not specify DR parameters). RDQM is a high availability solution that is available on Linux only. See Creating an HA RDQM for more details about creating an RDQM. You must be the `root` user to use this command. The default size for file system size is 3 GB. The default size for file system size is 3 GB. You can specify a different file system size using the `-fs` option. The default unit is GB (so `-fs 8` creates an 8 GB file system size). You can specify a different unit, for example, specify `-fs 1024M` to create a 1024 MB file system size.

Specify DR parameters to create a DR/HA RDQM on a secondary node. See Creating DR/HA RDQMs for details. The DR parameters are **-rr**, **-ri**, **-rl**, **-rn**, **-rp**.

-t *IntervalValue*

The trigger time interval in milliseconds for all queues controlled by this queue manager. This value specifies the length of time triggering is suspended, after the queue manager receives a trigger-generating message. That is, if the arrival of a message on a queue causes a trigger message to be put on the initiation queue, any message arriving on the same queue within the specified interval does not generate another trigger message.

You can use the trigger time interval to ensure that your application is allowed sufficient time to deal with a trigger condition before it is alerted to deal with another trigger condition on the same queue. You might choose to see all trigger events that happen; if so, set a low or zero value in this field.

Specify a value in the range 0 - 999999999. The default is 999999999 milliseconds; a time of more than 11 days. Allowing the default to be used effectively means that triggering is disabled after the first trigger message. However, an application can enable triggering again by servicing the queue using a command to alter the queue to reset the trigger attribute.

-u *DeadLetterQueue*

The name of the local queue that is to be used as the dead-letter (undelivered-message) queue. Messages are put on this queue if they cannot be routed to their correct destination.

The default is no dead-letter queue.

-x *MaximumUncommittedMessages*

The maximum number of uncommitted messages under any one sync point. The uncommitted messages are the sum of:

- The number of messages that can be retrieved from queues
- The number of messages that can be put on queues
- Any trigger messages generated within this unit of work

This limit does not apply to messages that are retrieved or put outside a sync point.

Specify a value in the range 1 - 999999999. The default value is 10000 uncommitted messages.

-z

Suppresses error messages.

This flag is used within IBM MQ to suppress unwanted error messages. Do not use this flag when using a command line. Using this flag can result in a loss of information.

Return codes

Table 25. Return code identifiers and descriptions

Return code	Description
0	Queue manager created
8	Queue manager exists
18	Invalid trigger interval
19	Invalid dead letter queue
20	Invalid default transmit queue
21	Invalid max handles value
22	Invalid max uncommitted messages value
25	Error creating the queue manager directory structure
37	Invalid queue manager description
38	The access group specified cannot be found
39	Invalid parameter specified
49	Queue manager stopping
58	Inconsistent use of installations detected
63	Invalid Native HA instance name
69	Storage unavailable
70	Queue space unavailable
71	Unexpected error
72	Queue manager name error
74	The IBM MQ service is not started
CP4I 93	Log replication is unavailable on this platform
95	Log replication is incompatible with RDQM
100	Log location invalid
105	The queue manager was created but could not be set as the default queue manager
111	Queue manager created. However, there was a problem processing the default queue manager definition in the product configuration file. The default queue manager specification might be incorrect
115	Invalid log size
119	Windows Permission denied (Windows only)
155	The group ID specified is not valid
156	The owning group ID can only be changed on AIX and Linux systems
157	The group ID chosen is invalid

Examples

- The following command creates a default queue manager called `Paint.queue.manager`, with a description of `Paint shop`, and creates the system and default objects. It also specifies that linear logging is to be used:

```
crtmqm -c "Paint shop" -ll -q Paint.queue.manager
```

- The following command creates a default queue manager called `Paint.queue.manager`, creates the system and default objects, and requests two primary and three secondary log files:

```
crtmqm -c "Paint shop" -ll -lp 2 -ls 3 -q Paint.queue.manager
```

- The following command creates a queue manager called `travel`, creates the system and default objects, sets the trigger interval to 5000 milliseconds (5 seconds), and specifies SYSTEM.DEAD.LETTER.QUEUE as its dead-letter queue.

```
crtmqm -t 5000 -u SYSTEM.DEAD.LETTER.QUEUE travel
```

- Linux AIX The following command creates a queue manager called QM1 on AIX and Linux systems, which has log and queue manager data folders in a common parent directory. The parent directory is to be shared on highly available networked storage to create a multi-instance queue manager. Before issuing the command, create other parameters `/MQHA`, `/MQHA/logs` and `/MQHA/qmgrs` owned by the user and group `mqm`, and with permissions `rwxrwxr-x`.

```
crtmqm -ld /MQHA/logs -md /MQHA/qmgrs QM1
```

Related concepts

Working with dead-letter queues

Related reference

strmqm (start queue manager)
Start a queue manager or ready it for standby operation.

endmqm (end queue manager)
Stop a queue manager or switch to a standby queue manager or to a replica queue manager.

dltmqm (delete queue manager)
Delete a queue manager.

setmqm (set the associated installation of a queue manager)
Set the associated installation of a queue manager.

Linux AIX dltmqinst (delete MQ installation)

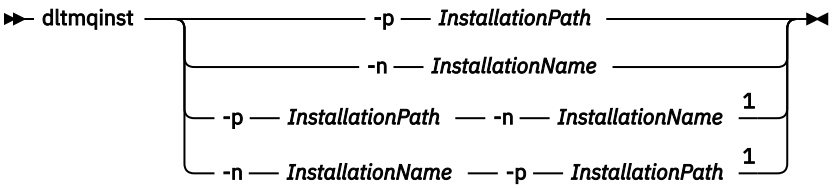
Delete installation entries from `mqinst.ini` on AIX and Linux systems.

Purpose

File `mqinst.ini` contains information about all IBM MQ installations on a system. For more information about `mqinst.ini`, see Installation configuration file, mqinst.ini.

Attention: Only the user `root` can run this command.

Syntax



Notes:

[1] When specified together, the installation name and installation path must refer to the same installation.

Parameters

-n *InstallationName*
The name of the installation.

-p *InstallationPath*
The installation path is the location where IBM MQ is installed.

Return codes

Table 26. Return code identifiers and descriptions

Return code	Description
0	Entry deleted without error
5	Entry still active
36	Invalid arguments supplied
44	Entry does not exist
59	Invalid installation specified
71	Unexpected error
89	ini file error
96	Could not lock ini file
98	Insufficient authority to access ini file
131	Resource problem

Example

1. This command deletes an entry with an installation name of `myInstallation`, and an installation path of `/opt/myInstallation`:

```
dltmqinst -n MyInstallation -p /opt/myInstallation
```

Note: You can only use the **dltmqinst** command on another installation from the one it runs from. If you only have one IBM MQ installation, the command will not work.

dltmqm (delete queue manager)

Delete a queue manager.

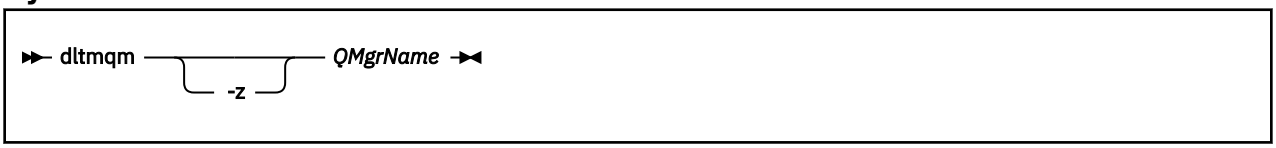
Purpose

Use the **dltmqm** command to delete a specified queue manager and all objects associated with it. Before you can delete a queue manager, you must end it using the **endmqm** command.

You must use the **dltmqm** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the `dspmq -o installation` command.

Windows On Windows, it is an error to delete a queue manager when queue manager files are open. If you get this error, close the files and reissue the command.

Syntax



Required parameters

QMgrName
The name of the queue manager to delete.

Optional parameters

-z
Suppresses error messages.

Return codes

Table 27. Return code identifiers and descriptions

Return code	Description
0	Queue manager deleted
3	Queue manager being created
5	Queue manager running
16	Queue manager does not exist
24	A process that was using the previous instance of the queue manager has not yet disconnected.
25	An error occurred while creating or checking the directory structure for the queue manager.
26	Queue manager running as a standby instance.
27	Queue manager could not obtain data lock.
29	Queue manager deleted, however there was a problem removing it from Active Directory.
33	An error occurred while deleting the directory structure for the queue manager.
39	Invalid parameter specified
49	Queue manager stopping
58	Inconsistent use of installations detected
62	The queue manager is associated with a different installation
69	Storage not available
71	Unexpected error
72	Queue manager name error
74	The IBM MQ service is not started.
100	Log location invalid.
112	Queue manager deleted. However, there was a problem processing the default queue manager definition in the product configuration file. The default queue manager specification might be incorrect.
119	Windows Permission denied (Windows only).

Examples

1. The following command deletes the queue manager `saturn.queue.manager`.

```
dltmqm saturn.queue.manager
```

2. The following command deletes the queue manager `travel` and also suppresses any messages caused by the command.

```
dltmqm -z travel
```

Usage notes

Windows On Windows, it is an error to delete a queue manager when queue manager files are open. If you get this error, close the files and reissue the command.

Deleting a cluster queue manager does not remove it from the cluster. To check whether the queue manager you want to delete is part of a cluster, issue the command **DIS CLUSQMGR(*)**. Then check whether this queue manager is listed in the output. If it is listed as a cluster queue manager you must remove the queue manager from the cluster before deleting it. See the related link for instructions.

If you do delete a cluster queue manager without first removing it from the cluster, the cluster continues to regard the deleted queue manager as a member of the cluster for at least 30 days. You can remove it from the cluster using the command **RESET CLUSTER** on a full repository queue manager. Re-creating a queue manager with an identical name and then trying to remove that queue manager from the cluster does not result in the cluster queue manager being removed from the cluster. This is because the newly created queue manager, although having the same name, does not have the same queue manager ID (QMID). Therefore it is treated as a different queue manager by the cluster.

Related reference

crtmqm (create queue manager)
Create a queue manager.

strmqm (start queue manager)
Start a queue manager or ready it for standby operation.

endmqm (end queue manager)
Stop a queue manager or switch to a standby queue manager or to a replica queue manager.

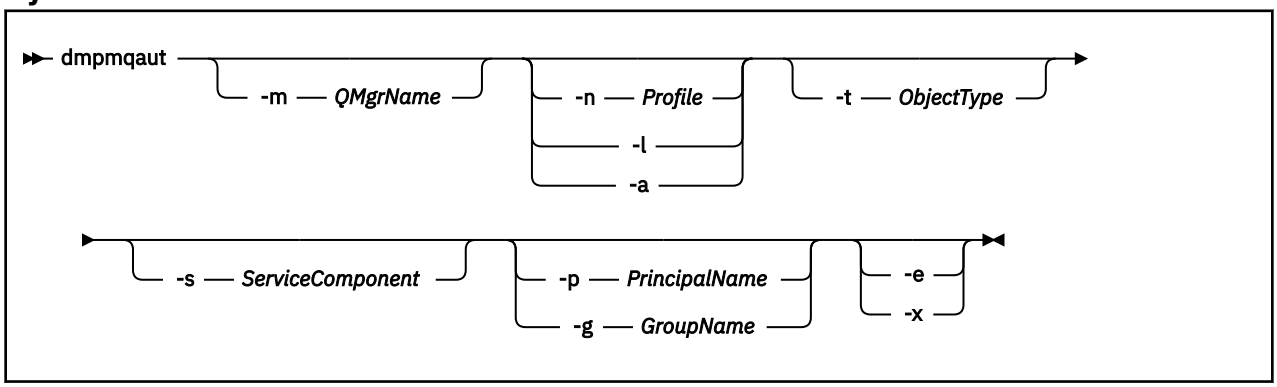
dmpmqaut (dump MQ authorizations)

Dump a list of current authorizations for a range of IBM MQ object types and profiles.

Purpose

Use the **dmpmqaut** command to dump the current authorizations to a specified object.

Syntax



Optional parameters

-m *QMgrName*
Dump authority records only for the queue manager specified. If you omit this parameter, only authority records for the default queue manager are dumped.

-n *Profile*
The name of the profile for which to dump authorizations. The profile name can be generic, using wildcard characters to specify a range of names as explained in Using OAM generic profiles on AIX, Linux, and Windows systems.

-l
Dump only the profile name and type. Use this option to generate a *terse* list of all defined profile names and types.

-a
Generate set authority commands.

-t *ObjectType*
The type of object for which to dump authorizations. Possible values are:
A table showing possible values, and descriptions, for the -t flag.

Value	Description
authinfo	An authentication information object, for use with TLS channel security
channel or **chl**	A channel
clntconn or **clcn**	A client connection channel
listener or **lstr**	A listener
namelist or **nl**	A namelist
process or **prcs**	A process
queue or **q**	A queue or queues matching the object name parameter
qmgr	A queue manager
rqmname or **rqmn**	A remote queue manager name
service or **srvc**	A service
topic or **top**	A topic

-s *ServiceComponent*
If installable authorization services are supported, specifies the name of the authorization service for which to dump authorizations. This parameter is optional; if you omit it, the authorization inquiry is made to the first installable component for the service.

Windows **-p *PrincipalName***
This parameter applies to Windows only; AIX and Linux systems keep only group authority records.

The name of a user for whom to dump authorizations to the specified object. The name of the principal can optionally include a domain name, specified in the following format:

```
userid@domain
```

For more information about including domain names on the name of a principal, see Principals and groups.

-g *GroupName*
The name of the user group for which to dump authorizations. You can specify only one name, which must be the name of an existing user group.

Windows For IBM MQ for Windows only, the group name can optionally include a domain name, specified in the following formats:

```
GroupName@domain
domain\GroupName
```

-e

Display all profiles used to calculate the cumulative authority that the entity has to the object specified in `-n Profile`. The variable *Profile* must not contain any wildcard characters.

The following parameters must also be specified:

- `-m QMgrName`
- `-n Profile`
- `-t ObjectType`

and either `-p PrincipalName`, or `-g GroupName`.

-x

Display all profiles with the same name as specified in **-n** `Profile`. This option does not apply to the QMGR object, so a dump request of the form `dmpmqaut -m QM -t QMGR ... -x` is not valid.

Examples

The following examples show the use of **dmpmqaut** to dump authority records for generic profiles:

1. This example dumps all authority records with a profile that matches queue a.b.c for principal user1.

   ```
   dmpmqaut -m qm1 -n a.b.c -t q -p user1
   ```

   The resulting dump would look something like this:

   ```
   profile:     a.b.*
   object type: queue
   entity:      user1
   type:        principal
   authority:   get, browse, put, inq
   ```

   Note: Linux AIX On AIX and Linux, you cannot use the -p option. You must use `-g groupname` instead.

2. This example dumps all authority records with a profile that matches queue a.b.c.

   ```
   dmpmqaut -m qmgr1 -n a.b.c -t q
   ```

   The resulting dump would look something like this:

   ```
   profile:     a.b.c
   object type: queue
   entity:      Administrator
   type:        principal
   authority:   all
   - - - - - - - - - - - - - - - -
   profile:     a.b.*
   object type: queue
   entity:      user1
   type:        principal
   authority:   get, browse, put, inq
   - - - - - - - - - - - - - - - -
   profile:     a.**
   object type: queue
   entity:      group1
   type:        group
   authority:   get
   ```

3. This example dumps all authority records for profile a.b.*, of type queue.

```
dmpmqaut -m qmgr1 -n a.b.* -t q
```

The resulting dump would look something like this:

```
profile:     a.b.*
object type: queue
entity:      user1
type:        principal
authority:   get, browse, put, inq
```

4. This example dumps all authority records for queue manager qmX.

```
dmpmqaut -m qmX
```

The resulting dump would look something like this:

```
profile:     q1
object type: queue
entity:      Administrator
type:        principal
authority:   all
- - - - - - - - - - - - - - - -
profile:     q*
object type: queue
entity:      user1
type:        principal
authority:   get, browse
- - - - - - - - - - - - - - - -
profile:     name.*
object type: namelist
entity:      user2
type:        principal
authority:   get
- - - - - - - - - - - - - - - -
profile:     pr1
object type: process
entity:      group1
type:        group
authority:   get
```

5. This example dumps all profile names and object types for queue manager qmX.

```
dmpmqaut -m qmX -l
```

The resulting dump would look something like this:

```
profile: q1, type: queue
profile: q*, type: queue
profile: name.*, type: namelist
profile: pr1, type: process
```

Note:

1. Windows For Windows only, all principals displayed include domain information, for example:

```
profile:     a.b.*
object type: queue
entity:      user1@domain1
type:        principal
authority:   get, browse, put, inq
```

2. Each class of object has authority records for each group or principal. These records have the profile name `@CLASS` and track the `crt` (create) authority common to all objects of that class. If the `crt` authority for any object of that class is changed then this record is updated. For example:

```
profile:     @class
object type: queue
entity:      test
entity type: principal
authority:   crt
```

This shows that members of the group `test` have `crt` authority to the class `queue`.

Attention: You cannot delete the @CLASS entries (the system is working as designed)

3. Windows For Windows only, members of the "Administrators" group are by default given full authority. This authority, however, is given automatically by the OAM, and is not defined by the authority records. The **dmpmqaut** command displays authority defined only by the authority records. Unless an authority record has been explicitly defined, therefore, running the **dmpmqaut** command against the "Administrators" group displays no authority record for that group.

Related reference

"setmqaut (grant or revoke authority)" on page 178
Change the authorizations to a profile, object, or class of objects. Authorizations can be granted to, or revoked from, any number of principals or groups.

"DISPLAY AUTHREC (display authority records) on Multiplatforms" on page 628
Use the MQSC command DISPLAY AUTHREC to display the authority records associated with a profile name.

"SET AUTHREC (set authority records) on Multiplatforms" on page 897
Use the MQSC command SET AUTHREC to set authority records associated with a profile name.

dmpmqcfg (dump queue manager configuration)

Use the **dmpmqcfg** command to dump the configuration of an IBM MQ queue manager.

Purpose

Use the **dmpmqcfg** command to dump the configuration of IBM MQ queue managers. If any default object has been edited, the **-a** option must be used if the dumped configuration will be used to restore the configuration.

CAUTION: When moving a queue manager from one operating system to another, you use **dmpmqcfg** to save the configuration information of the queue manager that you want to move, and then copy the object definitions across to the new queue manager that you create on the new operating system. You must take great care with copying the object definitions, because some manual modification of the definitions might be needed. For more information, see Moving a queue manager to a different operating system.

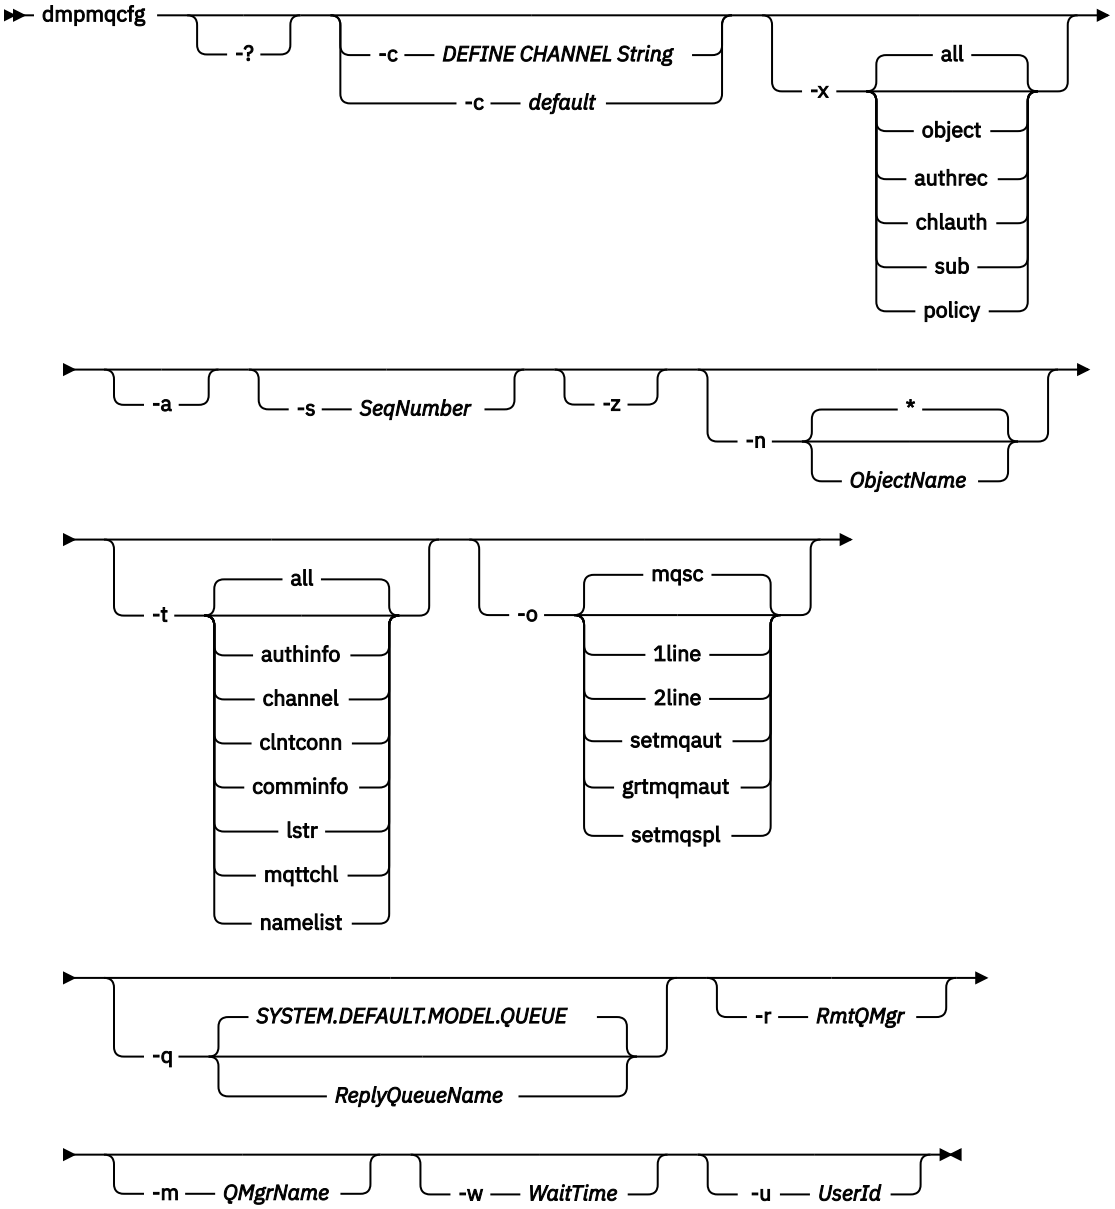
The **dmpmqcfg** utility dumps only subscriptions of type MQSUBTYPE_ADMIN, that is, only subscriptions that are created using the MQSC command **DEFINE SUB** or its PCF equivalent. The output from **dmpmqcfg** is a **runmqsc** command to enable the administration subscription to be re-created. Subscriptions that are created by applications using the MQSUB MQI call of type MQSUBTYPE_API are not part of the queue manager configuration, even if durable, and so are not dumped by **dmpmqcfg**. MQTT channels will only be returned for types -t all and -t mqttchl if the telemetry (MQXR) service is running. For instructions on how to start the telemetry service, see Administering MQ Telemetry.

From IBM MQ 8.0, the output of the **dmpmqcfg** is changed to ensure that password fields are commented out in the generated commands. This change brings the **dmpmqcfg** command in line with the DISPLAY commands, that show password fields as PASSWORD(********).

Note: The **dmpmqcfg** command does not make a backup of the Advanced Message Security policies. If you want to export the Advanced Message Security policies, ensure that you run **dspmqspl** with the `-export` flag. This command exports the policies for Advanced Message Security into a text file, which can be used for restoration purposes. For more information see "dspmqspl (display security policy)" on page 88.

Attention: The inquiries used by **dmpmqcfg** inquire only QSGDISP(QMGR) definitions by default. You can inquire additional definitions by using the environment variable **AMQ_DMPMQCFG_QSGDISP_DEFAULT**. For more information about the values that you can set with this environment variable, see **AMQ_DMPMQCFG_QSGDISP_DEFAULT**.

z/OS For example, you could use **AMQ_DMPMQCFG_QSGDISP_DEFAULT** to query a z/OS queue manager in a queue sharing group from an IBM MQ for Multiplatforms installation. Using the environment variable allows you to include shared objects that would otherwise not be included in the results.



Optional parameters

-?

Inquire the usage message for `dmpmqcfg`.

-c

Force a client mode connection. If the **-c** parameter is qualified with the option `default`, the default client connection process is used. If **-c** is omitted, the default is to attempt to connect to the queue manager first by using server bindings and then if this fails by using client bindings.

If the option is qualified with an MQSC DEFINE CHANNEL CHLTYPE(CLNTCONN) string then this is parsed and if successful, used to create a temporary connection to the queue manager.

-x [all|object|authrec|chlauth|sub|policy]
Filter the definition procedure to show `object` definitions, `authority records`, `channel authentication` records, durable `subscriptions` or `policy`. The default value `all` is that all types are returned.

Note that when you specify an export type of `policy`, the security policies for the queue manager are reported in the configuration information dumped.

-a
Return object definitions to show all attributes. The default is to return only attributes which differ from the defaults for the object type.

-s *SeqNumber*
Reset channel sequence number for sender, server and cluster sender channel types to the numeric value specified. The value `SeqNumber` must be in the range 1 - 999999999.

-z
Activate silent mode in which warnings, such as those which appear when inquiring attributes from a queue manager of a higher command level are suppressed.

-n [*|ObjectName]
Filter the definitions produced by object or profile name, the object/profile name can contain a single asterisk. The * option can be placed only at the end of the entered filter string.

@class authority records are included in **dmpmqcfg** output regardless of the object or profile filter specified.

Attention: You cannot delete the `@CLASS` entries (the system is working as designed)

-t
Choose a single type of object to export. The following table shows the possible values:

*Table 28. Possible values for **-t** parameter*

Value	Description
`all`	All object types
`authinfo`	An authentication information object
`channel` or `chl`	A channel
`comminfo`	A communications information object
`lstr` or `listener`	A listener
`mqttchl`	An MQTT channel
`namelist` or `nl`	A namelist
`process` or `prcs`	A process
`queue` or `q`	A queue
`qmgr`	A queue manager
`srvc` or `service`	A service
`topic` or `top`	A topic

-o [mqsc|1line|2line|setmqaut|grtmqmaut|setmqspl]
The following table shows the possible values:

*Table 29. Possible values for **-o** parameter options*

Value	Description
`mqsc`	Multi-line MQSC that can be used as direct input to **runmqsc**

*Table 29. Possible values for **-o** parameter options (continued)*	
Value	**Description**
`1line`	MQSC with all attributes on a single line for line diffing
`2line`	MQSC with output on two lines. The first line is an MQSC command string and the second is a commented version with immutable values.
ALW `setmqaut`	setmqaut statements for AIX, Linux, and Windows queue managers; valid only when `-x authrec` is specified.
Linux `grtmqmaut`	Linux only; generates iSeries syntax for granting access to the objects.
`setmqspl`	The security policies for the queue manager are reported in the format of **`setmqspl`** command lines. This format can be used to generate scripts to restore policy configuration to a queue manager. Note that the **`setmqspl`** command lines produced by this format includes parameters (-m) that specify the queue manager from which the definition was backed up. This implies that the definitions need to be replayed against the same queue manager. If you need to back up policy definitions from one queue manager, and restore them to a different queue manager, consider using the default MQSC format where the queue manager name is not explicitly specified.

-q
The name of the reply-to queue used when getting configuration information.

-r
The name of the remote queue manager/transmit queue when using queued mode. If this parameter is omitted the configuration for the directly connected queue manager (specified with the **-m** parameter) is dumped.

-m
The name of the queue manager to connect to. If omitted the default queue manager name is used.

-w *WaitTime*
The time, in seconds, that **dmpmqcfg** waits for replies to its commands.

Any replies received after a timeout are discarded, but the MQSC commands still run.

The check for timeout is performed once for each command reply.

Specify a time in the range 1 through 999999; the default value is 60 seconds.

Timed-out failure is indicated by:

- Nonzero return code to the calling shell or environment.
- Error message to `stdout` or `stderr`.

-u *UserId*
The ID of the user authorized to dump the configuration of queue managers.

Authorizations

You must have MQZAO_OUTPUT (+put) authority to access the command input queue (SYSTEM.ADMIN.COMMAND.QUEUE).

You must have MQZAO_DISPLAY (+dsp) authority and MQZAO_INPUT (+get) authority to access the default model queue (SYSTEM.DEFAULT.MODEL.QUEUE), to be able to create a temporary dynamic queue if using the default reply queue.

You must also have MQZAO_CONNECT (+connect) and MQZAO_INQUIRE (+inq) authority for the queue manager, and MQZAO_DISPLAY (+dsp) authority for every object that is requested.

No authority is required on the object type (RQMNAME) to limit, or restrict the use of, the **dmpmqcfg** command to display details about any OBJTYPE(RQMNAME).

Return code

If a failure occurs **dmpmqcfg** returns an error code. Otherwise, the command outputs a footer, an example of which follows:

```
********************************************************************************
* Script ended on 2016-01-05   at 05.10.09
* Number of Inquiry commands issued: 14
* Number of Inquiry commands completed: 14
* Number of Inquiry responses processed: 273
* QueueManager count: 1
* Queue count: 55
* NameList count: 3
* Process count: 1
* Channel count: 10
* AuthInfo count: 4
* Listener count: 1
* Service count: 1
* CommInfo count: 1
* Topic count: 5
* Subscription count: 1
* ChlAuthRec count: 3
* Policy count: 1
* AuthRec count: 186
* Number of objects/records: 273
********************************************************************************
```

Examples

To make these examples work you need to ensure that your system is set up for remote MQSC operation. See Configuring queue managers for remote administration.

```
dmpmqcfg -m MYQMGR -c "DEFINE CHANNEL(SYSTEM.ADMIN.SVRCONN) CHLTYPE(CLNTCONN)
CONNAME('myhost.mycorp.com(1414)')"
```

dumps all the configuration information from remote queue manager *MYQMGR* in MQSC format and creates an ad-hoc client connection to the queue manager using a client channel called *SYSTEM.ADMIN.SVRCONN*.

Note: You need to ensure that a server-connection channel with the same name exists.

```
dmpmqcfg -m LOCALQM -r MYQMGR
```

dumps all configuration information from remote queue manager *MYQMGR*, in MQSC format, connects initially to local queue manager *LOCALQM*, and sends inquiry messages through this local queue manager.

Note: You need to ensure that the local queue manager has a transmission queue named *MYQMGR*, with channel pairings defined in both directions, to send and receive replies between queue managers.

Related tasks

Multi Backing up queue manager configuration

Multi Restoring queue manager configuration

Related reference

“runmqsc (run MQSC commands)” on page 163

Run IBM MQ commands on a queue manager.

dmpmqlog (dump MQ formatted log)

Display and format a portion of the IBM MQ system log.

Purpose

Use the **dmpmqlog** command to dump a formatted version of the IBM MQ system log to standard out.

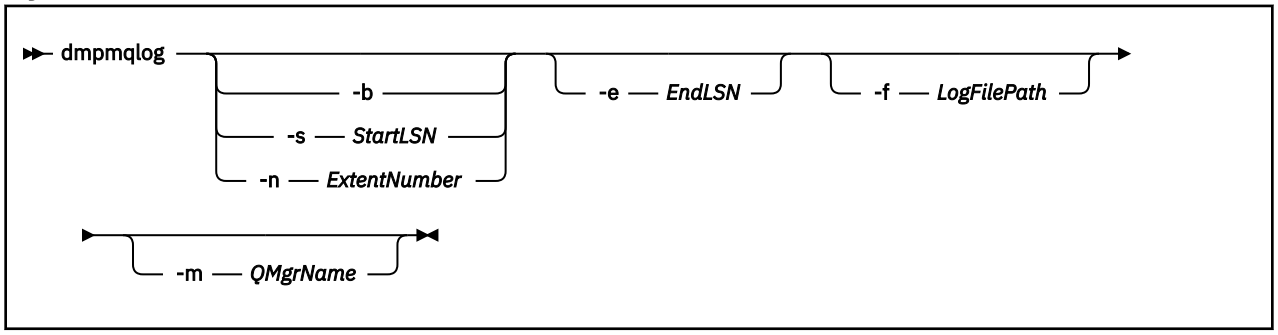
The log to be dumped must have been created on the same type of operating system as that being used to issue the command.

From IBM MQ 9.1.0, the **dmpmqlog** command outputs a timestamp with each log record as shown in the following example:

```
LOG RECORD - LSN <0:0:4615:42406>
**********

HLG Header: lrecsize 212, version 1, rmid 0, eyecatcher HLRH
Creation Time: 2017-01-30 13:50:31.146 GMT Standard Time (UTC +0)
```

Syntax



Optional parameters

Dump start point

Use one of the following parameters to specify the log sequence number (LSN) at which the dump should start. If you omit this, dumping starts by default from the LSN of the first record in the active portion of the log.

-b

Start dumping from the base LSN. The base LSN identifies the start of the log extent that contains the start of the active portion of the log.

-s *StartLSN*

Start dumping from the specified LSN. The LSN is specified in the format nnnn:nnnn:nnnn:nnnn.

If you are using a circular log, the LSN value must be equal to or greater than the base LSN value of the log.

-n *ExtentNumber*

Start dumping from the specified extent number. The extent number must be in the range 0 - 9999999.

This parameter is valid only for queue managers using linear logging.

-e *EndLSN*

End dumping at the specified LSN. The LSN is specified in the format nnnn:nnnn:nnnn:nnnn.

-f *LogFilePath*
The absolute (rather than relative) directory path name to the log files. The specified directory must contain the log header file (`amqhlctl.lfh`) and a subdirectory called `active`. The active subdirectory must contain the log files. By default, log files are assumed to be in the directories specified in the IBM MQ configuration information. If you use this option, queue names associated with queue identifiers are shown in the dump only if you use the -m option to name a queue manager name that has the object catalog file in its directory path.

On a system that supports long file names this file is called `qmqmobjcat` and, to map the queue identifiers to queue names, it must be the file used when the log files were created. For example, for a queue manager named qm1, the object catalog file is located in the directory `..\qmgrs\qm1\qmanager\`. To achieve this mapping, you might need to create a temporary queue manager, for example named tmpq, replace its object catalog with the one associated with the specific log files, and then start **dmpmqlog**, specifying **-m tmpq** and **-f** with the absolute directory path name to the log files.

-m *QMgrName*
The name of the queue manager. If you omit this parameter, the name of the default queue manager is used.

Note: Do not dump the log while the queue manager is running, and do not start the queue manager while **dmpmqlog** is running.

dmpmqmsg (queue load and unload)

Use the **dmpmqmsg** utility to copy or move the contents of a queue, or its messages, to a file. Formerly the IBM MQ **qload** utility.

Purpose

From IBM MQ 8.0, the **qload** utility, that previously shipped in IBM MQ Supportpac MO03, has been integrated into IBM MQ as the **dmpmqmsg** utility.

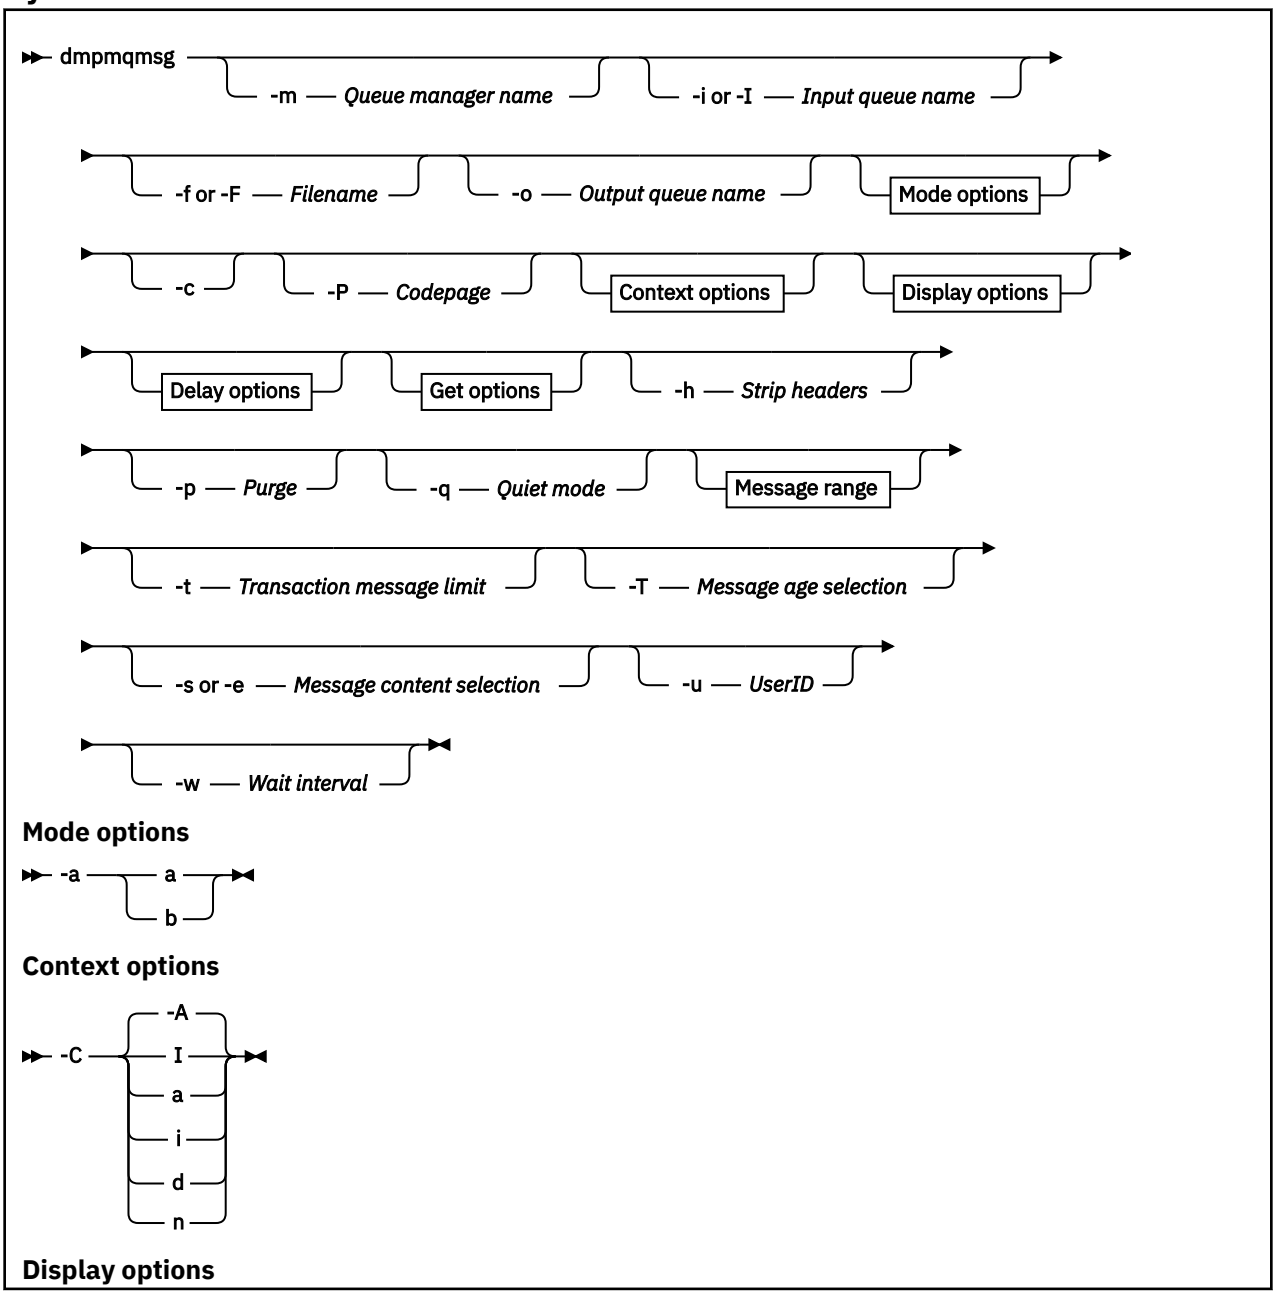
Linux AIX On AIX and Linux platforms the utility is available in `<installdir>./bin`

Windows On Windows platforms the utility is available in `<installdir>./bin64` as part of the server fileset.

z/OS On z/OS, the utility is available as an executable module, CSQUDMSG in the SCSQLOAD library, with an alias of QLOAD for compatibility. Sample JCL is also provided as member CSQ4QLOD in SCSQPROC.

For more information, see Using the **dmpmqmsg** utility.

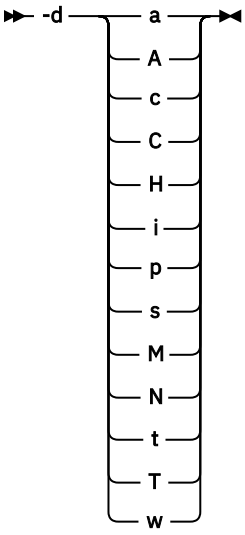
Syntax



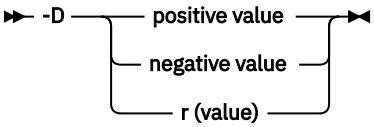
Mode options

Context options

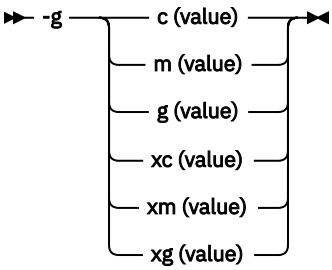
Display options



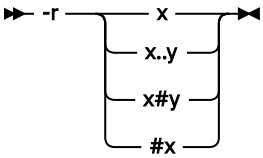
Delay options



Get options



Message range options



Optional parameters

-m *QueueManagerName*
The name of the queue manager on which the queue, or queues, exist.

-i or -I *Input queue name*
The name of the input queue.

Note: Using *-i* browses the queue (non-destructive get), whereas using *-I* deletes messages from the queue (destructive get).

-f or -F *Filename*
Specifies either the source or target file name.

Note:

- Using *-F* on a target file forces output to a file if it already exists. The program does not ask you if the file should be overwritten.
- Take care to ensure that appropriate access controls are set on the output file, as users who are not permitted to access messages on the queue might have access to read the output file.

Linux AIX On AIX and Linux, permissions for new files are set according to the current umask when the utility is run.

Windows On Windows, permissions for new files are inherited from the parent directory ACL.

-o *Output queue name*
Specifies the name of the output queue.

-a
Controls whether the file is opened in append or binary mode, by adding one of the following values to the keyword:

a
Append mode

b
Binary mode

-c
Connect in client mode.

If you do not select this flag, the utility runs in local mode, which is the default.

z/OS This option is not available on z/OS.

-P
Controls whether messages taken from a queue are converted.

Use the command

```
-P CCSID [ : X 'Encoding' ]
```

For example `-P850:111`

-C
Controls the context option, by adding one of the following values to the keyword:

A
Set all context. This is the default value.

I
Set identity context.

a
Pass all context.

p
Pass identity context.

Use of the *pass* options is not applicable if the source messages are browsed on a queue.

d
Default context.

n
No context.

-d
Controls the display option or options, by adding one or more of the following values to the keyword. For example `-dsCM`:

a
Add ASCII columns to the hexadecimal output in the file to aid readability.

A
Write ASCII lines of data wherever possible.

z/OS On EBCDIC platforms, data is instead written in EBCDIC.

c
Output *ApplicationOriginData* and *ApplicationIdentityData* as characters

C
Display the *Correlation Identifier* in the queue summary.

H
Do not write the file header.

Files created with this option are not loadable by the program as the program does not recognize the file format. However, if necessary you can use an editor to add an appropriate header manually, to make the file loadable.

i
Include the message index in the output.

p
Printable character output format.

This format is not code page safe. Loading a file written in this format, while running in a new code page does not guarantee to produce the same message.

s
Write a simple summary of the messages found on input.

M
Display the *Message Identifier* in the queue summary.

N
Do not write out the message descriptor content, only the message payload.

t
Text line output format.

This format is not code page safe. Loading a file written in this format, while running in a new code page does not guarantee to produce the same message.

T
Display the time the message has been on the queue.

w *Length*
Set the data width for the output.

-D
Add a delay, expressed in milliseconds, before writing a message to the output destination, by adding one of the following values to the keyword. For example:

-D*positive_value*
Add a fixed delay before putting a message. For example, `-D500` puts each message half a second apart.

-D*negative_value*
Add a random delay, up to the specified value before putting a message. For example, `-D-10000` adds a random delay of up to 10 seconds before putting a message.

r*value*
Replays the messages at a percentage of their original put speed. For example:

r
Replays messages at their original speed.

r50
Replays messages at half their original speed.

r200
Replays messages at twice their original speed.

-g
Filter by Message identifier, Correlation identifier, or Group identifier, by adding one of the following values to the keyword.

c*value*
Get by character Correlation identifier.

m*value*
Get by character Message identifier.

g*value*
Get by character Group identifier.

xc*value*
Get by hexadecimal Correlation identifier.

xm*value*
Get by hexadecimal Message identifier.

xg*value*
Get by hexadecimal Group identifier.

-h
Strip headers.

Any Dead Letter Queue header (MQDLH) or Transmission Queue header (MQXQH) is removed from the message before the message is written.

-o
Output queue name.

-p
Causes the source queue to be purged of messages as they are copied to the target destination.

-q
Sets quiet mode. When set, the program does not output its usual summary of activity.

-r

Note: If the **dmpmqmsg** command runs with the **-r** option set to *0*, the command copies all messages to the destination, whether that destination is a file or queue.

Sets the applicable message range by adding one of the following values to the keyword.

x
Only message x, for example, `-r10`. If `r` is `0`, copies all messages to the destination.

x..y
From message x to message y. For example, `-r 10..20`. `-r0..9` copies one to nine messages to the destination.

x#y
Output y messages starting at message x. For example, `-r 100#10.,-r0#4` copies one to four messages to the destination.

#x
Output the first x messages, for example, `-r #100`. `-r \#0` copies all messages to the destination.

-t
Sets the transaction message limit. The **dmpmqmsg** utility uses transactions to copy messages. Each transaction contains multiple messages, up to a maximum number that is set by the **-t** parameter. The default value is 200.

0
Transactions are not used, so messages are copied individually. If a failure occurs before the application completes its work, nothing is rolled back.

-1
All messages are copied in a single transaction. Use this value with caution because the number of messages on the queue might exceed either the MAXUMSGS parameter of the queue manager (which sets the maximum number of uncommitted messages within a unit of work), or the available log size.

n
The maximum number of messages in each transaction. For example, `-t1000` specifies that the **dmpmqmsg** utility copies up to 1000 messages in each transaction. Ensure that this number does not exceed the MAXUMSGS parameter of the queue manager. You can use the MQSC **DISPLAY QMGR** command to show the value of the MAXUMSGS parameter.

-T
Allows message selection based on message age.

See "Using message age" on page 61 for information on selection using message age.

Attention: The age is based on the **PutDate** and **PutTime** fields in the Message Descriptor (MQMD), compared to UTC for the system where the utility is running.

-s or -e
Allows message selection based on message content.

ALW On ASCII platforms (AIX, Linux, and Windows) use the **-s** option to search for a natively encoded string.

z/OS On EBCDIC platforms (z/OS) use the **-e** option to search for a natively encoded string.

See "Using message content" on page 62 for information on selection using message content.

-u
If you use the -u parameter to supply a user ID, you are prompted for a matching password.

If you have configured the CONNAUTH AUTHINFO record with CHCKLOCL(REQUIRED) or CHCKLOCL(REQDADM), you must use the -u parameter otherwise you will not be able to copy or move the contents of a queue.

If you specify this parameter and redirect stdin, a prompt will not be displayed and the first line of redirected input should contain the password.

-w
Wait interval, in seconds, for consuming messages. If specified the program waits for messages to arrive, for the specified period, before ending.

For examples on using the utility, see Examples of using the **dmpmqmsg** utility. If you store the output of the command in a file, see " Meaning of three letter codes in dmpmqmsg output file" on page 62 for the meaning of the codes in the second column of the information in that file.

Related reference

z/OS The IBM MQ for z/OS utilities

Message selection for dmpmqmsg

Message selection can be based on message age or message content.

Using message age

You can choose to process only messages older than a certain time interval using the `-T` flag.

Time interval can be specified in Days, Hours and Minutes. The general format being `[days:]hours:]minutes`.

The parameter can take one or two times, `-T [OlderThanTime][,YoungerThanTime]`.

For example:

- Display messages older than five minutes

```
dmpmqmsg -m QM1 -i Q1 -fstdout -T5
```

- Display messages younger than five minutes

```
dmpmqmsg -m QM1 -i Q1 -fstdout -T,5
```

- Display messages older than one day but younger than two days.

```
dmpmqmsg -m QM1 -i Q1 -fstdout -T1440,2880
```

- The following command copies messages older than one hour from Q1 to Q2.

```
dmpmqmsg -m QM1 -i Q1 -o Q2 -T1:0
```

- The following command moves messages older than one week from Q1 to Q2

```
dmpmqmsg -m QM1 -I Q1 -o Q2 -T7:0:0
```

Using message content

You can specify a maximum of three of each search string. If multiple strings are used, they are treated as follows:

Positive search strings
When multiple positive strings are used, then all the strings must be present for the search to match. For example, the command

```
dmpmqmsg -iMATCH -s LIVERPOOL -s CHELSEA
```

only returns messages that contain both strings.

Negative search strings
When multiple negative strings are used, then none of the strings must be present for the search to match. For example, the command

```
dmpmqmsg -IMATCH -S HOME -S DRAW
```

only returns messages that contain neither string.

Multi

Meaning of three letter codes in dmpmqmsg output file

The mapping between the codes from **dmpmqmsg** and the attribute names from amqsbcg.

The order of the attributes in the following table is not alphabetical. Instead, the order reflects the sequence of the attribute names from amqsbcg.

*Table 30. Mapping between the three letter codes in the output file from **dmpmqmsg** and the representation from amqsbcg*

File format attribute name (from dmpmqmsg)	Representation (from amqsbcg)
VER	Version
RPT	Report
MST	MsgType
EXP	Expiry
FDB	Feedback
ENC	Encoding
CCS	CodedCharSetId
FMT	Format PRI Priority

*Table 30. Mapping between the three letter codes in the output file from **dmpmqmsg** and the representation from amqsbcg (continued)*	
File format attribute name (from dmpmqmsg)	**Representation (from amqsbcg)**
PER	Persistence
MSI	MsgId
COI	CorrelId
BOC	BackoutCount
RTQ	ReplyToQ
RTM	ReplyToQMgr
USR	UserIdentifier
ACC	AccountingToken
AIX	ApplIdentityData
PAT	PutApplType
PAN	PutApplName
PTD	PutDate
PTT	PutTime
AOX	ApplOriginData
GRP	GroupId
MSQ	MsgSeqNumber
OFF	Offset
MSF	MsgFlags
ORL	OriginalLength

The Browser sample program

Multi dspmq (display queue managers)

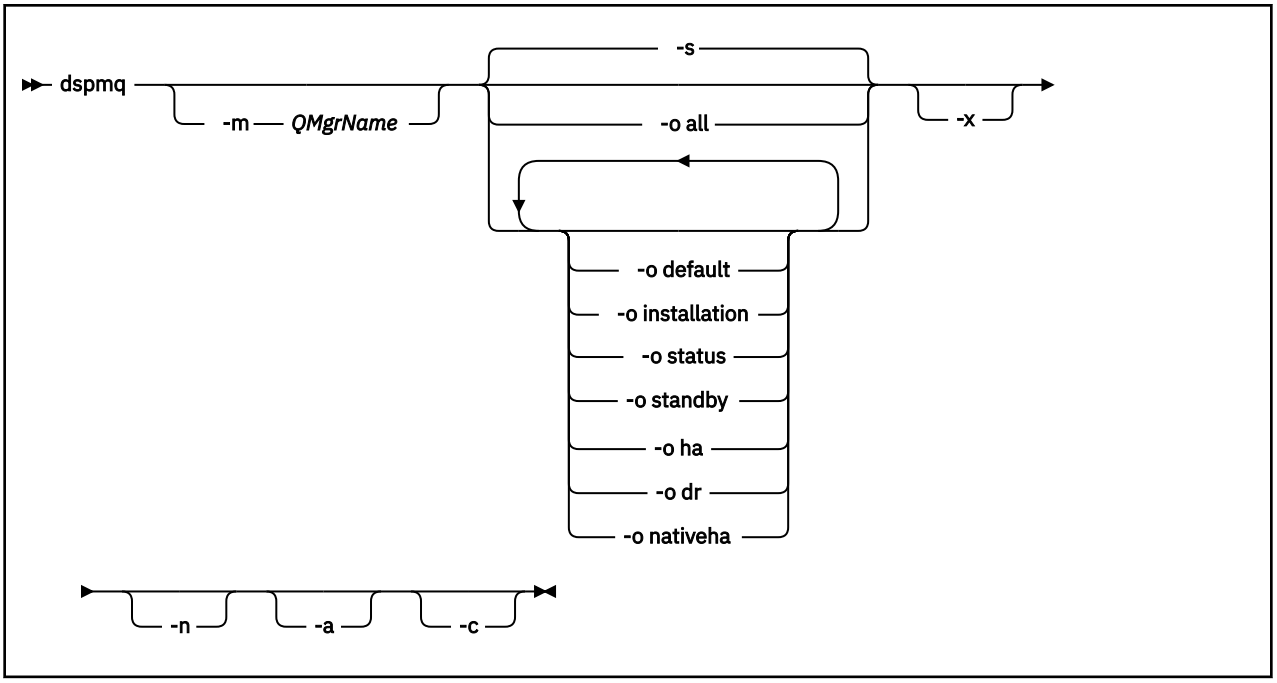
Display information about queue managers on Multiplatforms.

Purpose

Use the dspmq command to display names and details of the queue managers on a system.

z/OS The equivalent utility to dspmq on z/OS is CSQUDSPM.

Syntax



Required parameters

None

Optional parameters

-a
Displays information about the active queue managers only.

A queue manager is active if it is associated with the installation from which the **dspmq** command was issued and one or more of the following statements are true:

- The queue manager is running
- A listener for the queue manager is running
- A process is connected to the queue manager

-m *QMgrName*
The queue manager for which to display details. If you give no name, all queue manager names are displayed.

-n
Suppresses translation of output strings.

-s
The operational status of the queue managers is displayed. This parameter is the default status setting.

The parameter *-o status* is equivalent to *-s*.

-o all
The operational status of the queue managers is displayed, and whether any are the default queue manager.

ALW On AIX, Linux, and Windows, the installation name (INSTNAME), installation path (INSTPATH), and installation version (INSTVER) of the installation that the queue manager is associated with is also displayed.

-o default
Displays whether any of the queue managers are the default queue manager.

ALW **-o installation**
AIX, Linux, and Windows only.

Displays the installation name (INSTNAME), installation path (INSTPATH), and installation version (INSTVER) of the installation that the queue manager is associated with.

-o status
The operational status of the queue managers is displayed.

-o standby
Displays whether a queue manager currently permits starting a standby instance. The possible values are shown in Table 31 on page 65.

Table 31. Standby values

Value	Description
Permitted	The queue manager is running and is permitting standby instances.
Not permitted	The queue manager is running and is not permitting standby instances.
Not applicable	The queue manager is not running. You can start the queue manager and this instance becomes active if it starts successfully.

-o ha | HA
Indicates whether a queue manager is an HA RDQM (high availability replicated data queue manager) or not. If the queue manager is an HA RDQM, one of the following responses is displayed:

HA(Replicated)
Indicates that the queue manager is an HA RDQM.

HA()
Indicates that the queue manager is not an HA RDQM.

For example:

```
dspmq -o ha

QMNAME(RDQM8)                                           HA(Replicated)
QMNAME(RDQM9)                                           HA(Replicated)
QMNAME(RDQM7)                                           HA(Replicated)
QMNAME(QM7)                                             HA()
```

-o dr | DR
Indicates whether a queue manager is a DR RDQM (disaster recovery replicated data queue manager) or not. One of the following responses is displayed:

DRROLE()
Indicates that the queue manager is not configured for disaster recovery.

DRROLE(Primary)
Indicates that the queue manager is configured as the DR primary.

DRROLE(Secondary)
Indicates that the queue manager is configured as the DR secondary.

For example:

```
dspmq -o dr

QMNAME(RDQM13)                                          DRROLE(Primary)
QMNAME(RDQM14)                                          DRROLE(Primary)
QMNAME(RDQM15)                                          DRROLE(Secondary)
QMNAME(QM27)                                            DRROLE()
```

CP4I **-o nativeha | NATIVEHA**

Displays operational information for an instance in a Native HA configuration. Used on its own, displays ROLE, INSTANCE, INSYNC, and QUORUM fields. Combine with the `-x` parameter to view additional information on all the instances in the Native HA configuration (see Native HA instance values).

-x

Information about multi-instance queue manager instances is displayed. CP4I Displays information about Native HA queue manager instances if combined with the `-o nativeha` parameter.

The possible values for multi-instance queue manager instances are shown in Table 32 on page 66.

Table 32. Instance values

Value	Description
Active	The instance is the active instance.
Standby	The instance is a standby instance.

CP4I The possible values for Native HA queue manager instances are shown in Native HA instance values

Table 33. Native HA instance values

Name	Description
ROLE	Specifies the current role of the instance and is one of `Active`, `Replica`, or `Unknown`.
INSTANCE	The name provided for this instance of the queue manager when it was created using the **-lr** option of the **crtmqm** command.
INSYNC	Indicates whether the instance is able to take over as the active instance if required.
QUORUM	Reports the quorum status in the form *number_of_instances_in-sync/ number_of_instances_configured*.
REPLADDR	The replication address of the queue manager instance.
CONNACTV	Indicates whether the instance is connected to the active instance.
BACKLOG	Indicates the number of KB that the node is behind.
CONNINST	Indicates whether the named instance is connected to this instance.
ALTDATE	Indicates the date on which this information was last updated (blank if it has never been updated).
ALTTIME	Indicates the time at which this information was last updated (blank if it has never been updated).

For examples of **dspmq** output for Native HA instances, see Viewing the status of Native HA queue managers for IBM MQ certified containers.

-c
Shows the list of processes currently connected to the IPCC, QMGR, and PERSISTENT subpools for a queue manager.

For example, this list typically includes:

- Queue manager processes
- Applications, including those that are inhibiting shutdown
- Listeners

Queue manager states

The different states that a queue manager can be in are as follows:

- Starting
- Running
- Running as standby
- Running elsewhere
- Quiescing
- Ending immediately
- Ending pre-emptively
- Ended normally
- Ended immediately
- Ended unexpectedly
- Ended pre-emptively
- Status not available

Return codes

Table 34. Return code identifiers and descriptions

Return code	Description
0	Command completed normally
5	Queue manager running
36	Invalid arguments supplied
58	Inconsistent use of installations detected
71	Unexpected error
72	Queue manager name error

Examples

1. The following command displays queue managers on this server:

```
dspmq -o all
```

2. The following command displays standby information for queue managers on this server that have ended immediately:

```
dspmq -o standby
```

3. The following command displays standby information and instance information for queue managers on this server:

```
dspmq -o standby -x
```

dspmqaut (display object authorization)

dspmqaut displays the authorizations of a specific IBM MQ object.

Purpose

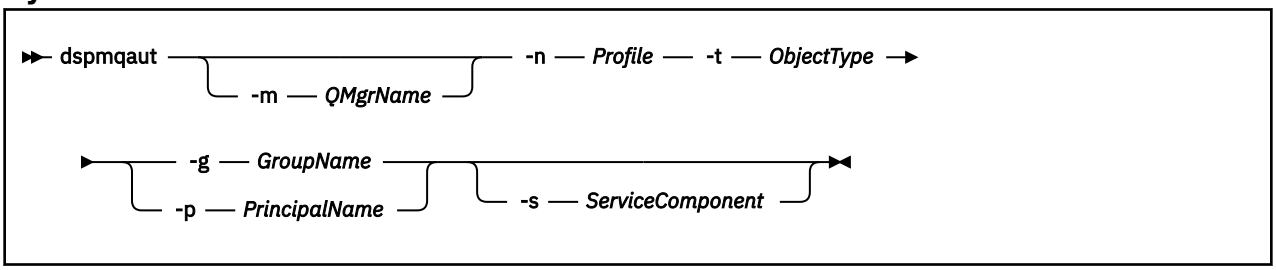
Use the **dspmqaut** command to display the current authorizations to a specified object.

If a user ID is a member of more than one group, this command displays the combined authorizations of all the groups.

Only one group or principal can be specified.

For more information about authorization service components, see Installable services, Service components, and Authorization service interface.

Syntax



Required parameters

-n *Profile*
The name of the profile for which to display authorizations. The authorizations apply to all IBM MQ objects with names that match the profile name specified.

This parameter is required, unless you are displaying the authorizations of a queue manager. In this case you must not include it and instead specify the queue manager name using the **-m** parameter.

-t *ObjectType*
The type of object on which to make the inquiry. Possible values are:

Table 35. The object type on which to make the inquiry.

Object Type	Description
authinfo	An authentication information object, for use with TLS channel security
channel or **chl**	A channel
clntconn or **clcn**	A client connection channel
listener or **lstr**	A Listener
namelist or **nl**	A namelist
process or **prcs**	A process
queue or **q**	A queue or queues matching the object name parameter
qmgr	A queue manager

Table 35. The object type on which to make the inquiry. (continued)	
Object Type	**Description**
rqmname or **rqmn**	A remote queue manager name
service or **srvc**	A service
topic or **top**	A topic

Optional parameters

-m *QMgrName*
The name of the queue manager on which to make the inquiry. This parameter is optional if you are displaying the authorizations of your default queue manager.

-g *GroupName*
The name of the user group on which to make the inquiry. You can specify only one name, which must be the name of an existing user group.

Windows For IBM MQ for Windows only, the group name can optionally include a domain name, specified in the following formats:

```
GroupName@domain
domain\GroupName
```

-p *PrincipalName*
The name of a user for whom to display authorizations to the specified object.

Windows For IBM MQ for Windows only, the name of the principal can optionally include a domain name, specified in the following format:

```
userid@domain
```

For more information about including domain names on the name of a principal, see Principals and groups.

-s *ServiceComponent*
If installable authorization services are supported, specifies the name of the authorization service to which the authorizations apply. This parameter is optional; if you omit it, the authorization inquiry is made to the first installable component for the service.

Returned parameters

Returns an authorization list, which can contain none, one, or more authorization values. Each authorization value returned means that any user ID in the specified group or principal has the authority to perform the operation defined by that value.

Table 36 on page 69 shows the authorities that can be given to the different object types.

Table 36. Specifying authorities for different object types											
Authority	**Queue**	**Process**	**Queue manager**	**Remote queue manager name**	**Namelist**	**Topic**	**Auth info**	**Clntconn**	**Channel**	**Listener**	**Service**
all	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
alladm	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes
allmqi	Yes	Yes	Yes	Yes	Yes	Yes	Yes	No	No	No	No
none	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes

Table 36. Specifying authorities for different object types (continued)

Authority	Queue	Process	Queue manager	Remote queue manager name	Namelist	Topic	Auth info	Clntconn	Channel	Listener	Service
altusr	No	No	Yes	No	No	No	No	No	No	No	No
browse	Yes	No	No	No	No	No	No	No	No	No	No
chg	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes
clr	Yes	No	No	No	No	Yes	No	No	No	No	No
connect	No	No	Yes	No	No	No	No	No	No	No	No
crt	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes
ctrl	No	No	No	No	No	Yes	No	No	Yes	Yes	Yes
ctrlx	No	No	No	No	No	No	No	No	Yes	No	No
dlt	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes
dsp	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes
get	Yes	No	No	No	No	No	No	No	No	No	No
pub	No	No	No	No	No	Yes	No	No	No	No	No
put	Yes	No	No	Yes	No	Yes	No	No	No	No	No
inq	Yes	Yes	Yes	No	Yes	No	Yes	No	No	No	No
passall	Yes	No	No	No	No	Yes	No	No	No	No	No
passid	Yes	No	No	No	No	Yes	No	No	No	No	No
resume	No	No	No	No	No	Yes	No	No	No	No	No
set	Yes	Yes	Yes	No	No	No	No	No	No	No	No
setall	Yes	No	Yes	No	No	Yes	No	No	No	No	No
setid	Yes	No	Yes	No	No	Yes	No	No	No	No	No
sub	No	No	No	No	No	Yes	No	No	No	No	No
system	No	No	Yes	No	No	No	No	No	No	No	No

The following list defines the authorizations associated with each value:

Table 37. Authorizations associated with each value.

Value	Description
all	Use all operations relevant to the object. `all` authority is equivalent to the union of the authorities `alladm`, `allmqi`, and `system` appropriate to the object type.
alladm	Perform all administration operations relevant to the object
allmqi	Use all MQI calls relevant to the object
altusr	Specify an alternative user ID on an MQI call
browse	Retrieve a message from a queue by issuing an `MQGET` call with the BROWSE option

Table 37. Authorizations associated with each value. (continued)

Value	Description
chg	Change the attributes of the specified object, using the appropriate command set
clr	Clear a queue (PCF command Clear queue only) or a topic
ctrl	Start, and stop the specified channel, listener, or service, and ping the specified channel.
ctrlx	Reset or resolve the specified channel
connect	Connect the application to the specified queue manager by issuing an MQCONN call
crt	Create objects of the specified type using the appropriate command set
dlt	Delete the specified object using the appropriate command set
dsp	Display the attributes of the specified object using the appropriate command set
get	Retrieve a message from a queue by issuing an MQGET call
inq	Make an inquiry on a specific queue by issuing an MQINQ call
passall	Pass all context
passid	Pass the identity context
pub	Publish a message on a topic using the MQPUT call.
put	Put a message on a specific queue by issuing an MQPUT call
resume	Resume a subscription using the MQSUB call.
set	Set attributes on a queue from the MQI by issuing an MQSET call
setall	Set all context
setid	Set the identity context
sub	Create, alter, or resume a subscription to a topic using the MQSUB call.
system	Use queue manager for internal system operations

The authorizations for administration operations, where supported, apply to these command sets:

- Control commands
- MQSC commands
- PCF commands

Return codes

Table 38. Return code identifiers and descriptions

Return code	Description
0	Successful operation
26	Queue manager running as a standby instance.
36	Invalid arguments supplied
40	Queue manager not available
49	Queue manager stopping
58	Inconsistent use of installations detected
69	Storage not available
71	Unexpected error
72	Queue manager name error
133	Unknown object name
145	Unexpected object name
146	Object name missing
147	Object type missing
148	Invalid object type
149	Entity name missing

Examples

- The following example shows a command to display the authorizations on queue manager `saturn.queue.manager` associated with user group `staff`:

```
dspmqaut -m saturn.queue.manager -t qmgr -g staff
```

  The results from this command are:

```
Entity staff has the following authorizations for object:
        get
        browse
        put
        inq
        set
        connect
        altusr
        passid
        passall
        setid
```

- The following example displays the authorities user1 has for queue a.b.c:

```
dspmqaut -m qmgr1 -n a.b.c -t q -p user1
```

  The results from this command are:

```
Entity user1 has the following authorizations for object:
        get
        put
```

dspmqcsv (display command server)

The status of a command server is displayed

Purpose

Use the **dspmqcsv** command to display the status of the command server for the specified queue manager.

The status can be one of the following:

- Starting
- Running
- Running with SYSTEM.ADMIN.COMMAND.QUEUE not enabled for gets
- Ending
- Stopped

You must use the **dspmqcsv** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the `dspmq -o installation` command.

Syntax

Required parameters

None

Optional parameters

QMgrName
The name of the local queue manager for which the command server status is being requested.

Return codes

Table 39. Return code identifiers and descriptions

Return code	Description
0	Command completed normally
10	Command completed with unexpected results
20	An error occurred during processing

Examples

The following command displays the status of the command server associated with `venus.q.mgr`:

```
dspmqcsv venus.q.mgr
```

Related commands

Table 40. Related command names and descriptions

Command	Description
strmqcsv	Start a command server
endmqcsv	End a command server

Related reference

"Command server commands" on page 7
A table of command server commands, showing the PCF command, MQSC command, and control command equivalents. The REST API resource and HTTP method equivalents, and IBM MQ Explorer equivalents, are included if available.

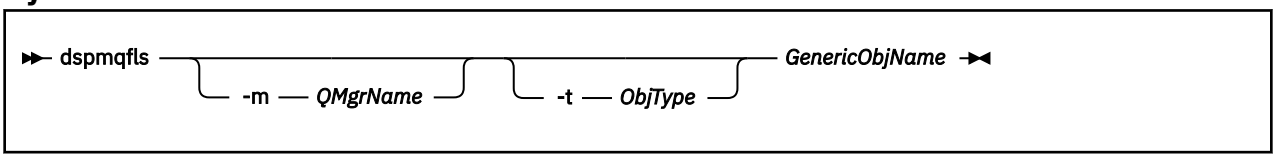
dspmqfls (display file names)

Display the file names corresponding to IBM MQ objects.

Purpose

Use the `dspmqfls` command to display the real file system name for all IBM MQ objects that match a specified criterion. You can use this command to identify the files associated with a particular object. This command is useful for backing up specific objects. See Understanding IBM MQ file names for information about name transformation.

Syntax



Required parameters

GenericObjName
The name of the object. The name is a string with no flag and is a required parameter. Omitting the name returns an error.

This parameter supports an asterisk (*) as a wildcard at the end of the string.

Optional parameters

-m *QMgrName*
The name of the queue manager for which to examine files. If you omit this name, the command operates on the default queue manager.

-t *ObjType*
The object type. The following list shows the valid object types. The abbreviated name is shown first followed by the full name.

Table 41. Valid object types.

Object Type	Description
***** or **all**	All object types; this parameter is the default
authinfo	Authentication information object, for use with TLS channel security

Table 41. Valid object types. (continued)	
Object Type	**Description**
channel or **chl**	A channel
clntconn or **clcn**	A client connection channel
catalog or **ctlg**	An object catalog
namelist or **nl**	A namelist
listener or **lstr**	A listener
process or **prcs**	A process
queue or **q**	A queue or queues matching the object name parameter
qalias or **qa**	An alias queue
qlocal or **ql**	A local queue
qmodel or **qm**	A model queue
qremote or **qr**	A remote queue
qmgr	A queue manager object
service or **srvc**	A service

Note:

1. The **dspmqfls** command displays the name of the directory containing the queue, not the name of the queue itself.
2. Linux AIX On AIX and Linux, you must prevent the shell from interpreting the meaning of special characters, for example, an asterisk (*). The way you do this depends on the shell you are using. It may involve the use of single quotation marks, double quotation marks, or a backslash.

Return codes

Table 42. Return code identifiers and descriptions

Return code	Description
0	Command completed normally
10	Command completed but not entirely as expected
20	An error occurred during processing

Examples

1. The following command displays the details of all objects with names beginning SYSTEM.ADMIN defined on the default queue manager.

```
dspmqfls SYSTEM.ADMIN*
```

2. The following command displays file details for all processes with names beginning PROC defined on queue manager RADIUS.

```
dspmqfls -m RADIUS -t prcs PROC*
```

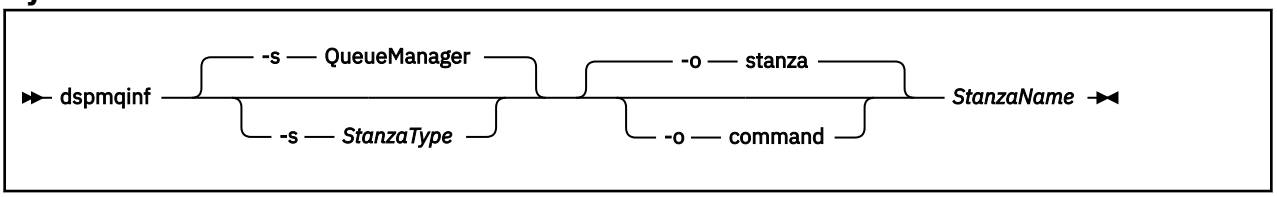
ALW dspmqinf (display configuration information)

Display IBM MQ configuration information (AIX, Linux, and Windows only).

Purpose

Use the **dspmqinf** command to display IBM MQ configuration information.

Syntax



Required parameters

StanzaName
The name of the stanza. That is, the value of the key attribute that distinguishes between multiple stanzas of the same type.

Optional parameters

-s *StanzaType*
The type of stanza to display. If omitted, the QueueManager stanza is displayed.

The only supported value of *StanzaType* is `QueueManager`.

-o stanza
Displays the configuration information in stanza format as it is shown in the `.ini` files. This format is the default output format.

Use this format to display stanza information in a format that is easy to read.

-o command
Displays the configuration information as an **addmqinf** command.

Information about the installation associated with the queue manager is not displayed using this parameter. The **addmqinf** command does not require information about the installation.

Use this format to paste into a command shell.

Return codes

Table 43. Return code identifiers and descriptions

Return code	Description
0	Successful operation
39	Bad command-line parameters
44	Stanza does not exist
58	Inconsistent use of installations detected
69	Storage not available
71	Unexpected error

Table 43. Return code identifiers and descriptions (continued)

Return code	Description
72	Queue manager name error

Examples

```
dspmqinf QM.NAME
```

The command defaults to searching for a QueueManager stanza named `QM.NAME` and displays it in stanza format.

```
QueueManager:
   Name=QM.NAME
   Prefix=/var/mqm
   Directory=QM!NAME
   DataPath=/MQHA/qmgrs/QM!NAME
   InstallationName=Installation1
```

The following command gives the same result:

```
dspmqinf -s QueueManager -o stanza QM.NAME
```

The next example displays the output in **addmqinf** format.

```
dspmqinf -o command QM.NAME
```

The output is on one line:

```
addmqinf -s QueueManager -v Name=QM.NAME -v Prefix=/var/mqm -v Directory=QM!NAME
         -v DataPath=/MQHA/qmgrs/QM!NAME
```

Usage notes

Use **dspmqinf** with **addmqinf** to create an instance of a multi-instance queue manager on a different server.

To use this command you must be an IBM MQ administrator and a member of the `mqm` group.

Related commands

Table 44. Related command names and descriptions

Command	Description
“addmqinf (add configuration information)” on page 13	Add queue manager configuration information
“rmvmqinf (remove configuration information)” on page 135	Remove queue manager configuration information

ALW dspmqinst (display IBM MQ installation)

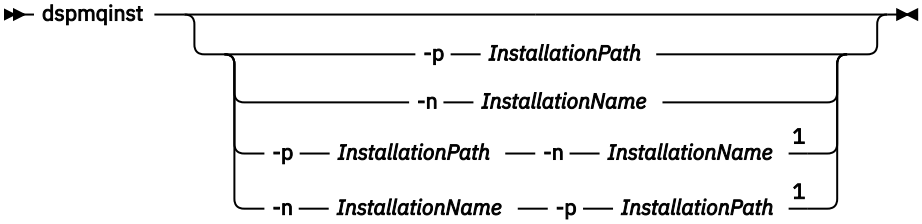
V 9.2.0 Display installation entries from `mqinst.ini` on AIX, Linux, and Windows, and display license entitlement information.

Purpose

The `mqinst.ini` file contains information about all IBM MQ installations on a system. For more information about `mqinst.ini`, see Installation configuration file, mqinst.ini. You can display information from all installation son the system, or about specific installations.

V 9.2.0 **dspmqinst** also displays information about license entitlement for each installation. The command displays the license type (Production, Trial, Beta, or Developer) and the licensed entitlement required for the IBM MQ installation. The required entitlement is reported based on the components that are installed and usage information that has been specified using the **setmqinst** command (see “setmqinst (set IBM MQ installation)” on page 194). See IBM MQ license information for more information about license types and entitlement.

Syntax



Notes:

1 When specified together, the installation name and installation path must refer to the same installation.

Required parameters

None

Optional parameters

-n *InstallationName*
The name of the installation.

-p *InstallationPath*
The installation path.

?
Display usage information.

Return codes

Table 45. Return code identifiers and descriptions

Return code	Description
0	Entry displayed without error
36	Invalid arguments supplied
44	Entry does not exist
59	Invalid installation specified

Table 45. Return code identifiers and descriptions (continued)

Return code	Description
71	Unexpected error
89	.ini file error
96	Could not lock .ini file
131	Resource problem

Examples

1. Display details of all IBM MQ installations on the system:

```
dspmqinst
```

2. Query the entry for the installation named *Installation3*:

```
dspmqinst -n Installation3
```

3. Query the entry with an installation path of `/opt/mqm`:

```
dspmqinst -p /opt/mqm
```

4. Query the entry for the installation named *Installation3*. Its expected installation path is `/opt/mqm`:

```
dspmqinst -n Installation3 -p /opt/mqm
```

5. V 9.2.0 The following examples show the output of **dspmqinst** for different license types and entitlements:

   - Output for an IBM MQ client installation:

```
InstName:      Installation1
InstDesc:      My installation
Identifier:    1
InstPath:      /opt/mqm
Version:       9.1.4.0
Primary:       No
State:         Available
License:       Production
Entitlement:   IBM MQ Client
```

   - Output for a standard IBM MQ server installation:

```
InstName:      Installation1
InstDesc:      My installation
Identifier:    1
InstPath:      /opt/mqm
Version:       9.1.4.0
Primary:       No
State:         Available
License:       Production
Entitlement:   IBM MQ
```

   - Output for an IBM MQ server installation that has been identified as a High Availability Replica:

```
InstName:      Installation1
InstDesc:      My installation
Identifier:    1
InstPath:      /opt/mqm
Version:       9.1.4.0
Primary:       No
State:         Available
License:       Production
Entitlement:   IBM MQ High Availability Replica
```

- Output for an IBM MQ Advanced server installation:

```
InstName:      Installation1
InstDesc:      My installation
Identifier:    1
InstPath:      /opt/mqm
Version:       9.1.4.0
Primary:       No
State:         Available
License:       Production
Entitlement:   IBM MQ Advanced
```

- Output for an IBM MQ Advanced server installation that has high availability replica entitlement:

```
InstName:      Installation1
InstDesc:      My installation
Identifier:    1
InstPath:      /opt/mqm
Version:       9.1.4.0
Primary:       No
State:         Available
License:       Production
Entitlement:   IBM MQ Advanced High Availability Replica
```

- V 9.2.2 Output for an IBM MQ Advanced server installation that has non production entitlement:

```
InstName:      Installation1
InstDesc:      My installation
Identifier:    1
InstPath:      /opt/mqm
Version:       9.2.2.0
Primary:       No
State:         Available
License:       Production
Entitlement:   IBM MQ Advanced (Non-production)
```

V 9.2.0 Linux dspmqlic (display IBM MQ license)

Display an IBM MQ license.

Purpose

On Linux (excluding IBM MQ Appliance) use the **dspmqlic** command to display the IBM MQ license in the appropriate language for the environment.

Syntax

Required parameters

None

Optional parameters

None

Return codes

Table 46. Return code identifiers and descriptions

Return code	Description
0	The license file is displayed in some language
20	An error occurred

Usage notes

You can change the language can by setting the LANG environment variable. Note that you might need to install the necessary operating system language pack to obtain the required information in a language other than English.

"strmqm (start queue manager)" on page 220
Start a queue manager or ready it for standby operation.

dspmqrte (display route information)

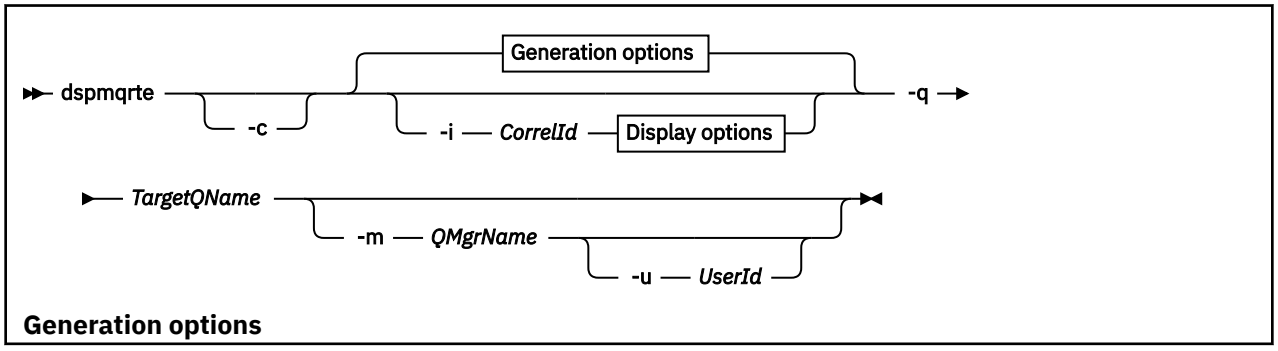
Determine the route that a message has taken through a queue manager network.

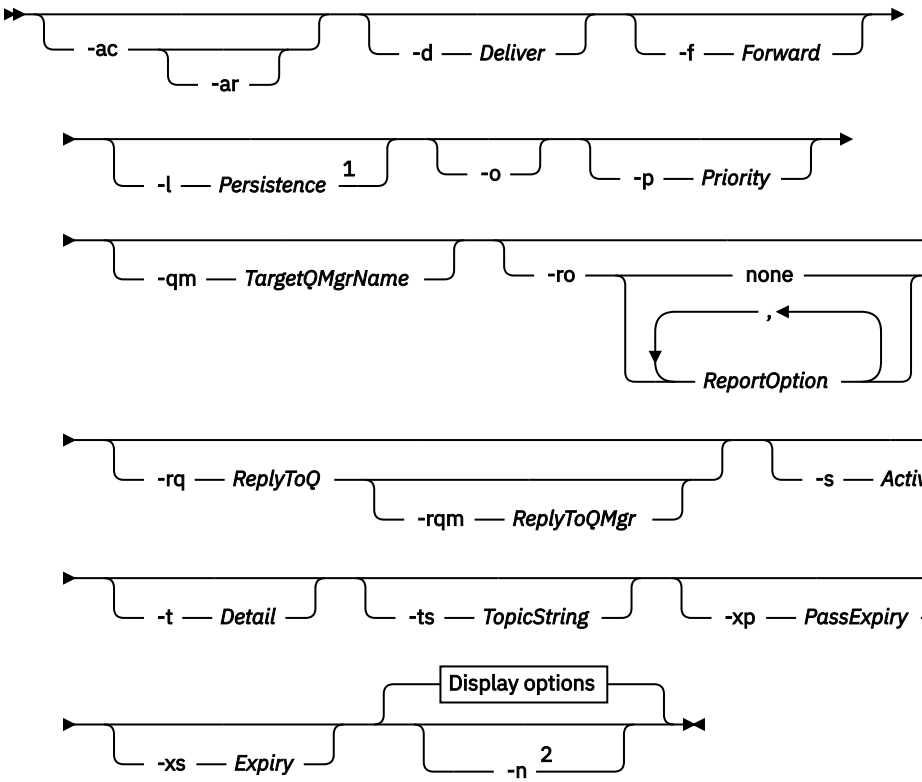
Purpose

The IBM MQ display route application (**dspmqrte**) command can be run on all platforms except z/OS. You can run the IBM MQ display route application as a client to an IBM MQ for z/OS queue manager by specifying the **-c** parameter when issuing the **dspmqrte** command.

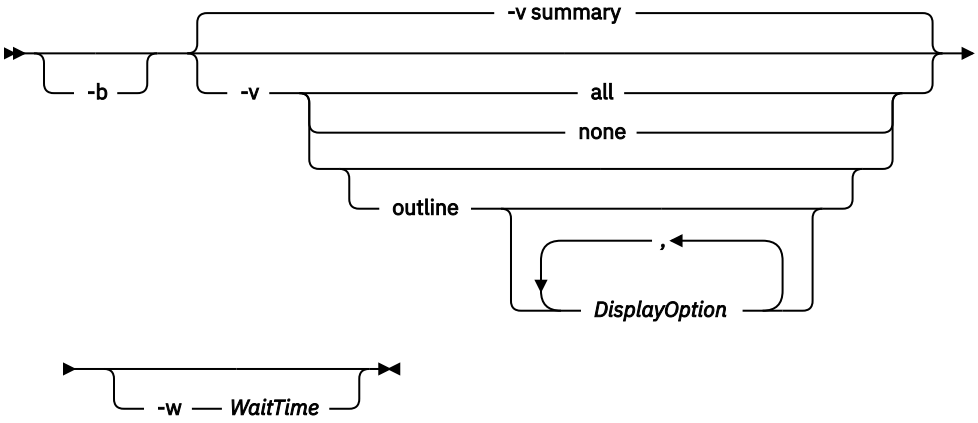
The IBM MQ display route application generates and puts a trace-route message into a queue manager network. As the trace-route message travels through the queue manager network, activity information is recorded. When the trace-route message reaches its target queue, the activity information is collected by the IBM MQ display route application and displayed. For more information, and examples of using the IBM MQ display route application, see IBM MQ display route application.

Syntax





Display options



Notes:

[1] If *Persistence* is specified as `yes`, and is accompanied by a request for a trace-route reply message (*-ar*), or any report generating options (*-ro ReportOption*), then you must specify the parameter *-rq ReplyToQ*. The reply-to queue must not resolve to a temporary dynamic queue.

[2] If this parameter is accompanied by a request for a trace-route reply message (`-ar`), or any of the report generating options (`-ro ReportOption`), then a specific (non-model) reply-to queue must be specified using `-rq ReplyToQ` . By default, activity report messages are requested.

Required parameters

-q *TargetQName*

If the IBM MQ display route application is being used to send a trace-route message into a queue manager network, *TargetQName* specifies the name of the target queue.

If the IBM MQ display route application is being used to view previously gathered activity information, *TargetQName* specifies the name of the queue where the activity information is stored.

Optional parameters

-c

Specifies that the IBM MQ display route application connects as a client application. For more information about how to set up client machines, see:

- AIX Installing an IBM MQ client on an AIX workstation
- Linux Installing an IBM MQ client on a Linux workstation
- Windows Installing an IBM MQ client on a Windows workstation
- IBM i Installing an IBM MQ client on an IBM i workstation

This parameter can be used only if the client component is installed.

-i *CorrelId*

This parameter is used when the IBM MQ display route application is used to display previously accumulated activity information only. There can be many activity reports and trace-route reply messages on the queue specified by `-q TargetQName`. *CorrelId* is used to identify the activity reports, or a trace-route reply message, related to a trace-route message. Specify the message identifier of the original trace-route message in *CorrelId*.

The format of *CorrelId* is a 48 character hexadecimal string.

-m *QMgrName*

The name of the queue manager to which the IBM MQ display route application connects. The name can contain up to 48 characters.

If you do not specify this parameter, the default queue manager is used.

Generation options

The following parameters are used when the IBM MQ display route application is used to put a trace-route message into a queue manager network.

-ac

Specifies that activity information is to be accumulated within the trace-route message.

If you do not specify this parameter, activity information is not accumulated within the trace-route message.

-ar

Requests that a trace-route reply message containing all accumulated activity information is generated in the following circumstances:

- The trace-route message is discarded by an IBM WebSphere MQ 7.0 queue manager.
- The trace-route message is put to a local queue (target queue or dead-letter queue) by a IBM WebSphere MQ 7.0 queue manager.
- The number of activities performed on the trace-route message exceeds the value of specified in `-s Activities`.

For more information about trace-route reply messages, see Trace-route reply message reference.

If you do not specify this parameter, a trace-route reply message is not requested.

-d *Deliver*

Specifies whether the trace-route message is to be delivered to the target queue on arrival. Possible values for *Deliver* are:

Table 47. Delivery parameter values.

Value	Description
`yes`	On arrival, the trace-route message is put to the target queue, even if the queue manager does not support trace-route messaging.

Table 47. Delivery parameter values. (continued)	
Value	**Description**
no	On arrival, the trace-route message is not put to the target queue.

If you do not specify this parameter, the trace-route message is not put to the target queue.

-f *Forward*
Specifies the type of queue manager that the trace-route message can be forwarded to. Queue managers use an algorithm when determining whether to forward a message to a remote queue manager. For details of this algorithm, see The cluster workload management algorithm. The possible values for *Forward* are:

Table 48. Forward parameter values.	
Value	**Description**
`all`	The trace-route message is forwarded to any queue manager. **Warning:** If forwarded to a queue manager before IBM WebSphere MQ 6.0, the trace-route message is not recognized and can be delivered to a local queue despite the value of the **`-d Deliver`** parameter.
`supported`	The trace-route message is only forwarded to a queue manager that honors the *Deliver* parameter from the *TraceRoute* PCF group.

If you do not specify this parameter, the trace-route message is only forwarded to a queue manager that honors the *Deliver* parameter.

-l *Persistence*
Specifies the persistence of the generated trace-route message. Possible values for *Persistence* are:

Table 49. Persistence parameter values.	
Value	**Description**
`yes`	The generated trace-route message is persistent. (MQPER_PERSISTENT).
no	The generated trace-route message is not persistent. (MQPER_NOT_PERSISTENT).
q	The generated trace-route message inherits its persistence value from the queue specified by `-q` *`TargetQName`*. (MQPER_PERSISTENCE_AS_Q_DEF).

A trace-route reply message, or any report messages, returned shares the same persistence value as the original trace-route message.

If *Persistence* is specified as `yes`, you must specify the parameter `-rq` *`ReplyToQ`*. The reply-to queue must not resolve to a temporary dynamic queue.

If you do not specify this parameter, the generated trace-route message is not persistent.

-o
Specifies that the target queue is not bound to a specific destination. Typically this parameter is used when the trace-route message is to be put across a cluster. The target queue is opened with option MQOO_BIND_NOT_FIXED.

If you do not specify this parameter, the target queue is bound to a specific destination.

-p *Priority*
Specifies the priority of the trace-route message. The value of *Priority* is either greater than or equal to 0, or MQPRI_PRIORITY_AS_Q_DEF. MQPRI_PRIORITY_AS_Q_DEF specifies that the priority value is taken from the queue specified by `-q` *`TargetQName`*.

If you do not specify this parameter, the priority value is taken from the queue specified by `-q` *`TargetQName`*.

-qm *TargetQMgrName*
Qualifies the target queue name; normal queue manager name resolution applies. The target queue is specified with `-q` *`TargetQName`*.

If you do not specify this parameter, the queue manager to which the IBM MQ display route application is connected is used as the reply-to queue manager.

-ro none | `ReportOption`

Table 50. ReportOption parameter values.

Value	Description
none	Specifies no report options are set.
ReportOption	Specifies report options for the trace-route message. Multiple report options can be specified using a comma as a separator. Possible values for *ReportOption* are: **activity** The report option MQRO_ACTIVITY is set. **coa** The report option MQRO_COA_WITH_FULL_DATA is set. **cod** The report option MQRO_COD_WITH_FULL_DATA is set. **exception** The report option MQRO_EXCEPTION_WITH_FULL_DATA is set. **expiration** The report option MQRO_EXPIRATION_WITH_FULL_DATA is set. **discard** The report option MQRO_DISCARD_MSG is set.

If `-ro` *`ReportOption`* or `-ro` none are not specified, then the MQRO_ACTIVITY and MQRO_DISCARD_MSG report options are specified.

-rq *ReplyToQ*
Specifies the name of the reply-to queue that all responses to the trace-route message are sent to. If the trace-route message is persistent, or if the **-n** parameter is specified, a reply-to queue must be specified that is not a temporary dynamic queue.

If you do not specify this parameter, the system default model queue, SYSTEM.DEFAULT.MODEL.QUEUE is used as the reply-to queue. Using this model queue causes a temporary dynamic queue, for the IBM MQ display route application, to be created.

-rqm *ReplyToQMgr*
Specifies the name of the queue manager where the reply-to queue is located. The name can contain up to 48 characters.

If you do not specify this parameter, the queue manager to which the IBM MQ display route application is connected is used as the reply-to queue manager.

-s *Activities*
Specifies the maximum number of recorded activities that can be performed on behalf of the trace-route message before it is discarded. This parameter prevents the trace-route message from being forwarded indefinitely if caught in an infinite loop. The value of *Activities* is either greater than or equal to 1, or MQROUTE_UNLIMITED_ACTIVITIES. MQROUTE_UNLIMITED_ACTIVITIES specifies that an unlimited number of activities can be performed on behalf of the trace-route message.

If you do not specify this parameter, an unlimited number of activities can be performed on behalf of the trace-route message.

-t *Detail*
Specifies the activities that are recorded. The possible values for *Detail* are:

Table 51. Detail parameter values.

Value	Description
`low`	Activities performed by user-defined application are recorded only.
`medium`	Activities specified in `low` are recorded. Additionally, activities performed by MCAs are recorded.
`high`	Activities specified in `low`, and `medium` are recorded. MCAs do not expose any further activity information at this level of detail. This option is available to user-defined applications that are to expose further activity information only. For example, if a user-defined application determines the route a message takes by considering certain message characteristics, the routing logic can be included with this level of detail.

If you do not specify this parameter, medium level activities are recorded.

-ts *TopicString*
Specifies a topic string to which the IBM MQ display route application is to publish a trace-route message, and puts this application into topic mode. In this mode, the application traces all of the messages that result from the publish request.

-xp *PassExpiry*
Specifies whether the report option MQRO_DISCARD_MSG and the remaining expiry time from the trace-route message is passed on to the trace-route reply message. Possible values for *PassExpiry* are:

Table 52. PassExpiry parameter values.

Value	Description
`yes`	The report option MQRO_PASS_DISCARD_AND_EXPIRY is specified in the message descriptor of the trace-route message. If a trace-route reply message, or activity reports, are generated for the trace-route message, the MQRO_DISCARD_MSG report option (if specified), and the remaining expiry time are passed on. This parameter is the default value.
`no`	The report option MQRO_PASS_DISCARD_AND_EXPIRY is not specified. If a trace-route reply message is generated for the trace-route message, the discard option and remaining expiry time from the trace-route message are not passed on.

If you do not specify this parameter, the MQRO_PASS_DISCARD_AND_EXPIRY report option is not specified in the trace-route message.

-xs *Expiry*
Specifies the expiry time for the trace-route message, in seconds.

If you do not specify this parameter, the expiry time is specified as 60 seconds.

-n
Specifies that activity information returned for the trace-route message is not to be displayed.

If this parameter is accompanied by a request for a trace-route reply message (`-ar`), or any of the report generating options from (`-ro` *`ReportOption`*), then a specific (non-model) reply-to queue must be specified using `-rq` *`ReplyToQ`*. By default, activity report messages are requested.

After the trace-route message is put to the specified target queue, a 48 character hexadecimal string is returned containing the message identifier of the trace-route message. The message identifier can be used by the IBM MQ display route application to display the activity information for the trace-route message at a later time. This can be done using the **-i** *CorrelId* parameter.

If you do not specify this parameter, activity information returned for the trace-route message is displayed in the form specified by the **-v** parameter.

Display options

The following parameters are used when the IBM MQ display route application is used to display collected activity information.

-b

Specifies that the IBM MQ display route application only browses activity reports or a trace-route reply message related to a message. This parameter allows activity information to be displayed again at a later time.

If you do not specify this parameter, the IBM MQ display route application gets activity reports and deletes them, or a trace-route reply message related to a message.

-v summary | all | none | outline *DisplayOption*

Table 53. DisplayOption parameter values.

Value	Description
summary	The queues that the trace-route message was routed through are displayed.
all	All available information is displayed.
none	No information is displayed.
outline *DisplayOption*	Specifies display options for the trace-route message. Multiple display options can be specified using a comma as a separator. If no values are supplied the subsequent information is displayed: • The application name • The type of each operation • Any operation-specific parameters Possible values for *DisplayOption* are: **activity** All non-PCF group parameters in *Activity* PCF groups are displayed. **identifiers** Values with parameter identifiers MQBACF_MSG_ID or MQBACF_CORREL_ID are displayed. This overrides *msgdelta*. **message** All non-PCF group parameters in *Message* PCF groups are displayed. When this value is specified, you cannot specify *msgdelta*. **msgdelta** All non-PCF group parameters in *Message* PCF groups, that have changed since the last operation, are displayed. When this value is specified, you cannot specify *message*. **operation** All non-PCF group parameters in *Operation* PCF groups are displayed. **traceroute** All non-PCF group parameters in *TraceRoute* PCF groups are displayed.

If you do not specify this parameter, a summary of the message route is displayed.

-w *WaitTime*
Specifies the time, in seconds, that the IBM MQ display route application waits for activity reports, or a trace-route reply message, to return to the specified reply-to queue.

If you do not specify this parameter, the wait time is specified as the expiry time of the trace-route message, plus 60 seconds.

-u *UserId*
The ID of the user authorized to determine the route that a message has taken through a queue manager network.

Return codes

Table 54. Return code identifiers and descriptions

Return code	Description
0	Command completed normally
10	Invalid arguments supplied
20	An error occurred during processing

Examples

1. The following command puts a trace-route message into a queue manager network with the target queue specified as TARGET.Q. Providing queue managers on route are enabled for activity recording, activity reports are generated. Depending on the queue manager attribute, ACTIVREC, activity reports are either delivered to the reply-to queue ACT.REPORT.REPLY.Q, or are delivered to a system queue. The trace-route message is discarded on arrival at the target queue.

   ```
   dspmqrte -q TARGET.Q -rq ACT.REPORT.REPLY.Q
   ```

   Providing one or more activity reports are delivered to the reply-to queue, ACT.REPORT.REPLY.Q, the IBM MQ display route application orders and displays the activity information.
2. The following command puts a trace-route message into a queue manager network with the target queue specified as TARGET.Q. Activity information is accumulated within the trace-route message, but activity reports are not generated. On arrival at the target queue, the trace-route message is discarded. Depending on the value of the target queue manager attribute, ROUTEREC, a trace-route reply message can be generated and delivered to either the reply-to queue, TRR.REPLY.TO.Q, or to a system queue.

   ```
   dspmqrte -ac -ar -ro discard -rq TRR.REPLY.TO.Q -q TARGET.Q
   ```

   Providing a trace-route reply message is generated, and delivered to the reply-to queue TRR.REPLY.TO.Q, the IBM MQ display route application orders and displays the activity information that was accumulated in the trace-route message.

For more examples of using the IBM MQ display route application and its output, see IBM MQ display route application examples.

dspmqspl (display security policy)

Use the **dspmqspl** command to display a list of all policies and details of a named policy.

Before you begin

- The queue manager on which you want to operate must be running.

- You must grant the necessary +connect, +inq and +chg authorities, using the setmqaut command, to connect to the queue manager and create a security policy.

For more information about configuring security see Setting up security.

Syntax

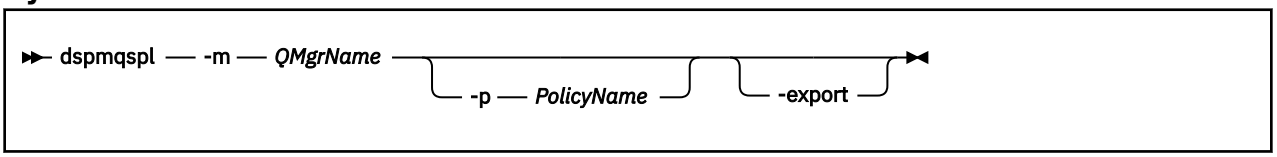


Table 55. dspmqspl command flags	
Command flag	**Explanation**
-m	Queue manager name (mandatory).
-p	Policy name.
-export The output is written to a DD named EXPORT	Adding this flag generates output which can easily be applied to a different queue manager.

Examples

The **dspmqspl** command shows the key reuse count for all policies. The following example is the output you receive on Multiplatforms:

```
Policy Details:
Policy name: PROT
Quality of protection: PRIVACY
Signature algorithm: SHA256
Encryption algorithm: AES256
Signer DNs: -
Recipient DNs:
  CN=Name, O=Organization, C=Country
Toleration: 0
Key Reuse Count: 0
- - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - -
Policy Details:
Policy name: PROT2
Quality of protection: CONFIDENTIALITY
Signature algorithm: NONE
Encryption algorithm: AES256
Signer DNs: -
Recipient DNs:
  CN=Name, O=Organization, C=Country
Toleration: 0
Key Reuse Count: 100
```

z/OS On z/OS, you can use the **dspmqspl** command with the CSQ0UTIL utility. For more information, see "The message security policy utility (CSQ0UTIL)" on page 2754.

Related reference

"SET POLICY (set security policy) on Multiplatforms" on page 915
Use the MQSC command SET POLICY to set a security policy.

"DISPLAY POLICY (display a security policy) on Multiplatforms" on page 737
Use the MQSC command DISPLAY POLICY to display a security policy.

"setmqspl (set security policy)" on page 201

Use the **setmqspl** command to define a new security policy, replace an already existing one, or remove an existing policy.

Linux AIX dspmqtrc (display formatted trace)

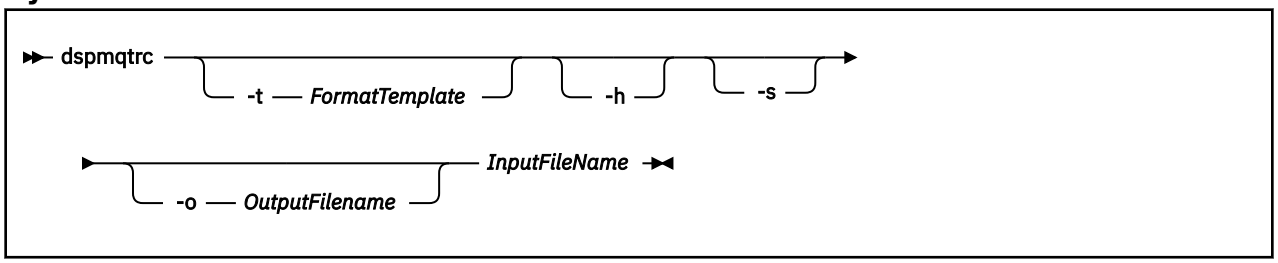
Format and display IBM MQ trace.

Purpose

The **dspmqtrc** command is supported on AIX, Linux, systems only. Use the **dspmqtrc** command to display IBM MQ formatted trace output.

The runtime TLS trace files have the names AMQ.SSL.TRC and AMQ.SSL.TRC.1. You cannot format any of the TLS trace files. The TLS trace files are binary files and, if they are transferred to IBM support by FTP, they must be transferred in binary transfer mode.

Syntax



Required parameters

InputFileName
The name of the file containing the unformatted trace, for example:

```
/var/mqm/trace/AMQ12345.01.TRC
```

If you provide one input file, **dspmqtrc** formats it to the output file you name. If you provide more than one input file, any output file you name is ignored, and formatted files are named AMQ *yyyyy*.*zz*.FMT, based on the PID of the trace file.

Optional parameters

-t *FormatTemplate*
The name of the template file containing details of how to display the trace. If this parameter is not supplied, the default template file location is used:

AIX For AIX systems, the default value is as follows:

```
MQ_INSTALLATION_PATH/lib/amqtrc2.fmt
```

Linux For Linux, the default value is as follows:

```
MQ_INSTALLATION_PATH/lib/amqtrc.fmt
```

MQ_INSTALLATION_PATH represents the high-level directory in which IBM MQ is installed.

-h
Omit header information from the report.

-s
Extract trace header and put to stdout.

-o *output_filename*
The name of the file into which to write formatted data.

Related commands

Table 56. Related command names and descriptions

Command	Description
endmqtrc	End trace
"strmqtrc (Start trace)" on page 225	Start trace

Command sets comparison: Other commands
A table of other commands, showing the command description, and its PCF command, MQSC command, and control command equivalents. The REST API resource and HTTP method equivalents, and IBM MQ Explorer equivalents, are included if available.

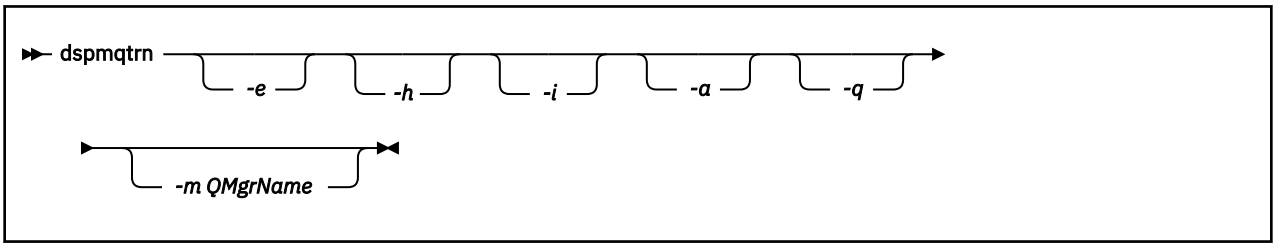
dspmqtrn (display incomplete transactions)

Display in-doubt and heuristically completed transactions.

Purpose

Use the **dspmqtrn** command to display details of transactions. This command includes transactions coordinated by IBM MQ and by an external transaction manager.

Syntax



Optional parameters

-e
Requests details of externally coordinated, in-doubt XA transactions. Such transactions are those for which the queue manager (RM) has been asked to prepare to commit, but has not yet been informed by the TM of the transaction outcome (commit or rollback).

-h
Requests details of externally coordinated transactions that were resolved by the **rsvmqtrn** command, and the external transaction coordinator has yet to acknowledge with an `xa-forget` command. This transaction state is termed *heuristically completed* by X/Open.

Note: If you do not specify **-e**, **-h**, or **-i**, details of both internally and externally coordinated in-doubt transactions are displayed, but details of externally coordinated, heuristically completed transactions are not displayed.

-i
Requests details of internally coordinated, in-doubt XA transactions. Such transactions are those for which the queue manager (TM) has asked each resource manager (RM) to prepare to commit, but an error was reported by one of the resource managers (for example, a network connection broke). In this state, the queue manager (TM) has yet to inform all resource managers of the transaction

outcome (commit or rollback), but stands ready to do so. For more information, see Displaying outstanding units of work with the dspmqtrn command.

Information about the state of the transaction in each of its participating resource managers is displayed. This information can help you assess the affects of failure in a particular resource manager.

Note: If you do not specify **-e** or **-i**, details of both internally and externally coordinated in-doubt transactions are displayed.

-a

Requests a list of all transactions known to the queue manager . The returned data includes transaction details for all transactions known to the queue manager. If a transaction is currently associated with an IBM MQ application connection, information related to that IBM MQ application connection is also returned. The data returned by this command might typically be correlated with the output of a `runmqsc` "DISPLAY CONN (display application connection information)" on page 707 command, and the output fields have the same meaning as in that command.

Not all of the fields are appropriate for all transactions. When the fields are not meaningful, they are displayed as blank. For example: The `UOWLOG` value when the command is issued against a circular logging queue manager.

-q

Specifying this parameter on its own is the same as specifying `-a -q`.

Displays all the data from the **-a** parameter and a list of up to 100 unique objects updated within the transaction. If more than 100 objects are updated in the same transaction, only the first 100 distinct objects are listed for each transaction.

-m *QMgrName*

The name of the queue manager for which to display transactions. If you omit the name, the transaction of the default queue manager are displayed.

Return codes

Table 57. Return code identifiers and descriptions

Return code	Description
0	Successful operation
26	Queue manager running as a standby instance.
36	Invalid arguments supplied
40	Queue manager not available
49	Queue manager stopping
58	Inconsistent use of installations detected
69	Storage not available
71	Unexpected error
72	Queue manager name error
102	No transactions found

Example

Here is a typical use of the command, showing the form that is usually requested by IBM MQ Support:

```
dspmqtrn -m <qmgrname> -q -a
```

The output generated would be long. As an illustration, here is what one XA transaction might look like in the output:

```
TranNum(0,12294)
   TRANSTATE(ACTIVE)
   UOWLOGDA(2024-11-04)
   UOWLOGTI(14.58.32)
   UOWSTDA(2024-11-04)
   UOWSTTI(14.58.32)
   UOWLOG( )
   EXTURID(XA_FORMATID[40]
   XA_GTRID[737871746732313400000000000000000000000000
   00000000000000000000000000004D8CF5C2E29D80014751A]
   XA_BQUAL[00000028000000100000003])
   OBJECT(TEST.Q)
```

Related tasks

Displaying outstanding units of work with the dspmqtrn command

Related reference

“rsvmqtrn (resolve transactions)” on page 137

Resolve in-doubt and heuristically completed transactions

dspmqver (display version information)

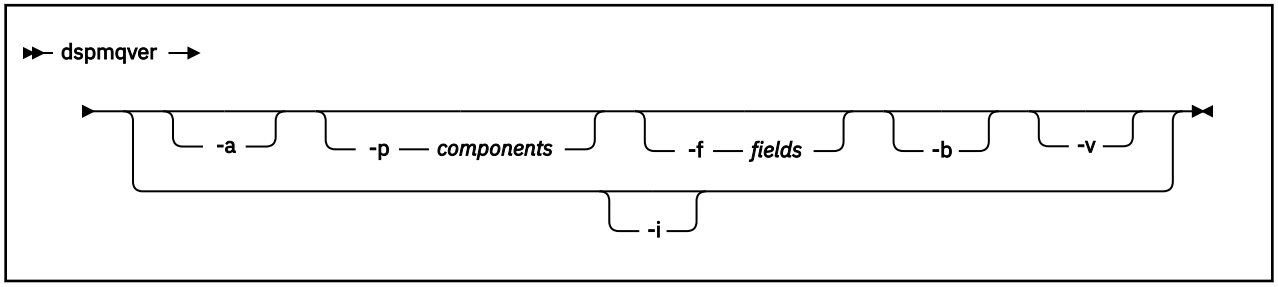
Display IBM MQ version and build information.

Purpose

Use the **dspmqver** command to display IBM MQ version and build information.

By default, the **dspmqver** command displays details of the installation from which it was invoked. A note is displayed if other installations exist; use the **-i** parameter to display their details.

Syntax



Optional parameters

-a

Display information about all fields and components.

V 9.2.0 For IBM MQ 9.1 and earlier, when 32-bit support is missing from a 64-bit system, the **dspmqver -a** command might issue a message suggesting that the 32 bit version of IBM Global Security Kit (GSKit) is not installed. For more information, see the "Command failure" section of this topic. This issue is fixed in IBM MQ 9.2.

-p *Components*

Display information for the components specified by *component*. Either a single component or multiple components can be specified. Enter either the value of a single component or the sum of the values of all the required components. Available components and related values are as follows:

Value	Description
1	IBM MQ server, or client.
2	IBM MQ classes for Java.
4	IBM MQ classes for Java Message Service.
8	WebScale Distribution Hub
16 "1" on page 94	Windows IBM MQ custom channel for Windows Communication Foundation
32	Windows IBM Message Service Client for .NET (XMS .NET) - this component is only available on Windows
64	GSKit V 9.2.0 For IBM MQ 9.1 and earlier, when 32-bit support is missing from a 64-bit system, the **dspmqver -a** command might issue a message suggesting that the 32 bit version of GSKit is not installed. For more information, see the "Command failure" section of this topic. This issue is fixed in IBM MQ 9.2.
128	Advanced Message Security
256	IBM MQ AMQP Service
512	IBM MQ Telemetry Service
1024	Other bundled components that are used by IBM MQ
2048	WebSphere Liberty profile
4096	IBM MQ Java Runtime Environment
8192	IBM MQ Replicated Data Queue Managers

Notes:

1. Windows Supported by IBM MQ for Windows only. If you have not installed Microsoft.NET 3 or later, the following error message is displayed:

   ```
   Title: WMQWCFCustomChannelLevel.exe - Application Error

   The application failed to initialize properly (0x0000135).
   ```

The default value is 1.

-f *Fields*

Display information for the fields specified by *field*. Specify either a single field or multiple fields. Enter either the value of a single field or the sum of the values of all the required fields. Available fields and related values are as follows:

Value	Description
1	Name
2	Version, in the form V.R.M.F: Where V =Version, R =Release, M =Modification, and F =Fix pack
4	Level
8	Build type
16	Platform

Value	Description
32	Addressing mode
64	Operating system
128	Installation path
256	Installation description
512	Installation name
1024	Maximum command level
2048	Primary installation
4096	Data Path
8192	License type

Information for each selected field is displayed on a separate line when the **dspmqver** command is run.

The default value is 8191. This displays information for all fields.

-b
Omit header information from the report.

-v
Display verbose output.

-i
Display information about all installations. You cannot use this option with other options. The installation from which the **dspmqver** command was issued is displayed first. For any other installations, only the following fields are displayed: Name, Version, Installation name, Installation description, Installation path, and Primary installation.

Return codes

Table 58. Return code identifiers and descriptions

Return code	Description
0	Command completed normally.
10	Command completed with unexpected results.
20	An error occurred during processing.

Examples

The following command displays IBM MQ version and build information, using the default settings for **-p** and **-f**:

```
dspmqver
```

The following command displays information about all fields and components and is the equivalent of specifying `dspmqver -p 63 -f 4095`:

```
dspmqver -a
```

The following command displays version and build information for the IBM MQ classes for Java:

```
dspmqver -p 2
```

The following command displays the Common Services for Java Platform Standard Edition, IBM MQ, Java Message Service Client, and IBM MQ classes for Java Message Service:

```
dspmqver -p 4
```

The following command displays the build level of the WebScale Distribution Hub:

```
dspmqver -p 8 -f 4
```

Windows The following command displays the name and build type for IBM MQ custom channel for Windows Communication Foundation:

```
dspmqver -p 16 -f 9
```

The following command displays information about installations of IBM MQ.

```
dspmqver -i
```

V 9.2.0 Example output for MQ.NET Standard classes:

```
Name:        IBM Message Service Client for .NET Standard
Version:     9.1.1.0
Level:       p911-LXXXX
Build Type:  Production
```

Command failure

V 9.2.0 *Failure when 32-bit support is missing from a 64-bit system*

V 9.2.0 In IBM MQ Versions 8.0, 9.0 and 9.1, the 32-bit and 64-bit versions of IBM Global Security Kit (GSKit) are bundled together. When you run `dspmqver -a` or `dspmqver -p 64`, the command checks both versions of GSKit. When 32-bit support is missing from a 64-bit system, you might get a message suggesting that the 32-bit version of GSKit is not installed. The GSKit issue is fixed in IBM MQ 9.2. For information about 64-bit Linux distributions that might no longer support 32-bit applications by default, and guidance on manually loading the 32-bit libraries for these platforms, see Hardware and software requirements on Linux systems.

Failure when viewing the IBM MQ classes for Java

The **dspmqver** command can fail if you try to view version or build information for the IBM MQ classes for Java, and you have not correctly configured your environment, or if the IBM MQ JRE component is not installed, and an alternative JRE could not be located.

For example, you might see the following message:

```
[root@blade883 ~]# dspmqver -p 2
AMQ8351: IBM MQ Java environment has not been configured
correctly, or the IBM MQ JRE feature has not been installed.
```

To resolve this problem, consider installing the IBM MQ JRE component if it is not already installed, or ensure that the path is configured to include the JRE, and that the correct environment variables are set; for example, by using `setjmsenv` or `setjmsenv64`.

For example:

```
export PATH=$PATH:/opt/mqm/java/jre/bin
cd /opt/mqm/java/bin/
. ./setjmsenv64

[root@blade883 bin]# dspmqver -p 2
```

```
Name:       IBM MQ classes for Java
Version:    8.0.0.0
Level:      k000-L110908
Build Type: Production
```

Linux AIX Note that the **setjmsenv** and **setjmsenv64** commands apply to AIX and Linux only.

Windows On Windows, if the IBM MQ JRE component is installed, you need to issue the **setmqenv** command to resolve error AMQ8351.

dspmqweb (display mqweb server configuration)

Display information about the status of the mqweb server, the configuration of the mqweb server, or the remote queue manager connection information for the IBM MQ Console. The mqweb server is used to support the IBM MQ Console and REST API.

Using the command on z/OS

z/OS

Before issuing either the **setmqweb** or **dspmqweb** commands on z/OS, you must set the WLP_USER_DIR environment variable, so that the variable points to your mqweb server configuration.

To do this, issue the following command:

```
export WLP_USER_DIR=WLP_user_directory
```

where *WLP_user_directory* is the name of the directory passed to **crtmqweb**. For example:

```
export WLP_USER_DIR=/var/mqm/web/installation1
```

See Create the mqweb server for more information.

You must also set the JAVA_HOME environment variable to reference a 64 bit version of Java on your system.

Purpose - dspmqweb status

Use the **dspmqweb** command to view information about the status of the mqweb server.

The mqweb server must be running to use the IBM MQ Console or the administrative REST API. If the server is running then the available root context URLs and associated ports that are used by the IBM MQ Console and administrative REST API are displayed by the **dspmqweb status** command.

Purpose - dspmqweb remote

V 9.2.3

Use the **dspmqweb remote** command to view details of the remote queue manager connections that are configured for use with the IBM MQ Console.

Purpose - dspmqweb properties

Use the **dspmqweb properties** command to view details of the configuration of the mqweb server. It is not necessary for the mqweb server to be running.

The following properties can be returned by the **dspmqweb properties** command on all platforms, including the IBM MQ Appliance:

ltpaExpiration
This configuration property is used to specify the time, in seconds, before the LTPA token expires.

maxTraceFiles
This configuration property is used to specify the maximum number of mqweb server log files that are generated by the mqweb server.

maxTraceFileSize
This configuration property is used to specify the maximum size, in MB, that each mqweb server log file can reach.

V 9.2.4 **mqConsoleMaxMsgCharsToDisplay**
This configuration property is used to specify the maximum characters to retrieve from each message when browsing a queue via the IBM MQ Console.

V 9.2.4 **mqConsoleMaxMsgRequestSize**
This configuration property is used to specify the maximum size, in MB, a browse request can be across all messages when browsing queues via the IBM MQ Console.

V 9.2.4 **mqConsoleMaxMsgsPerRequest**
This configuration property is used to specify the total number of messages to retrieve from a queue when browsing via the IBM MQ Console.

mqRestCorsAllowedOrigins
This configuration property is used to specify the origins that are allowed to access the REST API. For more information about CORS, see Configuring CORS for the REST API.

mqRestCorsMaxAgeInSeconds
This configuration property is used to specify the time, in seconds, that a web browser can cache the results of any CORS pre-flight checks.

mqRestCsrfValidation
This configuration property is used to specify whether CSRF validation checks are performed. A value of `false` removes the CSRF token validation checks.

mqRestGatewayEnabled
This configuration property is used to specify whether the administrative REST API gateway is enabled.

mqRestGatewayQmgr
This configuration property is used to specify the name of the queue manager to use as the gateway queue manager. This queue manager must be in the same installation as the mqweb server. A blank value indicates that no queue manager is configured as the gateway queue manager.

mqRestMessagingEnabled
This configuration property is used to specify whether the messaging REST API is enabled.

V 9.2.0 **mqRestMessagingFullPoolBehavior**
This configuration property is used to specify the behavior of the messaging REST API when all connections in the connection pool are in use.

The value can be one of the following values:

block
When all the connections in the pool are in use, wait for a connection to become available. When this option is used, the wait for a connection is indefinite.

Inactive connections are closed and removed from a queue manager pool automatically. The state of each queue manager pool is interrogated every 2 minutes, and any connections that have been inactive for the last 30 seconds are closed and removed from the associated pool.

error
When all the connections in the pool are in use, return an error.

overflow
When all the connections in the pool are in use, create a non-pooled connection to use. This connection is destroyed after it is used.

The value for this property is a string value. The default value is overflow.

V 9.2.0 **mqRestMessagingMaxPoolSize**

This configuration property is used to specify the maximum connection pool size for each queue manager connection pool.

The value for this property is an integer value. The default value is 20.

mqRestMftCommandQmgr

This configuration property is used to specify the name of the command queue manager to which create transfer and create, delete, or update resource monitor requests are submitted by the REST API for MFT.

mqRestMftCoordinationQmgr

This configuration property is used to specify the name of the coordination queue manager from which transfer details are retrieved by the REST API for MFT.

mqRestMftEnabled

This configuration property is used to specify whether the REST API for MFT is enabled.

mqRestMftReconnectTimeoutInMinutes

This configuration property is used to specify the length of time, in minutes, after which the REST API for MFT stops trying to connect to the coordination queue manager.

mqRestRequestTimeout

This configuration property is used to specify the time, in seconds, before a REST request times out.

traceSpec

This configuration property is used to specify the level of trace that is generated by the mqweb server. For a list of possible values, see Configuring logging for the IBM MQ Console and REST API.

z/OS ALW The following properties are the additional properties that can be returned by the **dspmqweb properties** command on z/OS, AIX, Linux, and Windows:

httpHost

This configuration property is used to specify the HTTP host name as an IP address, domain name server (DNS) host name with domain name suffix, or the DNS host name of the server where IBM MQ is installed.

An asterisk specifies all available network interfaces, and the value `localhost` allows only local connections.

httpPort

This configuration property is used to specify the HTTP port number that is used for HTTP connections.

A value of `-1` disables the port.

httpsPort

This configuration property is used to specify the HTTPS port number that is used for HTTPS connections.

A value of `-1` disables the port.

ltpaCookieName

This configuration property is used to specify the name of the LTPA token cookie name.

By default, the value of this property is `LtpaToken2_${env.MQWEB_LTPA_SUFFIX}` on AIX, Linux, and Windows , or `LtpaToken2_${httpsPort}` on z/OS, . The variable after the `LtpaToken2_` prefix is used by the mqweb server to generate a unique name for the cookie. You cannot set this variable, but you can change the `ltpaCookieName` to a value of your choosing.

maxMsgTraceFiles

This configuration property is used to specify the maximum number of messaging trace files that are generated by the mqweb server for the IBM MQ Console.

maxMsgTraceFileSize

This configuration property is used to specify the maximum size, in MB, that each messaging trace file can reach.

This property only applies to the IBM MQ Console.

mqConsoleAutostart
This configuration property is used to specify whether the IBM MQ Console automatically starts when the mqweb server starts.

V 9.2.0 **mqConsoleFrameAncestors**
This configuration property is used to specify the list of origins of web pages which can embed the IBM MQ Console in an IFrame.

V 9.2.3 **mqConsoleRemoteAllowLocal**
This configuration property is used to specify whether remote and local queue managers are visible in the IBM MQ Console when remote queue manager connections are allowed. When this property is set to true, both local and remote queue managers are displayed.

V 9.2.3 **mqConsoleRemotePollTime**
This configuration property is used to specify the time, in seconds, before the remote queue manager connections list is refreshed. On refresh, unsuccessful connections are retried.

V 9.2.3 **mqConsoleRemoteSupportEnabled**
This configuration property is used to specify whether the IBM MQ Console allows remote queue manager connections. When this property is set to true, remote queue manager connections are allowed.

V 9.2.3 **mqConsoleRemoteUIAdmin**
This configuration property is used to specify whether remote queue managers can be added to the IBM MQ Console by using the Console, or if remote queue managers can be added only by using the **setmqweb remote** command. When this property is set to true, remote queue managers can be added by using the IBM MQ Console.

mqRestAutostart
This configuration property is used to specify whether the REST API automatically starts when the mqweb server starts.

V 9.2.3 **remoteKeyfile**
This configuration property is used to specify the location of the key file that contains the initial encryption key that is used to decrypt the passwords that are stored in the remote queue manager connection information.

secureLtpa
This configuration property is used to specify whether the LTPA token is secured for all requests. An unsecured LTPA token is required in order send HTTP requests from a browser.

V 9.2.0 ALW The following properties are the additional properties that can be returned by the **dspmqweb properties** command on AIX, Linux, and Windows:

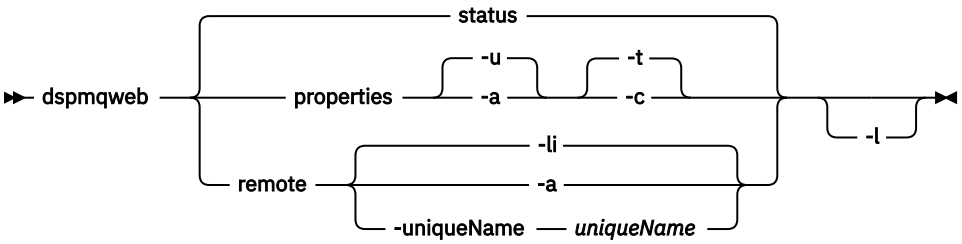
managementMode
This configuration property is used to specify whether queue managers and listeners are able to be created, deleted, started, and stopped by the IBM MQ Console.

The value for this property is a string value and can be one of the following values:

standard
Queue managers and listeners can be created and administered in the IBM MQ Console.

externallyprovisioned
Queue managers and listeners cannot be created in the IBM MQ Console. Only queue managers and listeners that are created outside of the IBM MQ Console can be administered.

Syntax



Optional parameters

status
Displays information about the status of the mqweb server. That is, whether the mqweb server is running. If the mqweb server is running, information about the available root context URLs and associated ports that are used by the IBM MQ Console and administrative REST API are displayed. The command returns non-zero if the mqweb server is not running, or its status could not be successfully queried.

For example:

```
Server mqweb is running.
URLs:
  https://localhost:9443/ibmmq/console/
  https://localhost:9443/ibmmq/rest/v1/
```

properties
Displays information about the configurable properties of the mqweb server. That is, which properties are configurable by the user and those that have been modified. It is not necessary for the mqweb server to be running.

-u
Displays only the configurable properties that have been modified by the user.

-a
Displays all available configurable properties, including those which have been modified by the user.

-t
Formats the output as text name-value pairs.

-c
Formats the output as command text which can be used as input to the corresponding **setmqweb properties** command.

V 9.2.3 **remote**
Displays information about the remote queue manager connections that are configured for use with the IBM MQ Console.

-li
Displays all the remote queue manager unique IDs.

-a
Displays all the remote queue manager connection definitions and properties.

-uniqueName *uniqueName*
Displays the remote queue manager connection definition and properties for the specified queue manager.

-l
Enable verbose logging. Diagnostic information is written to a mqweb server log-file.

Return codes

Table 59. Return code identifiers and descriptions

Return code	Description
0	Command successful.
>0	Command not successful.

For a full list of server command exit codes, see Liberty:server command options in the WebSphere Application Server documentation.

Related commands

Table 60. Related commands and descriptions

Command	Description
strmqweb	Start the mqweb server.
endmqweb	Stop the mqweb server.
setmqweb	Configure the mqweb server.

endmqcsv (end command server)

Stop the command server for a queue manager.

Purpose

Use the **endmqscv** command to stop the command server on the specified queue manager.

You must use the **endmqscv** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the `dspmq -o installation` command.

If the queue manager attribute, SCMDSERV, is specified as QMGR then changing the state of the command server using **endmqscv** does not effect how the queue manager acts upon the SCMDSERV attribute at the next restart.

Syntax

Required parameters

QMgrName
The name of the queue manager for which to end the command server.

Optional parameters

-c
Stops the command server in a controlled manner. The command server can complete the processing of any command message that it has already started. No new message is read from the command queue.

This parameter is the default.

-i

Stops the command server immediately. Actions associated with a command message currently being processed might not complete.

Return codes

Table 61. Return code identifiers and descriptions

Return code	Description
0	Command completed normally
10	Command completed with unexpected results
20	An error occurred during processing

Examples

1. The following command stops the command server on queue manager `saturn.queue.manager`:

   ```
   endmqcsv -c saturn.queue.manager
   ```

   The command server can complete processing any command it has already started before it stops. Any new commands received remain unprocessed in the command queue until the command server is restarted.
2. The following command stops the command server on queue manager `pluto` immediately:

   ```
   endmqcsv -i pluto
   ```

Related commands

Table 62. Related command names and descriptions

Command	Description
strmqcsv	Start a command server
dspmqcsv	Display the status of a command server

Related reference

"Command server commands" on page 7

A table of command server commands, showing the PCF command, MQSC command, and control command equivalents. The REST API resource and HTTP method equivalents, and IBM MQ Explorer equivalents, are included if available.

Windows endmqdnm (stop .NET monitor)

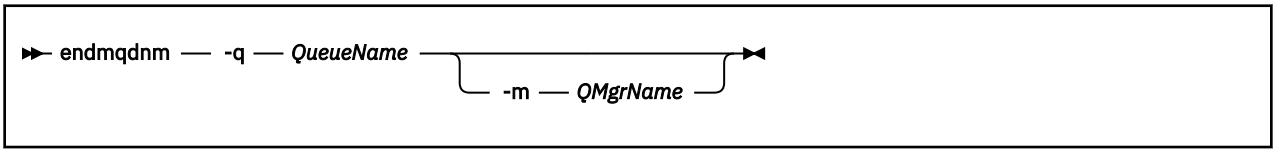
Stop the .NET monitor for a queue (Windows only).

Purpose

Note: The endmqdnm command applies to IBM MQ for Windows only.

Use the **endmqdnm** control command to stop a .NET monitor.

Syntax



Required parameters

-q *QueueName*
The name of the application queue that the .NET monitor is monitoring.

Optional parameters

-m *QMgrName*
The name of the queue manager that hosts the application queue.

If omitted, the default queue manager is used.

Return codes

Table 63. Return code identifiers and descriptions

Return code	Description
0	Successful operation
36	Invalid arguments supplied
40	Queue manager not available
58	Inconsistent use of installations detected
71	Unexpected error
72	Queue manager name error
133	Unknown object name error

Related tasks
Using the .NET monitor

endmqlsr (end listener)

End all listener process for a queue manager.

Purpose

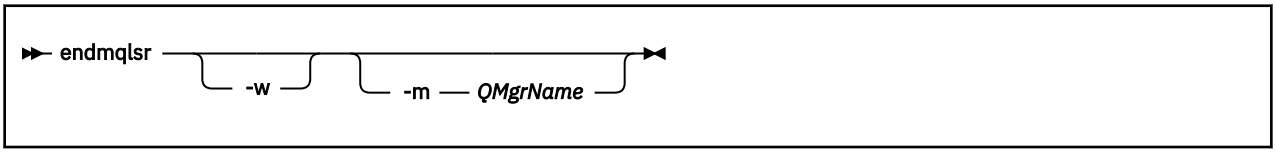
The **endmqlsr** command ends all listener processes for the specified queue manager.

You must use the **endmqlsr** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the `dspmq -o installation` command.

You do not have to stop the queue manager before issuing the **endmqlsr** command. If any of the listeners are configured to have inbound channels running within the **runmqlsr** listener process, rather than within a pool process, the request to end that listener might fail if channels are still active. In this case a message is written indicating how many listeners were successfully ended and how many listeners are still running.

If the listener attribute, CONTROL, is specified as QMGR then changing the state of the listener using **endmqlsr** does not effect how the queue manager acts upon the CONTROL attribute at the next restart.

Syntax



Optional parameters

-m *QMgrName*
The name of the queue manager. If you omit this parameter, the command operates on the default queue manager.

-w
Wait before returning control.

Control is returned to you only after all listeners for the specified queue manager have stopped.

Return codes

endmqm (end queue manager)

Stop a queue manager or switch to a standby queue manager or to a replica queue manager.

Purpose

Use the **endmqm** command to end (stop) a specified queue manager. This command stops a queue manager in the following modes:

- Controlled or quiesced shutdown
- Immediate shutdown
- Pre-emptive shut down
- Wait shutdown

The **endmqm** command stops all instances of a multi-instance queue manager in the same way as it stops a single instance queue manager. You can issue the **endmqm** on either the active instance, or one of the

standby instances of a multi-instance queue manager. You must issue **endmqm** on the active instance to end the queue manager.

If you issue the **endmqm** command on the active instance of a multi-instance queue manager, you can permit a standby instance to switch over to being the new active instance when the current active instance completes its shutdown.

If you issue the **endmqm** command on a standby instance of a multi-instance queue manager, you can end the standby instance by adding the `-x` option, and leave the active instance running. The queue manager reports an error if you issue **endmqm** on the standby instance without the `-x` option.

CP4I You can issue the **endmqm** command on the active or replica nodes of a Native HA group. A check is performed to see if stopping the specified instance breaks the group's quorum, and the command fails if it does. If you issue **endmqm -s** on the active instance, that instance stops and one of the replicas becomes the active instance. If you issue **endmqm -x** on a replica instance, the instance is stopped.

Issuing the **endmqm** command will affect any client application connected through a server-connection channel. The effect varies depending on the parameter used, but it is as though a **STOP CHANNEL** command was issued in one of the three possible modes. See Stopping MQI channels, for information about the effects of **STOP CHANNEL** modes on server-connection channels. The **endmqm** optional parameter descriptions state which STOP CHANNEL mode they will be equivalent to.

If you issue **endmqm** to stop a queue manager, reconnectable clients do not try to reconnect. To override this behavior, specify either the `-r` or `-s` option to enable clients to start trying to reconnect.

Note: If a queue manager or a channel ends unexpectedly, reconnectable clients start trying to reconnect.

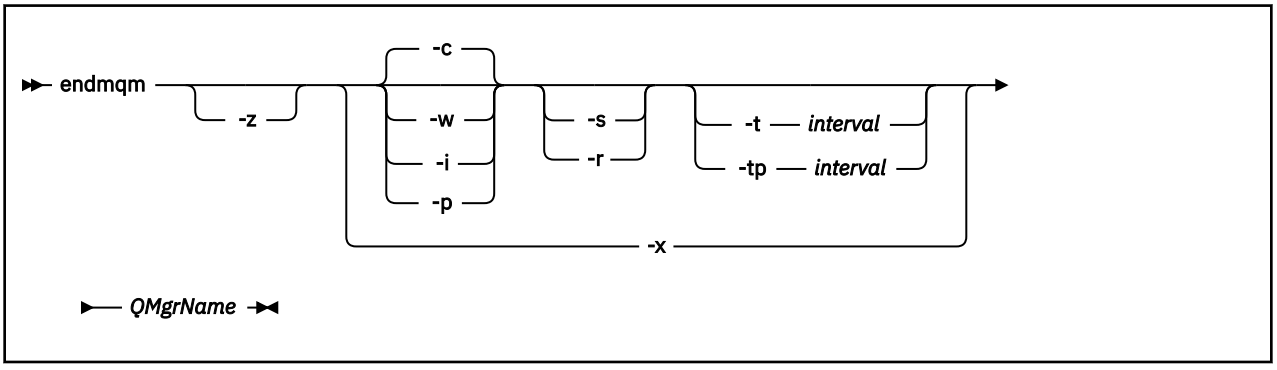
Note: The client might not reconnect to this queue manager. Depending on the MQCONNX reconnect option the client has used, and the definition of the queue manager group in the client connection table, the client might reconnect to a different queue manager. You can configure the client to force it to reconnect to the same queue manager.

You must use the **endmqm** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the `dspmq -o installation` command.

The attributes of the queue manager and the objects associated with it are not affected by the **endmqm** command. You can restart the queue manager using the **strmqm** (Start queue manager) command.

To delete a queue manager, stop it and then use the **dltmqm** (Delete queue manager) command.

Syntax



Required parameters

QMgrName
The name of the message queue manager to be stopped.

Optional parameters

-c

Controlled (or quiesced) shutdown. This parameter is the default.

The queue manager stops, but only after all applications have disconnected. Any MQI calls currently being processed are completed. In the unlikely event that a "dspmq (display queue managers)" on page 63 command is issued in the small timeframe between the applications disconnecting and the queue manager actually stopping, the "dspmq (display queue managers)" on page 63 command might transiently report the status as `Ending immediately` , even though a controlled shutdown was requested.

Control is returned to you immediately and you are not notified of when the queue manager has stopped.

The effect on any client applications connected through a server-connection channel is equivalent to a **STOP CHANNEL** command issued in `QUIESCE` mode.

-i

Immediate shutdown. The queue manager stops after it has completed all the MQI calls currently being processed. Any MQI requests issued after the command has been issued fail. Any incomplete units of work are rolled back when the queue manager is next started.

Control is returned after the queue manager has ended.

The effect on any client applications connected through a server-connection channel is equivalent to a **STOP CHANNEL** command issued in `FORCE` mode.

-p

Pre-emptive shutdown.

Important: Use this type of shutdown only in exceptional circumstances, for example, when a queue manager does not stop as a result of a normal **endmqm** command.

The queue manager might stop without waiting for applications to disconnect or for MQI calls to complete. This can give unpredictable results for IBM MQ applications. The shutdown mode is set to *immediate shutdown*. If the queue manager has not stopped after a few seconds, the shutdown mode is escalated, and all remaining queue manager processes are stopped.

The effect on any client applications connected through a server-connection channel is equivalent to a **STOP CHANNEL** command issued in `TERMINATE` mode.

-r

Start trying to reconnect reconnectable clients. This parameter has the effect of reestablishing the connectivity of clients to other queue managers in their queue manager group.

-s

For a multi-instance queue manager, switch over to a standby queue manager instance after shutting down. The command checks that there is a standby instance running before ending the active instance. It does not wait for the standby instance to start before ending. Connections to the queue manager are broken by the active instance shutting down. Reconnectable clients start trying to reconnect. You can configure the reconnection options of a client to reconnect only to another instance of the same queue manager, or to reconnect to other queue managers in the queue manager group.

For the active instance of a Native HA group, switch over to a replica instance after shutting down.

- Specify the `-r` option to help client applications to reconnect to another instance.
- If this instance is not the active instance in the Native HA group then the command fails.
- If ending this active instance would cause the group quorum to fail then the command fails. (If other instances end or become unavailable at the same time as you run this command, the quorum check

might not detect this, the Native HA group ends and can only be restarted when enough instances are available.)

-w

Wait shutdown.

This type of shutdown is equivalent to a controlled shutdown except that control is returned to you only after the queue manager has stopped. You receive the message `Waiting for queue manager qmName to end` while shutdown progresses. In the unlikely event that a "dspmq (display queue managers)" on page 63 command is issued in the small timeframe between the applications disconnecting and the queue manager actually stopping, the "dspmq (display queue managers)" on page 63 command might transiently report the status as `Ending immediately` , even though a controlled shutdown was requested.

The effect on any client applications connected through a server-connection channel is equivalent to a **STOP CHANNEL** command issued in `QUIESCE` mode.

-x

For a multi-instance queue manager, end a standby instance of the queue manager, without ending the active instance of the queue manager.

CP4I For a replica instance of a Native HA group, stop the instance:

- If this instance is the active instance in the Native HA group then the command fails.
- If ending this replica instance would cause the group quorum to fail then the command fails. (If other instances end or become unavailable at the same time as you run this command, the quorum check might not detect this, the Native HA group ends and can only be restarted when enough instances are available.)

-z

Suppresses error messages on the command.

V 9.2.0 **-t *<interval>***

The target time in which ending the queue manager within *<interval>* seconds is attempted, escalating the phases of application disconnection. Essential queue manager maintenance tasks are allowed to complete, which might prolong the phase of the queue manager ending. (For more information, see Ending a queue manager within a target time.)

V 9.2.0 **-tp *<interval>***

The target time in which ending the queue manager within *<interval>* seconds is attempted, escalating the phases of application disconnection. Essential queue manager maintenance tasks are interrupted if necessary.

These maintenance tasks include the attempt to retain non-persistent messages, when NPMCLASS is set to HIGH on a queue. (For more information, see Ending a queue manager within a target time.)

Return codes

Table 65. Return code identifiers and descriptions

Return code	Description
0	Queue manager ended
3	Queue manager being created
16	Queue manager does not exist
39	Invalid parameter specified

Table 65. Return code identifiers and descriptions (continued)

Return code	Description
40	Queue manager not available
49	Queue manager stopping
58	Inconsistent use of installations detected
62	The queue manager is associated with a different installation
69	Storage not available
71	Unexpected error
77	IBM MQ queue manager cannot switch over
79	Active instance of IBM MQ queue manager *QmgrName* not ended
90	Standby instance of IBM MQ queue manager *QmgrName* not ended
119	Permission denied

Examples

The following examples show commands that stop the specified queue managers.

1. This command ends the queue manager named `mercury.queue.manager` in a controlled way. All applications currently connected are allowed to disconnect.

```
endmqm mercury.queue.manager
```

2. This command ends the queue manager named `saturn.queue.manager` immediately. All current MQI calls complete, but no new ones are allowed.

```
endmqm -i saturn.queue.manager
```

The results of issuing **endmqm** to the local instance of a multi-instance queue manager are shown in Table 66 on page 109. The results of the command depend on whether the -s or -x switch is used, and the running status of local and remote instances of the queue manager.

Table 66. endmqm actions

endmqm option	Local machine	Remote machine	RC	Message	Result
	Active	None	0	-	Queue manager ended.
		Standby			Queue manager ended, including the standby instance.
	Standby	Active	90	AMQ8368	Standby instance of IBM MQ queue manager *QmgrName* not ended.
-s	Active	None	77	AMQ7276	IBM MQ queue manager cannot switch over.
		Standby	0	-	Queue manager QMNAME ended, permitting switchover to a standby instance.
	Standby	Active	90	AMQ8368	Standby instance of IBM MQ queue manager *QmgrName* not ended.

Table 66. endmqm actions (continued)					
endmqm option	**Local machine**	**Remote machine**	**RC**	**Message**	**Result**
-x	Active	None	79	AMQ8367	Active instance of IBM MQ queue manager *QmgrName* not ended.
		Standby			
	Standby	Active	0	-	Standby instance of queue manager QMNAME ended.

The following table shows the results of issuing **endmqm** to Native HA instances.

Table 67. endmqm actions					
endmqm option	**Local machine**	**Remote machine**	**RC**	**Message**	**Result**
	Active	None	0	-	Queue manager ended.
		Standby			Queue manager ended, including the standby instance.
	Standby	Active	90	AMQ8368	Standby instance of IBM MQ queue manager *QmgrName* not ended.
CP4I	Native HA Active	-	0	-	Active instance ended. Remaining instances communicate and elect a new Active, if they can find a quorum.
CP4I	Native HA Replica	-	0	-	Replica instance ended. Remaining instances continue, if they have quorum.
-s	Active	None	77	AMQ7276	IBM MQ queue manager cannot switch over.
		Standby	0	-	Queue manager QMNAME ended, permitting switchover to a standby instance.
	Standby	Active	90	AMQ8368	Standby instance of IBM MQ queue manager *QmgrName* not ended.
	Native HA Active	Quorum would remain	0	-	Active instance ended.
CP4I **-s**	Native HA Active	Quorum would be broken	79	AMQ7275	Instance has not ended because it would cause quorum to be lost.
	Native HA Replica	-	90	AMQ7277	This operation is not valid on a Replica instance.

Table 67. endmqm actions (continued)					
endmqm option	**Local machine**	**Remote machine**	**RC**	**Message**	**Result**
-x	Active	None	79	AMQ8367	Active instance of IBM MQ queue manager *QmgrName* not ended.
		Standby			
	Standby	Active	0	-	Standby instance of queue manager QMNAME ended.
CP4I **-x**	Native HA Active	-	79	AMQ8367	Active instance of IBM MQ queue manager 'MG' not ended.
	Native HA Replica	Quorum would remain	0	-	Replica instance ended.
	Native HA Replica	Quorum would be broken	90	AMQ7275	Instance has not ended because it would cause quorum to be lost.

Stop a queue manager or switch to a standby queue manager or to a replica queue manager.

dltmqm (delete queue manager)
Delete a queue manager.

Windows endmqsvc (end IBM MQ service)

End the IBM MQ service on Windows.

Purpose

The command ends the IBM MQ service on Windows. Run the command on Windows only.

If you are running IBM MQ on Windows systems with User Account Control (UAC) enabled, you must invoke **endmqsvc** with elevated privileges. To open an elevated command prompt, right click the command prompt icon and select **Run as administrator** (see Authority to administer IBM MQ on AIX, Linux, and Windows).

Run the command to end the service, if the service is running.

Restart the service for IBM MQ processes to pick up a new environment, including new security definitions.

Syntax

endmqsvc

Parameters

The **endmqsvc** command has no parameters.

You must set the path to the installation that contains the service. Either make the installation primary, run the **setmqenv** command, or run the command from the directory containing the **endmqsvc** binary file.

Related reference

"strmqsvc (start IBM MQ service)" on page 219
Start the IBM MQ service on Windows.

endmqtrc (end trace)

End trace for some or all of the entities that are being traced.

Purpose

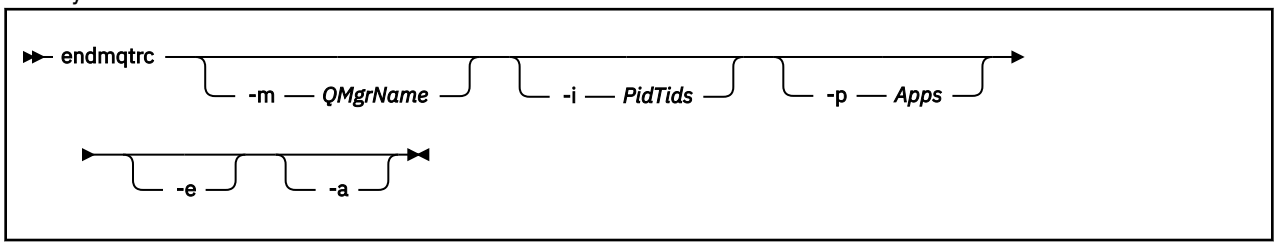
Use the **endmqtrc** command to end tracing for the specified entity or all entities. The **endmqtrc** command ends only the trace that is described by its parameters. Using **endmqtrc** with no parameters ends early tracing of all processes.

All **endmqtrc** commands set the type of output to *mqm* on strmqtrc.

Attention: There can be a slight delay between the **endmqtrc** command ending, and all trace operations actually completing. This is because IBM MQ processes are accessing their own trace files. As each process becomes active at different times, their trace files close independently of one another.

Syntax

The syntax of this command is as follows:



Optional parameters

-m *QMgrName*
The name of the queue manager for which to end tracing.

The *QMgrName* supplied must match exactly the *QMgrName* supplied on the **strmqtrc** command. If the **strmqtrc** command used wildcards, the **endmqtrc** command must use the same wildcard specification including the escaping of any wildcard characters to prevent them being processed by the command environment.

A maximum of one -m flag and associated queue manager name can be supplied on the command.

-i *PidTids*
Process identifier (PID) and thread identifier (TID) for which to end tracing. You cannot use the **-i** flag with the **-e** flag. If you try to use the **-i** flag with the **-e** flag, then an error message is issued. This parameter must only be used under the guidance of IBM Service personnel.

-p *Apps*
The named processes for which to end tracing. *Apps* is a comma-separated list. You must specify each name in the list exactly as the program name would be displayed in the "Program Name" FDC header. Asterisk (*) or question mark (?) wildcards are allowed. You cannot use the **-p** flag with the **-e** flag. If you try to use the **-p** flag with the **-e** flag, then an error message is issued.

-e
Ends early tracing of all processes.

Using **endmqtrc** with no parameters has the same effect as **endmqtrc -e**. You cannot specify the **-e** flag with the **-m** flag, the **-i** flag, or the **-p** flag.

-a
Ends all tracing.

Important: This flag must be specified alone.

Return codes

Table 68. Return code identifiers and descriptions

Return code	Description
AMQ5611	This message is issued if you supply invalid arguments to the command.
58	Inconsistent use of installations detected

Examples

This command ends tracing of data for a queue manager called QM1.

```
endmqtrc -m QM1
```

The following examples are a sequence that shows how the endmqtrc command ends only the trace that is described by its parameters.

1. The following command enables tracing for queue manager QM1 and process amqxxx.exe:

   ```
   strmqtrc -m QM1 -p amqxxx.exe
   ```

2. The following command enables tracing for queue manager QM2:

   ```
   strmqtrc -m QM2
   ```

3. The following command ends tracing for queue manager QM2 only. Tracing of queue manager QM1 and process amqxxx.exe continues:

   ```
   endmqtrc -m QM2
   ```

ALW migmqlog (migrate IBM MQ logs)

The **migmqlog** command migrates logs, and can also change the type of your queue manager logs from linear to circular or from circular to linear.

IBM i z/OS **migmqlog** is not supported on IBM i or z/OS.

Usage notes

Windows On Windows, running **migmqlog** enables you to move your queue manager logs to an Advanced Format disk

migmqlog can only run when the queue manager is inactive.

If the running of **migmqlog** is interrupted by, for example, a power failure, you should be rerun the same command until it completes normally.

A partially migrated log can not be used to start a queue manager, and the result of attempting to do so is not well defined.

migmqlog migrates logs 'in place', or migrates logs to a new location. When logs are migrated to a new log location, no change is made to any existing log files and all valid recovery log files in the old location are migrated to the new location.

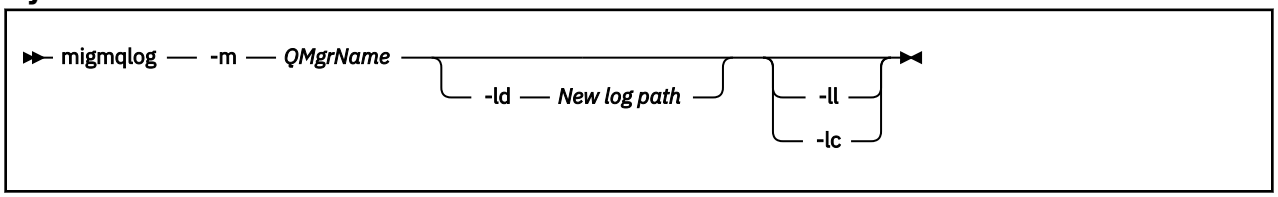
migmqlog updates the `qm.ini` file to reflect the new log configuration, that is, **LogType** and **LogPath**, as needed.

Following any log migration, the log is configured such that all future log writes occur with 4096 byte alignment, at minimum.

Windows For further information on migrating logs on Windows to be Advanced Format, see Migrating logs to an Advanced Format disk.

See Types of logging for more information about linear and circular logging.

Syntax



Required parameters

-m ***QMgrName***
The name of the queue manager on which to migrate logs.

Optional parameters

-ld ***New log path***
If you specify **-ld** and do not point to the existing log location, migration will be to a new log location.

If you do not specify **-ld**, or you specify **-ld** and point to the existing log location, migration will be 'in place'.

-ll
If you pass **-ll** to the command, and the queue manager is currently defined to be using circular logging, the queue manager will be reconfigured to use linear logging.

-lc
If you pass **-lc** to the command, and the queue manager is currently defined to be using linear logging, the queue manager will be reconfigured to use circular logging.

Related tasks

Migrating the log of your queue manager from linear to circular

Migrating the log of your queue manager from circular to linear

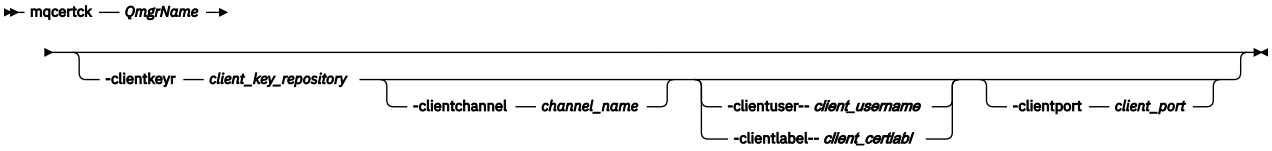
mqcertck (certify TLS setup)

Use the **mqcertck** command to diagnose potential TLS problems with your queue managers.

Purpose

The command can be used as a first check to determine why a connection using TLS has been unable to successfully connect to queue managers within your enterprise, and works with multiple certificates.

Syntax



Required parameters

QmgrName
Name of the queue manager to check for TLS errors.

Optional parameters

-clientkeyr *client_key_repository*
Required if you supply the **-clientuser**, **-clientlabel**, **-clientchannel**, or **-clientport** parameters.

Location of the client key repository used by a client application connecting to the referenced queue manager.

Important: You must supply the name without the `.kdb` extension.

-clientuser *client_username*
Cannot be used if you supplied the **-clientlabel** parameter.

User running the client application that connects to the referenced queue manager. If supplied, requires **-clientkeyr**.

-clientlabel *client_certlabl*
Cannot be used if you supplied the **-clientuser** parameter.

Certificate label that is given to the client that connects to the referenced queue manager by using one of the IBM MQ MQI client CERTLABL methods. If supplied, requires **-clientkeyr**.

-clientchannel *channel_name*

Name of the channel on the referenced queue manager to check for TLS errors. If supplied, requires **-clientkeyr**.

-clientport *port_number*
Specify a specific port to use when testing the client.

The value must be:

- An integer value between 1 and 65535 inclusive.
- A port number, which must be a free port that **mqcertck** can use during its client checks.
- Not be a port that is in use by the queue manager, or any other process on the machine running **mqcertck**.

If you do not specify a value, port 5857 is used. If supplied, requires **-clientkeyr**.

Examples

Example 1

After configuring an IBM MQ queue manager for TLS connections, you can use **mqcertck** to verify that no mistakes have been made, before attempting to start your channels.

The information returned in the example shows that no certificate has been found for queue manager qmgr.

```
[mqm@mq-host ~]$ mqcertck qmgr

EXPLANATION:
Queue managers will use a certificate with the label set in the Queue Manager's
CERTLABL attribute. There is no certificate with the label ibmwebspheremqqmgr
in the key repository being used by the queue manager The Key repository being
used is located at /var/mqm/qmgrs/qmgr/ssl/key.kdb.

ACTION:
A valid certificate with the label ibmwebspheremqqmgr needs to be added to the
key repository.

+-----------------------------------------------------------

This application has ended. See above for any problems found.

If there are problems then resolve these and run this tool again.

+-----------------------------------------------------------
```

Example 2

After creating a key repository, certificate, and exchanging certificates for a client application, you can use **mqcertck** to verify that a client application is able to connect to a queue manager.

To do this, you need to run **mqcertck** on the machine where the IBM MQ queue manager is running, and have access to the client key repository.

You can do this in a variety of ways, for example, a file system mount. After you have set up your machine, run the following command:

```
mqcertck QmgrName -clientkeyr Location_of_Client_Key_Repository
                     -clientlabel Client_certificate_label
```

For example:

```
mqcertck qmgr -clientkeyr  /var/mqm/qmgrs/qmgr/ssl/key
                     -clientlabel ibmwebspheremqqmgr
```

Check the output for any problems identified with your configuration.

Note that, if you are planning on having your clients connect anonymously, you can run the preceding command without the **-clientlabel** parameter.

Linux AIX mqconfig (check system configuration)

Checks that the system configuration meets the requirements to run IBM MQ (AIX and Linux platforms only).

Purpose

The **mqconfig** command is run to verify the system configuration matches or exceeds that which is required by an IBM MQ queue manager environment. The configuration values are minimum values, and large installations might require values greater than those checked by this command.

For further information about configuring your system for IBM MQ, see the *Operating system configuration and tuning information for IBM MQ* on the platform, or platforms, that your enterprise uses.

Syntax

Optional parameters

-v *Version*

The system requirements vary between different versions of IBM MQ. Specify the version of IBM MQ for which you need to verify the current system configuration.

The default value, if **-v** is not specified, is the current version.

Example

The following output is an example of what the command produces on a Linux system:

```
# mqconfig -v 8.0
mqconfig: V3.7 analyzing Red Hat Enterprise Linux Server release 6.5
(Santiago) settings for IBM MQ V8.0

System V Semaphores
semmsl   (sem:1) 500 semaphores           IBM>=32      PASS
semmns   (sem:2) 35 of 256000 semaphores  (0%)  IBM>=4096     PASS
semopm   (sem:3) 250 operations           IBM>=32      PASS
semmni   (sem:4) 3 of 1024 sets       (0%)  IBM>=128     PASS

System V Shared Memory
shmmax       68719476736 bytes         IBM>=268435456  PASS
shmmni       1549 of 4096 sets     (37%)  IBM>=4096     PASS
shmall       7464 of 2097152 pages   (0%)  IBM>=2097152   PASS

System Settings
file-max      4416 of 524288 files    (1%)  IBM>=524288    PASS

Current User Limits (root)
nofile    (-Hn) 10240 files            IBM>=10240    PASS
nofile    (-Sn) 10240 files            IBM>=10240    PASS
nproc    (-Hu) 11 of 30501 processes   (0%)  IBM>=4096     PASS
nproc    (-Su) 11 of 4096 processes    (1%)  IBM>=4096     PASS
```

Note: Any values listed in the `Current User Limits` section are resource limits for the user who ran **mqconfig**. If you normally start your queue managers as the `mqm` user, you should switch to `mqm` and run **mqconfig** there.

If other members of the `mqm` group (and perhaps root) also start queue managers, all those members should all run **mqconfig**, to ensure that their limits are suitable for IBM MQ.

The limits displayed by **mqconfig** are not applied to queue managers on Linux started with **systemd**.

Related tasks

Configuring and tuning the operating system on Linux

Windows Linux MQExplorer (launch IBM MQ Explorer)

Start IBM MQ Explorer (Windows and Linux x86-64 platforms only).

Purpose

You can start IBM MQ Explorer by using the **MQExplorer** command in the installation directory. The location of the **MQExplorer** command depends on how you installed IBM MQ Explorer.

Linux On Linux:

- If you are running the IBM MQ Explorer that was installed as part of a full IBM MQ server installation, the **MQExplorer** command is stored in *MQ_INSTALLATION_PATH*/bin, where *MQ_INSTALLATION_PATH* is the IBM MQ installation path.
- If you installed the stand-alone IBM MQ Explorer (MS0T SupportPac), **MQExplorer** is in *MQ_EXPLORER_INSTALLATION_PATH*, where *MQ_EXPLORER_INSTALLATION_PATH* is the IBM MQ Explorer (MS0T SupportPac) installation path.

Windows On Windows:

- If you are running the IBM MQ Explorer that was installed as part of a full IBM MQ server installation, the **MQExplorer.exe** command is stored in *MQ_INSTALLATION_PATH*/bin64, where *MQ_INSTALLATION_PATH* is the IBM MQ installation path.
- If you installed the stand-alone IBM MQ Explorer (MS0T SupportPac), MQExplorer.exe is in *MQ_EXPLORER_INSTALLATION_PATH*, where *MQ_EXPLORER_INSTALLATION_PATH* is the IBM MQ Explorer (MS0T SupportPac) installation path.

You can also launch IBM MQ Explorer by using the system menu on Linux, or the start menu on Windows. In both cases, you must left-click the installation that you want to launch.

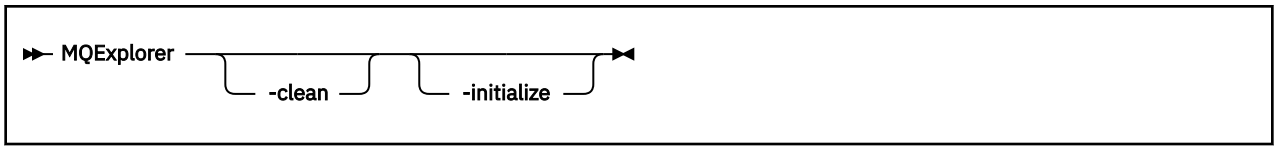
Linux On Linux, the system menu entry for IBM MQ Explorer is added to the **Development** category. Where it appears within the system menu is dependent on your Linux distribution (SUSE or Red Hat), and your desktop environment (GNOME or KDE).

- On SUSE
  - Left-click **Computer > More Applications...,** and find the installation of IBM MQ Explorer that you want to launch under the **Development** category.
- On Red Hat®
  - The installation of IBM MQ Explorer that you want to launch can be found under **Applications> Programming**.

Windows On Windows, open the start menu, and select the IBM MQ Explorer installation entry under the **IBM MQ** folder that corresponds to the installation that you want to launch. Each instance of IBM MQ Explorer listed is identified by the name that you chose for its installation.

Syntax

MQExplorer.exe (the MQExplorer command) supports standard Eclipse runtime options. The syntax of this command is as follows:



Optional parameters

-clean
Is passed to Eclipse. This parameter causes Eclipse to delete any cached data used by the Eclipse runtime.

-initialize
Is passed to Eclipse. This parameter causes Eclipse to discard configuration information used by the Eclipse runtime.

The graphical user interface (GUI) does not start.

Start IBM MQ Explorer (Windows and Linux x86-64 platforms only).

V 9.2.0 Linux mqlicense (accept license post installation)

From IBM MQ 9.2.0, use the mqlicense command on Linux to accept an IBM MQ license after installation.

Purpose

On Linux (excluding IBM MQ Appliance), from IBM MQ 9.2.0, use the **mqlicense** command to accept the IBM MQ license post installation.

Note: You must have the appropriate privileges to run this command on your system, typically root access on Linux.

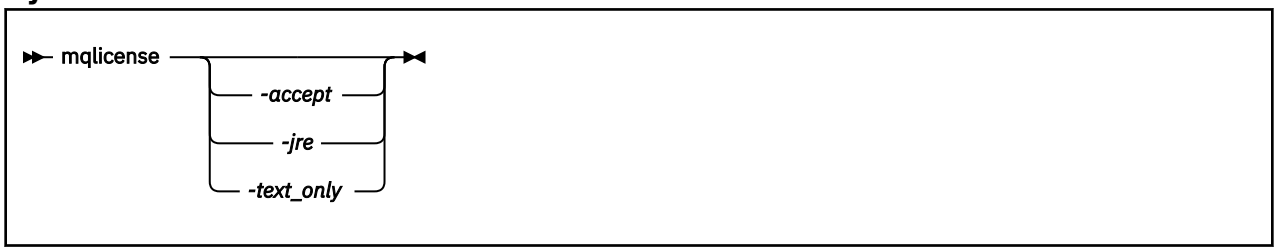
The license agreement is displayed in a language appropriate to your environment and you are prompted to accept or decline the terms of the license.

If possible, **mqlicense** opens an X-window to display the license.

If you need the license to be presented as text in the current shell, which can be read by a screen reader, type the following command:

```
mqlicense -text_only
```

Syntax



Required parameters

None

Optional parameters

-accept
Accept the IBM MQ license without it being displayed.

-jre
Path to the Java executable used to display the license.

-text_only
Display a text-only version of the license, which can be read by a screen-reader.

Return codes

Table 72. Return code identifiers and descriptions

Return code	Description
0	Successful completion. You can accept or decline the result, depending upon what you chose.
10	A warning occurred

Table 72. Return code identifiers and descriptions (continued)

Return code	Description
20	An error occurred

Usage notes

Note that running this command, with the environment variable **MQLICENSE=accept**, has the same effect as running with the **-accept** parameter.

Related concepts

License acceptance on IBM MQ for Linux

MQLICENSE

"dspmqlic (display IBM MQ license)" on page 80

Display an IBM MQ license.

V9.2.0.35 Multi mqperfck (MQ performance check)

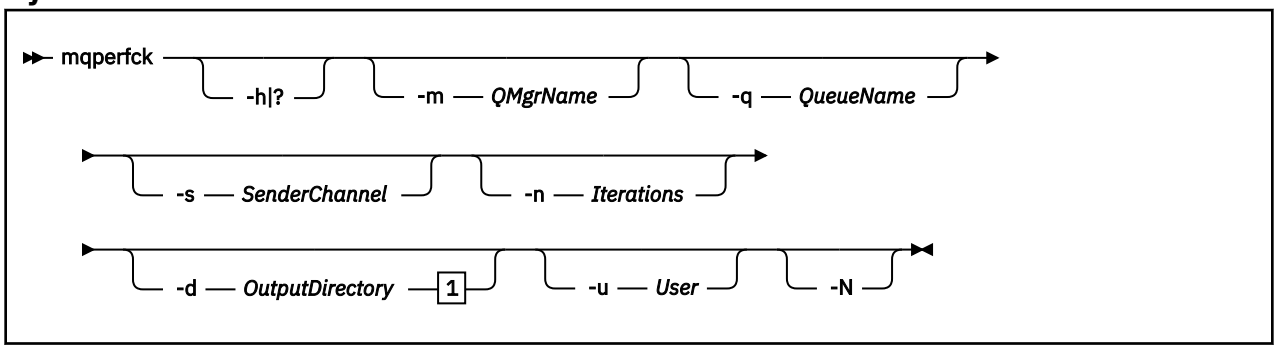
Use the **mqperfck** command to help understand the performance of your queue manager.

Purpose

The command can be used to gather information about the CPU and Log resources being used by a queue manager, and the activity on local queues and sender channels. Run this command when the work being processed by your queue manager is low, and when it is high, to compare the impact of different workloads on the queue manager.

The command produces an HTML report summarizing the workload. You can view the report in a web browser. For more information on how to interpret the report, see Interpreting the IBM MQ Performance Check Report.

Syntax



Notes:

1. MQ Appliance Not available on IBM MQ Appliance.

Required parameters

None.

Optional parameters

-h or -?
Display usage help text and exit.

-m QmgrName
The name of queue manager to connect to. If this is not specified, the command will attempt to connect to the default queue manager.

-q QueueName
The name of a local queue to analyze. You can analyze up to 10 queues by repeating this parameter. The queue must exist, it must be a local queue, and the user running the tool must have permission to open the queue for inquire.

-s SenderChannel
The name of a sender channel to analyze. You can analyze up to 10 channels by repeating this parameter. The channel must exist, it must have attribute **CHLTYPE(SDR)**, and the **MONCHL** attribute of the channel must be set to either LOW, MEDIUM, or HIGH. If the channel's **MONCHL** attribute is MQMON_Q_MGR, then the **MONCHL** attribute of the queue manager must be LOW, MEDIUM, or HIGH.

If the channel's transmission queue has not been provided on the command line using the **-q** parameter, and fewer than 10 queues have been requested, then the transmission queue will be automatically added to the list of queues that will be analyzed.

-n *Iterations*
The number of sampling iterations to perform. The default is 6. A new iteration begins when the queue manager publishes a set of resource statistics which typically happens every 10 seconds.

-d *OutputDirectory*
The directory to which the output file will be written.

If this parameter is omitted, then output will be written to the current directory.

This option is not available on the IBM MQ Appliance where output will always be written into the "mqdiag:" file system.

-u *User*
The user id to be used to authenticate the connection to the queue manager. If this parameter is specified, the command will prompt for a password. The password will not be displayed on the screen.

-N
Suppresses translation of the report.

Granting permissions to run the command

To subscribe to the system statistics, the command must be run by a member of the mqm group or a user who has permissions to topics in the $SYS/MQ branch of the topic tree. For more information, see System topics for monitoring and activity trace.

In addition, the command needs the following permissions to run:

Table 73. Permissions needed for each object type

Object name	Object type	Permissions
QmgrName	qmgr	+connect +inq +dsp
SYSTEM.DEFAULT.MODEL.QUEUE	queue	+get +dsp
SYSTEM.ADMIN.COMMAND.QUEUE	queue	+put
SYSTEM.ADMIN.TOPIC	topic	+sub

For each queue named on the command line (and any channel's transmission queues which are automatically added by the command) add the following permissions:

Table 74. Additional permissions for queues		
Object name	**Object type**	**Permissions**
QueueName	Queue	+inq

For each channel named on command line add the following permissions:

Table 75. Additional permissions for channels		
Object name	**Object type**	**Permissions**
ChannelName	Channel	+dsp

Examples

The following command creates a report containing six iterations of CPU and Log statistics for the default queue manager:

```
[mqm@mq-host ~]$ mqperfck
Connected to queue manager DFT.QMGR.
Creating file: mqperfcheck_DFT.QMGR_2024-12-20_132743-0.html
Waiting for messages.
Processing iteration 1 of 6.
Processing iteration 2 of 6.
Processing iteration 3 of 6.
Processing iteration 4 of 6.
Processing iteration 5 of 6.
Processing iteration 6 of 6.
Writing report summary.
```

The following command creates a report with three iterations of statistics for queue manager SENDER.QM, queue TESTQ, and channel TO.RECEIVER.QM. The report includes information about the channel's transmission queue:

```
[mqm@mq-host ~]$ mqperfck -m SENDER.QM -q TESTQ -s TO.RECEIVER.QM -n 3
Connected to queue manager SENDER.QM.
Creating file: mqperfcheck_SENDER.QM_2024-12-20_133202-0.html
Waiting for messages.
Processing iteration 1 of 3.
Processing iteration 2 of 3.
Processing iteration 3 of 3.
```

Metrics published on the system topics

mqrc (display return code and AMQ message information)

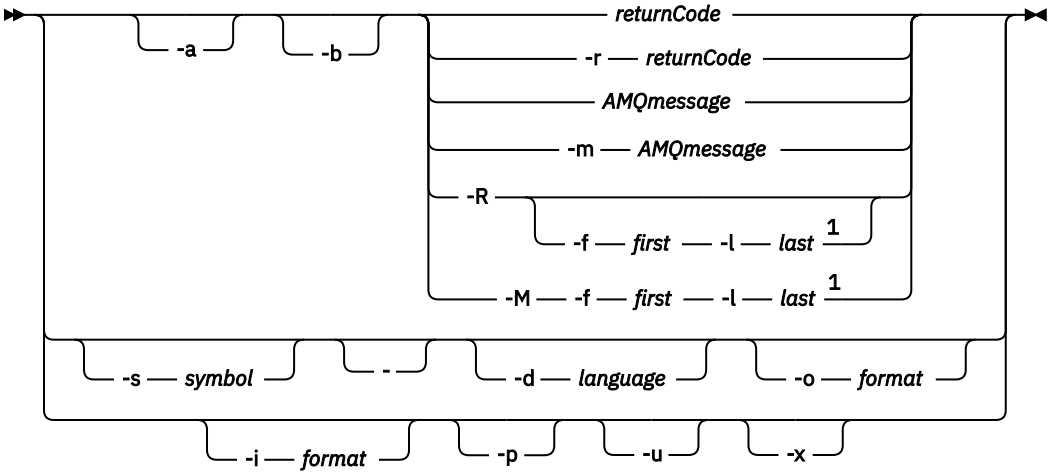
Display information about return codes and AMQ messages.

Purpose

You can use the **mqrc** command to display information about symbols, return codes, and AMQ messages. You can specify a range of return codes or AMQ messages, as well as specifying specific return codes or AMQ messages.

Numeric arguments are interpreted as decimal if they start with a digit 1 - 9, or hex if prefixed with 0x.

Syntax



Notes:

[1] If there is a problem with a message within a range, an indication is displayed before the message text. ? is displayed if there are no matching return codes for the message. ! is displayed if the message severity is different to the return code severity.

Parameters

returnCode
The return code to display

AMQmessage
The AMQ message to display

symbol
The symbol to display

-a
Try all severities to find message text

-b
Display messages without extended information

-f *first*
First number in a range

-l *last*
Last number in a range

-m *AMQmessage*
The AMQ message to list

-M
Display AMQ messages in a range

-r *returnCode*
The return code to display

-R
Display all return codes. If used with the **-f** and **-l** parameters, **-R** displays the return codes within a range.

-s *symbol*
The symbol to display

-
If a - is given as a trailing parameter, it indicates that further input will come from `stdin`.

ALW **-d *language***
Display the message in the specified language, for example, `Fr_FR`.

-i *format*
Determine the message to display from a message in the specified format, which must be one of the following:

text
The textual format of the **QMErrorLog** service, including the Insert attributes.

json
JSON format diagnostic messages, specified in UTF-8.

-o *format*
Display the message in the specified format, which must be one of the following:

mqrc
The format used by **mqrc** in previous versions of the product.

text
The textual format of the **QMErrorLog** service.

json
The JSON format, described in JSON format diagnostic messages.

ALW **-p**
Display the message explanation only. For example:

```
mqrc -p AMQ8118
```

displays

```
The queue manager insert_5 does not exist.
```

ALW **-u**
Display the user response only. For example:

```
mqrc -u AMQ8118
```

displays

```
Either create the queue manager (crtmqm command) or correct the queue manager name used in the command
and then try the command again.
```

-x
Display extended message information, including the message severity. For example, the following message has an error (**E**) severity of 30:

```
mqrc -x AMQ8118
536903960  0x20008118  E  30  urcMS_MQCONN_FAILED
536903960  0x20008118  E  30  zrc_CSPRC_Q_MGR_DOES_NOT_EXIST

MESSAGE:
IBM MQ queue manager does not exist.

EXPLANATION:
The queue manager <insert three> does not exist.

ACTION:
Either create the queue manager (crtmqm command) or correct the queue manager name used in the command
and then try the command again.
```

Examples

1. This command displays AMQ message 5005:

```
mqrc AMQ5005
```

2. This command displays return codes in the range 2505 - 2530:

```
mqrc -R -f 2505 -l 2530
```

3. Running the following command, where AMQERR01.json contains JSON formatted messages in any language, converts all messages into US English in the original textual **QMErrorLog** format:

```
cat AMQERR01.json | mqrc -d En_US -i json -o text -
```

Alternatively, you could take AMQERR01.LOG and convert it to JSON:

```
cat AMQERR01.LOG | mqrc -i text -o json -
```

4. Running the following command, where AMQERR01.LOG contains text formatted messages in any language, converts messages into US English:

```
cat AMQERR01.LOG | mqrc -d En_US -i text -o text -
```

rcdmqimg (record media image)

Write the image of an object or group of objects to the log for media recovery.

Purpose

Use the **rcdmqimg** command to write an image of an object, or group of objects, to the log for use in media recovery. This command can be used only when using linear logging. See Types of logging for more information about linear logging. Use the associated command **rcrmqobj** to re-create the object from the image.

Before IBM MQ 9.1.0, or when using **LogManagement**=*Manual*, the command does not run automatically as it must be run in accordance with, and as determined by, the usage of each individual customer of IBM MQ.

After IBM MQ 9.1.0, when using **LogManagement**=*Automatic* or *Archive*, the queue manager automatically records media images, however **rcdmqimg** can also be run manually as well, if required.

Running **rcdmqimg** moves the log sequence number (LSN) forwards and frees up old log files for archival or deletion.

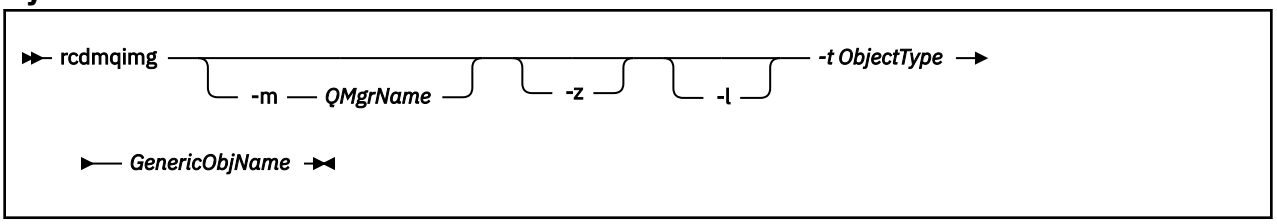
When determining when and how often to run **rcdmqimg**, consider these factors:

Disk space
If disk space is limited, regular running of **rcdmqimg** releases log files for archive or deletion.

Impact on normal system performance
rcdmqimg activity can take a long time if the queues on the system are deep. At this time, other system usage is slower and disk utilization increases because data is being copied from the queue files to the logs. Therefore, the ideal time to run **rcdmqimg** is when the queues are empty and the system is not being heavily used.

You use this command with an active queue manager. Further activity on the queue manager is logged so that, although the image becomes out of date, the log records reflect any changes to the object.

Syntax



Required parameters

GenericObjName
The name of the object to record. This parameter can have a trailing asterisk to record that any objects with names matching the portion of the name before the asterisk.

This parameter is required unless you are recording a queue manager object or the channel synchronization file. Any object name you specify for the channel synchronization file is ignored.

-t *ObjectType*
The types of object for which to record images. Valid object types are:

Table 76. Valid object types

Object Type	Description
all and *	All the object types; **ALL** for objtype and * for GenericObjName
authinfo	Authentication information object, for use with TLS channel security
channel or **chl**	Channels
clntconn or **clcn**	Client connection channels
catalog or **ctlg**	An object catalog
listener or **lstr**	Listeners
namelist or **nl**	Namelists
process or **prcs**	Processes
queue or **q**	All types of queue
qalias or **qa**	Alias queues
qlocal or **ql**	Local queues
qmodel or **qm**	Model queues
qremote or **qr**	Remote queues
qmgr	Queue manager object
service or **srvc**	Service
syncfile	Channel synchronization file.
topic or **top**	Topics

Note: Linux AIX When using IBM MQ for AIX or Linux systems, you must prevent the shell from interpreting the meaning of special characters, for example, an asterisk (*). How you do this depends on the shell you are using, but might involve the use of single quotation marks ('), double quotation marks (''), or a backslash (\).

Optional parameters

-m *QMgrName*
The name of the queue manager for which to record images. If you omit this parameter, the command operates on the default queue manager.

-z
Suppresses error messages.

-l
Writes messages containing the names of the oldest log files required to restart the queue manager and to perform media recovery. The messages are written to the error log and the standard error

destination. (If you specify both the -z and -l parameters, the messages are sent to the error log, but not to the standard error destination.)

When issuing a sequence of **rcdmqimg** commands, include the -l parameter only on the last command in the sequence, so that the log file information is gathered only once.

Return codes

Table 77. Return code identifiers and descriptions

Return code	Description
0	Successful operation
26	Queue manager running as a standby instance.
28	Object not media recoverable.
36	Invalid arguments supplied
40	Queue manager not available
49	Queue manager stopping
58	Inconsistent use of installations detected
68	Media recovery not supported
69	Storage not available
71	Unexpected error
72	Queue manager name error
119	User not authorized
128	No objects processed
131	Resource problem
132	Object damaged
135	Temporary object cannot be recorded

When are log extents deleted

Log extents are only deleted when the queue manager determines that they can be deleted. Note that log extents are not deleted immediately after recording the media image.

For example, if the starting media extent is 04, the queue manager does not delete this extent until the extent number moves forward, and the queue manager might or might not delete extents 01 to 04.

The logger event messages, and the IBM MQ queue manager error logs, show the log extents required for queue manager restart and media recovery.

Examples

The following command records an image of the queue manager object `saturn.queue.manager` in the log.

```
rcdmqimg -t qmgr -m saturn.queue.manager
```

Related commands

Table 78. Related command names and descriptions

Command	Description
rcrmqobj	Re-create a queue manager object

rcrmqobj (re-create object)

Re-create an object, or group of objects, from their images contained in the log.

Purpose

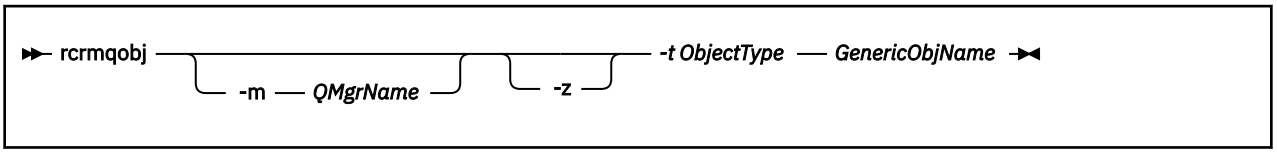
Use the **rcrmqobj** command to re-create an object, or group of objects, from their images.

Note: Use this command on a running queue manager.

- With *ObjectType* argument of `clchltab` or `syncfile`, this command re-creates the object files from the internal queue manager state.
- For other *ObjectType* arguments, the command can only be used when the queue manager is configured to use linear logging. Use the associated command, `rcdmqimg`, to record the object images to the log. The object is re-created from images in the log.

  All activity on the queue manager after the image was recorded is logged. To re-create an object, replay the log to re-create events that occurred after the object image was captured.

Syntax



Required parameters

GenericObjName
The name of the object to re-create. This parameter can have a trailing asterisk to re-create any objects with names matching the portion of the name before the asterisk.

This parameter is required, unless the object type is the channel synchronization file; any object name supplied for this object type is ignored.

-t *ObjectType*
The types of object to re-create. Valid object types are:

Table 79. Valid object types.

Object Type	Description
* or `all`	All object types
`authinfo`	Authentication information object, for use with TLS channel security
`channel` or `chl`	Channels
`clntconn` or `clcn`	Client connection channels
`clchltab`	Client channel table
`comminfo`	Communication information object

Table 79. Valid object types. (continued)	
Object Type	**Description**
`listener` or `lstr`	Listener
`namelist` or `nl`	Namelists
`process` or `prcs`	Processes
`queue` or `q`	All types of queue
`qalias` or `qa`	Alias queues
`qlocal` or `ql`	Local queues
`qmodel` or `qm`	Model queues
`qremote` or `qr`	Remote queues
`service` or `srvc`	Service
`syncfile`	Channel synchronization file. You can use this option when circular logs are configured but the `syncfile` fails if the channel scratchpad files, which are used to rebuild `syncfile`, are damaged or missing. You might want to do this if your system has reported the error message AMQ7353 (krcE_SYNCFILE_UPDATE_FAILED).
`topic` or `top`	Topics

Note: Linux AIX When using IBM MQ for AIX or Linux systems, you must prevent the shell from interpreting the meaning of special characters, for example, an asterisk (*). How you do this depends on the shell you are using, but might involve the use of single quotation marks ('), double quotation marks ("), or a backslash (\).

Optional parameters

-m *QMgrName*
The name of the queue manager for which to re-create objects. If omitted, the command operates on the default queue manager.

-z
Suppresses error messages.

Return codes

Table 80. Return code identifiers and descriptions

Return code	Description
0	Successful operation
26	Queue manager running as a standby instance.
28	Object not media recoverable.
36	Invalid arguments supplied
40	Queue manager not available
49	Queue manager stopping

Table 80. Return code identifiers and descriptions (continued)

Return code	Description
58	Inconsistent use of installations detected
66	Media image not available
68	Media recovery not supported
69	Storage not available
71	Unexpected error
72	Queue manager name error
119	User not authorized
128	No objects processed
135	Temporary object cannot be recovered
136	Object in use

Examples

1. The following command re-creates all local queues for the default queue manager:

```
rcrmqobj -t ql *
```

2. The following command re-creates all remote queues associated with queue manager `store`:

```
rcrmqobj -m store -t qr *
```

Related commands

Table 81. Related command names and descriptions

Command	Description
rcdmqimg	Record an object in the log

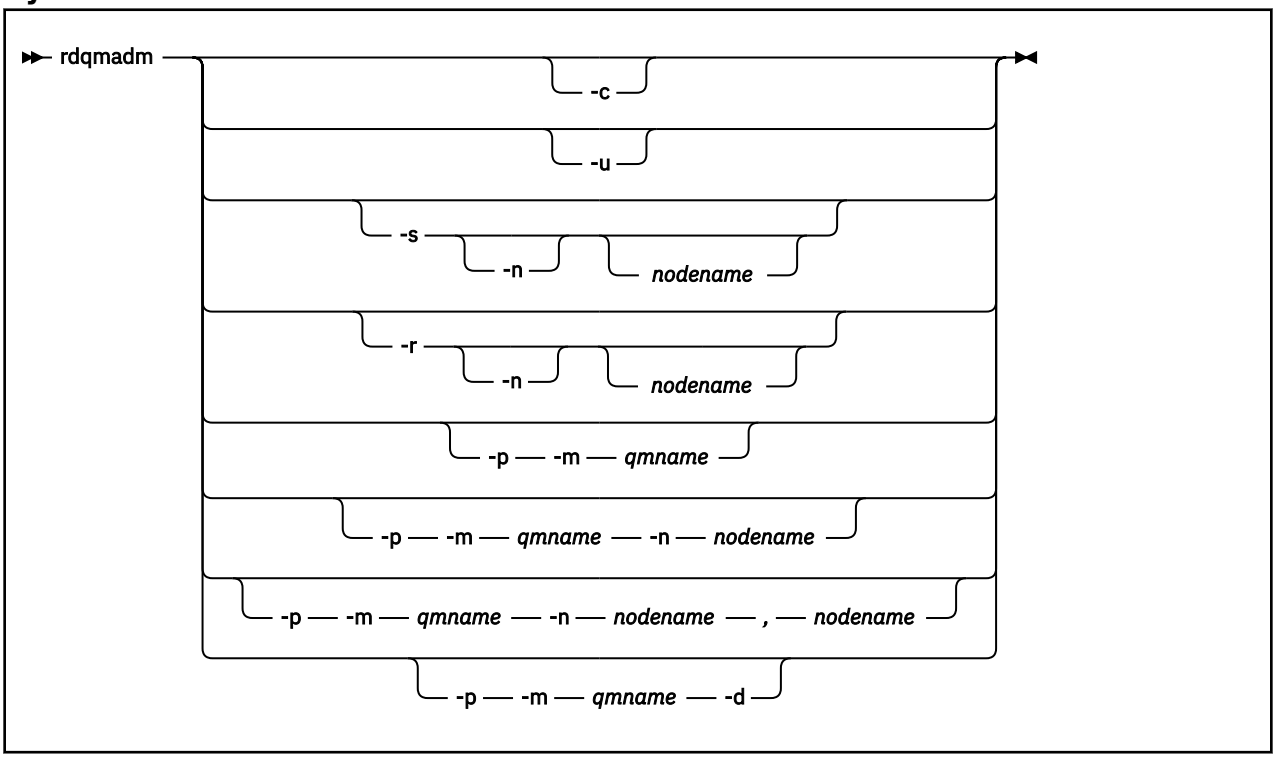
Linux rdqmadm (administer replicated data queue manager cluster)

Administer the cluster in a high availability RDQM configuration.

Purpose

Use the **rdqmadm** command to administer the Pacemaker cluster used in RDQM high availability configurations. (This command is not required for disaster recovery RDQM configurations.)

Syntax



Optional parameters

-c

Initialize the Pacemaker cluster, using the settings specified in the `/var/mqm/rdqm.ini` file. The same command must be run on each of the three nodes by the `root` user. (You can also run this command as a user in the `mqm` group if you have configured sudo, see Requirements for RDQM HA solution.) The command fails if the node is already part of a Pacemaker cluster. A node cannot be a member of two Pacemaker clusters.

-u

Delete the Pacemaker cluster configuration. The same command must be run on each of the three nodes by the `root` user. (You can also run this command as a user in the `mqm` group if you have configured sudo, see Requirements for RDQM HA solution.) The Pacemaker cluster configuration cannot be deleted if any replicated data queue managers (RDQMs) exist.

-s [-n *nodename*]

Suspend the local node (or the specified node if the `-n` *nodename* argument is supplied). The command can be run on any of the three nodes by a user in the haclient group, or by `root`. The node is taken offline. Any replicated data queue managers (RDQMs) running on that node are stopped and restarted on an active node. Queue manager data does not replicate to the offline node. The command fails if the specified node is the last active node.

-r [-n *nodename*]

Resume the local or specified node. The command can be run on any of the three nodes by a user in the haclient group, or by `root`. The node is brought online. If the node is the preferred location for any replicated data queue managers (RDQMs), the queue managers are stopped and restarted on this node.

-p -m *qmname* [-n *nodename*[,*nodename*]

Assign the local or specified node as the Preferred Location for the named queue manager. If the Pacemaker cluster is in a normal state and the Preferred Location is not the current primary node, the queue manager is stopped and restarted on the new Preferred Location. You can specify a comma-separated list of two node names to assign a second preference of Preferred Location.

-p -m *qmname* -d
Clear the Preferred Location so that the queue manager does not automatically return to a node when it is restored.

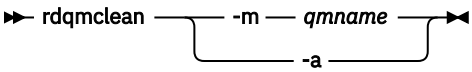
V 9.2.2 Linux rdqmclean (clear failed resource actions)

You use the **rdqmclean** command to clear failed resource actions from RDQM HA configurations.

Purpose

Failed resource actions arise when the Pacemaker component of an RDQM high availability configuration encounters some problem with a resource on one of the nodes in an HA group. Some failed resource actions prevent the resource from running on one or all nodes and must be cleared before Pacemaker can restart the resource. You must also resolve the cause of the resource failure.

Syntax



Optional parameters

-m *qmname*
Specify the name of the queue manager for which you are clearing failed resource actions.

-a
Clear all failed resource actions in the RDQM HA configuration.

Related concepts

Failed resource actions

Related tasks

Linux Viewing RDQM and HA group status

Linux rdqmdr (manage DR RDQM instances)

Change a primary disaster recovery replicated data queue manager (DR RDQM) to a secondary instance, or change a secondary instance to a primary.

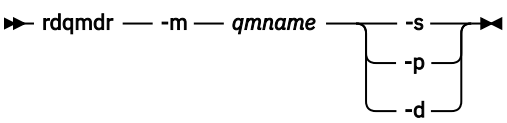
Purpose

Use the **rdqmdr** command to control whether an instance of a DR RDQM has the primary or secondary role.

You can also use **rdqmdr** on the node where you created a primary DR RDQM to retrieve the command that you need to create the secondary instance on the recovery node.

You must be `root` or a user in the `mqm` group with `sudo` privileges to use this command.

Syntax



Parameters

-m *qmname*
Specify the name of the DR RDQM that you are issuing the command for.

-s
Specify -s to make a DR RDQM that is currently in the primary role into the secondary.

-p
Specify -p to make a DR RDQM that is currently in the secondary role into the primary. This command fails if the primary instance of the queue manager is still running and the DR replication link is still functioning.

-d
Specify -d to return the **crtmqm** command required to create a secondary instance of the specified DR RDQM.

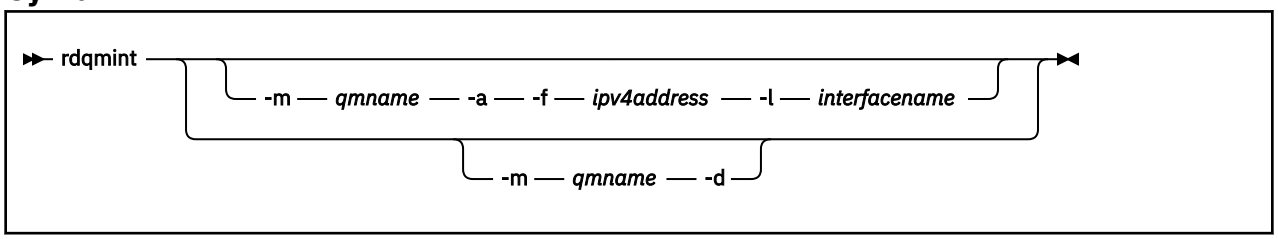
Linux rdqmint (add or delete floating IP address for RDQM)

Add or delete the floating IP address used to connect to a high availability replicated data queue manager (HA RDQM).

Purpose

Use the **rdqmint** command to add or delete the floating IP address that is used to connect to an HA RDQM regardless of which node in the high availability (HA) group is actually running the RDQM. (This command is not applicable to disaster recovery RDQM configurations.)

Syntax



Optional parameters

-m *qmname*
Specify the name of the RDQM for which you are adding or deleting a floating IP address.

-a
Specify this option to add a floating IP address.

-d
Specify this option to delete a floating IP address.

-f *ipv4address*
The IP address in dot decimal format.

The floating IP address must be a valid IPv4 address that is not already defined on any HA node, and it must belong to the same subnet as the static IP addresses defined for the local interface.

-l *interfacename*
The name of the physical interface that the floating IP address is bound to.

Examples

To specify a floating IP address for the queue manager RDQM1, enter the following command:

```
rdqmint -m RDQM1 -a 192.168.7.5 -l MQIF
```

To delete the floating IP address for the queue manager RDQM1, enter the following command:

```
rdqmint -m qmname -d
```

Linux rdqmstatus (display RDQM status)

Display the status of all the replicated data queue managers (RDQMs) on a node or detailed status of specified individual RDQMs. You can also display the online/offline status of the nodes in an HA group.

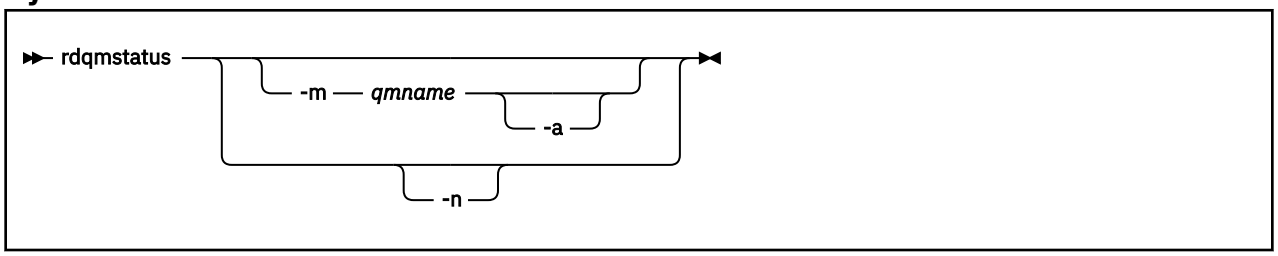
Purpose

Use the **rdqmstatus** command on its own to view a summary of the status of all RDQM queue managers on a node. You can specify a queue manager name to view detailed status for that RDQM, including details of failed resource actions. You can also view the availability status of all nodes in an HA group.

You can enter the command on any node in an HA group, or either node in a DR pair , or any node in a DR/HA configuration.

For examples of the output of the **rdqmstatus** command, see Viewing RDQM and HA group status, and Viewing DR RDQM status, and Viewing DR/HA RDQM and HA group status.

Syntax



Optional parameters

-m *qmname*
Specify the name of the RDQM for which you are requesting status.

V 9.2.2 **-a**
Optionally use with -m *qmname* to view failed resource actions associated with the specified queue manager (see Failed resource actions).

-n
Specify -n to list the three nodes in the HA group, and their current online or offline status.

V 9.2.0 Linux Viewing DR/HA RDQM and HA group status

ALW rmvmqinf (remove configuration information)

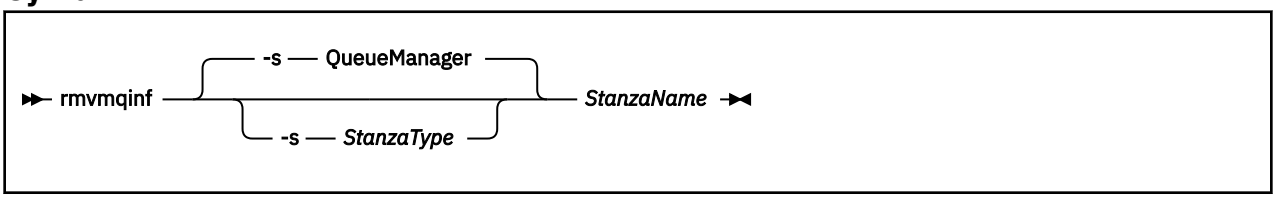
Remove IBM MQ configuration information (AIX, Linux, and Windows only).

Purpose

Use the **rmvmqinf** command to remove IBM MQ configuration information.

You must use the **rmvmqinf** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the `dspmq -o installation` command.

Syntax



Required parameters

StanzaName
The name of the stanza. That is, the value of the key attribute that distinguishes between multiple stanzas of the same type.

Optional parameters

-s *StanzaType*
The type of stanza to remove. If omitted, a QueueManager stanza is removed.

The only supported value of *StanzaType* is `QueueManager`.

Return codes

Table 82. Return code identifiers and descriptions

Return code	Description
0	Successful operation
5	Queue manager is running
26	Queue manager is running as a standby instance
39	Bad command line parameters
44	Stanza does not exist
49	Queue manager is stopping
58	Inconsistent use of installations detected
69	Storage is not available
71	Unexpected error
72	Queue manager name error

Example

```
rmvmqinf QM.NAME
```

Usage notes

Use `rmvmqinf` to remove an instance of a multi-instance queue manager.

To use this command you must be an IBM MQ administrator and a member of the `mqm` group.

“dspmqinf (display configuration information)” on page 76	Display queue manager configuration information

rsvmqtrn (resolve transactions)

Resolve in-doubt and heuristically completed transactions

Purpose

The **rsvmqtrn** command is used to resolve two different transaction states.

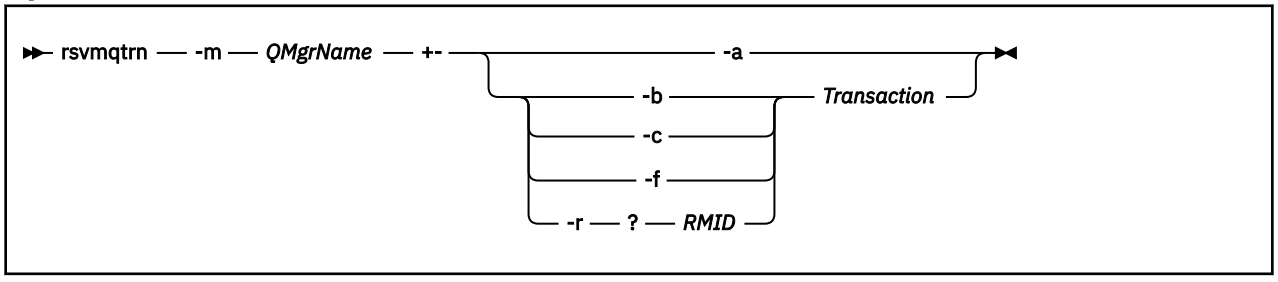
in-doubt transactions
Use the **rsvmqtrn** command to commit or back out internally or externally coordinated in-doubt transactions.

Note: Use this command only when you are certain that transactions cannot be resolved by the normal protocols. Issuing this command might result in the loss of transactional integrity between resource managers for a distributed transaction.

heuristically completed transactions
Use the **rsvmqtrn** command with the **-f** parameter for IBM MQ to remove all information about externally coordinated transactions that were previously resolved manually using the **rsvmqtrn** command, but the resolution has not been acknowledged by the transaction coordinator using the **xa-forget** command. Transactions that are manually resolved by a resource manager and unacknowledged by the transaction manager, are known as *heuristically completed* transactions by X/Open.

Note: Only use the **-f** option if the external transaction coordinator is permanently unavailable. The queue manager, as a resource manager, remembers the transactions that are committed or backed out manually by the `rsvmqtrn` command.

Syntax



Required parameters

-m *QMgrName*
The name of the queue manager.

Attention: The following parameters are mutually exclusive. You must supply the **-a** parameter on its own, or one of the other parameters together with its transaction number.

Optional parameters

-a
The queue manager resolves all internally coordinated, in-doubt transactions (that is, all global units of work).

-b
Backs out the named transaction. This flag is valid for externally coordinated transactions (that is, for external units of work) only.

-c
Commits the named transaction. This flag is valid for externally coordinated transactions (that is, external units of work) only.

-f
Forgets the named heuristically completed transaction. This flag is valid only for externally coordinated transactions (that is, external units of work) that are resolved, but unacknowledged by the transaction coordinator.

Note: Use only if the external transaction coordinator is never going to be able to acknowledge the heuristically completed transaction. For example, if the transaction coordinator has been deleted.

-r *RMID*
The participation of the resource manager in the in-doubt transaction can be ignored. This flag is valid for internally coordinated transactions only, and for resource managers that have had their resource manager configuration entries removed from the queue manager configuration information.

Note: The queue manager does not call the resource manager. Instead, it marks the participation of the resource manager in the transaction as being complete.

Transaction
The transaction number of the transaction being committed or backed out. Use the **dspmqtrn** command to find the relevant transaction number. This parameter is required with the **-b**, **-c**, **-f**, and **-r** *RMID* parameters and must be the last parameter when used.

Return codes

Table 84. Return code identifiers and descriptions

Return code	Description
0	Successful operation
26	Queue manager running as a standby instance.
32	Transactions could not be resolved
34	Resource manager not recognized
35	Resource manager not permanently unavailable
36	Invalid arguments supplied
40	Queue manager not available
49	Queue manager stopping
58	Inconsistent use of installations detected
69	Storage not available
71	Unexpected error
72	Queue manager name error
85	Transactions not known

V 9.2.0 V 9.2.0 runamscred: protect AMS keywords

The **runamscred** command protects passwords inside AMS configuration files.

V 9.2.2 There are two variants of this command:

- An MQI variant located in <IBM MQ installation root>/bin
- A Java variant located in <IBM MQ installation root>/java/bin

V 9.2.2 When using **runamscred** to protect AMS keywords, use the same variant for the AMS client that is going to use the AMS keywords. For example, use the Java variant to protect Java keywords.

Purpose

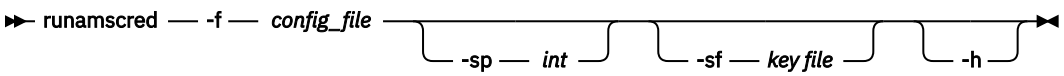
The **runamscred** command uses the encryption key contained in the file, indicated by one of four options. In order of priority, these are the:

1. **-sf** parameter
2. MQS_AMSCRED_KEYFILE environment variable
3. **amscred.keyfile** parameter in the configuration file
4. Default initial key file if none of the above options is specified.

Attention: V 9.2.2 You should not use the default initial key.

Syntax

runamscred



Parameters

-f *config_file*
Required. Path to the keystore configuration file to protect

-sp *int*
Optional. Algorithm to use for protecting passwords. The value can be:

0
Use the deprecated credentials protection method.

V 9.2.2 Not applicable for MQI clients

1

V 9.2.2 The IBM MQ 9.2.0 password protection algorithm.

V 9.2.2 **2**
Default: Use the more secure credentials protection method.

-sf *keyfile*
Optional. Path to a file containing the initial key.

-h
Optional. Displays command syntax.

Examples

Linux AIX To encrypt a password in the `/home/alice/keystore.conf` configuration file using the new algorithm, and store it in the new format, issue the following command:

```
runamscred -f /home/alice/keystore.conf
```

Linux AIX To encrypt a password in the `/home/alice/keystore.conf` configuration file, using an initial key in the `/etc/secure/alice_initial.key` file, together with the new algorithm, and store it in the new format, issue the following command:

```
runamscred -sf /etc/secure/alice_initial.key -f /home/alice/keystore.conf
```

Windows To encrypt a password in the `C:\Users\alice\keystore.conf` configuration file using the new algorithm, and store it in the new format, issue the following command:

```
runamscred -f C:\Users\alice\keystore.conf
```

Windows To encrypt a password in the `C:\Users\alice\keystore.conf` configuration file, using an initial key in the `C:\secure\alice_initial.key` file, together with the new algorithm, and store it in the new format, issue the following command:

```
runamscred -sf C:\secure\alice_initial.key -f C:\Users\alice\keystore.conf
```

Return codes

0
Command completed successfully.

1
Command ended unsuccessfully.

Deprecated Linux z/OS MQ Adv. VUE runmqbcb (run IBM MQ Bridge to blockchain) for IBM MQ 9.1.3 and earlier

Configure and run the IBM MQ Bridge to blockchain.

Notes:

- Deprecated The IBM MQ Bridge to blockchain is deprecated across all releases from November 22 2022 (see US Announcement letter 222-341).
- V 9.2.0.21 Removed For Long Term Support, IBM MQ Bridge to blockchain is removed at IBM MQ 9.2.0 CSU 21. If you have applications that will be impacted by this change, please contact IBM Support.

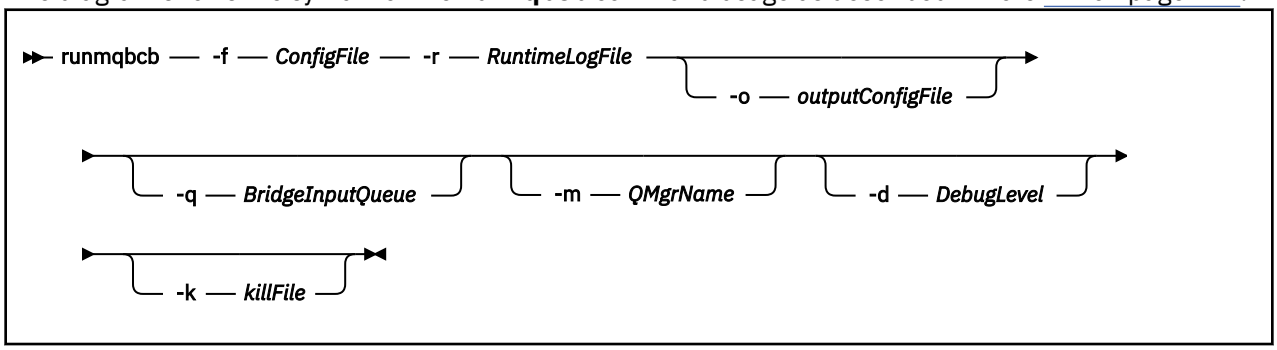
LTS

Attention: This format of the **runmqbcb** command is stabilized. From IBM MQ 9.1.4, if you have a Hyperledger Fabric network, use the command described in "runmqbcb (run IBM MQ Bridge to blockchain)" on page 144.

- Syntax
- Usage notes
- Command line parameters
- Configuration parameters

Syntax

The diagram shows the syntax for the **runmqbcb** command usage as described in note "1" on page 141.



Usage notes

1. You can run the **runmqbcb** command to start the IBM MQ Bridge to blockchain and connect to IBM Blockchain and IBM MQ. When the connections are made, the bridge is ready to receive and process request messages that are put on the queue manager input queue, send the correctly formatted queries and updates to the blockchain network, receive, process and put replies from the blockchain to the reply queue.

   ```
   runmqbcb -f ConfigFile -r RuntimeLogFile -m QMgrName -d DebugLevel -k killFile -r
   RuntimeLogFile
   ```

   When you use the command for runtime processing, the required parameters are **-f**, with the name of the previously created configuration file, and **-r** with the name of the log file. When the other command parameters are also given on the command line, they override the values in the configuration file. The same configuration file can be used by multiple bridges.

2. You can also use the **runmqbcb** command to generate a configuration file that is used to define the parameters that are needed for the bridge to connect to IBM Blockchain and IBM MQ.

   When you are creating the configuration file, the **-f** parameter is optional.

   ```
   runmqbcb -f inputConfigFile -o outputConfigFile
   ```

   When you run the command in this way, you are prompted to enter values for each of the configuration parameters. To keep an existing value press `Enter`. To remove an existing value press `Space`, then `Enter`. For more information, see "Configuration parameters" on page 142.

Command line parameters

-f *ConfigFile*

Configuration file. The **-f** parameter is required when you are running the **runmqbcb** command to start the IBM MQ Bridge to blockchain, as described in usage note "1" on page 141. You can optionally use the **-f** parameter to reuse some of the values from an existing *inputConfigFile*, as described in usage note "2" on page 141, and also enter some of the new values. If you do not specify the **-f** parameter when you are creating the configuration file, all the values for the parameters you are prompted for are empty.

-r *RuntimeLogFile*
Required. Location and name of the log file for trace information. You can specify the log file path and name in the configuration file or on the command line.

-o *outputConfigFile*
New configuration file. When you run the command with the **-o** parameter, **runmmbcb** command loads existing configuration values from the **-f** file and prompts for new values for each configuration parameter.

-q *BridgeInputQueue*
Name of the queue that the bridge waits for messages on.

-m *QMgrName*
Queue manager name.

-d *debugLevel*
Debug level, 1, or 2.

1
Terse debug information is displayed.

2
Verbose debug information is displayed.

-k *killFile*
A file to cause the bridge to exit. When you run the command with the **-k** parameter and specify a file, if the file exists, it causes the bridge program to exit. Using this file is an alternative way to stop the program when you don't want to use `Ctrl+C` or **kill** command. The file is deleted by the bridge on startup in case it exists. If the deletion fails, the bridge abends but monitors for the recreation of the file.

Configuration parameters

When you run the **runmqbcb** command to create the configuration file, the parameters are stepped through in six groups. Passwords are obfuscated and are not displayed as you type. The generated configuration file is in JSON format. You must use the **runmqbcb** command to create the configuration file. You cannot edit the passwords and security certificate information directly in the JSON file.

Connection to queue manager
Parameters relating to the IBM MQ queue manager.

IBM MQ Queue manager
Required. The IBM MQ Advanced queue manager that you are using with the IBM MQ Bridge to blockchain.

Bridge input queue

SYSTEM.BLOCKCHAIN.INPUT.QUEUE is the default queue where applications put request messages, this can be overridden in the configuration file or on the **runmqbcb** command line. User applications must have appropriate authorisation to put messages to this queue.

IBM MQ Channel
The bridge requires a svrcon channel to connect to the z/os queue manager remotely.

IBM MQ Conname
Uses standard connection name format of "host(port), host(port)" to enable multiple destinations such as for multi-instance queue managers.

IBM MQ CCDT URL
If a TLS connection is required to the queue manager, you must use a JNDI or CCDT definition.

JNDI implementation class name
The class name of your JNDI provider. The "queue manager name" parameter refers to the connection factory name when you are using JNDI.

JNDI provider URL
The endpoint of your JNDI service.

IBM MQ UserId
The **UserId** that is running the bridge must have permission to set identity context on the messages it sends as replies, these have the requester **UserId** set in the message. The bridge user must therefore have appropriate access to put to the reply queue.

IBM MQ Password
Password for the IBM MQ **UserId** that the bridge is using.

User identification
Parameters relating to user authentication details that the bridge uses to connect to the Hyperledger Composer REST server

Userid
The User Id provided by the bridge to Hyperledger Composer must be known and authorized to connect to the Hyperledger Composer endpoint, based on the user authentication configuration of the Hyperledger Composer REST server.

Password
The password for the User Id that the bridge is using to connect to Hyperledger Composer.

API path for login
The URL path to provide user credentials to the Hyperledger Composer REST server. Note that this URL differs, depending on the type of security provider configured.

REST server
Address for Hyperledger Composer REST server.

The location of the Hyperledger Composer REST server in "`host:port`" format. The protocol prefix of `http://` or `https://` should not be provided.

Location of PEM file for IBM Blockchain certificate
When using a TLS connection to the Hyperledger Composer REST server, a single PEM file is used to hold the Hyperledger certificates to authenticate the bridge with the Hyperledger Composer REST server. This PEM file must be copied to the system where the IBM MQ Bridge to blockchain is running, and specified in the configuration file.

Certificate stores for TLS connections
Parameters relating to certificate stores for TLS connections.

Personal keystore for TLS certificates
Keystore for security certificates that are used for IBM MQ.

Keystore password
Password for the keystore.

Trusted store for signer certificates
If you do not add the trusted store, the personal keystore for TLS certificates is used.

Trusted store password
If the personal keystore for TLS certificates is used, this is the password for the keystore for TLS certificates.

Use TLS for MQ connection
The bridge can use TLS when it connects to the queue manager.

Timeout for Blockchain operations

If you don't provide a truststore parameter, the keystore is used for both roles. The stores can be the same as the one configured for the IBM MQ connection in the CCDT or JNDI.

Behavior of bridge program
Parameters relating to the behavior of the IBM MQ Bridge to blockchain.

Required. Runtime logfile for copy of stdout/stderr
Path to and name of the log file for the tracing information.

The configuration is only read on startup of the bridge process. Changes to the configuration require a restart of the bridge.

Deprecated V 9.2.0 Linux MQ Adv. VUE runmqbcb (run IBM MQ Bridge to blockchain)

Configure and run the IBM MQ Bridge to blockchain on a Hyperledger Fabric network.

Notes:

- Deprecated The IBM MQ Bridge to blockchain is deprecated across all releases from November 22 2022 (see US Announcement letter 222-341).
- V 9.2.0.21 Removed For Long Term Support, IBM MQ Bridge to blockchain is removed at IBM MQ 9.2.0 CSU 21. If you have applications that will be impacted by this change, please contact IBM Support.

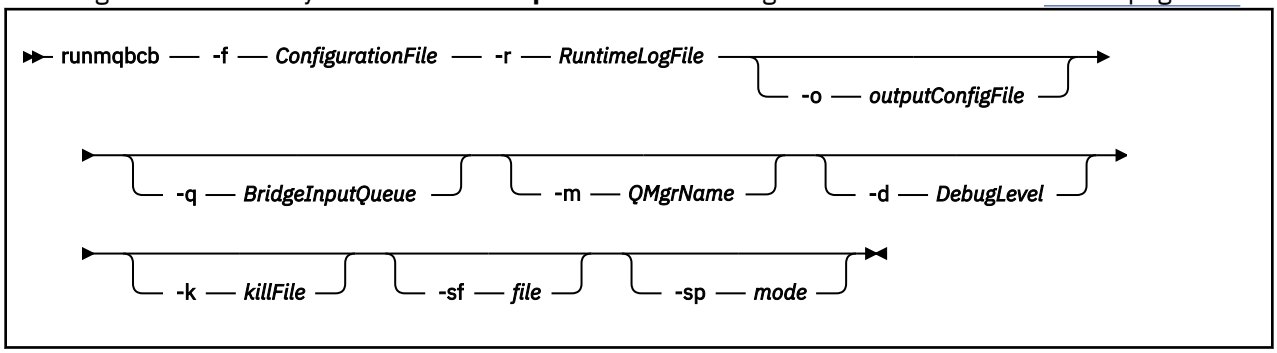
LTS

Attention: For IBM MQ 9.1.3 and earlier, this command has a different format. See "runmqbcb (run IBM MQ Bridge to blockchain) for IBM MQ 9.1.3 and earlier" on page 140.

- Syntax
- Usage notes
- Command line parameters
- Configuration parameters

Syntax

The diagram shows the syntax for the **runmqbcb** command usage as described in note "1" on page 144.



Usage notes

There are two available authentication mechanisms for the bridge to connect to Hyperledger Fabric, both of which require that you configure a username. This username will be associated with any operations processed through the IBM MQ Bridge to blockchain.

The first approach allows a Wallet (file) to be supplied from the administrator. The Wallet is a container holding certificates and so on.

The second approach is based on an administrator just providing certificates to you and not a standalone wallet. The configuration then requires the location of the certificate (typically a PEM file), along with a password to access it, and an associated organization name.

1. You can run the **runmqbcb** command to start the IBM MQ Bridge to blockchain and connect to Hyperledger Fabric and IBM MQ.

   When the connections are made, the bridge is ready to receive and process request messages that are put on the queue manager input queue, send the correctly formatted queries and updates to the blockchain network, receive, process and put replies from the blockchain to the reply queue.

   ```
   runmqbcb -f ConfigFile -q BridgeInputQueue -m QMgrName -d DebugLevel -k killFile -r
   RuntimeLogFile
   ```

When you use the command for runtime processing, the required parameters are **-f**, with the name of the previously created configuration file, and **-r** with the name of the log file. When the other command parameters are also given on the command line, they override the values in the configuration file. The same configuration file can be used by multiple bridges.

2. You can also use the **runmqbcb** command to generate a configuration file that is used to define the parameters that are needed for the bridge to connect to Hyperledger Fabric and IBM MQ.

   When you are creating the configuration file, the **-f** parameter is optional.

   ```
   runmqbcb -f inputConfigFile -o outputConfigFile [-b]
   ```

   When you run the command in this way, you are prompted to enter values for each of the configuration parameters. To keep an existing value press `Enter`. To remove an existing value press `Space`, then `Enter`. For more information, see "Configuration parameters" on page 146.

3. V 9.2.0 V 9.2.0 From IBM MQ 9.2.0, the usage of the enhanced protection parameters is as follows:

   Configuration mode

   Newly entered passwords are written to the output configuration file protected with the new key. Note that preexisting passwords are not changed in format.

   A warning is issued when the default key is being used, that is, you have not provided a keyfile.

   Provision of passwords in the `batch` configuration mode, using environment variables, continues unchanged; that is, the value of the environment variables is given in plain text.

   Runtime mode

   When a password is decrypted, warning messages are issued if the password is found to be in the old format, and the name of the parameter causing the warning is given in the message to encourage you to migrate. However, the bridge continues processing commands.

   Note: The warning message is not issued if you have specified the **-sp** *0* parameter on the command line, as you explicitly wanted to use old formats.

   A warning is also issued when the default key is being used, that is, you have not provided a keyfile.

   Errors occur if a password cannot be decrypted, for example, if you have specified the wrong keyfile.

Command line parameters

-f *ConfigurationFile*

Configuration file. The **-f** parameter is required when you are running the **runmqbcb** command to start the IBM MQ Bridge to blockchain, as described in usage note "1" on page 144. You can optionally use the **-f** parameter to reuse some of the values from an existing *inputConfigFile*, as described in usage note "2" on page 145, and also enter some of the new values. If you do not specify the **-f** parameter when you are creating the configuration file, all the values for the parameters you are prompted for are empty.

-r *RuntimeLogFile*

Required. Location and name of the log file for trace information. You can specify the log file path and name in the configuration file or on the command line.

-o *outputConfigFile*

New configuration file. When you run the command with the **-o** parameter, **runmmbcb** command loads existing configuration values from the **-f** file and prompts for new values for each configuration parameter.

-q *BridgeInputQueue*

Name of the queue that the bridge waits for messages on.

-m *QMgrName*

Queue manager name.

-d *debugLevel*
Debug level, 1, or 2.

1
Terse debug information is displayed.

2
Verbose debug information is displayed.

-k *killFile*
A file to cause the bridge to exit. When you run the command with the **-k** parameter and specify a file, if the file exists, it causes the bridge program to exit. Using this file is an alternative way to stop the program when you don't want to use `Ctrl+C` or **`kill`** command. The file is deleted by the bridge on startup in case it exists. If the deletion fails, the bridge abends but monitors for the recreation of the file.

-b
Use environment variables during configuration.

V 9.2.0 V 9.2.0 **-sf *file***
File containing password protection key.

V 9.2.0 V 9.2.0 **-sp *mode***
Password protection mode. The values can be:

V 9.2.2 **2**
Use the latest password protection mode. This is the default value from IBM MQ 9.2.2.

1
Use the IBM MQ 9.2 password protection mode for compatibility with versions earlier than IBM MQ 9.2.2. This is the default value in versions earlier than IBM MQ 9.2.2.

0
Use the deprecated password protection mode that is compatible with versions earlier than IBM MQ 9.2.

Configuration parameters

When you run the **runmqbcb** command to create the configuration file, the parameters are stepped through in six groups. Passwords are obfuscated and are not displayed as you type. The generated configuration file is in JSON format. You must use the **runmqbcb** command to create the configuration file. You cannot edit the passwords and security certificate information directly in the JSON file.

Connection to queue manager
Parameters relating to the IBM MQ queue manager.

IBM MQ Queue manager
Required. The IBM MQ Advanced queue manager that you are using with the IBM MQ Bridge to blockchain.

Bridge input queue

`SYSTEM.BLOCKCHAIN.INPUT.QUEUE` is the default queue where applications put request messages, this can be overridden in the configuration file or on the **runmqbcb** command line. User applications must have appropriate authorisation to put messages to this queue.

IBM MQ Channel
The bridge requires a svrcon channel to connect to the z/os queue manager remotely.

IBM MQ Conname
Uses standard connection name format of "host(port), host(port)" to enable multiple destinations such as for multi-instance queue managers.

IBM MQ CCDT URL
If a TLS connection is required to the queue manager, you must use a JNDI or CCDT definition.

JNDI implementation class name
The class name of your JNDI provider. The "queue manager name" parameter refers to the connection factory name when you are using JNDI.

JNDI provider URL
The endpoint of your JNDI service.

IBM MQ UserId
The **UserId** that is running the bridge must have permission to set identity context on the messages it sends as replies, these have the requester **UserId** set in the message. The bridge user must therefore have appropriate access to put to the reply queue.

IBM MQ Password
Password for the IBM MQ **UserId** that the bridge is using.

User identification
Parameters relating to user authentication details that the bridge uses to connect to the Hyperledger Fabric REST server

Userid
The User Id provided by the bridge to Hyperledger Fabric must be known and authorized to connect to the Hyperledger Fabric endpoint, based on the user authentication configuration of the Hyperledger Fabric REST server.

Password
The password for the User Id that the bridge is using to connect to Hyperledger Fabric.

API path for login
The URL path to provide user credentials to the Hyperledger Fabric REST server. Note that this URL differs, depending on the type of security provider configured.

Fabric server
Attributes applicable to the Hyperledger Fabric server.

Wallet
A file containing credentials for the user, usually supplied by a Hyperledger Fabric administrator.

User Name
Mandatory parameter.

User Certificate
If no **Wallet** is provided, you must supply your certificate, private key and organization.

User Private Key
Your private key. You must supply this along with your certificate and organization if no **Wallet** has been provided.

User Organization
Your organization. You must supply this along with your certificate and private key if no **Wallet** has been provided.

Network Configuration File
A JSON-format file, usually supplied by the Hyperledger Fabric administrator or tooling that describes the various servers, addresses and so on. The file must exist.

Commit Timeout
Timeout for update operations in seconds.

The default value is 15 seconds.

Discovery
Whether to enable discovery of unknown networks that are not listed in the network configuration file.

The value can be *Y* or *N*.

Updates sent to all peers
Whether update responses are needed from all peers. or just one.

The value can be *Y* or *N*. The default value is *Y*.

Updates sent to all organizations in the network
Should updates be sent to all of the organizations listed in the configuration, or just to the specific MSPID organization.

The value can be *Y* for all organizations, or *N* for the specific organization. The default value is *N*.

Location of PEM file for IBM Blockchain certificate
When using a TLS connection to the Hyperledger Fabric REST server, a single PEM file is used to hold the Hyperledger certificates to authenticate the bridge with the Hyperledger Fabric REST server. This PEM file must be copied to the system where the IBM MQ Bridge to blockchain is running, and specified in the configuration file.

Certificate stores for TLS connections
Parameters relating to certificate stores for TLS connections.

Personal keystore for TLS certificates
Keystore for security certificates that are used for IBM MQ.

Keystore password
Password for the keystore.

Trusted store for signer certificates
If you do not add the trusted store, the personal keystore for TLS certificates is used.

Trusted store password
If the personal keystore for TLS certificates is used, this is the password for the keystore for TLS certificates.

Use TLS for MQ connection
The bridge can use TLS when it connects to the queue manager.

Timeout for Blockchain operations

If you don't provide a truststore parameter, the keystore is used for both roles. The stores can be the same as the one configured for the IBM MQ connection in the CCDT or JNDI.

Behavior of bridge program
Parameters relating to the behavior of the IBM MQ Bridge to blockchain.

Required. Runtime logfile for copy of stdout/stderr
Path to and name of the log file for the tracing information.

The configuration is only read on startup of the bridge process. Changes to the configuration require a restart of the bridge.

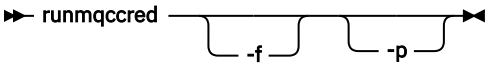
runmqccred (obfuscate passwords for mqccred exit)

Obfuscate passwords in the `.ini` file used by the **mqccred** security exit.

Purpose

Use the **runmqccred** command to process the **mqccred** exit `.ini` file to change all plain text passwords into an obfuscated form. This command should be run before using the `.ini` with the exit to ensure the exit runs successfully.

Syntax



Optional Parameters

-f

Specify a specific file to edit, other than the default file.

By default, the program locates the `.ini` file in the same way as the channel exit.

-p

By default the program fails with an error, if the filemode enables others to access the file you edited.

Use the **-p** flag to continue processing even when the error appears.

This might be necessary in situations where you might, for example, have mounted a UNIX file system onto your Windows machine using NFS, or some other protocol, and are trying to use the `.ini` file from there (perhaps to share the same `.ini` file across multiple accounts).

Since NFS does not support the Windows NT FS Access Control Lists, the exit would fail unless you bypass the permissions check.

Usage notes

The **runmqccred** program locates the ini file in the same way as the channel exit. The program also writes console messages saying which file is being modified, and any success or failure status.

Note that the channel exit can work with either **Password** or **OPW** attributes, but the expectation is that you will protect passwords.

Important: The **runmqccred** program works only from IBM MQ 8.0 or later. You must run the program on an IBM MQ 8.0 or later system and then transfer the output `.ini` file manually to a system running a previous version if you want to use clients there.

By default the exit only works when there are no plain text passwords in the file. You can override this by using the **NOCHECKS SCYDATA** option.

The **runmqccred** program also checks that the `.ini` file does not have excessive permissions set that allow other users to access it. By default the program fails with an error if the filemode enables others to access it. Use the **-p** flag to continue processing even when the error appears.

The **runmqccred** program is installed in the following folder:

Linux AIX **AIX and Linux**

The *MQ_INSTALLATION_PATH*`/usr/mqm/samp/mqccred/`

Windows **Windows platforms**

The *MQ_INSTALLATION_PATH*`\Tools\c\Samples\mqccred\`

If the file permissions are not secure enough **runmqccred** produces this message:

```
Configuration file 'C:\Users\User1\.mqs\mqccred.ini' is not secure.
Other users may be able to read it. No changes have been made to the file.
Use the -p option for runmqccred to bypass this error.
```

You can bypass this issue with the **-p** flag, but the exit will fail to run when put into production if you have not resolved this issue. When **runmqccred** runs successfully it informs you how many passwords have been obfuscated.

```
File 'C:\Users\User1\.mqs\mqccred.in' processed successfully.
Plaintext passwords found: 3
```

runmqchi (run channel initiator)

Run a channel initiator process to automate starting channels.

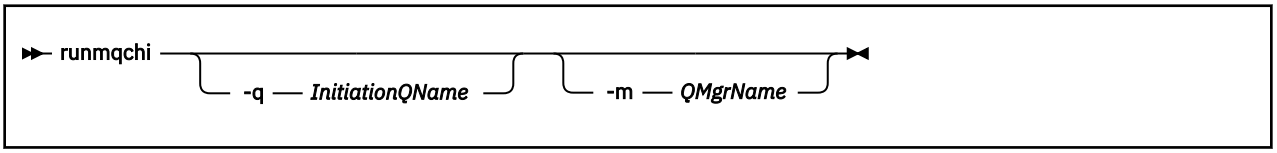
Purpose

Use the **runmqchi** command to run a channel initiator process.

You must use the **runmqchi** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the **dspmq -o installation** command.

The channel initiator is started by default as part of the queue manager.

Syntax



Optional parameters

-q *InitiationQName*
The name of the initiation queue to be processed by this channel initiator. If you omit it, SYSTEM.CHANNEL.INITQ is used.

-m *QMgrName*
The name of the queue manager on which the initiation queue exists. If you omit the name, the default queue manager is used.

Return codes

Table 86. Return code identifiers and descriptions

Return code	Description
0	Command completed normally
10	Command completed with unexpected results
20	An error occurred during processing

If errors occur that result in return codes of either 10 or 20, review the queue manager error log that the channel is associated with for the error messages, and the system error log for records of problems that occur before the channel is associated with the queue manager. For more information about error logs, see Error log directories.

runmqchl (run channel)

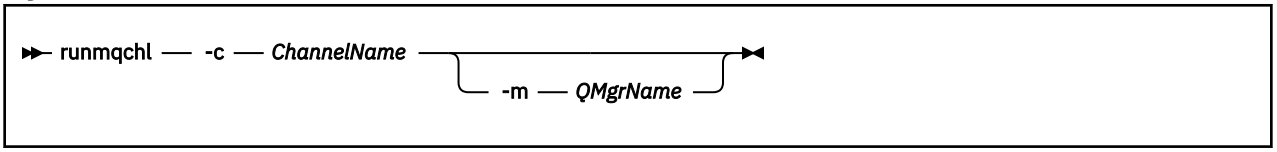
Start a sender or requester channel

Purpose

Use the **runmqchl** command to run either a sender (SDR) or a requester (RQSTR) channel.

The channel runs synchronously. To stop the channel, issue the MQSC command **STOP CHANNEL**.

Syntax



Required parameters

-c *ChannelName*
The name of the channel to run.

Optional parameters

-m *QMgrName*
The name of the queue manager with which this channel is associated. If you omit the name, the default queue manager is used.

Return codes

Table 87. Return code identifiers and descriptions

Return code	Description
0	Command completed normally
10	Command completed with unexpected results
20	An error occurred during processing

If return codes 10 or 20 are generated, review the error log of the associated queue manager for the error messages, and the system error log for records of problems that occur before the channel is associated with the queue manager.

runmqdlq (run dead-letter queue handler)

Start the dead-letter queue handler to monitor and process messages on the dead-letter queue.

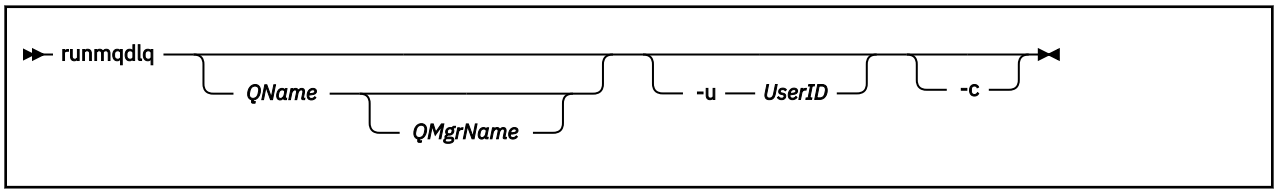
Purpose

Use the **runmqdlq** command to start the dead-letter queue (DLQ) handler, which monitors and handles messages on a dead-letter queue.

Before IBM MQ 9.2.3, this command is used on servers. If you want client mode you should compile **amqsdlq** in client mode. See The sample DLQ handler **amqsdlq** for more information.

V 9.2.3 From IBM MQ 9.2.3, you can use **runmqdlq** with the **-c** parameter to specify that it should connect to a queue manager by using a client connection.

Syntax



Description

Use the dead-letter queue handler to perform various actions on selected messages by specifying a set of rules that can both select a message and define the action to be performed on that message.

The **runmqdlq** command takes its input from `stdin`. When the command is processed, the results and a summary are put into a report that is sent to `stdout`.

By taking `stdin` from the keyboard, you can enter **runmqdlq** rules interactively.

By redirecting the input from a file, you can apply a rules table to the specified queue. The rules table must contain at least one rule.

If you use the DLQ handler without redirecting stdin from a file (the rules table), the DLQ handler reads its input from the keyboard:

- Linux AIX On AIX and Linux, the DLQ handler does not start to process the named queue until it receives an end_of_file (Ctrl+D) character.
- Windows On Windows, the DLQ handler does not start to process the named queue until you press the following sequence of keys: Ctrl+Z, Enter, Ctrl+Z, Enter.

For more information about rules tables and how to construct them, see The DLQ handler rules table.

Optional parameters

The MQSC command rules for comment lines and for joining lines also apply to the DLQ handler input parameters.

QName
The name of the queue to be processed.

If you omit the name, the dead-letter queue defined for the local queue manager is used. If you enter one or more blanks (' '), the dead-letter queue of the local queue manager is explicitly assigned.

QMgrName
The name of the queue manager that owns the queue to be processed.

If you omit the name, the default queue manager for the installation is used. If you enter one or more blanks (' '), the default queue manager for this installation is explicitly assigned.

-u *UserID*
If you use the **-u** parameter to supply a user ID, you are prompted for a matching password.

If you have configured the `CONNAUTH AUTHINFO` record with `CHCKLOCL(REQUIRED)` or `CHCKLOCL(REQDADM)`, you must use the **-u** parameter otherwise you will not be able to start a dead-letter queue handler for your queue manager with **runmqdlq**.

If you specify this parameter and redirect `stdin`, a prompt will not be displayed and the first line of redirected input should contain the password.

V 9.2.3 **-c**
Modifies the **runmqdlq** command to connect to a queue manager by using a client connection. The client channel definitions used to connect to the queue manager are located using the following environment variables in this order of precedence: **MQSERVER** , **MQCHLLIB** , and **MQCHLTAB** .

This option requires the client to be installed. If it is not installed an error message reporting the missing client libraries is issued.

Attention: runmqdlq is a `setuid` application that runs as the 'mqm' user regardless of which user started the application.

If you use a CCDT file, the 'mqm' group must have permission to read the CCDT file as well as 'execute' permission on the directory structure. Failure to grant the correct permissions results in **runmqdlq** failing with an AMQ9516 error.

Windows runmqdnm (run .NET monitor)

Start processing messages on a queue using the .NET monitor (Windows only).

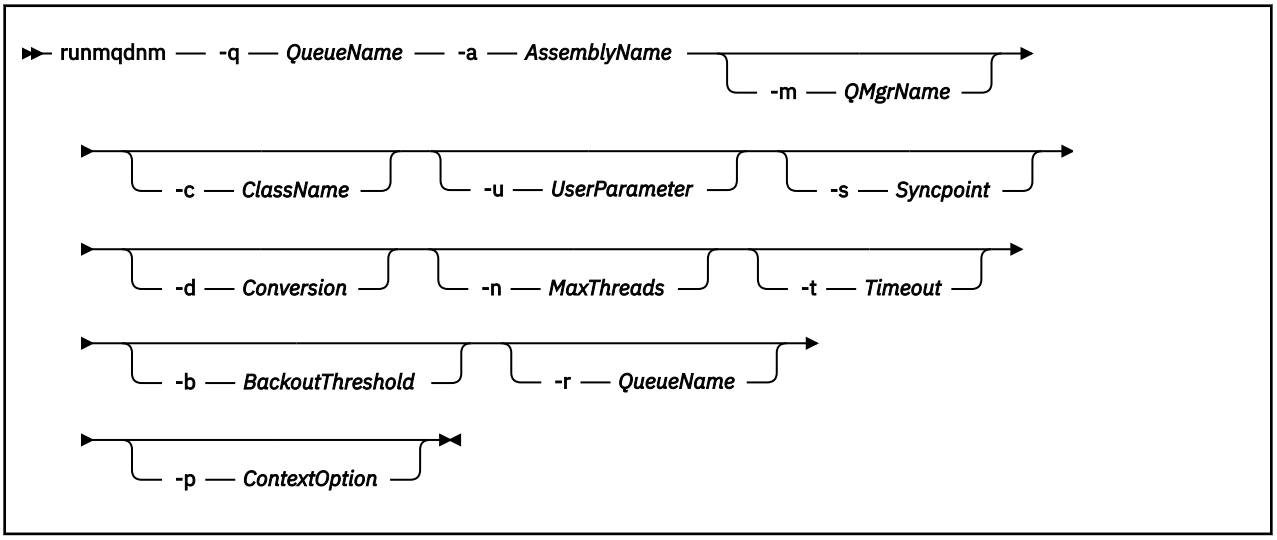
Purpose

Note: The **runmqdnm** command applies to IBM MQ for Windows only.

runmqdnm can be run from the command line, or as a triggered application.

Use the **runmqdnm** control command to start processing messages on an application queue with a .NET monitor.

Syntax



Required parameters

-q *QueueName*
The name of the application queue to monitor.

-a *AssemblyName*
The name of the .NET assembly.

Optional parameters

-m *QMgrName*
The name of the queue manager that hosts the application queue.

If omitted, the default queue manager is used.

-c *ClassName*
The name of the .NET class that implements the IMQObjectTrigger interface. This class must reside in the specified assembly.

If omitted, the specified assembly is searched to identify classes that implement the IMQObjectTrigger interface:

- If one class is found, then *ClassName* takes the name of this class.
- If no classes or multiple classes are found, then the .NET monitor is not started and a message is written to the console.

-u *UserData*
User-defined data. This data is passed to the Execute method when the .NET monitor calls it. User data must contain ASCII characters only, with no double quotation marks, NULLs, or carriage returns.

If omitted, null is passed to the Execute method.

-s *Syncpoint*
Specifies whether sync point control is required when messages are retrieved from the application queue. Possible values are:

Table 88. Syncpoint parameter values.	
Value	**Description**
YES	Messages are retrieved under sync point control (MQGMO_SYNCPOINT).
NO	Messages are not retrieved under sync point control (MQGMO_NO_SYNCPOINT).
PERSISTENT	Persistent messages are retrieved under sync point control (MQGMO_SYNCPOINT_IF_PERSISTENT).

If omitted, the value of *Syncpoint* is dependent on your transactional model:

- If distributed transaction coordination (DTC) is being used, then *Syncpoint* is specified as YES.
- If distributed transaction coordination (DTC) is not being used, then *Syncpoint* is specified as PERSISTENT.

-d *Conversion*
Specifies whether data conversion is required when messages are retrieved from the application queue. Possible values are:

Table 89. Conversion parameter values.	
Value	**Description**
YES	Data conversion is required (MQGMO_CONVERT).
NO	Data conversion is not required (no get message option specified).

If omitted, *Conversion* is specified as NO.

-n *MaxThreads*
The maximum number of active worker threads.

If omitted, *MaxThreads* is specified as 20.

-t *Timeout*
The time, in seconds, that the .NET monitor waits for further messages to arrive on the application queue. If you specify -1, the .NET monitor waits indefinitely.

If omitted when run from the command line, the .NET monitor waits indefinitely.

If omitted when run as a triggered application, the .NET monitor waits for 10 seconds.

-b *BackoutThreshold*
Specifies the backout threshold for messages retrieved from the application queue. Possible values are:

Table 90. BackoutThreshold parameter values.	
Value	**Description**
-1	The backout threshold is taken from the application queue attribute, BOTHRESH.
0	The backout threshold is not set.
1 or more	Explicitly sets the backout threshold.

If omitted, *BackoutThreshold* is specified as -1.

-r *QueueName*
The queue to which messages, with a backout count exceeding the backout threshold, are put.

If omitted, the value of *QueueName* is dependent on the value of the BOQNAME attribute from the application queue:

- If BOQNAME is non-blank, then *QueueName* takes the value of BOQNAME.
- If BOQNAME is blank, then *QueueName* is specified as the queue manager dead letter queue. If a dead letter queue has not been assigned to the queue manager, then backout processing is not available.

-p *ContextOption*
Specifies whether context information from a message that is being backed out is passed to the backed out message. Possible values are:

Table 91. ContextOption parameter values.

Value	Description
`NONE`	No context information is passed.
`IDENTITY`	Identity context information is passed only.
`ALL`	All context information is passed.

If omitted, *ContextOption* is specified as `ALL`.

Return codes

Table 92. Return code identifiers and descriptions

Return code	Description
0	Successful operation
36	Invalid arguments supplied
40	Queue manager not available
49	Queue manager stopping
58	Inconsistent use of installations detected
71	Unexpected error
72	Queue manager name error
133	Unknown object name error

Related tasks
Using the .NET monitor

runmqlsr (run listener)

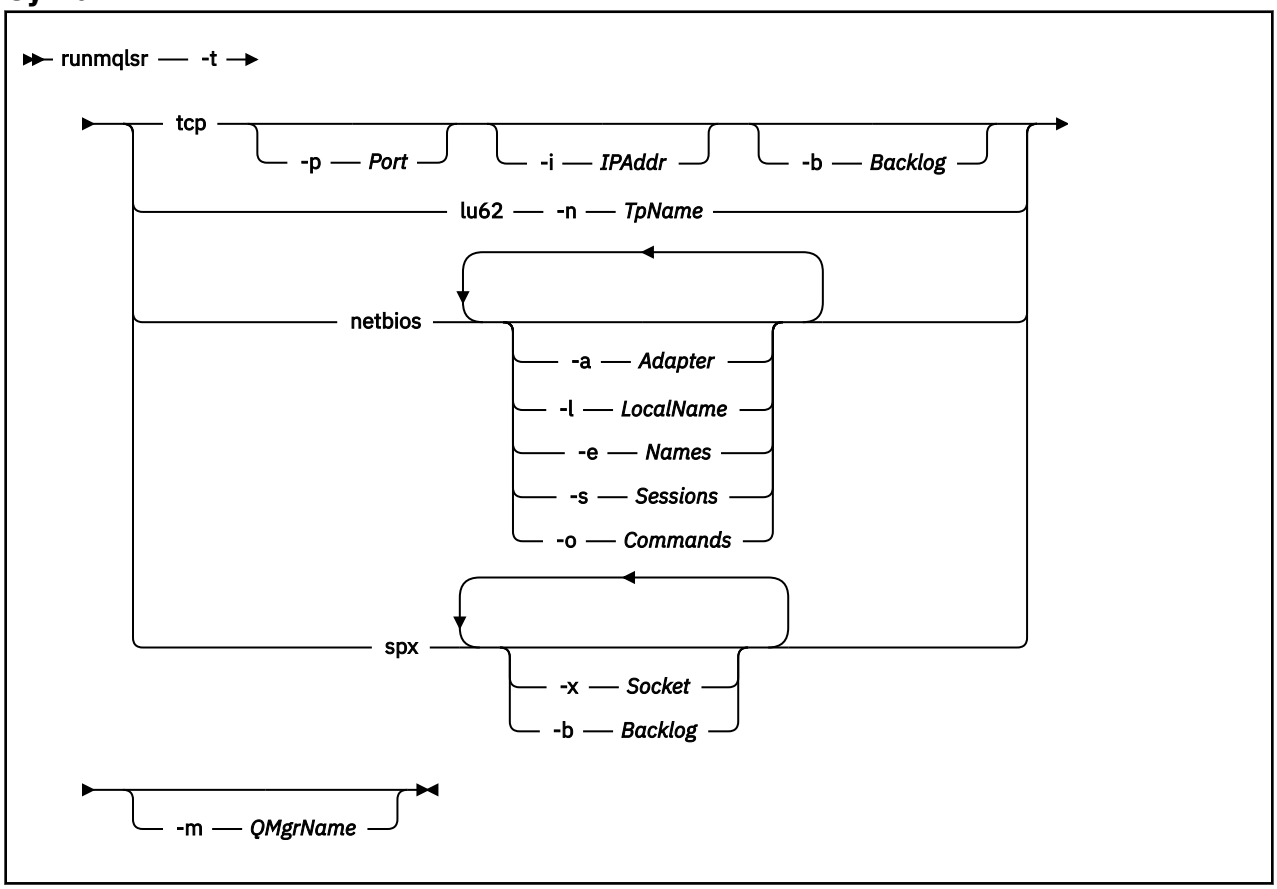
Run a listener process to listen for remote requests on various communication protocols.

Purpose

Use the **runmqlsr** command to start a listener process.

This command is run synchronously and waits until the listener process has finished before returning to the caller.

Syntax



Required parameters

-t
The transmission protocol to be used:

Table 93. Transmission protocol values.

Header	Header
`tcp`	Transmission Control Protocol / Internet Protocol (TCP/IP)
`lu62`	Windows SNA LU 6.2 (Windows only)
`netbios`	Windows NetBIOS (Windows only)
`spx`	Windows SPX (Windows only)

Optional parameters

-p *Port*
The port number for TCP/IP. This flag is valid for TCP only. If you omit the port number, it is taken from the queue manager configuration information, or from defaults in the program. The default value is 1414. It must not exceed 65535.

-i *IPAddr*
The IP address for the listener, specified in one of the following formats:

- IPv4 dotted decimal
- IPv6 hexadecimal notation

- Alphanumeric format

This flag is valid for TCP/IP only.

On systems that are both IPv4 and IPv6 capable you can split the traffic by running two separate listeners. One listening on all IPv4 addresses and one listening on all IPv6 addresses. If you omit this parameter, the listener listens on all configured IPv4 and IPv6 addresses.

-n *TpName*
The LU 6.2 transaction program name. This flag is valid only for the LU 6.2 transmission protocol. If you omit the name, it is taken from the queue manager configuration information.

-a *Adapter*
The adapter number on which NetBIOS listens. By default the listener uses adapter 0.

-l *LocalName*
The NetBIOS local name that the listener uses. The default is specified in the queue manager configuration information.

-e *Names*
The number of names that the listener can use. The default value is specified in the queue manager configuration information.

-s *Sessions*
The number of sessions that the listener can use. The default value is specified in the queue manager configuration information.

-o *Commands*
The number of commands that the listener can use. The default value is specified in the queue manager configuration information.

-x *Socket*
The SPX socket on which SPX listens. The default value is hexadecimal 5E86.

-m *QMgrName*
The name of the queue manager. By default the command operates on the default queue manager.

-b *Backlog*
The number of concurrent connection requests that the listener supports. See TCP, LU62, NETBIOS, and SPX for a list of default values and further information.

Return codes

Table 94. Return code identifiers and descriptions

Return code	Description
0	Command completed normally
4	Command completed after being ended by the **endmqlsr** command
10	Command completed with unexpected results
20	An error occurred during processing: the AMQMSRVN process did not start.

Examples

The following command runs a listener on the default queue manager using the NetBIOS protocol. The listener can use a maximum of five names, five commands, and five sessions. These resources must be within the limits set in the queue manager configuration information.

```
runmqlsr -t netbios -e 5 -s 5 -o 5
```

A table of listener commands, showing the PCF command, MQSC command, and control command equivalents. The REST API resource and HTTP method equivalents, and IBM MQ Explorer equivalents, are included if available.

Multi runmqras (collect IBM MQ troubleshooting information)

Use the **runmqras** command to gather IBM MQ troubleshooting information (MustGather data) together into a single archive, for example to submit to IBM Support.

Purpose

The **runmqras** command is used to gather troubleshooting information from a machine into a single archive. You can use this command to gather information about an application or IBM MQ failure, possibly for submitting to IBM when you report a problem.

The **runmqras** command requires a Java 7, or later, Java runtime environment (JRE) in order to run. If the IBM MQ JRE component (on Linux) or feature (on Windows) is not installed, then **runmqras** searches the system path for an alternative JRE and attempts to use that.

If no alternative could be found, error message AMQ8599 is output. In this case:

1. Install the IBM MQ JRE component, or install an alternative Java 7 JRE
2. Add the JRE to the system path
3. Rerun the command

By default, **runmqras** gathers information such as:

- IBM MQ FDC files
- Error logs (from all queue managers as well as the machine-wide IBM MQ error logs)
- Product versioning, status information, and output from various other operating system commands.

  Note, for example, the **runmqras** command does not gather user information that is contained in messages on queues.

Running without requesting more sections is intended as a starting point for general problem diagnosis, however, you can request more *sections* through the command line.

These additional *sections* gather more detailed information, depending on the type of problem being diagnosed. If non-default sections are needed by IBM support personnel, they will tell you.

The **runmqras** command can be run under any user ID, but the command gathers only information that the user ID can gather manually. In general, when debugging IBM MQ problems, run the command under:

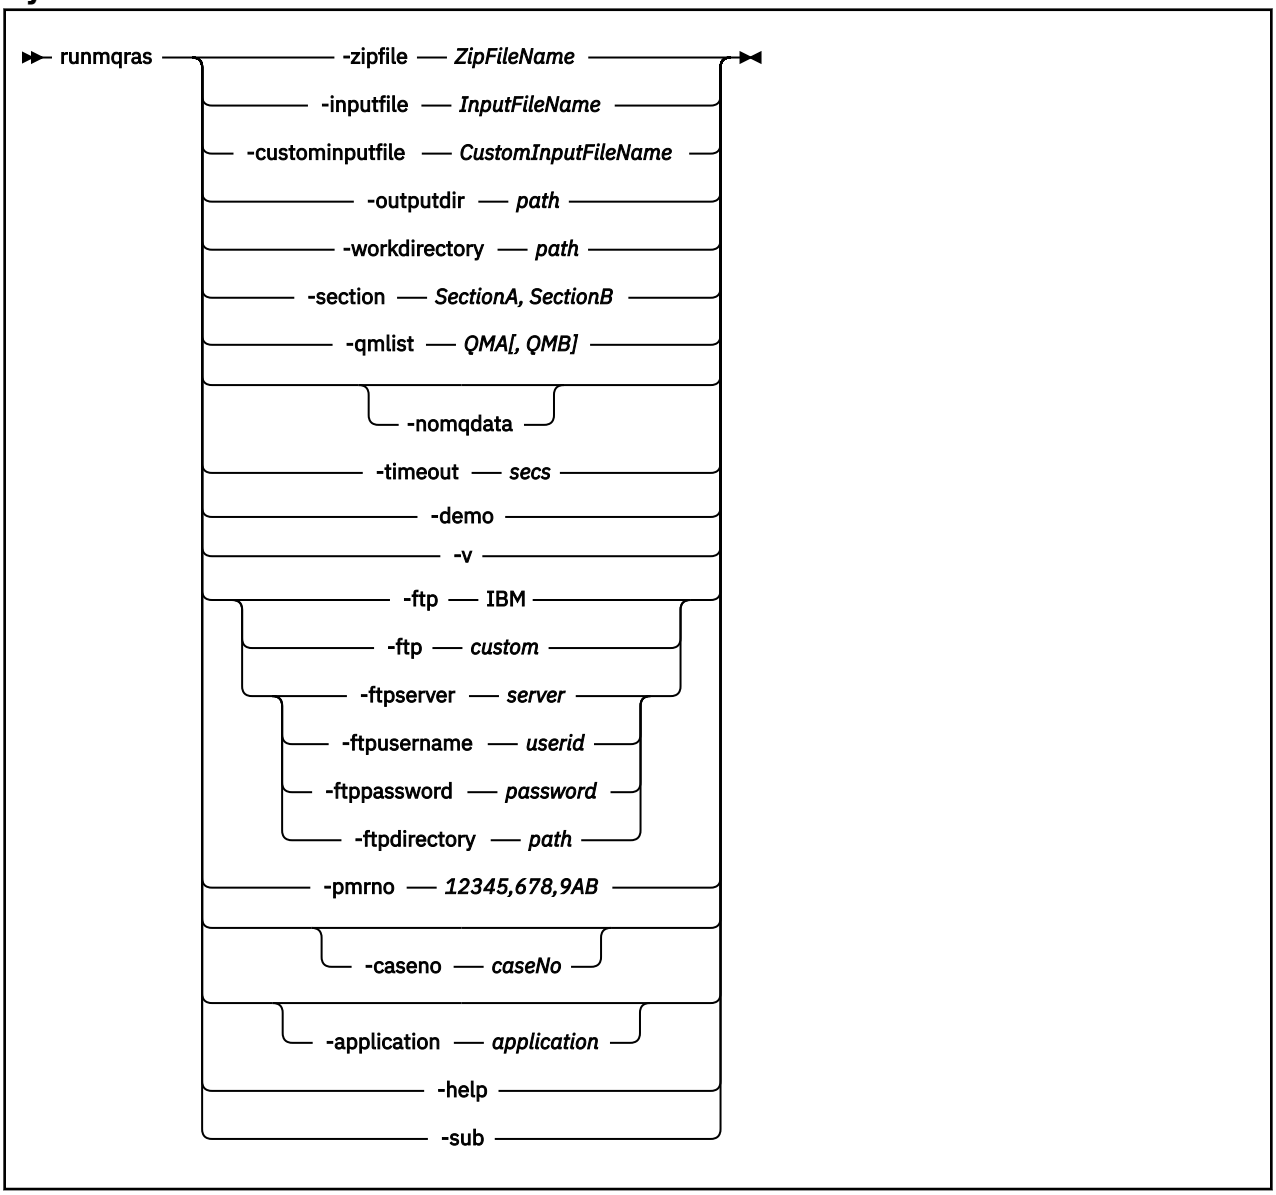
- Linux AIX The `mqm` user ID
- Windows A user ID in the `mqm` group.

to allow the command to gather queue manager files and command outputs.

Linux AIX The **runmqras** command, by default, retrieves the environment variable information. This applies to Linux and AIX.

Multi The **runmqras** command retrieves a listing of the queue manager's data directory by default. This applies to Multiplatforms. The userdata directory under the data directory is excluded.

Syntax



Keywords and parameters

All parameters are required unless the description states they are optional.

In every case, *QMgrName* is the name of the queue manager to which the command applies.

-inputfile *InputFileName*
Fully qualified name of the XML input file

-custominputfile *CustomInputFileName*
Fully qualified name of an additional XML input file

-zipfile *ZipFileName*
Supply the file name of the resulting archive.

runmqras appends the hostname to the name of the archive file. For example, if you run the following command:

```
runmqras -zipFile diagnostics.zip
```

the resulting archive file is called `diagnostics-`*`hostname`*`.zip`.

By default, the name of the archive file is `runmqras-`*`hostname`*`.zip` where *hostname* is the hostname that **runmqras** appends to the file name.

-outputdir ***path***
The directory in which the resulting output file is placed.

By default, the output directory is the same as the work directory.

-workdirectory ***path***
The directory that is used for storing the output from commands that are run during the processing of the tool. If supplied, this directory must either not exist, in which case it is created, or must be empty.

If you do not supply the path, a directory whose name starts with **runmqras** and is suffixed by the date and time is used:

- Linux AIX On AIX and Linux, the directory is under `/tmp`.
- Windows On Windows, the directory is under `%temp%`.

-section ***SectionA,SectionB***
The optional sections about which to gather more specific information. You must use a comma as the separator character between sections, with no spaces. For example:

```
runmqras -qmlist ESBSTGAPPQMVH2 -section defs,trace,cluster -caseno TEST123
```

By default, a generic section of documentation is collected, whereas more specific information can be gathered for a specified problem type; for example, a section name of *trace* gathers all of the contents of the trace directory.

The default collections can be avoided by supplying a section name of *nodefault*.

IBM support generally supplies you with the sections to use. Example available sections are:

all
Gathers all possible information, including all trace files, and diagnostics for many different types of problems. You must use this option only in certain circumstances and this option is not intended for general use.

default
IBM MQ logs, FDC files, basic configuration, and status.

Note: Always gathered unless you use the section name **nodefault**. Some information about the current environment (saved in `env.stdout` on Linux, AIX and IBM i, and in `set.stdout` on Windows) and current user limits (saved in `mqconfig.stdout` on Linux and AIX) might be altered by the **runmqras** command. If necessary, run the **env**, **set**, or **mqconfig** commands manually in your environment to check the actual values.

MQ Appliance On the IBM MQ Appliance, any files other than queue manager trace files present in the `mqtrace:` filesystem are now captured in the *default* section.

Note: You should continue to specify the *trace* section if you need to obtain any queue manager trace files present in the `mqtrace:` filesystem.

nodefault
Prevents the default collections from occurring, but other explicitly requested sections are still collected.

trace
Gathers all the trace file information plus the default information.

Note: Does not enable tracing.

defs
Gathers the queue manager definitions and status information.

cluster
Gathers cluster configuration and queue information.

dap
Gathers transaction and persistence information.

kernel
Gathers queue manager kernel information.

logger
Gathers recovery logging information.

topic
Gathers topic tree information.

QMGR
Gathers all queue manager files: queues, logs, and configuration files.

Linux AIX **leak**
Gathers IBM MQ process resource usage information.

This section applies to Linux, and AIX.

mft
Captures the data obtained by the **fteRas** command.

Note: `-section mft` only collects information for the default coordination queue manager topology.

mqweb
Gathers trace and configuration data for the mqweb server.

For more information, see Choosing sections to gather, in the IBM technote on using the IBM MQ **runmqras** command to collect data.

-qmlist *QMA[,QMB]*
A list of queue manager names on which the **runmqras** command is to be run.

This parameter does not apply to a client product because there are no queue managers from which to request direct output.

By supplying a comma-separated list, you can restrict the iteration across queue managers to a specific list of queue managers. By default, iteration of commands is across all queue managers.

V 9.2.4 V 9.2.0.3 **-noqmdata**
For Long Term Support from IBM MQ 9.2.0 Fix Pack 3 and for Continuous Delivery from IBM MQ 9.2.4, setting **-noqmdata** captures installation-level diagnostics only, skipping any queue manager-specific diagnostics.

The **-qmlist** parameter and the **-noqmdata** parameter cannot be used together. If both parameters are specified, the following error is returned:

```
Argument error: At most one of -noqmdata or -qmlist may be supplied
```

-timeout *secs*
The default timeout to give an individual command before the command stops waiting for completion.

By default, a timeout of 10 seconds is used. A value of zero means wait indefinitely.

-demo
Run in demonstration mode where no commands are processed, and no files gathered.

By running in demonstration mode, you can see exactly which commands would have been processed, and what files would have been gathered. The output `.zip` file contains a `console.log` file that documents exactly what would have been processed and gathered, should the command be run normally.

-v
Extends the amount of information that is logged in the `console.log` file, contained in the output `.zip` file.

-ftp `ibm|custom`
Allows the collected archive to be sent through basic FTP to a remote destination.

At the end of processing, the resultant archive can be sent through basic FTP, either directly into IBM, or to a site of your choosing.

If you select the `ibm` option, anonymous FTP is used to deliver the archive into the IBM ECuRep server. This process is identical to submitting the file manually using FTP.

Note if you select the `ibm` option, you must also provide the `pmrno` option, and all other FTP* options are ignored.

V 9.2.4 V 9.2.0.3

Important: For Long Term Support from IBM MQ 9.2.0 Fix Pack 3 and for Continuous Delivery from IBM MQ 9.2.4, the **`-ftp`** `IBM` option is no longer available. If you select this option, the following message is generated:

```
The FTP IBM option will no longer work as the IBM FTP servers have been disabled
```

-ftpserver *server*
An FTP server name to connect to, when an FTP custom option is used.

-ftpusername *userid*
The user ID to log in to the FTP server with, when an FTP custom option is used.

-ftppassword *password*
The password to log in to the FTP server with, when an FTP custom option is used.

-ftpdirectory *path*
The directory on the FTP server to place the resulting `.zip` file into, used when an FTP custom option is used.

-pmrno *12345,678,9AB*
A valid IBM PMR number (problem record number) against which to associate the documentation.

Use this option to ensure that the output is prefixed with your PMR number, so that when the information is sent to IBM, the information is automatically associated with that problem record.

Note: If you want to specify a Salesforce case number, use the **`-caseno`** parameter, not the **`-pmrno`** parameter.

It is not permitted to supply both the **`-caseno`** and **`-pmrno`** parameters together.

-caseno *caseNo*
A valid Salesforce case number.

Use this option to ensure that the output is prefixed with your case number, so that when the information is sent to IBM, the information is automatically associated with that case number.

Note: If you want to specify a PMR number, use the **`-pmrno`** parameter, not the **`-caseno`** parameter.

It is not permitted to supply both the **`-caseno`** and **`-pmrno`** parameters together.

V 9.2.0 **-application *application***
Collects information about valid applications.

-help
Provide simple help.

-sub
Shows the keywords that will be substituted in the xml.

Examples

This command gathers the default documentation from the IBM MQ installation, and all queue managers on a machine:

```
runmqras
```

This command gathers the default documentation from the IBM MQ installation on a machine into an output file with a name that starts with the appropriate case number:

```
runmqras -caseno TS123456789
```

This command gathers the default documentation from a machine, plus all trace files, the queue manager definitions, and status for all queue managers on the machine:

```
runmqras -section trace,defs
```

For more examples of how to use **runmqras**, see Collecting troubleshooting information automatically with runmqras.

Return codes

A non zero return code indicates failure.

Related tasks

Collecting troubleshooting information automatically with runmqras

Related information

Sending troubleshooting information to IBM

runmqsc (run MQSC commands)

Run IBM MQ commands on a queue manager.

Purpose

Use the **runmqsc** command to issue MQSC commands to a queue manager. MQSC commands enable you to perform administration tasks. For example, you can define, alter, or delete a local queue object. MQSC commands and their syntax are described in "MQSC commands reference" on page 233.

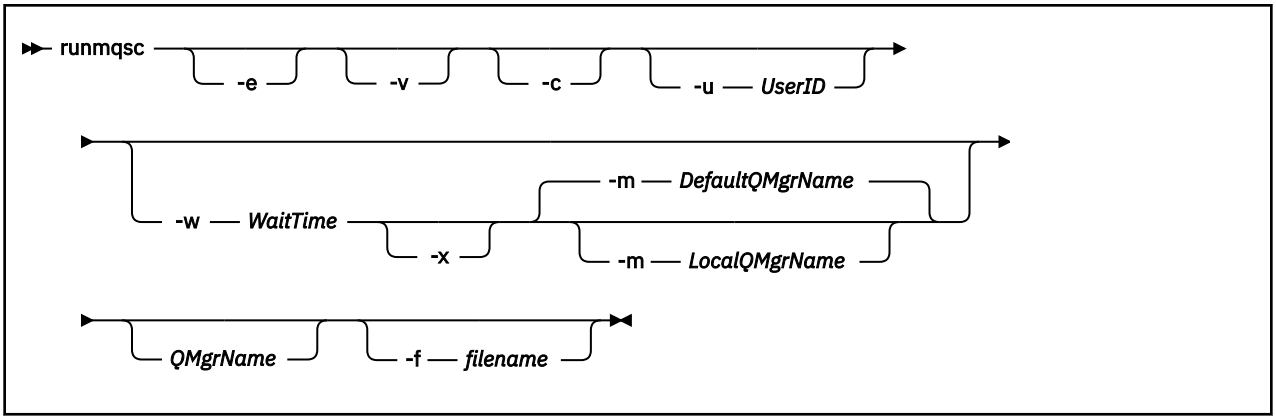
You must use the **runmqsc** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with by using the `dspmq -o installation` command.

To stop the **runmqsc** command, use the **end** command. You can also use the **exit** or the **quit** command.

You can make it easier to see that you are in an MQSC environment and see some details of the current environment by setting a prompt of your choice by using the MQPROMPT environment variable. For more information, see Setting the MQSC command prompt.

Syntax

You can use the **-n** parameter on its own, or you can use a number of other parameters in combination:



Description

You can start the **runmqsc** command in three ways:

Verify command
Verify MQSC commands but do not run them. An output report is generated indicating the success or failure of each command. This mode is available on a local queue manager only.

Run command directly
Send MQSC commands directly to a local queue manager.

Run command indirectly
Run MQSC commands on a remote queue manager. These commands are put on the command queue of a remote queue manager and run in the order in which they were queued. Reports from the commands are returned to the local queue manager.

The **runmqsc** command takes its input from `stdin`. When the commands are processed, the results and a summary are put into a report that is sent to `stdout`.

By taking `stdin` from the keyboard, you can enter MQSC commands interactively.

Alternatively, you can redirect `stdin` from a text file. By redirecting the input from a file, you can run a sequence of frequently used commands contained in the file. You can also redirect the output report to a file.

Note: If you run **runmqsc** in client mode by redirecting `stdin` from a text file, IBM MQ expects the first line of the input file to be a password.

Optional parameters

-c
Modifies the **runmqsc** command to connect to a queue manager by using a client connection. The client channel definitions used to connect to the queue manager are located using the following environment variables in this order of precedence: **MQSERVER**, **MQCHLLIB**, and **MQCHLTAB**.

This option requires the client to be installed. If it is not installed an error message reporting the missing client libraries is issued.

-e
Prevents source text for the MQSC commands from being copied into a report. This parameter is useful when you enter commands interactively.

-m *LocalQMgrName*
The local queue manager that you want to use to submit commands to the remote queue manager. If you omit this parameter the local default queue manager is used to submit commands to the remote queue manager. The **-w** parameter must also be specified.

-n
Modifies the **runmqsc** command to not connect to a queue manager. If this parameter is specified, all other command parameters must be omitted, otherwise an error message is issued.

This option requires the client libraries to be installed. If they are not installed an error message is issued.

MQSC commands entered in this mode are limited to managing the local channel definition file, which is located through the **MQCHLLIB** and **MQCHLTAB** environment variables, or the default values if not defined.

Note: If you add new entries into the local channel definition file, or alter existing entries, these changes are not reflected inside the queue manager. The queue manager does not read the contents of the local channel definition file. The CCDT file is a write-only file from the perspective of the queue manager. The queue manager does not read the contents of the CCDT file.

Only the following MQSC commands are recognized:

ALTER, **DEFINE**, **DELETE**, **DISPLAY AUTHINFO** (Only of type CRLLDAP or OCSP)
ALTER, **DEFINE**, **DELETE**, **DISPLAY CHANNEL** (Only of type CLNTCONN)

For the AUTHINFO management commands, the names of existing AUTHINFO definitions are mapped and addressed using the names `CRLLDAP`*n* or `OCSP` *n* (according to type), where *n* is the numeric order in which they appear in the channel definition file. New AUTHINFO definitions are appended to the client channel table in order. For example, the the following commands are issued:

```
DEFINE AUTHINFO(XYZ) AUTHTYPE(CRLLDAP) CONNAME('xyz')

DEFINE AUTHINFO(ABC) AUTHTYPE(CRLLDAP) CONNAME('abc')
```

This results in the `'xyz'` LDAP server being checked for a CRL first, if that CRL server is unavailable then the `'abc'` server is checked.

Using the **DISPLAY AUTHINFO(*) CONNAME** command shows this:

```
AMQ8566: Display authentication information details.
AUTHINFO(CRLLDAP1)
AUTHTYPE(CRLLDAP)            CONNAME(xyz)
AMQ8566: Display authentication information details.
AUTHINFO(CRLLDAP2)
AUTHTYPE(CRLLDAP)            CONNAME(abc)
```

Note: The client mode only supports inserting new entries at the end of the client channel table. If you want to change the order of precedence of the CRL LDAP servers, you must remove the existing objects from the list and reinsert them in the correct order at the end.

-u ***UserID***
If you use the **-u** parameter to supply a user ID, you are prompted for a matching password.

If you have configured the `CONNAUTH AUTHINFO` record with `CHCKLOCL(REQUIRED)` or `CHCKLOCL(REQDADM)`, you must use the **-u** parameter otherwise you will not be able to administer your queue manager with **runmqsc**.

If you specify this parameter and redirect `stdin`, a prompt will not be displayed and the first line of redirected input should contain the password.

-v
Verifies the specified commands without performing the actions. This mode is only available locally. The **-w** and **-x** parameters are ignored if they are specified at the same time as **-v**.

Important: The **-v** flag checks the syntax of the command only. Setting the flag does not check if any objects mentioned in the command actually exist.

For example, if the queue `Q1` does not exist in the queue manager, the following command is syntactically correct and does not generate any syntax errors: `runmqsc -v Qmgr display ql(Q1)`.

However, if you omit the **-v** flag, you receive error message AMQ8147.

-w *WaitTime*
Run the MQSC commands on another queue manager. You must have the required channel and transmission queues set up for this. For more information, see Configuring queue managers for remote administration.

This parameter is ignored if the **-v** parameter is specified.

WaitTime
The time, in seconds, that **runmqsc** waits for replies. Any replies received after this are discarded, but the MQSC commands still run. V 9.2.2 The wait time is set as the expiry time of the PCF command message, and the remaining time is set on the PCF reply messages by the command server. Specify a time in the range 1 through 999999.

Each command is sent as an Escape PCF to the command queue (SYSTEM.ADMIN.COMMAND.QUEUE) of the target queue manager.

The replies are received on queue SYSTEM.MQSC.REPLY.QUEUE and the outcome is added to the report. This can be defined as either a local queue or a model queue.

-x
The target queue manager is running under z/OS. This parameter applies only in indirect mode. The **-w** parameter must also be specified. In indirect mode, the MQSC commands are written in a form suitable for the IBM MQ for z/OS command queue.

QMgrName
The name of the target queue manager on which to run the MQSC commands. If not specified, the default queue manager is used.

V 9.2.0 Multi **-f *filename***
Read input to be processed from the supplied filename rather than standard input.

Return codes

Table 95. Return code identifiers and descriptions

Return code	Description
00	MQSC command file processed successfully
10	MQSC command file processed with errors; report contains reasons for failing commands
20	Error; MQSC command file not run

Examples

1. Enter this command at a command prompt:

```
runmqsc
```

   Now you can enter MQSC commands directly at the command prompt. No queue manager name is specified, so the MQSC commands are processed on the default queue manager.
2. Use one of these commands, as appropriate in your environment, to specify that MQSC commands are to be verified only:

```
runmqsc -v BANK < "/u/users/commfile.in"
runmqsc -v BANK < "c:\users\commfile.in"
```

   The queue manager name is BANK. The command verifies the MQSC commands in file `commfile.in` and displays the output in the current window.

3. These commands run the MQSC command file `mqscfile.in` against the default queue manager.

```
runmqsc < "/var/mqm/mqsc/mqscfile.in" > "/var/mqm/mqsc/mqscfile.out"

runmqsc < "C:\Program Files\IBM\MQ\mqsc\mqscfile.in" >
        "C:\Program Files\IBM\MQ\mqsc\mqscfile.out"
```

   In this example, the output is directed to file `mqscfile.out`.

4. This command submits commands to the QMREMOTE queue manager, using QMLOCAL to submit the commands.

```
runmqsc -w 30 -m QMLOCAL QMREMOTE
```

"dmpmqcfg (dump queue manager configuration)" on page 49

Use the **dmpmqcfg** command to dump the configuration of an IBM MQ queue manager.

Linux runmqsfb (run IBM MQ Bridge to Salesforce)

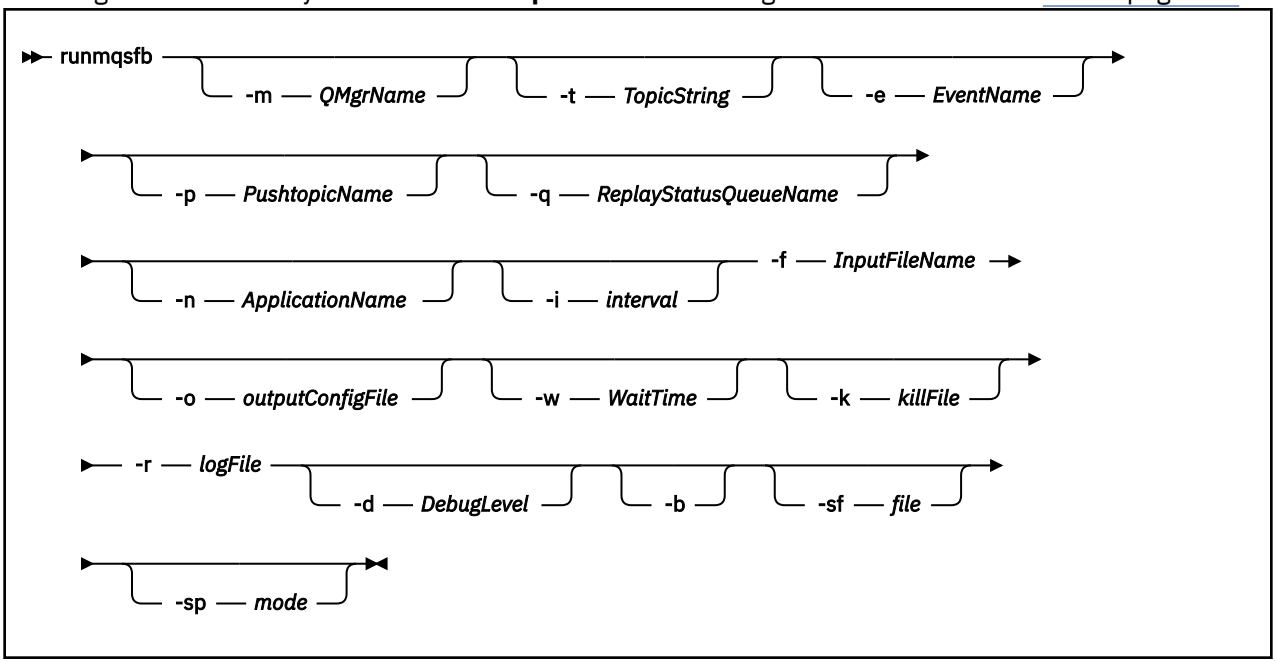
Configure and run the IBM MQ Bridge to Salesforce.

Note: Deprecated The IBM MQ Bridge to Salesforce is deprecated across all releases from November 22 2022 (see US Announcement letter 222-341).

- "Syntax" on page 167
- "Usage notes" on page 168
- "Command line parameters" on page 168
- Configuration parameters
- Examples

Syntax

The diagram shows the syntax for the **runmqsfb** command usage as described in note "1" on page 168.



Usage notes

1. You can run the **runmqsfb** command to start the IBM MQ Bridge to Salesforce and connect to Salesforce and IBM MQ. When the connections are made, the bridge receives Salesforce generated events and publishes them to an IBM MQ network, or create event messages for Salesforce platform events.

   ```
   runmqsfb -f configFile -r logFile -m QMgrName -t TopicString -e EventName -p PushtopicName
   -d debugLevel -i interval -w WaitTime -k killFile
   ```

   When you use the command for runtime processing, the required parameters are **-f**, with the name of the previously created configuration file, and **-r** with the name of the log file. When the other command parameters are also given on the command line, they override the values in the configuration file. The option allows a core default configuration to be created and provides a simple way to handle minor variations such as the queue manager name.

2. You can also use the **runmqsfb** command to generate a configuration file that is used to define the parameters that are needed to connect to Salesforce and IBM MQ.

   When you are creating the configuration file, the **-f** and **-b** parameters are optional, the input configuration file is included in the samples directory for the IBM MQ Bridge to Salesforce, `/opt/mqm/mqsf/samp`.

   ```
   runmqsfb [-b][-f inputConfigFile] -o outputConfigFile
   ```

   When you run the command in this way, you are prompted to enter values for each of the configuration parameters. To keep an existing value press `Enter`. To remove an existing value press `Space`, then `Enter`. For more information, see “Configuration parameters” on page 170.

3. V 9.2.0 V 9.2.0 From IBM MQ 9.2.0, the usage of the enhanced protection parameters is as follows:

   Configuration mode
   Newly entered passwords are written to the output configuration file protected with the new key. Note that preexisting passwords are not changed in format.

   A warning is issued when the default key is being used, that is, you have not provided a keyfile.

   Provision of passwords in the `batch` configuration mode, using environment variables, continues unchanged; that is, the value of the environment variables is given in plain text.

   Runtime mode
   When a password is decrypted, warning messages are issued if the password is found to be in the old format, and the name of the parameter causing the warning is given in the message to encourage you to migrate. However, the bridge continues processing commands.

   Note: The warning message is not issued if you have specified the **-sp** *0* parameter on the command line, as you explicitly wanted to use old formats.

   A warning is also issued when the default key is being used, that is, you have not provided a keyfile.

   Errors occur if a password cannot be decrypted, for example, if you have specified the wrong keyfile.

Command line parameters

-m ***QMgrName or ConnFactoryName***
Queue manager or Connection Factory name.

-r ***logFile***
Required. Location and name of the log file for trace information. You can specify the log file path and name in the configuration file or on the command line.

-t ***TopicString***
IBM MQ topic root.

-e *EventName*
Salesforce platform event name (can repeat). You can specify multiple **-e** entries on the command line, one for each event type that the bridge listens for. You must provide the base part of the event name. The bridge automatically adds "`/event`" or "`/topic`" prefixes when it connects to Salesforce. Multiple **-e** parameters can be comma-separated.

-p *PushtopicName*
Salesforce push topic name (can repeat). You can specify multiple **-p** entries on the command line, one for each topic type that the bridge listens for. You must provide the base part of the topic name. The bridge automatically adds "`/event`" or "`/topic`" prefixes when it connects to Salesforce. Multiple **-p** parameters can be comma-separated.

-i *interval*
Monitor interval. Enter 0 to disable monitoring.

-f *inputConfigFile*
Configuration file. The **-f** parameter is required when you are running the **runmqsfb** command to start the IBM MQ Bridge to Salesforce, as described in usage note "1" on page 168. You can optionally use the **-f** parameter to reuse some of the values from an existing *inputConfigFile*, as described in usage note "2" on page 168, and also enter some of the new values. If you do not specify the **-f** parameter when you are creating the configuration file, all the values for the parameters you are prompted for are empty.

V 9.2.0 **-n *ApplicationInstanceName***
If you have multiple instances of the bridge on the same queue manager,this option gives you a way to distinguish each instance in the monitoring. This identifier is added to the $SYS topic as part of the application name, so that monitors like **amqsrua** can get separate metadata trees.

If this option is not empty, the metadata root topic adds "_" together with the selected value to the application name. For example, setting it to "2" results in publications based on

```
$SYS/Application/runmqsfb_2/INFO/QMGR/<qmgr>/Monitor/METADATA
```

Note: There is no coordination between running bridge instances, so it is possible to have two instances with the same identifier. The only confusion this causes is in the monitoring statistics.

V 9.2.0 **-q *ReplyStatusQueueName***
The default value is SYSTEM.SALESFORCE.SYNCQ.

If you want to have multiple bridges accessing the same queue manager, and having inbound messages from Salesforce, then you must have separate synchronization queue settings for each.

If a bridge instance is not subscribed to any Salesforce topics, the synchronization queue is not used at all.

Note: The synchronization queue is accessed exclusively; that is, the bridge will not start if another instance already has the nominated queue open.

-o *outputConfigFile*
New configuration file. When you run the command with the **-o** parameter, **runmqsfb** command loads existing configuration values from the **-f** file and prompts for new values for each configuration parameter.

-k *killFile*
A file to cause the bridge to exit. When you run the command with the **-k** parameter and specify a file, if the file exists, it causes the bridge program to exit. Using this file is an alternative way to stop the program when you don't want to use `Ctrl+C` or **kill** command. The file is deleted by the bridge on startup in case it exists. If the deletion fails, the bridge abends but monitors for the recreation of the file.

-d *debugLevel*
Debug level, 1, or 2.

1
Terse debug information is displayed.

2
Verbose debug information is displayed.

-w *WaitTime*
Wait before fully starting.

-b
Use environment variables to drive the configuration, instead of interactive prompts. This allows the configuration to be set programatically.

The environment variables have the format "`runmqsfb_<attribute>`" where `<attribute>` is the JSON field in the generated configuration file. For example:

```
export runmqsfb_QueueManager=QM1
```

The environment variables are merged with the configuration specified in the *inputConfigurationFile* (-f option) to create the *outputConfigurationFile*.

One way of using this method, is for you to interactively create a configuration file that contains common attributes that are to be used by all instances of the IBM MQ Bridge to Salesforce, and then apply environment variables programmatically for just the few instance-unique parameters.

V 9.2.0 V 9.2.0 **-sf *file***
File containing password protection key.

V 9.2.0 V 9.2.0 **-sp *mode***
Password protection mode. The values can be:

V 9.2.2 **2**
Use the latest password protection mode. This is the default value from IBM MQ 9.2.2.

1
Use the IBM MQ 9.2 password protection mode for compatibility with versions earlier than IBM MQ 9.2.2. This is the default value in versions earlier than IBM MQ 9.2.2.

0
Use the deprecated password protection mode that is compatible with versions earlier than IBM MQ 9.2.

Configuration parameters

When you run the **runmqsfb** command to create the configuration file, the parameters are stepped through in four groups. Passwords are obfuscated and are not displayed as you type. The generated configuration file is in JSON format. You must use the **runmqsfb** command to create the configuration file. You cannot edit the passwords and security certificate information directly in the JSON file.

Connection to queue manager
Parameters relating to the IBM MQ queue manager.

IBM MQ Queue manager or JNDI CF
Required.

IBM MQ Base Topic
Required. All events are published by using the topic root as the prefix to the Salesforce event name.

IBM MQ Channel
Blank **channel** implies local bindings.

IBM MQ Conname
Uses standard connection name format of "host(port), host(port)" to enable multiple destinations such as for multi-instance queue managers. Blank **conname** implies local bindings.

IBM MQ Publication Error Queue
Required for creating platform event messages. IBM MQ error queue for processing bad input messages. The default queue *SYSTEM.SALESFORCE.ERRORQ* is created when you run the

mqsfbSyncQ.mqsc script command that also creates the required synchronization queue on the queue manager.

IBM MQ CCDT URL
If a TLS connection is required to the queue manager, you must use a JNDI or CCDT definition.

JNDI implementation class name
The class name of your JNDI provider. The "queue manager name" parameter refers to the connection factory name when you are using JNDI.

JNDI provider URL
The endpoint of your JNDI service.

IBM MQ UserId

IBM MQ Password

Connection to Salesforce
Parameters relating to Salesforce.

Salesforce Userid (required)
Required. Log in email for your Salesforce account.

Salesforce password (required)
Required. Password for your Salesforce account.

Salesforce security token (required)
Required. Security token that you can generate from the **Security controls** section of the **Administer** menu of your Salesforce **Force.com Home** page.

Login Endpoint
Salesforce login endpoint URL, https://login.salesforce.com.

Consumer key
The consumer key that you generate when you add the IBM MQ Bridge to Salesforce as a connected application in your Salesforce account. For more information, see Step 5 in Configuring the IBM MQ Bridge to Salesforce

Consumer secret
The consumer secret that is generated along with the consumer key.

OAuth consumer key and secret values are optional but must be considered for production systems.

Certificate stores for TLS connections
Parameters relating to certificate stores for TLS connections.

Personal keystore for TLS certificates
Required. The keystore that you create in your Salesforce account. For more information, see Step 3 in Configuring the IBM MQ Bridge to Salesforce.

Keystore password
Required. The password that you create when you are exporting the keystore from your Salesforce account.

Trusted store for signer certificates
Required. If you do not add the trusted store, the personal keystore for TLS certificates is used.

Trusted store password
Required. If the personal keystore for TLS certificates is used, this is the password for the keystore for TLS certificates.

Use TLS for MQ connection
If you are using TLS for your IBM MQ connectivity, you can use the same keystore that you used to connect to Salesforce.

For the Salesforce connection, a truststore must be available and contain at least the signer certificates to validate the Salesforce system. Only TLS 1.1 and TLS 1.2 protocols are supported for connection to Salesforce. A user certificate is not required. If you don't provide a truststore parameter, the keystore is used for both roles. The stores can be the same as the one configured for the IBM MQ connection in the CCDT or JNDI.

Behavior of bridge program
Parameters relating to the behavior of the IBM MQ Bridge to Salesforce.

Push topic names
You can provide one push topic name at a time and then move on to the next parameter by pressing `enter`.

Platform event names
You can provide one platform event name at a time and then move on to the next parameter by pressing `enter`.

Monitoring frequency
IBM MQ Monitoring frequency.

At least once delivery
Quality of service. At-least-once or at-most-once delivery.

Subscribe to IBM MQ publications for platform events
Required. The default option is *N*. You must enter *Y* to enable the bridge feature for creating event messages for Salesforce platform events.

Publish control data with the payload
On republish, send full message not only subject.

Delay before starting to process events
Delay before the bridge starts to process events.

Runtime logfile for copy of stdout/stderr
Path to and name of the log file for the tracing information.

V 9.2.0 **Bridge unique identifier**
The default value is no Bridge unique identifier specified.

If you have multiple instances of the bridge on the same queue manager,this option gives you a way to distinguish each instance in the monitoring. This identifier is added to the $SYS topic as part of the application name, so that monitors like **amqsrua** can get separate metadata trees.

If this option is not empty, the metadata root topic adds "_" together with the selected value to the application name. For example, setting it to "2" results in publications based on

```
$SYS/Application/runmqsfb_2/INFO/QMGR/<qmgr>/Monitor/METADATA
```

Note: There is no coordination between running bridge instances, so it is possible to have two instances with the same identifier. The only confusion this causes is in the monitoring statistics.

V 9.2.0 **Treat unknown Salesforce topic as warning**
The default option is *N*.

You must set this option to *Y* to continue with a warning, instead of exiting if a push topic or an event is not known to Salesforce during the subscribe.

This option can be useful when creation of the topics in Salesforce is done independently, and might not be available immediately. This allows the bridge to run for the topics that are known.

The bridge still needs restarting, or forced through a reconnection sequence, for example, restarting the queue manager, before it tries to subscribe to the topic again.

V 9.2.0 **Continue to retry after maximum reconnection attempts**
The default option is *N*.

You must set this option to *Y* to not exit after the final retry timer. Instead, keep retrying at the last interval forever.

V 9.2.0 **At-least-once delivery for IBM MQ publications?**
The value can be *Y* or *N*, and the default value is not set. The value is inherited from another quality of service attribute.

This attribute determines whether a durable or non-durable subscription is made for IBM MQ publications. It separates the existing quality of service, that is:

- At-most-once for a non durable subscription, or
- At-least-once for a durable subscription

into different attributes for each direction of flow.

This is useful for situations where you want to have at-most-once inbound messages from Salesforce, not bothering with the **ReplayId**, but still want to send saved outbound messages from IBM MQ (at-least-once) after an outage.

If not set, the existing quality of service value is used. Note that this happens if you have migrated from an older version without updating the configuration file, that is, run the configuration process.

V 9.2.0 **MQ Replay Status Queue**

The default value is SYSTEM.SALESFORCE.SYNCQ.

If you want to have multiple bridges accessing the same queue manager, and having inbound messages from Salesforce, then you must have separate synchronization queue settings for each.

If a bridge instance is not subscribed to any Salesforce topics, the synchronization queue is not used at all.

Note: The synchronization queue is accessed exclusively; that is, the bridge will not start if another instance already has the nominated queue open.

V 9.2.0 **Number of logfiles**

The default value is 3.

Allow rotating log files for the output recording. If the value is greater than one, the configured log file name is used as a base with "`.0`", "`.1`", and so on, appended or inserted before the filetype.

If you use the default value, do not add an index.

Note that normal **stdout** and **stderr** handling is unaffected.

V 9.2.0 **Maximum size of each logfile**

The default value is 2097152 bytes (2 MB) .

If you configure more than one log file, this is when the log switch is made.

If you configure only one log file, this parameter is ignored.

Push topic names and **Platform event names** can be entered individually or as a comma-separated list, in the same way as the command line **-p** and **-e** parameters are entered. The **Startup wait interval** provides an option to delay the initial processing of events. For example, if the bridge and the IBM MQ applications that use it are all run as services, the order in which they start cannot be sequenced. Therefore, events might be republished before applications are prepared to receive them. When you delay the bridge startup, you give the applications the time to start and subscribe to events and push topics.

The configuration is only read on startup of the bridge process. Changes to the configuration require a restart, such as through the IBM MQ Service definitions.

Examples

The **-f** parameter is optional when you use the **runmqsfb** to create the configuration file as described in the usage note “2” on page 168.

```
runmqsfb -f inputConfigFile -o outputConfigFile
```

In this example, the *outputConfigFile* is created:

```
runmqsfb -o outputConfigFile
```

The **-f** parameter is required when you use the **runmqsfb** command to run the IBM MQ Bridge to Salesforce, as described in the usage note "1" on page 168.

```
runmqsfb -f inputConfigFile -r logFile
```

Related tasks

Configuring IBM MQ for use with Salesforce push topics and platform events

Tracing the IBM MQ Bridge to Salesforce

Monitoring the IBM MQ Bridge to Salesforce

runmqtmc (start client trigger monitor)

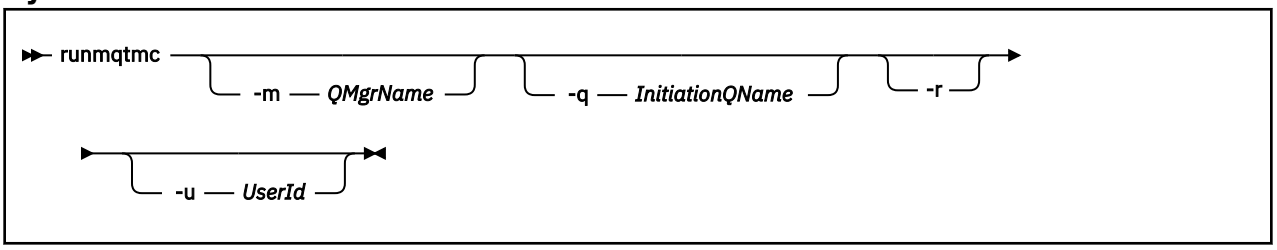
Start the trigger monitor on a client.

Purpose

Use the **runmqtmc** command to start a trigger monitor for a client. For further information about using trigger monitors, see Trigger monitors.

When a trigger monitor starts, it continuously monitors the specified initiation queue. The trigger monitor does not stop until the queue manager ends, see "endmqm (end queue manager)" on page 105. While the client trigger monitor is running it keeps the dead letter queue open.

Syntax



Optional parameters

-m ***QMgrName***
The name of the queue manager on which the client trigger monitor operates, by default the default queue manager.

-q ***InitiationQName***
The name of the initiation queue to be processed, by default SYSTEM.DEFAULT.INITIATION.QUEUE.

-r
Specifies that the client trigger monitor automatically reconnects.

-u ***UserId***
The ID of the user authorized to get the triggered message.

Note that using this option does not affect the authority of the triggered program, that might have its own authentication options.

Note: As the **runmqtmc** command makes a standard client connection, you can send a user ID and password, and have the password encrypted, using the mqccred security exit.

Return codes

For IBM MQ 9.1.3 and earlier, and for LTS before IBM MQ 9.2.0, the value of `0` is not used and the value is reserved. The trigger monitor is designed to run continuously and therefore not to end.

Table 96. Return code identifiers and descriptions

Return code	Description
0	V 9.2.0 From IBM MQ 9.1.4, client trigger monitor interrupted because the queue manager is ending, or the channel is stopped.
10	Trigger monitor interrupted by an error.
20	Error; client trigger monitor not run.

Examples

For examples of using this command, see The Triggering sample programs.

Related reference

"runmqtrm (start trigger monitor)" on page 175
Start the trigger monitor on a server.

runmqtrm (start trigger monitor)

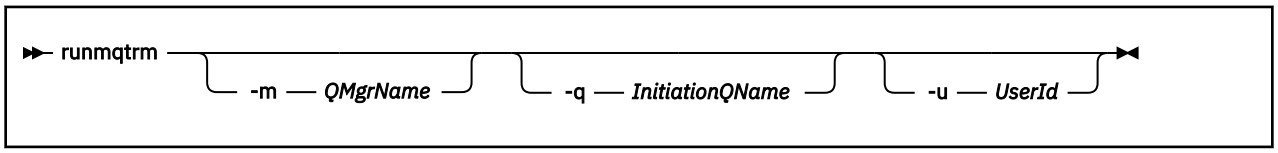
Start the trigger monitor on a server.

Purpose

Use the **runmqtrm** command to start a trigger monitor. For further information about using trigger monitors, see Initiation queue processing by trigger monitors.

When a trigger monitor starts, it continuously monitors the specified initiation queue. The trigger monitor does not stop until the queue manager ends, see "endmqm (end queue manager)" on page 105. While the trigger monitor is running it keeps the dead letter queue open.

Syntax



Optional parameters

-m *QMgrName*
The name of the queue manager on which the trigger monitor operates, by default the default queue manager.

-q *InitiationQName*
Specifies the name of the initiation queue to be processed, by default SYSTEM.DEFAULT.INITIATION.QUEUE.

-u *UserId*
The ID of the user authorized to read the initiation queue, and get the triggered message.

Note that using this option does not affect the authority of the triggered program, that might have its own authentication options.

Return codes

For IBM MQ 9.1.3 and earlier, and for LTS before IBM MQ 9.2.0, the value of `0` is not used and the value is reserved. The trigger monitor is designed to run continuously and therefore not to end.

Table 97. Return code identifiers and descriptions

Return code	Description
0	V 9.2.0 From IBM MQ 9.2.0, trigger monitor interrupted because the queue manager is ending.
10	Trigger monitor interrupted by an error.
20	Error; trigger monitor not run.

Related reference
"runmqtmc (start client trigger monitor)" on page 174
Start the trigger monitor on a client.

V 9.2.3 runp11cred (protect PKCS #11 cryptographic hardware passwords)

The **runp11cred** command protects passwords, before being supplied to PKCS #11 cryptographic hardware configuration strings, using the MQSSLCRYP environment variable or the mqclient.ini **SSLCryptoHardware** SSL stanza attribute.

Purpose

When run, the **runp11cred** command prompts to securely read a password to protect. **runp11cred** then uses an encryption key contained in the file, indicated by one of three options. In order of priority, these are the:

1. **-sf** parameter
2. MQS_SSLCRYP_KEYFILE environment variable
3. Default initial key file if neither of the above options is specified.

Attention: You should not use the default initial key.

Syntax

Store the encrypted password in the appropriate property in the cryptographic hardware configuration string, stored in either the `mqclient.ini` file, or the MQSSLCRYP environment variable.

Optional Parameters

-sf *keyfile*
Path to a file containing the initial key.

-sp *int*
Algorithm to use for protecting passwords. The value can be:

1
The IBM MQ 9.2.0 password protection algorithm.

2
Default value: use the more secure credentials protection method.

Examples

```
>runp11cred
```

```
5724-H72 (C) Copyright IBM Corp. 1994, 2025.
Enter password:
*******
Credentials are encrypted using the default encryption key. For more secure
protection of stored credentials, use a custom, strong encryption key.

```

Return codes

0
Command completed successfully

1
Command completed unsuccessfully

ALW runswchl (switch cluster channel)

runswchl (switch cluster channel) on AIX, Linux, and Windows.

Purpose

The command switches or queries the cluster transmission queues associated with cluster-sender channels.

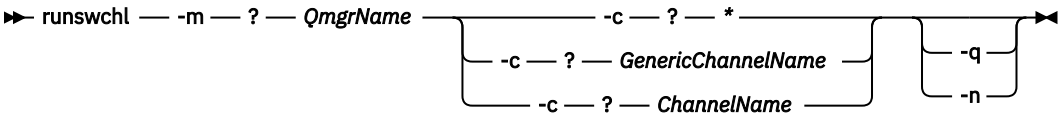
Usage notes

You must log on as an Administrator to run this command.

The command switches all the stopped or inactive cluster-sender channels that match the -c parameter, require switching, and can be switched. The command reports back on the channels that are switched, the channels that do not require switching, and the channels it cannot switch because they are not stopped or inactive.

If you set the -q parameter, the command does not perform the switch, but it provides the list of channels that would be switched.

Syntax



Required parameters

-m *QmgrName*
The queue manager to run the command against. The queue manager must be started.

-c *
All the cluster-sender channels

-c *GenericChannelName*
All matching cluster-sender channels

-c *ChannelName*
Single cluster-sender channel.

Optional parameters

-q
Display the state of one or more channels. If you omit this parameter, the commands switches any stopped or inactive channels that require switching.

-n
When switching transmission queues, do not transfer messages from the old queue to the new transmission queue.

Note: Take care with the `-n` option: messages on the old transmission queue are not transferred unless you associate the transmission queue with another cluster-sender channel.

Return codes

0
The command completed successfully

10
The command completed with warnings.

20
The command completed with errors.

Examples

To display the configuration state of cluster-sender channel `TO.QM2`:

```
RUNSWCHL -m QM1 -c TO.QM2 -q
```

To switch the transmission queue for cluster-sender channel `TO.QM3` without moving the messages on it:

```
RUNSWCHL -m QM1 -c TO.QM3 -n
```

To switch the transmission queue for cluster-sender channel `TO.QM3` and move the messages on it:

```
RUNSWCHL -m QM1 -c TO.QM3
```

To display the configuration state of all cluster-sender channels on `QM1`:

```
RUNSWCHL -m QM1 -c * -q
```

To display the configuration state of all cluster-sender channels with a generic name of `TO.*`:

```
RUNSWCHL -m QM1 -c TO.* -q
```

Related tasks

Clustering: Switching cluster transmission queues

`setmqaut` (grant or revoke authority)

Change the authorizations to a profile, object, or class of objects. Authorizations can be granted to, or revoked from, any number of principals or groups.

For more information about authorization service components, see Configuring installable services, Service components, and Authorization service interface.

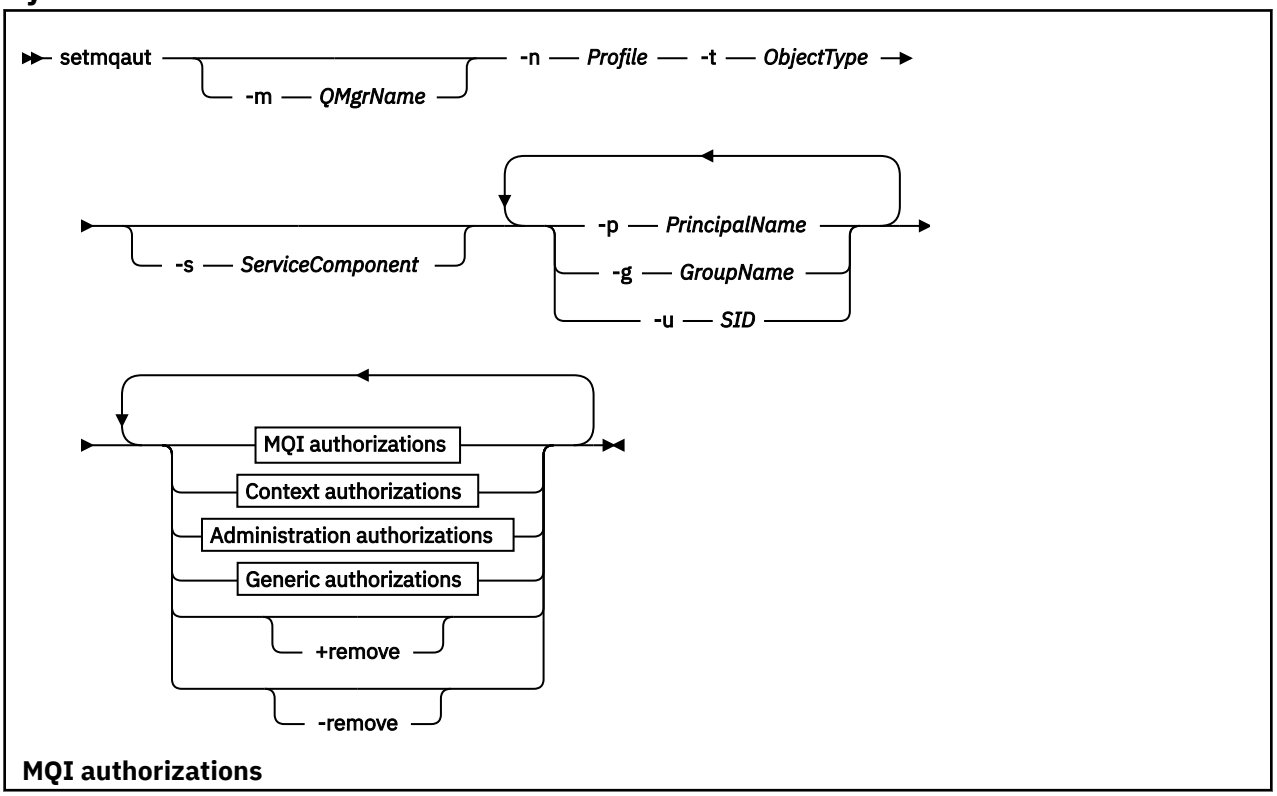
For more information about how authorizations work, see How authorizations work.

Linux AIX From IBM MQ 8.0, on UNIX and Linux systems, the object authority manager (OAM) can use user-based authorization as well as group-based authorization. For more information about user-based authorizations, see OAM user-based permissions on AIX and Linux systems.

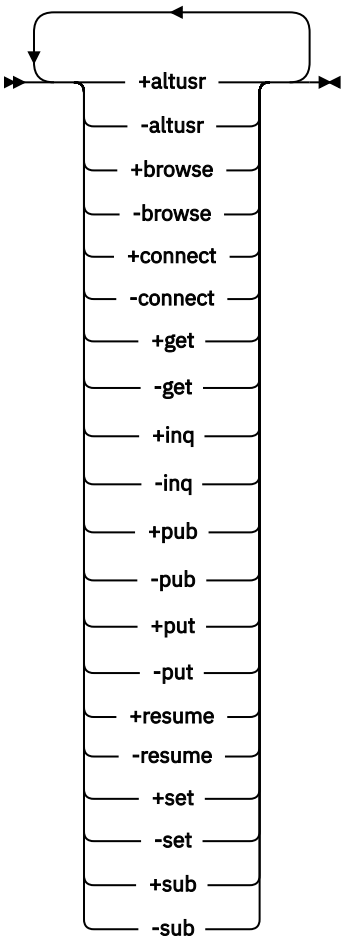
Linux AIX If you specify the **-p** (principal) option, IBM MQ authorization uses groups, instead. This means that if you enter `setmqaut -p username ...`, the primary group of the specified user is the one that is associated with the authorization being updated.

Note: The previous statement does not apply if you have configured your Object Authority Manager (OAM) to allow users.

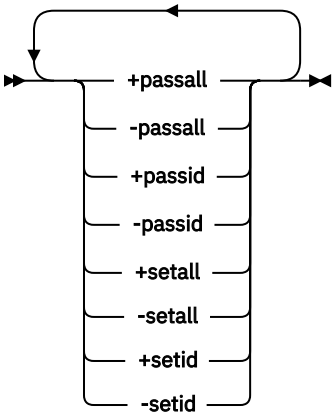
Syntax



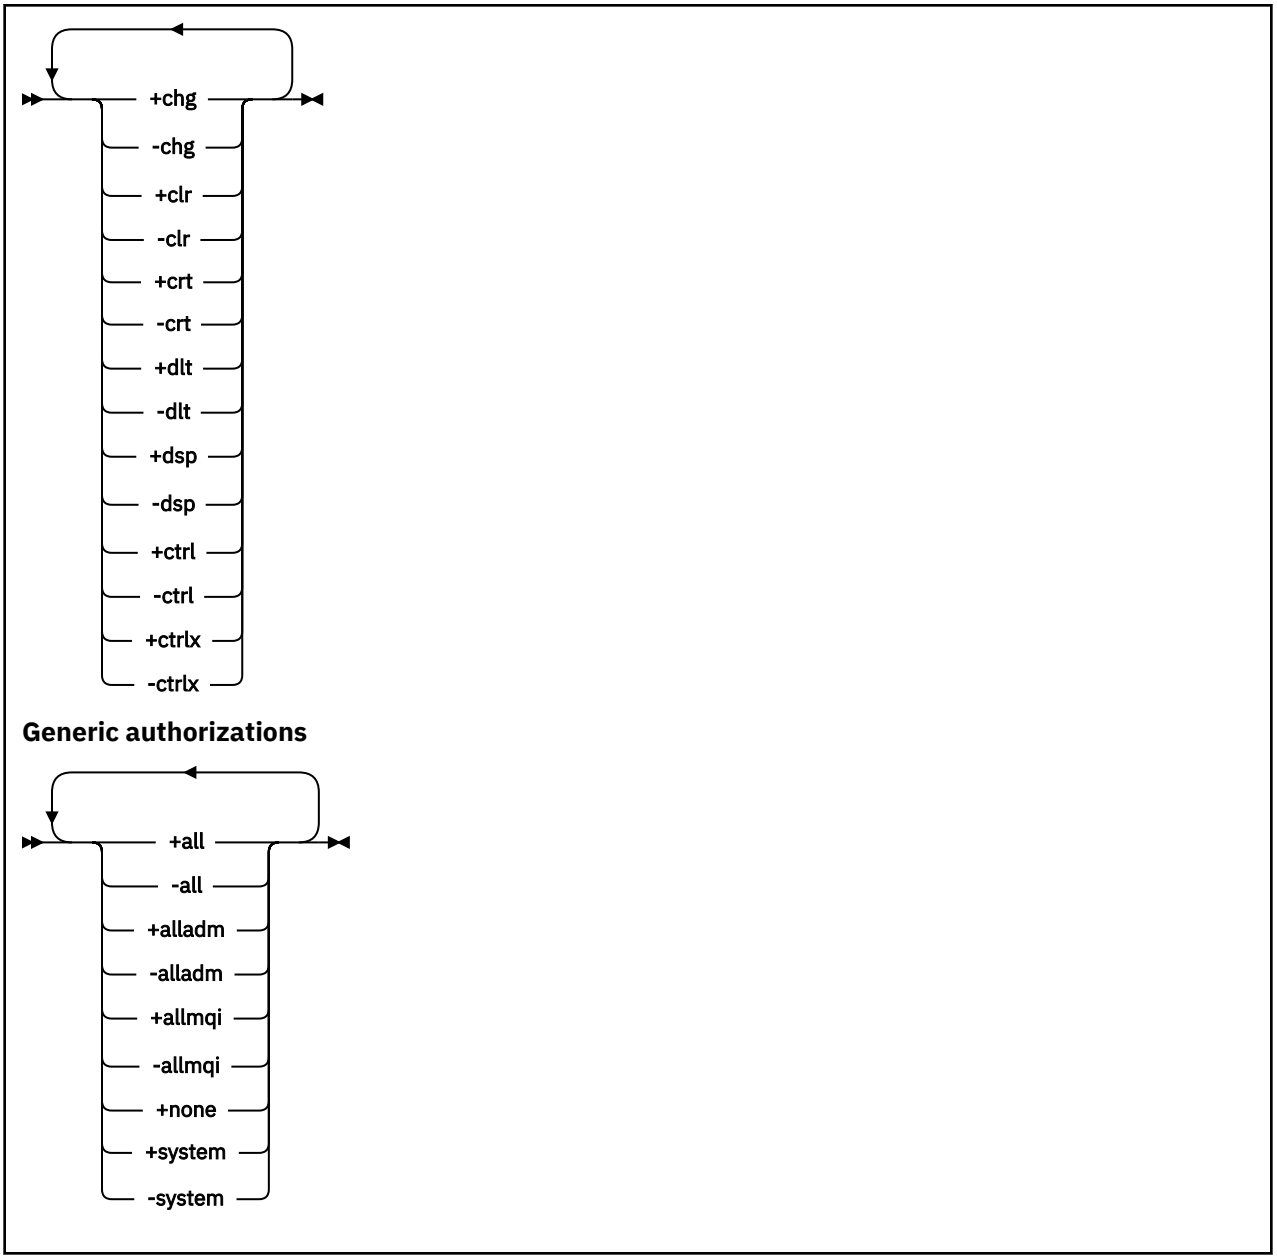
MQI authorizations



Context authorizations



Administration authorizations



Description

Use **setmqaut** both to grant an authorization, that is, give a principal or user group permission to perform an operation, and to revoke an authorization, that is, remove the permission to perform an operation. You can specify a number of parameters:

- Queue manager name
- Principals and user groups
- Object type
- Profile name
- Service component

The authorizations that can be given are categorized as follows:

- Authorizations for issuing MQI calls
- Authorizations for MQI context
- Authorizations for issuing commands for administration tasks

- Generic authorizations

Each authorization to be changed is specified in an authorization list as part of the command. Each item in the list is a string prefixed by a plus sign (+) or a minus sign (-). For example, if you include `+put` in the authorization list, you grant authority to issue MQPUT calls against a queue. Alternatively, if you include `-put` in the authorization list, you revoke the authority to issue MQPUT calls.

On AIX, Linux, and Windows, you can use the **SecurityPolicy** attribute to control the queue manager authorization:

- Windows On Windows systems, the **SecurityPolicy** attribute applies only if the service specified is the default authorization service, that is, the OAM. The **SecurityPolicy** attribute allows you to specify the security policy for each queue manager.
- Linux AIX On UNIX and Linux systems, for IBM MQ 8.0 and later, the value of the **SecurityPolicy** attribute specifies whether the queue manager uses user-based or group-based authorization. If you do not include this attribute, the default, which uses group-based authorization, is used.

For more information about the **SecurityPolicy** attribute, see Configuring installable services, Configuring authorization service stanzas on Windows, and Configuring authorization service stanzas on UNIX and Linux.

For more information about the effect of the `user` and `group` settings of the **SecurityPolicy** attribute, see OAM user-based permissions on UNIX and Linux systems.

You can specify any number of principals, user groups, and authorizations in a single **setmqaut** command, but you must specify at least one principal or user group.

If a principal is a member of more than one user group, the principal effectively has the combined authorities of all those user groups.

Windows On Windows systems, the principal also has all the authorities that are granted to it explicitly using the **setmqaut** command.

Linux AIX On AIX and Linux, if the **SecurityPolicy** attribute is set to `user`, the principal has all the authorities that are granted to it explicitly using the **setmqaut** command. However, if the **SecurityPolicy** attribute is set to `group` or `default`, or if the **SecurityPolicy** attribute is not set, all authorities are held by user groups internally, not by principals. Granting authorities to groups has the same implications as it did before IBM MQ 8.0:

- If you use the **setmqaut** command to grant an authority to a principal, the authority is granted to the primary user group of the principal. This means that the authority is effectively granted to all members of that user group.
- If you use the **setmqaut** command to revoke an authority from a principal, the authority is revoked from the primary user group of the principal. This means that the authority is effectively revoked from all members of that user group.

To alter authorizations for a cluster sender channel that has been automatically generated by a repository, see Channel definition commands.

Required parameters

-t *ObjectType*
The type of object for which to change authorizations.

Possible values are as follows:

Table 98. ObjectType values.	
Value	**Description**
authinfo	An authentication information object
channel or **chl**	A channel
clntconn or **clcn**	A client connection channel
comminfo	A communication information object
listener or **lstr**	A listener
namelist or **nl**	A namelist
process or **prcs**	A process
queue or **q**	A queue
qmgr	A queue manager
rqmname or **rqmn**	A remote queue manager name
service or **srvc**	A service
topic or **top**	A topic

-n *Profile*
The name of the profile for which to change authorizations. The authorizations apply to all IBM MQ objects with names that match the profile name specified. The profile name can be generic, using wildcard characters to specify a range of names as explained in Using OAM generic profiles on AIX, Linux, and Windows systems.

This parameter is required, unless you are changing the authorizations of a queue manager, in which case you must not include it. To change the authorizations of a queue manager use the queue manager name, for example

```
setmqaut -m QMGR -t qmgr -p user1 +connect
```

where *QMGR* is the name of the queue manager and *user1* is the principal for which you are adding or removing permissions.

Each class of object has authority records for each group or principal. These records have the profile name `@CLASS` and track the `crt` (create) authority common to all objects of that class. If the `crt` authority for any object of that class is changed then this record is updated. For example:

```
profile:   @class
object type: queue
entity:   test
entity type: principal
authority:  crt
```

This shows that members of the group `test` have `crt` authority to the class `queue`.

Attention: You cannot delete the `@CLASS` entries (the system is working as designed)

Optional parameters

-m *QMgrName*
The name of the queue manager of the object for which to change authorizations. The name can contain up to 48 characters.

This parameter is optional if you are changing the authorizations of your default queue manager.

-p *PrincipalName*
The name of the principal for which to change authorizations.

Windows For IBM MQ for Windows only, the name of the principal can optionally include a domain name, specified in the following format:

```
userid@domain
```

For more information about including domain names on the name of a principal, see Principals and groups on UNIX, Linux and Windows.

You must have at least one principal or group.

-g *GroupName*
The name of the user group for which to change authorizations. You can specify more than one group name, but each name must be prefixed by the -g flag.

Windows For IBM MQ for Windows only, the group name can optionally include a domain name, specified in the following formats:

```
GroupName@domain
domain\GroupName
```

The IBM MQ Object Authority Manager validates the users and groups at the domain level, only if you set the **GroupModel** attribute to *GlobalGroups* in the Securing stanza of the queue manager.

-u *SID*
The SID for which authorities are to be removed. You can specify more than one SID, but each name must be prefixed by the -u flag.

This option must be used with either `+remove` or `-remove`.

This parameter is only valid on IBM MQ for Windows.

-s *ServiceComponent*
The name of the authorization service to which the authorizations apply (if your system supports installable authorization services). This parameter is optional; if you omit it, the authorization update is made to the first installable component for the service.

+remove or -remove
Remove all the authorities from IBM MQ objects that match the specified profile.

Authorizations
The authorizations to be granted or revoked. Each item in the list is prefixed by a plus sign (+) or a minus sign (-). The plus sign indicates that authority is to be granted. The minus sign indicates that authority is to be revoked.

For example, to grant authority to issue MQPUT calls, specify +put in the list. To revoke the authority to issue MQPUT calls, specify -put.

Table 99 on page 184 shows the authorities that can be given to the different object types.

Table 99. Specifying authorities for different object types

Authority	Queue	Process	Queuemanager	Remote queuemanager name	Namelist	Topic	Authinfo	Clntconn	Channel	Listener	Service	Comminfo
`all` [1]	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
`alladm` [2]	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
`allmqi` [3]	Yes	Yes	Yes	Yes	Yes	Yes	Yes	No	No	No	No	No

Table 99. Specifying authorities for different object types (continued)

Authority	Queue	Process	Queuemanager	Remote queuemanager name	Namelist	Topic	Authinfo	Clntconn	Channel	Listener	Service	Cominfo
none	Yes	Yes	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes
altusr	No	No	Yes	No	No	No	No	No	No	No	No	No
browse	Yes	No	No	No	No	No	No	No	No	No	No	No
chg	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
clr	Yes	No	No	No	No	Yes	No	No	No	No	No	No
connect	No	No	Yes	No	No	No	No	No	No	No	No	No
crt	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
ctrl [4]	No	No	Yes	No	No	Yes	No	No	Yes	Yes	Yes	No
ctrlx	No	No	No	No	No	No	No	No	Yes	No	No	No
dlt	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
dsp	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
get	Yes	No	No	No	No	No	No	No	No	No	No	No
pub	No	No	No	No	No	Yes	No	No	No	No	No	No
put	Yes	No	No	Yes	No	No	No	No	No	No	No	No
inq	Yes	Yes	Yes	No	Yes	No	Yes	No	No	No	No	No
passall	Yes	No	No	No	No	No	No	No	No	No	No	No
passid	Yes	No	No	No	No	No	No	No	No	No	No	No
resume	No	No	No	No	No	Yes	No	No	No	No	No	No
set	Yes	Yes	Yes	No	No	No	No	No	No	No	No	No
setall [5]	Yes	No	Yes	No	No	No	No	No	No	No	No	No
setid [5]	Yes	No	Yes	No	No	Yes	No	No	No	No	No	No
sub	No	No	No	No	No	Yes	No	No	No	No	No	No
system	No	No	Yes	No	No	No	No	No	No	No	No	No

Notes:

1. The authority `all` is equivalent to the union of the authorities `alladm`, `allmqi`, and `system` appropriate to the object type.

2. The authority `alladm` is equivalent to the union of the individual authorities `chg`, `clr`, `dlt`, `dsp`, `ctrl`, and `ctrlx` appropriate to the object type. `crt` authority is not included in the subset `alladm`.
3. The authority `allmqi` is equivalent to the union of the individual authorities `altusr`, `browse`, `connect`, `get`, `inq`, `pub`, `put`, `resume`, `set`, and `sub` appropriate to the object type.
4. The authority `ctrl` on the qmgr object is included when the you specify `alladm` on the **setmqaut** command.
5. To use `setid` or `setall` authority, authorizations must be granted on both the appropriate queue object and also on the queue manager object. `setid` and `setall` are included in `allmqi`.

Description of specific authorities

You should not grant a user an authority (for example, `set` authority on a queue manager, or `system` authority) that allows the user to access IBM MQ privileged options, unless the required authority is specifically documented, and required to run any IBM MQ command, or IBM MQ API call.

For example, a user requires system authority to run the **setmqaut** command.

chg

A user needs `chg` authority to make any authorization changes on the queue manager. The authorization changes include:

- Changing the authorizations to a profile, object, or class of objects
- Creating and modifying channel authentication records, and so on

A user also needs `chg` authority to change or set the attributes of an IBM MQ object, using PCF or MQSC commands.

ctrl

Within CHLAUTH rules it is possible to insist that users connecting are not privileged.

For the channel to check whether a user is privileged, the real user id running the channel process must have `+ctrl` authority on the qmgr object.

For example, when the SVRCONN channel is running as a thread in an amqrmppa process and the real uid for this process is a userid named `mqadmin` (the userid that started the queue manager), then `mqadmin` must have `+ctrl` authority on the qmgr object.

crt

If you grant an entity `+crt` authority to the queue manager, then that entity also gains `+crt` authority for each object class.

However, when you remove `+crt` authority against the queue manager object that only removes the authority on the queue manager object class; `crt` authority for other objects classes are not removed.

Note that `crt` authority on the queue manager object has no functional use, and is available for backwards-compatibility purposes only.

dlt

Note that the `dlt` authority against the queue manager object has no functional use, and is available for backwards-compatibility purposes only.

set

A user needs `set` authority against the queue to change or set the attributes of a queue using the MQSET API call.

`set` authority on the queue manager is not required for any administrative purpose, or for any application connecting to the queue manager.

However, a user needs `set` authority against the queue manager to set privileged connection options.

Note that `set` authority on the process object has no functional use, and is available for backwards-compatibility purposes only.

Important: Privileged connection options are internal to the queue manager and are not available in IBM MQ API calls used by IBM MQ applications.

system

The **setmqaut** command makes a privileged IBM MQ connection to the queue manager.

Any user who runs IBM MQ commands that makes a privileged IBM MQ connection needs `system` authority on the queue manager.

Return codes

Table 100. Return code identifiers and descriptions

Return code	Explanation
0	Successful operation
26	Queue manager running as a standby instance.
36	Invalid arguments supplied
40	Queue manager not available
49	Queue manager stopping
58	Inconsistent use of installations detected
69	Storage not available
71	Unexpected error
72	Queue manager name error
133	Unknown object name
145	Unexpected object name
146	Object name missing
147	Object type missing
148	Invalid object type
149	Entity name missing
150	Authorization specification missing
151	Invalid authorization specification

Examples

1. This example shows a command that specifies that the object on which authorizations are being given is the queue orange.queue on queue manager saturn.queue.manager.

```
setmqaut -m saturn.queue.manager -n orange.queue -t queue
         -g tango +inq +alladm
```

The authorizations are given to a user group called tango, and the associated authorization list specifies that the user group can:

- Issue MQINQ calls
- Perform all administration operations on that object

2. In this example, the authorization list specifies that a user group called foxy:
   - Cannot issue any MQI calls to the specified queue
   - Can perform all administration operations on the specified queue

```
setmqaut -m saturn.queue.manager -n orange.queue -t queue
         -g foxy -allmqi +alladm
```

3. This example gives user1 full access to all queues with names beginning a.b. on queue manager qmgr1. The profile applies to any object with a name that matches the profile.

```
setmqaut -m qmgr1 -n a.b.* -t q -p user1 +all
```

4. This example deletes the specified profile.

```
setmqaut -m qmgr1 -n a.b.* -t q -p user1 -remove
```

5. This example creates a profile with no authority.

```
setmqaut -m qmgr1 -n a.b.* -t q -p user1 +none
```

Use the MQSC command SET AUTHREC to set authority records associated with a profile name.

OAM user-based permissions on AIX and Linux

Authorizations for MQI calls

Table 101. Authorizations for MQI calls.

Value	Description
altusr	Use another user's authority for the queue manager. Also required for channel operations where the asserting userid is different from the one associated with the connection handle. (For example, an assigned dedicated profile on the receiver MCA end, or when processing a RESET CHL SEQNUM() request from remote systems.) If you are using IBM WebSphere MQ prior to IBM WebSphere MQ 7.0.1 Fix Pack 4.4, you must set +altusr for the group containing the user ID specified in MCAUSER on a receiver channel. This action prevents error message AMQ2035 appearing if you reset the sequence number of the corresponding sender channel.
browse	Retrieve a message from a queue using an MQGET call with the BROWSE option.
connect	Connect the application to the specified queue manager using an MQCONN call.
get	Retrieve a message from a queue using an MQGET call.

Table 101. Authorizations for MQI calls. (continued)	
Value	**Description**
inq	Make an inquiry on a specific queue using an MQINQ call.
pub	Publish a message on a topic using the MQPUT call.
put	Put a message on a specific queue using an MQPUT call.
resume	Resume a subscription using the MQSUB call.
set	Set attributes on a queue from the MQI using an MQSET call.
sub	Create, alter or resume a subscription to a topic using the MQSUB call.

Note: If you open a queue for multiple options, you must be authorized for each option.

Authorizations for context

Table 102. Authorizations for context.	
Value	**Description**
passall	Pass all context on the specified queue. All the context fields are copied from the original request.
passid	Pass identity context on the specified queue. The identity context is the same as that of the request.
setall	Set all context on the specified queue. This is used by special system utilities.
setid	Set identity context on the specified queue. This is used by special system utilities. In order to modify any of the message context options, you must have the appropriate authorizations to issue the call. For example, in order to use MQOO_SET_IDENTITY_CONTEXT or MQPMO_SET_IDENTITY_CONTEXT, you must have `+setid` permission.

Note: To use `setid` or `setall` authority, authorizations must be granted on both the appropriate queue object and also on the queue manager object.

Authorizations for commands

Table 103. Authorizations for commands.	
Value	**Description**
chg	Change the attributes of the specified object.
clr	Clear the specified queue or a topic.
crt	Create objects of the specified type.

Table 103. Authorizations for commands. (continued)	
Value	**Description**
dlt	Delete the specified object. Note, that the dlt authority has no effect on a queue manager object.
dsp	Display the attributes of the specified object.
ctrl	For listeners and services, start and stop the specified channel, listener, or service. For channels, start, stop, and ping the specified channel. For topics, define, alter, or delete subscriptions.
ctrlx	Reset or resolve the specified channel.

Authorizations for generic operations

Table 104. Authorizations for generic operations.	
Value	**Description**
all	Use all operations applicable to the object. `all` authority is equivalent to the union of the authorities `alladm`, `allmqi`, and `system` appropriate to the object type.
alladm	Use all administration operations applicable to the object.
allmqi	Use all MQI calls applicable to the object.
none	No authority. Use this authorization to create profiles without authority. When an authority is given to an object or group that was previously showing "none", then the authorization changes to the authority just applied. However, when the "none" authorization is added to an object or group with an existing alternative authority, the authority does not change.
system	Use queue manager for internal system operations.

Windows setmqcrl (set CRL LDAP server definitions)

Administer certificate revocation list (CRL) LDAP definitions in an Active Directory (Windows only).

Purpose

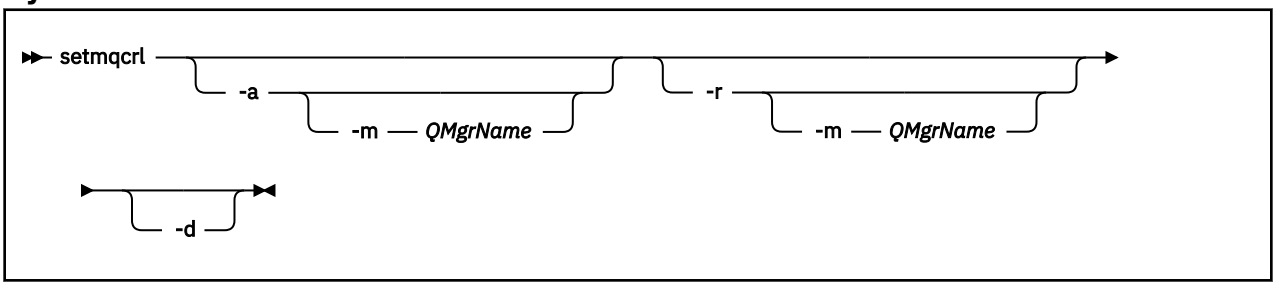
Note: The **setmqcrl** command applies to IBM MQ for Windows only.

Use the **setmqcrl** command to configure and administer support for publishing CRL (certificate revocation list) LDAP definitions in an Active Directory.

A domain administrator must use this command, or setmqscp**setmqcrl**, initially to prepare the Active Directory for IBM MQ usage and to grant IBM MQ users and administrators the relevant authorities to access and update the IBM MQ Active Directory objects. You can also use the `setmqcrl` command to display all the currently configured CRL server definitions available on the Active Directory, that is, those definitions referred to by the queue manager's CRL namelist.

The only types of CRL servers supported are LDAP servers.

Syntax



Optional parameters

You must specify one of `-a` (add), `-r` (remove) or `-d` (display).

-a
Adds the IBM MQ MQI client connections Active Directory container, if it does not already exist. You must be a user with the appropriate privileges to create subcontainers in the *System* container of your domain. The IBM MQ folder is called `CN=IBM-MQClientConnections`. Do not delete this folder in any other way than by using the **setmqscp** command.

-d
Displays the IBM MQ CRL server definitions.

-r
Removes the IBM MQ CRL server definitions.

-m [* | qmgr]
Modifies the specified parameter (**-a** or **-r**) so that only the specified queue manager is affected. You must include this option with the **-a** parameter.

*** | qmgr**
* specifies that all queue managers are affected. This enables you to migrate a specific IBM MQ CRL server definitions file from one queue manager alone.

Examples

The following command creates the IBM-MQClientConnections folder and allocates the required permissions to IBM MQ administrators for the folder, and to child objects created subsequently. (In this, it is functionally equivalent to `setmqscp -a`.)

```
setmqcrl -a
```

The following command migrates existing CRL server definitions from a local queue manager, Paint.queue.manager, to the Active Directory.

Note: The command first deletes any other CRL definitions from the Active Directory.

```
setmqcrl -a -m Paint.queue.manager
```

ALW setmqenv (set IBM MQ environment)

Use the **setmqenv** command to set up the IBM MQ environment on AIX, Linux, and Windows.

Purpose

You can use the **setmqenv** command to automatically set up the environment for use with an installation of IBM MQ. Alternatively, you can use the **crtmqenv** command to create a list of environment variables and values to manually set each environment variable for your system; see “crtmqenv (create IBM MQ environment)” on page 27 for more information.

Note: Any changes you make to the environment are not persistent. If you log out, and log in again, your changes are lost.

You can specify which installation the environment is set up for by specifying a queue manager name, an installation name, or an installation path. You can also set up the environment for the installation that issues the **setmqenv** command by issuing the command with the **-s** parameter.

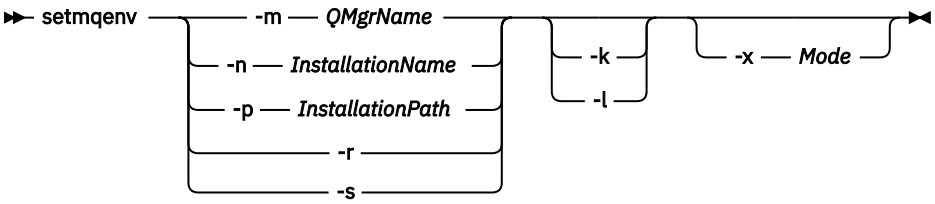
The **setmqenv** command sets the following environment variables, appropriate to your system:

- CLASSPATH
- INCLUDE
- LIB
- MANPATH
- MQ_DATA_PATH
- MQ_ENV_MODE
- MQ_FILE_PATH
- MQ_INSTALLATION_NAME
- MQ_INSTALLATION_PATH
- MQ_JAVA_INSTALL_PATH
- MQ_JAVA_DATA_PATH
- MQ_JAVA_LIB_PATH
- MQ_JAVA_JVM_FLAG
- MQ_JRE_PATH
- PATH

Usage notes

- The **setmqenv** command removes all directories for all IBM MQ installations from the environment variables before adding new references to the installation for which you are setting up the environment for. Therefore, if you want to set any additional environment variables that reference IBM MQ, set the variables after issuing the **setmqenv** command. For example, if you want to add *MQ_INSTALLATION_PATH*`/java/lib` to *LD_LIBRARY_PATH*, you must do so after running the **setmqenv** command.
- In some shells, command-line parameters cannot be used with **setmqenv** and any **setmqenv** command issued is assumed to be a `setmqenv -s` command. The command produces an informational message that the command has been run as if a `setmqenv -s` command had been issued. Therefore, in these shells you must ensure that you issue the command from the installation for which you want to set the environment for. In these shells, you must set the *LD_LIBRARY_PATH* variable manually. Use the **crtmqenv** command with the **-l** or **-k** parameter to list the *LD_LIBRARY_PATH* variable and value. Then use this value to set the *LD_LIBRARY_PATH*.

Syntax



Optional Parameters

-m *QMgrName*
Set the environment for the installation associated with the queue manager *QMgrName*.

-n *InstallationName*
Set the environment for the installation named *InstallationName*.

-p *InstallationPath*
Set the environment for the installation in the path *InstallationPath*.

-r
Remove all installations from the environment.

-s
Set the environment for the installation that issued the **setmqenv** command.

Linux AIX **-k**
Applies to AIX and Linux only. If the **-k** flag is specified:

- AIX On AIX, the *LIBPATH* environment variable is set.
- Linux On Linux, the *LD_LIBRARY_PATH* environment variable is set.

Include the *LD_LIBRARY_PATH* or *LIBPATH* environment variable in the environment, adding the path to the IBM MQ libraries at the start of the current *LD_LIBRARY_PATH* or *LIBPATH* variable.

Linux AIX **-l**
Applies to AIX and Linux only. If the **-l** flag is specified:

- AIX On AIX, the *LIBPATH* environment variable is set.
- Linux On Linux, the *LD_LIBRARY_PATH* environment variable is set.

Include the *LD_LIBRARY_PATH* or *LIBPATH* environment variable in the environment, adding the path to the IBM MQ libraries at the end of the current *LD_LIBRARY_PATH* or *LIBPATH* variable.

-x *Mode*
Mode can take the value 32 or 64.

Create a 32-bit or 64-bit environment. If this parameter is not specified, the environment matches that of the queue manager or installation specified in the command.

Any attempt to display a 64-bit environment with a 32-bit installation fails.

Return codes

Table 105. Return code identifiers and descriptions

Return code	Description
0	Command completed normally.
10	Command completed with unexpected results.
20	An error occurred during processing.

Examples

Linux AIX The following examples assume that a copy of IBM MQ is installed in the `/opt/mqm` directory on an AIX or Linux system.

Notes:

- The period character (`.`) used at the beginning of each command makes the **setmqenv** script run in the current shell. Therefore, the environment changes made by the **setmqenv** script are applied to the

current shell. Without the period character (`.`), the environment variables are changed in another shell, and the changes are not applied to the shell from which the command is issued.

- Some shells, for example the Ubuntu 18.04 default shell, do not pass parameters when you use the period character at the beginning of a command. If you are using such a shell, the following warning is issued and any parameters to the command are ignored:

  ```
  $ . /opt/mqm/bin/setmqenv -sAMQ8588W: No parameter was detected.
  ```

  The environment has been set for the installation from which the **setmqenv** command was issued.

  To pass parameters into **setmqenv** for such shells, you must use the following environment variable: **MQ_ENV_OPTIONS**=*<your options>*.

  For example, to remove IBM MQ from the environment, issue the command:

  ```
  $ MQ_ENV_OPTIONS=-r . /opt/mqm/bin/setmqenv
  ```

- The following command sets up the environment for an installation installed in the `/opt/mqm` directory:

  ```
  . /opt/mqm/bin/setmqenv -s
  ```

- The following command sets up the environment for an installation installed in the `/opt/mqm2` directory, and includes the path to the installation at the end of the current value of the *LD_LIBRARY_PATH* variable:

  ```
  . /opt/mqm/bin/setmqenv -p /opt/mqm2 -l
  ```

- The following command sets up the environment for queue manager `QM1` in a 32-bit environment:

  ```
  . /opt/mqm/bin/setmqenv -m QM1 -x 32
  ```

Windows The following example assumes that a copy of IBM MQ is installed in `C:\Program Files\IBM\MQ` on a Windows system. This command sets up the environment for an installation called `Installation1`:

```
"C:\Program Files\IBM\MQ\bin\setmqenv.cmd" -n Installation1
```

“crtmqenv (create IBM MQ environment)” on page 27
Create a list of environment variables for an installation of IBM MQ, on AIX, Linux, and Windows.

ALW setmqinst (set IBM MQ installation)

Set IBM MQ installations, on AIX, Linux, and Windows.

Purpose

V 9.2.0 You can use the **setmqinst** command to change the installation description of an installation, to set or unset an installation as the primary installation, or to set the entitlement of the installation. To change the primary installation, you must unset the current primary installation before you can set a new primary installation. This command updates information contained in the `mqinst.ini` file.

You can use the **dspmqinst** command to display the installations.

After unsetting the primary installation, the **setmqinst** command will not be available unless you specify the full path or have an appropriate installation directory on your PATH (or equivalent). The default path in a system standard location will have been deleted.

On AIX and Linux platforms you should not assume that the current directory is in the path. If you are in `/opt/mqm/bin` and want to run, for example, `/opt/mqm/bin/dspmqver` you need to enter "**/opt/mqm/bin/dspmqver**" or "**./dspmqver**".

File `mqinst.ini` contains information about all IBM MQ installations on a system. For more information about `mqinst.ini`, see Installation configuration file, mqinst.ini.

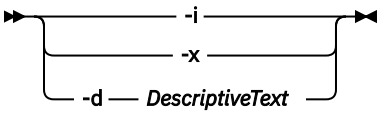
Attention: Only the user `root` can run this command.

On AIX and Linux systems, you must run this command as root. On Windows systems, you must run this command as a member of the Administrators group. The command does not have to be run from the installation you are modifying.

Note: By default, user `mqm` does not have sufficient authority to use this command.

Syntax

Action



Installation

Entitlement

Parameters

-d *DescriptiveText*
Text that describes the installation.

The text can be up to 64 single-byte characters, or 32 double-byte characters. The default value is all blanks. You must use double quotation marks around the text if it contains spaces.

-i
Set this installation as the primary installation.

-x
Unset this installation as the primary installation.

-n *InstallationName*
The name of the installation to modify.

-p *InstallationPath*
The path of the installation to modify, for example, `opt/mqm`. You must use double quotation marks around the path if it contains spaces.

V 9.2.0 **-l *entitlement* -e y|yes|n|no**
Set or unset the entitlement of the installation.

The entitlement can be set only if an applicable component is installed and entitlement is not already set to IBM MQ Advanced for Developers. *entitlement* is one of the following values:

hareplica
Sets the entitlement to High Availability Replica.

This entitlement cannot be set with the IBM MQ Advanced (Non-production) entitlement.

advanced
Sets the entitlement to IBM MQ Advanced.

V 9.2.2 V 9.2.0.3 **nonprod**
Sets the entitlement to IBM MQ Advanced (Non-production).

This entitlement cannot be set with the High Availability Replica entitlement.

The server component must be installed to set this entitlement.

The entitlement is picked up automatically by the IBM License Metric Tool (ILMT) after it is set. See IBM MQ license information.

Use **-e y** or **-e yes** to set the entitlement.

Use **-e n** or **-e no** to unset the entitlement.

Return codes

Table 106. Return code identifiers and descriptions

Return code	Description
0	Entry set without error
36	Invalid arguments supplied
37	Descriptive text was in error
44	Entry does not exist
59	Invalid installation specified
71	Unexpected error
89	ini file error
96	Could not lock ini file
98	Insufficient authority to access ini file
131	Resource problem

Examples

1. This command sets the installation with the name of `myInstallation` as the primary installation:

```
setmqinst -i -n myInstallation
```

2. This command sets the installation with an installation path of `/opt/myInstallation` as the primary installation:

```
setmqinst -i -p /opt/myInstallation
```

3. This command unsets the installation named myInstallation as the primary installation:

```
setmqinst -x -n myInstallation
```

4. This command unsets the installation with an installation path of `/opt/myInstallation` as the primary installation:

```
setmqinst -x -p /opt/myInstallation
```

5. This command sets the descriptive text for the installation named `myInstallation`:

   ```
   setmqinst -d "My installation" -n myInstallation
   ```

   The descriptive text is enclosed in quotation marks as it contains spaces.

6. V 9.2.0 This command specifies that the installation at `/opt/myInstallation` has High Availability Replica entitlement:

   ```
   setmqinst -l hareplica -e yes -p /opt/myInstallation
   ```

7. V 9.2.0 This command specifies that the installation `myInstallation` does not have High Availability Replica entitlement:

   ```
   setmqinst -l hareplica -e no -n myInstallation
   ```

8. V 9.2.2 V 9.2.0.3 This command specifies that the installation `myInstallation` has non-production entitlement:

   ```
   setmqinst -l nonprod -e y -n myInstallation
   ```

9. V 9.2.2 V 9.2.0.3 This command specifies that the installation at `/opt/myInstallation` does not have non-production entitlement:

   ```
   setmqinst -l nonprod -e n -p /opt/myInstallation
   ```

Choosing a primary installation
Changing the primary installation

ALW setmqm (set queue manager)

Set the associated installation of a queue manager.

Purpose

Use the **setmqm** command to set the associated IBM MQ installation of a queue manager. The queue manager can then be administered using only the commands of the associated installation. For example, when a queue manager is started with **strmqm**, it must be the **strmqm** command of the installation that was specified by the **setmqm** command.

For more information about using this command, including information about when to use it, see Associating a queue manager with an installation.

This command is only applicable to AIX, Linux, and Windows.

Usage notes

- You must use the **setmqm** command from the installation you want to associate the queue manager with.
- The installation name specified by the **setmqm** command must match the installation from which the **setmqm** command is issued.
- You must stop the queue manager before executing the **setmqm** command. The command fails if the queue manager is still running.
- Once you have set the associated installation of a queue manager using the **setmqm** command, migration of the queue manager's data occurs when you start the queue manager using the **strmqm** command.

- Once you have started the queue manager on an installation, you cannot then use **setmqm** to set the associated installation to an earlier version of IBM MQ, as it is not possible to migrate back to earlier versions of IBM MQ.
- You can find out which installation is associated with a queue manager by using the **dspmq** command. See "dspmq (display queue managers)" on page 63 for more information.

Syntax

Required Parameters

-m *QMgrName*
The name of the queue manager to set the associated installation for.

-n *InstallationName*
The name of the installation that the queue manager is to be associated with. The installation name is not case-sensitive.

Return codes

Table 107. Return code identifiers and descriptions

Return code	Description
0	Queue manager set to an installation without error
5	Queue manager running
36	Invalid arguments supplied
59	Invalid installation specified
60	Command not executed from the installation named by the -n parameter
61	Invalid installation name for this queue manager
69	Resource problem
71	Unexpected error
72	Queue manager name error
119	User not authorized

Examples

1. This command associates a queue manager QMGR1, with an installation with the installation name of myInstallation.

```
MQ_INSTALLATION_PATH/bin/setmqm -m QMGR1 -n myInstallation
```

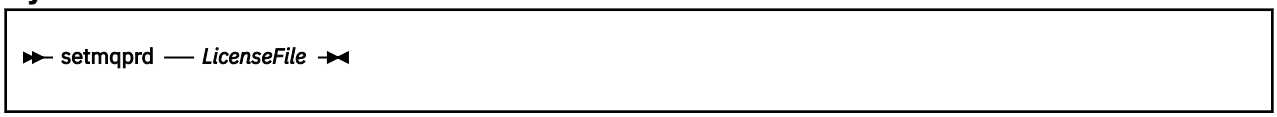
setmqprd (enroll production license)

Enroll an IBM MQ production license.

A license is normally enrolled as part of the installation process.

Note: You must have the appropriate privileges to run this command on your system. AIX and Linux require root access, and Windows with UAC (User Account Control) requires Administrator access to run this command.

Syntax



Required parameters

LicenseFile

Specifies the fully-qualified name of the production license certificate file.

The full license file is `amqpcert.lic`:

- AIX Linux On AIX and Linux, it is in the */MediaRoot*`/licenses` directory on the installation media.
- Windows On Windows it is in the *\MediaRoot*`\licenses` directory on the installation media. It is installed into the `bin` directory on the IBM MQ installation path.
- IBM i On IBM i, issue the command

  ```
  CALL PGM(QMQM/SETMQPRD) PARM('LICENSE_PATH/amqpcert.lic')
  ```

  where *LICENSE_PATH* is the path to the `amqpcert.lic` file that you obtained.

Trial license conversion

A trial license installation is identical to a production license installation, except for the "count-down" message that is displayed when you start a queue manager on an installation with a trial license. Parts of IBM MQ that are not installed on the server, such as the IBM MQ MQI client, continue to work after the expiry of the trial license. You do not need to run **setmqprd** to enroll them with a production license.

When a trial license expires, you can still uninstall IBM MQ. You can also reinstall IBM MQ with a full production license.

Run **setmqprd** to enroll a production license after installing and using a installation with a trial license.

Related tasks

AIX Converting a trial license on AIX

IBM i Converting a trial license on IBM i

Linux Converting a trial license on Linux

Windows Converting a trial license on Windows

Windows setmqscp (set service connection points)

Publish client connection channel definitions in an Active Directory (Windows only).

Purpose

Note: The **setmqscp** command applies to IBM MQ for Windows only.

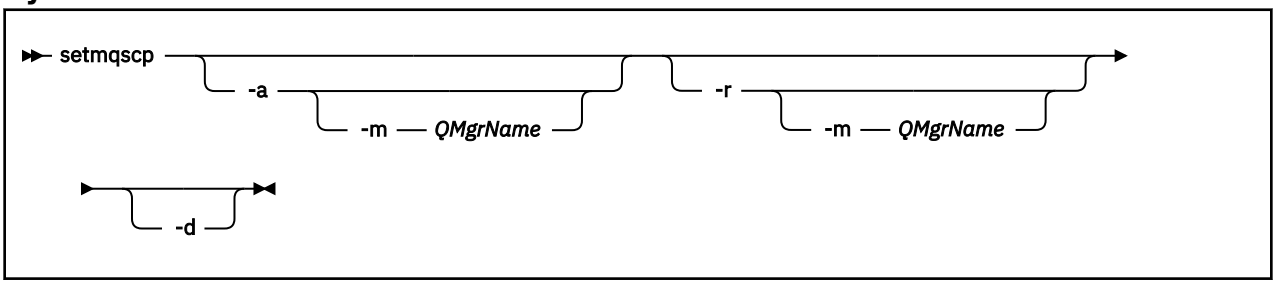
Use the **setmqscp** command to configure and administer support for publishing client connection channel definitions in an Active Directory.

Initially, this command is used by a domain administrator to:

- Prepare the Active Directory for IBM MQ use
- Grant IBM MQ users and administrators the relevant authorities to access and update the IBM MQ Active Directory objects

You can also use the **setmqscp** command to display all the currently configured client connection channel definitions available on the Active Directory.

Syntax



Optional parameters

You must specify one of -a (add), -r (remove) or -d (display).

-a
Adds the IBM MQ MQI client connections Active Directory container, if it does not already exist. You must be a user with the appropriate privileges to create subcontainers in the *System* container of your domain. The IBM MQ folder is called `CN=IBM-MQClientConnections`. Do not delete this folder in any other way than by using the `setmqscp -r` command.

-d
Displays the service connection points.

-r
Removes the service connection points. If you omit **-m**, and no client connection definitions exist in the IBM-MQClientConnections folder, the folder itself is removed from the Active Directory.

-m [* | qmgr]
Modifies the specified parameter (-a or -r) so that only the specified queue manager is affected.

*** | qmgr**
* specifies that all queue managers are affected. This enables you to migrate a specific client connection table file from one queue manager alone, if required.

Examples

The following command creates the IBM-MQClientConnections folder and allocates the required permissions to IBM MQ administrators for the folder, and to child objects created subsequently:

```
setmqscp -a
```

The following command migrates existing client connection definitions from a local queue manager, Paint.queue.manager, to the Active Directory:

```
setmqscp -a -m Paint.queue.manager
```

The following command migrates all client connection definitions on the local server to the Active Directory:

```
setmqscp -a -m *
```

setmqspl (set security policy)

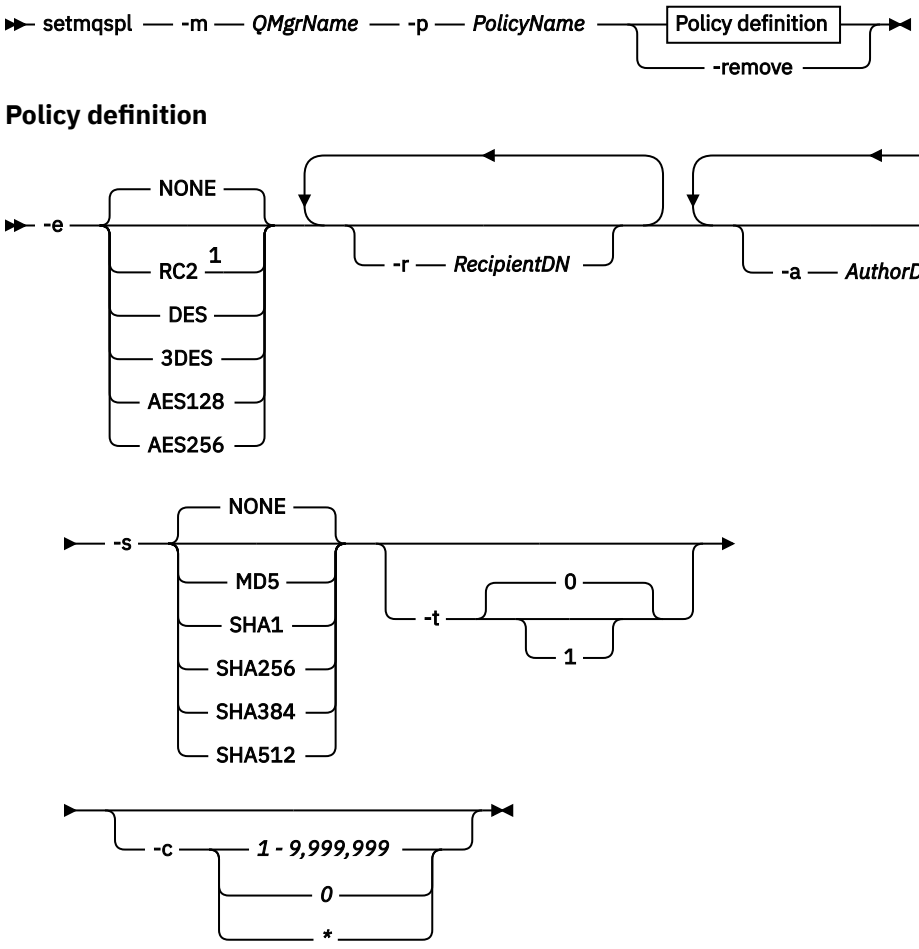
Use the **setmqspl** command to define a new security policy, replace an already existing one, or remove an existing policy.

Before you begin

- The queue manager on which you want to operate must be running.
- You must grant the necessary +connect, +inq and +chg authorities, using the setmqaut command, to connect to the queue manager and create a security policy.

For more information about configuring security see Setting up security.

Syntax



Notes:

[1] If an encryption algorithm is selected, a recipient DN must also be provided.
[2] If an author DN is provided, a signing algorithm must also be selected.

Table 108. setmqspl command flags

Command flag	Explanation
-m	Queue manager name. This flag is mandatory for all actions on security policies.

Table 108. `setmqspl` command flags (continued)	
Command flag	**Explanation**
-p	Policy name. Set the policy name to the name of the queue you want the policy to apply to.
-e	Digital encryption algorithm. Advanced Message Security supports the following encryption algorithms: RC2, DES, 3DES, AES128, AES256. The default value is NONE. **Important:** • The name of the encryption algorithm must be provided in uppercase • z/OS On z/OS encryption algorithm RC2 is not supported for confidentiality policies.
-r	The distinguished name (DN) of the message recipient (if provided, the certificate pertaining to the DN is used to encrypt a given message). Recipients can be specified, only if the encryption algorithm is different from NONE. Multiple recipients can be included for a message. Each DN must be provided with a separate **-r** flag. **Important:** • DN attribute names must be in uppercase. • Commas must be used as a name separators. • To avoid command interpreter errors, place quotation marks around the DNs. For example: `-r "CN=alice, O=ibm, C=US"`
-a	Signature DN that is validated during message retrieval. Only messages signed by a user with a provided DN are accepted during the retrieval. Signature DNs can be specified only if the signature algorithm is different from NONE. Multiple authorized signers can be specified, each authorized signer needs to have a separate **-a** flag. **Important:** The attribute in the DN name must be in uppercase. Specify CN= rather than cn=. The attribute values in the DN are case sensitive so, for example, CN=USERID1 is different from CN=userid1.

Table 108. `setmqspl` command flags (continued)	
Command flag	**Explanation**
-s	Digital signature algorithm. Advanced Message Security supports the following values: MD5, SHA1, SHA256, SHA384, and SHA512. All must be in uppercase. The default value is NONE. **Important:** • For the SHA384 and SHA512 cryptographic hash functions, keys used for signing must be longer than 768 bits. • The name of the signature algorithm must be provided in uppercase. • From IBM MQ 9.0, with the `Confidentiality` policy, the signature algorithm must be NONE. For more information about the `Confidentiality` policy, see Qualities of protection available with AMS.
-t	The toleration flag indicates whether messages that do not meet the requirements of the policy can still be successfully browsed or retrieved by an application. Toleration may be useful for example when introducing a policy to a queue which already contains unprotected messages. Valid values include: • **0 (default)** Toleration flag off. • **1** Toleration flag on. Toleration is optional and facilitates staged implementation, where policies were applied to queues but those queues may already contain messages that have no policy, or still receive messages from remote systems that do not have the security policy set.

Table 108. `setmqspl` command flags (continued)	
Command flag	**Explanation**
-c	The key reuse count can be provided as an integer from 1 through 9,999,999. Special values are: • **0** Keys are not reused. • *** Allows applications to reuse an encryption key an unlimited number of times. If you omit the **-c** parameter when defining a policy, a key reuse count of 0 is assumed for backwards compatibility with previous versions of Advanced Message Security and IBM WebSphere MQ Extended Security Edition. Note that a non-zero key reuse count is only valid for a confidentiality policy. If you attempt to create or modify an integrity or privacy policy, with a non-zero key reuse count, you receive error message `AMQ9091: Key reuse is not valid for policy` and the policy operation fails.
-remove	Delete policy. Only the policy name flag, **-p** is valid for use in combination with this flag.

Examples

The following list shows examples of some valid **setmqspl** commands on Multiplatforms:

```
setmqspl -m QMGR -p PROT -s SHA256
setmqspl -m QMGR -p PROT -s SHA256 -a "CN=Alice, O=IBM, C=US"
setmqspl -m QMGR -p PROT -s SHA256 -e AES128 -a "CN=Alice, O=IBM, C=US" -r "CN=Bob, O=IBM, C=GB"
setmqspl -m QMGR -p PROT -e AES128 -r "CN=Bob, O=IBM, C=GB" -c 50
```

The following list shows examples of **setmqspl** commands that are not valid:

- No recipients specified:

```
setmqspl -m QMGR -p PROT -e AES128
```

- Key reuse not valid for an `Integrity` policy:

```
setmqspl -m QMGR -p PROT -s SHA256 -c 1
```

- Key reuse is not valid for a `Privacy` policy:

```
setmqspl -m QMGR -p PROT -s SHA256 -e AES128 -r "CN=Bob, O=IBM, C=GB" -c 1
```

z/OS On z/OS, you can use the **setmqspl** command with the CSQ0UTIL utility. For more information, see "The message security policy utility (CSQ0UTIL)" on page 2754.

Related reference

"SET POLICY (set security policy) on Multiplatforms" on page 915

Use the **dspmqspl** command to display a list of all policies and details of a named policy.

setmqweb (set mqweb server configuration)

V 9.2.0 Configure the mqweb server.

Purpose

- You can use the **setmqweb properties** command to configure the mqweb server. Changes to properties take effect dynamically, within a few seconds, unless otherwise stated.

  Attention: When you use the **setmqweb properties** command to change the property values in the `mqwebuser.xml` file, you need to ensure that the file is encoded in UTF-8. Using a different encoding corrupts the file during updates.

- ULW z/OS V 9.2.3 You can use the **setmqweb remote** command to set up remote queue manager connections to use with the IBM MQ Console.
- V 9.2.0 z/OS You can use the **setmqweb pid** command to change the product ID (PID) that the mqweb server runs under. By default, on z/OS, the mqweb server runs under the PID that is chosen when using the crtmqweb command. Before using **setmqweb pid** you should ensure the mqweb server has been stopped by using the MVS **STOP** command on the mqweb server started task. See Product usage recording with IBM MQ for z/OS products for more information on PIDs and how they are used on z/OS.

Using the command on z/OS

z/OS

Before issuing either the **setmqweb** or **dspmqweb** commands on z/OS, you must set the WLP_USER_DIR environment variable, so that the variable points to your mqweb server configuration.

To do this, issue the following command:

```
export WLP_USER_DIR=WLP_user_directory
```

where *WLP_user_directory* is the name of the directory passed to **crtmqweb**. For example:

```
export WLP_USER_DIR=/var/mqm/web/installation1
```

See Create the mqweb server for more information.

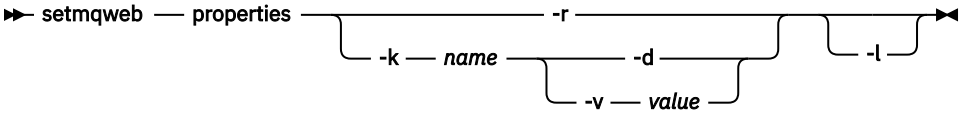
You must also set the JAVA_HOME environment variable to reference a 64 bit version of Java on your system.

The user ID executing the command needs write access to the following directories:

- *WLP_user_directory* and its subdirectories.
- `/tmp` or to another directory that is referenced by the *TMPDIR* variable. If you do not have access to `/tmp`, the command fails with message `FSUMF315 Cannot define temporary file`. If you need to set the *TMPDIR* variable, issue the following command in the z/OS UNIX shell: `export TMPDIR=`*user_directory*

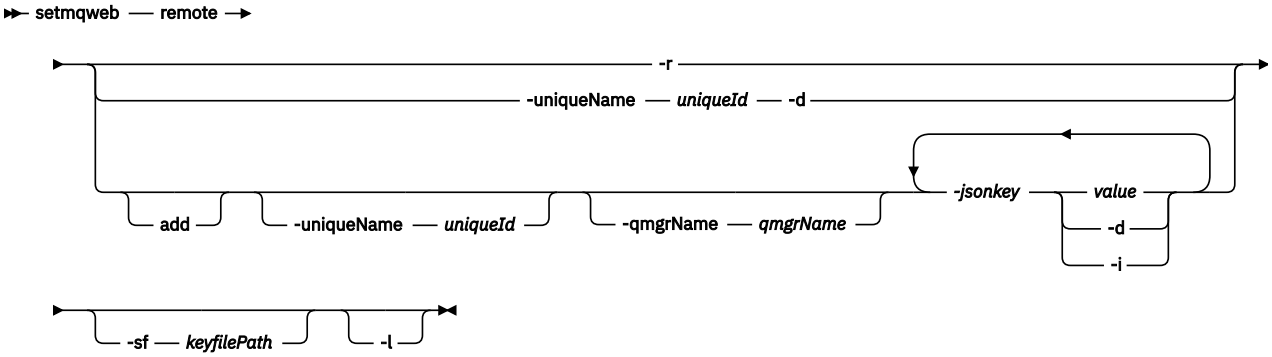
When the **setmqweb properties** variant of the command is used to modify the mqweb server configuration, the owner of the `mqwebuser.xml` file is changed to the user ID that issued the command, and the file permissions are set to those indicated by the user's **umask**.

Syntax relating to the *properties* variant



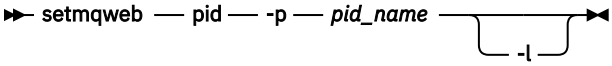
Syntax relating to the *remote* variant

ULW z/OS V 9.2.3



Syntax relating to the *pid* variant

V 9.2.0 z/OS



Parameters relating to the *properties* variant

-r

Reset to default values. This parameter removes all user-modified configuration properties from the `mqwebuser.xml` file.

-k *name*

The name of the configuration property to add, update, or remove to or from the `mqwebuser.xml` file. The following values are the valid values for *name* on all platforms, including the IBM MQ Appliance:

ltpaExpiration

This configuration property is used to specify the time, in minutes, before the LTPA token expires.

The value for this property is an integer value. The default value is 120 minutes.

maxTraceFiles

This configuration property is used to specify the maximum number of mqweb server log files that are generated by the mqweb server.

The value for this property is an integer value. The default value is 2.

maxTraceFileSize

This configuration property is used to specify the maximum size, in MB, that each mqweb server log file can reach.

The value for this property is an integer value. The default value is 200.

V 9.2.4 **mqConsoleMaxMsgCharsToDisplay**

This configuration property is used to specify the maximum characters to retrieve from each message when browsing a queue via the IBM MQ Console.

The value for this property is an integer. The default value is 1024.

V 9.2.4 **mqConsoleMaxMsgRequestSize**

This configuration property is used to specify the maximum size, in MB, a browse request can be across all messages when browsing queues via the IBM MQ Console.

The value for this property is an integer. The default value is 1.

V 9.2.4 **mqConsoleMaxMsgsPerRequest**

This configuration property is used to specify the total number of messages to retrieve from a queue when browsing via the IBM MQ Console.

The value for this property is an integer. The default value is 1000.

mqRestCorsAllowedOrigins

This configuration property is used to specify the origins that are allowed to access the REST API. For more information about CORS, see Configuring CORS for the REST API.

The value for this property is a string value.

mqRestCorsMaxAgeInSeconds

This configuration property is used to specify the time, in seconds, that a web browser can cache the results of any CORS pre-flight checks.

The value for this property is an integer value. The default value is 0.

mqRestCsrfValidation

This configuration property is used to specify whether CSRF validation checks are performed. A value of `false` removes the CSRF token validation checks.

The value for this property is a boolean value. the default value is true.

mqRestGatewayEnabled

This configuration property is used to specify whether the administrative REST API gateway is enabled.

The value for this property is a boolean value. The default value is true.

mqRestGatewayQmgr

This configuration property is used to specify the name of the queue manager to use as the gateway queue manager. This queue manager must be in the same installation as the mqweb server. A blank value indicates that no queue manager is configured as the gateway queue manager.

The value for this property is a string value. If this value can be interpreted as number or a boolean value, it must be enclosed in double quotation marks.

mqRestMessagingEnabled

This configuration property is used to specify whether the messaging REST API is enabled.

The value for this property is a boolean value. The default value is true.

V 9.2.0 **mqRestMessagingFullPoolBehavior**

This configuration property is used to specify the behavior of the messaging REST API when all connections in the connection pool are in use.

The value can be one of the following values:

block

When all the connections in the pool are in use, wait for a connection to become available. When this option is used, the wait for a connection is indefinite.

Inactive connections are closed and removed from a queue manager pool automatically. The state of each queue manager pool is interrogated every 2 minutes, and any connections that have been inactive for the last 30 seconds are closed and removed from the associated pool.

error

When all the connections in the pool are in use, return an error.

overflow

When all the connections in the pool are in use, create a non-pooled connection to use. This connection is destroyed after it is used.

The value for this property is a string value. The default value is overflow.

V 9.2.0 **mqRestMessagingMaxPoolSize**

This configuration property is used to specify the maximum connection pool size for each queue manager connection pool.

The value for this property is an integer value. The default value is 20.

V 9.2.0 **mqRestMftCommandQmgr**

This configuration property is used to specify the name of the command queue manager to which create transfer and create, delete or update resource monitor requests are submitted by the REST API for MFT.

The value for this property is a string value. If this value can be interpreted as number or a boolean value, it must be enclosed in double quotation marks.

Changes to the value of this property take effect when the mqweb server is next started.

mqRestMftCoordinationQmgr

This configuration property is used to specify the name of the coordination queue manager from which transfer details are retrieved by the REST API for MFT.

The value for this property is a string value. If this value can be interpreted as number or a boolean value, it must be enclosed in double quotation marks.

Changes to the value of this property take effect when the mqweb server is next started.

mqRestMftEnabled

This configuration property is used to specify whether the REST API for MFT is enabled.

The value for this property is a boolean value. The default value is false.

Changes to the value of this property take effect when the mqweb server is next started.

mqRestMftReconnectTimeoutInMinutes

This configuration property is used to specify the length of time, in minutes, after which the REST API for MFT stops trying to connect to the coordination queue manager.

The value for this property is an integer value. The default value is 30.

Changes to the value of this property take effect when the mqweb server is next started.

mqRestRequestTimeout

This configuration property is used to specify the time, in seconds, before a REST request times out.

The value for this property is an integer value. The default value is 30.

V 9.2.0 **mqConsoleEarName**

This configuration property is used to switch between the New Web Console and the Dashboard Web Console.

The value for this property is a string value and is `"com.ibm.mq.webconsole"` to switch to the New Web Console, and `"com.ibm.mq.console"` to switch to the Dashboard Web Console.

The default value is `com.ibm.mq.webconsole`.

traceSpec

This configuration property is used to specify the level of trace that is generated by the mqweb server. For a list of possible values, see Configuring logging for the IBM MQ Console and REST API.

The value for this property is a string value. The default value is `*=info`.

ULW z/OS

The following values are the additional valid values for *name* on z/OS, UNIX, Linux, and Windows:

httpHost

This configuration property is used to specify the HTTP host name as an IP address, domain name server (DNS) host name with domain name suffix, or the DNS host name of the server where IBM MQ is installed.

You can use an asterisk in double quotation marks to specify all available network interfaces.

You can use the value `localhost` to allow only local connections.

The value for this property is a string value. The default value is localhost.

httpPort

This configuration property is used to specify the HTTP port number that is used for HTTP connections.

You can use a value of `-1` to disable the port.

The value for this property is an integer value. The default value is `-1`.

httpsPort

This configuration property is used to specify the HTTPS port number that is used for HTTPS connections.

You can use a value of `-1` to disable the port.

The value for this property is an integer value. The default value is 9443.

ltpaCookieName

This configuration property is used to specify the name of the LTPA token cookie name.

By default, the value of this property is `LtpaToken2_${env.MQWEB_LTPA_SUFFIX}` on AIX, Linux, and Windows , or `LtpaToken2_${httpsPort}` on z/OS. The variable after the `LtpaToken2_` prefix is used by the mqweb server to generate a unique name for the cookie. You cannot set this variable, but you can change the `ltpaCookieName` to a value of your choosing.

The value for this property is a string value.

maxMsgTraceFiles

This configuration property is used to specify the maximum number of messaging trace files that are generated by the mqweb server for the IBM MQ Console.

The value for this property is a integer value. The default value is 5.

maxMsgTraceFileSize

This configuration property is used to specify the maximum size, in MB, that each messaging trace file can reach.

This property only applies to the IBM MQ Console.

The value for this property is a integer value. The default value is 20.

mqConsoleAutostart

This configuration property is used to specify whether the IBM MQ Console automatically starts when the mqweb server starts.

The value for this property is a boolean value. The default value is true.

V 9.2.0 **mqConsoleFrameAncestors**

This configuration property is used to specify the list of origins of web pages which can embed the IBM MQ Console in an IFrame. For more information about this property, see embedding the IBM MQ Console in an IFrame.

The value for this property is a string.

V 9.2.3 **mqConsoleRemoteSupportEnabled**

This configuration property is used to specify whether the IBM MQ Console allows remote queue manager connections. When this property is set to true, remote queue manager connections are allowed.

The value for this property is a boolean value. The default value is true.

V 9.2.3 **mqConsoleRemoteAllowLocal**

This configuration property is used to specify whether remote and local queue managers are visible in the IBM MQ Console when remote queue manager connections are allowed. When this property is set to true, both local and remote queue managers are displayed.

The value for this property is a boolean. The default value is true.

V 9.2.3 **mqConsoleRemotePollTime**

This configuration property is used to specify the time, in seconds, before the remote queue manager connections list is refreshed. On refresh, unsuccessful connections are retried.

The value for this property is an integer. The default value is 300.

V 9.2.3 **mqConsoleRemoteUIAdmin**

This configuration property is used to specify whether remote queue managers can be added to the IBM MQ Console by using the Console, or if remote queue managers can be added only by using the **setmqweb remote** command. When this property is set to true, remote queue managers can be added by using the IBM MQ Console.

The value for this property is a boolean. The default value is false.

mqRestAutostart

This configuration property is used to specify whether the REST API automatically starts when the mqweb server starts.

The value for this property is a boolean value. The default value is true.

V 9.2.3 **remoteKeyfile**

The location of the key file that contains the initial encryption key that is used to decrypt the passwords that are stored in the remote queue manager connection information.

The initial key is a file that must contain a single line of at least one character. However, you should use a key that is at least 16 characters. For example, your initial key file could contain the following encryption key:

```
Th1sIs@n3Ncypt|onK$y
```

Ensure that your key file is adequately protected using the operating system permissions, and that the encryption key is unique to the key file.

If you do not provide a key file, a default key is used.

You can also provide the path to the key file by using the **MQS_WEBUI_REMOTE_KEYFILE** environment variable.

The key file provided here must match the same key file used to encrypt the password via the **-sf** parameter below.

secureLtpa

This configuration property is used to specify whether the LTPA token is secured for all requests. An unsecured LTPA token is required in order send HTTP requests from a browser.

The value for this property is a boolean value. The default value is true.

V 9.2.0 ALW

The following values are the additional valid values for *name* on AIX, Linux, and Windows:

managementMode

This configuration property is used to specify whether queue managers and listeners are able to be created, deleted, started, and stopped by the IBM MQ Console.

The value for this property is a string value and can be one of the following values:

standard
Queue managers and listeners can be created and administered in the IBM MQ Console.

externallyprovisioned
Queue managers and listeners cannot be created in the IBM MQ Console. Only queue managers and listeners that are created outside of the IBM MQ Console can be administered.

The default value is standard.

-d

Deletes the specified configuration property from the `mqwebuser.xml` file.

-v *value*

The value of the configuration property to add to, or update in, the `mqwebuser.xml` file. Any existing configuration properties of the same *name* are overwritten. Duplicate configuration properties are removed.

The value is case-sensitive. To specify an asterisk, multiple tokens, or an empty value, enclose the value in double quotation marks.

The *value* that is specified is not validated. If incorrect values are specified a subsequent attempt to start the mqweb server might fail.

Note: The value provided for a configuration property is converted into a Java Object, and some heuristic parsing is applied:

Numbers
If the value is numeric, it is parsed as a Java Number object, such as Integer or Double. Note that a prefix of `0` indicates an octal value, `0x` a hexadecimal one, and so on. For example, `0101` becomes an Integer with the decimal value 65.

Booleans
If the value matches `true` or `false`, it is parsed as a Boolean object.

Quoted values
If the value is enclosed in double quotation marks, it is parsed as a String object. If a single character is enclosed in single quotation marks, it is parsed as a Character object.

Other values
If none of the previous rules apply, then the value is parsed without change as a String object.

These rules are particularly important when providing string values. If such a value can be interpreted as a number or boolean then you must ensure that it is specified to the setmqweb command in double quotation marks. For example, if you give a queue manager a numeric name or call it TRUE, you must enclose the name in double quotation marks.

You must escape double quotation marks on the command line. For example, you might specify

```
setmqweb properties -k mqRestGatewayQmgr - v "\"0101\""
```

to set a gateway queue manager name that resembles a number.

-l

Enable verbose logging. Diagnostic information is written to an mqweb server log file.

Parameters relating to the *remote* variant

add

Add a new entry to the remote queue manager connection information instead of editing an existing entry.

-uniqueName *uniqueID*

The unique name for the remote queue manager definition.

If this parameter is omitted, the queue manager name must be specified, and the queue manager name is used as the unique name.

The unique name must be specified in the following cases:

- to delete a remote queue manager connection.
- to add a new remote queue manager connection, when a queue manger with the same name already exists in the remote queue manager connection information.
- to modify a remote queue manager connection, when there is more than one queue manager with the same name in the remote queue manager connection information.

-qmgrName *qmgrName*

The name of the queue manager to add or update.

This parameter must be specified to add a new remote queue manager connection.

-sf *keyfilePath*

The location of the key file that contains the initial encryption key that is used to encrypt the passwords that are stored in the remote queue manager connection information.

The initial key is a file that must contain a single line of at least one character. However, you should use a key that is at least 16 characters. For example, your initial key file could contain the following encryption key:

```
Th1sIs@n3Ncypt|onK$y
```

Ensure that your key file is adequately protected using the operating system permissions, and that the encryption key is unique to the key file.

If you do not provide a key file, a default key is used.

You can also provide the path to the key file by using the **MQS_REMOTE_KEYFILE** environment variable.

***-jsonkey value*|-d|-i**

jsonkey

The name of the property to add, update, or remove. To add or update a value, specify the value after the *jsonkey* property. To delete a value, specify the **-d** flag after the *jsonkey* property.

There are two types of properties that you can add, update, or remove. The first type are global properties that you can set with the **setmqweb remote** command without specifying a queue manager name or unique name. The second type are properties that are specific to a single remote queue manager connection. These properties can be set with the **setmqweb remote** command only if you also specify a queue manager name, a unique name, or both.

The following values are valid *jsonkey* values that do not require you to specify a queue manager name or unique name in the **setmqweb remote** command:

globalTrustStorePath

The path to the trust store JKS file. This trust store is used for all remote connections unless it is overridden by specific remote queue manager connection information in the **trustStorePath** entry..

This value is a string value.

globalTrustStorePassword

The password for the global trust store.

This value is a string value, and it is encrypted in the remote queue manager connection information.

globalKeyStorePath

The path to the key store JKS file. This key store is used for all remote connections unless it is overridden by a specific remote queue manager connection information in the **keyStorePath** entry.

globalKeyStorePassword

The password for the global key store.

This value is a string value, and it is encrypted in the remote queue manager connection information.

The following values are valid *jsonkey* values that require you to specify a queue manger name or unique name in the **setmqweb remote** command:

ccdtURL

The path to the CCDT file that is associated with the remote queue manager.

This value is a string value.

username

The username that is used for the remote queue manager connection.

This value is a string value.

password
The password that is associated with the username that is used for the remote queue manager connection.

This value is a string value, and it is encrypted in the remote queue manager connection information.

enableMutualTLS
Whether this remote queue manager connection should add a key store to enable mutual TLS.

This value is a boolean value.

trustStorePath
The path to the trust store JKS file.

This value is a string value, and it overrides the global trust store value.

trustStorePassword
The password for the trust store file.

This value is a string value, and it is encrypted in the remote queue manager connection information.

keyStorePath
The path to the key store JKS file.

This value is a string value, and it overrides the global key store value.

keyStorePassword
The password for the key store file.

This value is a string value, and it is encrypted in the remote queue manager connection information.

value
The value of the json key entry to add or update.

The values are case-sensitive and must be enclosed in double quotation marks

-d
Delete the specified property from the remote connection information.

-i
Enable interactive mode for the specified json key entry. You are then prompted for the json key value as the command runs.

-d
Delete the connection information for the queue manager with the specified unique name.

-r
Reset and remove all remote connection information.

-l
Enable verbose logging. Diagnostic information is written to an mqweb server log file.

Parameters relating to the *pid* variant

Before using **setmqweb pid** you should ensure the mqweb server has been stopped by using the MVS **STOP** command on the mqweb server started task.

-p *pid_name*
Specifies the PID that the mqweb server will run under. *pid_name* should be one of:

MQ
The mqweb server runs under IBM MQ for z/OS (5655-MQ9)

VUE
The mqweb server runs under IBM MQ for z/OS Value Unit Edition (5655-VU9)

ADVANCEDVUE
the mqweb server runs under IBM MQ Advanced for z/OS VUE (5655-AV1)

-l
Enable verbose logging. Diagnostic information is written to an mqweb server log file.

Return codes

Table 109. Return code identifiers and descriptions

Return code	Description
0	Command successful.
>0	Command not successful.

For a full list of server command exit codes, see Liberty:server command options in the WebSphere Application Server documentation.

Examples

V 9.2.3

The following example sets the path to the global key store for remote queue manager connections:

```
setmqweb remote -globalTrustStorePath “c:\supersecure\keys.jks”
```

The following example creates a new entry for a queue manager, QM2, in the remote queue manager connection information. The example sets the CCDT URL, a username and password to use with the connection, and a key store path:

```
setmqweb remote add -qmgrName “QM2” -ccdtURL “c:\myccdts\cdt.json” -username “user” -password
“password” -keyStorePath “c:\supersecure\keys.jks”
```

The following example creates a new entry for a different queue manager that is also named QM2, and specifies a unique name to differentiate between the two QM2 queue managers. The example sets the CCDT URL, a username, and a password. The example uses the **-i** option to interactively enter the password that is associated with the username when the command runs:

```
setmqweb remote add -uniqueName qm2remote -qmgrName “QM2” -ccdtURL “c:\myccdts\cdt.json”
-username “mqadmin” -password -i
```

Related commands

Table 110. Related commands and descriptions

Command	Description
strmqweb	Start the mqweb server.
endmqweb	Stop the mqweb server.
dspmqweb	Display the status or configuration of the mqweb server.

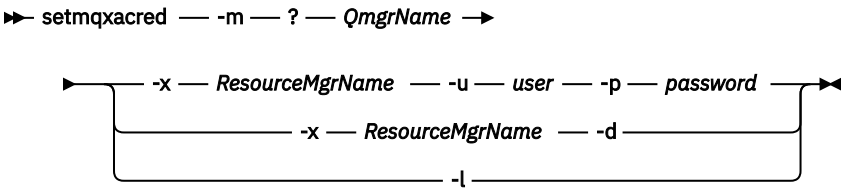
setmqxacred (add XA credentials)

Use the **setmqxacred** command to add or modify credentials in the IBM MQ XA credentials store.

Purpose

The **setmqxacred** command adds new credentials to the IBM MQ XA credentials store, or modifies or deletes existing credentials.

Syntax



Required parameters

-m *QmgrName*
The queue manager for which authentication details are stored.

Optional parameters

-x *ResourceMgrName*

Specifies the resource manager name as defined in the `qm.ini` file.

-u *user*

Specifies the user name to use to connect to the database.

-p *password*

Specifies the password for the user.

-d

Deletes the credentials for the named resource manager.

-l

Lists the credentials in the queue manager store.

Examples

To add credentials for the queue manager `QM1` for the resource `mqdb2`:

```
# setmqxacred -m QM1 -x mydb2 -u user1 -p Password1
Successfully added credentials for XA Resource Manager mydb2
```

To delete the credentials for the queue manager `QM1` for the resource `mqdb2`:

```
# setmqxacred -m QM1 -x mydb2 -d
Successfully removed credentials for XA Resource Manager mydb2
```

To list details about the credentials stored in the credentials store.

```
# setmqxacred -m QM1 -l
ResourceName(mydb2) UserName(user1)
ResourceName(myora) UserName(user2)
```

Multi strmqbrk (migrate a version 6.0 publish/subscribe broker to later version)

Migrate the persistent state of an IBM WebSphere MQ 6.0 publish/subscribe broker to a later version queue manager.

Purpose

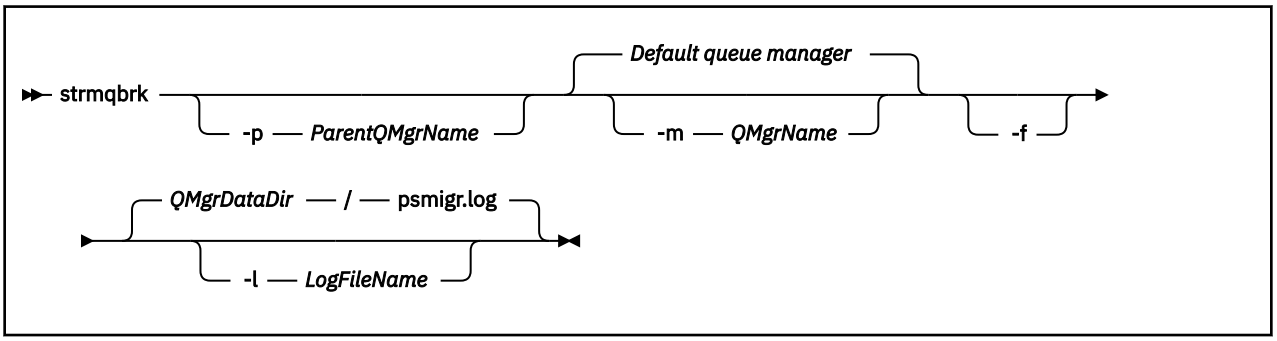
Use the **strmqbrk** command to migrate the state of an IBM WebSphere MQ 6.0 publish/subscribe broker to a later version queue manager. If the queue manager has already been migrated, no action is taken.

In IBM WebSphere MQ 6.0, **strmqbrk** started a broker. IBM MQ 8.0 or later publish/subscribe cannot be started in this manner. To enable publish/subscribe for a queue manager, use the **ALTER QMGR** command.

You can also use the **runmqbrk** command. This has the same parameters as **strmqbrk** and exactly the same effect.

Syntax for AIX, Linux, and Windows

ALW



Optional parameters for AIX, Linux, and Windows

ALW

-p *ParentQMgrName*

Note: This option is deprecated. **strmqbrk** migrates the parent connection automatically.

If you specify the current parent queue manager, a warning message is issued and migration continues. If you specify a different queue manager, a error is issued and migration is not performed.

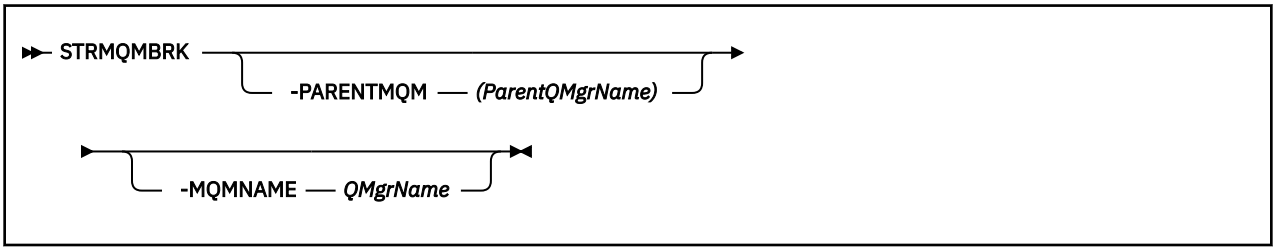
-m *QMgrName*
The name of the queue manager to be migrated. If you do not specify this parameter, the command is routed to the default queue manager.

-f
Force migration. This option specifies that objects created during the migration replace existing objects with the same name. If this option is not specified, if migration would create a duplicate object, a warning is issued, the object is not created, and migration continues.

-l *LogFileName*
Log migration activity to the file specified in *LogFileName*.

Syntax for IBM i

IBM i



Optional parameters for IBM i

IBM i

-PARENTMQM *ParentQMgrName)*

Note: This option is deprecated.

If you specify the current parent queue manager, a warning message is issued and migration continues. If you specify a different queue manager, a warning is issued and migration is not performed.

-MQMNAME ***QMgrName***
The name of the queue manager to be migrated. If you do not specify this parameter, the command is routed to the default queue manager.

Related reference
"ALTER QMGR (alter queue manager settings)" on page 331
Use the MQSC command **ALTER QMGR** to alter the queue manager parameters for the local queue manager.

Windows Linux strmqcfg (start IBM MQ Explorer)

Start IBM MQ Explorer (Windows and Linux x86-64 platforms only).

Purpose

Windows For IBM MQ for Windows only, note that if you use `runas` to execute this command, you must define the Environment Variable *APPDATA* to set a path to a directory that the user you are running as has access. For example:

```
set APPDATA=C:\Users\user_name\AppData\Roaming
```

You can use the following command to identify the path that *APPDATA* is set to:

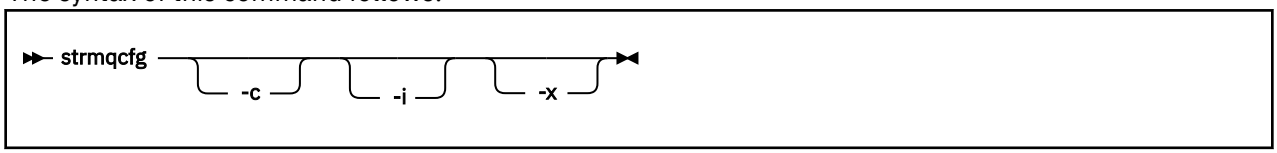
```
set APPDATA
```

Linux On Linux, to start IBM MQ Explorer successfully, you must be able to write a file to your home directory, and the home directory must exist.

Note: The preferred way to start IBM MQ Explorer is by using the system menu on Linux, or the start menu on Windows, or by using the `MQExplorer` executable file.

Syntax

The syntax of this command follows:



Optional parameters

-c
-clean is passed to Eclipse. This parameter causes Eclipse to delete any cached data used by the Eclipse runtime.

-i
-clean -initialize is passed to Eclipse. This parameter causes Eclipse to delete any cached data as well as discard configuration information used by the Eclipse runtime.

IBM MQ Explorer starts briefly and then ends without displaying the user interface.

-x
Output debug messages to the console.

Related tasks
Launching IBM MQ Explorer

Related reference

"MQExplorer (launch IBM MQ Explorer)" on page 118
Start IBM MQ Explorer (Windows and Linux x86-64 platforms only).

strmqcsv (start command server)

Start the command server for a queue manager.

Purpose

Use the **strmqcsv** command to start the command server for the specified queue manager. This enables IBM MQ to process commands sent to the command queue.

You must use the **strmqcsv** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the `dspmq -o installation` command.

If the queue manager attribute, SCMDSERV, is specified as QMGR then changing the state of the command server using **strmqcsv** does not effect how the queue manager acts upon the SCMDSERV attribute at the next restart.

Syntax

Required parameters

None

Optional parameters

-a
Blocks the following PCF commands from modifying or displaying authority information:

- Inquire authority records (`MQCMD_INQUIRE_AUTH_RECS`)
- Inquire entity authority (`MQCMD_INQUIRE_ENTITY_AUTH`)
- Set authority record (`MQCMD_SET_AUTH_REC`).
- Delete authority record (`MQCMD_DELETE_AUTH_REC`).

QMgrName
The name of the queue manager on which to start the command server. If omitted, the default queue manager is used.

Return codes

Table 111. Return code identifiers and descriptions

Return code	Description
0	Command completed normally
10	Command completed with unexpected results
20	An error occurred during processing

Examples

The following command starts a command server for queue manager `earth`:

```
strmqcsv earth
```

Related commands

Table 112. Related command names and descriptions

Command	Description
endmqcsv	End a command server
dspmqcsv	Display the status of a command server

Windows strmqsvc (start IBM MQ service)

Start the IBM MQ service on Windows.

Purpose

The command starts the IBM MQ service on Windows. Run the command on Windows only.

If you are running IBM MQ on Windows systems with User Account Control (UAC) enabled, you must invoke **strmqsvc** with elevated privileges.

Run the command to start the service, if it has not been started automatically, or if the service has ended.

Restart the service for IBM MQ processes to pick up a new environment, including new security definitions.

Syntax

strmqsvc

Parameters

The **strmqsvc** command has no parameters.

You must set the path to the installation that contains the service. Either make the installation primary, run the **setmqenv** command, or run the command from the directory containing the **strmqsvc** binary file.

Related reference

"endmqsvc (end IBM MQ service)" on page 111

End the IBM MQ service on Windows.

strmqm (start queue manager)

Start a queue manager or ready it for standby operation.

Purpose

Use the **strmqm** command to start a queue manager.

You must use the **strmqm** command from the installation that is associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the `dspmq -o installation` command.

If a queue manager has no associated installation and there is no installation of IBM WebSphere MQ 7.0.1 on the system, the **strmqm** command associates the queue manager with the installation that issued the **strmqm** command.

If the queue manager startup takes more than a few seconds IBM MQ shows intermittent messages detailing the startup progress.

Usage notes

From IBM MQ 9.1, IBM MQ supports the use of back-up queue managers. That is, a queue manager where log extents are asynchronously copied to a backup machine, and where replay of the log records is periodically driven by use of the command **strmqm -r**. When the backup queue manager needs to be activated, use the command **strmqm -a** and then start the queue manager normally.

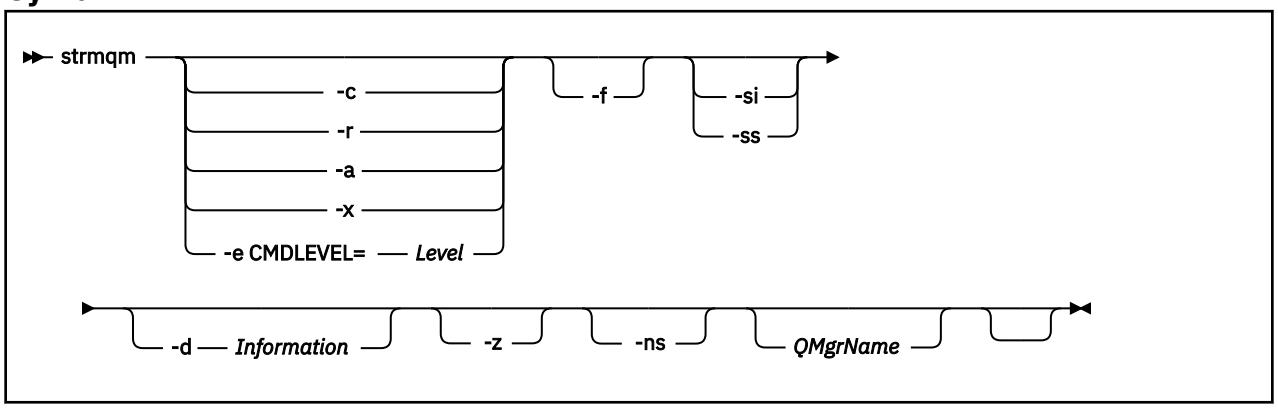
Attention: You cannot use **LogManagement**=*Automatic*, along with a backup queue manager, as extents might be reused before they are backed up. Furthermore, if you run the command **strmqm -r** together with **LogManagement**=*Automatic*, the command fails.

UNIX From IBM MQ 9.1, the security of *data path*`/log/`*qm* on UNIX systems is changed from 2775 to 2770.

The **strmqm** command checks the syntax of the CHANNELS and SSL stanzas in the `qm.ini` file early on, before starting the queue manager fully. If the `qm.ini` file contains any errors, this check makes it much easier to see what is wrong, and correct it quickly. If an error is found, **strmqm** outputs an AMQ9224 error message, describing the full details of the position of the error in the `qm.ini` file. It also ends immediately without starting the queue manager.

V 9.2.0 Linux From IBM MQ 9.2.0, you can use the environment variable **MQLICENSE** to accept or view the license.

Syntax



Optional parameters

-a

Activate the specified backup queue manager. The backup queue manager is not started.

When activated, a backup queue manager can be started by using the control command `strmqm` *QMgrName*. The requirement to activate a backup queue manager prevents accidental startup.

When activated, a backup queue manager can no longer be updated.

For more information about using backup queue managers, see Backing up and restoring IBM MQ queue manager data.

-c

Starts the queue manager, redefines the default and system objects, then stops the queue manager. Any existing system and default objects that belong to the queue manager are replaced if you specify this flag, and any non-default system object values are reset (for example, the value of MCAUSER is set to blank).

Use the **crtmqm** command to create the default and system objects for a queue manager.

Note: If you run `strmqm -c` on a queue manager that is being used as a Managed File Transfer coordination queue manager you must re-run the MQSC script that defines the coordination queue manager objects. This script is in a file called *queue_manager_name*`.mqsc`, which is in the Managed File Transfer configuration directory.

The `-c` option is not available for Native HA queue managers.

-d *Information*

Specifies whether information messages are displayed. Possible values for *Information* are as follows:

Value	Description
all	All information messages are displayed. This value is the default value.
minimal	The minimal number of information messages are displayed.
none	No information messages are displayed. This parameter is equivalent to **-z**.

The *-z* parameter takes precedence over this parameter.

-e CMDLEVEL = *Level*

Enables a command level for this queue manager, and then stops the queue manager.

The queue manager is now able to use all functions that are provided by the specified command level. You can start the queue manager only with an installation that supports the new command level.

This option is only valid if the current command level that is used by the queue manager is lower than the maximum command level supported by the installation. Specify a command level that is greater than the current command level of the queue manager and less than or equal to the maximum command level supported by the installation.

Use exactly the command level as a value for *Level* that is associated with the function you want to enable.

This flag cannot be specified with -a, -c, -r or -x.

-f

Use this option if you know that a queue manager is not starting because its data directories are missing or corrupted.

The **strmqm** `-f` *qmname* command attempts to re-create the queue manager data directory and reset file permissions. If it is successful, the queue manager starts, unless the queue manager configuration information is missing. If the queue manager fails to start because the configuration information is missing, re-create the configuration information, and restart the queue manager.

In releases of the product before IBM WebSphere MQ 7.0.1, **strmqm**, with no -f option, automatically repaired missing data directories and then tried to start. This behavior is changed.

From IBM WebSphere MQ 7.0.1 onwards, the default behavior of **strmqm**, with no -f option, is not to recover missing or corrupted data directories automatically, but to report an error, such as AMQ6235 or AMQ7001, and not start the queue manager.

You can think of the -f option as performing the recover actions that used to be performed automatically by **strmqm**.

The reason for the change to the behavior of **strmqm** is that with the support for networked file storage in IBM WebSphere MQ 7.0.1, the most likely cause of missing or corrupted queue manager data directories is a configuration error that can be rectified, rather than the data directories are corrupted or irretrievably unavailable.

You must not use **strmqm** -f to re-create the queue manager data directories if you can restore the directories by correcting the configuration.

Possible solutions to problems with **strmqm** are to make the networked file storage location accessible to the queue manager, or to ensure the gid and uid of the mqm group and user ID on the server hosting the queue manager match the gid and uid of the mqm group and user ID on the server that is hosting the queue manager data directory.

From IBM WebSphere MQ 7.0.1, if you are performing media recovery for a queue manager, then you must use the -f option to re-create the queue manager data directory.

-ns

Prevents any of the following processes from starting automatically when the queue manager starts:

- The channel initiator
- The command server
- Listeners
- Services

This parameter also runs the queue manager as if the CONNAUTH attribute is blank, regardless of its current value. Client applications cannot connect because there are no listeners. Authorization of applications and control commands will occur based on the local OS user under which you run them. If the queue manager had previously used LDAP users/groups for its authorization records, then:

1. These records will be ignored while the queue manager is running in **-ns** mode.
2. You should not make changes to authorization records or create new objects while in this mode, because the authorization records that are created or amended in this mode will then contain user names derived from the operating system, not the LDAP repository.

Administrative changes must be made by using **runmqsc** because the command server is not running.

To re-enable the normal authorization service processing, that is, return the effective CONNAUTH value to its normal setting, you must end and start the queue manager without the **-ns** parameter.

-r

Updates the backup queue manager. The backup queue manager is not started.

IBM MQ updates the objects of the backup queue manager by reading the queue manager log and replaying updates to the object files.

For more information about using backup queue managers, see Backing up and restoring IBM MQ queue manager data.

Note:

The -r option is not available for Native HA queue managers.

-si

Interactive (manual) queue manager startup type. This option is available on IBM MQ for Windows only.

The queue manager runs under the logged on (interactive) user. Queue managers that are configured with interactive startup end when the user who started them logs off.

If you set this parameter, it overrides any startup type set previously by the **crtmqm** command, the **amqmdain** command, or the IBM MQ Explorer.

If you do not specify a startup type of either `-si` or `-ss`, the queue manager startup type that is specified on the **crtmqm** command is used.

Windows **-ss**

Service (manual) queue manager startup type. This option is available on IBM MQ for Windows only.

The queue manager runs as a service. Queue managers that are configured with service startup continue to run even after the interactive user is logged off.

If you set this parameter, it overrides any startup type set previously by the **crtmqm** command, the **amqmdain** command, or the IBM MQ Explorer.

-x

Start an instance of a multi-instance queue manager on the local server, permitting it to be highly available. If an instance of the queue manager is not already running elsewhere, the queue manager starts and the instance becomes active. The active instance is ready to accept local and remote connections to the queue manager on the local server.

If a multi-instance queue manager instance is already active on a different server the new instance becomes a standby, permitting it to takeover from the active queue manager instance. While it is in standby, it cannot accept local or remote connections.

You must not start a second instance of a queue manager on the same server.

The default behavior, omitting the `-x` optional parameter, is to start the instance as a single instance queue manager, forbidding standby instances from being started.

-z

Suppresses error messages.

This flag is used within IBM MQ to suppress unwanted information messages. Because using this flag can result in loss of information, do not use it when you are entering commands on a command line.

This parameter takes precedence over the `-d` parameter.

QMgrName

The name of a local queue manager. If omitted, the default queue manager is used.

Return codes

Table 113. Return code identifiers and descriptions

Return code	Description
0	Queue manager started.
1	The location chosen for the queue manager data directory is invalid
3	Queue manager being created.
5	Queue manager running.
16	Queue manager does not exist.
23	Log not available.
24	A process that was using the previous instance of the queue manager has not yet disconnected.
30	A standby instance of the queue manager started. The active instance is running elsewhere.

Table 113. Return code identifiers and descriptions (continued)

Return code	Description
31	The queue manager already has an active instance. The queue manager permits standby instances.
39	Invalid parameter specified.
43	The queue manager already has an active instance. The queue manager does not permit standby instances.
47	The queue manager already has the maximum number of standby instances.
49	Queue manager stopping.
58	Inconsistent use of installations detected.
62	The queue manager is associated with a different installation.
69	Storage not available.
71	Unexpected error.
72	Queue manager name error.
74	The IBM MQ service is not started.
91	The command level is outside the range of acceptable values.
92	The queue manager's command level is greater or equal to the specified value.
94	A replica instance of the queue manager has been started.
100	Log location invalid.
114	Invalid QM.INI file stanza.
119	User not authorized to start the queue manager.

Examples

The following command starts the queue manager `account`:

```
strmqm account
```

End the IBM MQ service on Windows.

strmqtrc (Start trace)

Enable trace at a specified level of detail, or report the level of tracing in effect.

Purpose

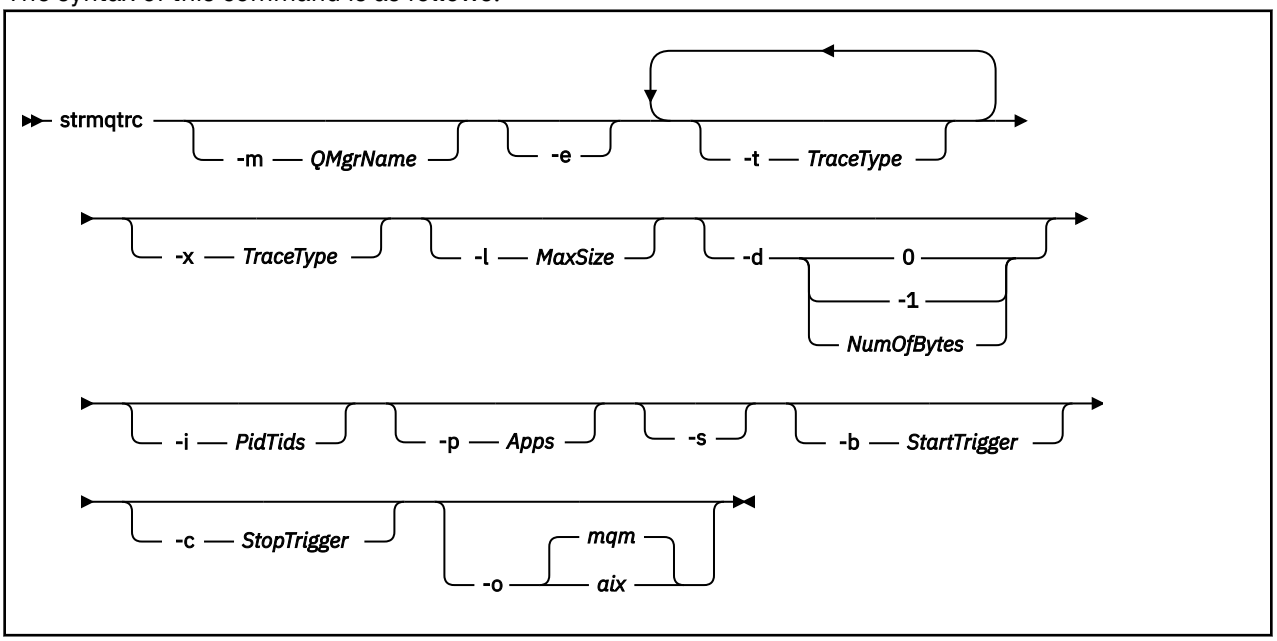
Use the **strmqtrc** command to enable tracing.

You must use the **strmqtrc** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with by using the **dspmq** command as follows:

```
dspmq -o installation
```

Syntax

The syntax of this command is as follows:



Description

The **strmqtrc** command enables tracing. The command has optional parameters that specify the level of tracing you want:

- One or more queue managers
- Levels of trace detail
- One or more IBM MQ processes. The processes can be either part of the IBM MQ product or customer applications that use the IBM MQ API
- Specific threads within customer applications, either by IBM MQ thread number or by operating system thread number
- Events. These can be either the entry or exit from internal IBM MQ functions or the occurrence of a first failure data capture (FDC).

Each combination of parameters on an individual invocation of the command are interpreted by IBM MQ as having a logical AND between them. You can start the strmqtrc command multiple times, regardless of

whether tracing is already enabled. If tracing is already enabled, the trace options that are in effect are modified to those specified on the most recent invocation of the command. Multiple invocations of the command, without an intervening enqmqtrc command, are interpreted by IBM MQ as having a logical OR between them. The maximum number of concurrent strmqtrc commands that can be in effect at one time is 16.

Optional parameters

-m *QMgrName*
The name of the queue manager to trace.

The following wildcards are allowed: asterisk (*), replacing zero or more characters, and question mark (?), replacing any single character. In command environments such as the UNIX shell, where the asterisk (*) and question mark (?) characters have special meaning, you must either escape the wildcard character or enclose it in quotation marks to prevent the command environment from operating on the wildcard character.

-e
Requests early tracing of all processes, making it possible to trace the creation or startup of a queue manager. If you include this parameter, any process belonging to any component of any queue manager traces its early processing. The default is not to perform early tracing.

Use the following command to trace a client:

```
strmqtrc -e
```

You cannot use the **-e** parameter with the **-m** parameter, **-i** parameter, the **-p** parameter, the **-c** parameter, or the **-b** parameter. If you try to use the **-e** parameter with the **-m** parameter, the **-i** parameter, the **-p** parameter, the **-c** parameter, or the **-b** parameter, then an error message is issued.

-t *TraceType*
The points to trace and the amount of trace detail to record. By default **all** trace points are enabled and a default-detail trace is generated.

Alternatively, you can supply one or more of the options in the following list. For each *Tracetype* value you specify, including `-t all`, specify either `-t parms` or `-t detail` to obtain the appropriate level of trace detail. If you do not specify either `-t parms` or `-t detail` for any particular trace type, only a default-detail trace is generated for that trace type.

Attention: When using the `-t api` option, you will see trace of the MQI calls, with all the input and output data blocks dumped in hexadecimal form.

You should be aware that IBM MQ internal programs also make MQI calls, and you will see trace files for those programs. Normally, the program names begin `amq` or `runmq`.

You should be aware that **amqrmppa** programs host many threads, some of which receive MQI calls over the network from client applications. In these threads you will see MQI calls in the `-t api` traces, but you must remember that the input arguments to those MQI calls traced in the **amqrmppa** program might not match every detail of the MQI calls made originally by the client.

Therefore, if you need to know, reliably, the input arguments to MQI calls made by the client application, you must use `-t api` tracing on the client machine directly.

If you supply multiple trace types, each must have its own **-t** parameter. You can include any number of **-t** parameters, if each has a valid trace type associated with it.

It is not an error to specify the same trace type on multiple **-t** parameters.

Table 114. TraceType parameter values.	
Value	**Description**
`all`	Output data for every trace point in the system (the default). The all parameter activates tracing at default detail level.
V 9.2.0 `amqp`	Output data for the AMQP service
`api`	Output data for trace points associated with the MQI and major queue manager components.
`commentary`	Output data for trace points associated with comments in the IBM MQ components.
`comms`	Output data for trace points associated with data flowing over communications networks.
`csdata`	Output data for trace points associated with internal data buffers in common services.
`csflows`	Output data for trace points associated with processing flow in common services.
`detail`	Activate tracing at high-detail level for flow processing trace points.
`explorer`	Output data for trace points associated with the IBM MQ Explorer.
`java`	Output data for trace points associated with applications using the IBM MQ classes for Java API.
`lqmdata`	Output data for trace points associated with internal data buffers in the local queue manager.
`lqmflows`	Output data for trace points associated with processing flow in the local queue manager.
`mqxr`	Output data for the Telemetry (MQXR) service.
`otherdata`	Output data for trace points associated with internal data buffers in other components.
`otherflows`	Output data for trace points associated with processing flow in other components.
`parms`	Activate tracing at default-detail level for flow processing trace points.
`remotedata`	Output data for trace points associated with internal data buffers in the communications component.
`remoteflows`	Output data for trace points associated with processing flow in the communications component.
`servicedata`	Output data for trace points associated with internal data buffers in the service component.
`serviceflows`	Output data for trace points associated with processing flow in the service component.
`spldata`	Output data for trace points associated with buffers and control blocks that use a security policy (AMS) operation.

Table 114. TraceType parameter values. (continued)	
Value	**Description**
`splflows`	Output data for trace points associated with entry and exit data for functions that use a security policy (AMS) operation.
`ssl`	Output data associated with using IBM Global Security Kit (GSKit) to enable TLS channel security.
`versiondata`	Output data for trace points associated with the version of IBM MQ running.

-x *TraceType*
The points **not** to trace. By default **all** trace points are enabled and a default-detail trace is generated. The trace points you can specify are those listed for the **-t** parameter.

You can use the **-x** parameter with *Tracetype* values to exclude those entry points you do not want to record. This is useful in reducing the amount of trace produced.

If you supply multiple trace types, each must have its own **-x** parameter. You can include any number of **-x** parameters, if each has a valid *Tracetype* associated with it.

-l *MaxSize*
The maximum size of a trace file (AMQ*ppppp*.*qq*.TRC) in megabytes (MB), where *ppppp* refers to the operating system process ID of the particular IBM MQ process being traced and *qq* is a sequence number if there is already a file with that name. For example, if you specify a *MaxSize* of 1, the size of the trace is limited to 1 MB.

When a trace file reaches the specified maximum, it is renamed to AMQ*ppppp*.*qq*.TRS and a new AMQ*ppppp*.*qq*.TRC file is started. If a previous copy of an AMQ*ppppp*.*qq*.TRS file exists, it is deleted.

The highest value that *MaxSize* can be set to is 2048 MB.

-d
Trace options. The value can be:

0
Trace no user data.

-1 or all
Trace all user data.

NumOfBytes

- For a communication trace; trace the specified number of bytes of data including the transmission segment header (TSH).
- For an MQPUT or MQGET call; trace the specified number of bytes of message data held in the message buffer.
- Values in the range 1 through 15 are not allowed.

-i *PidTids*
Process identifier (PID) and thread identifier (TID) to which the trace generation is restricted. You cannot use the **-i** parameter with the **-e** parameter. If you try to use the **-i** parameter with the **-e** parameter, then an error message is issued.

The precise format of this parameter is `PID[.TID]`. For example:

Coding **-i** *12345* traces all threads in PID 12345, whereas
Coding **-i** *12345.67* traces only thread 67 in PID 12345

This parameter is not supported for .NET clients if NMQ_MQ_LIB is set to `managed`, so that the client uses managed IBM MQ problem diagnostics.

-p *Apps*

The named processes to which the trace generation is restricted. *Apps* is a comma-separated list. You must specify each name in the list exactly as the program name would be displayed in the "Program Name" FDC header. Asterisk (*) or question mark (?) wildcards are allowed. You cannot use the **-p** parameter with the **-e** parameter. If you try to use the **-p** parameter with the **-e** parameter, then an error message is issued.

This parameter is not supported for .NET clients if NMQ_MQ_LIB is set to `managed`, so that the client uses managed IBM MQ problem diagnostics.

-s

Reports the tracing options that are currently in effect. You must use this parameter on its own with no other parameters.

A limited number of slots are available for storing trace commands. When all slots are in use, then no more trace commands can be accepted unless they replace an existing slot. Slot numbers are not fixed, so if the command in slot number 0 is removed, for example by an **endmqtrc** command, then all the other slots move up, with slot 1 becoming slot 0, for example. An asterisk (*) in a field means that no value is defined, and is equivalent to the asterisk wildcard.

An example of the output from this command is as follows:

```
Listing Trace Control Array

Used slots = 2 of 15

EarlyTrace    [OFF]
TimedTrace    [OFF]
TraceUserData [0]
MaxSize       [0]
Trace Type    [1]

Slot position 1

Untriggered
Queue Manager [avocet]
Application   [*]
PID.TID       [*]
TraceOptions  [1f4ffff]
TraceInterval    [0]
Trace Start Time [0]
Trace Stop  Time [0]
Start Trigger [KN346050K]
Start Trigger [KN346080]

Slot position 2

Untriggered
Queue Manager [*]
Application   [*]
PID.TID       [*]
TraceOptions  [1fcffff]
TraceInterval    [0]
Trace Start Time [0]
Trace Stop  Time [0]
Start Trigger [KN346050K]
Start Trigger [KN346080]
```

This parameter is not supported for .NET clients if NMQ_MQ_LIB is set to `managed`, so that the client uses managed IBM MQ problem diagnostics.

-b *Start_Trigger*

FDC probe IDs for which tracing must be turned on. *Start_Trigger* is a comma-separated list of FDC probe IDs. You can use asterisk (*) and question mark (?) wildcards in the specification of probe IDs. You cannot use the **-b** parameter with the **-e** parameter. If you try to use the **-b** parameter with the **-e** parameter, then an error message is issued. This parameter must only be used under the guidance of IBM Service personnel.

Table 115. Start trigger and effect	
Start_Trigger	**Effect**
FDC=comma-separated list of FDC probe IDs.	Turns on tracing when any FDCs with the specified FDC probe IDs are generated.

This parameter is not supported for .NET clients if NMQ_MQ_LIB is set to `managed`, so that the client uses managed IBM MQ problem diagnostics.

-c *Stop_Trigger*
FDC probe IDs for which tracing must be turned off, or interval in seconds after which tracing must be turned off. *Stop_Trigger* is a comma-separated list of FDC probe IDs. You can use asterisk (*) and question mark (?) wildcards in the specification of probe IDs. This parameter should be used only under the guidance of IBM Service personnel.

Table 116. Stop triggers and their effects	
Stop_Trigger	**Effect**
FDC=comma-separated list of FDC probe IDs.	Turns tracing off when any FDCs with the specified FDC probe IDs are generated.
interval=n where n is an unsigned integer between 1 and 32,000,000.	Turns tracing off n seconds after it starts or, if it tracing is already enabled, turns tracing off n seconds after this instance of the command is issued.

This parameter is not supported for .NET clients if NMQ_MQ_LIB is set to `managed`, so that the client uses managed IBM MQ problem diagnostics.

-o

`mqm`
Enables IBM MQ trace as in previous releases.

This is the default value if no -o option is supplied.

AIX **`aix`**
Enables IBM MQ to write AIX system trace, provided AIX system trace is enabled.

As previously, you must use the AIX operating system trace command for any output to actually be produced.

This is a legacy option, and you should use this option only when directed to do so by IBM service personnel.

Return codes

Table 117. Return code identifiers and descriptions

Return code	Description
AMQ7024	Non-valid arguments supplied to the command.
AMQ7077	You are not authorized to perform the requested operation.
AMQ8304	Nine concurrent traces (the maximum) already running.
58	Inconsistent use of installations detected

Examples of enabling tracing at different levels of detail

Linux AIX This command enables tracing of processing flow from common services and the local queue manager for a queue manager called QM1 on IBM MQ for AIX or Linux systems. Trace data is generated at the default level of detail.

```
strmqtrc -m QM1 -t csflows -t lqmflows -t parms
```

This command disables tracing of TLS activity on a queue manager called QM1. Other trace data is generated at the parms level of detail.

```
strmqtrc -m QM1 -x ssl -t parms
```

This command enables high-detail tracing of the processing flow for all components:

```
strmqtrc -t all -t detail
```

Examples of enabling tracing for an FDC

This command enables tracing when FDC KN346050 or FDC KN346080 occur on any process that is using queue manager QM1:

```
strmqtrc -m QM1 -b FDC=KN346050,KN346080
```

This command enables tracing when FDC KN34650 occurs, and stops tracing when FDC KN346080 occurs. In both cases the FDC must occur on a process that is using queue manager QM1:

```
strmqtrc -m QM1 -b FDC=KN346050 -c FDC=KN346080
```

Examples of using the -p and -m parameters for individual and multiple invocations of **strmqtrc**

The following examples use the **-p** and **-m** parameters to show:

- How a combination of parameters on an individual invocation of the command are interpreted by IBM MQ as having a logical AND between them.
- How multiple invocations of the command, without an intervening enqmqtrc command, are interpreted by IBM MQ as having a logical OR between them:

1. This command enables tracing for all threads that result from any executing process called amqxxx.exe:

   ```
   strmqtrc -p amqxxx.exe
   ```

2. After running the **strmqtrc** command as shown in step 1, you can then enter either of the following commands without an intervening **endmqtrc** command.
   - If you start the following command after the command in step 1, without an intervening **endmqtrc** command, then tracing is limited to all threads that result from any executing process called amqxxx.exe *and* that are using queue manager QM2:

     ```
     strmqtrc -p amqxxx.exe -m QM2
     ```

   - If you start the following command after the command in step 1, without an intervening **endmqtrc** command, then tracing is limited to all processes and threads that result from executing amqxxx.exe *or* that are using queue manager QM2:

     ```
     strmqtrc -m QM2
     ```

Example of enabling dynamic tracing of LDAP client library code shipped with IBM MQ

From IBM MQ 9.1.0 Fix Pack 4 and IBM MQ 9.1.4, it is possible to switch LDAP client trace on and off without also stopping or starting the queue manager.

You can use the following command to switch on the trace:

```
strmqtrc -m QMNAME -t servicedata
```

To enable this behavior, it is also necessary to set an environment variable AMQ_LDAP_TRACE to a non-null value. For more information, see Enabling dynamic tracing of LDAP client library code.

Related commands

Command	Description
dspmqtrc	Display formatted trace output
endmqtrc	End trace

Related reference

Command sets comparison: Other commands
A table of other commands, showing the command description, and its PCF command, MQSC command, and control command equivalents. The REST API resource and HTTP method equivalents, and IBM MQ Explorer equivalents, are included if available.

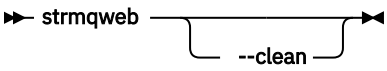
strmqweb (start mqweb server)

Start the mqweb server that is used to support the IBM MQ Console and REST API.

Purpose

Use the **strmqweb** command to start the mqweb server. You must start the mqweb server as a privileged user to use the IBM MQ Console or the REST API.

Syntax



Optional parameters

--clean

Cleans all persistent cached information that is related to the specified server instance, which includes OSGi resolver metadata and persistent OSGi bundle data. If you use this option, the server will be required to recompute any cached data at the next startup, which might take more time than a restart that can reuse cached data.

Note: This option is not necessary for normal operation. IBM® service might request that you use this option when providing an interim fix, or if there is a suspected problem with the cached data.

Return codes

Table 119. Return code identifiers and descriptions

Return code	Description

Syntax diagrams

The syntax for a command and its options is presented in the form of a syntax diagram called a railroad diagram. Railroad diagrams are a visual format suitable for sighted users. It tells you what options you can supply with the command, how to enter them, indicates relationships between different options, and sometimes different values of an option.

Each railroad diagram begins with a double right arrow and ends with a right and left arrow pair. Lines beginning with a single right arrow are continuation lines. You read a railroad diagram from left to right and from top to bottom, following the direction of the arrows.

Other conventions used in railroad diagrams are shown in Table 121 on page 236.

Table 121. How to read railroad diagrams

Convention	Meaning
	You must specify values A, B, and C. Required values are shown on the main line of a railroad diagram.
	You may specify value A. Optional values are shown below the main line of a railroad diagram.
	Values A, B, and C are alternatives, one of which you must specify.

Table 121. How to read railroad diagrams (continued)	
Convention	**Meaning**
	Values A, B, and C are alternatives, one of which you might specify.
	This shows that a value (for example, A, or B, or C) must be selected, and if another is to be selected then a comma must be used between the values.
	You might specify value A multiple times. The separator in this example is optional.
	Values A, B, and C are alternatives, one of which you might specify. If you specify none of the values shown, the default A (the value shown above the main line) is used.
 **Name** 	The railroad fragment Name is shown separately from the main railroad diagram.
Punctuation and uppercase values	Specify exactly as shown.

ALTER AUTHINFO (alter authentication information object)

Use the MQSC command **ALTER AUTHINFO** to alter an authentication information object. These objects contain the definitions required to perform certificate revocation checking using OCSP or Certificate Revocation Lists (CRLs) on LDAP servers.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

Parameters not specified in the **ALTER AUTHINFO** command result in the existing values for those parameters being left unchanged.

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

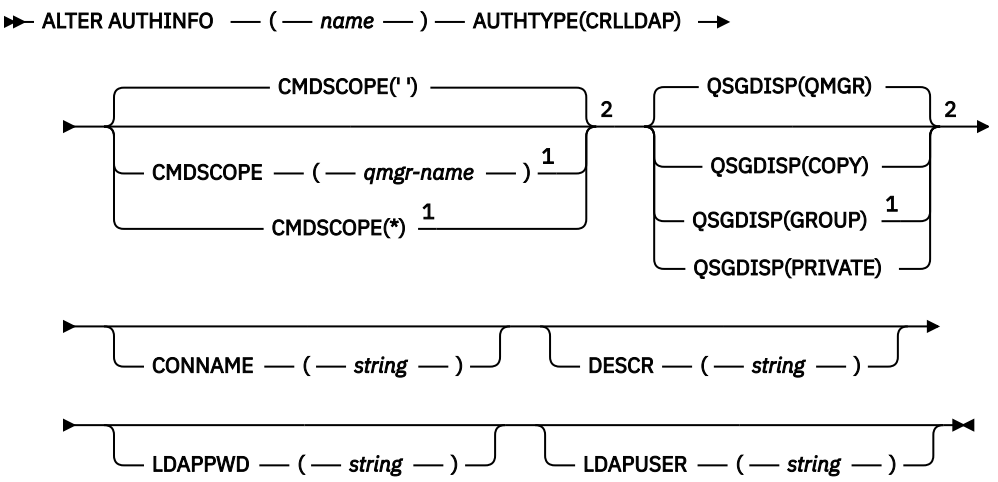
There are separate syntax diagrams for each **AUTHTYPE** parameter option:

- Syntax diagram for TYPE(CRLLDAP)
- Syntax diagram for TYPE(OCSP)
- Syntax diagram for TYPE(IDPWOS)
- Syntax diagram for TYPE(IDPWLDAP)
- “Parameter descriptions for ALTER AUTHINFO” on page 240

Synonym: **ALT AUTHINFO**

Syntax diagram for AUTHTYPE(CRLLDAP)

ALTER AUTHINFO

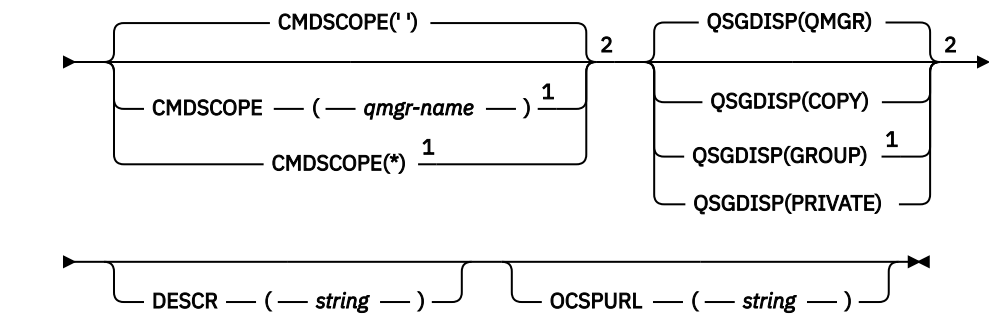


Notes:

[1] Valid only when the queue manager is a member of a queue sharing group. You can use queue sharing groups only on IBM MQ for z/OS.
[2] Valid only on z/OS.

Syntax diagram for AUTHTYPE(OCSP)

ALTER AUTHINFO

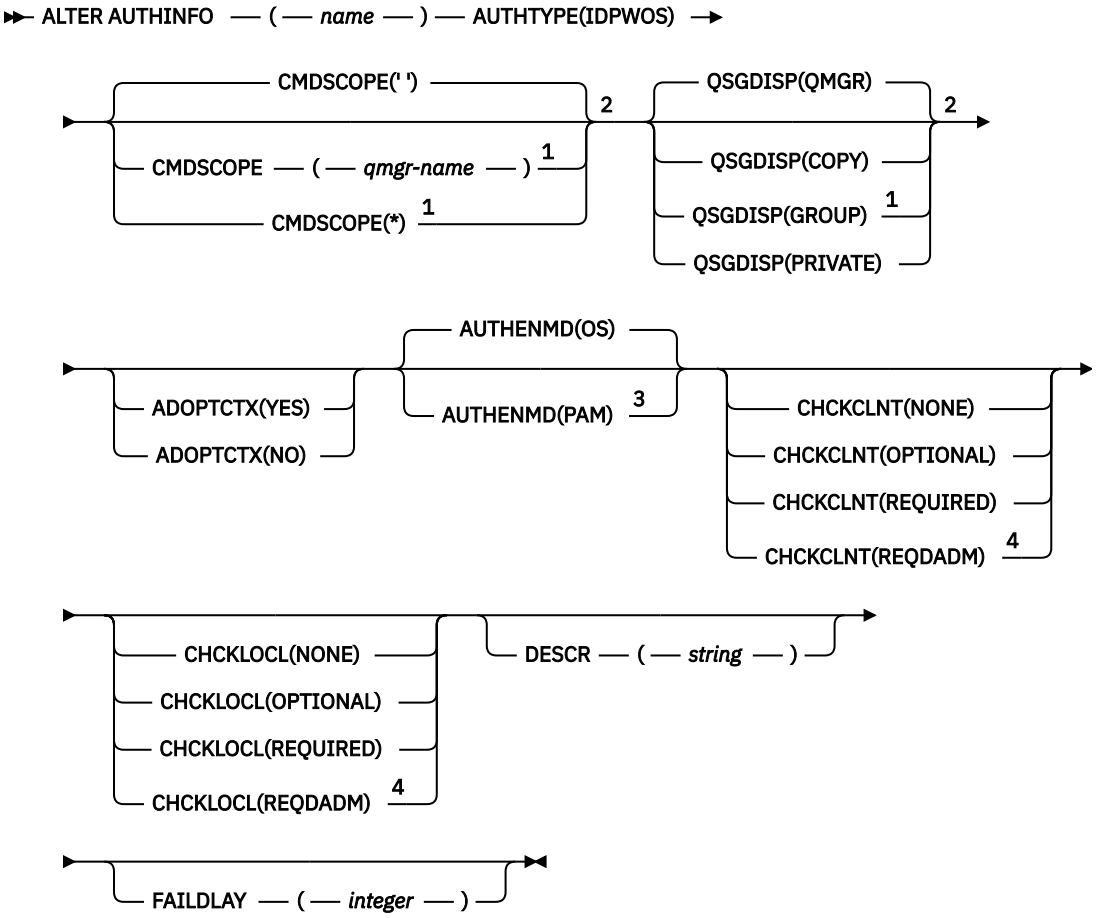


Notes:

[1] Valid only when the queue manager is a member of a queue sharing group. You can use queue sharing groups only on IBM MQ for z/OS.
[2] Valid only on z/OS.

Syntax diagram for AUTHTYPE(IDPWOS)

ALTER AUTHINFO



Notes:

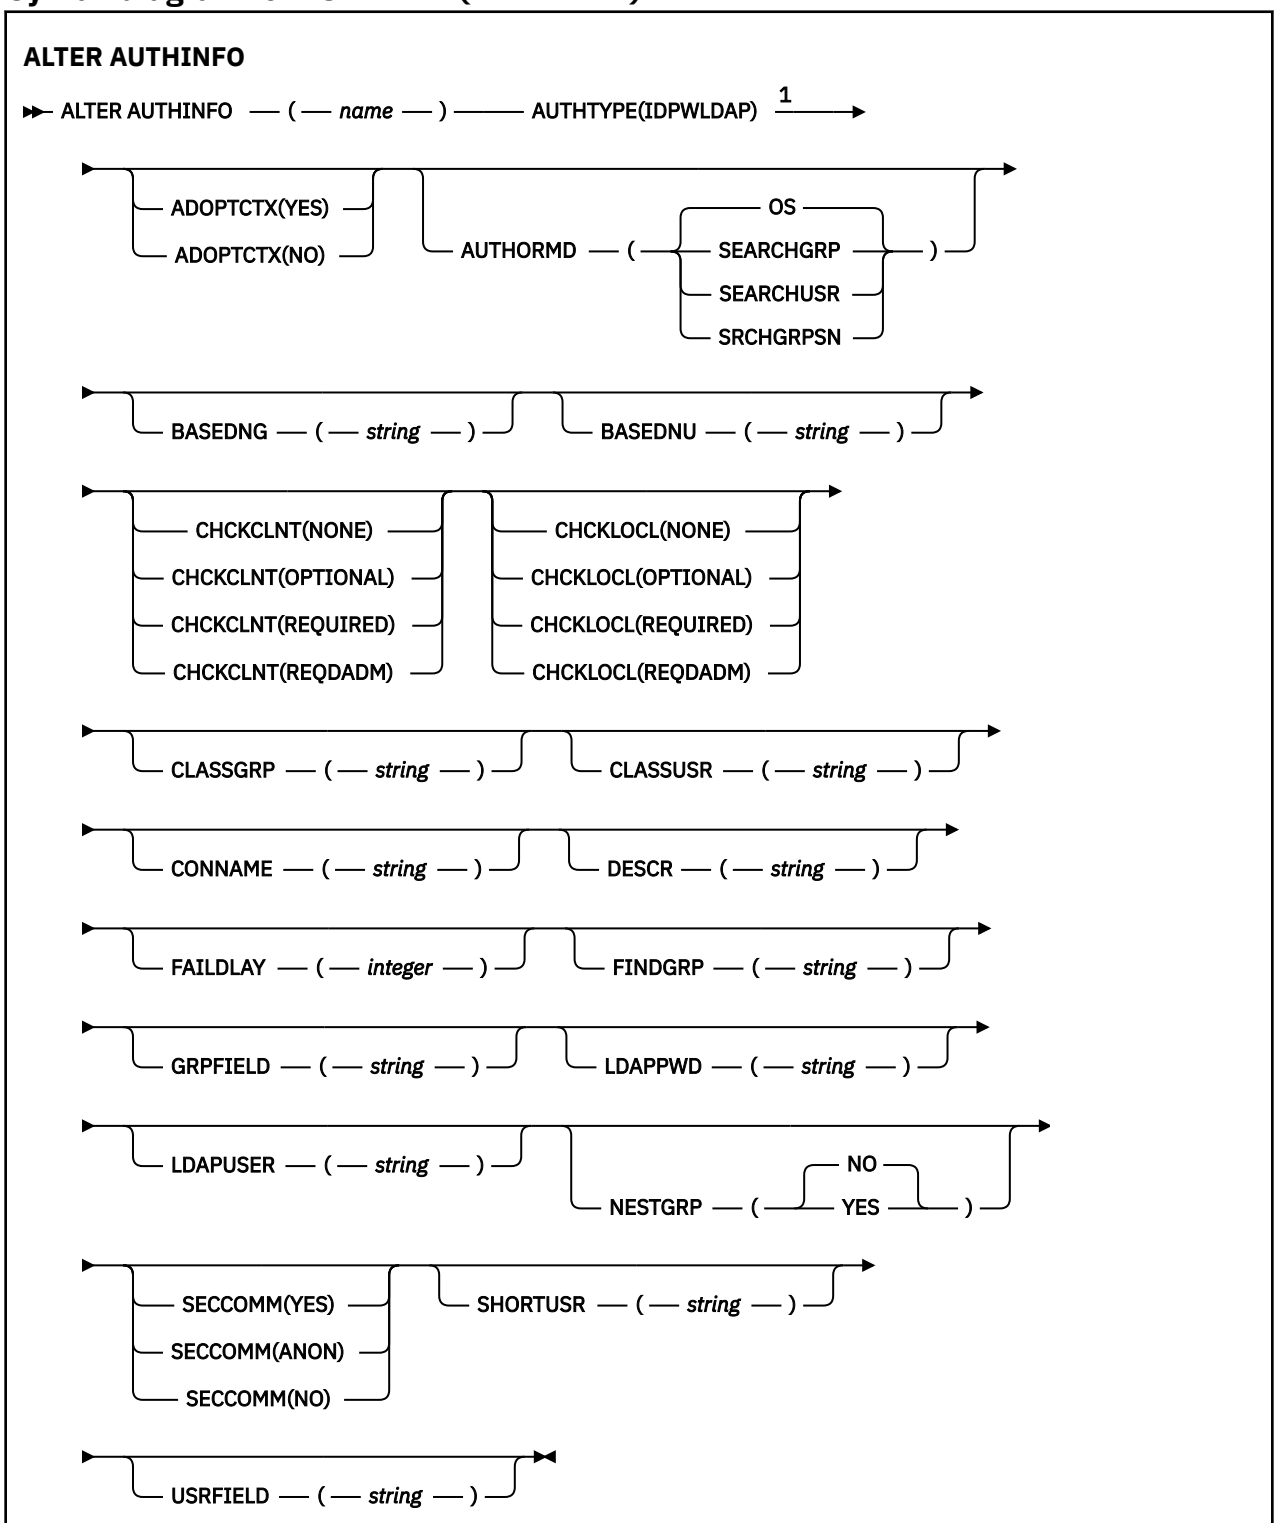
[1] Valid only when the queue manager is a member of a queue sharing group. You can use queue sharing groups only on IBM MQ for z/OS.

[2] Valid only on z/OS.

[3] Not valid on z/OS and PAM value can be set only on AIX and Linux.

[4] Not valid on z/OS.

Syntax diagram for AUTHTYPE(IDPWLDAP)



Notes:

1 Not valid on z/OS.

Parameter descriptions for ALTER AUTHINFO

name
Name of the authentication information object. This parameter is required.

The name must not be the same as any other authentication information object name currently defined on this queue manager (unless **REPLACE** or **ALTER** is specified). See Rules for naming IBM MQ objects.

ADOPTCTX
Whether to use the presented credentials as the context for this application. This means that they are used for authorization checks, shown on administrative displays, and appear in messages.

YES
The user ID presented in the MQCSP structure, which has been successfully validated by password, is adopted as the context to use for this application. Therefore, this user ID will be the credentials checked for authorization to use IBM MQ resources.

If the user ID presented is an LDAP user ID, and authorization checks are done using operating system user IDs, the SHORTUSR associated with the user entry in LDAP will be adopted as the credentials for authorization checks to be done against.

NO
Authentication is performed on the user ID and password presented in the MQCSP structure, but then the credentials are not adopted for further use. Authorization is performed using the user ID that the application is running under.

The **ADOPTCTX** attribute is only valid for an **AUTHTYPE** of IDPWOS and IDPWLDAP.

AUTHENMD
Authentication method. Whether to use the operating system or Pluggable Authentication Method (PAM) to authenticate user passwords.

OS

Use the traditional UNIX password verification method.

PAM
Use the PAM to authenticate the user password.

You can set the PAM value only on AIX and Linux.

Changes to this attribute are effective only after you run the REFRESH SECURITY TYPE(CONNAUTH) command.

The **AUTHENMD** attribute is valid only for an **AUTHTYPE** of IDPWOS.

AUTHORMD
Authorization method.

OS
Use operating system groups to determine permissions associated with a user.

This is how IBM MQ has previously worked, and is the default value.

SEARCHGRP
A group entry in the LDAP repository contains an attribute listing the Distinguished Name of all the users belonging to that group. Membership is indicated by the attribute defined in FINDGRP. This value is typically *member* or *uniqueMember*.

SEARCHUSR
A user entry in the LDAP repository contains an attribute listing the Distinguished Name of all the groups to which the specified user belongs. The attribute to query is defined by the FINDGRP value, typically *memberOf*.

SRCHGRPSN
A group entry in the LDAP repository contains an attribute listing the short user name of all the users belonging to that group. The attribute in the user record that contains the short user name is specified by SHORTUSR.

Membership is indicated by the attribute defined in FINDGRP. This value is typically *memberUid*.

Note: This authorization method should only be used if all user short names are distinct.

Many LDAP servers use an attribute of the group object to determine group membership and you should, therefore, set this value to SEARCHGRP.

Microsoft Active Directory typically stores group memberships as a user attribute. The IBM Tivoli Directory Server supports both methods.

In general, retrieving memberships through a user attribute will be faster than searching for groups that list the user as a member.

AUTHTYPE
The type of authentication information.

CRLLDAP
Certificate Revocation List checking is done using LDAP servers.

IDPWLDAP
Connection authentication user ID and password checking is done using an LDAP server.

IDPWOS
Connection authentication user ID and password checking is done using the operating system.

OCSP
Certificate revocation checking is done using OCSP.

An authentication information object with **AUTHTYPE(OCSP)** does not apply for use on IBM i or z/OS queue managers. However, it can be specified on those platforms to be copied to the client channel definition table (CCDT) for client use.

The **AUTHTYPE** parameter is required.

You cannot define an authentication information object as LIKE another authentication object with a different **AUTHTYPE**. You cannot alter the **AUTHTYPE** of an authentication information object after you have created it.

BASEDNG
Base DN for groups.

In order to be able to find group names, this parameter must be set with the base DN to search for groups in the LDAP server.

BASEDNU(*base DN*)
In order to be able to find the short user name attribute, SHORTUSR, this parameter must be set with the base DN to search for users within the LDAP server.

The **BASEDNU** attribute is valid only for an **AUTHTYPE** of IDPWLDAP.

CHCKCLNT
This attribute determines the authentication requirements for client applications, and is valid only for an **AUTHTYPE** of IDPWOS or IDPWLDAP. The possible values are:

NONE
No user ID and password checks are made. If any user ID or password is supplied by a client application, the credentials are ignored.

OPTIONAL
Client applications are not required to provide a user ID and password.

Any applications that do provide a user ID and password in the MQCSP structure have them authenticated by the queue manager against the password store indicated by the **AUTHTYPE**.

The connection is only allowed to continue if the user ID and password are valid.

This option might be useful during migration, for example.

REQUIRED
All client applications must provide a user ID and password in the MQCSP structure. This user ID and password is authenticated by the queue manager against the password store indicated by the **AUTHTYPE**.

The connection will only be allowed to continue if the user ID and password are valid.

REQDADM
All client applications using a privileged user ID must provide a user ID and password in the MQCSP structure. Any locally bound applications using a non-privileged user ID are not required to provide a user ID and password and are treated as with the OPTIONAL setting.

Any provided user ID and password are authenticated by the queue manager against the password store indicated by the **AUTHTYPE**. The connection is only allowed to continue if the user ID and password are valid.

Note: The REQDADM value for the **CHCKCLNT** attribute is irrelevant if the authentication type is LDAP. This is because there is no concept of privileged user ID when using LDAP user accounts. LDAP user accounts and groups must be assigned permission explicitly.

A privileged user is one that has full administrative authorities for IBM MQ. See Privileged users for more information.

z/OS This setting is not allowed on z/OS systems.

Important:

1. This attribute can be overridden by the **CHCKCLNT** attribute of the CHLAUTH rule that matches the client connection. The CONNAUTH *AUTHINFO CHCKCLNT* attribute on the queue manager therefore determines the default client checking behavior for client connections that do not match a CHLAUTH rule, or where the CHLAUTH rule matched has **CHCKCLNT** ASQMGR.
2. If you select NONE and the client connection matches a CHLAUTH record with **CHCKCLNT** REQUIRED (or REQDADM on platforms other than z/OS), the connection fails. You receive the following message:
   - Multi AMQ9793 on Multiplatforms.
   - z/OS CSQX793E on z/OS.
3. This parameter is valid only with **TYPE(USERMAP)**, **TYPE(ADDRESSMAP)** and TYPE (SSLPEERMAP), and only when **USERSRC** is not set to NOACCESS.
4. This parameter applies only to inbound connections that are server-connection channels.

CHCKLOCL
This attribute determines the authentication requirements for locally bound applications, and is valid only for an **AUTHTYPE** of IDPWOS or IDPWLDAP.

MQ Appliance For information about use of this attribute on IBM MQ Appliance, see Control commands on the IBM MQ Appliance in the IBM MQ Appliance documentation.

The possible values are:

NONE
No user ID and password checks are made. If any user ID or password is supplied by a locally bound application, the credentials are ignored.

OPTIONAL
Locally bound applications are not required to provide a user ID and password.

Any applications that do provide a user ID and password in the MQCSP structure have them authenticated by the queue manager against the password store indicated by the **AUTHTYPE**.

The connection is only allowed to continue if the user ID and password are valid.

This option might be useful during migration, for example.

REQUIRED
All locally bound applications must provide a user ID and password in the MQCSP structure. This user ID and password will be authenticated by the queue manager against the password store indicated by the **AUTHTYPE**. The connection will only be allowed to continue if the user ID and password are valid.

z/OS If your user ID has UPDATE access to the BATCH profile in the MQCONN class, you can treat **CHCKLOCL(REQUIRED)** as if it is **CHCKLOCL(OPTIONAL)**. That is, you do not have to supply a password, but if you do, the password must be the correct one.

See Using **CHCKLOCL** on locally bound applications.

REQDADM
All locally bound applications using a privileged user ID must provide a user ID and password in the MQCSP structure. Any locally bound applications using a non-privileged user ID are not required to provide a user ID and password and are treated as with the OPTIONAL setting.

Any provided user ID and password will be authenticated by the queue manager against the password store indicated by the **AUTHTYPE**. The connection will only be allowed to continue if the user ID and password are valid.

A privileged user is one that has full administrative authorities for IBM MQ. See Privileged users for more information.

z/OS (This setting is not allowed on z/OS systems.)

CLASSGRP
The LDAP object class used for group records in the LDAP repository.

If the value is blank, `groupOfNames` is used.

Other commonly used values include `groupOfUniqueNames` or `group`.

CLASSUSR(*LDAP class user*)
The LDAP object class used for user records in the LDAP repository.

If blank, the value defaults to `inetOrgPerson`, which is generally the value needed.

For Microsoft Active Directory, the value you require is often *user*.

This attribute is valid only for an **AUTHTYPE** of IDPWLDAP.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

' '
The command runs on the queue manager on which it was entered.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of * is the same as entering the command on every queue manager in the queue sharing group.

CONNAME(*connection_name*)
The host name, IPv4 dotted decimal address, or IPv6 hexadecimal notation of the host on which the LDAP server is running, with an optional port number.

If you specify the connection name as an IPv6 address, only systems with an IPv6 stack are able to resolve this address. If the **AUTHINFO** object is part of the CRL namelist of the queue manager, ensure that any clients using the client channel table generated by the queue manager can resolve the connection name.

z/OS On z/OS, if a **CONNAME** is to resolve to an IPv6 network address, a level of z/OS that supports IPv6 for connection to an LDAP server is required.

The syntax for **CONNAME** is the same as for channels. For example,

```
conname('hostname (nnn)')
```

where *nnn* is the port number.

The maximum length for the field is:

- Multi 264 characters on Multiplatforms.
- z/OS 48 characters on z/OS.

This attribute is valid only for an **AUTHTYPE** of CRLLDAP and IDPWLDAP, when the attribute is mandatory.

When used with an **AUTHTYPE** of IDPWLDAP, this can be a comma separated list of connection names.

DESCR(*string*)
Plain-text comment. It provides descriptive information about the authentication information object when an operator issues the **DISPLAY AUTHINFO** command (see "DISPLAY AUTHINFO (display authentication information)" on page 622).

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

FAILDLAY(*delay time*)
When a user ID and password are provided for connection authentication, and the authentication fails due to the user ID or password being incorrect, this is the delay, in seconds, before the failure is returned to the application.

This can aid in avoiding busy loops from an application that simply retries, continuously, after receiving a failure.

The value must be in the range 0 - 60 seconds. The default value is 1.

The **FAILDLAY** attribute is valid only for an **AUTHTYPE** of IDPWOS and IDPWLDAP.

FINDGRP
Name of the attribute used within an LDAP entry to determine group membership.

When AUTHORMD = *SEARCHGRP*, the **FINDGRP** attribute is typically set to *member* or *uniqueMember*.

When AUTHORMD = *SEARCHUSR*, the **FINDGRP** attribute is typically set to *memberOf*.

When AUTHORMD = *SRCHGRPSN*, the **FINDGRP** attribute is typically set to *memberUid*.

When left blank, if:

- AUTHORMD = *SEARCHGRP*, the **FINDGRP** attribute defaults to *memberOf*
- AUTHORMD = *SEARCHUSR*, the **FINDGRP** attribute defaults to *member*
- AUTHORMD = *SRCHGRPSN*, the **FINDGRP** attribute defaults to *memberUid*

GRPFIELD
LDAP attribute that represents a simple name for the group.

If the value is blank, commands like **setmqaut** must use a qualified name for the group. The value can either be a full DN, or a single attribute.

LDAPPWD(*LDAP_password*)
The password associated with the Distinguished Name of the user who is accessing the LDAP server. Its maximum size is 32 characters.

z/OS On z/OS, the **LDAPPWD** used for accessing the LDAP server might not be the one defined in the AUTHINFO object. If more than one AUTHINFO object is placed in the namelist referred to by the QMGR parameter **SSLCRLNL**, the **LDAPPWD** in the first AUTHINFO object is used for accessing all LDAP Servers.

The **GRPFIELD** attribute is valid only for an **AUTHTYPE** of CRLLDAP and IDPWLDAP.

LDAPUSER(*LDAP_user*)
The Distinguished Name of the user who is accessing the LDAP server. (See the SSLPEER parameter for more information about distinguished names.)

The maximum size for the user name is:

- Multi 1024 characters on Multiplatforms.
- z/OS 256 characters on z/OS.

z/OS On z/OS, the **LDAPUSER** used for accessing the LDAP server might not be the one defined in the AUTHINFO object. If more than one AUTHINFO object is placed in the namelist referred to by the QMGR parameter **SSLCRLNL**, the **LDAPUSER** in the first AUTHINFO object is used for accessing all LDAP Servers.

V 9.2.0 From IBM MQ 9.2.0, if more than one OCSP type AUTHINFO objects is referenced in the NAMELIST, only the first entry will be used.

Multi On Multiplatforms, the maximum accepted line length is defined to be BUFSIZ, which can be found in stdio.h.

The **LDAPUSER** attribute is valid only for an **AUTHTYPE** of CRLLDAP and IDPWLDAP.

NESTGRP
Group nesting.

NO
Only the initially discovered groups are considered for authorization.

YES
The group list is searched recursively to enumerate all the groups to which a user belongs.

The group's Distinguished Name is used when searching the group list recursively, regardless of the authorization method selected in AUTHORMD.

OCSPURL(*Responder URL*)
The URL of the OCSP responder used to check for certificate revocation. This value must be an HTTP URL containing the host name and port number of the OCSP responder. If the OCSP responder is using port 80, which is the default for HTTP, then the port number can be omitted. HTTP URLs are defined in RFC 1738.

This field is case sensitive. It must start with the string `http://` in lowercase. The rest of the URL might be case sensitive, depending on the OCSP server implementation. To preserve case, use single quotation marks to specify the OCSPURL parameter value, for example:

```
OCSPURL ('http://ocsp.example.ibm.com')
```

This parameter is applicable only for **AUTHTYPE(OCSP)**, when it is mandatory.

z/OS **QSGDISP**
This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

Table 122. Behavior for each of the QSGDISP values

QSGDISP	ALTER
COPY	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters **QSGDISP(COPY)**. Any object residing in the shared repository, or any object defined using a command that had the parameters **QSGDISP(QMGR)**, is not affected by this command.

Table 122. Behavior for each of the QSGDISP values (continued)

QSGDISP	**ALTER**

GROUP	The object definition resides in the shared repository. The object was defined using a command that had the parameters **QSGDISP(GROUP)**. Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command. If the command is successful, the following command is generated and sent to all active queue managers in the queue sharing group to attempt to refresh local copies on page set zero:
	`DEFINE AUTHINFO(name)`
	`REPLACE QSGDISP(COPY)`
	The ALTER for the group object takes effect regardless of whether the generated command with **QSGDISP(COPY)** fails.

PRIVATE	The object resides on the page set of the queue manager that executes the command, and was defined with **QSGDISP(QMGR)** or **QSGDISP(COPY)**. Any object residing in the shared repository is unaffected.
QMGR	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters **QSGDISP(QMGR)**. Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

SECCOMM
Whether connectivity to the LDAP server should be done securely using TLS

YES
Connectivity to the LDAP server is made securely using TLS.

The certificate used is the default certificate for the queue manager, named in CERTLABL on the queue manager object, or if that is blank, the one described in Digital certificate labels, understanding the requirements.

The certificate is located in the key repository specified in SSLKEYR on the queue manager object. A cipherspec will be negotiated that is supported by both IBM MQ and the LDAP server.

If the queue manager is configured to use **SSLFIPS(YES)** or SUITEB cipher specs, then this is taken account of in the connection to the LDAP server as well.

ANON
Connectivity to the LDAP server is made securely using TLS just as for **SECCOMM(YES)** with one difference.

No certificate is sent to the LDAP server; the connection will be made anonymously. To use this setting, ensure that the key repository specified in SSLKEYR, on the queue manager object, does not contain a certificate marked as the default.

NO
Connectivity to the LDAP server does not use TLS.

The **SECCOMM** attribute is valid only for an **AUTHTYPE** of IDPWLDAP.

SHORTUSR(*user name*)
A field in the user record to be used as a short user name in IBM MQ.

This field must contain values of 12 characters or less. This short user name is used for the following purposes:

- If LDAP authentication is enabled, but LDAP authorization is not enabled, this is used as an operating system user ID for authorization checks. In this case, the attribute must represent an operating system user ID.

- If LDAP authentication and authorization are both enabled, this is used as the user ID carried with the message in order for the LDAP user name to be rediscovered when the user ID inside the message needs to be used.

  For example, on another queue manager, or when writing report messages. In this case, the attribute does not need to represent an operating system user ID, but must be a unique string. An employee serial number is an example of a good attribute for this purpose.

The **SHORTUSR** attribute is valid only for an **AUTHTYPE** of IDPWLDAP and is mandatory.

USRFIELD(*user field*)
If the user ID provided by an application for authentication does not contain a qualifier for the field in the LDAP user record, that is, it does not contain an ' = ' sign, this attribute identifies the field in the LDAP user record that is used to interpret the provided user ID.

This field can be blank. If this is the case, any unqualified user IDs use the SHORTUSR parameter to interpret the provided user ID.

The contents of this field are concatenated with an ' = ' sign, together with the value provided by the application, to form the full user ID to be located in an LDAP user record. For example, the application provides a user of `fred` and this field has the value `cn`, then the LDAP repository will be searched for `cn=fred`.

The **USRFIELD** attribute is valid only for an **AUTHTYPE** of IDPWLDAP.

z/OS ALTER BUFFPOOL (alter buffer pool settings) on z/OS

Use the MQSC command **ALTER BUFFPOOL** to dynamically change the settings of a predefined buffer pool on z/OS.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

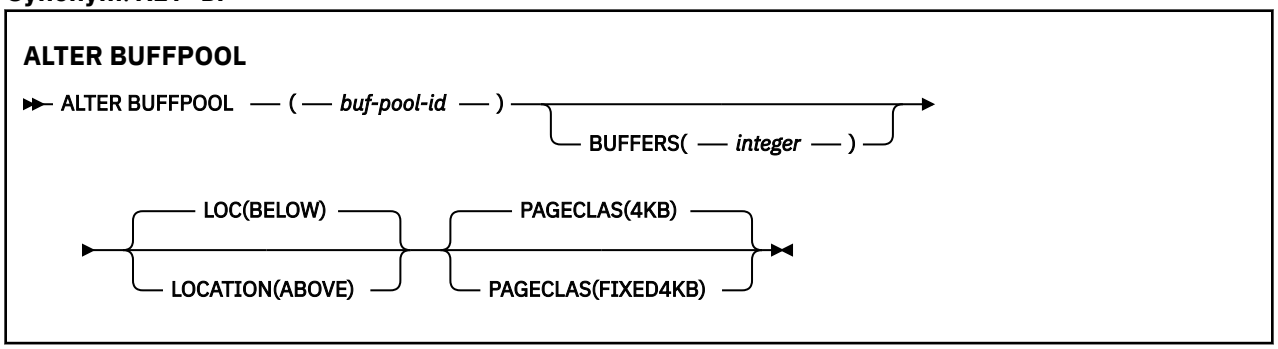
Parameters not specified in the **ALTER BUFFPOOL** command result in the existing values for those parameters being left unchanged.

You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Usage notes for ALTER BUFFPOOL" on page 249
- "Parameter descriptions for ALTER BUFFPOOL" on page 249

Syntax diagram

Synonym: **ALT BP**



Usage notes for ALTER BUFFPOOL

1. Buffers are added or removed according to whether the value is more than or less than the current allocation (which can be shown by the DISPLAY USAGE command).
2. If there is insufficient storage, of the type specified by the PAGECLAS attribute to add the requested number, as many as possible are added.
3. The command runs asynchronously. Message CSQP023I is sent to the console when the command is complete.
4. **ALTER BUFFPOOL** cannot be issued from CSQINPT.
5. If you have made changes to buffer pools by using the ALTER BUFFPOOL command, particularly if you have reduced the buffer pools by large quantities, you should recycle the queue manager as soon as possible, to clear up any storage fragmentation caused by the change in buffer pool size.

   Failure to recycle the queue manager, might result in you receiving the following error code, `ABEND878-10 - Virtual private region depleted`, caused by the fragmentation of region storage in the IBM MQ MSTR address space.

6. V 9.2.0 Certain buffer pool parameters require **OPMODE** to be set to *NEWFUNC* at IBM MQ for z/OS 9.0.0. If you enable these parameters at IBM MQ for z/OS 9.1.0 or later, and subsequently migrate back to IBM MQ for z/OS 9.0.0, ensure that you are using **OPMODE**=*NEWFUNC* at those releases. Affected parameters are:

   - A **LOCATION** value of *ABOVE*
   - A **PAGECLAS** value of *FIXED4KB*
   - A `buf-pool-id` greater than 15

Parameter descriptions for ALTER BUFFPOOL

(buf-pool-id)
Buffer pool identifier.

This parameter is an integer in the range zero through 99.

See usage note "6" on page 249.

BUFFERS(*integer*)
This parameter is optional and is the number of 4096 byte buffers to be used in this buffer pool.

If the value of the **LOCATION** parameter is `BELOW`, the minimum value of buffers is 100 and the maximum value is 500,000. If the value of the **LOCATION** parameter is `ABOVE`, then valid values are in the range of 100 to 999999999 (nine nines). The storage used for buffers in a buffer pool with **LOCATION ABOVE** is obtained in multiples of 4MB. Therefore specifying a **BUFFERS** value which is a multiple of 1024 will make the most efficient use of storage.

See Buffers and buffer pools for guidance on the number of buffers you can define in each buffer pool.

When defining a buffer pool care should be taken to ensure that there is sufficient storage available for it either above or below the bar. For more information, see Address space storage.

Note: Creating a large buffer pool can take several minutes depending on size of the buffer pool and machine configuration. In some cases message CSQP061I might be output.

LOCATION or LOC(BELOW or ABOVE)
LOCATION and **LOC** are synonyms and either, but not both, can be used.

The **LOCATION** or **LOC** parameter specifies where the memory used by the specified buffer pool is located.

Attention: From IBM MQ 9.1, LOCATION(BELOW) is deprecated and you should use LOCATION(ABOVE) only.

This memory location can be either `ABOVE` (64 bit) or `BELOW` (31 bit) the bar, with `BELOW` being the default.

See usage note "6" on page 249.

When altering a buffer pool, you should take care to make sure that there is sufficient storage available if increasing the number of buffers, or changing the **LOCATION** value. Switching the location of the buffer pool can be a CPU and I/O intensive task. You should perform this task when the queue manager is not being heavily used.

For more information, see Address space storage.

PAGECLAS(4KB or FIXED4KB)

Optional parameter that describes the type of virtual storage pages used for backing the buffers in the buffer pool.

This attribute applies to all buffers in the buffer pool, including any that are added later as a result of using the **ALTER BUFFPOOL** command. The default value is 4KB, which means that pageable 4KB pages are used to back the buffers in the pool.

4KB is the only valid value if the buffer pool has its location attribute set to BELOW. If the buffer pool has its LOCATION attribute set to ABOVE, it is also possible to specify FIXED4KB. This means that fixed 4KB pages, which are permanently in real storage and will never be paged out to auxiliary storage, are used to back the buffers in the buffer pool.

See usage note "6" on page 249.

The **PAGECLAS** attribute of a buffer pool can be altered at any time. However, the alteration only takes place when the buffer pool switches location from above the bar to below the bar, or the other way round. Otherwise, the value is stored in the log of the queue manager and is applied when the queue manager next restarts.

The current value of **PAGECLAS** can be checked by issuing the **DISPLAY USAGE PSID(*)** command. Doing this also results in a CSQP062I message being output, if the current value of **PAGECLAS** is different from the value in the log of the queue manager. For example:

- Buffer pool 7 currently has **LOCATION(ABOVE)** and **PAGECLAS(4KB)** specified. If **ALTER BUFFPOOL(7) PAGECLAS(FIXED4KB)** is specified, the buffer pool continues to be backed by pageable 4KB pages as the **LOCATION** has not been changed.
- Buffer pool 8 currently has **LOCATION(BELOW)** and **PAGECLAS(4KB)** specified. If **ALTER BUFFPOOL(8) LOCATION(ABOVE) PAGECLAS(FIXED4KB)** is specified, the buffer pool is moved above the bar and has its buffers backed by fixed 4KB pages, if any are available.

When you specify **PAGECLAS(FIXED4KB)** the whole buffer pool is backed by page-fixed 4KB pages, so ensure that there is sufficient real storage available on the LPAR. Otherwise, the queue manager might not start, or other address spaces might be impacted; for more information, see Address space storage.

See IBM MQ Support Pac MP16: IBM MQ for z/OS - Capacity planning & tuning for advice on when to use the FIXED4KB value of the **PAGECLAS** attribute.

z/OS ALTER CFSTRUCT (alter CF application structure) on z/OS

On z/OS, use the MQSC command **ALTER CFSTRUCT** to alter the CF application structure backup and recovery parameters, and offload environment parameters for any specified application structure.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

Parameters not specified in the **ALTER CFSTRUCT** command result in the existing values for those parameters being left unchanged.

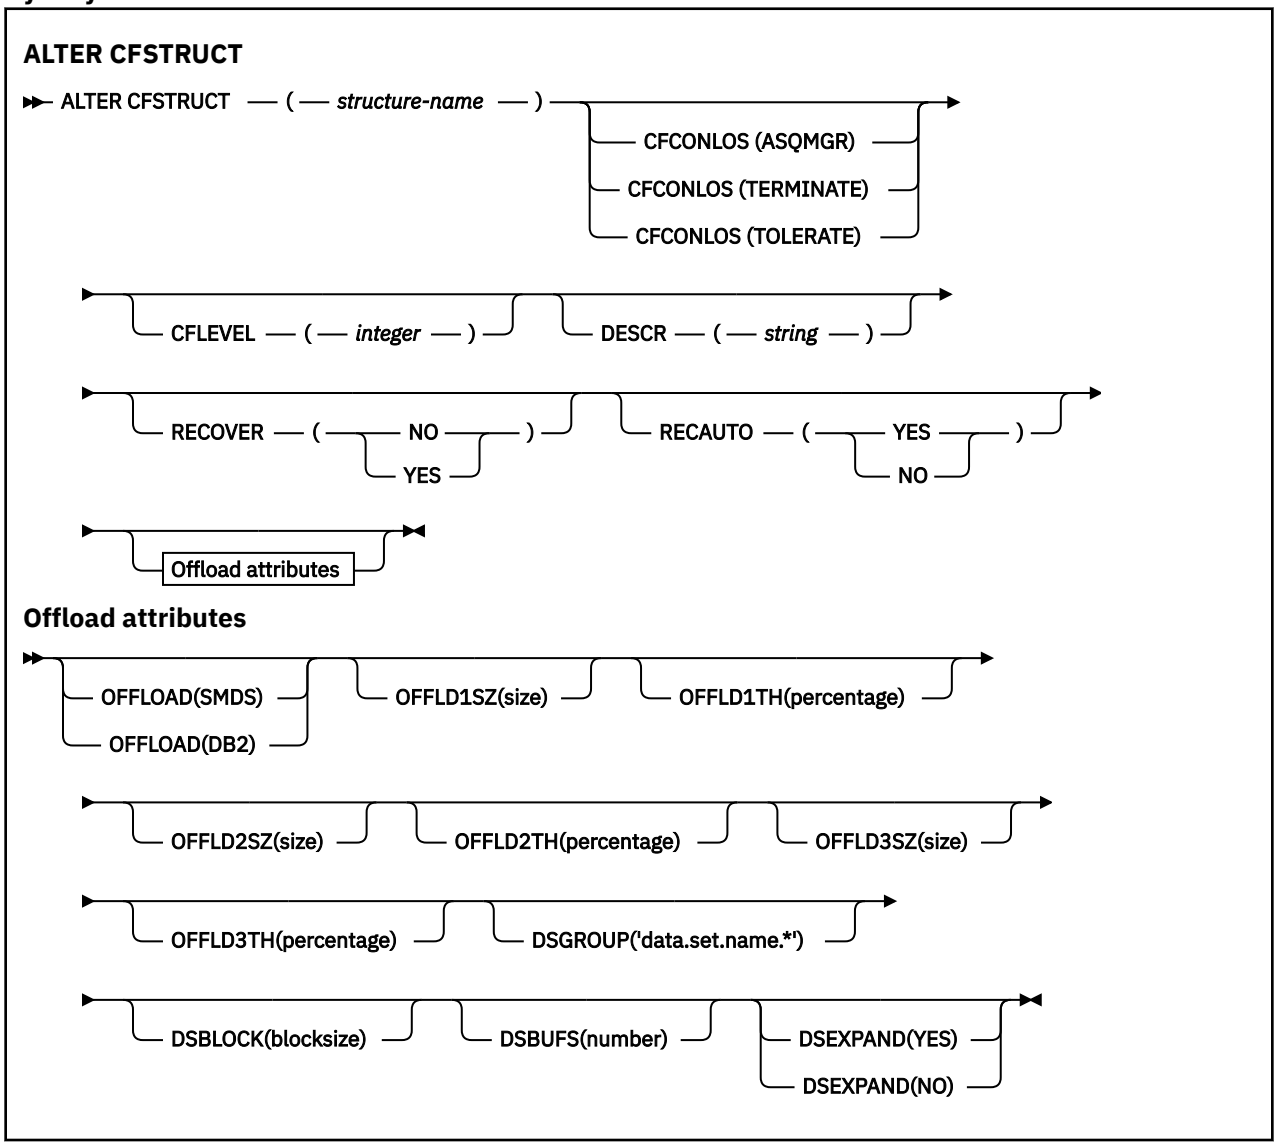
You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Usage notes" on page 251

- "Parameter descriptions for ALTER CFSTRUCT" on page 251

Syntax diagram

Synonym: **ALT CFSTRUCT**



Usage notes

- This command cannot specify the CF administration structure (CSQ_ADMIN).
- This command is valid only when the queue manager is a member of a queue sharing group.

Parameter descriptions for ALTER CFSTRUCT

(structure-name)

Name of the coupling facility application structure with queue manager CF level capability and backup and recovery parameters you want to define. This parameter is required.

The name:

- Cannot have more than 12 characters.
- Must start with an uppercase letter (A through Z).
- Can include only the characters A through Z and 0 through 9.

The name of the queue sharing group to which the queue manager is connected is prefixed to the name you supply. The name of the queue sharing group is always four characters, padded with @ symbols if necessary. For example, if you use a queue sharing group named NY03 and you supply the name PRODUCT7, the resultant coupling facility structure name is NY03PRODUCT7. The administrative structure for the queue sharing group (in this case NY03CSQ_ADMIN) cannot be used for storing messages.

CFCONLOS
This parameter specifies the action to be taken when a queue manager loses connectivity to the CF structure. The value can be:

ASQMGR

The action taken is based on the setting of the **CFCONLOS** queue manager attribute.

TERMINATE

The queue manager terminates when connectivity to the structure is lost. This is the default value when **CFLEVEL** is increased to 5.

TOLERATE

The queue manager tolerates loss of connectivity to the structure without terminating.

The **CFCONLOS** parameter is only valid from **CFLEVEL(5)**.

CFLEVEL(*integer*)
Specifies the functional capability level for this CF application structure. Value can be one of the following:

1
A CF structure that can be "auto-created" by a queue manager at command level 520.

2
A CF structure at command level 520 that can only be created or deleted by a queue manager at command level 530 or greater.

3
A CF structure at command level 530. This **CFLEVEL** is required if you want to use persistent messages for either one or both of the following reasons:

- On shared queues, if **RECOVER(YES)** is set.
- For message grouping when a local queue is defined with **INDXTYPE(GROUPID)**.

You can only increase the value of **CFLEVEL** to 3 if all the queue managers in the queue sharing group are at command level 530 or greater - this is to ensure that there are no latent command level 520 connections to queues referencing the structure.

You can only decrease the value of **CFLEVEL** from 3 if all the queues that reference the CF structure are both empty (have no messages or uncommitted activity) and closed.

4
This **CFLEVEL** supports all the **CFLEVEL(3)** functions. **CFLEVEL(4)** allows queues defined with CF structures at this level to have messages with a length greater than 63 KB.

Only a queue manager with a command level of 600 or greater can connect to a CF structure at **CFLEVEL(4)**.

You can only increase the value of **CFLEVEL** to 4 if all the queue managers in the queue sharing group are at command level 600 or greater.

You can only decrease the value of **CFLEVEL** from 4 if all the queues that reference the CF structure are both empty (have no messages or uncommitted activity) and closed.

5
This **CFLEVEL** supports all functions for **CFLEVEL(4)**. In addition, **CFLEVEL(5)** enables the following new functions. If altering an existing **CFSTRUCT** to **CFLEVEL(5)**, you must review other attributes as indicated:

- Queues defined with CF structures at this level can have message data offloaded to either shared message data sets (SMDS), or Db2®, under control of the **OFFLOAD** attribute. The offload threshold and size parameters (such as **OFFLD1TH**, and **OFFLD1SZ**) determine whether any particular messages are offloaded given its size and current CF structure utilization. If using SMDS offload, the **DSGROUP**, **DSBUFS**, **DSEXPAND** and **DSBLOCK** attributes are respected.
- Structures at **CFLEVEL(5)** allow the queue manager to tolerate a loss of connectivity to the CF structure. The **CFCONLOS** attribute determines queue manager behavior when a loss of connectivity is detected, and the **RECAUTO** attribute controls subsequent automatic structure recovery behavior.
- Messages containing IBM MQ message properties are stored in a different format on shared queues in a **CFLEVEL(5)** structure. This format leads to internal processing optimizations. Additional application migration capabilities are also available and these are enabled via the queue **PROPCTL** attribute.

Only a queue manager with a command level of 710 or above can connect to a CF structure at **CFLEVEL(5)**.

Note: You can decrease the value of **CFLEVEL** from 5 if all the queues that reference the CF structure are both empty, that is the queues, and CF structure have no messages or uncommitted activity, and are closed.

DESCR(*string*)
Plain-text comment that provides descriptive information about the object when an operator issues the **DISPLAY CFSTRUCT** command.

The string should contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

OFFLOAD
Specify whether offloaded message data is to be stored in a group of shared message data sets or in Db2.

SMDS
Offload messages from coupling facility to shared message data set (SMDS).

DB2
Offload messages from coupling facility to Db2. This value is the default assumption when **CFLEVEL** is increased to 5.

Offloading messages using Db2 has significant performance impact. If you want to use offload rules as a means of increasing capacity, the SMDS option should be specified.

This parameter is only valid from **CFLEVEL(5)**. At **CFLEVEL(4)** any message offloading is always to Db2, and only applies to messages greater than the maximum coupling facility entry size.

Note: If you change the offload technique (from Db2 to SMDS or the other way) then all new messages will be written using the new method but any existing large messages stored using the previous technique can still be retrieved. The relevant Db2 message table or shared message data sets will continue to be used until the queue managers have detected that there are no further messages stored in the old format.

If SMDS is specified, then the **DSGROUP** parameter is also required. It can be specified either on the same command or on a previous **DEFINE** or **ALTER** command for the same structure.

OFFLD1TH(*percentage*) OFFLD1SZ(*size*)
OFFLD2TH(*percentage*) OFFLD2SZ(*size*)
OFFLD3TH(*percentage*) OFFLD3SZ(*size*)
Specify rules for when messages smaller than the maximum coupling facility entry size are to be offloaded to external storage (shared message data sets or Db2 tables) instead of being stored in the application structure. These rules can be used to increase the effective capacity of the structure. The offloaded message still requires an entry in the coupling facility containing message control

information, and a descriptor referring to the offloaded message data, but the amount of structure space required is less than the amount that would be needed to store the whole message.

If the message data is very small (less than approximately 140 bytes) it may fit into the same coupling facility entry as the message control information, without needing additional data elements. In this case, no space can be saved, so any offload rules are ignored and the message data is not offloaded.

Messages exceeding the maximum coupling facility entry size (63.75 KB including control information) are always offloaded as they cannot be stored in a coupling facility entry. Messages where the message body exceeds 63 KB are also offloaded to ensure that enough space is available for the control information. Additional rules to request offloading of smaller messages can be specified using these pairs of keywords. Each rule indicates that when the usage of the structure (in either elements or entries) exceeds the specified threshold percentage value, the message data will be offloaded if the total size of the coupling facility entry required to store the whole message (including message data, headers and descriptors) exceeds the specified size value. Headers and descriptors typically require approximately 400 bytes.

percentage
The usage threshold percentage value is an integer in the range 0 (meaning this rule always applies) to 100 (meaning this rule only applies when the structure is full).

size
The message size value should be specified as an integer followed by K, giving the number of kilobytes in the range 0K to 64K. As messages exceeding 63.75 KB are always offloaded, the value 64K is allowed as a simple way to indicate that the rule is not being used.

In general, the smaller the numbers, the more messages are offloaded.

A message is offloaded if any offload rule matches. The normal convention is that a later rule would be for a higher usage level and a smaller message size than an earlier one, but no check is made for consistency or redundancy between the rules.

When structure **ALTER** processing is active, the number of used elements or entries can temporarily exceed the reported total number, giving a percentage exceeding 100, because the new elements or entries are made available during **ALTER** processing but the total is only updated when the **ALTER** completes. At such times, a rule specifying 100 for the threshold may temporarily take effect. If a rule is not intended to be used at all, it should specify 64K for the size.

The default values assumed for the offload rules when defining a new structure at **CFLEVEL(5)** or upgrading an existing structure to **CFLEVEL(5)** depend on the **OFFLOAD** method option. For **OFFLOAD(SMDS)**, the default rules specify increasing amounts of offloading as the structure becomes full. This increases the effective structure capacity with minimal performance impact. For **OFFLOAD(Db2)**, the default rules have the same threshold values as for SMDS but the size values are set to 64K so that the rules never apply and messages are offloaded only if they are too large to be stored in the structure, as for **CFLEVEL(4)**.

For **OFFLOAD(SMDS)** the defaults are:

- **OFFLD1TH(70) OFFLD1SZ(32K)**
- **OFFLD2TH(80) OFFLD2SZ(4K)**
- **OFFLD3TH(90) OFFLD3SZ(0K)**

For **OFFLOAD(Db2)** the defaults are:

- **OFFLD1TH(70) OFFLD1SZ(64K)**
- **OFFLD2TH(80) OFFLD2SZ(64K)**
- **OFFLD3TH(90) OFFLD3SZ(64K)**

If the **OFFLOAD** method option is changed from Db2 to SMDS or back when the current offload rules all match the default values for the old method, the offload rules are switched to the default values for the new method. However, if any of the rules have been changed, the current values are kept when switching method.

These parameters are only valid from **CFLEVEL(5)**. At **CFLEVEL(4)**, any message offloading is always to Db2, and only applies to messages greater than the maximum coupling facility entry size.

DSGROUP
For **OFFLOAD(SMDS)**, specify the generic data set name to be used for the group of shared message data sets associated with this structure (one for each queue manager), with exactly one asterisk indicating where the queue manager name should be inserted to form the specific data set name.

'*data.set.name.*'
The value must be a valid data set name when the asterisk is replaced by a queue manager name of up to four characters. The queue manager name can form all or part of any qualifier in the data set name.

The entire parameter value must be enclosed in quotation marks.

This parameter cannot be changed after any data sets have been activated for the structure.

If SMDS is specified, then the **DSGROUP** parameter must also be specified.

The **DSGROUP** parameter is only valid from **CFLEVEL(5)**.

DSBLOCK
For **OFFLOAD(SMDS)**, specify the logical block size, which is the unit in which shared message data set space is allocated to individual queues.

8K
16K
32K
64K
128K
256K
512K
1M
Each message is written starting at the next page within the current block and is allocated further blocks as needed. A larger size decreases space management requirements and reduces I/O for large messages, but increases buffer space requirements and disk space requirements for small queues.

This parameter cannot be changed after any data sets have been activated for the structure.

The **DSBLOCK** parameter is only valid from **CFLEVEL(5)**.

DSBUFS
For **OFFLOAD(SMDS)**, specify the number of buffers to be allocated in each queue manager for accessing shared message data sets, as a number in the range 1 - 9999. The size of each buffer is equal to the logical block size. SMDS buffers are allocated in memory objects residing in z/OS 64-bit storage (above the bar).

number
This parameter can be overridden for individual queue managers using the **DSBUFS** parameter on **ALTER SMDS**.

When this parameter is altered, any queue managers which are already connected to the structure (and which do not have an individual DSBUFS override value) dynamically increase or decrease the number of data set buffers being used for this structure to match the new value. If the specified target value cannot be reached, the affected queue manager adjusts the DSBUFS parameter associated with its own individual SMDS definition (as for the **ALTER SMDS** command) to match the actual new number of buffers.

These buffers use virtual storage. You should work with the z/OS systems programmer to ensure there is sufficient auxiliary storage available before increasing the number of buffers.

The **DSBUFS** parameter is only valid from **CFLEVEL(5)**.

DSEXPAND
For **OFFLOAD(SMDS)**, this parameter controls whether the queue manager should expand a shared message data set when it becomes nearly full, and further blocks are required in the data set.

YES
Expansion is supported.

Each time expansion is required, the data set is expanded by the secondary allocation specified when the data set was defined. If no secondary allocation was specified, or it was specified as zero, then a secondary allocation amount of approximately 10% of the existing size is used

NO
No automatic data set expansion is to take place.

This parameter can be overridden for individual queue managers using the **DSEXPAND** parameter on **ALTER SMDS**.

If an expansion attempt fails, the **DSEXPAND** override for the affected queue manager is automatically changed to N0 to prevent further expansion attempts, but it can be changed back to YES using the **ALTER SMDS** command to enable further expansion attempts.

When this parameter is altered, any queue managers which are already connected to the structure (and which do not have an individual **DSEXPAND** override value) immediately start using the new parameter value.

The **DSEXPAND** parameter is only valid from **CFLEVEL(5)**.

RECOVER
Specifies whether CF recovery is supported for the application structure. Values are:

NO or N
CF application structure recovery is not supported.

YES or Y
CF application structure recovery is supported.

You can only set **RECOVER(YES)** if the structure has a **CFLEVEL** of 3 or higher. Set **RECOVER(YES)** if you intend to use persistent messages.

You can only change **RECOVER(NO)** to **RECOVER(YES)** if all the queue managers in the queue sharing group are at command level 530 or greater ; this is to ensure that there are no latent command level 520 connections to queues referencing the **CFSTRUCT**.

You can only change **RECOVER(YES)** to **RECOVER(NO)** if all the queues that reference the CF structure are both empty (have no messages or uncommitted activity) and closed.

RECAUTO
Specifies the automatic recovery action to be taken when a queue manager detects that the structure is failed or when a queue manager loses connectivity to the structure and no systems in the SysPlex have connectivity to the Coupling Facility that the structure is allocated in. Values can be:

YES or Y
The structure and associated shared message data sets which also need recovery are automatically recovered.

NO or N
The structure is not automatically recovered. This is the default value when **CFLEVEL** is increased to 5.

This parameter has no effect for structures defined with **RECOVER(NO)**.

The **RECAUTO** parameter is only valid from **CFLEVEL(5)**.

ALTER CHANNEL (alter channel settings)

Use the MQSC command **ALTER CHANNEL** to alter the parameters of a channel.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

Parameters not specified in the **ALTER CHANNEL** command result in the existing values for those parameters being left unchanged.

You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

Synonym: **ALT CHL**

- "Separate syntax diagrams" on page 257
- "Usage notes" on page 257
- "Parameter descriptions for ALTER CHANNEL" on page 257

Usage notes

- Changes take effect after the channel is next started.
- For cluster channels (the CLUSSDR and CLUSRCVR columns in the table), if an attribute can be set on both channels, set it on both and ensure that the settings are identical. If there is any discrepancy between the settings, those that you specify on the CLUSRCVR channel are likely to be used. This is explained in Cluster channels.
- If you change the **XMITQ** name or the **CONNAME**, you must reset the sequence number at both ends of the channel. (See "RESET CHANNEL (reset message sequence number for a channel)" on page 872 for information about the **SEQNUM** parameter.)
- Successful completion of the command does not mean that the action completed. To check for true completion, see the ALTER CHANNEL step in Checking that async commands for distributed networks have finished.

Separate syntax diagrams

See "Syntax diagrams" on page 295 for a link to the syntax diagram for each type of channel.

Parameter descriptions for ALTER CHANNEL

The following table shows the parameters that are relevant for each type of channel. There is a description of each parameter after the table. Parameters are optional unless the description states that they are required.

Table 123. DEFINE and ALTER CHANNEL parameters

AFFINITY
The channel affinity attribute is used so client applications that connect multiple times using the same queue manager name can choose whether to use the same client channel definition for each connection. This attribute is intended to be used when multiple applicable channel definitions are available.

PREFERRED
The first connection in a process reading a client channel definition table (CCDT) creates a list of applicable definitions based on the weighting with any applicable **CLNTWGHT(0)** definitions first and in alphabetical order. Each connection in the process attempts to connect using the first definition in the list. If a connection is unsuccessful the next definition is used. Unsuccessful non-**CLNTWGHT(0)** definitions are moved to the end of the list. **CLNTWGHT(0)** definitions remain at the start of the list and are selected first for each connection. For C, C++ and .NET (including fully managed .NET) clients the list is updated if the CCDT has been modified since the list was created. Each client process with the same host name creates the same list.

NONE
The first connection in a process reading a CCDT creates a list of applicable definitions. All connections in a process select an applicable definition based on the weighting with any

applicable **CLNTWGHT(0)** definitions selected first in alphabetical order. For C, C++ and .NET (including fully managed .NET) clients the list is updated if the CCDT has been modified since the list was created.

For example, suppose the CCDT includes the following definitions:

```
CHLNAME(A) QMNAME(QM1) CLNTWGHT(3)
CHLNAME(B) QMNAME(QM1) CLNTWGHT(4)
CHLNAME(C) QMNAME(QM1) CLNTWGHT(4)
```

The first connection in a process creates its own ordered list based on the weightings. So it might, for example, create the ordered list `CHLNAME(B), CHLNAME(A), CHLNAME(C)`.

For **AFFINITY(PREFERRED)**, each connection in the process attempts to connect using **CHLNAME(B)**. If a connection is unsuccessful the definition is moved to the end of the list which now becomes `CHLNAME(A), CHLNAME(C), CHLNAME(B)`. Each connection in the process then attempts to connect using **CHLNAME(A)**.

For **AFFINITY(NONE)**, each connection in the process attempts to connect using one of the three definitions selected at random based on the weightings.

When sharing conversations is enabled with a non-zero channel weighting and **AFFINITY(NONE)**, multiple connections in a process using the same queue manager name can connect using different applicable definitions rather than sharing an existing channel instance.

Multi **AMQPKA(*integer*)**

The keep alive time for an AMQP channel in milliseconds. If the AMQP client has not sent any frames within the keep alive interval, then the connection is closed with a `amqp:resource-limit-exceeded` AMQP error condition.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of AMQP

BATCHHB(*integer*)

Specifies whether batch heartbeats are to be used. The value is the length of the heartbeat in milliseconds.

Batch heartbeats allow a sending channel to verify that the receiving channel is still active just before committing a batch of messages, so that if the receiving channel is not active, the batch can be backed out rather than becoming in-doubt, as would otherwise be the case. By backing out the batch, the messages remain available for processing so they could, for example, be redirected to another channel.

If the sending channel has had a communication from the receiving channel within the batch heartbeat interval, the receiving channel is assumed to be still active. If not, a 'heartbeat' is sent to the receiving channel to check.

The value must be in the range zero through 999999. A value of zero indicates that batch heartbeating is not used.

The **BATCHHB** parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, CLUSSDR, and CLUSRCVR.

BATCHINT(*integer*)

The minimum amount of time, in milliseconds, that a channel keeps a batch open.

The batch is terminated when one of the following conditions is met:

- **BATCHSZ** messages have been sent.
- **BATCHLIM** bytes have been sent.
- The transmission queue is empty and **BATCHINT** is exceeded.

The value must be in the range 0 - 999999999. Zero means that the batch is terminated as soon as the transmission queue becomes empty, or the **BATCHSZ** or **BATCHLIM** limit is reached.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, CLUSSDR, or CLUSRCVR.

BATCHLIM(*integer*)

The limit, in kilobytes, of the amount of data that can be sent through a channel before taking a sync point. A sync point is taken after the message that caused the limit to be reached has flowed across the channel. A value of zero in this attribute means that no data limit is applied to batches over this channel.

The batch is terminated when one of the following conditions is met:

- **BATCHSZ** messages have been sent.
- **BATCHLIM** bytes have been sent.
- The transmission queue is empty and **BATCHINT** is exceeded.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, CLUSSDR, or CLUSRCVR.

The value must be in the range 0 - 999999. The default value is 5000.

The **BATCHLIM** parameter is supported on all platforms.

BATCHSZ(*integer*)

The maximum number of messages that can be sent through a channel before taking a sync point.

The maximum batch size used is the lowest of the following values:

- The **BATCHSZ** of the sending channel.
- The **BATCHSZ** of the receiving channel.
- z/OS On z/OS, three less than the maximum number of uncommitted messages allowed at the sending queue manager (or one if this value is zero or less).
- Multi On Multiplatforms, the maximum number of uncommitted messages allowed at the sending queue manager (or one if this value is zero or less).
- z/OS On z/OS, three less than the maximum number of uncommitted messages allowed at the receiving queue manager (or one if this value is zero or less).
- Multi On Multiplatforms, the maximum number of uncommitted messages allowed at the receiving queue manager (or one if this value is zero or less).

The maximum number of uncommitted messages is specified by the **MAXUMSGS** parameter of the **ALTER QMGR** command.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, RCVR, RQSTR, CLUSSDR, or CLUSRCVR.

The value must be in the range 1 through 9999.

CERTLABL

Certificate label for this channel to use.

The label identifies which personal certificate in the key repository is sent to the remote peer. If this attribute is blank, the certificate is determined by the queue manager **CERTLABL**, or z/OS on z/OS the **CERTQSGL** (if the queue manager is part of a queue sharing group) parameter.

Note that inbound channels (including receiver, requester, cluster-receiver, unqualified server, and server-connection channels) only send the configured certificate if the IBM MQ version of the remote peer fully supports certificate label configuration, and the channel is using a TLS CipherSpec. See Interoperability of Elliptic Curve and RSA CipherSpecs for further information.

An unqualified server channel is one that does not have the CONNAME field set.

In all other cases, the queue manager **CERTLABL** parameter determines the certificate sent. In particular, the following only ever receive the certificate configured by the **CERTLABL** parameter of the queue manager, regardless of the channel-specific label setting:

- All current Java and JMS clients.
- Versions of IBM MQ before IBM MQ 8.0.

You do not need to run the **REFRESH SECURITY TYPE(SSL)** command if you make any changes to **CERTLABL** on a channel. However, you must run a **REFRESH SECURITY TYPE(SSL)** command if you make any changes to **CERTLABL** on the queue manager.

Note: It is an error to inquire, or set, this attribute for cluster-sender channels. If you attempt to do so, you receive the error MQRCCF_WRONG_CHANNEL_TYPE. However, the attribute is present in cluster-sender channel objects (including MQCD structures) and a channel auto-definition (CHAD) exit might set it programmatically if required.

channel-name)
The name of the new channel definition.

This parameter is required on all types of channel.

Multi On CLUSSDR channels, it can take a different form from the other channel types. If your convention for naming cluster-sender channels includes the name of the queue manager, you can define a cluster-sender channel using the +QMNAME+ construction. After connection to the matching cluster-receiver channel, IBM MQ substitutes the correct repository queue manager name in place of +QMNAME+ in the cluster-sender channel definition. For more information see Components of a cluster.

The name must not be the same as any existing channel defined on this queue manager (unless **REPLACE** or **ALTER** is specified).

z/OS On z/OS, client-connection channel names can duplicate others.

The maximum length of the string is 20 characters, and the string must contain only valid characters; see Rules for naming IBM MQ objects.

CHLTYPE
Channel type. This parameter is required. It must follow immediately after the *(channel-name)* parameter on all platforms except z/OS.

SDR
Sender channel

SVR
Server channel

RCVR
Receiver channel

RQSTR
Requester channel

CLNTCONN
Client-connection channel

SVRCONN
Server-connection channel

CLUSSDR
Cluster-sender channel

CLUSRCVR
Cluster-receiver channel

Note: If you are using the **REPLACE** option, you cannot change the channel type.

CLNTWGHT
The client channel weighting attribute is used so client channel definitions can be selected at random based on their weighting when more than one suitable definition is available. Specify a value in the range 0 - 99.

The special value 0 indicates that no random load balancing is performed and applicable definitions are selected in alphabetical order. To enable random load balancing the value can be in the range 1 through 99 where 1 is the lowest weighting and 99 is the highest.

When a client issues an MQCONN with queue manager name "**name*" and more than one suitable definition is available in the CCDT the choice of definition to use is randomly selected based on the weighting with any applicable **CLNTWGHT(0)** definitions selected first in alphabetical order. The distribution is not guaranteed.

For example, suppose the CCDT includes the following two definitions:

```
CHLNAME(TO.QM1) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address1) CLNTWGHT(2)
CHLNAME(TO.QM2) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address2) CLNTWGHT(4)
```

A client MQCONN with queue manager name "*GRP1" would choose one of the two definitions based on the weighting of the channel definition. (A random integer 1 - 6 would be generated. If the integer was in the range 1 through 2 address1 would be used otherwise address2 would be used). If this connection was unsuccessful the client would then use the other definition.

The CCDT might contain applicable definitions with both zero and non-zero weighting. In this situation, the definitions with zero weightings are chosen first and in alphabetical order. If these connections are unsuccessful the definitions with non-zero weighting are chosen based on their weighting.

For example, suppose the CCDT includes the following four definitions:

```
CHLNAME(TO.QM1) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address1) CLNTWGHT(1)
CHLNAME(TO.QM2) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address2) CLNTWGHT(2)
CHLNAME(TO.QM3) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address3) CLNTWGHT(0)
CHLNAME(TO.QM4) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address4) CLNTWGHT(0)
```

A client MQCONN with queue manager name "*GRP1" would first choose definition "TO.QM3". If this connection was unsuccessful the client would then choose definition "TO.QM4". If this connection was also unsuccessful the client would then randomly choose one of the remaining two definitions based on their weighting.

CLNTWGHT support is added for all supported transport protocols.

CLUSNL(*nlname*)
The name of the namelist that specifies a list of clusters to which the channel belongs.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of CLUSSDR and CLUSRCVR channels. Only one of the resultant values of CLUSTER or CLUSNL can be nonblank, the other must be blank.

CLUSTER(*clustername*)
The name of the cluster to which the channel belongs. The maximum length is 48 characters conforming to the rules for naming IBM MQ objects.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of CLUSSDR or CLUSRCVR. Only one of the resultant values of CLUSTER or CLUSNL can be nonblank, the other must be blank.

CLWLPRTY(*integer*)
Specifies the priority of the channel for the purposes of cluster workload distribution. The value must be in the range zero through 9 where zero is the lowest priority and 9 is the highest.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of CLUSSDR or CLUSRCVR.

For more information about this attribute, see CLWLPRTY queue attribute.

CLWLRANK(*integer*)
Specifies the rank of the channel for the purposes of cluster workload distribution. The value must be in the range zero through 9 where zero is the lowest rank and 9 is the highest.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of CLUSSDR or CLUSRCVR.

For more information about this attribute, see CLWLRANK channel attribute.

CLWLWGHT(*integer*)
Specifies the weighting to be applied to the channel for the purposes of cluster workload distribution so that the proportion of messages sent down the channel can be controlled. The value must be in the range 1 through 99 where 1 is the lowest rank and 99 is the highest.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of CLUSSDR or CLUSRCVR.

For more information about this attribute, see CLWLWGHT channel attribute.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

' '
The command is executed on the queue manager on which it was entered.

qmgr-name
The command is executed on the queue manager you specify, providing the queue manager is active within the queue sharing group. You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

*****
The command is executed on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of * is the same as entering the command on every queue manager in the queue sharing group.

COMPHDR
The list of header data compression techniques supported by the channel. For sender, server, cluster-sender, cluster-receiver, and client-connection channels, the values specified are in order of preference with the first compression technique supported by the remote end of the channel being used.

The mutually supported compression techniques of the channel are passed to the message exit of the sending channel where the compression technique used can be altered on a per message basis. Compression alters the data passed to send and receive exits.

NONE
No header data compression is performed.

SYSTEM
Header data compression is performed.

COMPMSG
The list of message data compression techniques supported by the channel. For sender, server, cluster-sender, cluster-receiver, and client-connection channels, the values specified are in order of preference with the first compression technique supported by the remote end of the channel being used.

The mutually supported compression techniques of the channel are passed to the message exit of the sending channel where the compression technique used can be altered on a per message basis. Compression alters the data passed to send and receive exits.

NONE
No message data compression is performed.

RLE
Message data compression is performed using run-length encoding.

ZLIBFAST
Message data compression is performed using ZLIB encoding with speed prioritized.

z/OS On z/OS systems with zEDC Express facility enabled, compression can be offloaded to zEDC Express.

ZLIBHIGH
Message data compression is performed using ZLIB encoding with compression prioritized.

ANY
Any compression technique supported by the queue manager can be used. This value is only valid for receiver, requester, and server-connection channels.

CONNAME(*string*)
Connection name.

For cluster-receiver channels (when specified) **CONNAME** relates to the local queue manager, and for other channels it relates to the target queue manager.

z/OS On z/OS, the maximum length of the string is 48 characters.

Multi On Multiplatforms, the maximum length of the string is 264 characters

A workaround to the 48 character limit might be one of the following suggestions:

- Set up your DNS servers so that you use, for example, host name of "myserver" instead of "myserver.location.company.com", ensuring you can use the short host name.
- Use IP addresses.

Specify **CONNAME** as a comma-separated list of names of machines for the stated **TRPTYPE**. Typically only one machine name is required. You can provide multiple machine names to configure multiple connections with the same properties. The connections are usually tried in the order they are specified in the connection list until a connection is successfully established. The order is modified for clients if the **CLNTWGHT** attribute is provided. If no connection is successful, the channel attempts the connection again, as determined by the attributes of the channel. With client channels, a connection-list provides an alternative to using queue manager groups to configure multiple connections. With message channels, a connection list is used to configure connections to the alternative addresses of a multi-instance queue manager.

This parameter is required for channels with a channel type (**CHLTYPE**) of SDR, RQSTR, CLNTCONN, and CLUSSDR. It is optional for SVR channels, and for CLUSRCVR channels of **TRPTYPE(TCP)**, and is not valid for RCVR or SVRCONN channels.

Providing multiple connection names in a list was first supported in IBM WebSphere MQ 7.0.1. It changes the syntax of the **CONNAME** parameter. Earlier clients and queue managers connect using the first connection name in the list, and do not read the rest of the connection names in the list. In order for the earlier clients and queue managers to parse the new syntax, you must specify a port number on the first connection name in the list. Specifying a port number avoids problems when connecting to the channel from a client or queue manager that is running at a level earlier than IBM WebSphere MQ 7.0.1.

Multi On Multiplatforms, the TCP/IP connection name parameter of a cluster-receiver channel is optional. If you leave the connection name blank, IBM MQ generates a connection name for you, assuming the default port and using the current IP address of the system. You can override the default port number, but still use the current IP address of the system. For each connection name leave the IP name blank, and provide the port number in parentheses; for example:

```
(1415)
```

The generated **CONNAME** is always in the dotted decimal (IPv4) or hexadecimal (IPv6) form, rather than in the form of an alphanumeric DNS host name.

Note: If you are using any of the special characters in your connection name (for example, parentheses) you must enclose the string in single quotation marks.

The value you specify depends on the transport type (**TRPTYPE**) to be used:

LU 6.2

- Multi On Multiplatforms, **CONNAME** is the name of the CPI-C communications side object. Or, if the **TPNAME** is not blank, **CONNAME** is the fully qualified name of the partner logical unit.
- z/OS On z/OS, there are two forms in which to specify the value:

  Logical unit name
  The logical unit information for the queue manager, comprising the logical unit name, TP name, and optional mode name. Logical unit name can be specified in one of three forms:

Table 124. Logical unit name forms and examples

Form	Example
luname	IGY12355
luname/TPname	IGY12345/APING
luname/TPname/modename	IGY12345/APINGD/#INTER

  For the first form, the TP name and mode name must be specified for the **TPNAME** and **MODENAME** parameters; otherwise these parameters must be blank.

  Note: For client-connection channels, only the first form is allowed.

  Symbolic name
  The symbolic destination name for the logical unit information for the queue manager, as defined in the side information data set. The **TPNAME** and **MODENAME** parameters must be blank.

  Note: For cluster-receiver channels, the side information is on the other queue managers in the cluster. Alternatively, in this case it can be a name that a channel auto-definition exit can resolve into the appropriate logical unit information for the local queue manager.

  The specified or implied LU name can be that of a VTAM generic resources group.

  For more information, see Configuration parameters for an LU 6.2 connection.

NetBIOS
A unique NetBIOS name (limited to 16 characters).

SPX
The 4 byte network address, the 6 byte node address, and the 2 byte socket number. These values must be entered in hexadecimal, with a period separating the network and node addresses. The socket number must be enclosed in brackets, for example:

```
CONNAME('0a0b0c0d.804abcde23a1(5e86)')
```

TCP
Either the host name, or the network address of the remote machine (or the local machine for cluster-receiver channels). This address can be followed by an optional port number, enclosed in parentheses.

If the **CONNAME** is a host name, the host name is resolved to an IP address.

The IP stack used for communication depends on both the value specified for **CONNAME** and the value specified for **LOCLADDR**. See LOCLADDR for information about how this value is resolved.

z/OS On z/OS, the connection name can include the IP_name of an z/OS dynamic DNS group or a Network Dispatcher input port.

Important: Do not include the IP_name or input port for channels with a channel type (**CHLTYPE**) of CLUSSDR.

On all platforms, when you define a channel with a channel type (**CHLTYPE**) of CLUSRCVR that is using TCP/IP, you do not need to specify the network address of your queue manager. IBM MQ generates a **CONNAME** for you, assuming the default port and using the current IPv4 address of the system. If the system does not have an IPv4 address, the current IPv6 address of the system is used.

Note: If you are using clustering between IPv6-only and IPv4-only queue managers, do not specify an IPv6 network address as the **CONNAME** for CLUSRCVR channels. A queue manager that is capable only of IPv4 communication is unable to start a cluster sender channel definition that specifies the CONNAME in IPv6 hexadecimal form. Consider, instead, using host names in a heterogeneous IP environment.

CONVERT
Specifies whether the sending message channel agent attempts conversion of the application message data, if the receiving message channel agent cannot perform this conversion.

NO
No conversion by sender

YES
Conversion by sender

z/OS On z/OS, N and Y are accepted as synonyms of NO and YES.

The **CONVERT** parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, CLUSSDR, or CLUSRCVR.

DEFCDISP
Specifies the default channel disposition of the channel.

PRIVATE
The intended disposition of the channel is as a PRIVATE channel.

FIXSHARED
The intended disposition of the channel is as a FIXSHARED channel.

SHARED
The intended disposition of the channel is as a SHARED channel.

This parameter does not apply to channels with a channel type (**CHLTYPE**) of CLNTCONN, CLUSSDR, or CLUSRCVR.

DEFRECON
Specifies whether a client connection automatically reconnects a client application if its connection breaks.

NO (default)
Unless overridden by **MQCONNX**, the client is not reconnected automatically.

YES
Unless overridden by **MQCONNX**, the client reconnects automatically.

QMGR
Unless overridden by **MQCONNX**, the client reconnects automatically, but only to the same queue manager. The QMGR option has the same effect as MQCNO_RECONNECT_Q_MGR.

DISABLED
Reconnection is disabled, even if requested by the client program using the **MQCONNX** MQI call.

Table 125. Automatic reconnection depends on the values set in the application and in the channel definition				
DEFRECON	**Reconnection options set in the application**			
	MQCNO_RECONNECT	MQCNO_RECONNECT_Q_MGR	MQCNO_RECONNECT_AS_DEF	MQCNO_RECONNECT_DISABLED
NO (default)	YES	QMGR	NO	NO
YES	YES	QMGR	YES	NO
QMGR	YES	QMGR	QMGR	NO
DISABLED	NO	NO	NO	NO

DESCR(*string*)
Plain-text comment. It provides descriptive information about the channel when an operator issues the **DISPLAY CHANNEL** command.

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

DISCINT(*integer*)
The minimum time in seconds for which the channel waits for a message to arrive on the transmission queue, after a batch ends, before terminating the channel. A value of zero causes the message channel agent to wait indefinitely.

The value must be in the range zero through 999 999.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SVRCONN , SDR, SVR, CLUSSDR, CLUSRCVR.

For SVRCONN channels using the TCP protocol, this parameter is the minimum time in seconds for which the SVRCONN instance remains active without any communication from its partner client. A value of zero disables this disconnect processing. The SVRCONN inactivity interval only applies between IBM MQ API calls from a client, so no client is disconnected during an extended MQGET with wait call. This attribute is ignored for SVRCONN channels using protocols other than TCP.

HBINT(*integer*)

This attribute specifies the approximate time between heartbeat flows that are to be passed from a sending MCA when there are no messages on the transmission queue.

Heartbeat flows unblock the receiving MCA, which is waiting for messages to arrive or for the disconnect interval to expire. When the receiving MCA is unblocked it can disconnect the channel without waiting for the disconnect interval to expire. Heartbeat flows also free any storage buffers that have been allocated for large messages and close any queues that have been left open at the receiving end of the channel.

The value is in seconds and must be in the range 0 through 999999. A value of zero means that no heartbeat flows are to be sent. The default value is 300. To be most useful, the value needs to be less than the disconnect interval value.

For server-connection and client-connection channels, heartbeats can flow from both the server side as well as the client side independently. If no data has been transferred across the channel for the heartbeat interval, the client-connection MQI agent sends a heartbeat flow and the server-connection MQI agent responds to it with another heartbeat flow. This happens irrespective of the state of the channel, for example, irrespective of whether it is inactive while making an API call, or is inactive waiting for client user input. The server-connection MQI agent is also capable of initiating a heartbeat to the client, again irrespective of the state of the channel. To prevent both server-connection and

client-connection MQI agents heart beating to each other at the same time, the server heartbeat is flowed after no data has been transferred across the channel for the heartbeat interval plus 5 seconds.

For server-connection and client-connection channels working in the channel mode before IBM WebSphere MQ 7.0, heartbeats flow only when a server MCA is waiting for an MQGET command with the WAIT option specified, which it has issued on behalf of a client application.

For more information, see Heartbeat interval (HBINT).

KAINT(*integer*)
The value passed to the communications stack for KeepAlive timing for this channel.

For this attribute to be effective, TCP/IP keepalive must be enabled both in the queue manager and in TCP/IP.

z/OS On z/OS, you enable TCP/IP keepalive in the queue manager by issuing the **ALTER QMGR TCPKEEP(YES)** command; if the**TCPKEEP** queue manager parameter is NO, the value is ignored, and the KeepAlive facility is not used.

Multi On Multiplatforms, TCP/IP keepalive is enabled when the **KEEPALIVE=YES** parameter is specified in the TCP stanza in the distributed queuing configuration file, `qm.ini`, or through the IBM MQ Explorer.

Keepalive must also be enabled within TCP/IP itself. Refer to your TCP/IP documentation for information about configuring keepalive:

- AIX On AIX, use the **no** command.
- Windows On Windows, edit the registry.
- z/OS On z/OS, update your TCP/IP PROFILE data set and add or change the **INTERVAL** parameter in the TCPCONFIG section.

z/OS Although this parameter is available on all platforms, its setting is implemented only on z/OS.

Multi On Multiplatforms, you can access and modify the parameter, but it is only stored and forwarded; there is no functional implementation of the parameter. This functionality is useful in a clustered environment where a value set in a cluster-receiver channel definition on AIX, for example, flows to (and is implemented by) z/OS queue managers that are in, or join, the cluster.

Multi On Multiplatforms, if you need the functionality provided by the **KAINT** parameter, use the Heartbeat Interval (**HBINT**) parameter, as described in HBINT.

(*integer*)
The KeepAlive interval to be used, in seconds, in the range 1 through 99 999.

0
The value used is that specified by the INTERVAL statement in the TCP profile configuration data set.

AUTO
The KeepAlive interval is calculated based upon the negotiated heartbeat value as follows:

- If the negotiated **HBINT** is greater than zero, KeepAlive interval is set to that value plus 60 seconds.
- If the negotiated **HBINT** is zero, the value used is that specified by the INTERVAL statement in the TCP profile configuration data set.

This parameter is valid for all channel types. It is ignored for channels with a **TRPTYPE** other than TCP or SPX.

LIKE(*channel-name*)
The name of a channel. The parameters of this channel are used to model this definition.

If this field is not completed, and you do not complete the parameter fields related to the command, the values are taken from one of the following default channels, depending upon the channel type:

SYSTEM.DEF.SENDER
Sender channel

SYSTEM.DEF.SERVER
Server channel

SYSTEM.DEF.RECEIVER
Receiver channel

SYSTEM.DEF.REQUESTER
Requester channel

SYSTEM.DEF.SVRCONN
Server-connection channel

SYSTEM.DEF.CLNTCONN
Client-connection channel

SYSTEM.DEF.CLUSSDR
Cluster-sender channel

SYSTEM.DEF.CLUSRCVR
Cluster-receiver channel

This parameter is equivalent to defining the following object for a sender channel, and similarly for other channel types:

```
LIKE(SYSTEM.DEF.SENDER)
```

These default channel definitions can be altered by the installation to the default values required.

z/OS On z/OS, the queue manager searches page set zero for an object with the name you specify and a disposition of QMGR or COPY. The disposition of the **LIKE** object is not copied to the object and channel type you are defining.

Note:

1. **QSGDISP(GROUP)** objects are not searched.
2. # **LIKE** is ignored if **QSGDISP(COPY)** is specified. However, the group object defined is used as a **LIKE** object.

LOCLADDR(*string*)
LOCLADDR is the local communications address for the channel. For channels other than AMQP channels, use this parameter if you want a channel to use a particular IP address, port, or port range for outbound communications. **LOCLADDR** might be useful in recovery scenarios where a channel is restarted on a different TCP/IP stack. **LOCLADDR** is also useful to force a channel to use an IPv4 or IPv6 stack on a dual-stack system. You can also use **LOCLADDR** to force a channel to use a dual-mode stack on a single-stack system.

Note: AMQP channels do not support the same format of **LOCLADDR** as other IBM MQ channels. For the format supported by AMQ, see the next parameter **AMQP: LOCLADDR**.

For channels other than AMQP channels, the **LOCLADDR** parameter is valid only for channels with a transport type (**TRPTYPE**) of TCP. If **TRPTYPE** is not TCP, the data is ignored and no error message is issued.

The value is the optional IP address, and optional port or port range used for outbound TCP/IP communications. The format for this information is as follows:

```
LOCLADDR([ip-addr][(low-port[,high-port])][,[ip-addr][(low-port[,high-port])]])
```

The maximum length of **LOCLADDR**, including multiple addresses, is MQ_LOCAL_ADDRESS_LENGTH.

If you omit **LOCLADDR**, a local address is automatically allocated.

Note, that you can set **LOCLADDR** for a C client using the Client Channel Definition Table (CCDT).

All the parameters are optional. Omitting the `ip-addr` part of the address is useful to enable the configuration of a fixed port number for an IP firewall. Omitting the port number is useful to select a particular network adapter without having the identify a unique local port number. The TCP/IP stack generates a unique port number.

Specify *[,[ip-addr][(low-port[,high-port])]]* multiple times for each additional local address. Use multiple local addresses if you want to specify a specific subset of local network adapters. You can also use *[,[ip-addr][(low-port[,high-port])]]* to represent a particular local network address on different servers that are part of a multi-instance queue manager configuration.

ip-addr
`ip-addr` is specified in one of three forms:

IPv4 dotted decimal
For example, `192.0.2.1`

IPv6 hexadecimal notation
For example, `2001:DB8:0:0:0:0:0:0`

Alphanumeric host name form
For example `WWW.EXAMPLE.COM`

low-port and high-port
`low-port` and `high-port` are port numbers enclosed in parentheses.

The following table shows how the **LOCLADDR** parameter can be used:

*Table 126. Examples of how the **LOCLADDR** parameter can be used*

LOCLADDR	Meaning
9.20.4.98	Channel binds to this address locally
9.20.4.98, 9.20.4.99	Channel binds to either IP address. The address might be two network adapters on one server, or a different network adapter on two different servers in a multi-instance configuration.
9.20.4.98(1000)	Channel binds to this address and port 1000 locally
9.20.4.98(1000,2000)	Channel binds to this address and uses a port in the range 1000 - 2000 locally
(1000)	Channel binds to port 1000 locally
(1000,2000)	Channel binds to port in range 1000 - 2000 locally

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, RQSTR, CLNTCONN, CLUSSDR, OR CLUSRCVR.

On CLUSSDR channels, the IP address and port to which the outbound channel binds, is a combination of fields. It is a concatenation of the IP address, as defined in the **LOCLADDR** parameter, and the port range from the cluster cache. If there is no port range in the cache, the port range defined in the **LOCLADDR** parameter is used.

z/OS This port range does not apply to z/OS systems.

Even though this parameter is similar in form to **CONNAME**, it must not be confused with it. The **LOCLADDR** parameter specifies the characteristics of the local communications, whereas the **CONNAME** parameter specifies how to reach a remote queue manager.

When a channel is started, the values specified for **CONNAME** and **LOCLADDR** determine the IP stack to be used for communication; see Table 3 and Local Address (**LOCLADDR**).

If the TCP/IP stack for the local address is not installed or configured, the channel does not start and an exception message is generated.

z/OS For example, on z/OS systems, the message is "CSQO015E: Command issued but no reply received." The message indicates that the `connect()` request specifies an interface address that is not known on the default IP stack. To direct the connect() request to the alternative stack, specify the **LOCLADDR** parameter in the channel definition as either an interface on the alternative stack, or a DNS host name. The same specification also works for listeners that might not use the default stack. To find the value to code for **LOCLADDR**, run the **NETSTAT HOME** command on the IP stacks that you want to use as alternatives.

Table 127. How the IP stack to be used for communication is determined

Protocols supported	CONNAME	LOCLADDR	Action of channel
IPv4 only	IPv4 address [1]		Channel binds to IPv4 stack
	IPv6 address [2]		Channel fails to resolve **CONNAME**
	IPv4 and 6 host name [3]		Channel binds to IPv4 stack
	IPv4 address	IPv4 address	Channel binds to IPv4 stack
	IPv6 address	IPv4 address	Channel fails to resolve **CONNAME**
	IPv4 and 6 host name	IPv4 address	Channel binds to IPv4 stack
	Any address [4]	IPv6 address	Channel fails to resolve **LOCLADDR**
	IPv4 address	IPv4 and 6 host name	Channel binds to IPv4 stack
	IPv6 address	IPv4 and 6 host name	Channel fails to resolve **CONNAME**
	IPv4 and 6 host name	IPv4 and 6 host name	Channel binds to IPv4 stack

Table 127. How the IP stack to be used for communication is determined (continued)

Protocols supported	CONNAME	LOCLADDR	Action of channel
IPv4 and IPv6	IPv4 address		Channel binds to IPv4 stack
	IPv6 address		Channel binds to IPv6 stack
	IPv4 and 6 host name		Channel binds to stack determined by **IPADDRV**
	IPv4 address	IPv4 address	Channel binds to IPv4 stack
	IPv6 address	IPv4 address	Channel fails to resolve **CONNAME**
	IPv4 and 6 host name	IPv4 address	Channel binds to IPv4 stack
	IPv4 address	IPv6 address	Channel maps **CONNAME** to IPv6 [5]
	IPv6 address	IPv6 address	Channel binds IPv6 stack
	IPv4 and 6 host name	IPv6 address	Channel binds IPv6 stack
	IPv4 address	IPv4 and 6 host name	Channel binds to IPv4 stack
	IPv6 address	IPv4 and 6 host name	Channel binds to IPv6 stack
	IPv4 and 6 host name	IPv4 and 6 host name	Channel binds to stack determined by **IPADDRV**
IPv6 only	IPv4 address		Channel maps **CONNAME** to IPv6 [5]
	IPv6 address		Channel binds to IPv6 stack
	IPv4 and 6 host name		Channel binds to IPv6 stack
	Any address	IPv4 address	Channel fails to resolve **LOCLADDR**
	IPv4 address	IPv6 address	Channel maps **CONNAME** to IPv6 [5]
	IPv6 address	IPv6 address	Channel binds to IPv6 stack
	IPv4 and 6 host name	IPv6 address	Channel binds to IPv6 stack
	IPv4 address	IPv4 and 6 host name	Channel maps **CONNAME** to IPv6 [5]
	IPv6 address	IPv4 and 6 host name	Channel binds to IPv6 stack
	IPv4 and 6 host name	IPv4 and 6 host name	Channel binds to IPv6 stack

Table 127. How the IP stack to be used for communication is determined (continued)

Protocols supported	CONNAME	LOCLADDR	Action of channel

Notes:

1. IPv4 address. An IPv4 host name that resolves only to an IPv4 network address or a specific dotted notation IPv4 address, for example `1.2.3.4`. This note applies to all occurrences of ' IPv4 address' in this table.
2. IPv6 address. An IPv6 host name that resolves only to an IPv6 network address or a specific hexadecimal notation IPv6 address, for example `4321:54bc`. This note applies to all occurrences of ' IPv6 address' in this table.
3. IPv4 and 6 host name. A host name that resolves to both IPv4 and IPv6 network addresses. This note applies to all occurrences of ' IPv4 and 6 host name' in this table.
4. Any address. IPv4 address, IPv6 address, or IPv4 and 6 host name. This note applies to all occurrences of 'Any address' in this table.
5. Maps IPv4 **CONNAME** to IPv4 mapped IPv6 address. IPv6 stack implementations that do not support IPv4 mapped IPv6 addressing fail to resolve the **CONNAME**. Mapped addresses might require protocol translators in order to be used. The use of mapped addresses is not recommended.

AMQP: LOCLADDR(*ip-addr*)

Note: For the format of **LOCLADDR** that other IBM MQ channels use, see the previous parameter **LOCLADDR**.

For AMQP channels, **LOCLADDR** is the local communications address for the channel. Use this parameter if you want to force the client to use a particular IP address. **LOCLADDR** is also useful to force a channel to use an IPv4 or IPv6 address if a choice is available, or to use a particular network adapter on a system with multiple network adapters.

The maximum length of **LOCLADDR** is `MQ_LOCAL_ADDRESS_LENGTH`.

If you omit **LOCLADDR**, a local address is automatically allocated.

`ip-addr`
`ip-addr` is a single network address, specified in one of three forms:

IPv4 dotted decimal
For example, `192.0.2.1`

IPv6 hexadecimal notation
For example, `2001:DB8:0:0:0:0:0:0`

Alphanumeric host name form
For example, `WWW.EXAMPLE.COM`

If an IP address is entered, only the address format is validated. The IP address itself is not validated.

LONGRTY(*integer*)
When a sender, server, or cluster-sender channel is attempting to connect to the remote queue manager, and the count specified by **SHORTRTY** has been exhausted, this parameter specifies the maximum number of further attempts that are made to connect to the remote queue manager, at intervals specified by **LONGTMR**.

If this count is also exhausted without success, an error is logged to the operator, and the channel is stopped. The channel must then be restarted with a command (it is not started automatically by the channel initiator).

The value must be in the range zero through 999999999.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, `CLUSSDR`, or `CLUSRCVR`.

LONGTMR(*integer*)
For long retry attempts, this parameter is the maximum number of seconds to wait before reattempting connection to the remote queue manager.

The time is approximate; zero means that another connection attempt is made as soon as possible.

The interval between retries might be extended if the channel has to wait to become active.

The value must be in the range zero through 999999999.

Note: For implementation reasons, the maximum retry interval that can be used is 999,999; values exceeding this maximum are treated as 999,999. Similarly, the minimum retry interval that can be used is 2; values less than this minimum are treated as 2.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, CLUSSDR, or CLUSRCVR.

MAXINST(*integer*)

The maximum number of simultaneous instances of an individual server-connection channel or AMQP channel that can be started.

The value must be in the range zero through 999999999.

A value of zero prevents all client access on this channel.

If the value of this parameter is reduced to a number that is less than the number of instances of the server-connection channel that are currently running, then those running instances are not affected. However, new instances cannot start until sufficient existing instances have ceased to run so that the number of currently running instances is less than the value of this parameter.

If an AMQP client attempts to connect to an AMQP channel, and the number of connected clients has reached **MAXINST**, the channel closes the connection with a close frame. The close frame contains the following message: `amqp:resource-limit-exceeded`. If a client connects with an ID that is already connected (that is, it performs a client-takeover), and the client is permitted to take over the connection, the takeover will succeed regardless of whether the number of connected clients has reached **MAXINST**.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SVRCONN or AMQP.

MAXINSTC(*integer*)
The maximum number of simultaneous individual server-connection channels that can be started from a single client. In this context, connections that originate from the same remote network address are regarded as coming from the same client.

The value must be in the range zero through 999999999.

A value of zero prevents all client access on this channel.

If the value of this parameter is reduced to a number that is less than the number of instances of the server-connection channel that is currently running from individual clients, then those running instances are not affected. However, new instances from those clients cannot start until sufficient instances have ceased to run that the number of running instances is less than the value of this parameter.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SVRCONN.

MAXMSGL(*integer*)
Specifies the maximum message length that can be transmitted on the channel. This parameter is compared with the value for the partner and the actual maximum used is the lower of the two values. The value is ineffective if the MQCB function is being executed and the channel type (**CHLTYPE**) is SVRCONN.

The value zero means the maximum message length for the queue manager.

Multi On Multiplatforms, specify a value in the range zero through to the maximum message length for the queue manager.

z/OS On z/OS, specify a value in the range zero through 104857600 bytes (100 MB).

See the **MAXMSGL** parameter of the **ALTER QMGR** command for more information.

MCANAME(*string*)
Message channel agent name.

This parameter is reserved, and if specified must only be set to blanks (maximum length 20 characters).

MCATYPE
Specifies whether the message-channel-agent program on an outbound message channel runs as a thread or a process.

PROCESS
The message channel agent runs as a separate process.

THREAD
The message channel agent runs as a separate thread

In situations where a threaded listener is required to service many incoming requests, resources can become strained. In this case, use multiple listener processes and target incoming requests at specific listeners through the port number specified on the listener.

Multi On Multiplatforms, this parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, RQSTR, CLUSSDR, or CLUSRCVR.

z/OS On z/OS, this parameter is supported only for channels with a channel type of CLUSRCVR. When specified in a CLUSRCVR definition, **MCATYPE** is used by a remote machine to determine the corresponding CLUSSDR definition.

MCAUSER(*string*)
Message channel agent user identifier.

Note: An alternative way of providing a user ID for a channel to run under is to use channel authentication records. With channel authentication records, different connections can use the same channel while using different credentials. If both **MCAUSER** on the channel is set and channel authentication records are used to apply to the same channel, the channel authentication records take precedence. The **MCAUSER** on the channel definition is only used if the channel authentication record uses **USERSRC(CHANNEL)**. For more details, see Channel authentication records.

This parameter interacts with **PUTAUT**, see the definition of that parameter for more information.

If it is nonblank, it is the user identifier that is to be used by the message channel agent for authorization to access IBM MQ resources, including (if **PUTAUT** is DEF) authorization to put the message to the destination queue for receiver or requester channels.

If it is blank, the message channel agent uses its default user identifier.

The default user identifier is derived from the user ID that started the receiving channel. The possible values are:

- z/OS On z/OS, the user ID assigned to the channel-initiator started task by the z/OS started-procedures table.
- Multi For TCP/IP, on Multiplatforms, the user ID from the `inetd.conf` entry, or the user that started the listener.
- Multi For SNA, on Multiplatforms, the user ID from the SNA server entry or, in the absence of this user ID the incoming attach request, or the user that started the listener.
- For NetBIOS or SPX, the user ID that started the listener.

The maximum length of the string is:

- Windows 64 characters on Windows.

  V 9.2.0 For channels with a **CHLTYPE** of AMQP, before IBM MQ 9.1.1, the MCAUSER user ID setting is only supported for user IDs up to 12 characters in length. From IBM MQ 9.1.1 Continuous Delivery, and from IBM MQ 9.2.0 Long Term Support, the 12 character limit is removed.
- 12 characters on platforms other than Windows.

Windows On Windows, you can optionally qualify a user identifier with the domain name in the format `user@domain`.

This parameter is not valid for channels with a channel type (**CHLTYPE**) of SDR, SVR, CLNTCONN, CLUSSDR.

MODENAME(*string*)
LU 6.2 mode name (maximum length 8 characters).

This parameter is valid only for channels with a transport type (**TRPTYPE**) of LU 6.2. If **TRPTYPE** is not LU 6.2, the data is ignored and no error message is issued.

If specified, this parameter must be set to the SNA mode name unless the **CONNAME** contains a side-object name, in which case it must be set to blanks. The actual name is then taken from the CPI-C Communications Side Object, or APPC side information data set.

z/OS See Configuration parameters for an LU 6.2 connection for more information about configuration parameters for an LU 6.2 connection for your platform.

This parameter is not valid for channels with a channel type (**CHLTYPE**) of RCVR or SVRCONN.

MONCHL
Controls the collection of online monitoring data for channels:

QMGR
Collect monitoring data according to the setting of the queue manager parameter MONCHL.

OFF
Monitoring data collection is turned off for this channel.

LOW
If the value of the queue manager **MONCHL** parameter is not NONE, online monitoring data collection is turned on, with a low rate of data collection, for this channel.

MEDIUM
If the value of the queue manager **MONCHL** parameter is not NONE, online monitoring data collection is turned on, with a moderate rate of data collection, for this channel.

HIGH
If the value of the queue manager **MONCHL** parameter is not NONE, online monitoring data collection is turned on, with a high rate of data collection, for this channel.

For cluster channels, the value of this parameter is not replicated in the repository and, therefore, not used in the auto-definition of cluster-sender channels.

For auto-defined cluster-sender channels, the value of this parameter is taken from the queue manager attribute **MONACLS**. If you want to modify the value, use the command `ALTER QMGR MONACLS(HIGH)`, then restart the auto-defined sender channel.

Changes to this parameter take effect only on channels started after the change occurs.

MRDATA(*string*)
Channel message-retry exit user data. The maximum length is 32 characters.

This parameter is passed to the channel message-retry exit when it is called.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of RCVR, RQSTR, or CLUSRCVR.

MREXIT(*string*)
Channel message-retry exit name.

The format and maximum length of the name is the same as for MSGEXIT, however you can only specify one message-retry exit.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of RCVR, RQSTR, or CLUSRCVR.

MRRTY(*integer*)
The number of times the channel tries again before it decides it cannot deliver the message.

This parameter controls the action of the MCA only if the message-retry exit name is blank. If the exit name is not blank, the value of **MRRTY** is passed to the exit to use, but the number of retries performed (if any) is controlled by the exit, and not by this parameter.

The value must be in the range zero through 999999999. A value of zero means that no retries are performed.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of RCVR, RQSTR, or CLUSRCVR.

MRTMR(*integer*)
The minimum interval of time that must pass before the channel can try the MQPUT operation again. This time interval is in milliseconds.

This parameter controls the action of the MCA only if the message-retry exit name is blank. If the exit name is not blank, the value of **MRTMR** is passed to the exit to use, but the retry interval is controlled by the exit, and not by this parameter.

The value must be in the range zero through 999 999 999. A value of zero means that the retry is performed as soon as possible (if the value of **MRRTY** is greater than zero).

This parameter is valid only for channels with a channel type (**CHLTYPE**) of RCVR, RQSTR, or CLUSRCVR.

MSGDATA(*string*)
User data for the channel message exit. The maximum length is 32 characters.

This data is passed to the channel message exit when it is called.

ALW On AIX, Linux, and Windows, you can specify data for more than one exit program by specifying multiple strings separated by commas. The total length of the field must not exceed 999 characters.

IBM i On IBM i, you can specify up to 10 strings, each of length 32 characters. The first string of data is passed to the first message exit specified, the second string to the second exit, and so on.

z/OS On z/OS, you can specify up to eight strings, each of length 32 characters. The first string of data is passed to the first message exit specified, the second string to the second exit, and so on.

On other platforms, you can specify only one string of message exit data for each channel.

Note: This parameter is accepted but ignored for server-connection and client-connection channels.

MSGEXIT(*string*)
Channel message exit name.

If this name is nonblank, the exit is called at the following times:

- Immediately after a message has been retrieved from the transmission queue (sender or server), or immediately before a message is put to a destination queue (receiver or requester).

  The exit is given the entire application message and transmission queue header for modification.
- At initialization and termination of the channel.

ALW On AIX, Linux, and Windows, you can specify the name of more than one exit program by specifying multiple strings separated by commas. However, the total number of characters specified must not exceed 999.

IBM i On IBM i, you can specify the names of up to 10 exit programs by specifying multiple strings separated by commas.

z/OS On z/OS, you can specify the names of up to eight exit programs by specifying multiple strings separated by commas.

On other platforms, you can specify only one message exit name for each channel.

For channels with a channel type (**CHLTYPE**) of CLNTCONN or SVRCONN, this parameter is accepted but ignored, because message exits are not invoked for such channels.

The format and maximum length of the name depends on the environment:

- Linux AIX On AIX and Linux, it is of the form:

  ```
  libraryname(functionname)
  ```

  The maximum length of the string is 128 characters.
- Windows On Windows, it is of the form:

  ```
  dllname(functionname)
  ```

  where *dllname* is specified without the suffix .DLL. The maximum length of the string is 128 characters.
- IBM i On IBM i, it is of the form:

  ```
  progname libname
  ```

  where *progname* occupies the first 10 characters and *libname* the second 10 characters (both padded to the right with blanks if necessary). The maximum length of the string is 20 characters.
- z/OS On z/OS, it is a load module name, maximum length 8 characters (128 characters are allowed for exit names for client-connection channels, subject to a maximum total length including commas of 999).

NETPRTY(*integer*)
The priority for the network connection. Distributed queuing chooses the path with the highest priority if there are multiple paths available. The value must be in the range zero through 9; zero is the lowest priority.

This parameter is valid only for CLUSRCVR channels.

NPMSPEED
The class of service for nonpersistent messages on this channel:

FAST
Fast delivery for nonpersistent messages; messages might be lost if the channel is lost. Messages are retrieved using MQGMO_SYNCPOINT_IF_PERSISTENT and so are not included in the batch unit of work.

NORMAL
Normal delivery for nonpersistent messages.

If the sending side and the receiving side do not agree about this parameter, or one does not support it, NORMAL is used.

Notes:

1. If the active recovery logs for IBM MQ for z/OS are switching and archiving more frequently than expected, given that the messages being sent across a channel are non-persistent, setting NPMSPEED(FAST) on both the sending and receiving ends of the channel can minimize the SYSTEM.CHANNEL.SYNCQ updates.
2. If you are seeing high CPU usage relating to updates to the SYSTEM.CHANNEL.SYNCQ, setting NPMSPEED(FAST) can significantly reduce the CPU usage.

This parameter is valid only for channels with a **CHLTYPE** of SDR, SVR, RCVR, RQSTR, CLUSSDR, or CLUSRCVR.

PASSWORD(*string*)
Password used by the message channel agent when attempting to initiate a secure LU 6.2 session with a remote message channel agent. The maximum length is 12 characters.

Multi On Multiplatforms, this parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, RQSTR, CLNTCONN, or CLUSSDR.

z/OS On z/OS, it is supported only for channels with a channel type (**CHLTYPE**) of CLNTCONN.

Although the maximum length of the parameter is 12 characters, only the first 10 characters are used.

PORT(*integer*)
The port number used to connect an AMQP channel. The default port for AMQP 1.0 connections is 5672. If you are already using port 5672, you can specify a different port.

PROPCTL
Property control attribute.

Specifies what happens to properties of messages when the message is about to be sent to a V6 or prior queue manager (a queue manager that does not understand the concept of a property descriptor).

This parameter is applicable to Sender, Server, Cluster Sender, and Cluster Receiver channels.

This parameter is optional.

Permitted values are:

COMPAT
COMPAT allows applications which expect JMS-related properties to be in an MQRFH2 header in the message data to continue to work unmodified.

Table 128. Range of results, depending on which mesage properties are set, when PROPCTL value is COMPAT

Message properties	**Result**
The message contains a property with a prefix of mcd., jms., usr. or mqext.	All optional message properties (where the **Support** value is MQPD_SUPPORT_OPTIONAL), except properties in the message descriptor or extension, are placed in one or more MQRFH2 headers in the message data before the message it sent to the remote queue manager.
The message does not contain a property with a prefix of mcd., jms., usr. or mqext.	All message properties, except properties in the message descriptor or extension, are removed from the message before the message is sent to the remote queue manager.
The message contains a property where the **Support** field of the property descriptor is not set to MQPD_SUPPORT_OPTIONAL	The message is rejected with reason MQRC_UNSUPPORTED_PROPERTY and treated in accordance with its report options.

Table 128. Range of results, depending on which mesage properties are set, when PROPCTL value is COMPAT (continued)

Message properties	Result
The message contains one or more properties where the **Support** field of the property descriptor is set to MQPD_SUPPORT_OPTIONAL but other fields of the property descriptor are set to non-default values.	The properties with non-default values are removed from the message before the message is sent to the remote queue manager.
The MQRFH2 folder that would contain the message property needs to be assigned with the *content='properties'* attribute	The properties are removed to prevent MQRFH2 headers with unsupported syntax flowing to a V6 or prior queue manager.

NONE
All properties of the message, except properties in the message descriptor or extension, are removed from the message before the message is sent to the remote queue manager.

If the message contains a property where the **Support** field of the property descriptor is not set to MQPD_SUPPORT_OPTIONAL then the message is rejected with reason MQRC_UNSUPPORTED_PROPERTY and treated in accordance with its report options.

ALL
All properties of the message are included with the message when it is sent to the remote queue manager. The properties, except properties in the message descriptor (or extension), are placed in one or more MQRFH2 headers in the message data.

PUTAUT
Specifies which user identifiers are used to establish authority to put messages to the destination queue (for messages channels) or to execute an MQI call (for MQI channels).

DEF
The default user ID is used.

z/OS On z/OS, DEF might involve using both the user ID received from the network and that derived from **MCAUSER**.

CTX
The user ID from the *UserIdentifier* field of the message descriptor is used.

z/OS On z/OS, CTX might involve also using the user ID received from the network or that derived from **MCAUSER**, or both.

z/OS **ONLYMCA**
The user ID derived from **MCAUSER** is used. Any user ID received from the network is not used. This value is supported only on z/OS.

z/OS **ALTMCA**
The user ID from the *UserIdentifier* field of the message descriptor is used. Any user ID received from the network is not used. This value is supported only on z/OS.

z/OS On z/OS, the user IDs that are checked, and how many user IDs are checked, depends on the setting of the MQADMIN RACF® class hlq.RESLEVEL profile. Depending on the level of access the user ID of the channel initiator has to hlq.RESLEVEL, zero, one or two user IDs are checked. To see how many user IDs are checked, see RESLEVEL and channel initiator connections. For more information about which user IDs are checked, see User IDs used by the channel initiator.

z/OS On z/OS, this parameter is valid only for channels with a channel type (**CHLTYPE**) of RCVR, RQSTR, CLUSRCVR, or SVRCONN. CTX and ALTMCA are not valid for SVRCONN channels.

Multi On Multiplatforms, this parameter is valid only for channels with a channel type (**CHLTYPE**) of RCVR, RQSTR, or CLUSRCVR.

QMNAME(*string*)
Queue manager name.

For channels with a channel type (**CHLTYPE**) of CLNTCONN, this parameter is the name of a queue manager to which an application that is running in a client environment and using the client channel definition table can request connection. This parameter need not be the name of the queue manager on which the channel is defined, to allow a client to connect to different queue managers.

For channels of other types, this parameter is not valid.

z/OS **QSGDISP**
This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

Table 129. Behavior for each of the QSGDISP values

QSGDISP	**ALTER**
COPY	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters **QSGDISP(COPY)**. Any object residing in the shared repository, or any object defined using a command that had the parameters **QSGDISP(QMGR)**, is not affected by this command.

GROUP	The object definition resides in the shared repository. The object was defined using a command that had the parameters **QSGDISP(GROUP)**. Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command. If the command is successful, the following command is generated and sent to all active queue managers in the queue sharing group to attempt to refresh local copies on page set zero:
	`DEFINE CHANNEL(channel-name) CHLTYPE(type)`
	`REPLACE QSGDISP(COPY)`
	The **ALTER** for the group object takes effect regardless of whether the generated command with **QSGDISP(COPY)** fails.

PRIVATE	The object resides on the page set of the queue manager that executes the command, and was defined with **QSGDISP(QMGR)** or **QSGDISP(COPY)**. Any object residing in the shared repository is unaffected.
QMGR	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters **QSGDISP(QMGR)**. Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

RCVDATA(*string*)
Channel receive exit user data (maximum length 32 characters).

This parameter is passed to the channel receive exit when it is called.

ALW On AIX, Linux, and Windows, you can specify data for more than one exit program by specifying multiple strings separated by commas. The total length of the field must not exceed 999 characters.

IBM i On IBM i, you can specify up to 10 strings, each of length 32 characters. The first string of data is passed to the first receive exit specified, the second string to the second exit, and so on.

z/OS On z/OS, you can specify up to eight strings, each of length 32 characters. The first string of data is passed to the first receive exit specified, the second string to the second exit, and so on.

On other platforms, you can specify only one string of receive exit data for each channel.

RCVEXIT(*string*)
Channel receive exit name.

If this name is nonblank, the exit is called at the following times:

- Immediately before the received network data is processed.

  The exit is given the complete transmission buffer as received. The contents of the buffer can be modified as required.
- At initialization and termination of the channel.

ALW On AIX, Linux, and Windows, you can specify the name of more than one exit program by specifying multiple strings separated by commas. However, the total number of characters specified must not exceed 999.

IBM i On IBM i, you can specify the names of up to 10 exit programs by specifying multiple strings separated by commas.

z/OS On z/OS, you can specify the names of up to eight exit programs by specifying multiple strings separated by commas.

On other platforms, you can specify only one receive exit name for each channel.

The format and maximum length of the name is the same as for **MSGEXIT**.

SCYDATA(*string*)
Channel security exit user data (maximum length 32 characters).

This parameter is passed to the channel security exit when it is called.

SCYEXIT(*string*)
Channel security exit name.

If this name is nonblank, the exit is called at the following times:

- Immediately after establishing a channel.

  Before any messages are transferred, the exit is able to instigate security flows to validate connection authorization.
- Upon receipt of a response to a security message flow.

  Any security message flows received from the remote processor on the remote queue manager are given to the exit.
- At initialization and termination of the channel.

The format and maximum length of the name is the same as for **MSGEXIT** but only one name is allowed.

SENDDATA(*string*)
Channel send exit user data. The maximum length is 32 characters.

This parameter is passed to the channel send exit when it is called.

ALW On AIX, Linux, and Windows, you can specify data for more than one exit program by specifying multiple strings separated by commas. The total length of the field must not exceed 999 characters.

IBM i On IBM i, you can specify up to 10 strings, each of length 32 characters. The first string of data is passed to the first send exit specified, the second string to the second exit, and so on.

z/OS On z/OS, you can specify up to eight strings, each of length 32 characters. The first string of data is passed to the first send exit specified, the second string to the second exit, and so on.

On other platforms, you can specify only one string of send exit data for each channel.

SENDEXIT(*string*)
Channel send exit name.

If this name is nonblank, the exit is called at the following times:

- Immediately before data is sent out on the network.

  The exit is given the complete transmission buffer before it is transmitted. The contents of the buffer can be modified as required.
- At initialization and termination of the channel.

ALW On AIX, Linux, and Windows, you can specify the name of more than one exit program by specifying multiple strings separated by commas. However, the total number of characters specified must not exceed 999.

IBM i On IBM i, you can specify the names of up to 10 exit programs by specifying multiple strings separated by commas.

z/OS On z/OS, you can specify the names of up to eight exit programs by specifying multiple strings separated by commas.

On other platforms, you can specify only one send exit name for each channel.

The format and maximum length of the name is the same as for **MSGEXIT**.

SEQWRAP(*integer*)
When this value is reached, sequence numbers wrap to start again at 1.

This value is nonnegotiable and must match in both the local and remote channel definitions.

The value must be in the range 100 through 999999999.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, RCVR, RQSTR, CLUSSDR, or CLUSRCVR.

SHARECNV(*integer*)
Specifies the maximum number of conversations that can be sharing each TCP/IP channel instance. A **SHARECNV** value of:

1
Specifies no sharing of conversations over a TCP/IP channel instance. Client heartbeating is available whether in an MQGET call or not. Read ahead and client asynchronous consumption are also available, and channel quiescing is more controllable.

0
Specifies no sharing of conversations over a TCP/IP channel instance.

The value must be in the range zero through 999999999.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of CLNTCONN or SVRCONN. If the client-connection **SHARECNV** value does not match the server-connection **SHARECNV** value, the lower of the two values is used. This parameter is ignored for channels with a transport type (**TRPTYPE**) other than TCP.

All the conversations on a socket are received by the same thread.

High **SHARECNV** limits have the advantage of reducing queue manager thread usage. However, if many conversations sharing a socket are all busy, there is a possibility of delays as the conversations contend with one another to use the receiving thread. In this situation, a lower **SHARECNV** value is better.

The number of shared conversations does not contribute to the **MAXINST** or **MAXINSTC** totals.

Note: You should restart the client for this change to take effect.

SHORTRTY(*integer*)
The maximum number of attempts that are made by a sender, server, or cluster-sender channel to connect to the remote queue manager, at intervals specified by **SHORTTMR**, before the (normally longer) **LONGRTY** and **LONGTMR** are used.

Retry attempts are made if the channel fails to connect initially (whether it is started automatically by the channel initiator or by an explicit command), and also if the connection fails after the channel has successfully connected. However, if the cause of the failure is such that more attempts are unlikely to be successful, they are not attempted.

The value must be in the range zero through 999999999.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, CLUSSDR, or CLUSRCVR.

SHORTTMR(*integer*)
For short retry attempts, this parameter is the maximum number of seconds to wait before reattempting connection to the remote queue manager.

The time is approximate; zero means that another connection attempt is made as soon as possible.

The interval between retries might be extended if the channel has to wait to become active.

The value must be in the range zero through 999999999.

Note: For implementation reasons, the maximum retry interval that can be used is 999999; values exceeding this maximum are treated as 999999. Similarly, the minimum retry interval that can be used is 2; values less than this minimum are treated as 2.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, CLUSSDR, or CLUSRCVR.

V 9.2.0 z/OS **SPLPROT**
SPLPROT (Security Policy Protection) specifies how a server-to-server Message Channel Agent should deal with message protection when AMS is active and an applicable policy exists.

This parameter applies to z/OS only, from IBM MQ 9.1.3 onwards.

The permitted values are:

PASSTHRU
Pass through, unchanged, any messages sent or received by the message channel agent for this channel.

This value is valid for channels with a channel type (**CHLTYPE**) of SDR, SVR, RCVR, or RQSTR, and is the default value.

REMOVE
Remove any AMS protection from messages retrieved from the transmission queue by the message channel agent, and send the messages to the partner.

When the message channel agent gets a message from the transmission queue, if an AMS policy is defined for the transmission queue, it is applied to remove any AMS protection from the message prior to sending the message across the channel. If an AMS policy is not defined for the transmission queue, the message is sent as is.

This value is valid only for channels with a channel type of SDR or SVR.

ASPOLICY
Based on the policy defined for the target queue, apply AMS protection to inbound messages prior to putting them on to the target queue.

When the message channel agent receives an inbound message, if an AMS policy is defined for the target queue, AMS protection is applied to the message prior to the message being put to the target queue. If an AMS policy is not defined for the target queue, the message is put to the target queue as is.

This value is valid only for channels with a channel type of RCVR or RQSTR.

SSLCAUTH

Defines whether IBM MQ requires a certificate from the TLS client. The initiating end of the channel acts as the TLS client, so this parameter applies to the end of the channel that receives the initiation flow, which acts as the TLS server.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of RCVR, SVRCONN, CLUSRCVR, SVR, or RQSTR.

The parameter is used only for channels with **SSLCIPH** specified. If **SSLCIPH** is blank, the data is ignored and no error message is issued.

REQUIRED

IBM MQ requires and validates a certificate from the TLS client.

OPTIONAL

The peer TLS client system might still send a certificate. If it does, the contents of this certificate are validated as normal.

SSLCIPH*(string)*

Specifies the CipherSpec that is used on the channel. The maximum length is 32 characters.

Attention: IBM i z/OS On IBM MQ for z/OS, you can also specify the four digit hexadecimal code of a CipherSpec, whether or not it appears in the following table. On IBM i, you can also specify the two digit hexadecimal code of a CipherSpec, whether or not it appears in the following table. Also, on IBM i, installation of AC3 is a prerequisite for the use of TLS. You should not specify hexadecimal cipher values in SSLCIPH, because it is unclear from the value which cipher will be used, and the choice of which protocol to be used is indeterminate. Using hexadecimal cipher values can lead to CipherSpec mismatch errors.

The **SSLCIPH** values must specify the same CipherSpec on both ends of the channel.

This parameter is valid on all channel types that use transport type **TRPTYPE(TCP)**. If the parameter is blank, no attempt is made to use TLS on the channel.

V 9.2.4 ALW If SecureCommsOnly is enabled, plain text communication is not supported and the channel fails to start.

The value for this parameter is also used to set the value of SECPROT, which is an output field on the DISPLAY CHSTATUS command.

Note: When **SSLCIPH** is used with a telemetry channel, it means TLS Cipher Suite. See the **SSLCIPH** description for **DEFINE CHANNEL** (MQTT).

V 9.2.0 z/OS ALW From IBM MQ 9.1.1, you can specify a value of ANY_TLS12, which represents a subset of acceptable CipherSpecs that use the TLS 1.2 protocol; these CipherSpecs are listed in the following table. See Migrating existing security configurations to use the ANY_TLS12 CipherSpec for information on changing your existing security configurations to use the ANY_TLS12 value.

V 9.2.0 ALW From IBM MQ 9.1.4, on AIX, Linux, and Windows, IBM MQ provides an expanded set of alias CipherSpecs that includes ANY_TLS12_OR_HIGHER, and ANY_TLS13_OR_HIGHER. These alias CipherSpecs are listed in the following table.

Attention: If your enterprise needs to guarantee that a certain CipherSpec is negotiated and used, you must not use an alias CipherSpec value such as ANY_TLS12.

V 9.2.0 For information on changing your existing security configurations to use the ANY_TLS12_OR_HIGHER CipherSpec, see Migrating existing security configurations to use the ANY_TLS12_OR_HIGHER CipherSpec.

Table 130. CipherSpecs you can use with IBM MQ TLS support

Platform support "1" on page 290	CipherSpec name	Hex code	Protocol used	MAC algorithm	Encryption algorithm (encryption bits)	FIPS "2" on page 290	Suite B
Alias CipherSpecs							
All	ANY_TLS13_OR_HIGHER "3" on page 290 "4" on page 290 "5" on page 290	N/A	Negotiated	Negotiated	Negotiated	Negotiated	Negotiated
All	ANY_TLS13 "4" on page 290 "5" on page 290 "6" on page 290	N/A	TLS 1.3	Negotiated	Negotiated	Negotiated	Negotiated
All	ANY_TLS12_OR_HIGHER "4" on page 290 "5" on page 290 "7" on page 290	N/A	Negotiated	Negotiated	Negotiated	Negotiated	Negotiated
All	ANY_TLS12 "8" on page 290	N/A	TLS 1.2	Negotiated	Negotiated	Negotiated	Negotiated
All	ANY "9" on page 290	N/A	Negotiated	Negotiated	Negotiated	Negotiated	Negotiated
CipherSpecs for TLS 1.3							
All	TLS_AES_128_GCM_SHA256 "4" on page 290	1301	TLS 1.3	GCM	AES-128 with GCM (128)	Yes	No
All	TLS_AES_256_GCM_SHA384 "4" on page 290	1302	TLS 1.3	GCM	AES-256 with GCM (256)	Yes	No
All	TLS_CHACHA20_POLY1305_SHA256 "4" on page 290	1303	TLS 1.3	POLY1305	CHACHA20 (256)	No	No

Table 130. CipherSpecs you can use with IBM MQ TLS support (continued)

Platform support "1" on page 290	CipherSpec name	Hex code	Protocol used	MAC algorithm	Encryption algorithm (encryption bits)	FIPS "2" on page 290	Suite B

Notes:

1. For a list of platforms covered by each platform icon, see Release and platform icons in the product documentation.
2. Specifies whether the CipherSpec is FIPS-certified on a FIPS-certified platform. See Federal Information Processing Standards (FIPS) for an explanation of FIPS.
3. ALW The ANY_TLS13_OR_HIGHER alias CipherSpec negotiates the highest level of security that the remote end will allow but will only connect using a TLS 1.3 or higher protocol.
4. z/OS To use TLS 1.3, or the ANY CipherSpec, on IBM MQ for z/OS, the operating system must be z/OS 2.4 or later.
5. IBM i To use TLS 1.3, or the ANY CipherSpec, on IBM i the underlying operating system version must support TLS 1.3. See System TLS support for TLSv1.3 for more information.
6. ALW The ANY_TLS13 alias CipherSpec represents a subset of acceptable CipherSpecs that use the TLS 1.3 protocol, as listed in this table for each platform.
7. ALW The ANY_TLS12_OR_HIGHER alias CipherSpec negotiates the highest level of security that the remote end will allow but will only connect using a TLS 1.2 or higher protocol.
8. The ANY_TLS12 CipherSpec represents a subset of acceptable CipherSpecs that use the TLS 1.2 protocol, as listed in this table for each platform.
9. ALW The ANY alias CipherSpec negotiates the highest level of security that the remote end will allow.
10. IBM i These CipherSpecs are not enabled on IBM i 7.4 systems that have System Value QSSLCSLCTL set to *OPSSYS.
11. ALW These CipherSpecs use an 8-octet Integrity Check Value (ICV) instead of a 16-octet ICV.
12. This CipherSpec cannot be used to secure a connection from the IBM MQ Explorer to a queue manager unless the appropriate unrestricted policy files are applied to the JRE used by the Explorer.
13. Linux Windows Following a recommendation by GSKit, TLS 1.2 GCM CipherSpecs have a restriction which means that after 2^24.5 TLS records are sent, using the same session key, the connection is terminated with message AMQ9288E. This GCM restriction is active, regardless of the FIPS mode being used.

    To prevent this error from happening, avoid using TLS 1.2 GCM Ciphers, enable secret key reset, or start your IBM MQ queue manager or client with the environment variable `GSK_ENFORCE_GCM_RESTRICTION=GSK_FALSE` set. For GSKit libraries, you must set this environment variable on both sides of the connection, and apply it to both client to queue manager connections and queue manager to queue manager connections. Note that this setting affects unmanaged .NET clients, but not Java or managed .NET clients. For more information, see AES-GCM cipher restriction.

    This restriction does not apply to IBM MQ for z/OS.

For more information about CipherSpecs, see Enabling CipherSpecs.

When you request a personal certificate, you specify a key size for the public and private key pair. The key size that is used during the SSL handshake can depend on the size stored in the certificate and on the CipherSpec:

- z/OS ALW On z/OS, AIX, Linux, and Windows, when a CipherSpec name includes _EXPORT, the maximum handshake key size is 512 bits. If either of the certificates exchanged during the SSL handshake has a key size greater than 512 bits, a temporary 512-bit key is generated for use during the handshake.
- z/OS For z/OS, System SSL state that if a TLS V1.3 connection is being negotiated:
  - The minimum key size for an RSA peer certificate is the larger of the following two values: 2048, or the value specified in the GSK_PEER_RSA_MIN_KEY_SIZE attribute.
  - The minimum key size for an ECC peer certificate is the larger of the following two values: 256, or the value specified in the GSK_PEER_ECC_MIN_KEY_SIZE attribute.
- ALW On UNIX, Linux, and Windows, when a CipherSpec name includes _EXPORT1024, the handshake key size is 1024 bits.
- Otherwise the handshake key size is the size stored in the certificate.

SSLPEER(*string*)

Specifies the filter to use to compare with the Distinguished Name of the certificate from the peer queue manager or client at the other end of the channel. (A Distinguished Name is the identifier of the TLS certificate.) If the Distinguished Name in the certificate received from the peer does not match the **SSLPEER** filter, the channel does not start.

Note: An alternative way of restricting connections into channels by matching against the TLS Subject Distinguished Name, is to use channel authentication records. With channel authentication records, different TLS Subject Distinguished Name patterns can be applied to the same channel. If both **SSLPEER** on the channel and a channel authentication record are used to apply to the same channel, the inbound certificate must match both patterns in order to connect. For more information, see Channel authentication records.

This parameter is optional; if it is not specified, the Distinguished Name of the peer is not checked at channel startup. (The Distinguished Name from the certificate is still written into the **SSLPEER** definition held in memory, and passed to the security exit). If **SSLCIPH** is blank, the data is ignored and no error message is issued.

This parameter is valid for all channel types.

The **SSLPEER** value is specified in the standard form used to specify a Distinguished Name. For example:

```
SSLPEER('SERIALNUMBER=4C:D0:49:D5:02:5F:38,CN="H1_C_FR1",O=IBM,C=GB')
```

You can use a semi-colon as a separator instead of a comma.

The possible attribute types supported are:

Table 131. Attribute types supported by SSLPEER

Summary attribute	**Description**
SERIALNUMBER	Certificate serial number
MAIL	Email address
E	Email address (Deprecated in preference to MAIL)
UID or USERID	User identifier
CN	Common Name
T	Title
OU	Organizational Unit name

Table 131. Attribute types supported by SSLPEER (continued)	
Summary attribute	**Description**
DC	Domain component
O	Organization name
STREET	Street / First line of address
L	Locality name
ST (or SP or S)	State or Province name
PC	Postal code / zip code
C	Country
UNSTRUCTUREDNAME	Host name
UNSTRUCTUREDADDRESS	IP address
DNQ	Distinguished name qualifier

IBM MQ accepts only uppercase letters for the attribute types.

If any of the unsupported attribute types are specified in the **SSLPEER** string, an error is output either when the attribute is defined or at run time (depending on which platform you are running on), and the string is deemed not to have matched the Distinguished Name of the flowed certificate.

If the Distinguished Name of the flowed certificate contains multiple OU (organizational unit) attributes, and **SSLPEER** specifies these attributes to be compared, they must be defined in descending hierarchical order. For example, if the Distinguished Name of the flowed certificate contains the OUs `OU=Large Unit, OU=Medium Unit, OU=Small Unit`, specifying the following **SSLPEER** values works:

```
('OU=Large Unit,OU=Medium Unit')
('OU=*,OU=Medium Unit,OU=Small Unit')
('OU=*,OU=Medium Unit')
```

but specifying the following **SSLPEER** values fails:

```
('OU=Medium Unit,OU=Small Unit')
('OU=Large Unit,OU=Small Unit')
('OU=Medium Unit')
('OU=Small Unit, Medium Unit, Large Unit')
```

As indicated in these examples, attributes at the low end of the hierarchy can be omitted. For example, `('OU=Large Unit,OU=Medium Unit')` is equivalent to `('OU=Large Unit,OU=Medium Unit,OU=*')`

If two DNs are equal in all respects except for their DC values, the same matching rules apply as for OUs except that in DC values the left-most DC is the lowest-level (most specific) and the comparison ordering differs accordingly.

Any or all the attribute values can be generic, either an asterisk (*) on its own, or a stem with initiating or trailing asterisks. Asterisks allow the **SSLPEER** to match any Distinguished Name value, or any value starting with the stem for that attribute.

If an asterisk is specified at the beginning or end of any attribute value in the Distinguished Name on the certificate, you can specify '*' to check for an exact match in **SSLPEER**. For example, if you have an attribute of `CN='Test*'` in the Distinguished Name of the certificate, you can use the following command:

```
SSLPEER('CN=Test\*')
```

ALW The maximum length of the parameter is 1024 bytes on AIX, Linux, and Windows.

IBM i The maximum length of the parameter is 1024 bytes on IBM i.

z/OS The maximum length of the parameter is 256 bytes on z/OS.

Channel authentication records provide greater flexibility when using **SSLPEER** and support 1024 bytes on all platforms.

STATCHL
Controls the collection of statistics data for channels:

QMGR
The value of the **STATCHL** parameter of the queue manager is inherited by the channel.

OFF
Statistics data collection is turned off for this channel.

LOW
If the value of the **STATCHL** parameter of the queue manager is not NONE, statistics data collection is turned on, with a low rate of data collection, for this channel.

MEDIUM
If the value of the **STATCHL** parameter of the queue manager is not NONE, statistics data collection is turned on, with a moderate rate of data collection, for this channel.

HIGH
If the value of the **STATCHL** parameter of the queue manager is not NONE, statistics data collection is turned on, with a high rate of data collection, for this channel.

Changes to this parameter take effect only on channels started after the change occurs.

z/OS On z/OS systems, enabling this parameter simply turns on statistics data collection, regardless of the value you select. Specifying LOW, MEDIUM, or HIGH makes no difference to your results. This parameter must be enabled in order to collect channel accounting records.

For cluster channels, the value of this parameter is not replicated in the repository and used in the auto-definition of cluster-sender channels. For auto-defined cluster-sender channels, the value of this parameter is taken from the attribute **STATACLS** of the queue manager. This value might then be overridden in the channel auto-definition exit.

Multi V 9.2.3 **TMPMODEL(*string*)**
The name of the model queue to be used while creating a temporary queue (maximum length 48 characters).

The default queue is SYSTEM.DEFAULT.MODEL.QUEUE.

Multi V 9.2.3 **TMPQPRFX(*string*)**
The temporary queue name prefix to add to the beginning of the model queue when deriving a temporary queue name (maximum length 48 characters).

The default is AMQP.*.

TPNAME(*string*)
LU 6.2 transaction program name (maximum length 64 characters).

This parameter is valid only for channels with a transport type (**TRPTYPE**) of LU 6.2.

Set this parameter to the SNA transaction program name, unless the **CONNAME** contains a side-object name in which case set it to blanks. The actual name is taken instead from the CPI-C Communications Side Object, or the APPC side information data set.

z/OS See Configuration parameters for an LU 6.2 connection for more information about configuration parameters for an LU 6.2 connection for your platform.

Windows z/OS On Windows SNA Server, and in the side object on z/OS, the **TPNAME** is wrapped to uppercase.

This parameter is not valid for channels with a channel type (**CHLTYPE**) of RCVR.

TPROOT
The topic root for an AMQP channel. The default value for **TPROOT** is SYSTEM.BASE.TOPIC. With this value, the topic string an AMQP client uses to publish or subscribe has no prefix, and the client can exchange messages with other IBM MQ publish/subscribe applications. To have AMQP clients publish and subscribe under a topic prefix, first create an IBM MQ topic object with a topic string set to the prefix you want, then set **TPROOT** to the name of the IBM MQ topic object you created.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of AMQP

TRPTYPE
Transport type to be used.

On all platforms, this parameter is optional because, if you do not enter a value, the value specified in the SYSTEM.DEF.*channel-type* definition is used. However, no check is made that the correct transport type has been specified if the channel is initiated from the other end.

z/OS On z/OS, if the SYSTEM.DEF.*channel-type* definition does not exist, the default is LU62.

This parameter is required on all other platforms.

LU62
SNA LU 6.2

NETBIOS
Windows NetBIOS (supported only on Windows, and DOS).

z/OS This attribute also applies to z/OS for defining client-connection channels that connect to servers on the platforms supporting NetBIOS.

SPX
Windows Sequenced packet exchange (supported only on Windows, and DOS).

z/OS This attribute also applies to z/OS for defining client-connection channels that connect to servers on the platforms supporting SPX.

TCP
Transmission Control Protocol - part of the TCP/IP protocol suite

Multi **USECLTID**
Specifies that the client ID should be used for authorization checks for an AMQP channel, instead of the **MCAUSER** attribute value.

NO
The MCA user ID should be used for authorization checks.

YES
The client ID should be used for authorization checks.

USEDLQ
Determines whether the dead-letter queue is used when messages cannot be delivered by channels.

NO
Messages that cannot be delivered by a channel are treated as a failure. The channel either discards the message, or the channel ends, in accordance with the **NPMSPEED** setting.

YES
When the **DEADQ** queue manager attribute provides the name of a dead-letter queue, then it is used, else the behavior is as for NO. YES is the default value.

USERID(*string*)
Task user identifier. The maximum length is 12 characters.

This parameter is used by the message channel agent when attempting to initiate a secure LU 6.2 session with a remote message channel agent.

Multi On Multiplatforms, this parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, RQSTR, CLNTCONN, or CLUSSDR.

z/OS On z/OS, it is supported only for CLNTCONN channels.

Although the maximum length of the parameter is 12 characters, only the first 10 characters are used.

On the receiving end, if passwords are kept in encrypted format and the LU 6.2 software is using a different encryption method, an attempt to start the channel fails with invalid security details. You can avoid invalid security details by modifying the receiving SNA configuration to either:

- Turn off password substitution, or
- Define a security user ID and password.

XMITQ(*string*)
Transmission queue name.

The name of the queue from which messages are retrieved. See Rules for naming IBM MQ objects.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR or SVR. For these channel types, this parameter is required.

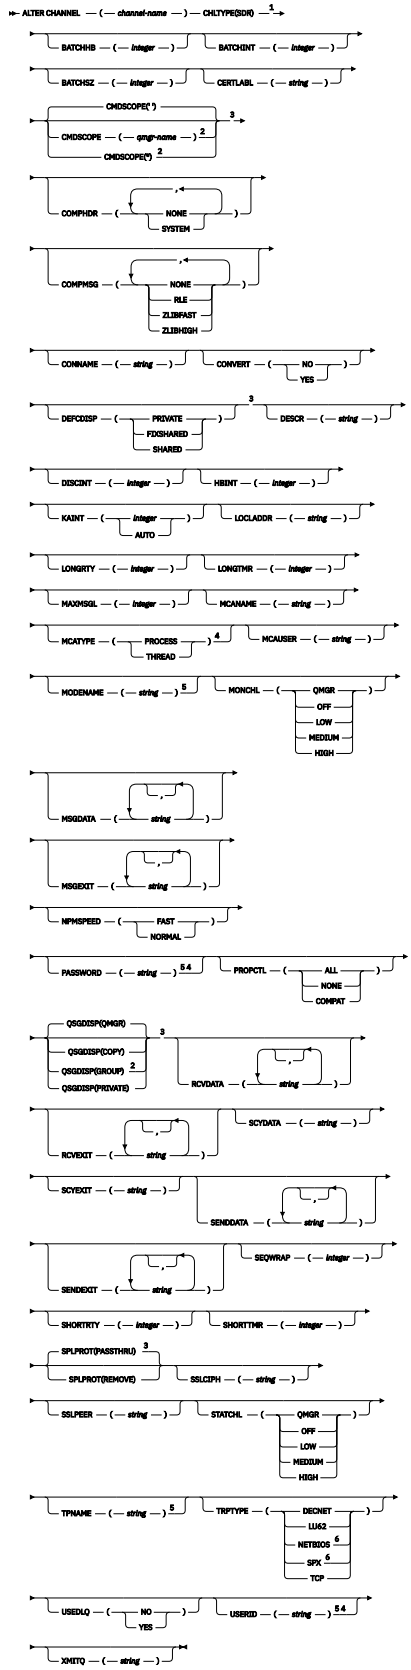
Syntax diagrams

There is a separate syntax diagram for each type of channel.

Sender channel

Syntax diagram for a sender channel when using the **ALTER CHANNEL** command.

ALTER CHANNEL



Notes:

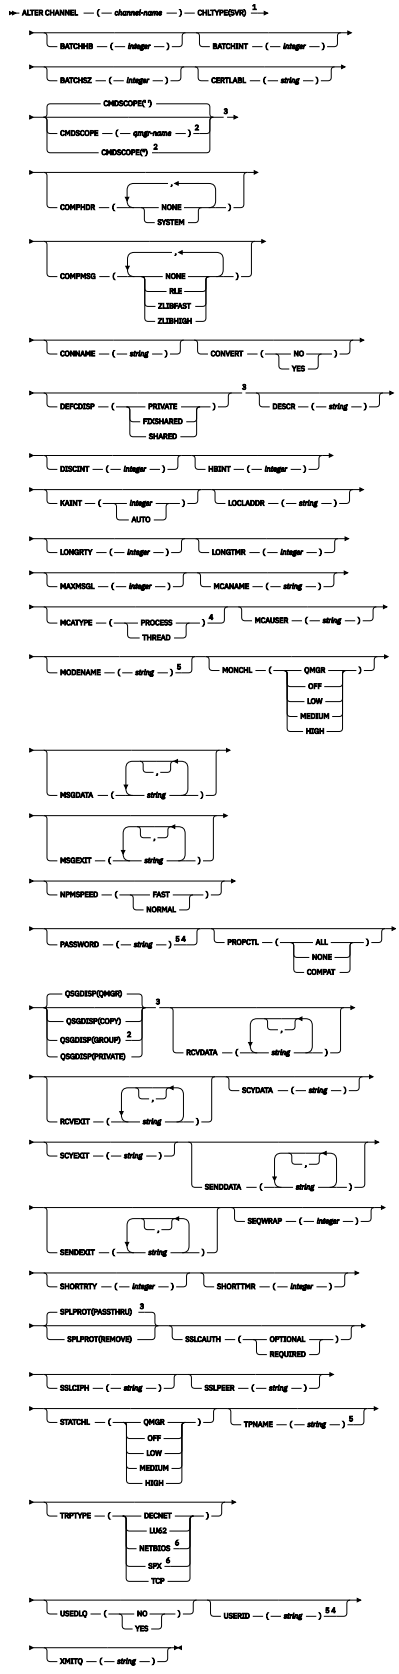
[1] This parameter must follow immediately after the channel name except on z/OS.
[2] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[3] Valid only on z/OS.
[4] Not valid on z/OS.
[5] Valid only if TRPTYPE is LU62.
[6] Valid only Windows.

The parameters are described in "ALTER CHANNEL (alter channel settings)" on page 256.

Server channel

Syntax diagram for a server channel when using the **ALTER CHANNEL** command.

ALTER CHANNEL



Notes:

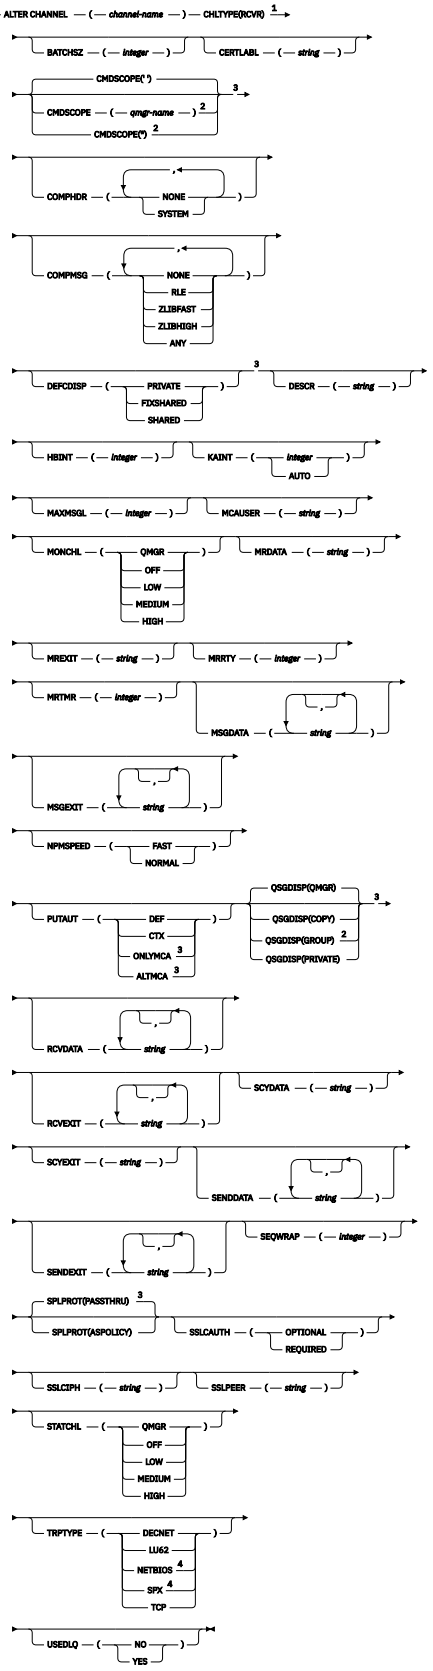
[1] This parameter must follow immediately after the channel name except on z/OS.
[2] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[3] Valid only on z/OS.
[4] Not valid on z/OS.
[5] Valid only if TRPTYPE is LU62.
[6] Valid only on Windows.

The parameters are described in "ALTER CHANNEL (alter channel settings)" on page 256.

Receiver channel

Syntax diagram for a receiver channel when using the **ALTER CHANNEL** command.

ALTER CHANNEL



Notes:

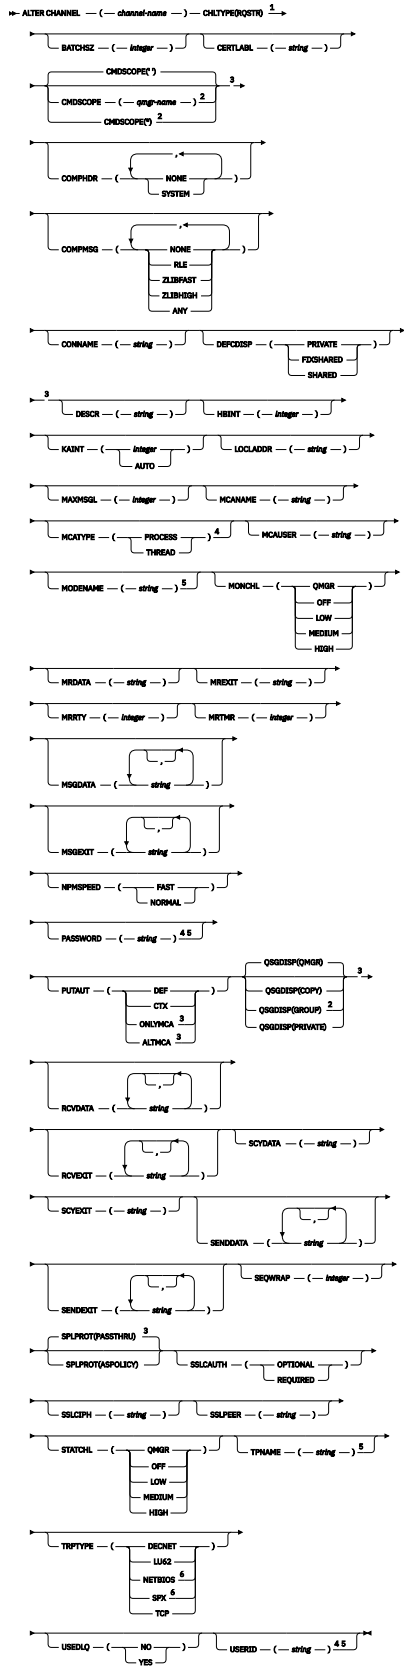
[1] This parameter must follow immediately after the channel name except on z/OS.
[2] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[3] Valid only on z/OS.
[4] Valid only on Windows.

The parameters are described in “ALTER CHANNEL (alter channel settings)” on page 256.

Requester channel

Syntax diagram for a requester channel when using the **ALTER CHANNEL** command.

ALTER CHANNEL



Notes:

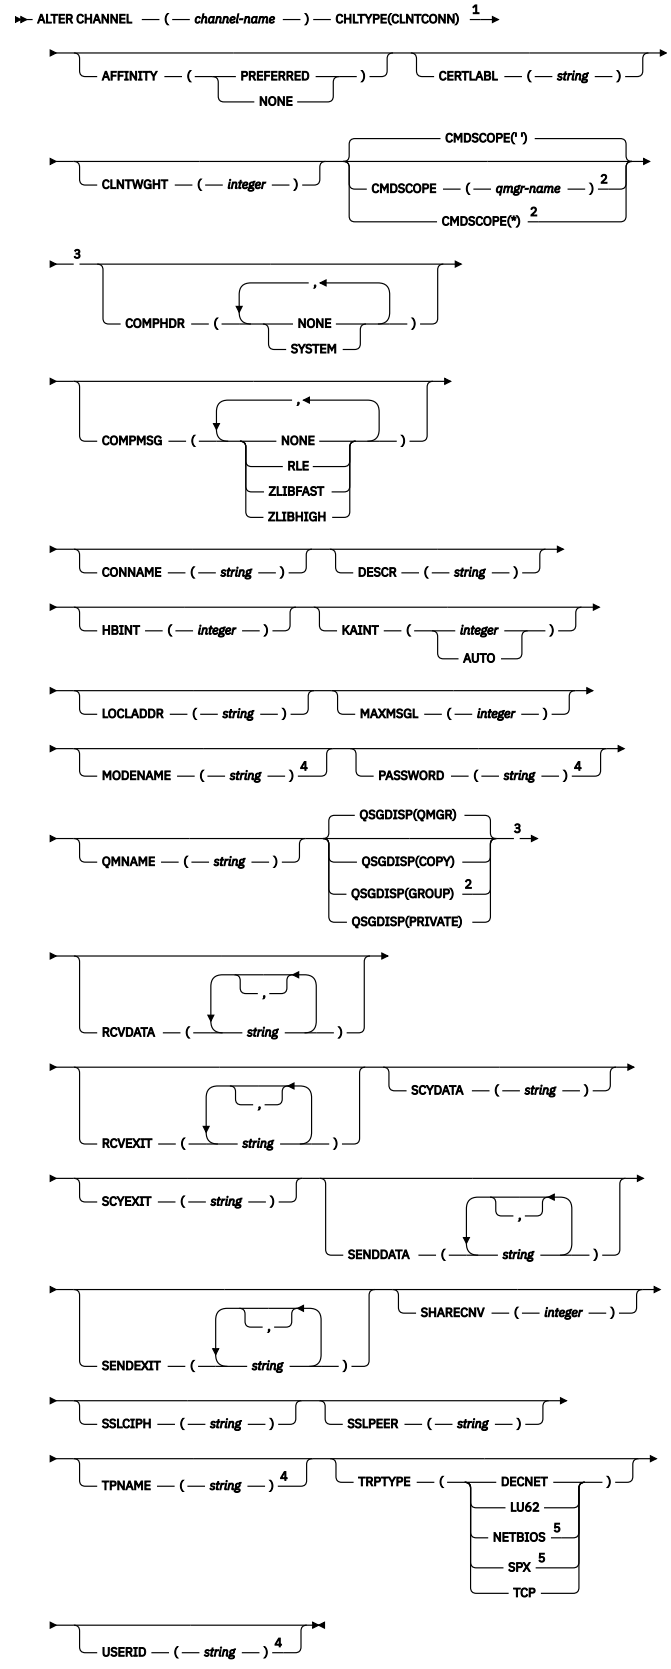
[1] This parameter must follow immediately after the channel name except on z/OS.
[2] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[3] Valid only on z/OS.
[4] Not valid on z/OS.
[5] Valid only if TRPTYPE is LU62.
[6] Valid only on Windows.

The parameters are described in "ALTER CHANNEL (alter channel settings)" on page 256.

Client-connection channel

Syntax diagram for a client-connection channel when using the **ALTER CHANNEL** command.

ALTER CHANNEL



Notes:

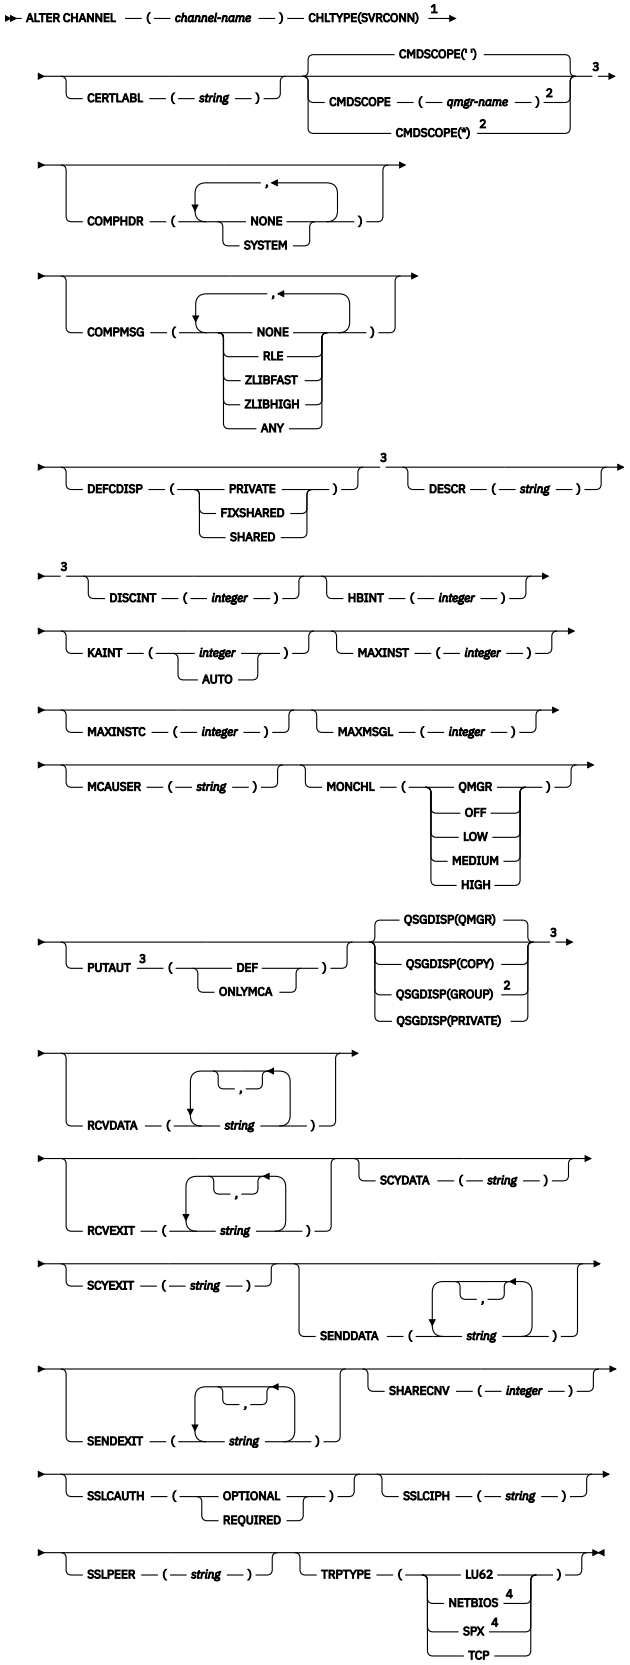
[1] This parameter must follow immediately after the channel name except on z/OS.
[2] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[3] Valid only on z/OS.
[4] Valid only if TRPTYPE is LU62.
[5] Valid only for clients to be run on DOS and Windows.

The parameters are described in “ALTER CHANNEL (alter channel settings)” on page 256.

Server-connection channel

Syntax diagram for a server-connection channel when using the **ALTER CHANNEL** command.

ALTER CHANNEL



Notes:

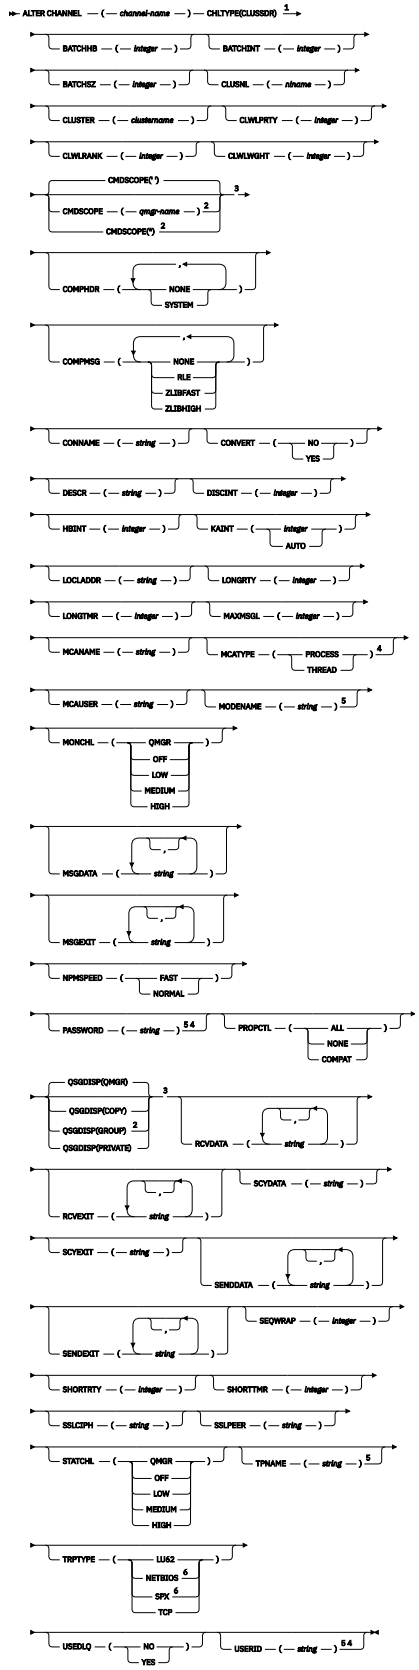
[1] This parameter must follow immediately after the channel name except on z/OS.
[2] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[3] Valid only on z/OS.
[4] Valid only for clients to be run on Windows.

The parameters are described in “ALTER CHANNEL (alter channel settings)” on page 256.

Cluster-sender channel

Syntax diagram for a cluster-sender channel when using the **ALTER CHANNEL** command.

ALTER CHANNEL



Notes:

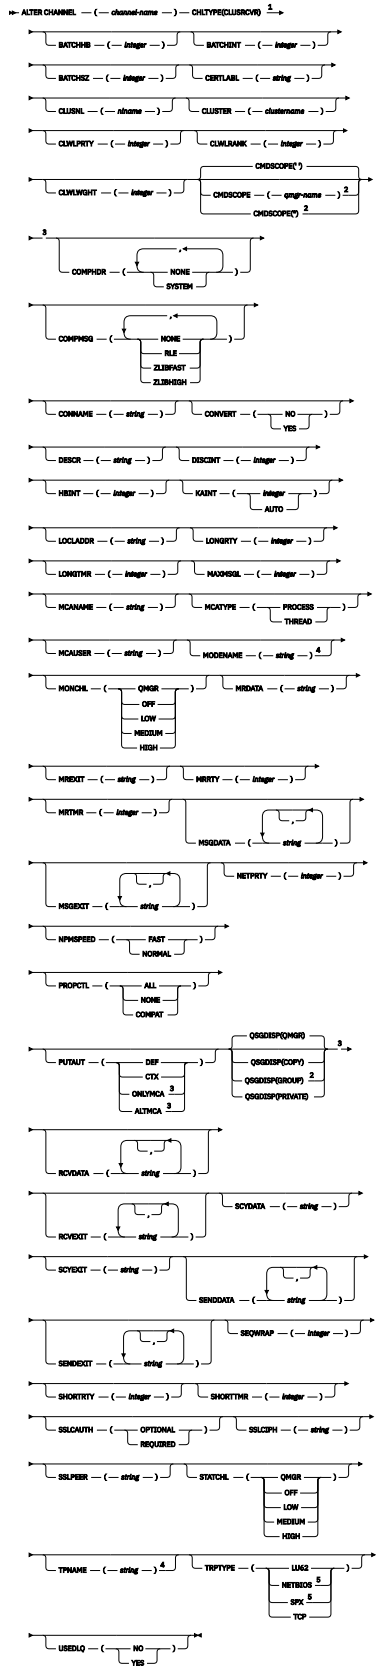
[1] This parameter must follow immediately after the channel name except on z/OS.
[2] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[3] Valid only on z/OS.
[4] Not valid on z/OS.
[5] Valid only if TRPTYPE is LU62.
[6] Valid only Windows.

The parameters are described in "ALTER CHANNEL (alter channel settings)" on page 256.

Cluster-receiver channel

Syntax diagram for a cluster-receiver channel when using the **ALTER CHANNEL** command.

ALTER CHANNEL



Notes:

[1] This parameter must follow immediately after the channel name except on z/OS.
[2] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[3] Valid only on z/OS.
[4] Valid only if TRPTYPE is LU62.
[5] Valid only on Windows.

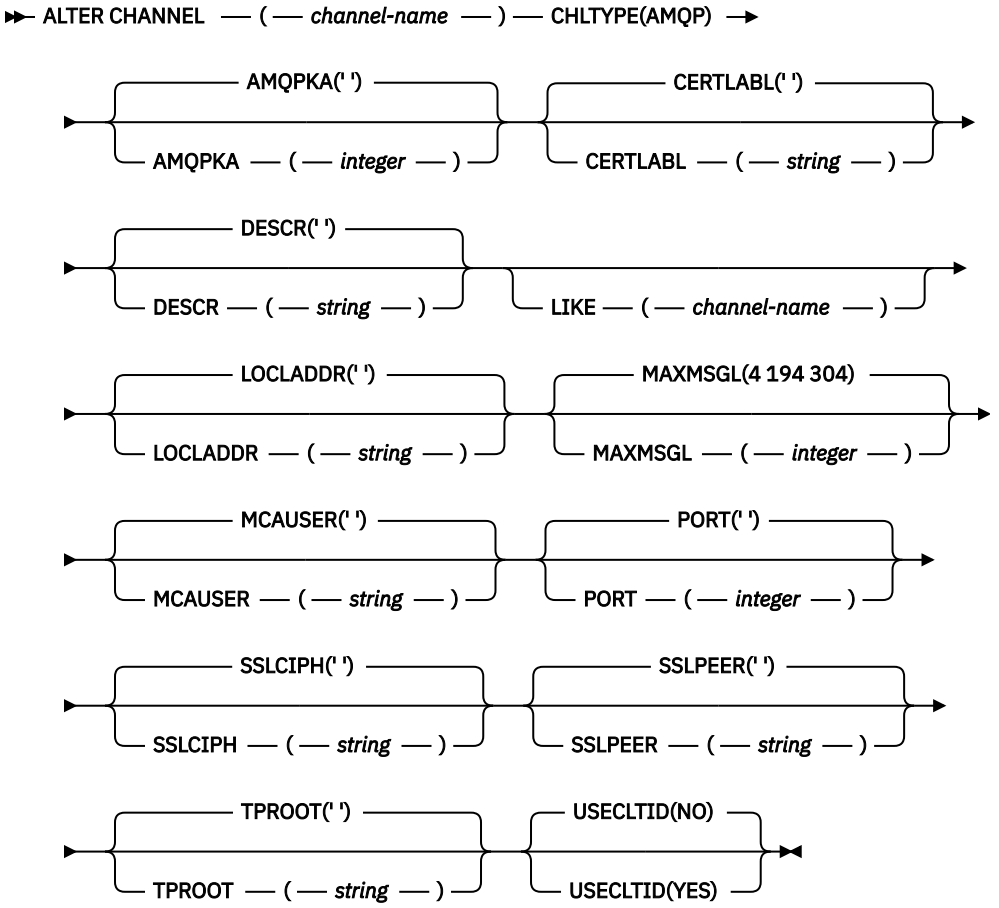
The parameters are described in "ALTER CHANNEL (alter channel settings)" on page 256.

ALW *AMQP channel*

Syntax diagram for an AMQP channel when using the **ALTER CHANNEL** command.

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See "Syntax diagrams" on page 236.

DEFINE CHANNEL



The parameters are described in "ALTER CHANNEL (alter channel settings)" on page 256.

Windows Linux AIX ALTER CHANNEL (alter channel settings) MQTT

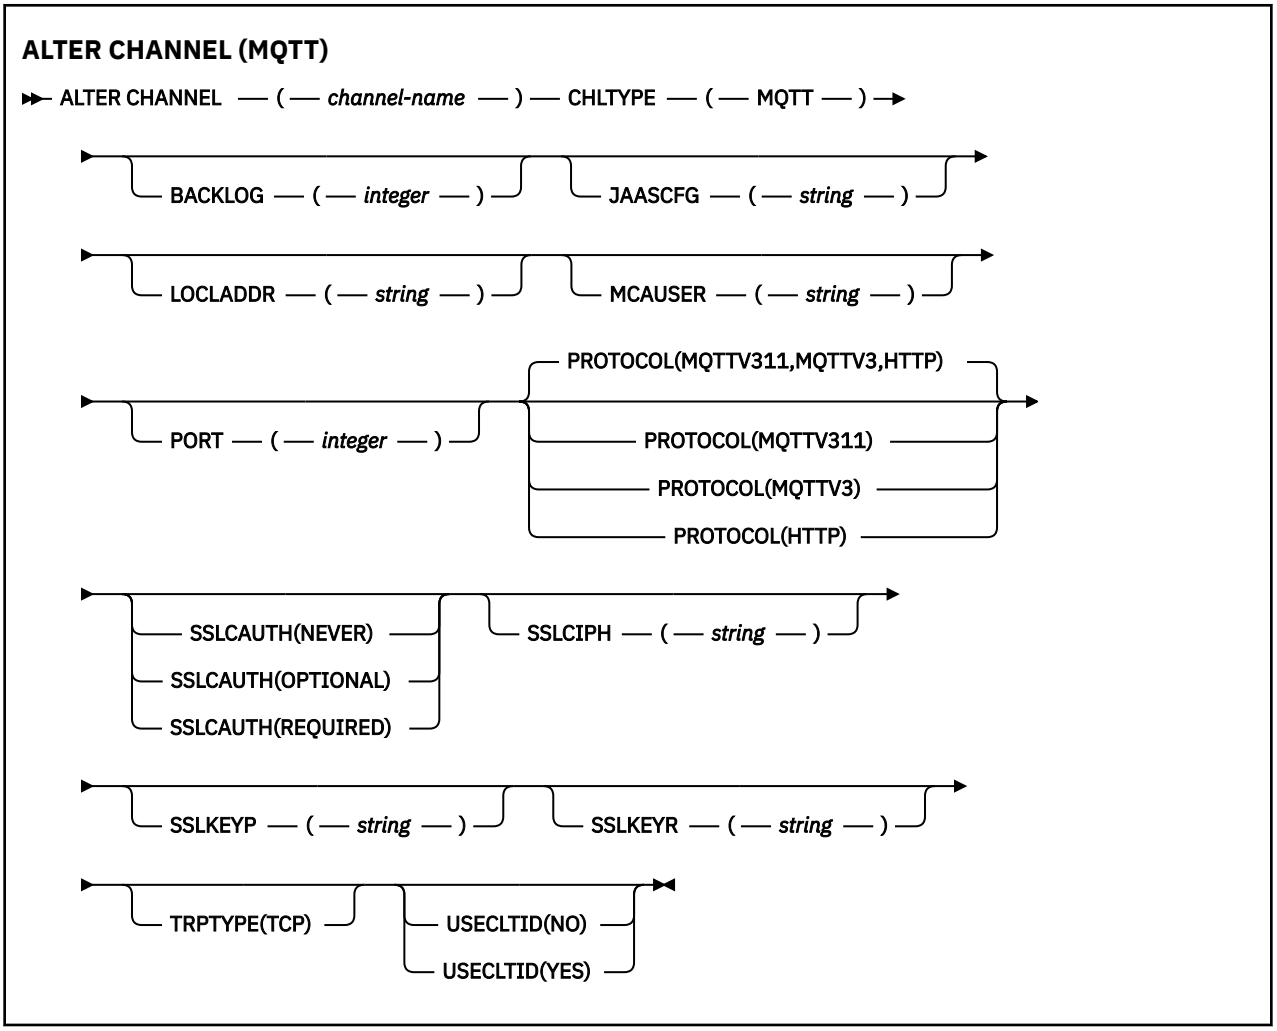
Syntax diagram for a telemetry channel when using the **ALTER CHANNEL** command.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

Synonym: **ALT CHL**

ALTER CHANNEL (MQTT)



Usage notes

The telemetry (MQXR) service must be running when you issue this command. For instructions on how to start the telemetry (MQXR) service, see Configuring a queue manager for telemetry on Linux or Configuring a queue manager for telemetry on Windows .

Parameter descriptions for ALTER CHANNEL (MQTT)

(channel-name)

The name of the channel definition.

BACKLOG(*integer*)

The number of outstanding connection requests that the telemetry channel can support at any one time. When the backlog limit is reached, any further clients trying to connect will be refused connection until the current backlog is processed.

The value is in the range 0 - 999999999.

The default value is 4096.

CHLTYPE

Channel type. MQTT (telemetry) channel.

JAASCFG (*string*)

The name of a stanza in the JAAS configuration file.

See Authenticating an MQTT client Java app with JAAS

LOCLADDR (*ip-addr*)

LOCLADDR is the local communications address for the channel. Use this parameter if you want to force the client to use a particular IP address. LOCLADDR is also useful to force a channel to use an IPv4 or IPv6 address if a choice is available, or to use a particular network adapter on a system with multiple network adapters.

The maximum length of **LOCLADDR** is MQ_LOCAL_ADDRESS_LENGTH.

If you omit **LOCLADDR**, a local address is automatically allocated.

ip-addr
ip-addr is a single network address, specified in one of three forms:

IPv4 dotted decimal
For example 192.0.2.1

IPv6 hexadecimal notation
For example 2001:DB8:0:0:0:0:0:0

Alphanumeric host name form
For example WWW.EXAMPLE.COM

If an IP address is entered, only the address format is validated. The IP address itself is not validated.

MCAUSER(*string*)

Message channel agent user identifier.

The maximum length of the string is 12 characters. On Windows, you can optionally qualify a user identifier with the domain name in the format user@domain.

If this parameter is nonblank, and **USECLNTID** is set to NO, then this user identifier is used by the telemetry service for authorization to access IBM MQ resources.

If this parameter is blank, and **USECLNTID** is set to NO, then the user name flowed in the MQTT CONNECT Packet is used. See MQTT client identity and authorization.

PORT(*integer*)

The port number on which the telemetry (MQXR) service accepts client connections. The default port number for a telemetry channel is 1883; and the default port number for a telemetry channel secured using SSL is 8883. Specifying a port value of 0 causes MQTT to dynamically allocate an available port number.

PROTOCOL

The following communication protocols are supported by the channel:

MQTTV311
The channel accepts connections from clients using the protocol defined by the MQTT 3.1.1 Oasis standard. The functionality provided by this protocol is almost identical to that provided by the pre-existing MQTTV3 protocol.

MQTTV3
The channel accepts connections from clients using the MQTT V3.1 Protocol Specification from mqtt.org.

HTTP
The channel accepts HTTP requests for pages, or WebSockets connections to MQ Telemetry.

To accept connections from clients using different protocols, specify the acceptable values as a comma-delimited list. For example if you specify `MQTTV3,HTTP` the channel accepts connections from clients using either MQTTV3 or HTTP. If you specify no client protocols, the channel accepts connections from clients using any of the supported protocols.

If you are using IBM MQ 8.0.0 Fix Pack 3 or later, and your configuration includes an MQTT channel that was last modified in an earlier version of the product, you must explicitly change the protocol setting to prompt the channel to use the `MQTTV311` option. This is so even if the channel does not specify any client protocols, because the specific protocols to use with the channel are stored at the time the channel is configured, and previous versions of the product have no awareness of the `MQTTV311` option. To prompt a channel in this state to use the `MQTTV311` option, explicitly add the option then save your changes. The channel definition is now aware of the option. If you subsequently change the settings again, and specify no client protocols, the `MQTTV311` option is still included in the stored list of supported protocols.

SSLCAUTH

Defines whether IBM MQ requires a certificate from the TLS client. The initiating end of the channel acts as the TLS client, so this parameter applies to the end of the channel that receives the initiation flow, which acts as the TLS server.

NEVER
IBM MQ never requests a certificate from the TLS client.

REQUIRED
IBM MQ requires and validates a certificate from the TLS client.

OPTIONAL
IBM MQ lets the TLS client decide whether to provide a certificate. If the client sends a certificate, the contents of this certificate are validated as normal.

SSLCIPH*(string)*

When **SSLCIPH** is used with a telemetry channel, it means TLS Cipher Suite. The TLS cipher suite is the one supported by the JVM that is running the telemetry (MQXR) service. If the parameter is blank, no attempt is made to use TLS on the channel.

If you plan to use SHA-2 cipher suites, see System requirements for using SHA-2 cipher suites with MQTT channels.

SSLKEYP(*string*)

The passphrase for the TLS key repository.

V 9.2.4 If the MQXR service is configured for encryption of passphrases by specifying the **-sf** option in STARTARG for the service, then the pass phrase will be encrypted. For more information on encryption of passphrases, see Encryption of passphrases for MQTT TLS channels.

SSLKEYR(*string*)

The full path name of the TLS key repository file, the store for digital certificates and their associated private keys. If you do not specify a key file, TLS is not used.

The maximum length of the string is 256 characters;

- Linux AIX On AIX and Linux, the name is of the form *pathname/keyfile*.
- Windows On Windows, the name is of the form *pathname\keyfile*.

where *keyfile* is specified without the suffix `.jks`, and identifies a Java keystore file.

TRPTYPE (*string*)

The transmission protocol to be used:

TCP
TCP/IP.

USECLTID

Decide whether you want to use the MQTT client ID for the new connection as the IBM MQ user ID for that connection. If this property is specified, the user name supplied by the client is ignored.

If you set this parameter to YES, then **MCAUSER** must be blank.

If **USECLNTID** is set to NO, and **MCAUSER** is blank, then the user name flowed in the MQTT CONNECT Packet is used. See MQTT client identity and authorization.

Multi ALTER COMMINFO (alter communication information object) on Multiplatforms

Use the MQSC command ALTER COMMINFO to alter the parameters of a communication information object.

Using MQSC commands

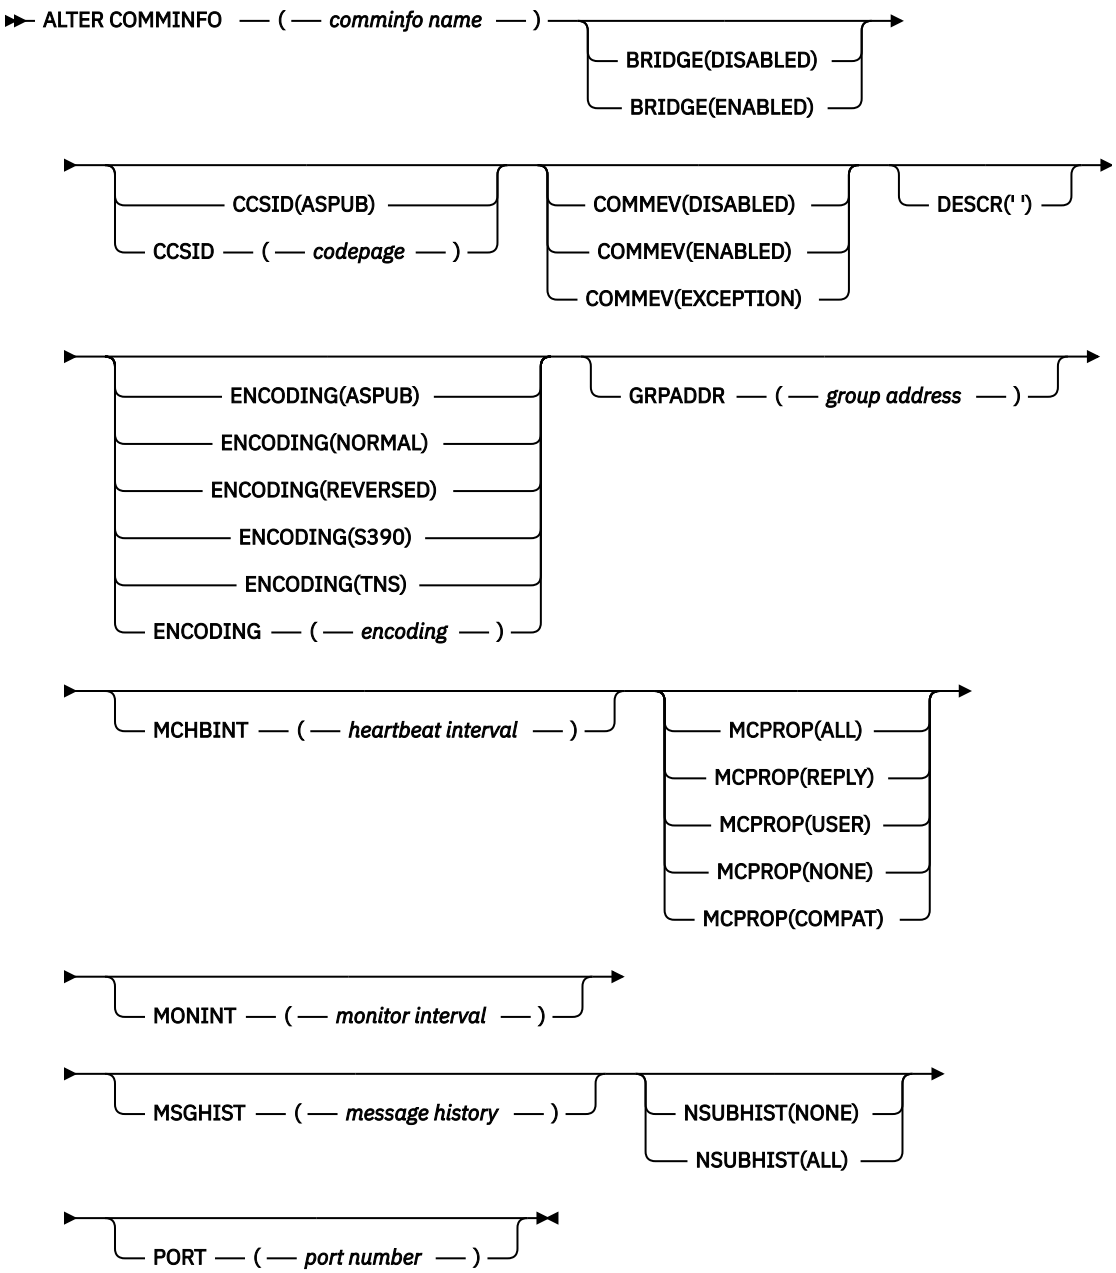
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

Parameters not specified in the **ALTER COMMINFO** command result in the existing values for those parameters being left unchanged.

- Syntax diagram
- "Parameter descriptions for ALTER COMMINFO" on page 316

Synonym: ALT COMMINFO

ALTER COMMINFO



Notes:

Parameter descriptions for ALTER COMMINFO

(comminfo name)
Name of the communications information object. This parameter is required.

The name must not be the same as any other communications information object name currently defined on this queue manager. See Rules for naming IBM MQ objects.

BRIDGE
Controls whether publications from applications not using Multicast are bridged to applications using Multicast. Bridging does not apply to topics that are marked as **MCAST(ONLY)**. As these topics can only be Multicast traffic, it is not applicable to bridge to the queue's publish/subscribe domain.

DISABLED
Publications from applications not using Multicast are not bridged to applications that do use Multicast.

ENABLED
Publications from applications not using Multicast are bridged to applications that do use Multicast.

CCSID(*integer*)
The coded character set identifier that messages are transmitted on. Specify a value in the range 1 through 65535.

The CCSID must specify a value that is defined for use on your platform, and use a character set that is appropriate to the queue manager's platform. If you use this parameter to change the CCSID, applications that are running when the change is applied continue to use the original CCSID therefore you must stop and restart all running applications before you continue. Running applications include the command server and channel programs. Stop and restart all running applications, stop and restart the queue manager after changing this parameter.

The CCSID can also be set to ASPUB, which means that the coded character set is taken from that supplied in the published message.

COMMEV
Controls whether event messages are generated for Multicast handles that are created using this COMMINFO object. Events are only generated if they are enabled using the **MONINT** parameter.

DISABLED
Publications from applications not using Multicast are not bridged to applications that do use Multicast.

ENABLED
Publications from applications not using Multicast are bridged to applications that do use Multicast.

EXCEPTION
Event messages are written if the message reliability is below the reliability threshold. The reliability threshold is set to 90 by default.

DESCR(*string*)
Plain-text comment. It provides descriptive information about the communication information object when an operator issues the DISPLAY COMMINFO command (see “DISPLAY COMMINFO (display communication information) on Multiplatforms” on page 704).

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

ENCODING
The encoding that the messages are transmitted in.

ASPUB
The encoding of the message is taken from that supplied in the published message.

NORMAL

REVERSED

S390

TNS

encoding

GRPADDR
The group IP address or DNS name.

It is the responsibility of the administrator to manage the group addresses. It is possible for all multicast clients to use the same group address for every topic; only the messages that match outstanding subscriptions on the client are delivered. Using the same group address can be inefficient because every client has to examine and process every multicast packet in the network. It is more efficient to allocate different IP group addresses to different topics or sets of topics, but this allocation requires careful management, especially if other non-MQ multicast applications are in use on the network.

MCHBINT
The heartbeat interval is measured in milliseconds, and specifies the frequency at which the transmitter notifies any receivers that there is no further data available.

MCPROP
The multicast properties control how many of the MQMD properties and user properties flow with the message.

All
All user properties and all the fields of the MQMD are transported.

Reply
Only user properties, and MQMD fields that deal with replying to the messages, are transmitted. These properties are:

- MsgType
- MessageId
- CorrelId
- ReplyToQ
- ReplyToQmgr

User
Only the user properties are transmitted.

NONE
No user properties or MQMD fields are transmitted.

COMPAT
This value causes the transmission of the message to be done in a compatible mode to RMM allowing some inter-operation with the current XMS applications and Broker RMM applications.

XMS .NET Multicast messaging (using RMM) was deprecated from IBM MQ 9.2 and will be removed in a future release of XMS .NET.

MONINT(*integer*)
How frequently, in seconds, that monitoring information is updated. If events messages are enabled, this parameter also controls how frequently event messages are generated about the status of the Multicast handles created using this COMMINFO object.

A value of 0 means that there is no monitoring.

MSGHIST
The maximum message history is the amount of message history that is kept by the system to handle retransmissions in the case of NACKs (negative acknowledgments).

A value of 0 gives the least level of reliability.

NSUBHIST
The new subscriber history controls whether a subscriber joining a publication stream receives as much data as is currently available, or receives only publications made from the time of the subscription.

NONE
A value of NONE causes the transmitter to transmit only publication made from the time of the subscription.

ALL
A value of ALL causes the transmitter to retransmit as much history of the topic as is known. In some circumstances, this retransmission can give a similar behavior to retained publications.

Note: Using the value of ALL might have a detrimental effect on performance if there is a large topic history because all the topic history is retransmitted.

PORT(*integer*)
The port number to transmit on.

Multi ALTER LISTENER (alter an existing listener) on Multiplatforms

Use MQSC command **ALTER LISTENER** to alter the parameters of an existing IBM MQ listener definition. If the listener is already running, any changes you make to its definition are effective only after the next time that the listener is started.

Using MQSC commands

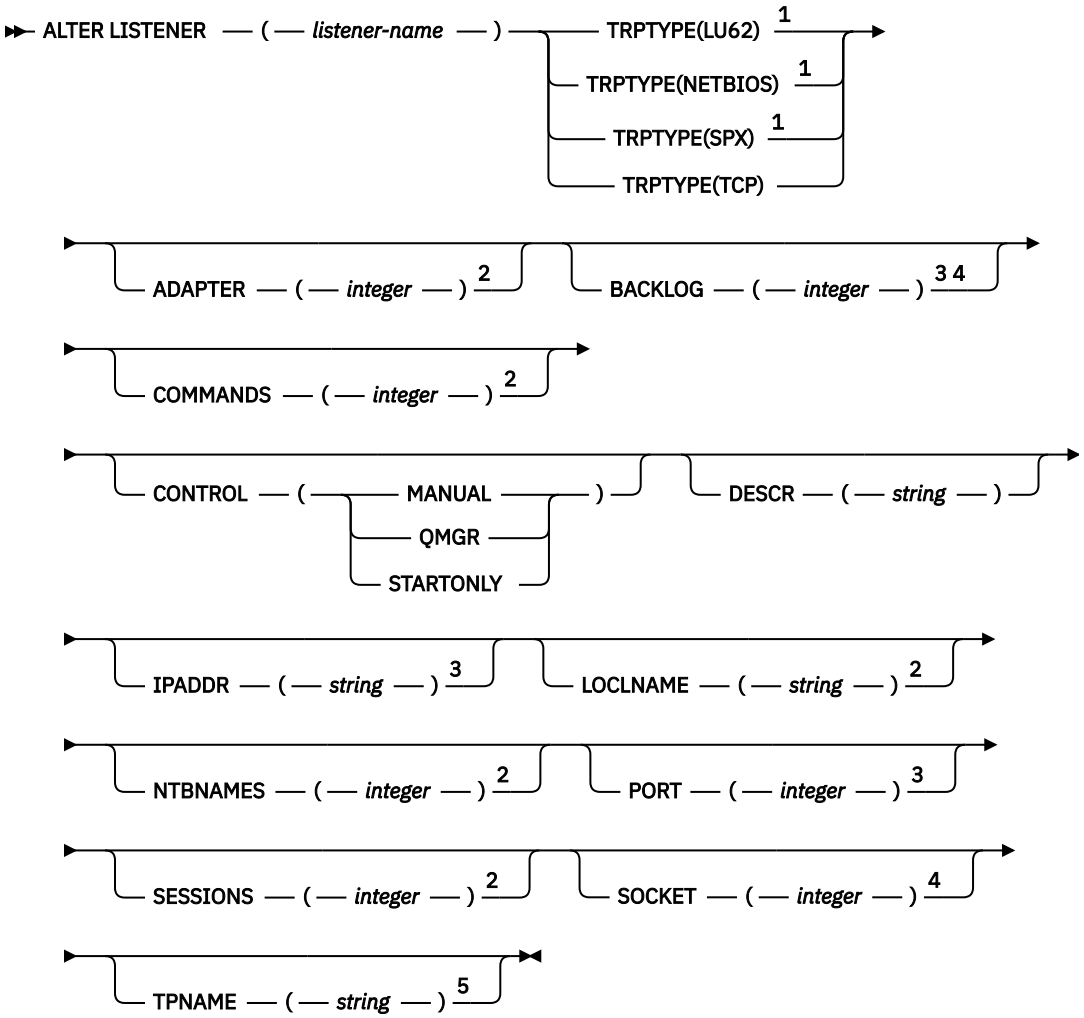
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

Parameters not specified in the **ALTER LISTENER** command result in the existing values for those parameters being left unchanged.

- Syntax diagram
- “Parameter descriptions for ALTER LISTENER” on page 320

Synonym: ALT LSTR

ALTER LISTENER



Notes:

[1] Valid only on Windows.
[2] Valid only on Windows when TRPTYPE is NETBIOS.
[3] Valid when TRPTYPE is TCP.
[4] Valid on Windows when TRPTYPE is SPX.
[5] Valid only on Windows when TRPTYPE is LU62.

Parameter descriptions for ALTER LISTENER

(listener-name)
Name of the IBM MQ listener definition (see Rules for naming IBM MQ objects). This is required.

The name must not be the same as any other listener definition currently defined on this queue manager (unless REPLACE is specified).

Windows **ADAPTER(*integer*)**
The adapter number on which NetBIOS listens. This parameter is valid only on Windows when TRPTYPE is NETBIOS.

BACKLOG(*integer*)
The number of concurrent connection requests that the listener supports.

Windows **COMMANDS(*integer*)**
The number of commands that the listener can use. This parameter is valid only on Windows when **TRPTYPE** is NETBIOS.

CONTROL(*string*)
Specifies how the listener is to be started and stopped.:

MANUAL
The listener is not to be started automatically or stopped automatically. It is to be controlled by use of the **START LISTENER** and **STOP LISTENER** commands.

QMGR
The listener being defined is to be started and stopped at the same time as the queue manager is started and stopped.

STARTONLY
The listener is to be started at the same time as the queue manager is started, but is not requested to stop when the queue manager is stopped.

DESCR(*string*)
Plain-text comment. It provides descriptive information about the listener when an operator issues the **DISPLAY LISTENER** command (see "DISPLAY LISTENER (display listener information) on Multiplatforms" on page 724).

It should contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

IPADDR(*string*)
IP address for the listener specified in IPv4 dotted decimal, IPv6 hexadecimal notation, or alphanumeric host name form. If you do not specify a value for this parameter, the listener listens on all configured IPv4 and IPv6 stacks.

LIKE(*listener-name*)
The name of a listener, with parameters that are used to model this definition.

This parameter applies only to the **DEFINE LISTENER** command.

If this field is not filled in, and you do not complete the parameter fields related to the command, the values are taken from the default definition for listeners on this queue manager. This is equivalent to specifying:

```
LIKE(SYSTEM.DEFAULT.LISTENER)
```

A default listener is provided but it can be altered by the installation of the default values required. See Rules for naming IBM MQ objects.

Windows **LOCLNAME(*string*)**
The NetBIOS local name that the listener uses. This parameter is valid only on Windows when **TRPTYPE** is NETBIOS.

Windows **NTBNAMES(*integer*)**
The number of names that the listener can use. This parameter is valid only on Windows when **TRPTYPE** is NETBIOS.

PORT(*integer*)
The port number for TCP/IP. This is valid only when TRPTYPE is TCP. It must not exceed 65535.

Windows **SESSIONS(*integer*)**
The number of sessions that the listener can use. This parameter is valid only on Windows when **TRPTYPE** is NETBIOS.

SOCKET(*integer*)
The SPX socket on which to listen. This is valid only if **TRPTYPE** is SPX.

Windows **TPNAME(*string*)**
The LU 6.2 transaction program name (maximum length 64 characters). This parameter is valid only on Windows when **TRPTYPE** is LU62.

TRPTYPE(*string*)
The transmission protocol to be used:

Windows **LU62**
SNA LU 6.2. This is valid only on Windows.

Windows **NETBIOS**
NetBIOS. This is valid only on Windows.

Windows **SPX**
Sequenced packet exchange. This is valid only on Windows.

TCP
TCP/IP.

Related tasks
Using the TCP listener backlog option on AIX and Linux

ALTER NAMELIST (alter a list of names)

Use the MQSC command **ALTER NAMELIST** to alter a list of names. This list is most commonly a list of cluster names or queue names.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

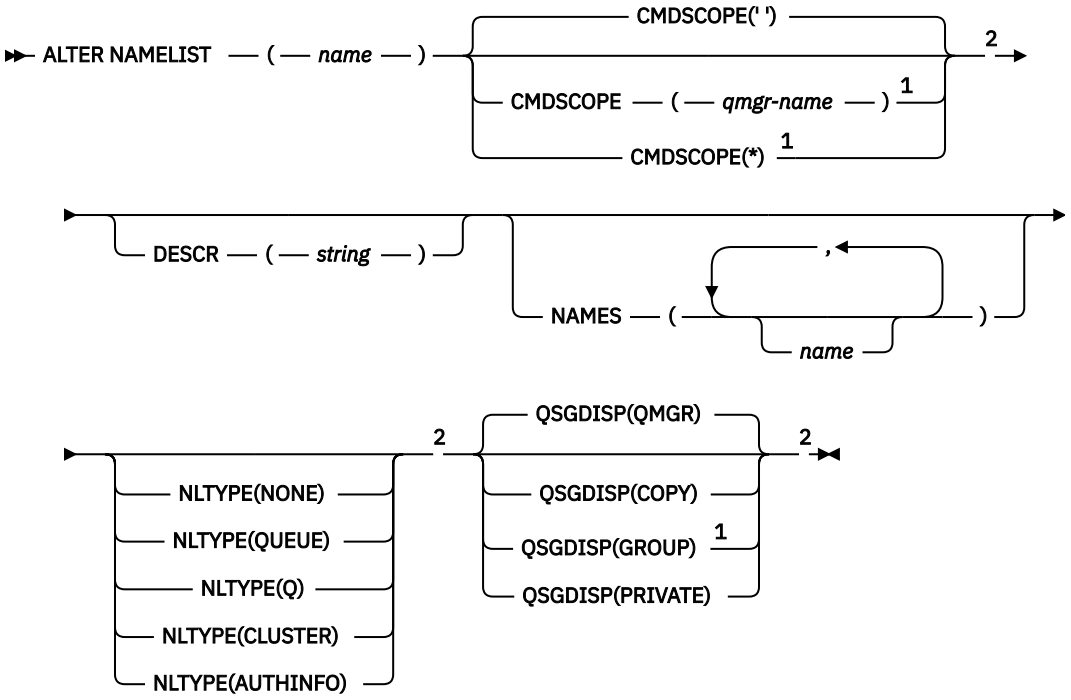
Parameters not specified in the **ALTER NAMELIST** command result in the existing values for those parameters being left unchanged.

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- “Usage notes” on page 323
- “Parameter descriptions for ALTER NAMELIST” on page 323

Synonym: ALT NL

ALTER NAMELIST



Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[2] Valid only on z/OS.

Usage notes

Successful completion of the command does not mean that the action completed. To check for true completion, see the ALTER NAMELIST step in Checking that async commands for distributed networks have finished.

Parameter descriptions for ALTER NAMELIST

(name)
Name of the list.

The name must not be the same as any other namelist name currently defined on this queue manager (unless **REPLACE** or **ALTER** is specified). See Rules for naming IBM MQ objects.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

' '
The command runs on the queue manager on which it was entered.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of specifying * is the same as entering the command on every queue manager in the queue sharing group.

DESCR(*string*)
Plain-text comment. It provides descriptive information about the namelist when an operator issues the **DISPLAY NAMELIST** command (see “DISPLAY NAMELIST (display a list of names)” on page 733).

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

NAMES(*name, ...*)
List of names.

The names can be of any type, but must conform to the rules for naming IBM MQ objects, with a maximum length of 48 characters.

An empty list is valid: specify **NAMES()**. The maximum number of names in the list is 256.

z/OS **NLTYPE**
Indicates the type of names in the namelist.

This parameter is valid only on z/OS.

NONE
The names are of no particular type.

QUEUE or Q
A namelist that holds a list of queue names.

CLUSTER
A namelist that is associated with clustering, containing a list of the cluster names.

AUTHINFO
This namelist is associated with TLS and contains a list of authentication information object names.

Namelists used for clustering must have **NLTYPE(CLUSTER)** or **NLTYPE(NONE)**.

Namelists used for TLS must have **NLTYPE(AUTHINFO)**.

z/OS **QSGDISP**
This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

Table 132. Behavior for each of the QSGDISP values

QSGDISP	ALTER
COPY	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters **QSGDISP(COPY)**. Any object residing in the shared repository, or any object defined using a command that had the parameters QSGDISP(QMGR), is not affected by this command.

Table 132. Behavior for each of the QSGDISP values (continued)

QSGDISP	ALTER

GROUP	The object definition resides in the shared repository. The object was defined using a command that had the parameters **QSGDISP(GROUP)**. Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command. If the command is successful, the following command is generated and sent to all active queue managers in the queue sharing group to attempt to refresh local copies on page set zero:
	`DEFINE NAMELIST(name)`
	`REPLACE QSGDISP(COPY)`
	The **ALTER** for the group object takes effect regardless of whether the generated command with **QSGDISP(COPY)** fails.

PRIVATE	The object resides on the page set of the queue manager that executes the command, and was defined with **QSGDISP(QMGR)** or **QSGDISP(COPY)**. Any object residing in the shared repository is unaffected.
QMGR	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters **QSGDISP(QMGR)**. Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

ALTER PROCESS (alter an existing process definition)

Use the MQSC command **ALTER PROCESS** to alter the parameters of an existing IBM MQ process definition.

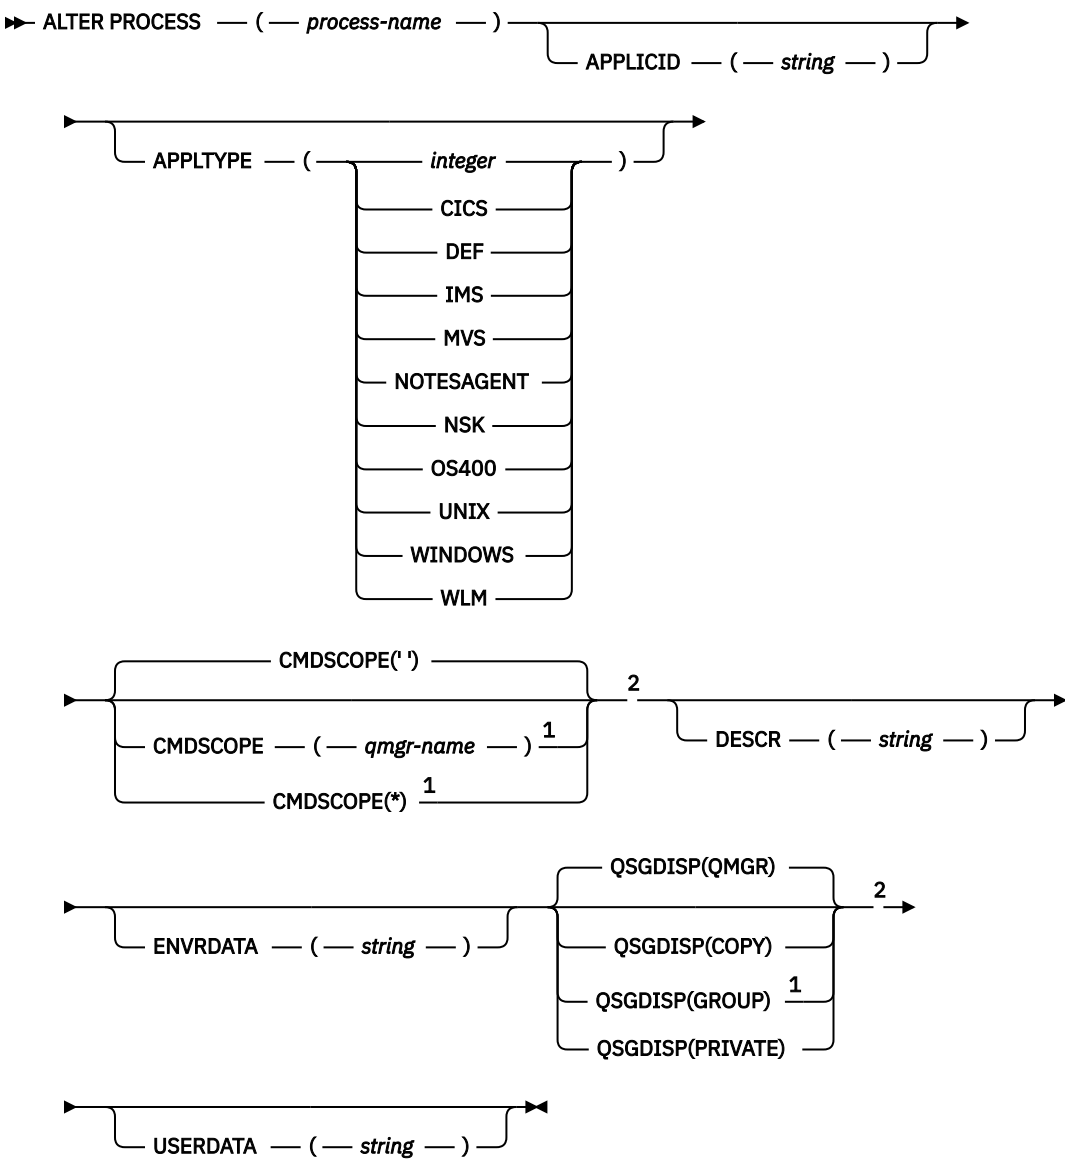
Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

Synonym: ALT PRO

ALTER PROCESS



Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[2] Valid only on z/OS.

Parameter descriptions for ALTER PROCESS

process-name
Name of the IBM MQ process definition (see Rules for naming IBM MQ objects). *process-name* is required.

The name must not be the same as any other process definition currently defined on this queue manager (unless **REPLACE** is specified).

APPLICID(*string*)
The name of the application to be started. The name might typically be a fully qualified file name of an executable object. Qualifying the file name is particularly important if you have multiple IBM MQ installations, to ensure the correct version of the application is run. The maximum length is 256 characters.

For a CICS® application the name is a CICS transaction ID, and for an IMS application it is an IMS transaction ID.

z/OS On z/OS, for distributed queuing, it must be "CSQX start".

APPLTYPE(*string*)
The type of application to be started. Valid application types are:

integer
A system-defined application type in the range zero through 65 535 or a user-defined application type in the range 65 536 through 999 999 999.

For certain values in the system range, a parameter from the following list can be specified instead of a numeric value:

CICS
Represents a CICS transaction.

z/OS **IMS**
Represents an IMS transaction.

z/OS **MVS**
Represents a z/OS application (batch or TSO).

NOTESAGENT
Represents a Lotus Notes agent.

IBM i **OS400**
Represents an IBM i application.

UNIX **UNIX**
Represents a Linux or AIX application.

Windows **WINDOWS**
Represents a Windows application.

z/OS **WLM**
Represents a z/OS workload manager application.

DEF
Specifying DEF causes the default application type for the platform at which the command is interpreted to be stored in the process definition. This default cannot be changed by the installation. If the platform supports clients, the default is interpreted as the default application type of the server.

Only use application types (other than user-defined types) that are supported on the platform at which the command runs:

- z/OS On z/OS: CICS, IMS, MVS, UNIX, WINDOWS, WLM, and DEF are supported
- IBM i On IBM i: OS400, CICS, and DEF are supported
- Linux AIX On AIX and Linux: UNIX, WINDOWS, CICS, and DEF are supported
- Windows On Windows, UNIX, WINDOWS, CICS, and DEF are supported

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

' '
The command runs on the queue manager on which it was entered.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

In a shared queue environment, you can provide a different queue manager name from the one you are using to enter the command. The command server must be enabled.

***
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect is the same as entering the command on every queue manager in the queue sharing group.

DESCR(*string*)
Plain-text comment. It provides descriptive information about the object when an operator issues the **DISPLAY PROCESS** command.

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: Use characters from the coded character set identifier (CCSID) for this queue manager. Other characters might be translated incorrectly if the information is sent to another queue manager.

ENVRDATA(*string*)
A character string that contains environment information pertaining to the application to be started. The maximum length is 128 characters.

The meaning of **ENVRDATA** is determined by the trigger-monitor application. The trigger monitor provided by IBM MQ appends **ENVRDATA** to the parameter list passed to the started application. The parameter list consists of the MQTMC2 structure, followed by one blank, followed by **ENVRDATA** with trailing blanks removed.

Note:

1. z/OS On z/OS, **ENVRDATA** is not used by the trigger-monitor applications provided by IBM MQ.
2. z/OS On z/OS, if **APPLTYPE** is `WLM`, the default values for the ServiceName and ServiceStep fields in the work information header (MQWIH) can be supplied in **ENVRDATA**. The format must be:

   ```
   SERVICENAME=servname,SERVICESTEP=stepname
   ```

   where:

   SERVICENAME=
   is the first 12 characters of **ENVRDATA**.

   servname
   is a 32-character service name. It can contain embedded blanks or any other data, and have trailing blanks. It is copied to the MQWIH as is.

   SERVICESTEP=
   is the next 13 characters of **ENVRDATA**.

   stepname
   is a 1 - 8 character service step name. It is copied as-is to the MQWIH, and padded to eight characters with blanks.

   If the format is incorrect, the fields in the MQWIH are set to blanks.
3. Linux AIX On AIX and Linux, **ENVRDATA** can be set to the ampersand character to make the started application run in the background.

z/OS **QSGDISP**
This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

Table 133. Behavior for each of the QSGDISP values

QSGDISP	ALTER
COPY	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters **QSGDISP(COPY)**. Any object residing in the shared repository, or any object defined using a command that had the parameters **QSGDISP(QMGR)**, is not affected by this command.

GROUP	The object definition resides in the shared repository. The object was defined using a command that had the parameters **QSGDISP(GROUP)**. On the page set of the queue manager that executes the command, only a local copy of the object is altered by this command. If the command is successful, the following command is generated.
	`DEFINE PROCESS(process-name)`
	`REPLACE QSGDISP(COPY)`
	The command is sent to all active queue managers in the queue sharing group to attempt to refresh local copies on page set zero. The **ALTER** for the group object takes effect regardless of whether the generated command with **QSGDISP(COPY)** fails.

PRIVATE	The object resides on the page set of the queue manager that executes the command, and was defined with **QSGDISP(QMGR)** or **QSGDISP(COPY)**. Any object residing in the shared repository is unaffected.
QMGR	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters **QSGDISP(QMGR)**. Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

USERDATA(*string*)
A character string that contains user information pertaining to the application defined in the **APPLICID** that is to be started. The maximum length is 128 characters.

The meaning of **USERDATA** is determined by the trigger-monitor application. The trigger monitor provided by IBM MQ simply passes **USERDATA** to the started application as part of the parameter list. The parameter list consists of the MQTMC2 structure (containing **USERDATA**), followed by one blank, followed by **ENVRDATA** with trailing blanks removed.

For IBM MQ message channel agents, the format of this field is a channel name of up to 20 characters. See Managing objects for triggering for information about what **APPLICID** to provide to message channel agents.

Windows For Microsoft Windows, the character string must not contain double quotation marks if the process definition is going to be passed to **runmqtrm**.

z/OS ALTER PSID (change page set expansion method) on z/OS

Use the MQSC command **ALTER PSID** to change the expansion method for a page set.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

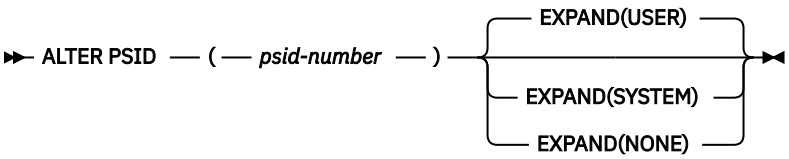
Parameters not specified in the **ALTER PSID** command result in the existing values for those parameters being left unchanged.

You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Parameter descriptions for ALTER PSID" on page 330

Synonym: ALT PSID

ALTER PSID



Parameter descriptions for ALTER PSID

(psid-number)
Identifier of the page set. This is required.

EXPAND
Controls how the queue manager should expand a page set when it becomes nearly full, and further pages are required in it.

USER
The secondary extent size that was specified when the page set was defined is used. If no secondary extent size was specified, or if it was specified as zero, then no dynamic page set expansion can take place.

At restart, if a previously used page set has been replaced with a data set that is smaller, it is expanded until it reaches the size of the previously used data set. Only one extent is required to reach this size.

SYSTEM

A secondary extent size that is approximately 10 per cent of the current size of the page set is used. It might be rounded up depending on the characteristics of the DASD.

The secondary extent size that was specified when the page set was defined is ignored; dynamic expansion can occur if it was zero or not specified.

NONE
No further page set expansion is to take place.

Usage note

You can use **ALTER PSID** to reset an internal IBM MQ indicator that prevents the page set from being expanded; for example, after the data set has been **ALTER**ed to **ADDVOLUMES**.

In this instance, although the **EXPAND** keyword must be specified with a value, you do not have to change the value from that already configured. For example, if **DISPLAY USAGE** shows page set 3 configured with **EXPAND(SYSTEM)**, you issue the following command to allow IBM MQ to retry page set expansion:

```
ALTER PSID(3) EXPAND(SYSTEM)
```

Related reference
"DISPLAY USAGE (display usage information) on z/OS" on page 849

Use the MQSC command DISPLAY USAGE to display information about the current state of a page set, to display information about the log data sets, or to display information about the shared message data sets.

ALTER QMGR (alter queue manager settings)

Use the MQSC command **ALTER QMGR** to alter the queue manager parameters for the local queue manager.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

Parameters not specified in the **ALTER QMGR** command result in the existing values for those parameters being left unchanged.

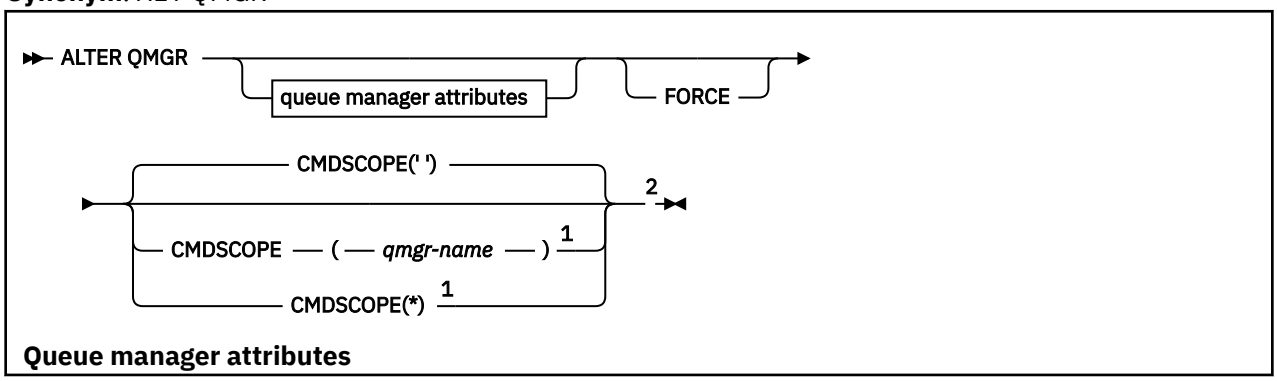
z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

This information is divided into three sections:

- "ALTER QMGR" on page 331
- "Parameter descriptions for ALTER QMGR" on page 333
- "Queue manager parameters" on page 333

ALTER QMGR

Synonym: ALT QMGR



Queue manager attributes

Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.

[2] Valid only on z/OS.

[3] Not valid on z/OS.
[4] Valid only on AIX, Linux, and Windows.
[5] Not valid on IBM i.

Parameter descriptions for ALTER QMGR

The parameters you specify override the current values. Attributes that you do not specify are unchanged.

Note:

1. If you do not specify any parameters, the command completes successfully, but no queue manager options are changed.
2. Changes made using this command persist when the queue manager is stopped and restarted.

FORCE
Specify this parameter to force completion of the command if both of the following statements are true:

- The **DEFXMITQ** parameter is specified
- An application has a remote queue open, the resolution for which would be affected by this change

If **FORCE** is not specified in these circumstances, the command is unsuccessful.

Queue manager parameters

These parameters are the queue manager parameters for the **ALTER QMGR** command:

Multi **ACCTCONO**
Specifies whether applications can override the settings of the **ACCTQ** and **ACCTMQI** queue manager parameters:

DISABLED
Applications cannot override the settings of the **ACCTQ** and **ACCTMQI** parameters.

This is the queue manager's initial default value.

ENABLED
Applications can override the settings of the **ACCTQ** and **ACCTMQI** parameters by using the options field of the MQCNO structure of the MQCONNX API call.

Changes to this parameter are effective for connections to the queue manager that occur after the change.

This parameter is valid only on Multiplatforms.

Multi **ACCTINT(*integer*)**
The time interval, in seconds, at which intermediate accounting records are written.

Specify a value in the range 1 through 604800.

Changes to this parameter are effective for connections to the queue manager that occur after the change.

This parameter is valid only on Multiplatforms.

Multi **ACCTMQI**
Specifies whether accounting information for MQI data is to be collected:

OFF
MQI accounting data collection is disabled.

This is the queue manager's initial default value.

ON
MQI accounting data collection is enabled.

If queue manager attribute **ACCTCONO** is set to ENABLED, the value of this parameter can be overridden using the options field of the MQCNO structure.

Changes to this parameter are effective for connections to the queue manager that occur after the change.

This parameter is valid only on Multiplatforms.

ACCTQ
Specifies whether accounting data is to be collected for all queues.

z/OS On z/OS, the data collected is class 3 accounting data (thread-level and queue-level accounting).

OFF
Accounting data collection is disabled for all queues which specify QMGR as the value for their ACCTQ parameter.

ON
Accounting data collection is enabled for all queues which specify QMGR as the value of their ACCTQ parameter.

z/OS On z/OS systems, you must switch on class 3 accounting by the START TRACE command.

NONE
Accounting data collection for all queues is disabled regardless of the value of the ACCTQ parameter of the queue.

Changes to this parameter are effective only for connections to the queue manager occurring after the change to the parameter.

z/OS **ACTCHL(*integer*)**
The maximum number of channels that can be *active* at any time, unless the value is reduced below the number of currently active channels.

Specify a value from 1 through 9999 that is not greater than the value of MAXCHL. MAXCHL defines the maximum number of channels available.

If you change this value, you must also review the MAXCHL, LU62CHL, and TCPCHL values to ensure that there is no conflict of values

For an explanation of which channel states are considered active; see Channel states.

If the value of ACTCHL is reduced to less than its value when the channel initiator was initialized, channels continue to run until they stop. When the number of running channels falls below the value of ACTCHL, more channels can be started. Increasing the value of ACTCHL to more than its value when the channel initiator was initialized does not have immediate effect. The higher value of ACTCHL takes effect at the next channel initiator restart.

Sharing conversations do not contribute to the total for this parameter.

This parameter is valid only on z/OS.

ACTIVREC
Specifies whether activity reports are generated if requested in the message:

DISABLED
Activity reports are not generated.

MSG
Activity reports are generated and sent to the reply queue specified by the originator in the message causing the report.

This is the queue manager's initial default value.

QUEUE
Activity reports are generated and sent to SYSTEM.ADMIN.ACTIVITY.QUEUE

See Activity recording.

Multi **ACTVCONO**
Specifies whether applications can override the settings of the **ACTVTRC** queue manager parameter:

DISABLED
Applications cannot override the settings of the **ACTVTRC** queue manager parameter.

This is the queue manager's initial default value.

ENABLED
Applications can override the settings of the **ACTVTRC** queue manager parameter by using the options field of the MQCNO structure of the MQCONNX API call.

Changes to this parameter are effective for connections to the queue manager that occur after the change.

This parameter is valid only on Multiplatforms.

Multi **ACTVTRC**
Specifies whether MQI application activity tracing information is to be collected. See Setting ACTVTRC to control collection of activity trace information.

OFF
IBM MQ MQI application activity tracing information collection is not enabled.

This is the queue manager's initial default value.

ON
IBM MQ MQI application activity tracing information collection is enabled.

If the queue manager attribute **ACTVCONO** is set to ENABLED, the value of this parameter can be overridden using the options field of the MQCNO structure.

Changes to this parameter are effective for connections to the queue manager that occur after the change.

This parameter is valid only on Multiplatforms.

z/OS **ADOPTCHK**
Specifies which elements are checked to determine whether an MCA is adopted. The check is made when a new inbound channel is detected with the same name as an already active MCA.

ALL
Check the queue manager name and the network address. Perform this check to prevent your channels from being inadvertently or maliciously shut down.

This is the queue manager's initial default value.

NETADDR
Check the network address.

NONE
Do no checking.

QMNAME
Check the queue manager name.

Changes to this parameter take effect the next time that a channel attempts to adopt an MCA.

This parameter is valid only on z/OS.

z/OS **ADOPTMCA**
Specifies whether an orphaned instance of an MCA restarts immediately when a new inbound channel request matching the **ADOPTCHK** parameter is detected:

ALL
Adopt all channel types.

This is the queue manager's initial default value.

NO
Adoption of orphaned channels is not required.

Changes to this parameter take effect the next time that a channel attempts to adopt an MCA.

This parameter is valid only on z/OS.

AUTHOREV
Specifies whether authorization (Not Authorized) events are generated:

DISABLED
Authorization events are not generated.

This is the queue manager's initial default value.

ENABLED
Authorization events are generated.

z/OS This value is not supported on z/OS.

z/OS **BRIDGEEV**
Specifies whether IMS bridge events are generated.

DISABLED
IMS bridge events are not generated.

This is the queue manager's initial default value.

ENABLED
All IMS bridge events are generated.

This parameter is valid only on z/OS.

Multi **CCSID(*integer*)**
The coded character set identifier for the queue manager. The CCSID is the identifier used with all character string fields defined by the API. If the CCSID in the message descriptor is set to the value `MQCCSI_Q_MGR`, the value applies to application data in the body of a message. The value is set when the message is put to a queue.

Specify a value in the range 1 through 65535. The CCSID specifies a value that is defined for use on your platform, and use a character set that is appropriate to the platform.

If you use this parameter to change the CCSID, applications that are running when the change is applied continue to use the original CCSID. Therefore, stop and restart all running applications before you continue including the command server and channel programs. To stop and restart all running applications, stop and restart the queue manager after changing the parameter value.

This parameter is valid only on Multiplatforms. See Code page conversion for details of the supported CCSIDs for each platform.

z/OS To carry out the equivalent tasks on z/OS, use CSQ6SYSP to set your system parameters.

CERTLABL
Certificate label for this queue manager to use. The label identifies which personal certificate in the key repository has been selected.

The default and migrated queue manager values are:

- ALW On AIX, Linux, and Windows: *ibmwebspheremqxxxx* where *xxxx* is the queue manager name folded to lowercase.
- IBM i On IBM i:
  - If you specified SSLKEYR(*SYSTEM), the value is blank.

    Note that it is forbidden to use a nonblank queue manager CERTLABL with SSLKEYR(*SYSTEM). Attempting to do so results in an MQRCCF_Q_MGR_ATTR_CONFLICT error.
  - Otherwise, *ibmwebspheremqxxxx* where *xxxx* is the queue manager name folded to lowercase.
- z/OS On z/OS: *ibmWebSphereMQXXXX* where *XXXX* is the queue manager name.

See z/OS systems for more information.

You should specify the preceding values. However, leaving **CERTLABL** as a blank value on the queue manager is interpreted by the system to mean the default values specified.

Important: You must run a REFRESH SECURITY TYPE(SSL) command if you make any changes to **CERTLABL** on the queue manager. However, you do not need to run the REFRESH SECURITY TYPE(SSL) command if you make any changes to **CERTLABL** on a channel.

z/OS **CERTQSGL**

Queue sharing group (QSG) certificate label.

This parameter takes precedence over **CERTLABL** in the event that the queue manager is a member of a QSG.

The default value for this parameter is *ibmWebSphereMQXXXX* where *XXXX* is the queue sharing group name.

This parameter is valid only on z/OS.

See z/OS systems for more information.

Multi **CERTVPOL**

Specifies which TLS certificate validation policy is used to validate digital certificates received from remote partner systems. This attribute can be used to control how strictly the certificate chain validation conforms to industry security standards.

ANY
Apply each of the certificate validation policies supported by the secure sockets library and accept the certificate chain if any of the policies considers the certificate chain valid. This setting can be used for maximum backwards compatibility with older digital certificates which do not comply with the modern certificate standards.

RFC5280
Apply only the RFC 5280 compliant certificate validation policy. This setting provides stricter validation than the ANY setting, but rejects some older digital certificates.

For more information about certificate validation policies, see Certificate validation policies in IBM MQ.

Changes to the parameter take effect only after a **REFRESH SECURITY TYPE(SSL)** command is issued.

This parameter is valid only on Multiplatforms.

z/OS **CFCONLOS**

Specifies the action to be taken when the queue manager loses connectivity to the administration structure, or any CF structure with **CFCONLOS** set to ASQMGR.

TERMINATE
The queue manager terminates when connectivity to CF structures is lost.

TOLERATE
The queue manager tolerates loss of connectivity to CF structures without terminating.

This parameter is valid only on z/OS.

Multi **CHAD**
Specifies whether receiver and server-connection channels can be defined automatically:

DISABLED
Auto-definition is not used.

This is the queue manager's initial default value.

ENABLED
Auto-definition is used.

Cluster-sender channels can always be defined automatically, regardless of the setting of this parameter.

This parameter is valid only on Multiplatforms.

Multi **CHADEV**
Specifies whether channel auto-definition events are generated.

DISABLED
Auto-definition events are not generated.

This is the queue manager's initial default value.

ENABLED
Auto-definition events are generated.

This parameter is valid only on Multiplatforms.

CHADEXIT(*string*)
Auto-definition exit name.

If this name is nonblank, the exit is called when an inbound request for an undefined receiver, server-connection, or cluster-sender channel is received. It is also called when starting a cluster-receiver channel.

The format and maximum length of the name depends on the environment:

- Linux AIX On AIX and Linux, it is of the form *libraryname(functionname)*. The maximum length is 128 characters.
- Windows On Windows, it is of the form *dllname(functionname)* where *dllname* is specified without the suffix `.DLL`. The maximum length is 128 characters.
- IBM i On IBM i, it is of the form:

  ```
  progname libname
  ```

  where *program name* occupies the first 10 characters and *libname* the second 10 characters (both blank-padded to the right if necessary). The maximum length of the string is 20 characters.
- z/OS On z/OS, it is a load module name, the maximum length is eight characters.

z/OS On z/OS, the **CHADEXIT** parameter applies only to cluster-sender and cluster-receiver channels.

z/OS **CHIADAPS(*integer*)**
The number of channel initiator adapter subtasks to use for processing IBM MQ calls.

Specify a value in the range 0 - 9999. Suggested settings are:

- Test system: 8

- Production system: 30

Changes to this parameter take effect when the channel initiator is restarted.

For more information about the relationship between CHIADAPS, CHIDISPS and MAXCHL, see Tailor the channel initiator parameters.

This parameter is valid only on z/OS.

z/OS **CHIDISPS (*integer*)**
The number of dispatchers to use in the channel initiator.

Specify a value in the range 1 through 9999. Suggested settings are:

- Test system: 5
- Production system: 20

Changes to this parameter take effect when the channel initiator is restarted.

For more information about the relationship between CHIADAPS, CHIDISPS and MAXCHL, see Tailor the channel initiator parameters.

This parameter is valid only on z/OS.

z/OS **CHISERVP**
This parameter is reserved for IBM use only; it is not for general use.

This parameter is valid only on z/OS.

CHLAUTH
Specifies whether the rules defined by channel authentication records are used. CHLAUTH rules can still be set and displayed regardless of the value of this attribute.

Changes to this parameter take effect the next time that an inbound channel attempts to start. Channels that are currently started are unaffected by changes to this parameter.

DISABLED
Channel authentication records are not checked.

ENABLED
Channel authentication records are checked.

CHLEV
Specifies whether channel events are generated.

DISABLED
Channel events are not generated. This is the queue manager's initial default value.

ENABLED
All channel events are generated.

EXCEPTION
All exception channel events are generated.

CLWLDATA(*string*)
Cluster workload exit data. The maximum length of the string is 32 characters.

This string is passed to the cluster workload exit when it is called.

CLWLEXIT(*string*)
Cluster workload exit name.

If this name is nonblank, the exit is called when a message is put to a cluster queue. The format and maximum length of the name depends on the environment:

- Linux AIX On AIX and Linux, it is of the form *libraryname(functionname)*. The maximum length is 128 characters.

- Windows On Windows, it is of the form *dllname(functionname)*, where *dllname* is specified without the suffix `.DLL`. The maximum length is 128 characters.
- z/OS On z/OS, it is a load module name. The maximum length is eight characters.
- IBM i On IBM i, it is of the form:

  ```
  progname libname
  ```

  where *program name* occupies the first 10 characters and *libname* the second 10 characters (both blank-padded to the right if necessary). The maximum length is 20 characters.

CLWLLEN(*integer*)
The maximum number of bytes of message data that is passed to the cluster workload exit.

Specify a value in the range:

- ALW 0 - 999,999,999 on AIX, Linux, and Windows.
- IBM i 0 - 999,999,999 on IBM i.
- z/OS 0 - 100 MB on z/OS systems.

CLWLMRUC(*integer*)
The maximum number of most recently used outbound cluster channels.

Specify a value in the range 1 through 999,999,999.

See CLWLMRUC queue manager attribute.

CLWLUSEQ
The attribute applies to queues with the queue attribute **CLWLUSEQ** set to QMGR. It specifies the behavior of an MQPUT operation when the target queue has a local instance and at least one remote cluster instance. It does not apply if the MQPUT originates from a cluster channel.

Specify either:

LOCAL
The local queue is the only target for MQPUT operations.

This is the queue manager's initial default value.

ANY
The queue manager treats the local queue as another instance of the cluster queue for the purposes of workload distribution.

See CLWLUSEQ queue manager attribute.

CMDEV
Specifies whether command events are generated:

DISABLED
Command events are not generated.

This is the queue manager's initial default value.

ENABLED
Command events are generated for all successful commands.

NODISPLAY
Command events are generated for all successful commands, other than DISPLAY commands.

z/OS **CMDSCOPE**
Specifies how the command is run when the queue manager is a member of a queue sharing group.

'

The command is run on the queue manager on which it was entered.

qmgr-name
The command is run on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a different queue manager. You can do so if you are using a queue sharing group environment, and if the command server is enabled. You can then specify a different queue manager to the one on which the command is entered.

*****

The command is run on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of entering this value is the same as entering the command on every queue manager in the queue sharing group.

This parameter is valid only on z/OS.

CONFIGEV
Specifies whether configuration events are generated:

ENABLED
Configuration events are generated. After setting this value, issue `REFRESH QMGR TYPE(CONFIGEV)` commands for all objects to bring the queue manager configuration up to date.

DISABLED
Configuration events are not generated.

This is the queue manager's initial default value.

CONNAUTH
The name of an authentication information object that is used to provide the location of user ID and password authentication. If **CONNAUTH** is blank, no user ID and password checking is done by the queue manager. The maximum length of the string is `MQ_AUTH_INFO_NAME_LENGTH`.

Only authentication information objects with type IDPWOS or IDPWLDAP can be specified; other types result in an error message when:

- Multi The OAM reads the configuration on Multiplatforms.
- z/OS The security component reads the configuration on z/OS.

Changes to this configuration, or the object to which it refers, take effect when a **REFRESH SECURITY TYPE(CONNAUTH)** command is issued.

If you leave **CONNAUTH** blank, and attempt to connect to a channel that has one of the following options set in the **CHCKCLNT** field, the connection fails:

- Multi `REQDADM`
- z/OS `REQUIRED`

CUSTOM(*string*)
The custom attribute for new features.

This attribute is reserved for the configuration of new features before named attributes are introduced. It can contain the values of zero or more attributes as pairs of attribute name and value, separated by at least one space. The attribute name-value pairs have the form `NAME(VALUE`. Escape a single quotation mark with another single quotation mark.

No values are defined for **Custom**.

DEADQ(*string*)
The local name of a dead-letter queue (or undelivered-message queue) on which messages that cannot be routed to their correct destination are put.

The queue named must be a local queue; see Rules for naming IBM MQ objects.

DEFCLXQ

The **DEFCLXQ** attribute controls which transmission queue is selected by default by cluster-sender channels to get messages from, to send the messages to cluster-receiver channels.

SCTQ

All cluster-sender channels send messages from SYSTEM.CLUSTER.TRANSMIT.QUEUE. The correlID of messages placed on the transmission queue identifies which cluster-sender channel the message is destined for.

SCTQ is set when a queue manager is defined. This behavior is implicit in versions of IBM WebSphere MQ, earlier than IBM WebSphere MQ 7.5. In earlier versions, the queue manager attribute **DEFCLXQ** was not present.

CHANNEL

Each cluster-sender channel sends messages from a different transmission queue. Each transmission queue is created as a permanent dynamic queue from the model queue SYSTEM.CLUSTER.TRANSMIT.MODEL.QUEUE.

If the queue manager attribute, **DEFCLXQ**, is set to CHANNEL,the default configuration is changed to cluster-sender channels being associated with individual cluster transmission queues. The transmission queues are permanent-dynamic queues created from the model queue SYSTEM.CLUSTER.TRANSMIT.MODEL.QUEUE. Each transmission queue is associated with one cluster-sender channel. As one cluster-sender channel services a cluster transmission queue, the transmission queue contains messages for only one queue manager in one cluster. You can configure clusters so that each queue manager in a cluster contains only one cluster queue. In this case, the message traffic from a queue manager to each cluster queue is transferred separately from messages to other queues.

DEFXMITQ(*string*)

Local name of the default transmission queue on which messages destined for a remote queue manager are put. The default transmission queue is used if there is no other suitable transmission queue defined.

The cluster transmission queue must not be used as the default transmission queue of the queue manager.

The queue named must be a local transmission queue; see Rules for naming IBM MQ objects.

DESCR(*string*)

Plain-text comment. It provides descriptive information about the queue manager.

It contains only displayable characters. The maximum length of the string is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

If the characters in the descriptive information are in the coded character set identifier (CCSID) for this queue manager they are translated correctly. They are translated when the descriptive information is sent to another queue manager. If they are not in the CCSID for this queue manager, they might be translated incorrectly.

z/OS **DNSGROUP(*string*)**

This parameter is no longer used. See z/OS: WLM/DNS no longer supported.

z/OS **DNSWLM**

This parameter is no longer used. See z/OS: WLM/DNS no longer supported.

NO

This value is the only value accepted.

z/OS **EXPRYINT**

Specifies how often queues are scanned to discard expired messages:

OFF

Queues are not scanned. No internal expiry processing is performed.

integer
The approximate interval in seconds at which queues are scanned. Each time that the expiry interval is reached, the queue manager looks for candidate queues that are worth scanning to discard expired messages.

The queue manager maintains information about the expired messages on each queue, and therefore whether a scan for expired messages is worthwhile. So, only a selection of queues is scanned at any time.

The value must be in the range 1 through 99999999. The minimum scan interval used is 5 seconds, even if you specify a lower value.

You must set the same **EXPRYINT** value for all queue managers within a queue sharing group that support this attribute. Shared queues are scanned by only one queue manager in a queue sharing group. This queue manager is either the first queue manager to restart, or the first queue manager for which **EXPRYINT** is set.

Changes to **EXPRYINT** take effect when the current interval expires. Changes also take effect if the new interval is less than the unexpired portion of the current interval. In this case, a scan is scheduled and the new interval value takes immediate effect.

This parameter is valid only on z/OS.

z/OS **GROUPUR**

This parameter controls whether CICS and XA client applications can establish transactions with a GROUP unit of recovery disposition.

The property can be enabled only when the queue manager is a member of a queue sharing group.

ENABLED
CICS and XA client applications can establish transactions with a group unit of recovery disposition by specifying a queue sharing group name when they connect.

DISABLED
CICS and XA client applications must connect using a queue manager name.

This parameter is valid only on z/OS.

z/OS **IGQ**

Specifies whether intra-group queuing is used.

The **IGQ** parameter is valid only on z/OS when the queue manager is a member of a queue sharing group.

ENABLED
Message transfer between queue managers within a queue sharing group uses the shared transmission queue, `SYSTEM.QSG.TRANSMIT.QUEUE`.

DISABLED
Message transfer between queue managers within a queue sharing group uses non-shared transmission queues and channels. Queue managers that are not part of a queue sharing group also use this mechanism.

If intra-group queuing is enabled, but the intra-group queuing agent is stopped, use the following command to restart it:

```
ALTER QMGR IGQ(ENABLED)
```

This parameter is valid only on z/OS.

z/OS **IGQAUT**

Specifies the type of authority checking and, therefore, the user IDs, to be used by the IGQ agent (IGQA). This parameter establishes the authority to put messages to a destination queue.

The **IGQAUT** parameter is valid only on z/OS when the queue manager is a member of a queue sharing group.

DEF
Indicates that the default user ID is used to establish authority to put messages to a destination queue.

For a one user ID check, the default user ID is the user ID of a queue manager within the queue sharing group. The default user ID is the user ID of the queue manager that put the messages to the SYSTEM.QSG.TRANSMIT.QUEUE. This user ID is referred to as the QSGSEND user ID.

For two user ID checks, the default second user ID is the IGQ user ID.

CTX
Indicates that the user ID from a *UserIdentifier* field is used to establish authority to put messages to a destination queue. The user ID is the *UserIdentifier* field in the message descriptor of a message on the SYSTEM.QSG.TRANSMIT.QUEUE.

For one user ID check, the QSGSEND user ID is used.

For two user ID checks, the QSGSEND user ID, the IGQ user ID and the alternate user ID are used. The alternate user ID is taken from the *UserIdentifier* field in the message descriptor of a message on the SYSTEM.QSG.TRANSMIT.QUEUE. The alternate user ID is referred to as ALT.

ONLYIGQ
Indicates that only the IGQ user ID is used to establish authority to put messages to a destination queue.

For all ID checks, the IGQ user ID is used.

ALTIGQ
Indicates that the IGQ user ID and the ALT user ID are used to establish authority to put messages to a destination queue.

For one user ID check, the IGQ user ID is used.

For two user ID checks, the IGQ user ID and the ALT user ID are used.

This parameter is valid only on z/OS.

z/OS **IGQUSER**
Nominates a user ID to be used by the IGQ agent (IGQA) to establish authority to put messages to a destination queue. The user ID is referred to as the IGQ user ID.

This parameter is valid only on z/OS when the queue manager is a member of a queue sharing group. Possible values are:

Blanks
Indicates that the user ID of the receiving queue manager within the queue sharing group is used.

Specific user ID
Indicates that the user ID specified in the **IGQUSER** parameter of the receiving queue manager is used.

Note:

1. As the receiving queue manager has authority to all queues it can access, security checking might not be performed for this user ID type.
2. As the value of blanks has a special meaning, you cannot use IGQUSER to specify a real user ID of blanks.

This parameter is valid only on z/OS.

Multi **IMGINTVL**
The target frequency with which the queue manager automatically writes media images, in minutes since the previous media image for the object.

Possible values are:

1 - 999 999 999
The time in minutes at which the queue manager automatically writes media images.

The default value is 60 minutes.

OFF
Automatic media images are not written on a time interval basis.

This parameter is valid only on Multiplatforms.

Multi **IMGLOGLN**
The target size of recovery log, written before the queue manager automatically writes media images, in number of megabytes since the previous media image for the object. This limits the amount of log to be read when recovering an object.

Possible values are:

1 - 999 999 999
The target size of the recovery log in megabytes.

OFF
Automatic media images are not written based on the size of log written.

OFF is the default value.

This parameter is valid only on Multiplatforms.

Multi **IMGRCOVO**
Specifies whether authentication information, channel, client connection, listener, namelist, process, alias queue, remote queue, and service objects are recoverable from a media image, if linear logging is being used.

Possible values are:

NO
The “rcdmqimg (record media image)” on page 126 and“rcrmqobj (re-create object)” on page 129 commands are not permitted for these objects, and automatic media images, if enabled, are not written for these objects.

YES
These objects are recoverable.

YES is the default value.

This parameter is valid only on Multiplatforms.

Multi **IMGRCOVQ**
Specifies the default **IMGRCOVQ** attribute for local and permanent dynamic queue objects, when used with this parameter.

Possible values are:

NO
The **IMGRCOVQ** attribute for local and permanent dynamic queue objects is set to NO.

YES
The **IMGRCOVQ** attribute for local and permanent dynamic queue objects is set to YES.

YES is the default value.

This parameter is valid only on Multiplatforms.

Multi **IMGSCHED**
Whether the queue manager automatically writes media images.

Possible values are:

AUTO
The queue manager attempts to automatically write a media image for an object, before **IMGINTVL** minutes have elapsed, or **IMGLOGLN** megabytes of recovery log have been written, since the previous media image for the object was taken.

The previous media image might have been taken manually or automatically, depending on the settings of **IMGINTVL** or **IMGLOGLN**.

MANUAL
Automatic media images are not written.

MANUAL is the default value.

This parameter is valid only on Multiplatforms.

INHIBTEV
Specifies whether inhibit events are generated. The events are generated for Inhibit Get and Inhibit Put.

ENABLED
Inhibit events are generated.

DISABLED
Inhibit events are not generated.

This is the queue manager's initial default value.

IPADDRV
Specifies which IP protocol is to be used for channel connections.

IPV4
The IPv4 IP address is to be used.

This is the queue manager's initial default value.

IPV6
The IPv6 IP address is to be used.

This parameter is used only in systems running IPv4 and IPv6. It applies to channels defined only with a **TRPTYPE** of TCP when either of the following two conditions is true:

- The **CONNAME** parameter of the channel contains a host name that resolves to both an IPv4 and an IPv6 address, and the **LOCLADDR** parameter is not specified.
- The value of the **CONNAME** and **LOCLADDR** parameters of the channel is a host name that resolves to both an IPv4 and IPv6 address.

LOCALEV
Specifies whether local error events are generated, caused by an application or the queue manager not being able to access a local queue or other local object, for example, because the object has not been defined:

ENABLED
Local error events are generated.

DISABLED
Local error events are not generated.

This is the queue manager's initial default value.

Multi **LOGGEREV**
Specifies whether recovery log events are generated:

DISABLED
Logger events are not generated.

This is the queue manager's initial default value.

ENABLED
Logger events are generated. This value is not valid on queue managers that are using circular logs.

This parameter is valid only on Multiplatforms.

z/OS **LSTRTMR(*integer*)**
The time interval, in seconds, between attempts by IBM MQ to restart a listener after an APPC or TCP/IP failure. When the listener is restarted on TCP/IP, it uses the same port and IP address as it used when it first started.

Specify a value in the range 5 through 9999.

Changes to this parameter take effect for listeners that are later started. Listeners that are currently started are unaffected by changes to this parameter.

This parameter is valid only on z/OS.

z/OS **LUGROUP(*string*)**
The generic LU name to be used by the LU 6.2 listener that handles inbound transmissions for the queue sharing group. The maximum length of this parameter is eight characters.

If this name is blank, the listener cannot be used.

Changes to this parameter take effect for listeners that are later started. Listeners that are currently started are unaffected by changes to this parameter.

This parameter is valid only on z/OS.

z/OS **LUNAME(*string*)**
The name of the LU to use for outbound LU 6.2 transmissions. Set this parameter to be the same as the name of the LU to be used by the listener for inbound transmissions. The maximum length of this parameter is eight characters.

If this name is blank, the APPC/MVS default LU name is used. This name is variable, so LUNAME must always be set if you are using LU 6.2

Changes to this parameter take effect when the channel initiator is restarted.

This parameter is valid only on z/OS.

z/OS **LU62ARM(*string*)**
The suffix of the APPCPM member of SYS1.PARMLIB. This suffix nominates the LUADD for this channel initiator. When automatic restart manager (ARM) restarts the channel initiator, the z/OS command SET APPC= *xx* is issued.

If you do not provide a value for this parameter, no SET APPC= *xx* command is issued.

The maximum length of this parameter is two characters.

Changes to this parameter take effect when the channel initiator is restarted.

This parameter is valid only on z/OS.

z/OS **LU62CHL(*integer*)**
The maximum number of channels that can be current, or clients that can be connected, that use the LU 6.2 transmission protocol.

Specify a value 0- 9999 that is not greater than the value of MAXCHL. MAXCHL defines the maximum number of channels available. If you specify zero, the LU 6.2 transmission protocol is not used.

If you change this value, also review the MAXCHL, LU62CHL, and ACTCHL values. Ensure that there is no conflict of values and if necessary, raise the value of MAXCHL and ACTCHL.

If the value of this parameter is reduced, any current channels that exceed the new limit continue to run until they stop.

If the value of **LU62CHL** is non-zero when the channel initiator starts up, the value can be modified dynamically. If the value of **LU62CHL** is zero when the channel initiator starts up, a later ALTER command does not take effect. In this case, you should carry out an ALTER command, either before the channel initiator starts, or in CSQINP2 before you issue the **START CHINIT** command.

This parameter is valid only on z/OS.

MARKINT(*integer*)
The time interval, expressed in milliseconds, for which messages marked as browsed by a call to MQGET, with the get message option MQGMO_MARK_BROWSE_CO_OP, are expected to remain mark-browsed.

If messages are marked for more than approximately **MARKINT** milliseconds, the queue manager might automatically unmark messages. It might unmark messages that are marked as browsed for the cooperating set of handles.

This parameter does not affect the state of any message marked as browse by a call to MQGET with the get message option MQGMO_MARK_BROWSE_HANDLE.

Specify a value up to the maximum of 999,999,999. The default value is 5000.

Attention: You should not reduce the value below the default of 5000.

The special value NOLIMIT indicates that the queue manager does not automatically unmark messages by this process.

z/OS **MAXCHL(*integer*)**
The maximum number of channels that can be *current* (including server-connection channels with connected clients).

Specify a value in the range 1- 9999. If you change this value, also review the **TCPCHL**, **LU62CHL**, and **ACTCHL** values to ensure that there is no conflict of values. If necessary, increase the number of active channels with the **ACTCHL** value. The values of **ACTCHL**, **LU62CHL**, and **TCPCHL** must not be greater than the maximum number of channels. Suggested settings are:

- Test system: 200
- Production system: 1000

For an explanation of which channel states are considered current; see Channel states.

If the value of this parameter is reduced, any current channels that exceed the new limit continue to run until they stop.

If the value of MAXCHL is reduced to less than its value when the channel initiator was initialized, channels continue to run until they stop. When the number of running channels falls below the value of MAXCHL, more channels can be started. Increasing the value of MAXCHL to more than its value when the channel initiator was initialized does not have immediate effect. The higher value of MAXCHL takes effect at the next channel initiator restart.

Sharing conversations do not contribute to the total for this parameter.

For more information about the relationship between **CHIADAPS**, **CHIDISPS**, and **MAXCHL**, see Tailor the channel initiator parameters.

This parameter is valid only on z/OS.

MAXHANDS(*integer*)
The maximum number of open handles that any one connection can have at the same time.

This value is a value in the range 0 - 999,999,999.

MAXMSGL(*integer*)
The maximum length of messages allowed on queues for this queue manager.

This value is in the range 32 KB through 100 MB.

Ensure that you also consider the length of any message properties when deciding the value for the MAXMSGL parameter of a channel.

If you reduce the maximum message length for the queue manager, you must also reduce the maximum message length of the SYSTEM.DEFAULT.LOCAL.QUEUE definition. You must also reduce the maximum message length for all other queues defined on the queue manager. This change ensures that the limit of the queue manager is not less than the limit of any of the queues associated with it. If you do not change these lengths, and applications inquire only the **MAXMSGL** value of the queue, they might not work correctly.

Note that by adding the digital signature and key to the message, Advanced Message Security increases the length of the message.

MAXPROPL (*integer*)
The maximum length of property data in bytes that can be associated with a message.

This value is in the range 0 through 100 MB (104 857 600 bytes).

The special value NOLIMIT indicates that the size of the properties is not restricted, except by the upper limit.

MAXUMSGS(*integer*)
The maximum number of uncommitted messages within a sync point.

MAXUMSGS is a limit on the number of messages that can be retrieved, plus the number of messages that can be put, within any single sync point. The limit does not apply to messages that are put or retrieved outside sync point.

The number includes any trigger messages and report messages generated within the same unit of recovery.

If existing applications and queue manager processes are putting and getting a larger number of messages in sync point, reducing **MAXUMSGS** might cause problems.

z/OS An example of queue manager processes that might be affected is clustering on z/OS.

Specify a value in the range 1 through 999,999,999. The default value is 10000.

MAXUMSGS has no effect on MQ Telemetry. MQ Telemetry tries to batch requests to subscribe, unsubscribe, send, and receive messages from multiple clients into batches of work within a transaction.

MONACLS
Controls the collection of online monitoring data for auto-defined cluster-sender channels:

QMGR
Collection of online monitoring data is inherited from the setting of the **MONCHL** parameter of the queue manager.

This is the queue manager's initial default value.

OFF
Monitoring for the channel is disabled.

LOW
Unless **MONCHL** is NONE, monitoring is enabled with a low rate of data collection with a minimal effect on system performance. The data collected is not likely to be the most current.

MEDIUM
Unless **MONCHL** is NONE, monitoring is enabled with a moderate rate of data collection with limited effect on system performance.

HIGH
Unless MONCHL is NONE, monitoring is enabled with a high rate of data collection with a likely effect on system performance. The data collected is the most current available.

A change to this parameter takes effect only on channels started after the change occurs. Any channel started before the change to the parameter continues with the value in force at the time that the channel started.

MONCHL
Controls the collection of online monitoring data for channels. The channels defined with **MONCHL(QMGR)** are affected by changing the QMGR **MONCHL** attribute.

OFF
Online monitoring data collection is turned off for channels specifying a value of QMGR in their **MONCHL** parameter.

This is the queue manager's initial default value.

NONE
Online monitoring data collection is turned off for channels regardless of the setting of their **MONCHL** parameter.

LOW
Online monitoring data collection is turned on, with a low ratio of data collection, for channels specifying a value of QMGR in their **MONCHL** parameter.

MEDIUM
Online monitoring data collection is turned on, with a moderate ratio of data collection, for channels specifying a value of QMGR in their **MONCHL** parameter.

HIGH
Online monitoring data collection is turned on, with a high ratio of data collection, for channels specifying a value of QMGR in their **MONCHL** parameter.

A change to this parameter takes effect only on channels started after the change occurs. Any channel started before the change to the parameter continues with the value in force at the time that the channel started.

MONQ
Controls the collection of online monitoring data for queues.

OFF
Online monitoring data collection is turned off for queues specifying a value of QMGR in their **MONQ** parameter.

This is the queue manager's initial default value.

NONE
Online monitoring data collection is turned off for queues regardless of the setting of their **MONQ** parameter.

LOW
Online monitoring data collection is turned on for queues specifying a value of QMGR in their **MONQ** parameter.

MEDIUM
Online monitoring data collection is turned on for queues specifying a value of QMGR in their **MONQ** parameter.

HIGH
Online monitoring data collection is turned on for queues specifying a value of QMGR in their **MONQ** parameter.

In contrast to **MONCHL**, there is no distinction between the values LOW, MEDIUM, and HIGH. These values all turn data collection on, but do not affect the rate of collection.

Changes to this parameter are effective only for queues opened after the parameter is changed.

z/OS **OPORTMAX(*integer*)**
The maximum value in the range of port numbers to be used when binding outgoing channels. When all the port numbers in the specified range are used, outgoing channels bind to any available port number.

Specify a value in the range 0 - 65535. A value of zero means that all outgoing channels bind to any available port number.

Specify a corresponding value for **OPORTMIN** to define a range of port numbers. Ensure that the value you specify for **OPORTMAX** is greater than or equal to the value you specify for **OPORTMIN**.

Changes to this parameter take effect for channels that are later started. Channels that are currently started are unaffected by changes to this parameter.

This parameter is valid only on z/OS.

z/OS **OPORTMIN(*integer*)**
The minimum value in the range of port numbers to be used when binding outgoing channels. When all the port numbers in the specified range are used, outgoing channels bind to any available port number.

Specify a value in the range 0 - 65535.

Specify a corresponding value for **OPORTMAX** to define a range of port numbers. Ensure that the value you specify for **OPORTMIN** is less than or equal to the value you specify for **OPORTMAX**.

Changes to this parameter take effect for channels that are later started. Channels that are currently started are unaffected by changes to this parameter.

This parameter is valid only on z/OS.

PARENT(*parentname*)
The name of the parent queue manager to which the local queue manager is to connect as its child in a hierarchy.

A blank value indicates that the queue manager has no parent queue manager.

If there is an existing parent queue manager it is disconnected.

IBM MQ hierarchical connections require that the queue manager attribute **PSMODE** is set to ENABLED.

The value of **PARENT** can be set to a blank value if **PSMODE** is set to DISABLED.

Before a queue manager can connect to a queue manager as its child in a hierarchy, channels must exist in both directions. The channels must exist between the parent queue manager and the child queue manager.

If a parent is already defined, the **ALTER QMGR PARENT** command disconnects from the original parent and sends a connection flow to the new parent queue manager.

Successful completion of the command does not mean that the action completed. To check that this command has completed, see the ALTER QMGR step in Checking that async commands for distributed networks have finished.

PERFMEV
Specifies whether performance-related events are generated:

ENABLED
Performance-related events are generated.

DISABLED
Performance-related events are not generated.

This is the queue manager's initial default value.

z/OS On IBM MQ for z/OS, all the queue managers in a queue sharing group must have the same setting.

PSCLUS
Controls whether this queue manager participates in publish subscribe activity across any clusters in which it is a member. No clustered topic objects can exist in any cluster when modifying from ENABLED to DISABLED.

For more information about **PSCLUS**, see Inhibiting clustered publish/subscribe.

Note: To change a **PSCLUS** parameter status, the CHIN address space needs to be running.

ENABLED
This queue manager can define clustered topic objects, publish to subscribers on other queue managers, and register subscriptions that receive publications from other queue managers. All queue managers in the cluster running a version of IBM MQ that supports this option must specify **PSCLUS(ENABLED)** for the publish/subscribe activity to function as expected. ENABLED is the default value when a queue manager is created.

DISABLED
This queue manager cannot define clustered topic objects and ignores their definition on any other queue manager in the cluster.

Publications are not forwarded to subscribers elsewhere in the cluster, and subscriptions are not registered other than on the local queue manager.

To ensure that no publish/subscribe activity occurs in the cluster, all queue managers must specify **PSCLUS(DISABLED)**. As a minimum, full repositories must be consistent in enabling or disabling publish/subscribe participation.

PSMODE
Controls whether the publish/subscribe engine and the queued publish/subscribe interface are running. It controls whether applications can publish or subscribe by using the application programming interface. It also controls whether the queues that are monitored by the queued publish/subscribe interface, are monitored.

Changing the **PSMODE** attribute can change the **PSMODE** status. Use one of the following commands to determine the current state of the publish/subscribe engine and the queued publish/subscribe interface:

- **DISPLAY PUBSUB**
- IBM i **DSPMQM** (on IBM i only)

COMPAT
The publish/subscribe engine is running. It is therefore possible to publish or subscribe by using the application programming interface.

The queued publish/subscribe interface is not running. Any publish/subscribe messages put to the queues that are monitored by the queued publish/subscribe interfaces are not acted upon.

Use this setting for compatibility with IBM Integration Bus (formerly known as WebSphere Message Broker) V6 or earlier versions that use this queue manager.

DISABLED
The publish/subscribe engine and the queued publish/subscribe interface are not running. It is therefore not possible to publish or subscribe by using the application programming interface. Any publish/subscribe messages put to the queues that are monitored by the queued publish/subscribe interfaces are not acted upon.

If a queue manager is in a publish/subscribe cluster or hierarchy, it might receive publish/subscribe messages from other queue managers in the cluster or hierarchy. Examples of such messages are publication messages or proxy subscriptions. While **PSMODE** is set to DISABLED those messages are not processed. For this reason, disable any queue manager in a publish/subscribe cluster or hierarchy only for as long as there is little build-up of messages.

ENABLED
The publish/subscribe engine and the queued publish/subscribe interface are running. It is therefore possible to publish or subscribe by using the application programming interface and the queues that are being monitored by the queued publish/subscribe interface.

This is the queue manager's initial default value.

Note: If a queue manager is in a publish/subscribe cluster or hierarchy, and you change **PSMODE** to ENABLED, you might have to run the command **REFRESH QMGR TYPE(PROXY)**. The command ensures that non-durable subscriptions are known across the cluster or hierarchy when **PSMODE** is set back to ENABLED. The circumstance in which you must run the command is as follows. If **PSMODE** is changed from ENABLED to DISABLED and back to ENABLED, and one or more non-durable subscriptions exist across all three stages.

PSNPMSG
If the queued publish/subscribe interface cannot process a non-persistent input message it might attempt to write the input message to the dead-letter queue. Whether it attempts to do so depends on the report options of the input message. The attempt to write the input message to the dead-letter queue might fail. In this case, the queued publish/subscribe interface might discard the input message. If MQRO_DISCARD_MSG is specified on the input message, the input message is discarded. If MQRO_DISCARD_MSG is not set, setting **PSNPMSG** to KEEP prevents the input message from being discarded. The default is to discard the input message.

Note: If you specify a value of IFPER for **PSSYNCPT**, you must not specify a value of KEEP for **PSNPMSG**.

DISCARD
Non-persistent input messages might be discarded if they cannot be processed.

KEEP
Non-persistent input messages are not discarded if they cannot be processed. In this situation, the queued publish/subscribe interface continues to try to process this message again at appropriate intervals and does not continue processing subsequent messages.

PSNPRES
The **PSNPRES** attribute controls whether the queued publish/subscribe interface writes an undeliverable reply message to the dead-letter queue, or discards the message. The choice is necessary if the queued publish/subscribe interface cannot deliver a reply message to the reply-to queue.

For new queue managers, the initial value is NORMAL. If you specify a value of IFPER for **PSSYNCPT**, you must not specify a value of KEEP or SAFE for **PSNPRES**.

Multi For migrated queue managers on Multiplatforms, the value depends on DLQNonPersistentResponse and DiscardNonPersistentResponse.

NORMAL
Non-persistent responses which cannot be placed on the reply queue are put on the dead-letter queue. If they cannot be placed on the dead-letter queue then they are discarded.

SAFE
Non-persistent responses which cannot be placed on the reply queue are put on the dead-letter queue. If the response cannot be sent and cannot be placed on the dead-letter queue, the queued publish/subscribe interface backs out of the current operation. It tries again at appropriate intervals, and does not continue processing subsequent messages.

DISCARD
Non-persistent responses which cannot be placed on the reply queue are discarded

KEEP

Non-persistent responses are not placed on the dead-letter queue or discarded. Instead the queued publish/subscribe interface backs out the current operation and then tries it again at appropriate intervals and does not continue processing subsequent messages.

PSRTYCNT
If the queued publish/subscribe interface fails to process a command message under sync point, the unit of work is backed out. The command tries to process the message a number of times again, before the publish/subscribe broker processes the command message according to its report options instead. This situation can arise for a number of reasons. For example, if a publish message cannot be delivered to a subscriber, and it is not possible to put the publication on the dead letter queue.

The initial value for this parameter on a new queue manager is 5.

Range is 0 - 999,999,999.

PSSYNCPT
Controls whether the queued publish/subscribe interface processes command messages (publishes or delete publication messages) under sync point.

YES
All messages are processed under sync point.

IFPER
Only persistent messages are part of the sync point

The initial value of the queue manager is IFPER.

z/OS **RCVTIME (*integer*)**
The approximate length of time that a TCP/IP channel waits to receive data, including heartbeats, from its partner before returning to the inactive state.

This parameter applies only to message channels and to MQI server-connection and client-connection channels where **SHARECNV** is greater than zero, when the channel receive timeout is set based on the negotiated heartbeat interval in the same way as for message channels. This number can be qualified as follows:

- To specify that this number is a multiplier to apply to the negotiated **HBINT** value to determine how long a channel is to wait, set **RCVTTYPE** to MULTIPLY. Specify a **RCVTIME** value of zero or in the range 2 through 99. If you specify zero, the channel continues to wait indefinitely to receive data from its partner.
- To specify that **RCVTIME** is the number of seconds to add to the negotiated **HBINT** value to determine how long a channel is to wait, set **RCVTTYPE** to ADD. Specify an **RCVTIME** value in the range 1 through 999999.
- To specify that **RCVTIME** is a value, in seconds, that the channel is to wait, set **RCVTTYPE** to EQUAL. Specify an RCVTIME value in the range 0 - 999,999. If you specify zero, the channel continues to wait indefinitely to receive data from its partner.

Note: For MQI channels that use sharing conversations, the heartbeat interval used by **ReceiveTimeout**, **ReceiveTimeMin**, or **ReceiveTimeoutType** is five seconds greater than the negotiated heartbeat interval.

For channels with **SHARECNV** equal to zero, **RCVTMIN** does not apply.

Changes to this parameter take effect for channels that are later started. Channels that are currently started are unaffected by changes to this parameter.

For more information, see Checking that the other end of the channel is still available.

This parameter is valid only on z/OS.

z/OS **RCVTMIN(*integer*)**
The minimum length of time that a TCP/IP channel waits to receive data, including heartbeats, from its partner before returning to an inactive state.

This parameter applies only to message channels and to MQI server-connection and client-connection channels where **SHARECNV** is greater than zero, when the channel receive timeout is set based on the negotiated heartbeat interval in the same way as for message channels.

Note: For MQI channels that use sharing conversations, the heartbeat interval used by **ReceiveTimeout**, **ReceiveTimeMin**, or **ReceiveTimeoutType** is five seconds greater than the negotiated heartbeat interval.

For channels with **SHARECNV** equal to zero, **RCVTMIN** does not apply.

The TCP/IP channel wait time can be configured relative to the negotiated value of **HBINT**. If **RCVTTYPE** is MULTIPLY or ADD, the resultant value might be less than the value set in **RCVTMIN**. In this case, the TCP/IP channel wait time is set to **RCVTMIN**. If **RCVTTYPE** is EQUAL then **RCVTMIN** does not apply.

Specify a value, in seconds, between zero and 999999.

Changes to this parameter take effect for channels that are later started. Channels that are currently started are unaffected by changes to this parameter.

For more information, see Checking that the other end of the channel is still available.

This parameter is valid only on z/OS.

z/OS **RCVTTYPE**

The qualifier to apply to the value in **RCVTIME**.

MULTIPLY
Specifies that **RCVTIME** is a multiplier to be applied to the negotiated **HBINT** value to determine how long a channel waits.

ADD
Specifies that **RCVTIME** is a value, in seconds, to be added to the negotiated **HBINT** value to determine how long a channel waits.

EQUAL
Specifies that **RCVTIME** is a value, in seconds, representing how long the channel waits.

Changes to this parameter take effect for channels that are later started. Channels that are currently started are unaffected by changes to this parameter.

For more information, see Checking that the other end of the channel is still available.

This parameter is valid only on z/OS.

REMOTEEV

Specifies whether remote error events are generated, caused by an application or the queue manager not being able to access a remote queue on another queue manager, for example, the transmission queue not being correctly defined:

DISABLED
Remote error events are not generated.

This is the queue manager's initial default value.

ENABLED
Remote error events are generated.

z/OS If you are using the reduced function form of IBM MQ for z/OS supplied with WebSphere Application Server, only DISABLED is valid.

REPOS(*clustername*)

The name of a cluster for which this queue manager provides a repository manager service. The maximum length is 48 characters conforming to the rules for naming IBM MQ objects.

You can specify either the **REPOS** or the **REPOSNL** parameter, but not both. Both **REPOS** and **REPOSNL** might be blank, or **REPOS** might be blank and the namelist specified by **REPOSNL** might be empty. In these cases, this queue manager does not have a full repository. It might be a client of other repository services defined in the cluster.

Use a cluster-sender channel to connect this queue manager to at least one other full repository queue manager in the cluster (if specifying **REPOS**) or in each cluster named in the namelist (if

specifying **REPOSNL**). See the information in Components of a cluster for details about using cluster-sender channels with full repository queue managers.

Successful completion of the command does not mean that the action completed. To check for true completion, see the ALTER QMGR step in Checking that async commands for distributed networks have finished.

REPOSNL(*nlname*)
The name of a namelist of clusters for which this queue manager provides a repository manager service. The maximum length is 48 characters conforming to the rules for naming an IBM MQ namelist object.

See the description of **REPOS** for information on specifying either **REPOS** or **REPOSNL**.

REVDNS
Controls whether reverse lookup of the host name from a Domain Name Server (DNS) is done for the IP address from which a channel has connected. This attribute has an effect only on channels using a transport type (TRPTYPE) of TCP:

ENABLED
DNS host names are reverse looked-up for the IP addresses of inbound channels when this information is required. This setting is required for matching against CHLAUTH rules that contain host names, and to include the host name in error messages. The IP address is still included in messages that provide a connection identifier.

This is the initial default value for the queue manager.

DISABLED
DNS host names are not reverse looked-up for the IP addresses of inbound channels. With this setting any CHLAUTH rules using host names are not matched.

ROUTEREC
Specifies whether trace-route information is recorded if requested in the message. If this parameter is not set to `DISABLED`, it controls whether any reply generated is sent to `SYSTEM.ADMIN.TRACE.ROUTE.QUEUE`, or to the destination specified by the message itself. If **ROUTEREC** is not `DISABLED`, messages not yet at the final destination might have information added to them.

DISABLED
Trace-route information is not recorded.

MSG
Trace-route information is recorded and sent to the destination specified by the originator of the message causing the trace route record.

This is the queue manager's initial default value.

QUEUE
Trace-route information is recorded and sent to `SYSTEM.ADMIN.TRACE.ROUTE.QUEUE`.

Multi **SCHINIT**
Specifies whether the channel initiator starts automatically when the queue manager starts.

QMGR
The channel initiator starts automatically when the queue manager starts.

MANUAL
The channel initiator does not start automatically.

This parameter is valid only on Multiplatforms.

Multi **SCMDSERV**
Specifies whether the command server starts automatically when the queue manager starts.

QMGR
The command server starts automatically when the queue manager starts.

MANUAL
The command server does not start automatically.

This parameter is valid only on Multiplatforms.

z/OS **SCYCASE**
Specifies whether the security profiles are uppercase or mixed case.

UPPER
The security profiles are uppercase only. However, MXTOPIC and GMXTOPIC are used for topic security, and can contain mixed-case profiles.

MIXED
The security profiles are mixed case. MQCMDS and MQCONN are used for command and connection security but they can contain only uppercase profiles.

Changes to **SCYCASE** become effective after you run the following command:

```
REFFRESH SECURITY(*) TYPE(CLASSES)
```

This parameter is valid only on z/OS.

z/OS **SQQMNAME**
The **SQQMNAME** attribute specifies whether a queue manager in a queue sharing group opens a shared queue in the same group directly. The processing queue manager calls MQOPEN for a shared queue and sets the *ObjectQmgrName* parameter for the queue. If the shared queue is in the same queue sharing group as the processing queue manager, the queue can be opened directly by the processing queue manager. Set the **SQQMNAME** attribute to control if the queue is opened directly, or by the *ObjectQmgrName* queue manager. The attribute will also be honored when opening a QALIAS with copy disposition, if the target queue is a shared queue in the same queue sharing group as the processing queue manager. In this situation it is important that the QALIAS copy object on each queue manager in the queue sharing group has the same target queue.

USE
The *ObjectQmgrName* is used, and the appropriate transmission queue is opened.

IGNORE
The processing queue manager opens the shared queue directly. Setting the parameter to this value can reduce the traffic in your queue manager network.

This parameter is valid only on z/OS.

SSLCRLNL (*nlname*)

The name of a namelist of authentication information objects which are used to provide certificate revocation locations to allow enhanced TLS certificate checking.

Attention: The namelist can reference a maximum of one OCSP type AUTHINFO object only.

V 9.2.0 From IBM MQ 9.2.0, if more than one OCSP type AUTHINFO objects is referenced in the NAMELIST, only the first entry will be used.

If SSLCRLNL is blank, certificate revocation checking is not invoked unless one of the TLS certificates used contains an AuthorityInfoAccess or CrlDistributionPoint X.509 certificate extension.

Changes to SSLCRLNL, or to the names in a previously specified namelist, or to previously referenced authentication information objects become effective as follows:

- When a **REFRESH SECURITY TYPE(SSL)** command is issued.
- ALW On AIX, Linux, and Windows:
  - When a new channel process is started
  - For channels that run as threads of the channel initiator, when the channel initiator is restarted

  - For channels that run as threads of the listener, when the listener is restarted
- IBM i On IBM i:
  - When a new channel process is started
  - For channels that run as threads of the channel initiator, when the channel initiator is restarted
  - For channels that run as threads of the listener, when the listener is restarted

  On IBM i queue managers, this parameter is ignored. However, it is used to determine which authentication information objects are written to the AMQCLCHL.TAB file.
- z/OS On z/OS, when the channel initiator is restarted.

Only authentication information objects with types of CRLLDAP or OCSP are allowed in the namelist referred to by **SSLCRLNL**. Any other type results in an error message when the list is processed and is subsequently ignored.

SSLCRYP(*string*)
Sets the name of the parameter string required to configure the cryptographic hardware present on the system.

All supported cryptographic hardware supports the PKCS #11 interface. Specify a string of the following format:

```
GSK_PKCS11= the PKCS #11 driver path and file name>
; the PKCS #11 token label> ;
the PKCS #11 token password> ; symmetric cipher setting>
;
```

The PKCS #11 driver path is an absolute path to the shared library providing support for the PKCS #11 card. The PKCS #11 driver file name is the name of the shared library. An example of the value required for the PKCS #11 driver path and file name is `/usr/lib/pkcs11/PKCS11_API.so`

To access symmetric cipher operations through IBM Global Security Kit (GSKit), specify the symmetric cipher setting parameter. The value of this parameter is either:

SYMMETRIC_CIPHER_OFF
Do not access symmetric cipher operations.

SYMMETRIC_CIPHER_ON
Access symmetric cipher operations.

If the symmetric cipher setting parameter is not specified, it has the same effect as specifying SYMMETRIC_CIPHER_OF F.

The maximum length of the string is 256 characters.

If you specify a string that is not in the format listed, you get an error.

When the **SSLCRYP** value is changed, the cryptographic hardware parameters specified become the ones used for new TLS connection environments. The new information becomes effective:

- When a new channel process is started.
- For channels that run as threads of the channel initiator, when the channel initiator is restarted.
- For channels that run as threads of the listener, when the listener is restarted.
- When a **REFRESH SECURITY TYPE(SSL)** command is issued.

SSLEV
Specifies whether TLS events are generated.

DISABLED
TLS events are not generated.

This is the queue manager's initial default value.

ENABLED
All TLS events are generated.

z/OS ALW **SSLFIPS**

SSLFIPS specifies whether only FIPS-certified algorithms are to be used if cryptography is carried out in IBM MQ, rather than in cryptographic hardware. If cryptographic hardware is configured, the cryptographic modules used are those modules provided by the hardware product. These might, or might not, be FIPS-certified to a particular level. Whether the modules are FIPS-certified depends on the hardware product in use. For more information about FIPS, see the Federal Information Processing Standards (FIPS) manual.

NO

If you set **SSLFIPS** to NO, you can use either FIPS certified or non-FIPS certified CipherSpecs.

If the queue manager runs without using cryptographic hardware, refer to the CipherSpecs listed in Specifying CipherSpecs.

This is the queue manager's initial default value.

YES

Specifies that only FIPS-certified algorithms are to be used in the CipherSpecs allowed on all TLS connections from and to this queue manager.

For a listing of appropriate FIPS 140-2 certified CipherSpecs; see Specifying CipherSpecs.

Changes to **SSLFIPS** become effective as follows:

- Multi On AIX, Linux, and Windows:
  - when a **REFRESH SECURITY TYPE(SSL)** command is issued
  - when a new channel process is started
  - for channels that run as threads of the channel initiator, when the channel initiator is restarted
  - for channels that run as threads of the listener, when the listener is restarted
  - for channels that run as threads of a process pooling process, when the process pooling process is started or restarted and first runs a TLS channel. If the process pooling process has already run a TLS channel, and you want the change to become effective immediately, run the MQSC command **REFRESH SECURITY TYPE(SSL)**. The process pooling process is **amqrmppa**
- z/OS On z/OS, when the channel initiator is restarted.

This parameter is valid on z/OS, AIX, Linux, and Windows.

SSLKEYR(*string*)

The name of the Secure Sockets Layer key repository. The maximum length of the string is 256 characters. The format of the name depends on the environment.

z/OS On z/OS, the name is the name of a key ring.

Multi On Multiplatforms, the name is in stem format, which means that it includes the full path and the file name without an extension:

- IBM i On IBM i, the name is of the form *pathname/keyfile*, where *keyfile* is specified without the suffix .kdb, and identifies a GSKit key database file.
  - If you specify *SYSTEM, IBM MQ uses the system certificate store as the key repository for the queue manager. The queue manager is registered as a server application in the Digital Certificate Manager (DCM). You can assign any server/client certificate in the system store to the queue manager, because you registered it as a server application.
  - If you change the SSLKEYR parameter to a value other than *SYSTEM, IBM MQ unregisters the queue manager as an application with DCM.
- Linux AIX On AIX and Linux, the name is of the form *pathname/keyfile* where *keyfile* is specified without the suffix .kdb and identifies a GSKit CMS key database file.

- Windows On Windows, the name is of the form *pathname**keyfile* where *keyfile* is specified without the suffix .kdb and identifies a GSKit CMS key database file.

On Multiplatforms, the syntax of this parameter is validated to ensure that it contains a valid and absolute directory path.

If **SSLKEYR** is blank, channels using TLS do not start. If **SSLKEYR** is set to a value that does not correspond to a key ring or key database file, channels using TLS also do not start.

Changes to **SSLKEYR** become effective as follows:

- When a **REFRESH SECURITY TYPE(SSL)** command is issued.
- Multi On Multiplatforms:
  - When a new channel process is started.
  - For channels that run as threads of the channel initiator, when the channel initiator is restarted.
  - For channels that run as threads of the listener, when the listener is restarted.
  - For channels that run as threads of a process pooling process, **amqrmppa**, when the process pooling process is started or restarted and first runs a TLS channel. If the process pooling process has already run a TLS channel, and you want the change to become effective immediately, run the MQSC command **REFRESH SECURITY TYPE(SSL)**.
- z/OS On z/OS, when the channel initiator is restarted.

SSLRKEYC(*integer*)
The number of bytes to be sent and received within an TLS conversation before the secret key is renegotiated. The number of bytes includes control information.

SSLRKEYC is used only by TLS channels which initiate communication from the queue manager. For example, the sender channel initiates communication in a sender and receiver channel pairing.

If a value greater than zero is specified, the secret key is also renegotiated before message data is sent or received following a channel heartbeat. The count of bytes until the next secret key renegotiation is reset after each successful renegotiation.

Specify a value in the range 0 - 999,999,999. A value of zero means that the secret key is never renegotiated. If you specify an TLS secret key reset count in the range 1 - 32767 bytes (32 KB), TLS channels use a secret key reset count of 32 KB. The larger reset count value avoids the cost of excessive key resets which would occur for small TLS secret key reset values.

Attention: If your enterprise has applied APAR *PH30305*, the following statement no longer applies:

- Non-zero values less than 4096 (4 KB) might cause channels to fail to start, or might cause inconsistencies in the values of **SSLKEYDA**, **SSLKEYTI**, and **SSLRKEYS**.

z/OS **SSLTASKS(*integer*)**
The number of server subtasks to use for processing TLS calls. To use TLS channels, you must have at least two of these tasks running.

This value is in the range 0 - 9999. To avoid problems with storage allocation, do not set the **SSLTASKS** parameter to a value greater than 50.

Changes to this parameter are effective when the channel initiator is restarted.

This parameter is valid only on z/OS.

STATACLS
Specifies whether statistics data is to be collected for auto-defined cluster-sender channels:

QMGR
Collection of statistics data is inherited from the setting of the **STATCHL** parameter of the queue manager.

This is the queue manager's initial default value.

OFF
Statistics data collection for the channel is disabled.

LOW
Unless STATCHL is NONE, statistics data collection is switched on with a low ratio of data collection with a minimal effect on system performance.

MEDIUM
Unless STATCHL is NONE, statistics data collection is switched on with a moderate ratio of data collection.

HIGH
Unless STATCHL is NONE, statistics data collection is switched on with a high ratio of data collection.

A change to this parameter takes effect only on channels started after the change occurs. Any channel started before the change to the parameter continues with the value in force at the time that the channel started.

z/OS On z/OS systems, enabling this parameter simply turns on statistics data collection, regardless of the value you select. Specifying LOW, MEDIUM, or HIGH makes no difference to your results. This parameter must be enabled in order to collect channel accounting records.

STATCHL
Specifies whether statistics data is to be collected for channels:

NONE
Statistics data collection is turned off for channels regardless of the setting of their **STATCHL** parameter.

OFF
Statistics data collection is turned off for channels specifying a value of QMGR in their **STATCHL** parameter.

This is the queue manager's initial default value.

LOW
Statistics data collection is turned on, with a low ratio of data collection, for channels specifying a value of QMGR in their **STATCHL** parameter.

MEDIUM
Statistics data collection is turned on, with a moderate ratio of data collection, for channels specifying a value of QMGR in their **STATCHL** parameter.

HIGH
Statistics data collection is turned on, with a high ratio of data collection, for channels specifying a value of QMGR in their **STATCHL** parameter.

A change to this parameter takes effect only on channels started after the change occurs. Any channel started before the change to the parameter continues with the value in force at the time that the channel started.

z/OS On z/OS systems, enabling this parameter simply turns on statistics data collection, regardless of the value you select. Specifying LOW, MEDIUM, or HIGH makes no difference to your results. This parameter must be enabled in order to collect channel accounting records.

Multi **STATINT(*integer*)**
The time interval, in seconds, at which statistics monitoring data is written to the monitoring queue.

Specify a value in the range 1 through 604800.

Changes to this parameter take immediate effect on the collection of monitoring and statistics data.

This parameter is valid only on Multiplatforms.

Multi **STATMQI**

Specifies whether statistics monitoring data is to be collected for the queue manager:

OFF
Data collection for MQI statistics is disabled.

This is the queue manager's initial default value.

ON
Data collection for MQI statistics is enabled.

Changes to this parameter take immediate effect on the collection of monitoring and statistics data.

This parameter is valid only on Multiplatforms.

Multi **STATQ**

Specifies whether statistics data is to be collected for queues:

NONE
Statistics data collection is turned off for queues regardless of the setting of their **STATQ** parameter.

OFF
Statistics data collection is turned off for queues specifying a value of QMGR or OFF in their **STATQ** parameter. OFF is the default value.

ON
Statistics data collection is turned on for queues specifying a value of QMGR or ON in their **STATQ** parameter.

Statistics messages are generated only for queues which are opened after statistics collection is enabled. You do not need to restart the queue manager for the new value of STATQ to take effect.

This parameter is valid only on Multiplatforms.

STRSTPEV

Specifies whether start and stop events are generated:

ENABLED
Start and stop events are generated.

This is the queue manager's initial default value.

DISABLED
Start and stop events are not generated.

SUITEB

Specifies whether Suite B-compliant cryptography is used and what strength is required.

NONE
Suite B is not used. NONE is the default

128_BIT
Suite B 128-bit level security is used.

192_BIT
Suite B 192-bit level security is used

128_BIT,192_BIT
Both Suite B 128-bit and 192-bit level security is used

z/OS **TCPCHL(*integer*)**

The maximum number of channels that can be current, or clients that can be connected, that use the TCP/IP transmission protocol.

The maximum number of sockets used is the sum of the values in **TCPCHL** and **CHIDISPS**. The z/OS UNIX System Services **MAXFILEPROC** parameter (specified in the BPXPRM*xx* member of SYS1.PARMLIB) controls how many sockets each task is allowed, and thus how many channels

each dispatcher is allowed. In this case, the number of channels using TCP/IP is limited to the value of **MAXFILEPROC** multiplied by the value of **CHIDISPS**.

Specify a value 0-9999. The value must not be greater than the value of **MAXCHL**. **MAXCHL** defines the maximum number of channels available. TCP/IP might not support as many as 9999 channels. If so, the value you can specify is limited by the number of channels TCP/IP can support. If you specify zero, the TCP/IP transmission protocol is not used.

If you change this value, also review the **MAXCHL**, **LU62CHL**, and **ACTCHL** values to ensure that there is no conflict of values. If necessary, raise the value of **MAXCHL** and **ACTCHL**.

If the value of this parameter is reduced, any current channels that exceed the new limit continue to run until they stop.

Sharing conversations do not contribute to the total for this parameter.

If the value of **TCPCHL** is non-zero when the channel initiator starts up, the value can be modified dynamically. If the value of **TCPCHL** is zero when the channel initiator starts up, a later **ALTER** command does not take effect. In this case, you should carry out an **ALTER** command, either before the channel initiator starts, or in CSQINP2 before you issue the **START CHINIT** command.

This parameter is valid only on z/OS.

z/OS **TCPKEEP**

Specifies whether the **KEEPALIVE** facility is to be used to check that the other end of the connection is still available. If it is unavailable, the channel is closed.

NO
The TCP **KEEPALIVE** facility is not to be used.

This is the queue manager's initial default value.

YES
The TCP **KEEPALIVE** facility is to be used as specified in the TCP profile configuration data set. The interval is specified in the **KAINT** channel attribute.

Changes to this parameter take effect for channels that are later started. Channels that are currently started are unaffected by changes to this parameter.

This parameter is valid only on z/OS.

Using the **TCPKEEP** parameter is no longer required for 'modern' queue managers. The replacement is a combination of:

- using 'modern' client channels (**SHARECNV** <> 0)
- using receive timeout for message channels **RCVTIME**.

For more information, see the technote *Setting the TCP/IP KeepAlive interval to be used by IBM MQ*, at: https://www.ibm.com/support/pages/node/342737

z/OS **TCPNAME(*string*)**

The name of either the only, or preferred, TCP/IP stack to be used, depending on the value of **TCPSTACK**. This name is the name of the z/OS UNIX System Services stack for TCP/IP, as specified in the **SUBFILESYSTYPE** NAME parameter in the BPXPRM*xx* member of SYS1.PARMLIB. **TCPNAME** is only applicable in CINET multiple stack environments. The queue manager's initial default value is TCPIP.

In INET single stack environments the channel initiator uses the only available TCP/IP stack.

The maximum length of this parameter is eight characters.

Changes to this parameter take effect when the channel initiator is restarted.

This parameter is valid only on z/OS.

z/OS **TCPSTACK**

Specifies whether the channel initiator can use only the TCP/IP stack specified in **TCPNAME**, or optionally bind to any selected TCP/IP stack defined. This parameter is only applicable in CINET multiple stack environments.

SINGLE
The channel initiator can use only the TCP/IP address space specified in **TCPNAME**.

MULTIPLE
The channel initiator can use any TCP/IP address space available to it.

Changes to this parameter take effect when the channel initiator is restarted.

This parameter is valid only on z/OS.

z/OS **TRAXSTR**

Specifies whether the channel initiator trace starts automatically:

YES
Channel initiator trace is to start automatically.

NO
Channel initiator trace is not to start automatically.

Changes to this parameter take effect when the channel initiator is restarted. If you want to start or stop channel initiator trace without restarting the channel initiator, use the **START TRACE** or **STOP TRACE** commands after starting the channel initiator.

This parameter is valid only on z/OS.

z/OS **TRAXTBL(*integer*)**

The size, in megabytes, of the trace data space of the channel initiator.

Specify a value in the range 2 through 2048.

Note:

1. Changes to this parameter take effect immediately; any existing trace table contents are lost.
2. The **CHINIT** trace is stored in a dataspace called `qmidCHIN.CSQXTRDS`. When you use large z/OS data spaces, ensure that sufficient auxiliary storage is available on your system to support any related z/OS paging activity. You might also need to increase the size of your `SYS1.DUMP` data sets.

This parameter is valid only on z/OS.

TREELIFE (*integer*)

The lifetime, in seconds of non-administrative topics.

Non-administrative topics are those topics created when an application publishes to, or subscribes on, a topic string that does not exist as an administrative node. When this non-administrative node no longer has any active subscriptions, this parameter determines how long the queue manager waits before removing that node. Only non-administrative topics that are in use by a durable subscription remain after the queue manager is recycled.

Specify a value in the range 0 through 604000. A value of 0 means that non-administrative topics are not removed by the queue manager.

TRIGINT(*integer*)

A time interval expressed in milliseconds.

The **TRIGINT** parameter is relevant only if the trigger type (**TRIGTYPE**) is set to FIRST (see "DEFINE QLOCAL (define a new local queue)" on page 556 for details). In this case trigger messages are normally generated only when a suitable message arrives on the queue, and the queue was previously empty. Under certain circumstances, however, an additional trigger message can be generated with FIRST triggering even if the queue was not empty. These additional trigger messages are not generated more often than every **TRIGINT** milliseconds; see Special case of trigger type FIRST.

Specify a value in the range 0 - 999,999,999.

ALTER queues (alter queue settings)

Use the MQSC **ALTER** command to alter the parameters of a queue. A queue might be a local queue (**ALTER QLOCAL**), alias queue (**ALTER QALIAS**), model queue (**ALTER QMODEL**), a remote queue, a queue manager alias, or a reply-to queue alias (**ALTER QREMOTE**).

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

Parameters not specified in the **ALTER** queue commands result in the existing values for those parameters being left unchanged.

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- "Syntax diagrams for ALTER queues" on page 365
- "Usage notes for ALTER queues" on page 365
- "Parameter descriptions for ALTER QUEUE" on page 365

Syntax diagrams for ALTER queues

There is a separate syntax diagram for each type of channel:

- Syntax diagram for ALTER QALIAS
- Syntax diagram for ALTER QLOCAL
- Syntax diagram for ALTER QMODEL
- Syntax diagram for ALTER QREMOTE

Usage notes for ALTER queues

- Successful completion of the command does not mean that the action completed. To check for true completion, see the ALTER queues step in Checking that async commands for distributed networks have finished.

Parameter descriptions for ALTER QUEUE

The parameters that are relevant for each type of queue are tabulated in Table 134 on page 365. Each parameter is described after the table.

queue-name
Local name of the queue, except the remote queue where it is the local definition of the remote queue.

See Rules for naming IBM MQ objects.

ACCTQ
Specifies whether accounting data collection is to be enabled for the queue. On z/OS, the data collected is class 3 accounting data (thread-level and queue-level accounting). In order for accounting data to be collected for this queue, accounting data for this connection must also be enabled. Turn on accounting data collection by setting either the **ACCTQ** queue manager attribute, or the options field in the MQCNO structure on the MQCONNX call.

QMGR
The collection of accounting data is based on the setting of the **ACCTQ** parameter on the queue manager definition.

ON
Accounting data collection is enabled for the queue unless the **ACCTQ** queue manager parameter has a value of NONE.

z/OS On z/OS systems, you must enable class 3 accounting using the **START TRACE** command.

OFF
Accounting data collection is disabled for the queue.

BOQNAME(*queue-name*)
The excessive backout requeue name.

This parameter is supported only on local and model queues.

Use this parameter to set or change the back out queue name attribute of a local or model queue. Apart from allowing its value to be queried, the queue manager does nothing based on the value of this attribute. IBM MQ classes for JMS transfers a message that is backed out the maximum number of times to this queue. The maximum is specified by the **BOTHRESH** attribute.

BOTHRESH(*integer*)
The backout threshold.

This parameter is supported only on local and model queues.

Use this parameter to set or change the value of the back out threshold attribute of a local or model queue. Apart from allowing its value to be queried, the queue manager does nothing based on the value of this attribute. IBM MQ classes for JMS use the attribute to determine how many times to allow a message to be backed out. When the value is exceeded, the message is transferred to the queue named by the **BOQNAME** attribute.

Specify a value in the range 0 - 999,999,999.

z/OS **CFSTRUCT(*structure-name*)**
Specifies the name of the coupling facility structure where you want messages stored when you use shared queues.

This parameter is supported only on z/OS for local and model queues.

The name:

- Cannot have more than 12 characters
- Must start with an uppercase letter (A - Z)
- Can include only the characters A - Z and 0 - 9

The name of the queue sharing group to which the queue manager is connected is prefixed to the name you supply. The name of the queue sharing group is always four characters, padded with @ symbols if necessary. For example, if you use a queue sharing group named NY03 and you supply the name PRODUCT7, the resultant coupling facility structure name is NY03PRODUCT7. The administrative structure for the queue sharing group (in this case NY03CSQ_ADMIN) cannot be used for storing messages.

For **ALTER QLOCAL**, **ALTER QMODEL**, **DEFINE QLOCAL** with **REPLACE**, and **DEFINE QMODEL** with **REPLACE** the following rules apply:

- On a local queue with **QSGDISP**(SHARED), **CFSTRUCT** cannot change.
- If you change either the **CFSTRUCT** or **QSGDISP** value you must delete and redefine the queue. To preserve any of the messages on the queue you must offload the messages before you delete the queue. Reload the messages after you redefine the queue, or move the messages to another queue.
- On a model queue with **DEFTYPE**(SHAREDYN), **CFSTRUCT** cannot be blank.
- On a local queue with a **QSGDISP** other than SHARED, or a model queue with a **DEFTYPE** other than SHAREDYN, the value of **CFSTRUCT** does not matter.

For **DEFINE QLOCAL** with **NOREPLACE** and **DEFINE QMODEL** with **NOREPLACE**, the coupling facility structure:

- On a local queue with **QSGDISP**(SHARED) or a model queue with a **DEFTYPE**(SHAREDYN), **CFSTRUCT** cannot be blank.
- On a local queue with a **QSGDISP** other than SHARED, or a model queue with a **DEFTYPE** other than SHAREDYN, the value of **CFSTRUCT** does not matter.

Note: Before you can use the queue, the structure must be defined in the coupling facility Resource Management (CFRM) policy data set.

CLCHNAME(*channel name*)

This parameter is supported only on transmission queues.

CLCHNAME is the generic name of the cluster-sender channels that use this queue as a transmission queue. The attribute specifies which cluster-sender channels send messages to a cluster-receiver channel from this cluster transmission queue.

You can also set the transmission queue attribute **CLCHNAME** attribute to a cluster-sender channel manually. Messages that are destined for the queue manager connected by the cluster-sender channel are stored in the transmission queue that identifies the cluster-sender channel. They are not stored in the default cluster transmission queue. If you set the **CLCHNAME** attribute to blanks, the channel switches to the default cluster transmission queue when the channel restarts. The default queue is either SYSTEM.CLUSTER.TRANSMIT.*ChannelName* or SYSTEM.CLUSTER.TRANSMIT.QUEUE, depending on the value of the queue manager **DEFCLXQ** attribute.

By specifying asterisks, "" * "", in **CLCHNAME**, you can associate a transmission queue with a set of cluster-sender channels. The asterisks can be at the beginning, end, or any number of places in the middle of the channel name string. **CLCHNAME** is limited to a length of 48 characters, MQ_OBJECT_NAME_LENGTH. A channel name is limited to 20 characters: MQ_CHANNEL_NAME_LENGTH. If you specify an asterisk you must also set the SHARE attribute so that multiple channels can concurrently access the transmission queue.

z/OS If you specify a "*" in **CLCHNAME**, to obtain a channel profile name, you must specify the channel profile name within quotation marks. If you do not specify the generic channel name within quotation marks you receive message CSQ9030E.

The default queue manager configuration is for all cluster-sender channels to send messages from a single transmission queue, SYSTEM.CLUSTER.TRANSMIT.QUEUE. The default configuration can be modified by changing the queue manager attribute, **DEFCLXQ**. The default value of the attribute is SCTQ. You can change the value to CHANNEL. If you set the **DEFCLXQ** attribute to CHANNEL, each cluster-sender channel defaults to using a specific cluster transmission queue, SYSTEM.CLUSTER.TRANSMIT.*ChannelName*.

z/OS On z/OS, if this parameter is set, the queue:

- Must be shareable, by specifying the queue attribute SHARE.
- Must be indexed on the correlation ID by specifying INDXTYPE(CORRELID).
- Must not be a dynamic or a shared queue.

z/OS ALW **CLUSNL(*namelist name*)**

The name of the namelist that specifies a list of clusters to which the queue belongs.

This parameter is supported only on alias, local, and remote queues.

Changes to this parameter do not affect instances of the queue that are already open.

Only one of the resultant values of **CLUSNL** or **CLUSTER** can be non-blank; you cannot specify a value for both.

On local queues, this parameter cannot be set for the following queues:

- Transmission queues
- SYSTEM.CHANNEL.*xx* queues
- SYSTEM.CLUSTER.*xx* queues
- SYSTEM.COMMAND.*xx* queues
- z/OS On z/OS only, SYSTEM.QSG.*xx* queues

This parameter is valid only on the following platforms:

- AIX, Linux, and Windows
- z/OS

z/OS ALW **CLUSTER(*cluster name*)**

The name of the cluster to which the queue belongs.

This parameter is supported only on alias, local, and remote queues.

The maximum length is 48 characters conforming to the rules for naming IBM MQ objects. Changes to this parameter do not affect instances of the queue that are already open.

Only one of the resultant values of **CLUSNL** or **CLUSTER** can be non-blank; you cannot specify a value for both.

On local queues, this parameter cannot be set for the following queues:

- Transmission queues
- SYSTEM.CHANNEL.*xx* queues
- SYSTEM.CLUSTER.*xx* queues
- SYSTEM.COMMAND.*xx* queues
- z/OS On z/OS only, SYSTEM.QSG.*xx* queues

This parameter is valid only on the following platforms:

- AIX, Linux, and Windows
- z/OS

CLWLPRTY(*integer*)

Specifies the priority of the queue for the purposes of cluster workload distribution. This parameter is valid only for local, remote, and alias queues. The value must be in the range zero through 9 where zero is the lowest priority and 9 is the highest. For more information about this attribute, see CLWLPRTY queue attribute.

CLWLRANK (*integer*)

Specifies the rank of the queue for the purposes of cluster workload distribution. This parameter is valid only for local, remote, and alias queues. The value must be in the range zero through 9 where zero is the lowest rank and 9 is the highest. For more information about this attribute, see CLWLRANK queue attribute.

CLWLUSEQ

Specifies the behavior of an MQPUT operation when the target queue has a local instance and at least one remote cluster instance. The parameter has no effect when the MQPUT originates from a cluster channel. This parameter is valid only for local queues.

QMGR
The behavior is as specified by the **CLWLUSEQ** parameter of the queue manager definition.

ANY
The queue manager is to treat the local queue as another instance of the cluster queue for the purposes of workload distribution.

LOCAL
The local queue is the only target of the MQPUT operation.

z/OS **CMDSCOPE**

This parameter applies to z/OS only. It specifies where the command is run when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP or SHARED.

' '
The command runs on the queue manager on which it was entered.

QmgrName
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered. You can specify another name, only if you are using a queue sharing group environment and if the command server is enabled.

***
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of * is the same as entering the command on every queue manager in the queue sharing group.

CUSTOM(*string*)
The custom attribute for new features.

This attribute contains the values of attributes, as pairs of attribute name and value, separated by at least one space. The attribute name-value pairs have the form NAME(VALUE).

The maximum length is defined by the IBM MQ constant MQ_CUSTOM_LENGTH and is currently set to 128 on all platforms.

The CUSTOM attribute is intended to be used with the following IBM MQ attribute.

CAPEXPRY(*integer*)
The maximum time, expressed in tenths of a second, until a message put using an object handle with this object in the resolution path, becomes eligible for expiry processing.

For more information on message expiry processing, see Enforcing lower expiration times.

integer
The value must be in the range one through to 999 999 999.

NOLIMIT
There is no limit on the expiry time of messages put using this object. This is the default value.

Specifying a value for **CAPEXPRY** that is not valid, does not cause the command to fail. Instead the default value is used.

Note that existing messages in the queue, prior to a change in **CAPEXPRY**, are not affected by the change (that is, their expiry time remains intact). Only new messages that are put into the queue after the change in **CAPEXPRY** have the new expiry time.

DEFBIND
Specifies the binding to be used when the application specifies MQOO_BIND_AS_Q_DEF on the MQOPEN call, and the queue is a cluster queue.

OPEN
The queue handle is bound to a specific instance of the cluster queue when the queue is opened.

NOTFIXED
The queue handle is not bound to any instance of the cluster queue. The queue manager selects a specific queue instance when the message is put using MQPUT. It changes that selection later, if the need arises.

GROUP
Allows an application to request that a group of messages is allocated to the same destination instance.

Multiple queues with the same name can be advertised in a queue manager cluster. An application can send all messages to a single instance, MQOO_BIND_ON_OPEN. It can allow a workload management algorithm to select the most suitable destination on a per message basis, MQOO_BIND_NOT_FIXED. It can allow an application to request that a group of messages be all allocated to the same destination instance. The workload balancing reselects a destination between groups of messages, without requiring an MQCLOSE and MQOPEN of the queue.

The MQPUT1 call always behaves as if NOTFIXED is specified.

This parameter is valid on all platforms.

DEFPRESP
Specifies the behavior to be used by applications when the put response type, within the MQPMO options, is set to MQPMO_RESPONSE_AS_Q_DEF.

SYNC
Put operations to the queue specifying MQPMO_RESPONSE_AS_Q_DEF are issued as if MQPMO_SYNC_RESPONSE is specified instead.

ASYNC
Put operations to the queue specifying MQPMO_RESPONSE_AS_Q_DEF are issued as if MQPMO_ASYNC_RESPONSE is specified instead; see MQPMO options (MQLONG).

DEFPRTY(*integer*)
The default priority of messages put on the queue. The value must be in the range 0 - 9. Zero is the lowest priority, through to the **MAXPRTY** queue manager parameter. The default value of **MAXPRTY** is 9.

DEFPSIST
Specifies the message persistence to be used when applications specify the MQPER_PERSISTENCE_AS_Q_DEF option.

NO
Messages on this queue are lost across a restart of the queue manager.

YES
Messages on this queue survive a restart of the queue manager.

z/OS On z/OS, N and Y are accepted as synonyms of NO and YES.

DEFREADA
Specifies the default read ahead behavior for non-persistent messages delivered to the client. Enabling read ahead can improve the performance of client applications consuming non-persistent messages.

NO
Non-persistent messages are not read ahead unless the client application is configured to request read ahead.

YES
Non-persistent messages are sent to the client before an application requests them. Non-persistent messages can be lost if the client ends abnormally or if the client does not delete all the messages it is sent.

DISABLED
Read ahead of non-persistent messages in not enabled for this queue. Messages are not sent ahead to the client regardless of whether read ahead is requested by the client application.

DEFSOPT
The default share option for applications opening this queue for input:

EXCL
The open request is for exclusive input from the queue.

z/OS On z/OS, EXCL is the default value.

SHARED
The open request is for shared input from the queue.

Multi On Multiplatforms, SHARED is the default value.

DEFTYPE
Queue definition type.

This parameter is supported only on model queues.

PERMDYN
A permanent dynamic queue is created when an application issues an MQOPEN MQI call with the name of this model queue specified in the object descriptor (MQOD).

z/OS On z/OS, the dynamic queue has a disposition of QMGR.

z/OS **SHAREDYN**
This option is available on z/OS only.

A permanent dynamic queue is created when an application issues an MQOPEN API call with the name of this model queue specified in the object descriptor (MQOD).

The dynamic queue has a disposition of SHARED.

TEMPDYN
A temporary dynamic queue is created when an application issues an MQOPEN API call with the name of this model queue specified in the object descriptor (MQOD).

z/OS On z/OS, the dynamic queue has a disposition of QMGR.

z/OS Do not specify this value for a model queue definition with a **DEFPSIST** parameter of YES.

z/OS If you specify this option, do not specify **INDXTYPE**(MSGTOKEN).

DESCR(*string*)
Plain-text comment. It provides descriptive information about the object when an operator issues the **DISPLAY QUEUE** command.

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: Use characters that are in the coded character set identifier (CCSID) of this queue manager. If you do not do so and if the information is sent to another queue manager, they might be translated incorrectly.

ALW **DISTL**
Sets whether distribution lists are supported by the partner queue manager.

YES
Distribution lists are supported by the partner queue manager.

NO
Distribution lists are not supported by the partner queue manager.

Note: You do not normally change this parameter, because it is set by the MCA. However you can set this parameter when defining a transmission queue if the distribution list capability of the destination queue manager is known.

This parameter is valid only on AIX, Linux, and Windows.

FORCE
This parameter applies only to the **ALTER** command on alias, local and remote queues.

Specify this parameter to force completion of the command in the following circumstances.

For an alias queue, if both of the following statements are true:

- The **TARGET** parameter specifies a queue
- An application has this alias queue open

For a local queue, if both of the following statements are true:

- The **NOSHARE** parameter is specified
- More than one application has the queue open for input

FORCE is also needed if both of the following statements are true:

- The **USAGE** parameter is changed
- Either one or more messages are on the queue, or one or more applications have the queue open

Do not change the **USAGE** parameter while there are messages on the queue; the format of messages changes when they are put on a transmission queue.

For a remote queue, if both of the following statements are true:

- The **XMITQ** parameter is changed
- One or more applications has this queue open as a remote queue

FORCE is also needed if both of the following statements are true:

- Any of the **RNAME**, **RQMNAME**, or **XMITQ** parameters are changed
- One or more applications has a queue open that resolved through this definition as a queue manager alias

Note: FORCE is not required if this definition is in use as a reply-to queue alias only.

If **FORCE** is not specified in the circumstances described, the command is unsuccessful.

When you use the **ALTER QLOCAL** command with the **FORCE** parameter, IBM MQ force allows the changes with open handles on the queue. However, these existing open handles become invalid for some attributes and the next operation on these open handles will return the error message:

```
MQRC_OBJECT_CHANGED (2041)
```

Any of the following operations will fail with the error MQRC 2041:

- MQPUT
- MQGET
- MQINQ
- MQSET
- MQCTL
- MQCB

You can fix the applications that receive the error MQRC_OBJECT_CHANGED by the following steps:

1. Close the handle (MQCLOSE)
2. Reopen the object (MQOPEN) to select the new queue definition

GET

Specifies whether applications are to be permitted to get messages from this queue:

ENABLED
Messages can be retrieved from the queue, by suitably authorized applications.

DISABLED
Applications cannot retrieve messages from the queue.

This parameter can also be changed using the MQSET API call.

HARDENBO and NOHARDENBO

Specifies whether the count of the number of times that a message was backed out is hardened. When the count is hardened, the value of the **BackoutCount** field of the message descriptor is written to the log before the message is returned by an MQGET operation. Writing the value to the log ensures that the value is accurate across restarts of the queue manger.

This parameter is supported only on local and model queues.

When the backout count is hardened, the performance of MQGET operations for persistent messages on this queue is impacted.

HARDENBO
The message backout count for messages on this queue is hardened to ensure that the count is accurate.

NOHARDENBO
The message backout count for messages on this queue is not hardened and might not be accurate over queue manager restarts.

Note: z/OS This parameter affects only IBM MQ for z/OS. You can set this parameter on Multiplatforms but it is ineffective.

Multi **IMGRCOVQ**
Specifies whether a local or permanent dynamic queue object is recoverable from a media image, if linear logging is being used. Possible values are:

YES
These queue objects are recoverable.

NO
The "rcdmqimg (record media image)" on page 126 and"rcrmqobj (re-create object)" on page 129 commands are not permitted for these objects, and automatic media images, if enabled, are not written for these objects.

QMGR
If you specify QMGR, and the **IMGRCOVQ** attribute for the queue manager specifies YES, these queue objects are recoverable.

If you specify QMGR and the **IMGRCOVQ** attribute for the queue manager specifies NO, the "rcdmqimg (record media image)" on page 126 and"rcrmqobj (re-create object)" on page 129 commands are not permitted for these objects, and automatic media images, if enabled, are not written for these objects.

QMGR is the default value.

This parameter is not valid on z/OS.

z/OS **INDXTYPE**
The type of index maintained by the queue manager to expedite MQGET operations on the queue. For shared queues, the type of index determines the type of MQGET operations that can be used.

This parameter is supported only on z/OS.

This parameter is supported only on local and model queues.

Messages can be retrieved using a selection criterion only if an appropriate index type is maintained, as the following table shows:

Table 135. Index type required for different retrieval selection criteria

Retrieval selection criterion	**Index type required**	
	Shared queue	Other queue
None (sequential retrieval)	Any	Any
Message identifier	MSGID or NONE	Any
Correlation identifier	CORRELID	Any
Message and correlation identifiers	MSGID or CORRELID	Any
Group identifier	GROUPID	Any
Grouping	GROUPID	GROUPID
Message token	Not allowed	MSGTOKEN

where the value of **INDXTYPE** parameter has the following values:

NONE
No index is maintained. Use NONE when messages are typically retrieved sequentially or use both the message identifier and the correlation identifier as a selection criterion on the MQGET call.

MSGID
An index of message identifiers is maintained. Use MSGID when messages are typically retrieved using the message identifier as a selection criterion on the MQGET call with the correlation identifier set to NULL.

CORRELID
An index of correlation identifiers is maintained. Use CORRELID when messages are typically retrieved using the correlation identifier as a selection criterion on the MQGET call with the message identifier set to NULL.

GROUPID
An index of group identifiers is maintained. Use GROUPID when messages are retrieved using message grouping selection criteria.

Note:

1. You cannot set **INDXTYPE** to GROUPID if the queue is a transmission queue.
2. The queue must use a CF structure at CFLEVEL(3), to specify a shared queue with **INDXTYPE**(GROUPID).

z/OS **MSGTOKEN**
An index of message tokens is maintained. Use MSGTOKEN when the queue is a WLM-managed queue that you are using with the Workload Manager functions of z/OS.

Note: You cannot set **INDXTYPE** to MSGTOKEN if:

- The queue is a model queue with a definition type of SHAREDYN
- The queue is a temporary dynamic queue
- The queue is a transmission queue
- You specify **QSGDISP**(SHARED)

For queues that are not shared and do not use grouping or message tokens, the index type does not restrict the type of retrieval selection. However, the index is used to expedite **GET** operations on the queue, so choose the type that corresponds to the most common retrieval selection.

If you are altering or replacing an existing local queue, you can change the **INDXTYPE** parameter only in the cases indicated in the following table:

Table 136. Index type change permitted depending upon queue-sharing and presence of messages in the queue

Queue type		**NON-SHARED**			**SHARED**	
Queue state		Uncommitted activity	No uncommitted activity, messages present	No uncommitted activity, and empty	Open or messages present	Not open, and empty
Change **INDXTYPE** from:	To:	Change allowed?				
NONE	MSGID	No	Yes	Yes	No	Yes
NONE	CORRELID	No	Yes	Yes	No	Yes
NONE	MSGTOKEN	No	No	Yes	-	-
NONE	GROUPID	No	No	Yes	No	Yes
MSGID	NONE	No	Yes	Yes	No	Yes
MSGID	CORRELID	No	Yes	Yes	No	Yes
MSGID	MSGTOKEN	No	No	Yes	-	-

Table 136. Index type change permitted depending upon queue-sharing and presence of messages in the queue (continued)

Queue type		NON-SHARED			SHARED	
MSGID	GROUPID	No	No	Yes	No	Yes
CORRELID	NONE	No	Yes	Yes	No	Yes
CORRELID	MSGID	No	Yes	Yes	No	Yes
CORRELID	MSGTOKEN	No	No	Yes	-	-
CORRELID	GROUPID	No	No	Yes	No	Yes
MSGTOKEN	NONE	No	Yes	Yes	-	-
MSGTOKEN	MSGID	No	Yes	Yes	-	-
MSGTOKEN	CORRELID	No	Yes	Yes	-	-
MSGTOKEN	GROUPID	No	No	Yes	-	-
GROUPID	NONE	No	No	Yes	No	Yes
GROUPID	MSGID	No	No	Yes	No	Yes
GROUPID	CORRELID	No	No	Yes	No	Yes
GROUPID	MSGTOKEN	No	No	Yes	-	-

INITQ(*string*)
The local name of the initiation queue on this queue manager, to which trigger messages relating to this queue are written. See Rules for naming IBM MQ objects.

This parameter is supported only on local and model queues.

LIKE(*qtype-name*)
The name of a queue, with parameters that are used to model this definition.

If this field is not completed, the values of undefined parameter fields are taken from one of the following definitions. The choice depends on the queue type:

Table 137. Queue types and their corresponding definitions

Queue type	Definition
Alias queue	SYSTEM.DEFAULT.ALIAS.QUEUE
Local queue	SYSTEM.DEFAULT.LOCAL.QUEUE
Model queue	SYSTEM.DEFAULT.MODEL.QUEUE
Remote queue	SYSTEM.DEFAULT.REMOTE.QUEUE

For example, not completing this parameter is equivalent to defining the following value of **LIKE** for an alias queue:

```
LIKE(SYSTEM.DEFAULT.ALIAS.QUEUE)
```

If you require different default definitions for all queues, alter the default queue definitions instead of using the **LIKE** parameter.

z/OS On z/OS, the queue manager searches for an object with the name and queue type you specify with a disposition of QMGR, COPY, or SHARED. The disposition of the **LIKE** object is not copied to the object you are defining.

Note:

1. **QSGDISP**(GROUP) objects are not searched.
2. **LIKE** is ignored if **QSGDISP**(COPY) is specified.

z/OS ALW **MAXDEPTH(*integer*)**

The maximum number of messages allowed on the queue.

This parameter is supported only on local and model queues.

On the following platforms, specify a value in the range zero through 999999999:

- ALW AIX, Linux, and Windows
- z/OS z/OS

On any other IBM MQ platform, specify a value in the range zero through 640000.

Other factors can still cause the queue to be treated as full, for example, if there is no further hard disk space available.

If this value is reduced, any messages that are already on the queue that exceed the new maximum remain intact.

V 9.2.0 Multi **MAXFSIZE**

The maximum size, in megabytes, that a queue file can grow to. It is possible for a queue file to exceed this size if you have configured the value to be lower than the current queue file size.

If that happens the queue file no longer accepts new messages, but allows existing messages to be consumed. When the queue file size has dropped below the configured value, new messages can be put to the queue.

Note: This figure can differ from the value of the attribute configured on the queue, because internally the queue manager might need to use a larger block size to reach the chosen size. See Modifying IBM MQ queue files for more information on changing the size of queue files and block size and granularity.

When the granularity needs changing because this attribute has been increased, warning message AMQ7493W `Granularity changed` is written to the AMQERR logs. This gives you an indication that you need to plan for the queue to be emptied, in order for IBM MQ to adopt the new granularity.

Specify a value greater than or equal to 20, and less than or equal to 267,386,880.

The default value for this attribute is *DEFAULT*, which equates to a hard-coded value of 2,088,960 MB, the maximum for a queue in versions of IBM MQ prior to IBM MQ 9.1.5.

MAXMSGL(*integer*)

The maximum length (in bytes) of messages on this queue.

This parameter is supported only on local and model queues.

ALW On AIX, Linux, and Windows, specify a value in the range zero to the maximum message length for the queue manager. See the **MAXMSGL** parameter of the ALTER QMGR command, ALTER QMGR MAXMSGL.

z/OS On z/OS, specify a value in the range zero through 100 MB (104 857 600 bytes).

Message length includes the length of user data and the length of headers. For messages put on the transmission queue, there are additional transmission headers. Allow an additional 4000 bytes for all the message headers.

If this value is reduced, any messages that are already on the queue with length that exceeds the new maximum are not affected.

Applications can use this parameter to determine the size of buffer for retrieving messages from the queue. Therefore, the value can be reduced only if it is known that this reduction does not cause an application to operate incorrectly.

Note that by adding the digital signature and key to the message, Advanced Message Security increases the length of the message.

MONQ
Controls the collection of online monitoring data for queues.

This parameter is supported only on local and model queues.

QMGR
Collect monitoring data according to the setting of the queue manager parameter **MONQ**.

OFF
Online monitoring data collection is turned off for this queue.

LOW
If the value of the **MONQ** parameter of the queue manager is not NONE, online monitoring data collection is turned on for this queue.

MEDIUM
If the value of the **MONQ** parameter of the queue manager is not NONE, online monitoring data collection is turned on for this queue.

HIGH
If the value of the **MONQ** parameter of the queue manager is not NONE, online monitoring data collection is turned on for this queue.

There is no distinction between the values LOW, MEDIUM, and HIGH. These values all turn data collection on, but do not affect the rate of collection.

When this parameter is used in an **ALTER** queue command, the change is effective only when the queue is next opened.

MSGDLVSQ
Message delivery sequence.

This parameter is supported only on local and model queues.

PRIORITY
Messages are delivered (in response to MQGET API calls) in first-in-first-out (FIFO) order within priority.

FIFO
Messages are delivered (in response to MQGET API calls) in FIFO order. Priority is ignored for messages on this queue.

The message delivery sequence parameter can be changed from PRIORITY to FIFO while there are messages on the queue. The order of the messages already on the queue is not changed. Messages added to the queue later take the default priority of the queue, and so might be processed before some of the existing messages.

If the message delivery sequence is changed from FIFO to PRIORITY, the messages put on the queue while the queue was set to FIFO take the default priority.

Note: z/OS If **INDXTYPE**(GROUPID) is specified with **MSGDLVSQ**(PRIORITY), the priority in which groups are retrieved is based on the priority of the first message within each group. The priorities 0 and 1 are used by the queue manager to optimize the retrieval of messages in logical order. The first message in each group must not use these priorities. If it does, the message is stored as if it was priority two.

Multi **NPMCLASS**
The level of reliability to be assigned to non-persistent messages that are put to the queue:

NORMAL
Non-persistent messages are lost after a failure, or queue manager shutdown. These messages are discarded on a queue manager restart.

HIGH
The queue manager attempts to retain non-persistent messages on this queue over a queue manager restart or switch over.

z/OS You cannot set this parameter on z/OS.

PROCESS(*string*)
The local name of the IBM MQ process.

This parameter is supported only on local and model queues.

This parameter is the name of a process instance that identifies the application started by the queue manager when a trigger event occurs; see Rules for naming IBM MQ objects.

The process definition is not checked when the local queue is defined, but it must be available for a trigger event to occur.

If the queue is a transmission queue, the process definition contains the name of the channel to be started. This parameter is optional for transmission queues on the following platforms:

-

IBM i
-

AIX, Linux, and Windows
-

z/OS

If you do not specify it, the channel name is taken from the value specified for the **TRIGDATA** parameter.

PROPCTL
Property control attribute. The attribute is optional. It is applicable to local, alias, and model queues.

Note: If your application is opening an alias queue you must set this value on both the alias and target queues.

PROPCTL options are as follows. The options do not affect message properties in the MQMD or MQMD extension.

ALL

Set ALL so that an application can read all the properties of the message either in MQRFH2 headers, or as properties of the message handle.

The ALL option enables applications that cannot be changed to access all the message properties from MQRFH2 headers. Applications that can be changed, can access all the properties of the message as properties of the message handle.

In some cases, the format of data in MQRFH2 headers in the received message might be different to the format in the message when it was sent.

COMPAT
Set COMPAT so that unmodified applications that expect JMS-related properties to be in an MQRFH2 header in the message data continue to work as before. Applications that can be changed, can access all the properties of the message as properties of the message handle.

If the message contains a property with a prefix of `mcd.`, `jms.`, `usr.`, or `mqext.`, all message properties are delivered to the application. If no message handle is supplied, properties are returned in an MQRFH2 header. If a message handle is supplied, all properties are returned in the message handle.

If the message does not contain a property with one of those prefixes, and the application does not provide a message handle, no message properties are returned to the application. If a message handle is supplied, all properties are returned in the message handle.

In some cases, the format of data in MQRFH2 headers in the received message might be different to the format in the message when it was sent.

FORCE
Force all applications to read message properties from MQRFH2 headers.

Properties are always returned in the message data in an MQRFH2 header regardless of whether the application specifies a message handle.

A valid message handle supplied in the `MsgHandle` field of the MQGMO structure on the MQGET call is ignored. Properties of the message are not accessible using the message handle.

In some cases, the format of data in MQRFH2 headers in the received message might be different to the format in the message when it was sent.

NONE
If a message handle is supplied, all the properties are returned in the message handle.

All message properties are removed from the message body before it is delivered to the application.

PUT
Specifies whether messages can be put on the queue.

ENABLED
Messages can be added to the queue (by suitably authorized applications).

DISABLED
Messages cannot be added to the queue.

This parameter can also be changed using the MQSET API call.

QDEPTHHI(*integer*)
The threshold against which the queue depth is compared to generate a Queue Depth High event.

This parameter is supported only on local and model queues.

z/OS For more information about the effect that shared queues on z/OS have on this event; see Shared queues and queue depth events on z/OS.

This event indicates that an application put a message on a queue resulting in the number of messages on the queue becoming greater than or equal to the queue depth high threshold. See the **QDPHIEV** parameter.

The value is expressed as a percentage of the maximum queue depth (**MAXDEPTH** parameter), and must be in the range zero through 100 and no less than **QDEPTHLO**.

QDEPTHLO(*integer*)
The threshold against which the queue depth is compared to generate a Queue Depth Low event.

This parameter is supported only on local and model queues.

z/OS For more information about the effect that shared queues on z/OS have on this event; see Shared queues and queue depth events on z/OS.

This event indicates that an application retrieved a message from a queue resulting in the number of messages on the queue becoming less than or equal to the queue depth low threshold. See the **QDPLOEV** parameter.

The value is expressed as a percentage of the maximum queue depth (**MAXDEPTH** parameter), and must be in the range zero through 100 and no greater than **QDEPTHHI**.

QDPHIEV
Controls whether Queue Depth High events are generated.

This parameter is supported only on local and model queues.

A Queue Depth High event indicates that an application put a message on a queue resulting in the number of messages on the queue becoming greater than or equal to the queue depth high threshold. See the **QDEPTHHI** parameter.

ENABLED
Queue Depth High events are generated.

DISABLED
Queue Depth High events are not generated.

Note: The value of this parameter can change implicitly.

z/OS On z/OS, shared queues affect the event.

For more information about this event, see Queue Depth High.

QDPLOEV

Controls whether Queue Depth Low events are generated.

This parameter is supported only on local and model queues.

A Queue Depth Low event indicates that an application retrieved a message from a queue resulting in the number of messages on the queue becoming less than or equal to the queue depth low threshold. See the **QDEPTHLO** parameter.

ENABLED
Queue Depth Low events are generated.

DISABLED
Queue Depth Low events are not generated.

Note: The value of this parameter can change implicitly.

z/OS On z/OS, shared queues affect the event.

For more information about this event, see Queue Depth Low.

QDPMAXEV

Controls whether Queue Full events are generated.

This parameter is supported only on local and model queues.

A Queue Full event indicates that a put to a queue was rejected because the queue is full. The queue depth reached its maximum value.

ENABLED
Queue Full events are generated.

DISABLED
Queue Full events are not generated.

Note: The value of this parameter can change implicitly.

z/OS On z/OS, shared queues affect the event.

For more information about this event, see Queue Full.

z/OS **QSGDISP**

This parameter applies to z/OS only.

Specifies the disposition of the object within the group.

*Table 138. Action of **ALTER** depending on different values of **QSGDISP**.*

QSGDISP	**ALTER**
COPY	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters **QSGDISP**(COPY). Any object residing in the shared repository, or any object defined using a command that had the parameters **QSGDISP**(QMGR), is not affected by this command.

*Table 138. Action of **ALTER** depending on different values of **QSGDISP**. (continued)*

QSGDISP	**ALTER**

GROUP	The object definition resides in the shared repository. The object was defined using a command that had the parameters **QSGDISP**(GROUP). Any object residing on the page set of the queue manager that executes the command (except a local copy of the object), or any object defined using a command that had the parameters **QSGDISP**(SHARED), is not affected by this command. If the command is successful, the following command is generated and sent to all active queue managers in the queue sharing group to attempt to refresh local copies on page set zero:
	`DEFINE QUEUE(QNAME)`
	`REPLACE QSGDISP(COPY)`
	The ALTER for the group object takes effect regardless of whether the generated command with **QSGDISP**(COPY) fails.

PRIVATE	The object resides on the page set of the queue manager that executes the command, and was defined with **QSGDISP**(QMGR) or **QSGDISP**(COPY). Any object residing in the shared repository is unaffected.
QMGR	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters **QSGDISP**(QMGR). Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.
SHARED	This value applies only to local queues. The object definition resides in the shared repository. The object was defined using a command that had the parameters **QSGDISP**(SHARED). Any object residing on the page set of the queue manager that executes the command, or any object defined using a command that had the parameters **QSGDISP**(GROUP), is not affected by this command. If the queue is clustered, a command is generated and sent to all active queue managers in the queue sharing group to notify them of this clustered, shared queue.

QSVCIEV
Controls whether Service Interval High or Service Interval OK events are generated.

This parameter is supported only on local and model queues and is ineffective if it is specified on a shared queue.

A Service Interval High event is generated when a check indicates that no messages were retrieved from the queue for at least the time indicated by the **QSVCINT** parameter.

A Service Interval OK event is generated when a check indicates that messages were retrieved from the queue within the time indicated by the **QSVCINT** parameter.

Note: The value of this parameter can change implicitly. For more information, see the description of the Service Interval High and Service Interval OK events in Queue Service Interval High and Queue Service Interval OK.

HIGH
Service Interval High events are generated

OK
Service Interval OK events are generated

NONE
No service interval events are generated

QSVCINT(*integer*)
The service interval used for comparison to generate Service Interval High and Service Interval OK events.

This parameter is supported only on local and model queues and is ineffective if it is specified on a shared queue.

See the **QSVCIEV** parameter.

The value is in units of milliseconds, and must be in the range zero through 999999999.

RETINTVL(*integer*)
The number of hours from when the queue was defined, after which the queue is no longer needed. The value must be in the range 0 - 999,999,999.

This parameter is supported only on local and model queues.

The **CRDATE** and **CRTIME** can be displayed using the **DISPLAY QUEUE** command.

This information is available for use by an operator or a housekeeping application to delete queues that are no longer required.

Note: The queue manager does not delete queues based on this value, nor does it prevent queues from being deleted if their retention interval is not expired. It is the responsibility of the user to take any required action.

RNAME(*string*)
Name of remote queue. This parameter is the local name of the queue as defined on the queue manager specified by **RQMNAME**.

This parameter is supported only on remote queues.

- If this definition is used for a local definition of a remote queue, **RNAME** must not be blank when the open occurs.
- If this definition is used for a queue manager alias definition, **RNAME** must be blank when the open occurs.

  In a queue manager cluster, this definition applies only to the queue manager that made it. To advertise the alias to the whole cluster, add the **CLUSTER** attribute to the remote queue definition.
- If this definition is used for a reply-to queue alias, this name is the name of the queue that is to be the reply-to queue.

The name is not checked to ensure that it contains only those characters normally allowed for queue names; see Rules for naming IBM MQ objects.

RQMNAME(*string*)
The name of the remote queue manager on which the queue **RNAME** is defined.

This parameter is supported only on remote queues.

- If an application opens the local definition of a remote queue, **RQMNAME** must not be blank or the name of the local queue manager. When the open occurs, if **XMITQ** is blank there must be a local queue of this name, which is to be used as the transmission queue.
- If this definition is used for a queue manager alias, **RQMNAME** is the name of the queue manager that is being aliased. It can be the name of the local queue manager. Otherwise, if **XMITQ** is blank, when the open occurs there must be a local queue of this name, which is to be used as the transmission queue.
- If **RQMNAME** is used for a reply-to queue alias, **RQMNAME** is the name of the queue manager that is to be the reply-to queue manager.

The name is not checked to ensure that it contains only those characters normally allowed for IBM MQ object names; see Rules for naming IBM MQ objects.

ALW **SCOPE**
Specifies the scope of the queue definition.

This parameter is supported only on alias, local, and remote queues.

QMGR
The queue definition has queue manager scope. This means that the definition of the queue does not extend beyond the queue manager that owns it. You can open a queue for output that is owned by another queue manager in either of two ways:

1. Specify the name of the owning queue manager.
2. Open a local definition of the queue on the other queue manager.

CELL
The queue definition has cell scope. Cell scope means that the queue is known to all the queue managers in the cell. A queue with cell scope can be opened for output merely by specifying the name of the queue. The name of the queue manager that owns the queue need not be specified.

If there is already a queue with the same name in the cell directory, the command fails. The **REPLACE** option does not affect this situation.

This value is valid only if a name service supporting a cell directory is configured.

Restriction: The DCE name service is no longer supported.

This parameter is valid only on AIX, Linux, and Windows.

SHARE and NOSHARE
Specifies whether multiple applications can get messages from this queue.

This parameter is supported only on local and model queues.

SHARE
More than one application instance can get messages from the queue.

NOSHARE
Only a single application instance can get messages from the queue.

Multi **STATQ**
Specifies whether statistics data collection is enabled:

QMGR
Statistics data collection is based on the setting of the **STATQ** parameter of the queue manager.

ON
If the value of the **STATQ** parameter of the queue manager is not NONE, statistics data collection for the queue is enabled.

OFF
Statistics data collection for the queue is disabled.

If this parameter is used in an **ALTER** queue command, the change is effective only for connections to the queue manager made after the change to the parameter.

This parameter is valid only on Multiplatforms.

z/OS **STGCLASS(*string*)**
The name of the storage class.

This parameter is supported only on local and model queues.

Note: You can change this parameter only if the queue is empty and closed.

This parameter is an installation-defined name. The first character of the name must be uppercase A through Z, and subsequent characters either uppercase A through Z or numeric 0 through 9.

This parameter is valid only on z/OS; see Storage classes.

Multi V 9.2.3 **STREAMQ**
The name of a secondary queue where a copy of each message is put.

This parameter is valid only on AIX, Linux, and Windows.

Attention: If the user setting the **STREAMQ** attribute does not have change authority on the chosen stream queue, the command fails with error message AMQ8135E `Not Authorized`.

In addition, if the stream queue does not exist, error message AMQ8135E is returned instead of AMQ8147E `IBM MQ object not found`.

Multi V 9.2.3 **STRMQOS**

The quality of service to use when delivering messages to the streaming queue.

The value can be one of:

BESTEF
If the original message can be delivered, but the streamed message cannot, the original message is still delivered to its queue.

This is the default value.

MUSTDUP
The queue manager ensures that both the original message and the streamed message are successfully delivered to their queues.

If, for some reason, the streamed message cannot be delivered to its queue, then the original message is not delivered to its queue either. The putting application receives an error reason code and must try to put the message again.

This parameter is valid only on AIX, Linux, and Windows.

TARGET(*string*)
The name of the queue or topic object being aliased; See Rules for naming IBM MQ objects. The object can be a queue or a topic as defined by **TARGTYPE**. The maximum length is 48 characters.

This parameter is supported only on alias queues.

This object needs to be defined only when an application process opens the alias queue.

The TARGQ parameter, defined in IBM WebSphere MQ 6.0, is renamed to TARGET from version 7.0 and generalized to allow you to specify the name of either a queue or a topic. The default value for TARGET is a queue, therefore `TARGET(my_queue_name)` is the same as `TARGQ(my_queue_name)`. The TARGQ attribute is retained for compatibility with your existing programs. If you specify **TARGET**, you cannot also specify **TARGQ**.

TARGTYPE(*string*)
The type of object to which the alias resolves.

QUEUE
The alias resolves to a queue.

TOPIC
The alias resolves to a topic.

TRIGDATA(*string*)
The data that is inserted in the trigger message. The maximum length of the string is 64 bytes.

This parameter is supported only on local and model queues.

For a transmission queue, you can use this parameter to specify the name of the channel to be started.

This parameter can also be changed using the `MQSET` API call.

TRIGDPTH(*integer*)
The number of messages that have to be on the queue before a trigger message is written, if **TRIGTYPE** is `DEPTH`. The value must be in the range 1 - 999,999,999. The default value is 1.

This parameter is supported only on local and model queues.

This parameter can also be changed using the `MQSET` API call.

TRIGGER and NOTRIGGER
Specifies whether trigger messages are written to the initiation queue, named by the **INITQ** parameter, to trigger the application, named by the **PROCESS** parameter:

TRIGGER
Triggering is active, and trigger messages are written to the initiation queue.

NOTRIGGER
Triggering is not active, and trigger messages are not written to the initiation queue. This is the default value.

This parameter is supported only on local and model queues.

This parameter can also be changed using the MQSET API call.

TRIGMPRI(*integer*)
The message priority number that triggers this queue. The value must be in the range zero through to the **MAXPRTY** queue manager parameter; see "DISPLAY QMGR (display queue manager settings)" on page 747 for details. The default value is zero.

This parameter can also be changed using the MQSET API call.

TRIGTYPE
Specifies whether and under what conditions a trigger message is written to the initiation queue. The initiation queue is (named by the **INITQ** parameter.

This parameter is supported only on local and model queues.

FIRST
Whenever the first message of priority equal to or greater than the priority specified by the **TRIGMPRI** parameter of the queue arrives on the queue. This is the default value.

EVERY
Every time a message arrives on the queue with priority equal to or greater than the priority specified by the **TRIGMPRI** parameter of the queue.

DEPTH
When the number of messages with priority equal to or greater than the priority specified by **TRIGMPRI** is equal to the number indicated by the **TRIGDPTH** parameter.

NONE
No trigger messages are written.

This parameter can also be changed using the MQSET API call.

USAGE
Queue usage.

This parameter is supported only on local and model queues.

NORMAL
The queue is not a transmission queue.

XMITQ
The queue is a transmission queue, which is used to hold messages that are destined for a remote queue manager. When an application puts a message to a remote queue, the message is stored on the appropriate transmission queue. It stays there, awaiting transmission to the remote queue manager.

If you specify this option, do not specify values for **CLUSTER** and **CLUSNL**.

z/OS Additionally, on z/OS, do not specify **INDXTYPE**(MSGTOKEN) or **INDXTYPE**(GROUPID).

XMITQ(*string*)
The name of the transmission queue to be used for forwarding messages to the remote queue. **XMITQ** is used with either remote queue or queue manager alias definitions.

This parameter is supported only on remote queues.

If **XMITQ** is blank, a queue with the same name as **RQMNAME** is used as the transmission queue.

This parameter is ignored if the definition is being used as a queue manager alias and **RQMNAME** is the name of the local queue manager.

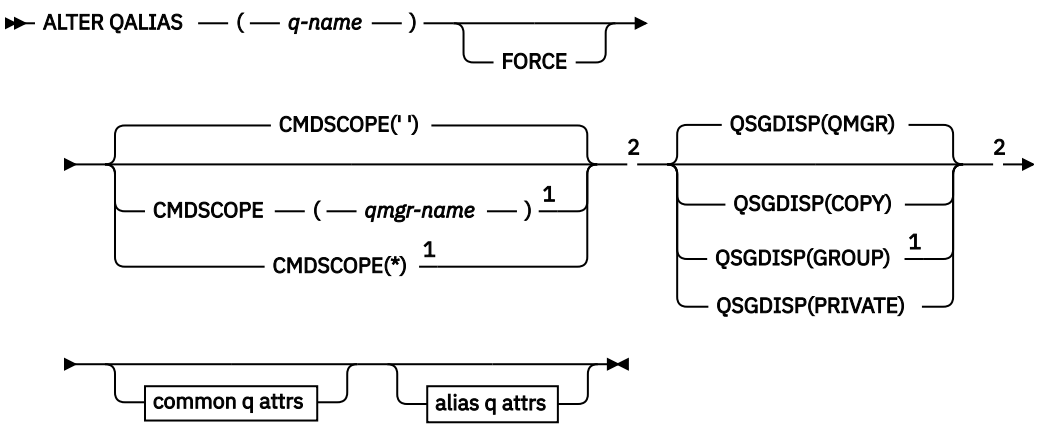
It is also ignored if the definition is used as a reply-to queue alias definition.

ALTER QALIAS

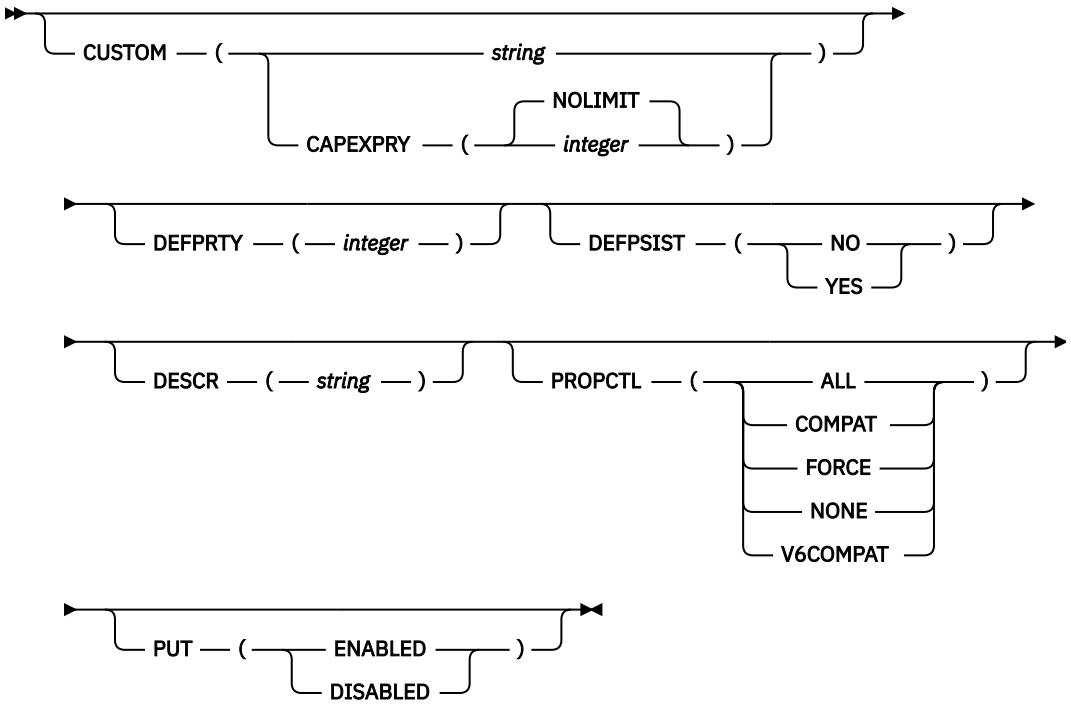
Use the MQSC command **ALTER QALIAS** to alter the parameters of an alias queue.

Synonym: ALT QA

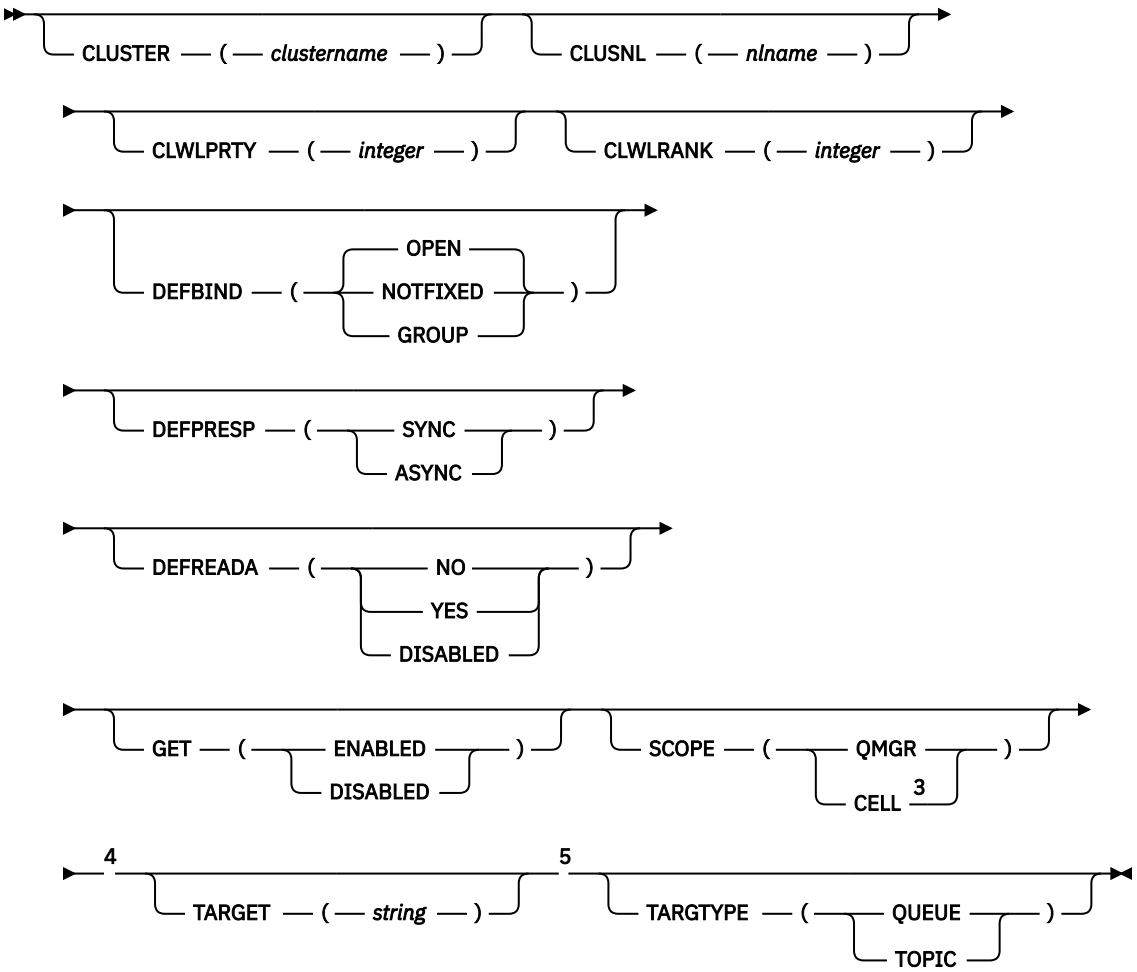
ALTER QALIAS



Common q attrs



Alias q attrs



Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[2] Valid only on z/OS.
[3] Valid only on AIX, Linux, and Windows systems.
[4] Not valid on z/OS.
[5] The TARGTYPE parameter is available for compatibility with previous releases. It is a synonym of TARGET; you cannot specify both parameters.

The parameters are described in "ALTER queues (alter queue settings)" on page 365.

Related concepts

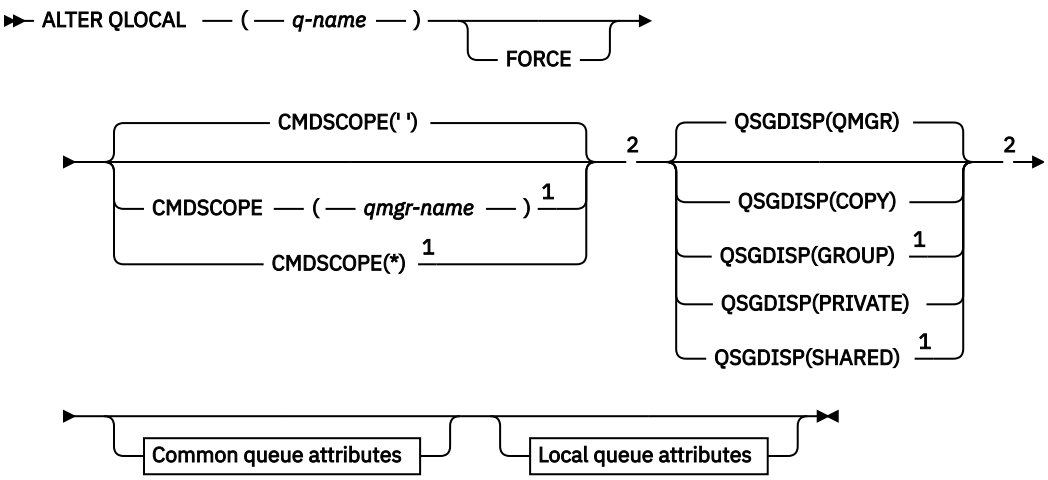
Working with alias queues

ALTER QLOCAL

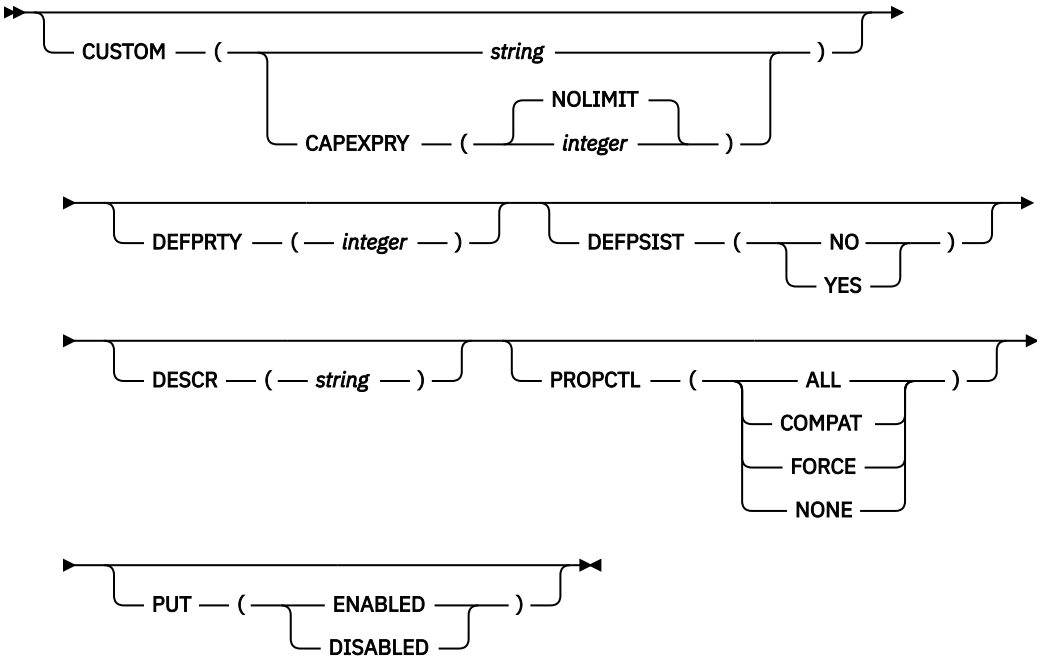
Use the MQSC command **ALTER QLOCAL** to alter the parameters of a local queue.

Synonym: ALT QL

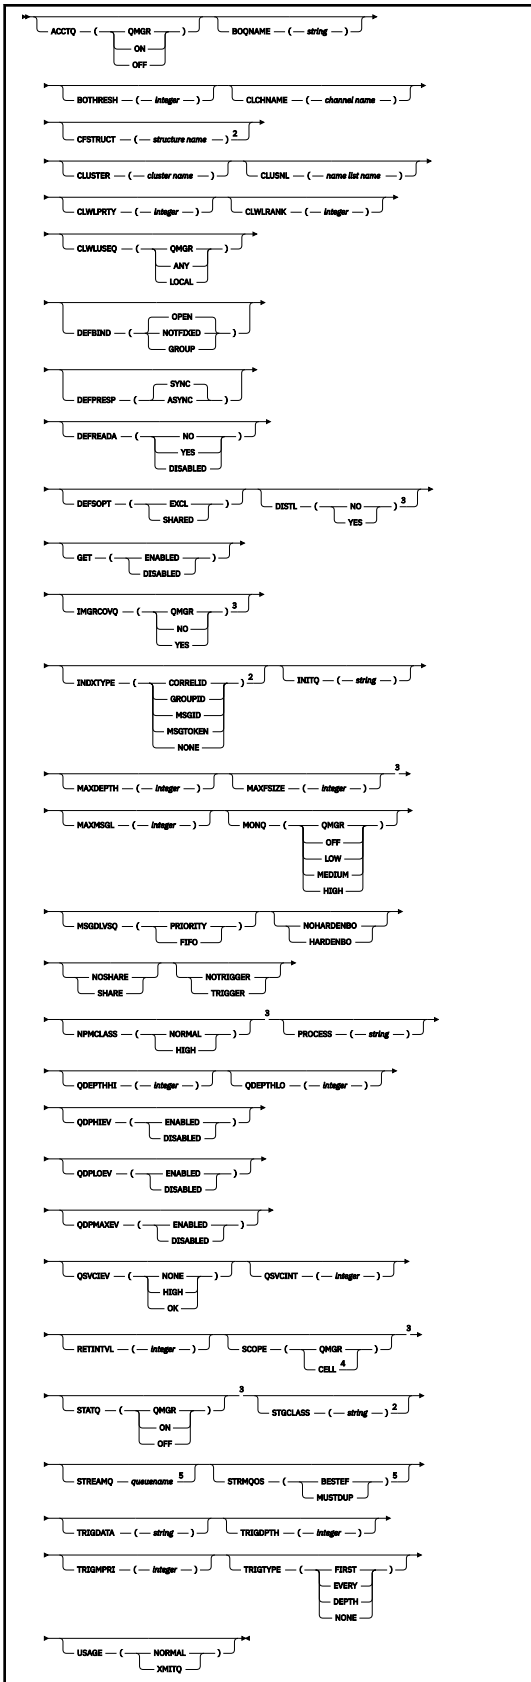
ALTER QLOCAL



Common queue attributes



Local queue attributes



Notes:

1 Valid only on z/OS when the queue manager is a member of a queue sharing group.

2 Valid only on z/OS.

[3] Not valid on z/OS.
[4] Valid only on AIX, Linux, and Windows systems.
[5] Valid on Multiplatforms.

The parameters are described in "ALTER queues (alter queue settings)" on page 365.

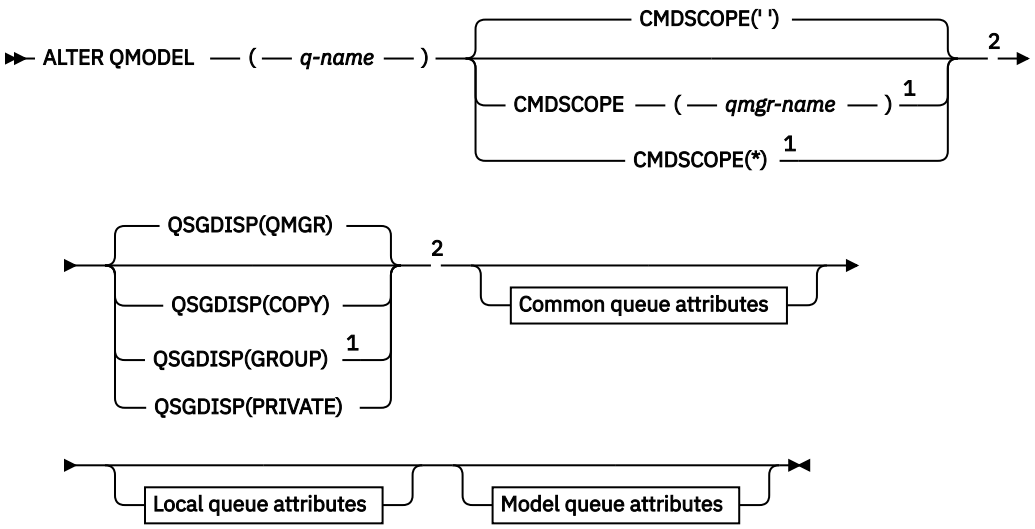
Related tasks
Changing local queue attributes

ALTER QMODEL

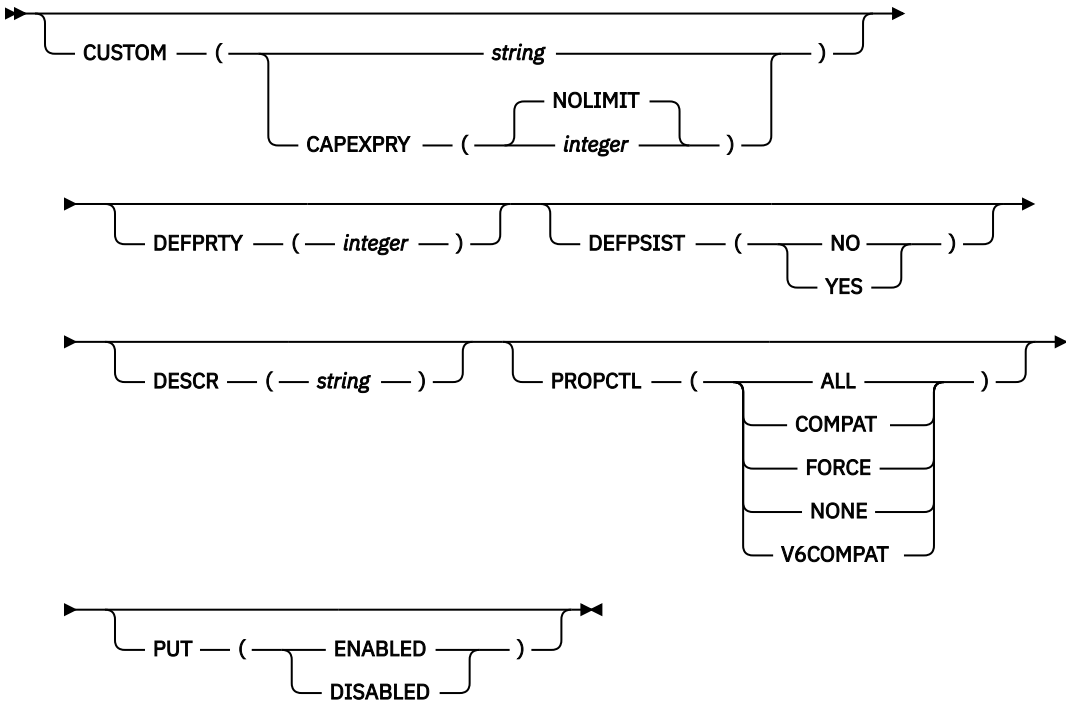
Use the MQSC command **ALTER QMODEL** to alter the parameters of a model queue.

Synonym: ALT QM

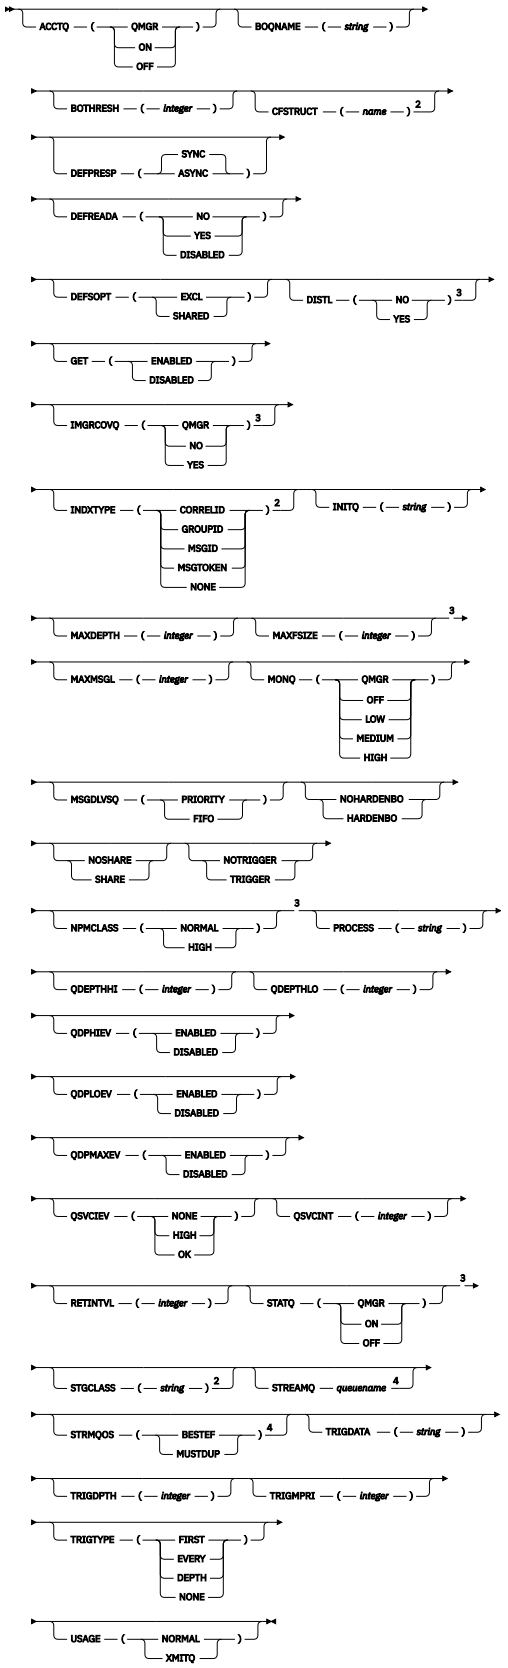
ALTER QMODEL



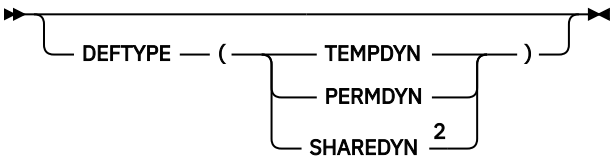
Common queue attributes



Local queue attributes



Model queue attributes



Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[2] Valid only on z/OS.
[3] Not valid on z/OS.
[4] Valid on Multiplatforms.

The parameters are described in "ALTER queues (alter queue settings)" on page 365.

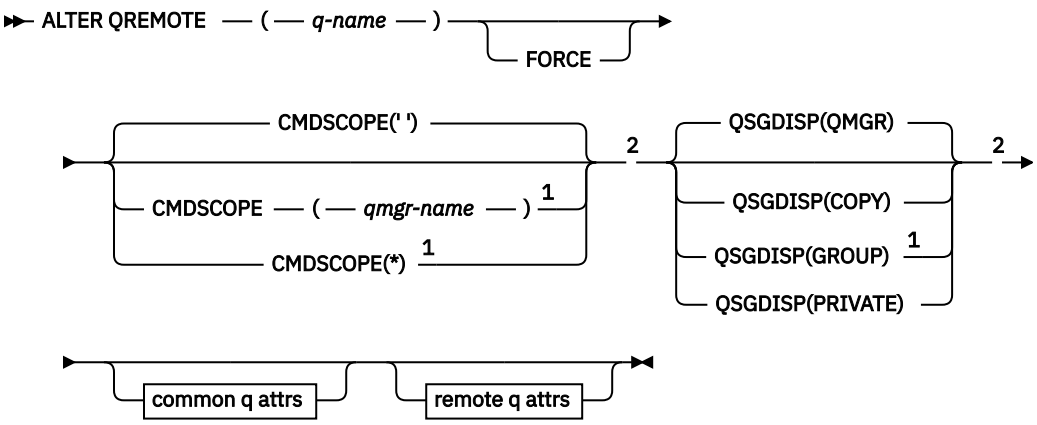
Related concepts
Working with model queues

ALTER QREMOTE

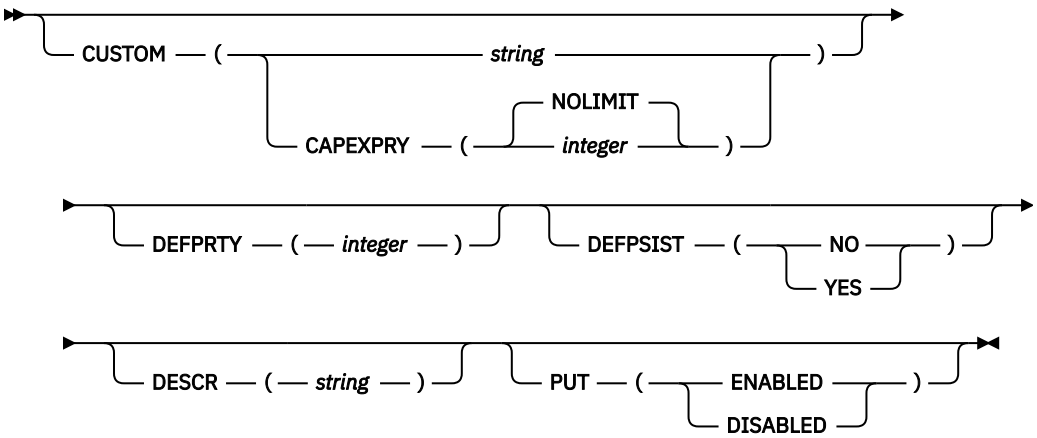
Use the MQSC command **ALTER QREMOTE** to alter the parameters of a local definition of a remote queue, a queue manager alias, or a reply-to queue alias.

Synonym: ALT QR

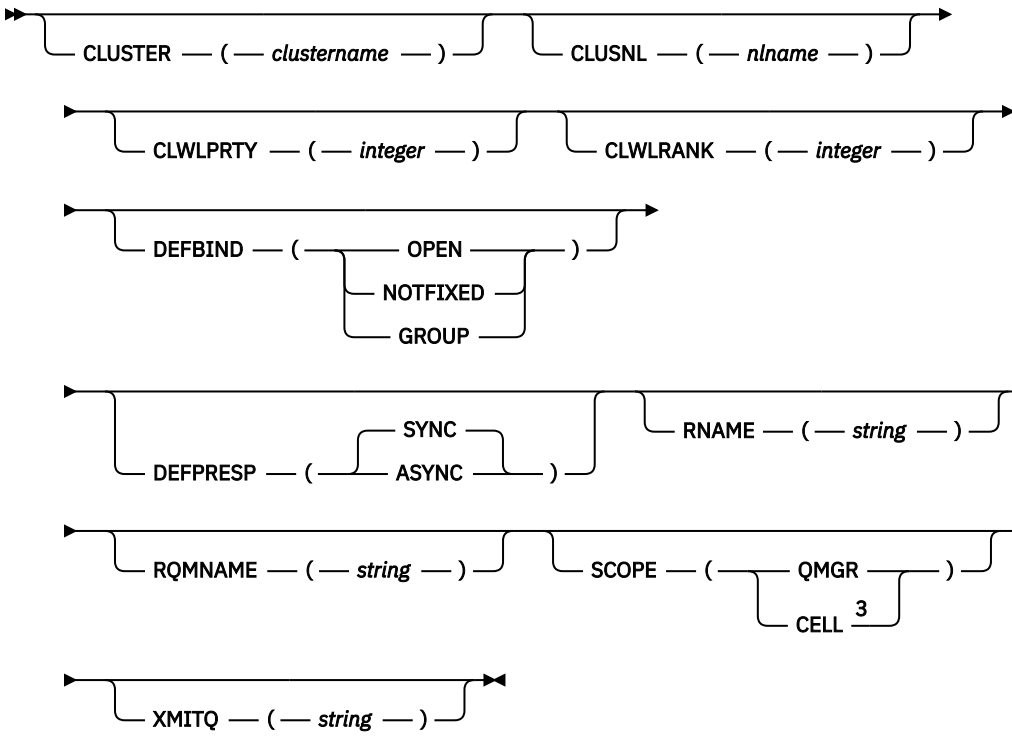
ALTER QREMOTE



Common q attrs



Remote q attrs



Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[2] Valid only on z/OS.
[3] Valid only on AIX, Linux, and Windows.

The parameters are described in "ALTER queues (alter queue settings)" on page 365.

z/OS ALTER SECURITY (alter security options) on z/OS

Use the MQSC command **ALTER SECURITY** to define system-wide security options.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

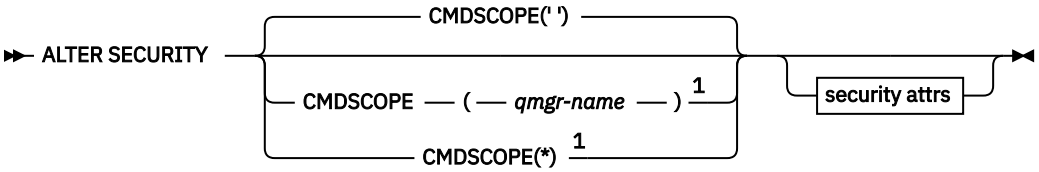
Parameters not specified in the **ALTER SECURITY** command result in the existing values for those parameters being left unchanged.

You can issue this command from sources 12CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

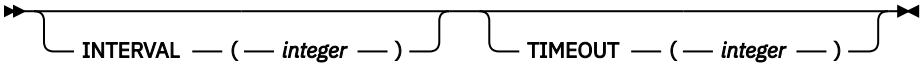
- Syntax diagram
- "Parameter descriptions for ALTER SECURITY" on page 397

Synonym: ALT SEC

ALTER SECURITY



Security attrs



Notes:

1 Valid only on z/OS when the queue manager is a member of a queue sharing group.

Parameter descriptions for ALTER SECURITY

The parameters you specify override the current parameter values. Attributes that you do not specify are unchanged.

Note: If you do not specify any parameters, the command completes successfully, but no security options are changed.

CMDSCOPE

This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE cannot be used for commands issued from the first initialization input data set CSQINP1.

' '

The command runs on the queue manager on which it was entered.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of * is the same as entering the command on every queue manager in the queue sharing group.

INTERVAL(*integer*)

The interval between checks for user IDs and their associated resources to determine whether the **TIMEOUT** has expired. The value is in minutes, in the range zero through 10080 (one week). If **INTERVAL** is specified as zero, no user timeouts occur.

TIMEOUT(*integer*)

How long security information about an unused user ID and associated resources is retained by IBM MQ. The value specifies a number of minutes in the range zero through 10080 (one week). If **TIMEOUT** is specified as zero, and **INTERVAL** is nonzero, all such information is discarded by the queue manager every **INTERVAL** number of minutes.

The length of time that an unused user ID and associated resources are retained by IBM MQ depends on the value of **INTERVAL**. The user ID times out at a time between **TIMEOUT** and **TIMEOUT** plus **INTERVAL**.

When the **TIMEOUT** and **INTERVAL** parameters are changed, the previous timer request is canceled and a new timer request is scheduled immediately, using the new **TIMEOUT** value. When the timer request is actioned, a new value for **INTERVAL** is set.

User ID timeouts

Multi ALTER SERVICE (alter a service definition) on Multiplatforms

Use the MQSC command **ALTER SERVICE** to alter the parameters of an existing IBM MQ service definition.

Using MQSC commands

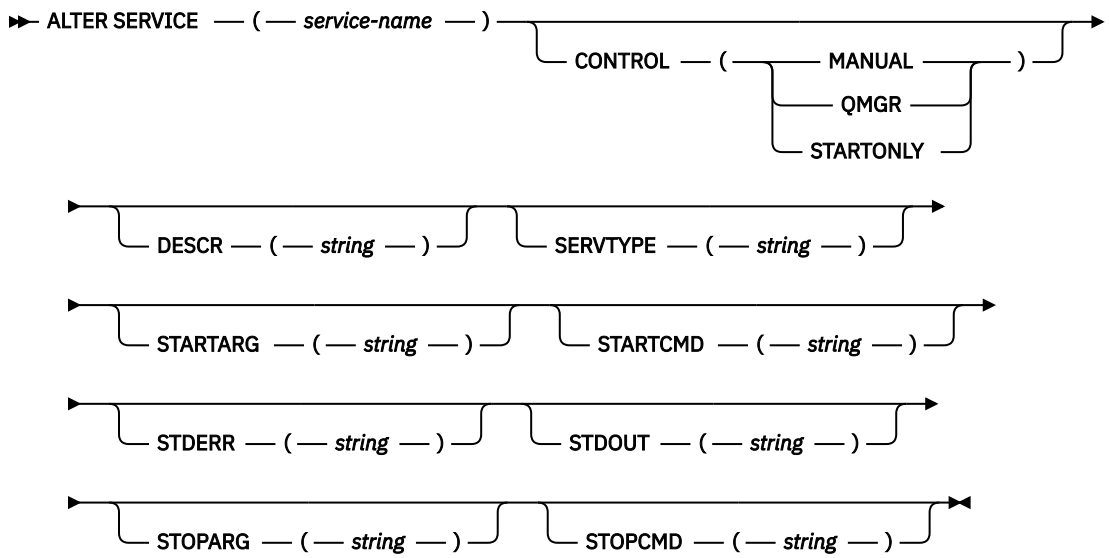
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

Parameters not specified in the **ALTER SERVICE** command result in the existing values for those parameters being left unchanged.

- Syntax diagram
- "Parameter descriptions for ALTER SERVICE" on page 398

Synonym:

ALTER SERVICE



Parameter descriptions for ALTER SERVICE

The parameter descriptions apply to the **ALTER SERVICE** and **DEFINE SERVICE** commands, with the following exceptions:

- The **LIKE** parameter applies only to the **DEFINE SERVICE** command.
- The **NOREPLACE** and **REPLACE** parameter applies only to the **DEFINE SERVICE** command.

(service-name)
Name of the IBM MQ service definition (see Rules for naming IBM MQ objects).

The name must not be the same as any other service definition currently defined on this queue manager (unless **REPLACE** is specified).

CONTROL(*string*)
Specifies how the service is to be started and stopped:

MANUAL
The service is not to be started automatically or stopped automatically. It is to be controlled by use of the **START SERVICE** and **STOP SERVICE** commands.

QMGR
The service being defined is to be started and stopped at the same time as the queue manager is started and stopped.

STARTONLY
The service is to be started at the same time as the queue manager is started, but is not requested to stop when the queue manager is stopped.

DESCR(*string*)
Plain-text comment. It provides descriptive information about the service when an operator issues the **DISPLAY SERVICE** command (see "DISPLAY SERVICE (display service information) on Multiplatforms" on page 799).

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

LIKE(*service-name*)
The name of a service the parameters of which are used to model this definition.

This parameter applies only to the **DEFINE SERVICE** command.

If this field is not completed, and you do not complete the parameter fields related to the command, the values are taken from the default definition for services on this queue manager. Not completing this parameter is equivalent to specifying:

```
LIKE(SYSTEM.DEFAULT.SERVICE)
```

A default service is provided but it can be altered by the installation of the default values required. See Rules for naming IBM MQ objects.

REPLACE and NOREPLACE
Whether the existing definition is to be replaced with this one.

This parameter applies only to the **DEFINE SERVICE** command.

REPLACE
The definition must replace any existing definition of the same name. If a definition does not exist, one is created.

NOREPLACE
The definition should not replace any existing definition of the same name.

SERVTYPE
Specifies the mode in which the service is to run:

COMMAND
A command service object. Multiple instances of a command service object can be executed concurrently. You cannot monitor the status of command service objects.

SERVER
A server service object. Only one instance of a server service object can be executed at a time. The status of server service objects can be monitored using the **DISPLAY SVSTATUS** command.

STARTARG(*string*)
Specifies the arguments to be passed to the user program at queue manager startup.

STARTCMD(*string*)
Specifies the name of the program which is to run. You must specify a fully qualified path name to the executable program.

STDERR(*string*)
Specifies the path to a file to which the standard error (stderr) of the service program is redirected. If the file does not exist when the service program is started, the file is created. If this value is blank then any data written to stderr by the service program is discarded.

STDOUT(*string*)
Specifies the path to a file to which the standard output (stdout) of the service program is redirected. If the file does not exist when the service program is started, the file is created. If this value is blank then any data written to stdout by the service program is discarded.

STOPARG(*string*)
Specifies the arguments to be passed to the stop program when instructed to stop the service.

STOPCMD(*string*)
Specifies the name of the executable program to run when the service is requested to stop. You must specify a fully qualified path name to the executable program.

Replaceable inserts can be used for any of the **STARTCMD**, **STARTARG**, **STOPCMD**, **STOPARG**, **STDOUT** or **STDERR** strings, for more information, see Replaceable inserts on service definitions.

Related concepts
Working with services
Related reference
"DEFINE SERVICE (create a new service definition) on Multiplatforms" on page 564
Use the MQSC command **DEFINE SERVICE** to define a new IBM MQ service definition, and set its parameters.

"DISPLAY SVSTATUS (display services status) on Multiplatforms" on page 819
Use the MQSC command **DISPLAY SVSTATUS** to display status information for one or more services. Only services with a **SERVTYPE** of SERVER are displayed.

"START SERVICE (start a service) on Multiplatforms" on page 932
Use the MQSC command **START SERVICE** to start a service. The identified service definition is started within the queue manager and inherits the environment and security variables of the queue manager.

"STOP SERVICE (stop a service) on Multiplatforms" on page 951
Use the MQSC command **STOP SERVICE** to stop a service.

Examples of using service objects

z/OS ALTER SMDS (alter shared message data sets) on z/OS

Use the MQSC command **ALTER SMDS** to alter the parameters of existing IBM MQ definitions relating to one or more shared message data sets associated with a specific application structure. It is only supported when the CFSTRUCT definition is using the option OFFLOAD(SMDS).

Using MQSC commands

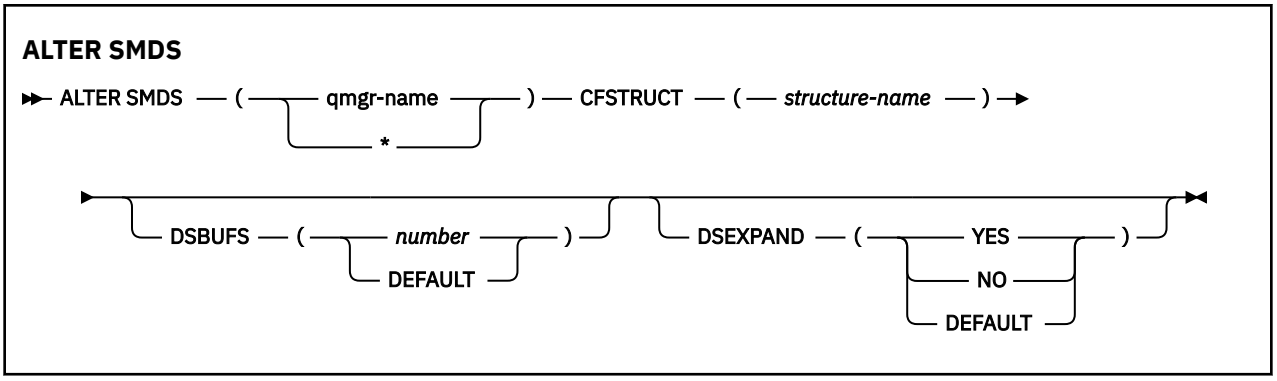
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

Parameters not specified in the **ALTER SMDS** command result in the existing values for those parameters being left unchanged.

You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Parameter descriptions for ALTER SMDS" on page 401

Synonym:



Parameter descriptions for ALTER SMDS

SMDS(*qmgr-name*|*)
Specify the queue manager for which the shared message data set properties are to be modified, or an asterisk to modify the properties for all data sets associated with the specified CFSTRUCT.

CFSTRUCT(*structure-name*)
Specify the coupling facility application structure for which the properties of one or more shared message data sets are to be modified.

DSBUFS(number|DEFAULT)
Specify an override value for the number of buffers to be allocated in the specified queue manager or queue managers for accessing shared message data sets for this structure, as a number in the range 1 to 9999, or specify DEFAULT to cancel a previous override and resume using the **DSBUFS** value from the CFSTRUCT definition. The size of each buffer is equal to the logical block size. SMDS buffers are allocated in memory objects residing in z/OS 64-bit storage (above the bar).

When this parameter is altered, any affected queue managers which are already connected to the structure dynamically increase or decrease the number of data set buffers being used for this structure to match the new value. If the specified target value cannot be reached, the affected queue manager replaces the specified **DSBUFS** parameter with the actual new number of buffers. If the queue manager is not active, the change will come into effect when the queue manager is restarted.

DSEXPAND(YES|NO|DEFAULT)
Specify an override value to be used by the specified queue manager or queue managers to control expansion of shared message data sets for this structure.

This parameter controls whether the queue manager should expand a shared message data set when it becomes nearly full, and further blocks are required in the data set.

YES
Expansion is supported.

Each time expansion is required, the data set is expanded by the secondary allocation specified when the data set was defined. If no secondary allocation was specified, or it was specified as zero, then a secondary allocation amount of approximately 10% of the existing size is used.

NO
No automatic data set expansion is to take place.

DEFAULT
Cancels a previous override.

If you used DEFAULT to cancel a previous override it resumes using the **DSEXPAND** value from the CFSTRUCT definition.

If an expansion attempt fails, the **DSEXPAND** override for the affected queue manager is automatically changed to NO to prevent further expansion attempts, but it can be changed back to YES using the **ALTER SMDS** command to enable further expansion attempts.

When this parameter is altered, any affected queue managers which are already connected to the structure immediately start using the new parameter value.

z/OS ALTER STGCLASS (alter storage class settings) on z/OS

Use the MQSC command **ALTER STGCLASS** to alter the characteristics of a storage class.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

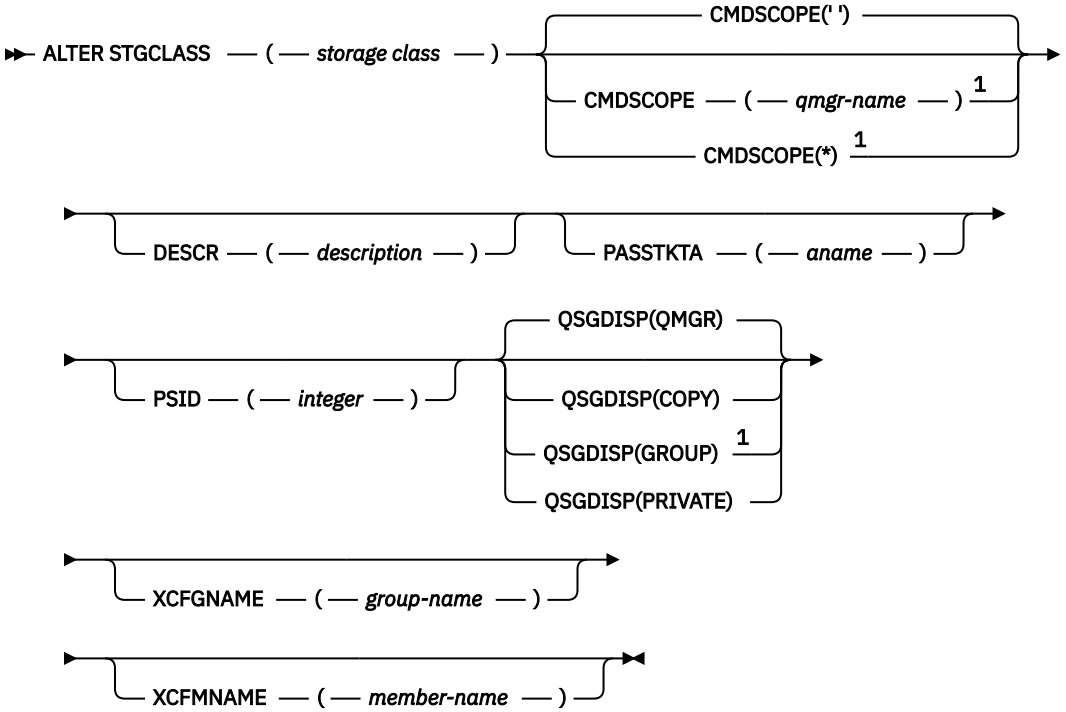
Parameters not specified in the **ALTER STGCLASS** command result in the existing values for those parameters being left unchanged.

You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Parameter descriptions for ALTER STGCLASS" on page 402

Synonym: ALT STC

ALTER STGCLASS



Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.

Parameter descriptions for ALTER STGCLASS

(storage-class)

Name of the storage class.

This name is one to 8 characters. The first character is in the range A through Z; subsequent characters are A through Z or 0 through 9.

Note: Exceptionally, certain all numeric storage class names are allowed, but are reserved for the use of IBM service personnel.

The storage class must not be the same as any other storage class currently defined on this queue manager.

CMDSCOPE
This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

' '
The command runs on the queue manager on which it was entered.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of * is the same as entering the command on every queue manager in the queue sharing group.

DESCR(*description*)
Plain-text comment. It provides descriptive information about the object when an operator issues the **DISPLAY STGCLASS** command.

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager

PASSTKTA(*application name*)
The application name that is passed to RACF when authenticating the PassTicket specified in the MQIIH header.

PSID(*integer*)
The page set identifier that this storage class is to be associated with.

Note: No check is made that the page set has been defined; an error is raised only when you try to put a message to a queue that specifies this storage class (MQRC_PAGESET_ERROR).

The string consists of two numeric characters, in the range 00 through 99. See "DEFINE PSID (define page set and buffer pool) on z/OS" on page 527.

QSGDISP
Specifies the disposition of the object in the group.

Table 139. Behavior for each of the QSGDISP values

QSGDISP	ALTER
COPY	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters **QSGDISP(COPY)**. Any object residing in the shared repository, or any object defined using a command that had the parameters **QSGDISP(QMGR)**, is not affected by this command.

Table 139. Behavior for each of the QSGDISP values (continued)	
QSGDISP	**ALTER**

GROUP	The object definition resides in the shared repository. The object was defined using a command that had the parameters **QSGDISP(GROUP)**. Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command. If the command is successful, the following command is generated and sent to all active queue managers in the queue sharing group to attempt to refresh local copies on page set zero:
	`DEFINE STGCLASS(storage-class)`
	`REPLACE QSGDISP(COPY)`
	The ALTER for the group object takes effect regardless of whether the generated command with **QSGDISP(COPY)** fails.

PRIVATE	The object resides on the page set of the queue manager that executes the command, and was defined with **QSGDISP(QMGR)** or **QSGDISP(COPY)**. Any object residing in the shared repository is unaffected.
QMGR	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters **QSGDISP(QMGR)**. Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

XCFGNAME(*group name*)
If you are using the IMS bridge, this name is the name of the XCF group to which the IMS system belongs. (This name is the group name specified in the IMS parameter list.)

This name is 1 - 8 characters. The first character is in the range A through Z; subsequent characters are A through Z or 0 - 9.

XCFMNAME(*member name*)
If you are using the IMS bridge, this name is the XCF member name of the IMS system within the XCF group specified in XCFGNAME. (This name is the member name specified in the IMS parameter list.)

This name is 1 - 16 characters. The first character is in the range A through Z; subsequent characters are A through Z or 0 - 9.

ALTER SUB (alter subscription settings)

Use the MQSC command **ALTER SUB** to alter the characteristics of an existing subscription.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

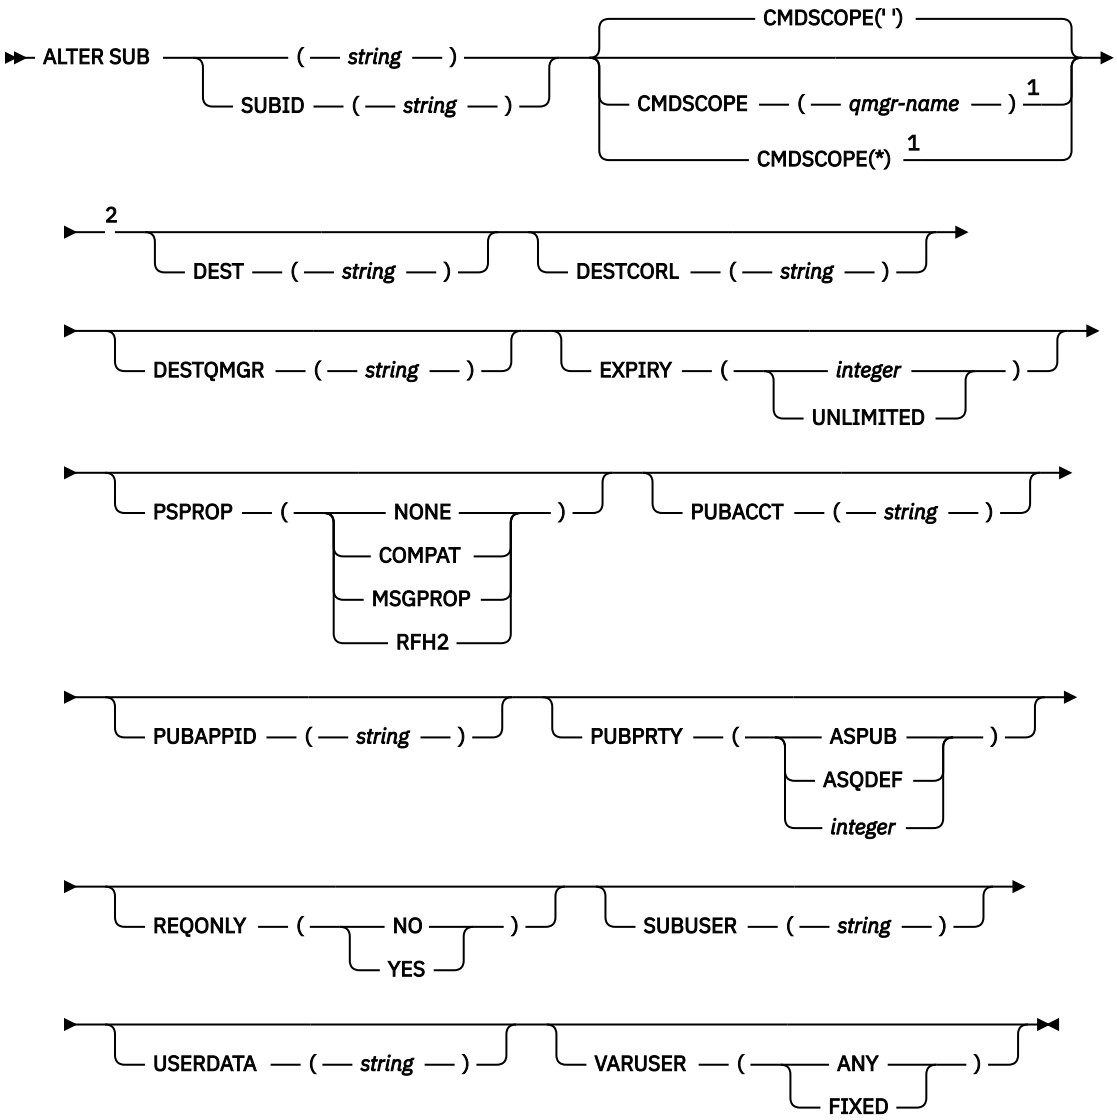
Parameters not specified in the **ALTER SUB** command result in the existing values for those parameters being left unchanged.

z/OS You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- “Usage notes for ALTER SUB” on page 405
- “Parameter descriptions for ALTER SUB” on page 406

Synonym: **ALT SUB**

ALTER SUB



Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[2] Valid only on z/OS.

Usage notes for ALTER SUB

1. The following forms are valid for the command:

```
ALT SUB(xyz)
ALT SUB SUBID(123)
ALT SUB(xyz) SUBID(123)
```

2. Although permitted on the **DEFINE** command, you cannot alter the following fields using **ALTER SUB**:
   - **TOPICOBJ**
   - **TOPICSTR**
   - **WSCHEMA**
   - **SELECTOR**

- **SUBSCOPE**
- **DESTCLAS**
- **SUBLEVEL**

3. At the time the **ALT SUB** command processes, no check is performed that the named **DEST** or **DESTQMGR** exists. These names are used at publishing time as the *ObjectName* and *ObjectQMgrName* for an MQOPEN call. These names are resolved according to the IBM MQ name resolution rules.
4. Subscriptions with a **SUBTYPE** of PROXY cannot be modified. Attempts to modify a proxy subscription by using the PCF interface return MQRCCF_SUBSCRIPTION_IN_USE. MQSC reports the following message:

   ```
   AMQ8469: IBM MQ subscription SYSTEM.PROXY in use.
   ```

Parameter descriptions for ALTER SUB

(string)
A mandatory parameter. Specifies the unique name for this subscription, see **SUBNAME** property.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of setting this value is the same as entering the command on every queue manager in the queue sharing group.

You cannot use CMDSCOPE as a filter keyword.

DEST(*string*)
The destination for messages published to this subscription; this parameter is the name of a queue.

DESTCORL(*string*)
The **CorrelId** used for messages published to this subscription.

A blank value (default) results in a system generated correlation identifier being used.

If set to ' 00000000000000000000000000000000000000000000000000000000 ' (48 zeros) the **CorrelId** set by the publishing application will be maintained in the copy of the message delivered to the subscription, unless messages are propagated across a publish/subscribe hierarchy.

If this byte string is enclosed in quotation marks, characters in the range A-F must be specified in uppercase.

Note: It is not possible to set the DESTCORL property programmatically with JMS.

DESTQMGR(*string*)
The destination queue manager for messages published to this subscription. You must define the channels to the remote queue manager, for example, the XMITQ, and a sender channel. If you do not, messages do not arrive at the destination.

EXPIRY
The time to expiry of the subscription object from the creation date and time.

(*integer*)
The time to expiry, in tenths of a second, from the creation date and time.

UNLIMITED
There is no expiry time. This is the default option supplied with the product.

PSPROP
The manner in which publish subscribe related message properties are added to messages sent to this subscription.

NONE
Do not add publish subscribe properties to the message.

COMPAT
Publish/subscribe properties are added within an MQRFH version 1 header unless the message was published in PCF format.

MSGPROP
Publish/subscribe properties are added as message properties.

RFH2
Publish/subscribe properties are added within an MQRFH version 2 header.

PUBACCT(*string*)
Accounting token passed by the subscriber, for propagation into messages published to this subscription in the `AccountingToken` field of the MQMD.

If this byte string is enclosed in quotation marks, characters in the range A-F must be specified in uppercase.

PUBAPPID(*string*)
Identity data passed by the subscriber, for propagation into messages published to this subscription in the `ApplIdentityData` field of the MQMD.

PUBPRTY
The priority of the message sent to this subscription.

ASPUB
Priority of the message sent to this subscription is taken from the priority supplied in the published message.

ASQDEF
Priority of the message sent to this subscription is taken from the default priority of the queue defined as a destination.

(integer)
An integer providing an explicit priority for messages published to this subscription.

REQONLY
Indicates whether the subscriber polls for updates using the MQSUBRQ API call, or whether all publications are delivered to this subscription.

NO
All publications on the topic are delivered to this subscription. This is the default value.

YES
Publications are only delivered to this subscription in response to an MQSUBRQ API call.

This parameter is equivalent to the subscribe option MQSO_PUBLICATIONS_ON_REQUEST.

SUBUSER(*string*)
Specifies the user ID that is used for security checks that are performed to ensure that publications can be put to the destination queue associated with the subscription. This ID is either the user ID associated with the creator of the subscription or, if subscription takeover is permitted, the user ID that last took over the subscription. The length of this parameter must not exceed 12 characters.

USERDATA(*string*)
Specifies the user data associated with the subscription. The string is a variable length value that can be retrieved by the application on an MQSUB API call and passed in a message sent to this

subscription as a message property. The **USERDATA** is stored in the RFH2 header in the mqps folder with the key Sud.

An IBM MQ classes for JMS application can retrieve the subscription user data from the message by using the constant JMS_IBM_SUBSCRIPTION_USER_DATA. For more information, see Retrieval of user subscription data.

VARUSER
Specifies whether a user other than the subscription creator can connect to and take over ownership of the subscription.

ANY
Any user can connect to and takeover ownership of the subscription.

FIXED
Takeover by another USERID is not permitted.

Related tasks
Changing local subscription attributes

ALTER TOPIC (alter topic settings)

Use the MQSC **ALTER TOPIC** command to alter the parameters of an existing IBM MQ topic object.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

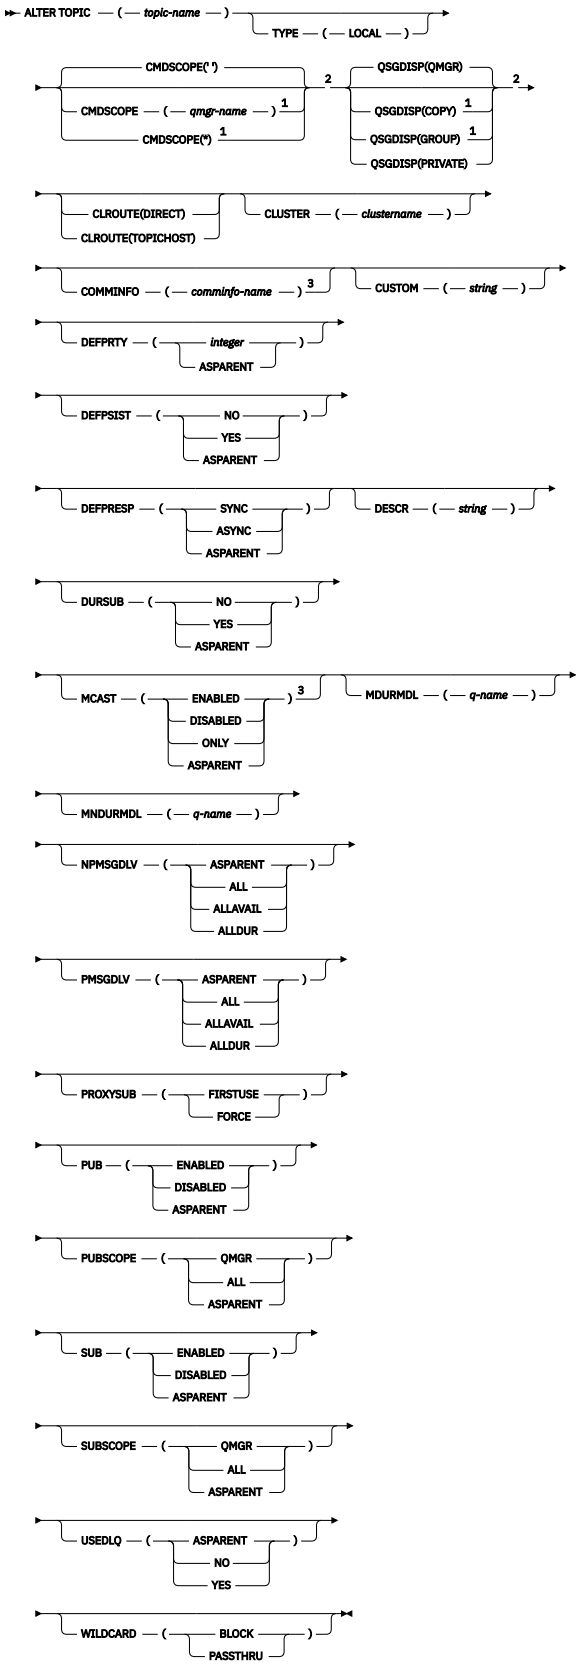
Parameters not specified in the **ALTER TOPIC** command result in the existing values for those parameters being left unchanged.

- Syntax diagram
- "Usage notes for ALTER TOPIC" on page 410
- "Parameter descriptions for ALTER TOPIC" on page 410

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

Synonym: ALT TOPIC

ALTER TOPIC



Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.

[2] Valid only on z/OS.
[3] Not valid on z/OS.

Usage notes for ALTER TOPIC

- Successful completion of the command does not mean that the action completed. To check for true completion, see the ALTER TOPIC step in Checking that async commands for distributed networks have finished.

Parameter descriptions for ALTER TOPIC

(topic-name)
Name of the IBM MQ topic definition (see Rules for naming IBM MQ objects). The maximum length is 48 characters.

The name must not be the same as any other topic definition currently defined on this queue manager (unless REPLACE is specified).

CLROUTE
The routing behavior to use for topics in the cluster defined by the **CLUSTER** parameter.

DIRECT
When you configure a direct routed clustered topic on a queue manager, all queue managers in the cluster become aware of all other queue managers in the cluster. When performing publish and subscribe operations, each queue manager can connect direct to any other queue manager in the cluster.

TOPICHOST
When you use topic host routing, all queue managers in the cluster become aware of the cluster queue managers that host the routed topic definition (that is, the queue managers on which you have defined the topic object). When performing publish and subscribe operations, queue managers in the cluster connect only to these topic host queue managers, and not directly to each other. The topic host queue managers are responsible for routing publications from queue managers on which publications are published to queue managers with matching subscriptions.

After a topic object has been clustered (through setting the **CLUSTER** property) you cannot change the value of the **CLROUTE** property. The object must be un-clustered (**CLUSTER** set to `' '`) before you can change the value. Un-clustering a topic converts the topic definition to a local topic, which results in a period during which publications are not delivered to subscriptions on remote queue managers; this should be considered when performing this change. See The effect of defining a non-cluster topic with the same name as a cluster topic from another queue manager. If you try to change the value of the **CLROUTE** property while it is clustered, the system generates an `MQRCCF_CLROUTE_NOT_ALTERABLE` exception.

See also Routing for publish/subscribe clusters: Notes on behavior and Designing publish/subscribe clusters.

CLUSTER
The name of the cluster to which this topic belongs.Setting this parameter to a cluster that this queue manager is a member of makes all queue managers in the cluster aware of this topic. Any publication to this topic or a topic string below it put to any queue manager in the cluster is propagated to subscriptions on any other queue manager in the cluster. For more details, see Distributed publish/subscribe networks.

' '
If no topic object above this topic in the topic tree has set this parameter to a cluster name, then this topic does not belong to a cluster. Publications and subscriptions for this topic are not propagated to publish/subscribe cluster-connected queue managers. If a topic node higher in the topic tree has a cluster name set, publications and subscriptions to this topic are also propagated throughout the cluster.

string
The topic belongs to this cluster. It is not recommended that this is set to a different cluster from a topic object above this topic object in the topic tree. Other queue managers in the cluster will honor this object's definition unless a local definition of the same name exists on those queue managers.

To prevent all subscriptions and publications being propagated throughout a cluster, leave this parameter blank on the system topics SYSTEM.BASE.TOPIC and SYSTEM.DEFAULT.TOPIC, except in special circumstances, for example to support migration.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

' '
The command runs on the queue manager on which it was entered.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of * is the same as entering the command on every queue manager in the queue sharing group.

COMMINFO(*comminfo-name*)
The name of the communication information object associated with this topic object.

CUSTOM(*string*)
The custom attribute for new features.

This attribute contains the values of attributes, as pairs of attribute name and value, separated by at least one space. The attribute name-value pairs have the form NAME(VALUE).

CAPEXPRY(*integer*)
The maximum time, expressed in tenths of a second, until a message published to a topic which inherits properties from this object, remains in the system until it becomes eligible for expiry processing.

For more information on message expiry processing, see Enforcing lower expiration times.

integer
The value must be in the range one through to 999 999 999.

NOLIMIT
There is no limit on the expiry time of messages put to this topic.

ASPARENT
The maximum message expiry time is based on the setting of the closest parent administrative topic object in the topic tree. This is the default value.

Specifying a value for CAPEXPRY that is not valid, does not cause the command to fail. Instead, the default value is used.

DEFPRTY(*integer*)
The default priority of messages published to the topic.

(*integer*)
The value must be in the range zero (the lowest priority), through to the **MAXPRTY** queue manager parameter (**MAXPRTY** is 9).

ASPARENT
The default priority is based on the setting of the closest parent administrative topic object in the topic tree.

DEFPSIST
Specifies the message persistence to be used when applications specify the MQPER_PERSISTENCE_AS_TOPIC_DEF option.

ASPARENT
The default persistence is based on the setting of the closest parent administrative topic object in the topic tree.

NO
Messages on this queue are lost during a restart of the queue manager.

YES
Messages on this queue survive a restart of the queue manager.

On z/OS, N and Y are accepted as synonyms of NO and YES.

DEFPRESP
Specifies the put response to be used when applications specify the MQPMO_RESPONSE_AS_DEF option.

ASPARENT
The default put response is based on the setting of the closest parent administrative topic object in the topic tree.

SYNC
Put operations to the queue that specify MQPMO_RESPONSE_AS_Q_DEF are issued as if MQPMO_SYNC_RESPONSE had been specified instead. Fields in the MQMD and MQPMO are returned by the queue manager to the application.

ASYNC
Put operations to the queue that specify MQPMO_RESPONSE_AS_Q_DEF are always issued as if MQPMO_ASYNC_RESPONSE had been specified instead. Some fields in the MQMD and MQPMO are not returned by the queue manager to the application. However, an improvement in performance might be seen for messages put in a transaction and any non-persistent messages

DESCR(*string*)
Plain-text comment. It provides descriptive information about the object when an operator issues the **DISPLAY TOPIC** command.

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

DURSUB
Specifies whether applications are permitted to make durable subscriptions on this topic.

ASPARENT
Whether durable subscriptions can be made on this topic is based on the setting of the closest parent administrative topic object in the topic tree.

NO
Durable subscriptions cannot be made on this topic.

YES
Durable subscriptions can be made on this topic.

MCAST
Specifies whether multicast is allowable in the topic tree. The values are:

ASPARENT
The multicast attribute of the topic is inherited from the parent.

DISABLED
No multicast traffic is allowed at this node.

ENABLED
Multicast traffic is allowed at this node.

ONLY
Only subscriptions from a multicast capable client are allowed.

MDURMDL(*string*)
The name of the model queue to be used for durable subscriptions that request that the queue manager manages the destination of its publications (see Rules for naming IBM MQ objects). The maximum length is 48 characters.

If **MDURMDL** is blank, it operates in the same way as ASPARENT values on other attributes. The name of the model queue to be used is based on the closest parent administrative topic object in the topic tree with a value set for **MDURMDL**.

If you use **MDURMDL** to specify a model queue for a clustered topic, you must ensure that the queue is defined on every queue manager in the cluster where a durable subscription using this topic can be made.

The dynamic queue created from this model has a prefix of SYSTEM.MANAGED.DURABLE

MNDURMDL(*string*)
The name of the model queue to be used for non-durable subscriptions that request that the queue manager manages the destination of its publications (see Rules for naming IBM MQ objects). The maximum length is 48 characters.

If **MNDURMDL** is blank, it operates in the same way as ASPARENT values on other attributes. The name of the model queue to be used is based on the closest parent administrative topic object in the topic tree with a value set for **MNDURMDL**.

If you use **MNDURMDL** to specify a model queue for a clustered topic, you must ensure that the queue is defined on every queue manager in the cluster where a non-durable subscription using this topic can be made.

The dynamic queue created from this model has a prefix of SYSTEM.MANAGED.NDURABLE.

NPMSGDLV
The delivery mechanism for non-persistent messages published to this topic:

ASPARENT
The delivery mechanism used is based on the setting of the first parent administrative node found in the topic tree relating to this topic.

ALL
Non-persistent messages must be delivered to all subscribers, irrespective of durability for the MQPUT call to report success. If a delivery failure to any subscriber occurs, no other subscribers receive the message and the MQPUT call fails.

ALLAVAIL
Non-persistent messages are delivered to all subscribers that can accept the message. Failure to deliver the message to any subscriber does not prevent other subscribers from receiving the message.

ALLDUR
Non-persistent messages must be delivered to all durable subscribers. Failure to deliver a non-persistent message to any non-durable subscribers does not return an error to the MQPUT call. If a delivery failure to a durable subscriber occurs, no subscribers receive the message and the MQPUT calls fails.

PMSGDLV
The delivery mechanism for persistent messages published to this topic:

ASPARENT
The delivery mechanism used is based on the setting of the first parent administrative node found in the topic tree relating to this topic.

ALL
Persistent messages must be delivered to all subscribers, irrespective of durability for the MQPUT call to report success. If a delivery failure to any subscriber occurs, no other subscribers receive the message and the MQPUT call fails.

ALLAVAIL
Persistent messages are delivered to all subscribers that can accept the message. Failure to deliver the message to any subscriber does not prevent other subscribers from receiving the message.

ALLDUR
Persistent messages must be delivered to all durable subscribers. Failure to deliver a persistent message to any non-durable subscribers does not return an error to the MQPUT call. If a delivery failure to a durable subscriber occurs, no subscribers receive the message and the MQPUT calls fails.

PROXYSUB
Controls when a proxy subscription is sent for this topic, or topic strings below this topic, to neighboring queue managers when in a publish/subscribe cluster or hierarchy. For more details, see Subscription performance in publish/subscribe networks.

FIRSTUSE
For each unique topic string at or below this topic object, a proxy subscription is asynchronously sent to all neighboring queue managers when a local subscription is created or a proxy subscription is received that is propagated to further directly connected queue managers in a hierarchy.

FORCE
A wildcard proxy subscription that matches all topic strings at and below this point in the topic tree is sent to neighboring queue managers even if no local subscriptions exist.

Note: The proxy subscription is sent when this value is set on **DEFINE** or **ALTER**. When set on a clustered topic, all queue managers in the cluster issue the wildcard proxy subscription to all other queue managers in the cluster.

PUB
Controls whether messages can be published to this topic.

ASPARENT
Whether messages can be published to the topic is based on the setting of the closest parent administrative topic object in the topic tree.

ENABLED
Messages can be published to the topic (by suitably authorized applications).

DISABLED
Messages cannot be published to the topic.

See also Special handling for the **PUB** parameter.

PUBSCOPE
Determines whether this queue manager propagates publications to queue managers as part of a hierarchy or as part of a publish/subscribe cluster.

Note: You can restrict the behavior on a publication-by-publication basis, using MQPMO_SCOPE_QMGR on the Put Message options.

ASPARENT
Whether this queue manager propagates publications to queue managers as part of a hierarchy or as part of a publish/subscribe cluster is based on the setting of the first parent administrative node found in the topic tree that relates to this topic.

QMGR
Publications for this topic are not propagated to connected queue managers.

ALL
Publications for this topic are propagated to hierarchically connected queue managers and to publish/subscribe cluster-connected queue managers.

z/OS **QSGDISP**

This parameter applies to z/OS only.

Specifies the disposition of the object within the group.

Table 140. Behavior for each of the QSGDISP values

QSGDISP	ALTER
COPY	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters **QSGDISP(COPY)**. Any object residing in the shared repository, or any object defined using a command that had the parameters **QSGDISP(QMGR)**, is not affected by this command.

GROUP	The object definition resides in the shared repository. The object was defined using a command that had the parameters **QSGDISP(GROUP)**. Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command. If the command is successful, the following command is generated and sent to all active queue managers in the queue sharing group to attempt to refresh local copies on page set zero:
	`DEFINE TOPIC(name)`
	`REPLACE QSGDISP(COPY)`
	The ALTER for the group object takes effect regardless of whether the generated command with **QSGDISP(COPY)** fails.

PRIVATE	The object resides on the page set of the queue manager that executes the command, and was defined with **QSGDISP(QMGR)** or **QSGDISP(COPY)**. Any object residing in the shared repository is unaffected.
QMGR	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters **QSGDISP(QMGR)**. Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

SUB
Controls whether applications are to be permitted to subscribe to this topic.

ASPARENT
Whether applications can subscribe to the topic is based on the setting of the closest parent administrative topic object in the topic tree.

ENABLED
Subscriptions can be made to the topic (by suitably authorized applications).

DISABLED
Applications cannot subscribe to the topic.

SUBSCOPE
Determines whether this queue manager subscribes to publications in this queue manager or in the network of connected queue managers. If subscribing to all queue managers, the queue manager propagates subscriptions to them as part of a hierarchy or as part of a publish/subscribe cluster.

Note: You can restrict the behavior on a subscription-by-subscription basis, using **MQPMO_SCOPE_QMGR** on the Subscription Descriptor or **SUBSCOPE(QMGR)** on **DEFINE SUB**.

Individual subscribers can override the **SUBSCOPE** setting of ALL by specifying the **MQSO_SCOPE_QMGR** subscription option when creating a subscription.

ASPARENT
Whether this queue manager subscribes to publications in the same way as the setting of the first parent administrative node found in the topic tree relating to this topic.

QMGR
Only publications that are published on this queue manager reach the subscriber.

ALL
A publication made on this queue manager or on another queue manager reaches the subscriber. Subscriptions for this topic are propagated to hierarchically connected queue managers and to publish/subscribe cluster-connected queue managers.

TOPICSTR(*string*)
The topic string represented by this topic object definition. This parameter is required and cannot contain the empty string.

The topic string must not be the same as any other topic string already represented by a topic object definition.

The maximum length of the string is 10,240 characters.

TYPE (topic-type)
If this parameter is used it must follow immediately after the *topic-name* parameter on all platforms

except z/OS.

LOCAL
A local topic object.

USEDLQ
Determines whether the dead-letter queue is used when publication messages cannot be delivered to their correct subscriber queue.

ASPARENT
Determines whether to use the dead-letter queue using the setting of the closest administrative topic object in the topic tree.

NO
Publication messages that cannot be delivered to their correct subscriber queue are treated as a failure to put the message. The MQPUT of an application to a topic fails in accordance with the settings of NPMSGDLV and PMSGDLV.

YES
When the DEADQ queue manager attribute provides the name of a dead-letter queue, then it is used. If the queue manager does not provide the name of a dead-letter queue, then the behavior is as for NO.

WILDCARD
The behavior of wildcard subscriptions with respect to this topic.

PASSTHRU
Subscriptions made to a wildcarded topic less specific than the topic string at this topic object receive publications made to this topic and to topic strings more specific than this topic.

BLOCK
Subscriptions made to a wildcarded topic less specific than the topic string at this topic object do not receive publications made to this topic or to topic strings more specific than this topic.

The value of this attribute is used when subscriptions are defined. If you alter this attribute, the set of topics covered by existing subscriptions is not affected by the modification. This scenario applies also if the topology is changed when topic objects are created or deleted; the set of topics matching subscriptions created following the modification of the WILDCARD attribute is created using the modified topology. If you want to force the matching set of topics to be re-evaluated for existing subscriptions, you must restart the queue manager.

Related tasks

Changing administrative topic attributes

z/OS ALTER TRACE (alter trace event settings) on z/OS

Use the MQSC command ALTER TRACE to change the trace events being traced for a particular active queue manager trace. ALTER TRACE stops the specified trace, and restarts it with the altered parameters.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

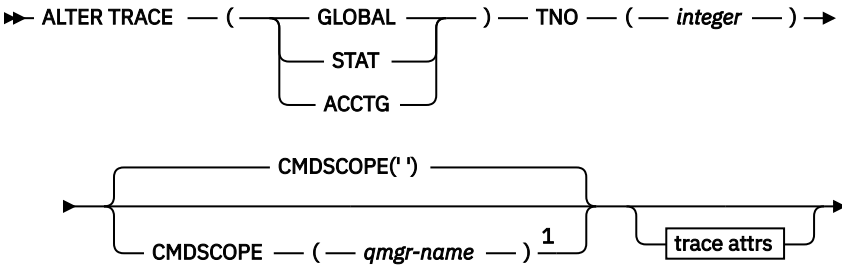
Parameters not specified in the ALTER TRACE command result in the existing values for those parameters being left unchanged.

You can issue this command from sources 12CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

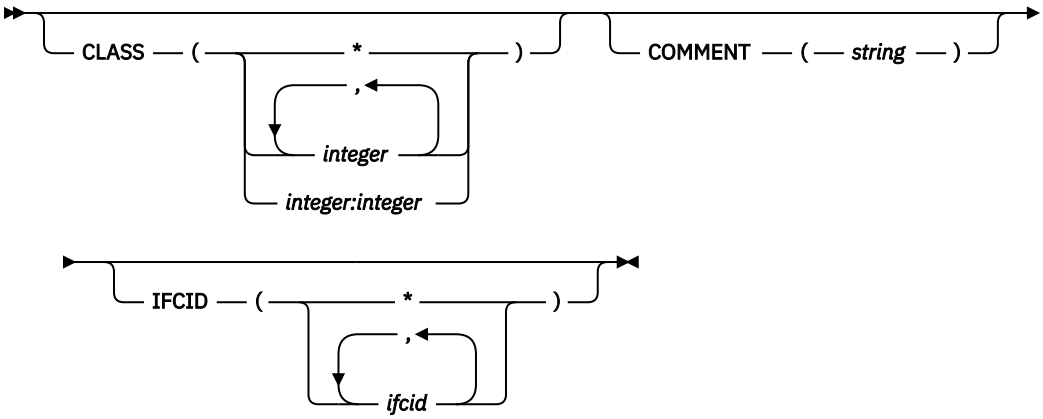
- Syntax diagram
- “Usage notes” on page 417
- “Parameter descriptions for ALTER TRACE” on page 418
- “Trace parameters” on page 418

Synonym: ALT TRACE

ALTER TRACE



Trace attrs



Notes:

1 Valid only on z/OS when the queue manager is a member of a queue sharing group.

Usage notes

Channel initiator traces cannot be altered.

Parameter descriptions for ALTER TRACE

Specify one of the following trace types:

GLOBAL
Service data from the entire queue manager (the synonym is G)

STAT
Statistical data (the synonym is S)

ACCTG
Accounting data (the synonym is A)

And:

TNO(*integer*)
The number of the trace to be altered (1 through 32). You can specify only one trace number.

CMDSCOPE
This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE cannot be used for commands issued from the first initialization input data set CSQINP1.

' '
The command runs on the queue manager on which it was entered.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

Trace parameters

CLASS(*integer*)
The new trace class. See "START TRACE (start trace) on z/OS" on page 934 for a list of allowed classes. A range of classes can be specified as *m:n* (for example, CLASS(01:03)).

For GLOBAL and CHINIT traces, CLASS(*) activates all classes.

For ACCTG and STAT traces, CLASS(*) activates classes 1 to 3. Channel initiator statistics and channel accounting data are not started with CLASS(*), and must be started with CLASS(4).

COMMENT(*string*)
A comment that is reproduced in the trace output record (except in the resident trace tables).

string is any character string. If it includes blanks, commas, or special characters, it must be enclosed between single quotation marks (').

IFCID(*ifcid*)
Reserved for IBM Service.

z/OS ARCHIVE LOG (back up the active log) on z/OS

Use the MQSC command ARCHIVE LOG as part of your backup procedure. It takes a copy of the current active log (or both logs if you are using dual logging).

Using MQSC commands

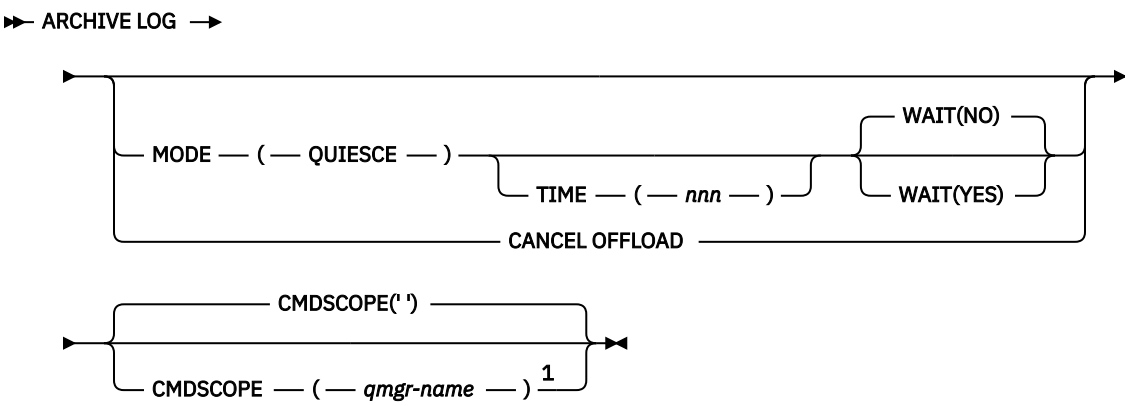
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 12CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- “Usage notes for ARCHIVE LOG” on page 419
- “Parameter descriptions for ARCHIVE LOG” on page 420

Synonym: ARC LOG

ARCHIVE LOG



Notes:

1 Valid only on z/OS when the queue manager is a member of a queue sharing group.

Usage notes for ARCHIVE LOG

ARCHIVE LOG performs the following actions:

1. Truncates the current active log data sets.
2. Continues logging, switching to the next active log data set.
3. Starts a task to offload the data sets.
4. Archives previous active log data sets not yet archived.

If the **MODE(QUIESCE)** parameter is used, the **ARCHIVE LOG** command quiesces (suspends) all user update activity on the current active log before the offload process. Once a system-wide point of consistency is reached (that is, when all currently active update users have reached a commit point), the current active log data set is immediately truncated, and the offload process is initiated. The resulting point of consistency is captured in the current active log before it is offloaded.

Normally, control returns to the user immediately, and the quiescing is done asynchronously. However, if the **WAIT(YES)** parameter is used, the quiescing is done synchronously, and control does not return to the user until it has finished.

- You cannot issue an **ARCHIVE LOG** command while a previous **ARCHIVE LOG** command is in progress.
- You cannot issue an **ARCHIVE LOG** command when the active log data set is the last available active log data set, because it would use all the available active log data set space, and IBM MQ would halt all processing until an offload had been completed.
- You can issue an **ARCHIVE LOG** command without the **MODE(QUIESCE)** option when a **STOP QMGR MODE(QUIESCE)** is in progress, but not when a **STOP QMGR MODE (FORCE)** is in progress.
- You can issue a **DISPLAY LOG** command to discover whether an **ARCHIVE LOG** command is active. If an **ARCHIVE LOG** command is active, the **DISPLAY** command returns message CSQV400I.
- You can issue an **ARCHIVE LOG** command even if archiving is not being used (that is, **OFFLOAD** is set to NO in the CSQ6LOGP system parameter macro), or dynamically using the **SET LOG** command. In this case, the current active log data sets are truncated and logging continues using the next active log data set, but there is no offloading to archive data sets.

Parameter descriptions for ARCHIVE LOG

All the parameters are optional. If none are specified, the current active log data sets are switched and offloaded immediately.

CANCEL OFFLOAD
Cancels any offloading currently in progress and restarts the offload process. The process starts with the oldest active log data set and proceeds through all the active data sets that need offloading.

Use this command only if the offload task does not appear to be working, or if you want to restart a previous offload attempt that failed.

CMDSCOPE
This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE cannot be used for commands issued from the first initialization input data set CSQINP1.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

MODE(QUIESCE)
Stops any new update activity on the queue manager, and brings all existing users to a point of consistency after a commit. When this state is reached, or the number of active users is zero, the current active log is archived.

The time that the queue manager waits to reach such a state is limited to the value specified by **QUIESCE** in the CSQ6ARVP system parameter macro. The value of **QUIESCE** can be overridden by the **TIME** parameter of this command. If activity has not quiesced in that time, the command fails; no offload is done, and logging continues with the current active log data set.

TIME(***nnn*** **)**
Overrides the quiesce time period specified by the **QUIESCE** value of the CSQ6ARVP system parameter macro.

nnn is the time, in seconds, in the range 001 through 999.

To specify the TIME parameter, you must also specify MODE(QUIESCE).

If you specify the TIME parameter, you must specify an appropriate value for the quiesce period. If you make the period too short or too long, one of the following problems might occur:

- The quiesce might not be complete
- IBM MQ lock contention might develop
- A timeout might interrupt the quiesce

WAIT
Specifies whether IBM MQ is to wait until the quiesce process has finished before returning to the issuer of the **ARCHIVE LOG** command.

To specify the **WAIT** parameter, you must also specify **MODE(QUIESCE)**.

NO
Specifies that control is returned to the issuer when the quiesce process starts. (The synonym is N.) This makes the quiesce process asynchronous to the issuer; you can issue further MQSC commands when the **ARCHIVE LOG** command returns control to you. This is the default.

YES
Specifies that control is returned to the issuer when the quiesce process finishes. (The synonym is Y.) This makes the quiesce process synchronous to the issuer; further MQSC commands are not processed until the **ARCHIVE LOG** command finishes.

Related tasks
Archiving logs with the ARCHIVE LOG command

z/OS BACKUP CFSTRUCT (back up a CF application structure) on z/OS

Use the MQSC command BACKUP CFSTRUCT to initiate a CF application structure backup.

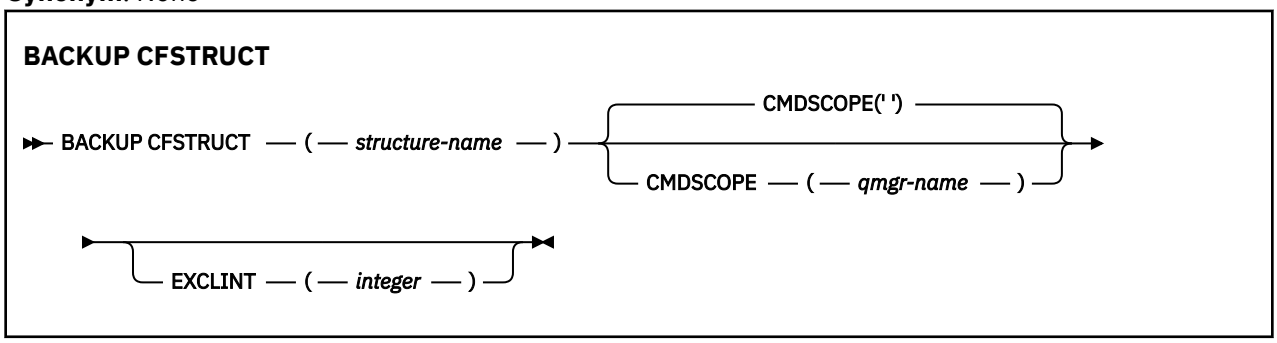
Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Usage notes for BACKUP CFSTRUCT" on page 421
- "Keyword and parameter descriptions for BACKUP CFSTRUCT" on page 421

Synonym: None



Usage notes for BACKUP CFSTRUCT

1. This command is valid only on z/OS when the queue manager is a member of a queue sharing group.
2. Only persistent shared queue messages are backed up. Non-persistent messages are not backed up and cannot be recovered
3. You can concurrently run separate backups for different application structures on different queue managers within the queue sharing group. You can also concurrently run separate backups for different application structures on the same queue manager.
4. This command fails if the specified CF structure is defined with either a CFLEVEL less than 3, or with RECOVER set to NO.
5. The command fails if a specified application structure is currently in the process of being backed up by another queue manager within the queue sharing group.

Keyword and parameter descriptions for BACKUP CFSTRUCT

structure-name
The name of the coupling facility (CF) application structure to be backed up. An asterisk (*) on its own specifies all recoverable CF structures. A trailing asterisk (*) matches all recoverable structure names with the specified stem followed by zero or more characters. The value (CSQ*) matches all recoverable CF structures with the specified stem (CSQ) followed by zero or more characters.

CMDSCOPE
This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and the command server is enabled.

EXCLINT(*integer*)
Specifies a value that defines a number of seconds that are used as an exclusion time. The backup excludes backing-up activity during this exclusion time. The exclusion time starts immediately before the back up starts. For example, if EXCLINT(30) is specified, the backup does not include the last 30 seconds worth of activity for this application-structure before back up started.

The value must be in the range 30 through 600. The default value is 30.

CLEAR QLOCAL (clear messages from local queue)

Use the MQSC command CLEAR QLOCAL to clear the messages from a local queue.

Using MQSC commands

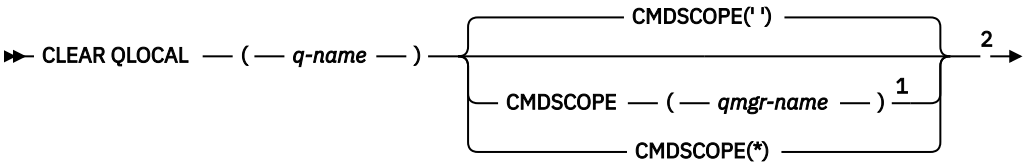
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

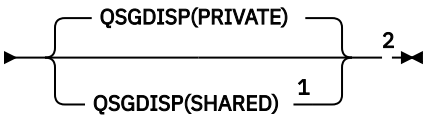
z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Parameter descriptions for CLEAR QLOCAL" on page 422

Synonym: CLEAR QL

CLEAR QLOCAL





Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[2] Valid only on z/OS.

Parameter descriptions for CLEAR QLOCAL

You must specify which local queue you want to clear.

The command fails if any one of the following occurs. The queue:

- Has uncommitted messages that have been put on the queue under syncpoint.
- Is currently open by an application (with any open options).
- Is currently open by a channel.

  For performance reasons, receiver channels cache opened queue handles for queues to which they deliver messages on behalf of remote queue managers. If a channel has cached a handle to this queue, it cannot be cleared.

  To resolve this, stop the channel. Alternatively, empty the queue by getting all the messages from it, instead of using the CLEAR QLOCAL command.

If an application has this queue open, or has a queue open that eventually resolves to this queue, the command fails. The command also fails if this queue is a transmission queue, and any queue that is, or resolves to, a remote queue that references this transmission queue, is open.

(q-name)
The name of the local queue to be cleared. The name must be defined to the local queue manager.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to SHARED.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

z/OS **QSGDISP**
Specifies whether the queue definition is shared. This parameter applies to z/OS only.

PRIVATE
Clear only the private queue named *q-name*. The queue is private if it was defined using a command that had the parameters QSGDISP(COPY) or QSGDISP(QMGR). This is the default value.

SHARED
Clear only the shared queue named *q-name*. The queue is shared if it was defined using a command that had the parameters QSGDISP(SHARED).

Related tasks
Clearing a local queue

CLEAR TOPICSTR (clear topic string)

Use the MQSC command CLEAR TOPICSTR to clear the retained message which is stored for the specified topic string.

Using MQSC commands

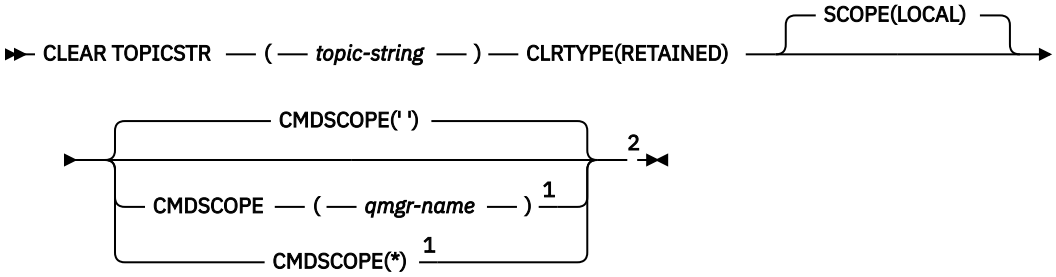
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- Usage notes for CLEAR TOPICSTR
- Parameter descriptions for CLEAR TOPICSTR

Synonym: None.

CLEAR TOPICSTR



Notes:

1 Valid only on z/OS when the queue manager is a member of a queue sharing group.
2 Valid only on z/OS.

Usage notes for CLEAR TOPICSTR

1. If the topic string specified has no retained message the command will complete successfully. You can find out whether a topic string has a retained message by using the DISPLAY TPSTATUS command. The RETAINED field shows whether there is a retained message.
2. The topic-string input parameter on this command must match the topic you want to act on. You are advised to keep the character strings in your topic strings as characters that can be used from location issuing the command. If you issue commands using MQSC, you will have fewer characters available to you than if you are using an application submitting PCF messages, such as the IBM MQ Explorer.
3. You might need to use CLEAR TOPICSTR to remove a retained publication from a publish/subscribe cluster. For example:
   - If you accidentally configure a retained publication, and then need to remove it from all cluster queue managers, you issue this command on all members of the cluster.
   - In a direct routed publish/subscribe cluster, if you move a publishing application to a new queue manager and the previous queue manager holds no subscriptions for the affected topic string, you need to ensure that the previous queue manager does not resend the old retained publication to other members of the cluster. To do this, wait until the application has published on the new queue manager, then issue this command on the previous queue manager to remove the retained publication held there.

   See also Design considerations for retained publications in publish/subscribe clusters

Parameter descriptions for CLEAR TOPICSTR

You must specify which topic string you want to remove the retained publication from.

(topic-string)
The topic string to be cleared. This string can represent several topics to be cleared by using wildcards as shown in the following table:

Table 141. Special characters for use in topic strings

Special Character	Behavior
#	Wildcard, multiple topic level
+	Wildcard, single topic level

Note: the '+' and '#' are not treated as wildcards if they are mixed in with other characters (including themselves) within a topic level. In the following string, the '#' and '+' characters are treated as ordinary characters.

```
level0/level1/#+/level3/level#
```

To illustrate the effect of wildcards, the following example is used.

Clearing the following topic:

```
/a/b/#/z
```

clears the following topics:

```
/a/b/z
/a/b/c/z
/a/b/c/y/z
```

CLRTYPE
This is a mandatory parameter.

The value must be:

RETAINED
Remove the retained publication from the specified topic string.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the name of the local queue manager, if the shared queue object definition has its queue sharing group disposition attribute QSGDISP set to SHARED.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

SCOPE
The scope of the deletion of retained messages.

The value can be:

LOCAL
The retained message is removed from the specified topic string at the local queue manager only. This is the default value.

DEFINE AUTHINFO (define an authentication information object)

Use the MQSC command **DEFINE AUTHINFO** to define an authentication information object. These objects contain the definitions required to perform certificate revocation checking using OCSP or Certificate Revocation Lists (CRLs) on LDAP servers, and the definitions required to enable user ID and password checking.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

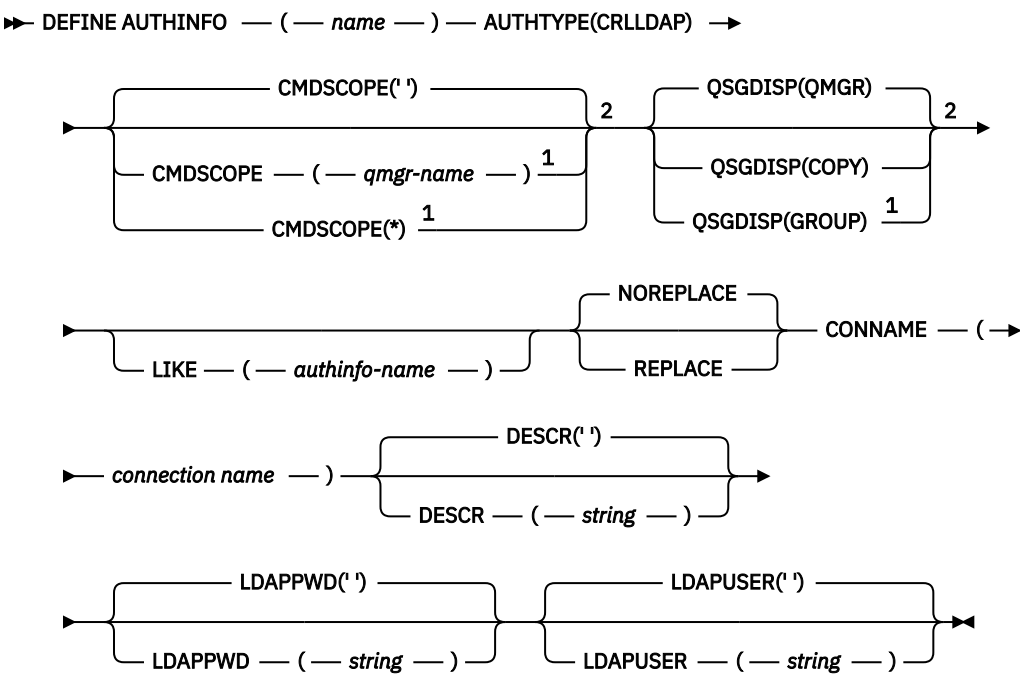
- "Usage notes for DEFINE AUTHINFO" on page 430
- "Parameter descriptions for DEFINE AUTHINFO" on page 430
- Syntax diagram for TYPE(CRLLDAP)
- Syntax diagram for TYPE(OCSP)
- Syntax diagram for TYPE(IDPWOS)
- Syntax diagram for TYPE(IDPWLDAP)

Synonym: DEF AUTHINFO

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See "Syntax diagrams" on page 236.

Syntax diagram for TYPE(CRLLDAP)

DEFINE AUTHINFO

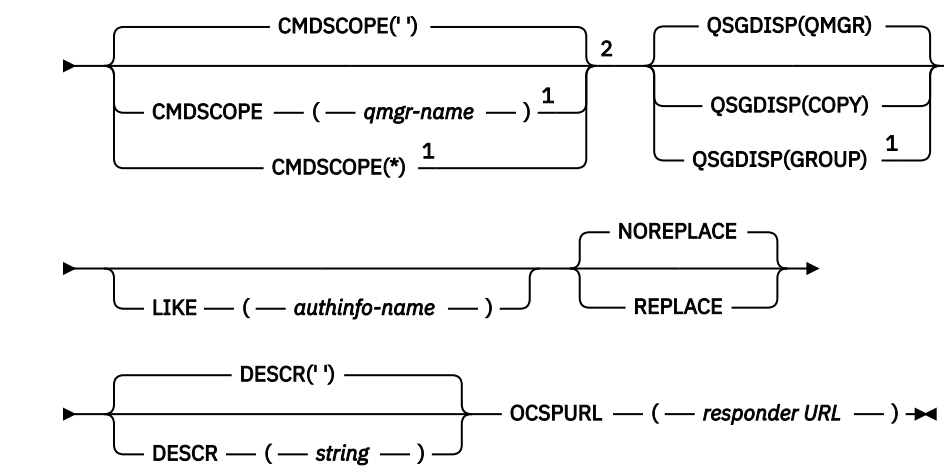


Notes:

[1] Valid only when the queue manager is a member of a queue sharing group. You can use queue sharing groups only on IBM MQ for z/OS.
[2] Valid only on z/OS.

Syntax diagram for TYPE(OCSP)

DEFINE AUTHINFO



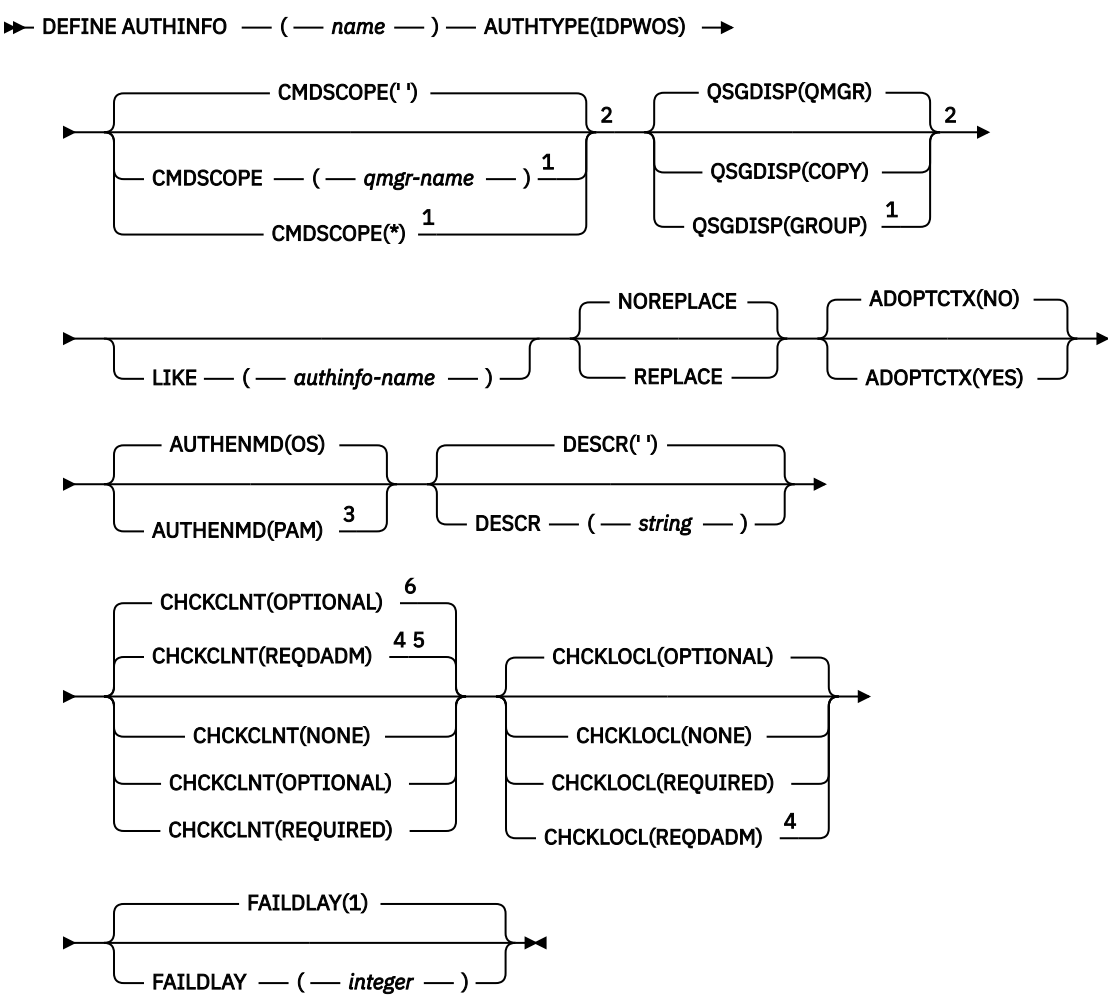
Notes:

[1] Valid only when the queue manager is a member of a queue sharing group. You can use queue sharing groups only on IBM MQ for z/OS.

[2] Valid only on z/OS.

Syntax diagram for TYPE(IDPWOS)

DEFINE AUTHINFO

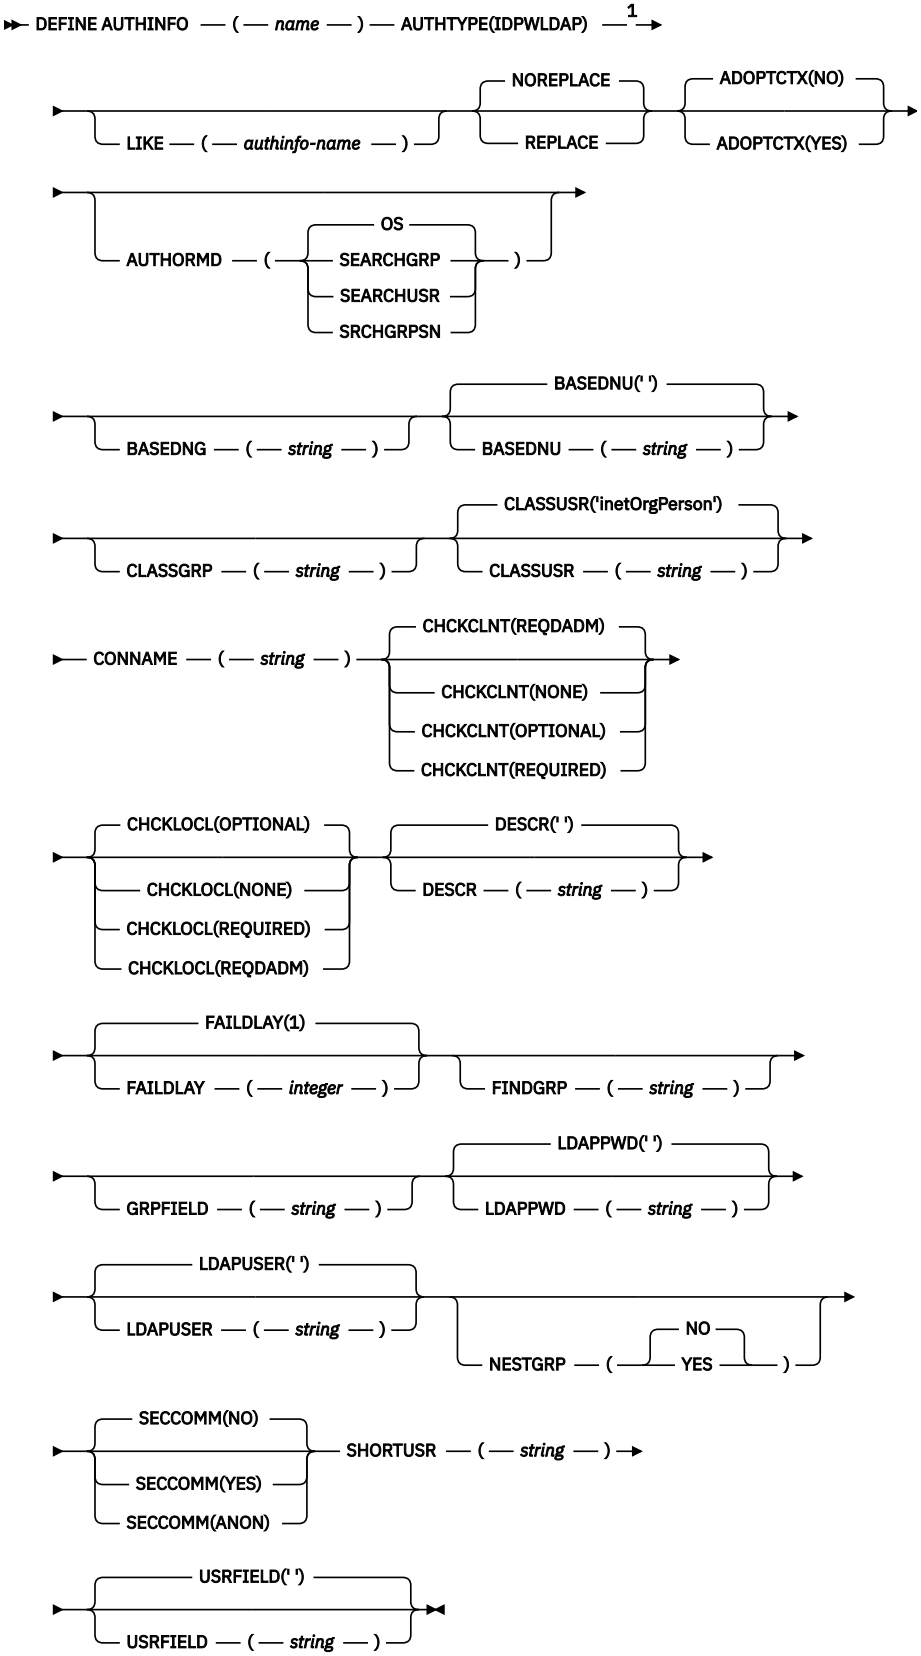


Notes:

[1] Valid only when the queue manager is a member of a queue sharing group. You can use queue sharing groups only on IBM MQ for z/OS.
[2] Valid only on z/OS.
[3] Not valid on z/OS and PAM value can be set only on AIX and Linux.
[4] Not valid on IBM MQ for z/OS.
[5] Default for platforms other than z/OS.
[6] Default for z/OS.

Syntax diagram for TYPE(IDPWLDAP)

DEFINE AUTHINFO



Notes:

[1] Not valid on IBM MQ for z/OS.

Usage notes for DEFINE AUTHINFO

IBM i On IBM i, authentication information objects of AUTHTYPE(CRLLDAP) and AUTHTYPE(OCSP) are only used for channels of type CLNTCONN through use of the AMQCLCHL.TAB. Certificates are defined by Digital Certificate Manager for each certificate authority, and are verified against the LDAP servers.

Attention: After running the DEFINE AUTHINFO command, you must restart the queue manager. If you do not restart the queue manager, the setmqaut command does not return the correct result.

Parameter descriptions for DEFINE AUTHINFO

name
Name of the authentication information object. This parameter is required.

The name must not be the same as any other authentication information object name currently defined on this queue manager (unless **REPLACE** or **ALTER** is specified). See Rules for naming IBM MQ objects.

ADOPTCTX
Whether to use the presented credentials as the context for this application. This means that they are used for authorization checks, shown on administrative displays, and appear in messages.

YES
The user ID presented in the MQCSP structure, which has been successfully validated by password, is adopted as the context to use for this application. Therefore, this user ID will be the credentials checked for authorization to use IBM MQ resources.

If the user ID presented is an LDAP user ID, and authorization checks are done using operating system user IDs, the SHORTUSR associated with the user entry in LDAP will be adopted as the credentials for authorization checks to be done against.

NO
Authentication will be performed on the user ID and password presented in the MQCSP structure, but then the credentials will not be adopted for further use. Authorization will be performed using the user ID the application is running under.

This attribute is only valid for an **AUTHTYPE** of IDPWOS and IDPWLDAP.

AUTHENMD
Authentication method. Whether to use the operating system or Pluggable Authentication Method (PAM) to authenticate user passwords.

Linux AIX **OS**
Use the traditional UNIX password verification method.

Linux AIX **PAM**
Use the PAM to authenticate the user password.

You can set the PAM value only on AIX and Linux.

Changes to this attribute are effective only after you run the REFRESH SECURITY TYPE(CONNAUTH) command.

This attribute is valid only for an **AUTHTYPE** of IDPWOS.

AUTHORMD
Authorization Method.

OS
Use operating system groups to determine permissions associated with a user.

This is how IBM MQ has previously worked, and is the default value.

SEARCHGRP
A group entry in the LDAP repository contains an attribute listing the Distinguished Name of all the users belonging to that group. Membership is indicated by the attribute defined in FINDGRP. This value is typically *member* or *uniqueMember*.

SEARCHUSR
A user entry in the LDAP repository contains an attribute listing the Distinguished Name of all the groups to which the specified user belongs. The attribute to query is defined by the FINDGRP value, typically *memberOf*.

SRCHGRPSN
A group entry in the LDAP repository contains an attribute listing the short user name of all the users belonging to that group. The attribute in the user record that contains the short user name is specified by SHORTUSR.

Membership is indicated by the attribute defined in FINDGRP. This value is typically *memberUid*.

Note: This authorization method should only be used if all user short names are distinct.

Many LDAP servers use an attribute of the group object to determine group membership and you should, therefore, set this value to SEARCHGRP.

Microsoft Active Directory typically stores group memberships as a user attribute. The IBM Tivoli Directory Server supports both methods.

In general, retrieving memberships through a user attribute will be faster than searching for groups that list the user as a member.

AUTHTYPE
The type of authentication information.

CRLLDAP
Certificate Revocation List checking is done using LDAP servers.

IDPWLDAP
Connection authentication user ID and password checking is done using an LDAP server.

Attention: z/OS This option is not available on IBM MQ for z/OS

IDPWOS
Connection authentication user ID and password checking is done using the operating system.

OCSP
Certificate revocation checking is done using OCSP.

An authentication information object with **AUTHTYPE(OCSP)** does not apply for use on queue managers on the following platforms:

- IBM i IBM i
- z/OS z/OS

However, it can be specified on those platforms to be copied to the client channel definition table (CCDT) for client use.

This parameter is required.

You cannot define an authentication information object as LIKE one with a different **AUTHTYPE**. You cannot alter the **AUTHTYPE** of an authentication information object after you have created it.

BASEDNG
Base DN for groups.

In order to be able to find group names, this parameter must be set with the base DN to search for groups in the LDAP server.

BASEDNU(*base DN*)
In order to be able to find the short user name attribute (see SHORTUSR) this parameter must be set with the base DN to search for users within the LDAP server.

This attribute is valid only for an **AUTHTYPE** of IDPWLDAP.

CHCKCLNT
This attribute determines the authentication requirements for client applications, and is valid only for an **AUTHTYPE** of IDPWOS or IDPWLDAP. The possible values are:

NONE
No user ID and password checks are made. If any user ID or password is supplied by a client application, the credentials are ignored.

OPTIONAL
Client applications are not required to provide a user ID and password.

Any applications that do provide a user ID and password in the MQCSP structure have them authenticated by the queue manager against the password store indicated by the **AUTHTYPE**.

The connection is only allowed to continue if the user ID and password are valid.

This option might be useful during migration, for example.

REQUIRED
All client applications must provide a user ID and password in the MQCSP structure. This user ID and password is authenticated by the queue manager against the password store indicated by the **AUTHTYPE**.

The connection will only be allowed to continue if the user ID and password are valid.

REQDADM
All client applications using a privileged user ID must provide a user ID and password in the MQCSP structure. Any locally bound applications using a non-privileged user ID are not required to provide a user ID and password and are treated as with the OPTIONAL setting.

Any provided user ID and password are authenticated by the queue manager against the password store indicated by the **AUTHTYPE**. The connection is only allowed to continue if the user ID and password are valid.

Note: The REQDADM value for the **CHCKCLNT** attribute is irrelevant if the authentication type is LDAP. This is because there is no concept of privileged user ID when using LDAP user accounts. LDAP user accounts and groups must be assigned permission explicitly.

A privileged user is one that has full administrative authorities for IBM MQ. See Privileged users for more information.

z/OS This setting is not allowed on z/OS systems.

Important:

1. This attribute can be overridden by the **CHCKCLNT** attribute of the CHLAUTH rule that matches the client connection. The CONNAUTH *AUTHINFO CHCKCLNT* attribute on the queue manager therefore determines the default client checking behavior for client connections that do not match a CHLAUTH rule, or where the CHLAUTH rule matched has **CHCKCLNT** ASQMGR.
2. If you select NONE and the client connection matches a CHLAUTH record with **CHCKCLNT** REQUIRED (or REQDADM on platforms other than z/OS), the connection fails. You receive the following message:
   - Multi AMQ9793 on Multiplatforms.
   - z/OS CSQX793E on z/OS.
3. This parameter is valid only with **TYPE(USERMAP)**, **TYPE(ADDRESSMAP)** and TYPE (SSLPEERMAP), and only when **USERSRC** is not set to NOACCESS.
4. This parameter applies only to inbound connections that are server-connection channels.

CHCKLOCL
This attribute determines the authentication requirements for locally bound applications, and is valid only for an **AUTHTYPE** of IDPWOS or IDPWLDAP.

MQ Appliance For information about use of this attribute on IBM MQ Appliance, see Control commands on the IBM MQ Appliance in the IBM MQ Appliance documentation.

The possible values are:

NONE
No user ID and password checks are made. If any user ID or password is supplied by a locally bound application, the credentials are ignored.

OPTIONAL
Locally bound applications are not required to provide a user ID and password.

Any applications that do provide a user ID and password in the MQCSP structure have them authenticated by the queue manager against the password store indicated by the **AUTHTYPE**.

The connection is only allowed to continue if the user ID and password are valid.

This option might be useful during migration, for example.

REQUIRED
All locally bound applications must provide a user ID and password in the MQCSP structure. This user ID and password will be authenticated by the queue manager against the password store indicated by the **AUTHTYPE**. The connection will only be allowed to continue if the user ID and password are valid.

z/OS If your user ID has UPDATE access to the BATCH profile in the MQCONN class, you can treat **CHCKLOCL(REQUIRED)** as if it is **CHCKLOCL(OPTIONAL)**. That is, you do not have to supply a password, but if you do, the password must be the correct one.

See Using **CHCKLOCL** on locally bound applications.

REQDADM
All locally bound applications using a privileged user ID must provide a user ID and password in the MQCSP structure. Any locally bound applications using a non-privileged user ID are not required to provide a user ID and password and are treated as with the OPTIONAL setting.

Any provided user ID and password will be authenticated by the queue manager against the password store indicated by the **AUTHTYPE**. The connection will only be allowed to continue if the user ID and password are valid.

A privileged user is one that has full administrative authorities for IBM MQ. See Privileged users for more information.

z/OS (This setting is not allowed on z/OS systems.)

CLASSGRP
The LDAP object class used for group records in the LDAP repository.

If the value is blank, groupOfNames is used.

Other commonly used values include groupOfUniqueNames or group.

CLASSUSR(*LDAP class name*)
The LDAP object class used for user records in the LDAP repository.

If blank, the value defaults to *inetOrgPerson*, which is generally the value needed.

For Microsoft Active Directory, the value you require is often *user*.

This attribute is valid only for an **AUTHTYPE** of *IDPWLDAP*.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

''
The command runs on the queue manager on which it was entered.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of * is the same as entering the command on every queue manager in the queue sharing group.

CONNAME(*connection name*)
The host name, IPv4 dotted decimal address, or IPv6 hexadecimal notation of the host on which the LDAP server is running, with an optional port number.

If you specify the connection name as an IPv6 address, only systems with an IPv6 stack are able to resolve this address. If the AUTHINFO object is part of the CRL namelist of the queue manager, ensure that any clients using the client channel table generated by the queue manager can resolve the connection name.

z/OS On z/OS, if a **CONNAME** is to resolve to an IPv6 network address, a level of z/OS that supports IPv6 for connection to an LDAP server is required.

The syntax for **CONNAME** is the same as for channels. For example,

```
conname(' hostname (nnn)')
```

where *nnn* is the port number.

The maximum length for the field depends on your platform:

- ALW On AIX, Linux, and Windows, the maximum length is 264 characters.
- IBM i On IBM i, the maximum length is 264 characters.
- z/OS On z/OS, the maximum length is 48 characters.

This attribute is valid only for an **AUTHTYPE** of CRLLDAP and IDPWLDAP, when the attribute is mandatory.

When used with an **AUTHTYPE** of IDPWLDAP, this can be a comma separated list of connection names.

DESCR(*string*)
Plain-text comment. It provides descriptive information about the authentication information object when an operator issues the **DISPLAY AUTHINFO** command (see “DISPLAY AUTHINFO (display authentication information)” on page 622).

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

FAILDLAY(*delay time*)
When a user ID and password are provided for connection authentication, and the authentication fails due to the user ID or password being incorrect, this is the delay, in seconds, before the failure is returned to the application.

This can aid in avoiding busy loops from an application that simply retries, continuously, after receiving a failure.

The value must be in the range 0 - 60 seconds. The default value is 1.

This attribute is only valid for an **AUTHTYPE** of IDPWOS and IDPWLDAP.

FINDGRP
Name of the attribute used within an LDAP entry to determine group membership.

When **AUTHORMD** = SEARCHGRP, the **FINDGRP** attribute is typically set to member or uniqueMember.

When **AUTHORMD** = SEARCHUSR, the **FINDGRP** attribute is typically set to memberOf.

When **AUTHORMD** = SRCHGRPSN, the **FINDGRP** attribute is typically set to memberUid.

When the **FINDGRP** attribute is left blank:

- If **AUTHORMD** = SEARCHGRP, the **FINDGRP** attribute defaults to memberOf.
- If **AUTHORMD** = SEARCHUSR, the **FINDGRP** attribute defaults to member.
- If **AUTHORMD** = SRCHGRPSN, the **FINDGRP** attribute defaults to memberUid.

GRPFIELD
LDAP attribute that represents a simple name for the group.

If the value is blank, commands like **setmqaut** must use a qualified name for the group. The value can either be a full DN, or a single attribute.

LDAPPWD(*LDAP password*)
The password associated with the Distinguished Name of the user who is accessing the LDAP server. Its maximum size is 32 characters.

This attribute is valid only for an **AUTHTYPE** of CRLLDAP and IDPWLDAP.

z/OS On z/OS, the **LDAPPWD** used for accessing the LDAP server might not be the one defined in the **AUTHINFO** object. If more than one **AUTHINFO** object is placed in the namelist referred to by the QMGR parameter **SSLCRLNL**, the **LDAPPWD** in the first **AUTHINFO** object is used for accessing all LDAP servers.

LDAPUSER(*LDAP user*)
The Distinguished Name of the user who is accessing the LDAP server. (See the SSLPEER parameter for more information about distinguished names.)

This attribute is valid only for an **AUTHTYPE** of CRLLDAP and IDPWLDAP.

The maximum size for the user name is as follows:

- Multi 1024 characters on Multiplatforms
- z/OS 256 characters on z/OS

z/OS On z/OS, the **LDAPUSER** used for accessing the LDAP Server might not be the one defined in the **AUTHINFO** object. If more than one **AUTHINFO** object is placed in the namelist referred to by the QMGR parameter **SSLCRLNL**, the **LDAPUSER** in the first **AUTHINFO** object is used for accessing all LDAP servers.

Multi On Multiplatforms, the maximum accepted line length is defined to be BUFSIZ, which can be found in stdio.h.

LIKE(*authinfo-name*)
The name of an authentication information object, with parameters that are used to model this definition.

z/OS On z/OS, the queue manager searches for an object with the name you specify and a disposition of QMGR or COPY. The disposition of the LIKE object is not copied to the object you are defining.

Note:

1. **QSGDISP (GROUP)** objects are not searched.

2. LIKE is ignored if **QSGDISP(COPY)** is specified. However, the group object defined is used as a LIKE object.

NESTGRP
Group nesting.

NO
Only the initially discovered groups are considered for authorization.

YES
The group list is searched recursively to enumerate all the groups to which a user belongs.

The group's Distinguished Name is used when searching the group list recursively, regardless of the authorization method selected in AUTHORMD.

OCSPURL(*Responder URL*)
The URL of the OCSP responder used to check for certificate revocation. This value must be an HTTP URL containing the host name and port number of the OCSP responder. If the OCSP responder is using port 80, which is the default for HTTP, then the port number can be omitted. HTTP URLs are defined in RFC 1738.

This field is case sensitive. It must start with the string http:// in lowercase. The rest of the URL might be case sensitive, depending on the OCSP server implementation. To preserve case, use single quotation marks to specify the OCSPURL parameter value, for example:

```
OCSPURL ('http://ocsp.example.ibm.com')
```

This parameter is applicable only for **AUTHTYPE(OCSP)**, when it is mandatory.

z/OS **QSGDISP**
This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

Table 142. Behavior for each of the QSGDISP values

QSGDISP	DEFINE

COPY	The object is defined on the page set of the queue manager that executes the command. It uses the **QSGDISP(GROUP)** object of the same name as the LIKE object.
	For example, if you issue the following command,
	`DEFINE AUTHINFO(auth_name)`
	`REPLACE QSGDISP(COPY)`
	the queue manager searches the shared configuration repository for an AUTHINFO definition called *auth_name*. If a matching AUTHINFO definition is found, the queue manager creates a local copy of this definition on the queue manager page set.
	For local queues, messages are stored on the page sets of each queue manager and are available only through that queue manager.

Table 142. Behavior for each of the QSGDISP values (continued)	
QSGDISP	**DEFINE**
GROUP	The object definition resides in the shared configuration repository. **QSGDISP(GROUP)** is allowed only if the queue manager is in a queue sharing group. If the DEFINE for the **QSGDISP(GROUP)** object is successful, the DEFINE AUTHINFO(*auth_name*) REPLACE QSGDISP(COPY) command is generated and sent to all active queue managers in the queue sharing group to make or refresh local copies on page set zero. The DEFINE for the group object takes effect regardless of whether the generated command with **QSGDISP(COPY)** fails.
PRIVATE	Not permitted.
QMGR	The object is defined on the page set of the queue manager that executes the command.

REPLACE and NOREPLACE
Whether the existing definition (and on z/OS, with the same disposition) is to be replaced with this one. This parameter is optional. Any object with a different disposition is not changed.

REPLACE
The definition must replace any existing definition of the same name. If a definition does not exist, one is created.

NOREPLACE
The definition must not replace any existing definition of the same name.

SECCOMM
Whether connectivity to the LDAP server should be done securely using TLS

YES
Connectivity to the LDAP server is made securely using TLS.

The certificate used is the default certificate for the queue manager, named in **CERTLABL** on the queue manager object, or if that is blank, the one described in Digital certificate labels, understanding the requirements.

The certificate is located in the key repository specified in **SSLKEYR** on the queue manager object. A cipherspec will be negotiated that is supported by both IBM MQ and the LDAP server.

If the queue manager is configured to use **SSLFIPS(YES)** or **SUITEB** cipher specs, then this is taken account of in the connection to the LDAP server as well.

ANON
Connectivity to the LDAP server is made securely using TLS just as for **SECCOMM(YES)** with one difference.

No certificate is sent to the LDAP server; the connection will be made anonymously. To use this setting, ensure that the key repository specified in **SSLKEYR**, on the queue manager object, does not contain a certificate marked as the default.

NO
Connectivity to the LDAP server does not use TLS.

This attribute is valid only for an **AUTHTYPE** of IDPWLDAP.

SHORTUSR(*LDAP field name*)
A field in the user record to be used as a short user name in IBM MQ.

This field must contain values of 12 characters or less. This short user name is used for the following purposes:

- If LDAP authentication is enabled, but LDAP authorization is not enabled, this is used as an operating system user ID for authorization checks. In this case, the attribute must represent an operating system user ID.
- If LDAP authentication and authorization are both enabled, this is used as the user ID carried with the message in order for the LDAP user name to be rediscovered when the user ID inside the message needs to be used.

  For example, on another queue manager, or when writing report messages. In this case, the attribute does not need to represent an operating system user ID, but must be a unique string. An employee serial number is an example of a good attribute for this purpose.

This attribute is valid only for an **AUTHTYPE** of `IDPWLDAP` and is mandatory.

USRFIELD(***LDAP field name*** **)**
If the user ID provided by an application for authentication does not contain a qualifier for the field in the LDAP user record, that is, it does not contain an equals (=) sign, this attribute identifies the field in the LDAP user record that is used to interpret the provided user ID.

This field can be blank. If this is the case, any unqualified user IDs use the **SHORTUSR** parameter to interpret the provided user ID.

The contents of this field will be concatenated with an ' = ' sign, together with the value provided by the application, to form the full user ID to be located in an LDAP user record. For example, the application provides a user of `fred` and this field has the value `cn`, then the LDAP repository will be searched for `cn=fred`.

This attribute is valid only for an **AUTHTYPE** of **IDPWLDAP**.

z/OS DEFINE BUFFPOOL (define a buffer pool) on z/OS

Use the MQSC command DEFINE BUFFPOOL to define a buffer pool that is used for holding messages in main storage.

Using MQSC commands

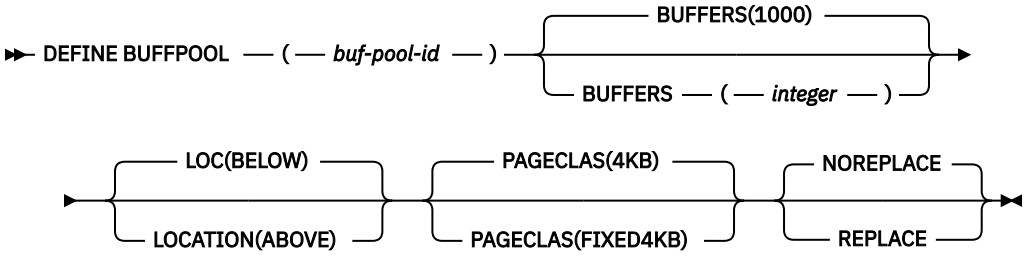
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 1. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- “Usage notes” on page 439
- “Parameter descriptions for DEFINE BUFFPOOL” on page 439

Synonym: DEF BP

DEFINE BUFFPOOL



Usage notes

1. Specify DEFINE BUFFPOOL commands in a data set identified by the CSQINP1 DD concatenation in the queue manager started task procedure.
2. Use the DISPLAY USAGE TYPE(PAGESET) command to display buffer pool information (see “DISPLAY USAGE (display usage information) on z/OS” on page 849).
3. Use the ALTER BUFFPOOL command to dynamically change the settings of a predefined buffer pool (see “ALTER BUFFPOOL (alter buffer pool settings) on z/OS” on page 248).
4. V 9.2.0 Certain buffer pool parameters require **OPMODE** to be set to *NEWFUNC* at IBM MQ for z/OS 9.0.0. If you enable these parameters at IBM MQ for z/OS 9.1.0 or later, and subsequently migrate back to IBM MQ for z/OS 9.0.0, ensure that you are using **OPMODE**=*NEWFUNC* at those releases. Affected parameters are:
   - A **LOCATION** value of *ABOVE*
   - A **PAGECLAS** value of *FIXED4KB*
   - A `buf-pool-id` greater than 15

Parameter descriptions for DEFINE BUFFPOOL

If more than one DEFINE BUFFPOOL command is issued for the same buffer pool, only the last one is processed.

(buf-pool-id)

Buffer pool identifier.

This parameter is an integer in the range zero through 99.

See usage note “4” on page 439.

BUFFERS(*integer*)

This parameter is required and is the number of 4096 byte buffers to be used in this buffer pool.

If the value of the **LOCATION** parameter is BELOW, the minimum value of buffers is 100 and the maximum value is 500,000. If the value of the **LOCATION** parameter is ABOVE, then valid values are in the range of 100 to 999999999 (nine nines). The storage used for buffers in a buffer pool with **LOCATION ABOVE** is obtained in multiples of 4MB. Therefore specifying a **BUFFERS** value which is a multiple of 1024 will make the most efficient use of storage.

LOCATION(LOC)(*BELOW* or *ABOVE*)

LOCATION and **LOC** are synonyms and either, but not both, can be used.

The **LOCATION** or **LOC** parameter specifies where the memory used by the specified buffer pool is located.

Attention: From IBM MQ 9.1, LOCATION(BELOW) is deprecated and you should use LOCATION(ABOVE) only.

This memory location can be either ABOVE (64 bit) or BELOW (31 bit) the bar. Valid values for this parameter are BELOW or ABOVE, with BELOW being the default.

See usage note “4” on page 439.

When altering a buffer pool, you should take care to make sure that there is sufficient storage available if increasing the number of buffers, or changing the **LOCATION** value. Switching the location of the buffer pool can be a CPU and I/O intensive task. You should perform this task when the queue manager is not being heavily used.

For more information, see Address space storage.

PAGECLAS(*4KB* or *FIXED4KB*)

Optional parameter that describes the type of virtual storage pages used for backing the buffers in the buffer pool.

This attribute applies to all buffers in the buffer pool, including any that are added later as a result of using the ALTER BUFFPOOL command. The default value is 4KB, which means that pageable 4KB pages are used to back the buffers in the pool.

4KB is the only valid value if the buffer pool has its location attribute set to BELOW. If the buffer pool has its LOCATION attribute set to ABOVE, it is also possible to specify FIXED4KB. This means that fixed 4KB pages, which are permanently in real storage and will never be paged out to auxiliary storage, are used to back the buffers in the buffer pool.

See usage note "4" on page 439.

The PAGECLAS attribute of a buffer pool can be altered at any time. However, the alteration only takes place when the buffer pool switches location from above the bar, to below the bar, or the other way round. Otherwise, the value is stored in the log of the queue manager and is applied when the queue manager next restarts.

When you specify PAGECLAS(FIXED4KB) the whole buffer pool is backed by page-fixed 4KB pages, so ensure that there is sufficient real storage available on the LPAR. Otherwise, the queue manager might not start, or other address spaces might be impacted; for more information, see Address space storage.

See IBM MQ Support Pac MP16: IBM MQ for z/OS - Capacity planning & tuning for advice on when to use the FIXED4KB value of the PAGECLAS attribute.

REPLACE/NOREPLACE

Optional attribute describing whether this definition of a buffer pool overrides any definition that might already be contained in the log of the queue manager.

The queue manager records the current buffer pool settings in checkpoint log records. These buffer pool settings are automatically restored when a queue manager is later restarted. This restoration occurs after processing of the CSQINP1 data set.

Therefore, if you have used ALTER BUFFPOOL since the buffer pool was last defined, any DEFINE BUFFPOOL command in CSQINP1 will be ignored at restart, unless the REPLACE attribute is specified.

Attention: If you specify the REPLACE attribute on the DEFINE BUFFPOOL command in CSQINP1, then sometime later you specify the ALTER BUFFPOOL command to increase the buffer pool size due to an increase in workload, and hence demand on buffer pool usage for example, this could lead to an issue when the queue manager is next restarted.

Following restart, your buffer pools would revert to the original size defined in CSQINP1 and hence not be able to handle the increased workload. Therefore, you should consider removing the REPLACE attribute from the DEFINE BUFFPOOL commands in CSQINP1 as soon as the buffer pools are successfully defined.

This will ensure that any changes made to the buffer pools, as a result of specifying ALTER BUFFPOOL commands, are preserved across restarts of the queue manager.

REPLACE

This definition of the buffer pool overrides the definition stored in the log of the queue manager, if there is one. If the definition in the log of the queue manager is different from this definition, the differences are discarded and message CSQP064I is issued.

NOREPLACE

This is the default value, and provides the same behavior as with previous releases of IBM MQ. If there is a definition of the buffer pool in the log of the queue manager that is used, and this definition is ignored.

Attention: The queue manager records the current buffer pool settings in checkpoint log records. These buffer pool settings are automatically restored when a queue manager is later restarted. This restoration occurs after processing of the CSQINP1 data set. Therefore, if you have used **ALTER BUFFPOOL** since the buffer pool was last defined, any **DEFINE BUFFPOOL** command in CSQINP1 has been ignored at restart, unless the **REPLACE** attribute has been specified.

z/OS DEFINE CFSTRUCT (define coupling facility application structure) on z/OS

Use the MQSC command DEFINE CFSTRUCT to define queue manager CF level capability, message offload environment, and backup and recovery parameters for a coupling facility application structure.

Using MQSC commands

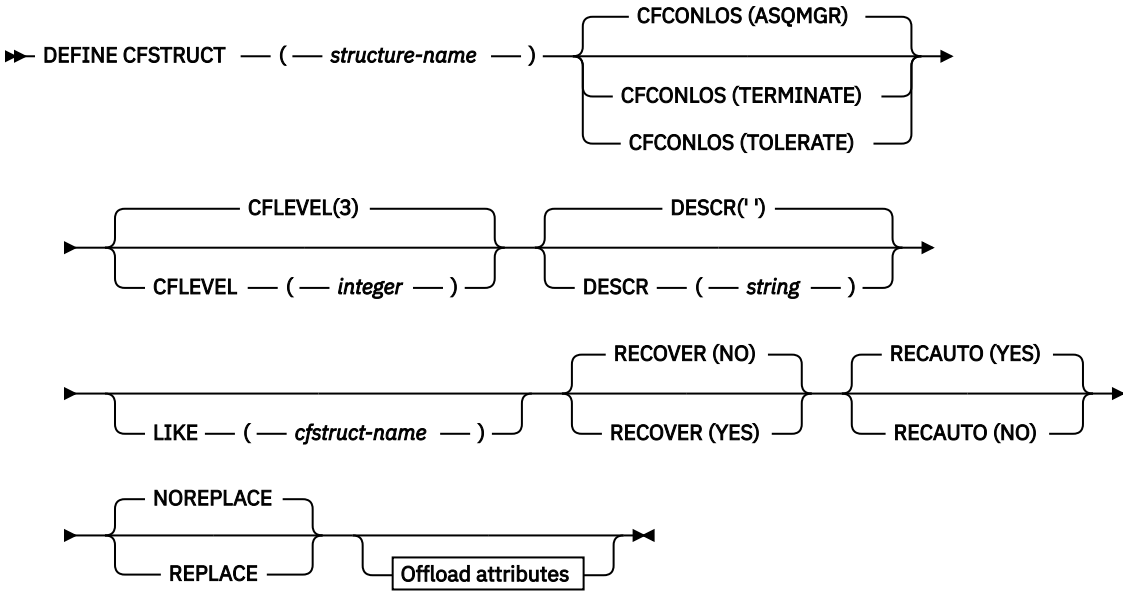
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

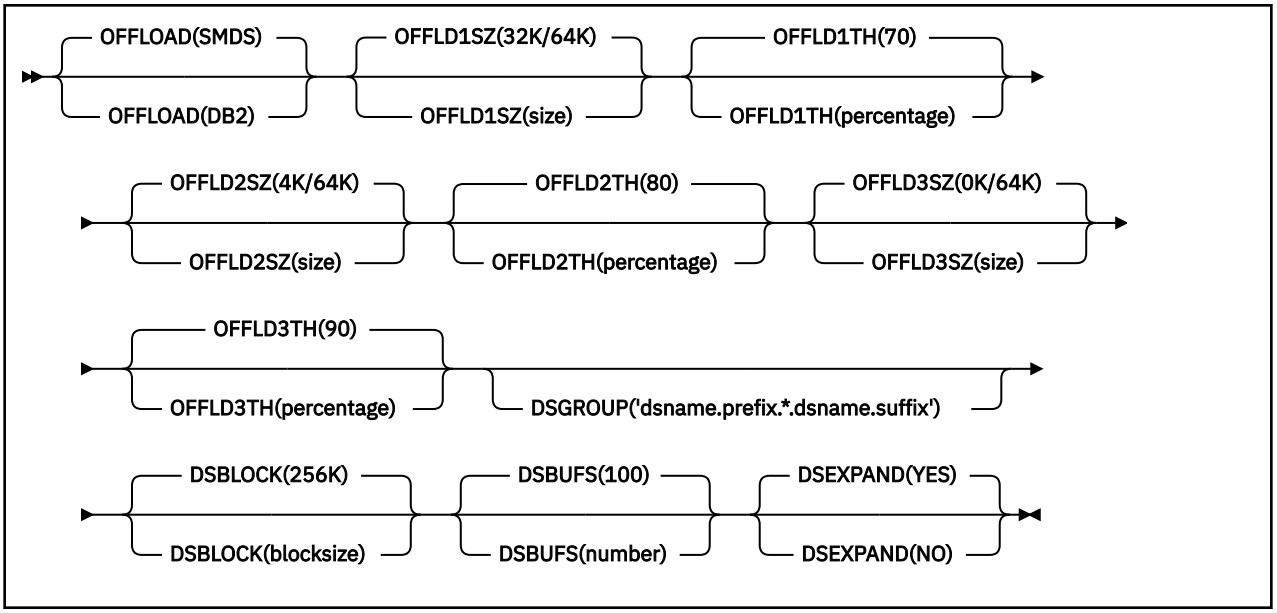
- Syntax diagram
- "Usage notes for DEFINE CFSTRUCT" on page 442
- "Parameter descriptions for DEFINE CFSTRUCT" on page 442

Synonym: DEF CFSTRUCT

DEFINE CFSTRUCT



Offload attributes



Usage notes for DEFINE CFSTRUCT

1. This command is valid only on z/OS when the queue manager is a member of a queue sharing group.
2. This command cannot specify the CF administration structure (CSQ_ADMIN).
3. Before any newly defined CF structure can be used by any queues, the structure must be defined in the Coupling Facility Resource Management (CFRM) policy data set.
4. Only CF structures with RECOVER(YES) defined can be backed up and recovered.

Parameter descriptions for DEFINE CFSTRUCT

(structure-name)
Name of the coupling facility application structure that has queue manager CF level capability and backup and recovery parameters you want to define. This parameter is required.

The name:

- Cannot have more than 12 characters.
- Must start with an uppercase letter (A through Z).
- Can include only the characters A through Z and 0 through 9.

The name of the queue sharing group to which the queue manager is connected is prefixed to the name you supply. The name of the queue sharing group is always four characters, padded with @ symbols if necessary. For example, if you use a queue sharing group named NY03 and you supply the name PRODUCT7, the resultant coupling facility structure name is NY03PRODUCT7. The administrative structure for the queue sharing group (in this case NY03CSQ_ADMIN) cannot be used for storing messages.

CFCONLOS

This parameter specifies the action to be taken when a queue manager loses connectivity to the CF structure. The value can be:

ASQMGR

The action taken is based on the setting of the CFCONLOS queue manager attribute.

TERMINATE

The queue manager ends when connectivity to the structure is lost.

TOLERATE

The queue manager tolerates loss of connectivity to the structure without terminating.

This parameter is only valid from CFLEVEL(5).

CFLEVEL(*integer*)

Specifies the functional capability level for this CF application structure. Value can be one of the following:

1

A CF structure that can be "auto-created" by a queue manager at command level 520.

2

A CF structure at command level 520 that can only be created or deleted by a queue manager at command level 530 or greater.

3

A CF structure at command level 530. This CFLEVEL is required if you want to use persistent messages on shared queues (if RECOVER(YES) is set), or for message grouping (when a local queue is defined with INDXTYPE(GROUPID)), or both.

You can only increase the value of CFLEVEL to 3 if all the queue managers in the queue sharing group are at command level 530 or greater - this is to ensure that there are no latent command level 520 connections to queues referencing the structure.

You can only decrease the value of CFLEVEL from 3 if all the queues that reference the CF structure are both empty (have no messages or uncommitted activity) and closed.

4

This CFLEVEL supports all the CFLEVEL(3) functions. CFLEVEL(4) allows queues defined with CF structures at this level to have messages with a length greater than 63 KB.

Only a queue manager with a command level of 600 or above can connect to a CF structure at CFLEVEL(4).

You can only increase the value of CFLEVEL to 4 if all the queue managers in the queue sharing group are at command level 600 or greater.

You can only decrease the value of CFLEVEL from 4 if all the queues that reference the CF structure are both empty (have no messages or uncommitted activity) and closed.

5

This CFLEVEL supports all functions for CFLEVEL(4). In addition, CFLEVEL(5) enables the following new functions. If altering an existing CFSTRUCT to CFLEVEL(5), you must review other attributes as indicated:

- queues defined with CF structures at this level can have message data offloaded to either shared message data sets (SMDS), or Db2, under control of the OFFLOAD attribute. The offload threshold and size parameters (such as OFFLD1TH, and OFFLD1SZ) determine whether any particular messages are offloaded given its size and current CF structure utilization. If using SMDS offload, the DSGROUP, DSBUFS, DSEXPAND and DSBLOCK attributes are respected.
- structures at CFLEVEL(5) allow the queue manager to tolerate a loss of connectivity to the CF structure. The CFCONLOS attribute determines queue manager behavior when a loss of connectivity is detected, and the RECAUTO attribute controls subsequent automatic structure recovery behavior.
- messages containing IBM MQ message properties are stored in a different format on shared queues in a CFLEVEL(5) structure. This format leads to internal processing optimizations. Additional application migration capabilities are also available and these are enabled via the queue PROPCTL attribute.

Only a queue manager with a command level of 710 or above can connect to a CF structure at CFLEVEL(5).

Note:

You can decrease the value of CFLEVEL from 5 if all the queues that reference the CF structure are both empty, that is the queues, and CF structure have no messages or uncommitted activity, and are closed.

DESCR(*string*)
Plain-text comment that provides descriptive information about the object when an operator issues the DISPLAY CFSTRUCT command.

The string should contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

LIKE(*cfstruct-name*)
The name of a CFSTRUCT object, with attributes used to model this definition.

The initial values of all attributes are copied from the object, except any DSGROUP attribute is ignored because each structure requires its own unique value.

OFFLOAD

Specify whether offloaded message data is to be stored in a group of shared message data sets or in Db2.

SMDS
Offload messages from coupling facility to shared message data set (SMDS). This value is the default assumption when a new structure is defined with CFLEVEL(5).

DB2
Offload messages from coupling facility to Db2. This value is the default assumption when an existing structure is increased to CFLEVEL(5) using DEFINE with the REPLACE option.

Offloading messages using Db2 has significant performance impact. If you want to use the offload rules as a means of increasing capacity, the SMDS option should be specified or assumed.

This parameter is only valid from CFLEVEL(5). At CFLEVEL(4) any message offloading is always to Db2, and only applies to messages greater than the maximum coupling facility entry size.

Note:

If you change the offload technique (from Db2 to SMDS or the other way) then all new messages will be written using the new method but any existing large messages stored using the previous technique can still be retrieved. The relevant Db2 message table or shared message data sets will continue to be used until the queue managers have detected that there are no further messages stored in the old format.

If SMDS is specified or assumed, then the DSGROUP parameter is also required. It can be specified either on the same command or on a previous DEFINE or ALTER command for the same structure.

OFFLD1TH(percentage) OFFLD1SZ(size)
OFFLD2TH(percentage) OFFLD2SZ(size)
OFFLD3TH(percentage) OFFLD3SZ(size)

Specify rules for when messages smaller than the maximum coupling facility entry size are to be offloaded to external storage (shared message data sets or Db2 tables) instead of being stored in the application structure. These rules can be used to increase the effective capacity of the structure. The offloaded message still requires an entry in the coupling facility containing message control information, and a descriptor referring to the offloaded message data, but the amount of structure space required is less than the amount that would be needed to store the whole message.

If the message data is very small (of the order of 100 bytes) it might fit into the same coupling facility entry as the message control information, without needing additional data elements. In this case,

no space can be saved, so any offload rules are ignored and the message data is not offloaded. The actual number varies, depending whether more than the default headers are used, or if message properties are being stored.

Messages exceeding the maximum coupling facility entry size (63.75 KB including control information) are always offloaded as they cannot be stored in a coupling facility entry. Messages where the message body exceeds 63 KB are also offloaded to ensure that enough space is available for the control information. Additional rules to request offloading of smaller messages can be specified using these pairs of keywords. Each rule indicates that when the usage of the structure (in either elements or entries) exceeds the specified threshold percentage value, the message data will be offloaded if the total size of the coupling facility entry required to store the whole message (including message data, headers and descriptors) exceeds the specified size value. The minimal set of headers and descriptors require approximately 400 bytes, however this could be greater if other headers or properties are added. This figure would also be greater if an MQMD version greater than 1 is used.

percentage
The usage threshold percentage value is an integer in the range 0 (meaning this rule always applies) to 100 (meaning this rule only applies when the structure is full). For example, OFFLD1TH(75) OFFLD1SZ(32K) means that when the structure is over 75% full, messages greater than 32 kilobytes in size are offloaded.

size
The message size value should be specified as an integer followed by K, giving the number of kilobytes in the range **0K** to **64K**. As messages exceeding 63.75 KB are always offloaded, the value 64K is allowed as a simple way to indicate that the rule is not being used.

In general, the smaller the numbers, the more messages are offloaded.

A message is offloaded if any offload rule matches. The normal convention is that a later rule would be for a higher usage level and a smaller message size than an earlier one, but no check is made for consistency or redundancy between the rules.

When structure ALTER processing is active, the number of used elements or entries can temporarily exceed the reported total number, giving a percentage exceeding 100, because the new elements or entries are made available during ALTER processing but the total is only updated when the ALTER completes. At such times, a rule specifying 100 for the threshold may temporarily take effect. If a rule is not intended to be used at all, it should specify 64K for the size.

The default values assumed for the offload rules when defining a new structure at CFLEVEL(5) or upgrading an existing structure to CFLEVEL(5) depend on the OFFLOAD method option. For OFFLOAD(SMDS), the default rules specify increasing amounts of offloading as the structure becomes full. This increases the effective structure capacity with minimal performance impact. For OFFLOAD(Db2), the default rules have the same threshold values as for SMDS but the size values are set to 64K so that the rules never apply and messages are offloaded only if they are too large to be stored in the structure, as for CFLEVEL(4).

For OFFLOAD(SMDS) the defaults are:

- OFFLD1TH(70) OFFLD1SZ(32K)
- OFFLD2TH(80) OFFLD2SZ(4K)
- OFFLD3TH(90) OFFLD3SZ(0K)

For OFFLOAD(Db2) the defaults are:

- OFFLD1TH(70) OFFLD1SZ(64K)
- OFFLD2TH(80) OFFLD2SZ(64K)
- OFFLD3TH(90) OFFLD3SZ(64K)

If the OFFLOAD method option is changed from Db2 to SMDS or back when the current offload rules all match the default values for the old method, the offload rules are switched to the default values

for the new method. However, if any of the rules have been changed, the current values are kept when switching method.

These parameters are only valid from CFLEVEL(5). At CFLEVEL(4) any message offloading is always to Db2, and only applies to messages greater than the maximum coupling facility entry size.

DSGROUP

For OFFLOAD(SMDS), specify the generic data set name to be used for the group of shared message data sets associated with this structure (one for each queue manager), with exactly one asterisk indicating where the queue manager name should be inserted to form the specific data set name.

dsname.prefix.*.dsname.suffix
The value must be a valid data set name when the asterisk is replaced by a queue manager name of up to four characters.

The entire parameter value must be enclosed in quotation marks.

This parameter cannot be changed after any data sets have been activated for the structure.

If SMDS is specified or assumed, then the DSGROUP parameter must also be specified.

This parameter is only valid from CFLEVEL(5).

DSBLOCK

For OFFLOAD(SMDS), specify the logical block size, which is the unit in which shared message data set space is allocated to individual queues.

8K
16K
32K
64K
128K
256K
512K
1M
Each message is written starting at the next page within the current block and is allocated further blocks as needed. A larger size decreases space management requirements and reduces I/O for large messages, but increases buffer space requirements and disk space requirements for small queues.

This parameter cannot be changed after any data sets have been activated for the structure.

This parameter is only valid from CFLEVEL(5).

DSBUFS

For OFFLOAD(SMDS), specify the number of buffers to be allocated in each queue manager for accessing shared message data sets, as a number in the range 1 - 9999. The size of each buffer is equal to the logical block size. SMDS buffers are allocated in memory objects residing in z/OS 64-bit storage (above the bar).

number
This parameter can be overridden for individual queue managers using the DSBUFS parameter on ALTER SMDS.

When this parameter is altered, any queue managers which are already connected to the structure (and which do not have an individual DSBUFS override value) dynamically increase or decrease the number of data set buffers being used for this structure to match the new value. If the specified target value cannot be reached, the affected queue manager adjusts the DSBUFS parameter associated with its own individual SMDS definition (as for the ALTER SMDS command) to match the actual new number of buffers.

This parameter is only valid from CFLEVEL(5).

DSEXPAND

For OFFLOAD(SMDS), this parameter controls whether the queue manager should expand a shared message data set when it becomes nearly full, and further blocks are required in the data set.

YES
Expansion is supported.

Each time expansion is required, the data set is expanded by the secondary allocation specified when the data set was defined. If no secondary allocation was specified, or it was specified as zero, then a secondary allocation amount of approximately 10% of the existing size is used

NO
No automatic data set expansion is to take place.

This parameter can be overridden for individual queue managers using the DSEXPAND parameter on ALTER SMDS.

If an expansion attempt fails, the DSEXPAND override for the affected queue manager is automatically changed to NO to prevent further expansion attempts, but it can be changed back to YES using the ALTER SMDS command to enable further expansion attempts.

When this parameter is altered, any queue managers which are already connected to the structure (and which do not have an individual DSEXPAND override value) immediately start using the new parameter value.

This parameter is only valid from CFLEVEL(5).

RECOVER
Specifies whether CF recovery is supported for the application structure. Values are:

NO
CF application structure recovery is not supported. (The synonym is **N**.)

YES
CF application structure recovery is supported. (The synonym is **Y**.)

You can only set RECOVER(YES) if the structure has a CFLEVEL of 3 or higher. Set RECOVER(YES) if you intend to use persistent messages.

You can only change RECOVER(NO) to RECOVER(YES) if all the queue managers in the queue sharing group are at command level 530 or greater; this is to ensure that there are no latent command level 520 connections to queues referencing the CFSTRUCT.

You can only change RECOVER(YES) to RECOVER(NO) if all the queues that reference the CF structure are both empty (have no messages or uncommitted activity) and closed.

RECAUTO
Specifies the automatic recovery action to be taken when a queue manager detects that the structure is failed or when a queue manager loses connectivity to the structure and no systems in the sysplex have connectivity to the coupling facility that the structure is allocated in. Values can be:

YES
The structure and associated shared message data sets which also need recovery will be automatically recovered (The synonym is **Y**.)

NO
The structure will not be automatically recovered. (The synonym is **N**.)

This parameter has no effect for structures defined with RECOVER(NO).

This parameter is only valid from CFLEVEL(5).

REPLACE and NOREPLACE
Defines whether the existing definition is to be replaced with this one. This parameter is optional.

REPLACE
The definition should replace any existing definition of the same name. If a definition does not exist, one is created. If you use the REPLACE option, all queues that use this CF structure must be empty and closed.

NOREPLACE
The definition should not replace any existing definition of the same name.

DEFINE CHANNEL (define a new channel)

Use the MQSC command **DEFINE CHANNEL** to define a new channel, and set its parameters.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

Synonym: DEF CHL

- "Syntax diagrams for DEFINE CHANNEL" on page 448
- "Usage notes for DEFINE CHANNEL" on page 448
- "Parameter descriptions for DEFINE CHANNEL" on page 448

Syntax diagrams for DEFINE CHANNEL

Synonym: DEF CHL

There is a separate syntax diagram for each type of channel:

- Syntax diagram for sender channel
- Syntax diagram for server channel
- Syntax diagram for receiver channel
- Syntax diagram for requester channel
- Syntax diagram for client-connection channel
- Syntax diagram for server-connection channel
- Syntax diagram for cluster-sender channel
- Syntax diagram for cluster-receiver channel
- ALW Syntax diagram for AMQP channel

Usage notes for DEFINE CHANNEL

- For CLUSSDR channels, you can specify the REPLACE option only for manually created channels.
- Successful completion of the command does not mean that the action completed. To check for true completion, see the DEFINE CHANNEL step in Checking that async commands for distributed networks have finished.

Parameter descriptions for DEFINE CHANNEL

The following table shows the parameters that are relevant for each type of channel:

SDR
"Sender channel" on page 488

SVR
"Server channel" on page 490

RCVR
"Receiver channel" on page 492

RQSTR
"Requester channel" on page 494

CLNTCONN
"Client-connection channel" on page 496

SVRCONN
"Server-connection channel" on page 498

CLUSSDR
"Cluster-sender channel" on page 500

CLUSRCVR
"Cluster-receiver channel" on page 502

Multi **AMQP**
"AMQP channel" on page 504

There is a description of each parameter after the table. Parameters are optional unless the description states that they are required.

AFFINITY

Use the channel affinity attribute when client applications connect multiple times using the same queue manager name. With the attribute, you can choose whether the client uses the same client channel definition for each connection. This attribute is intended to be used when multiple applicable channel definitions are available.

PREFERRED

The first connection in a process reading a client channel definition table (CCDT) creates a list of applicable definitions. The list is based on the weightings, with any applicable **CLNTWGHT(0)** definitions first and in alphabetic order. Each connection in the process attempts to connect using the first definition in the list. If a connection is unsuccessful the next definition is used. Unsuccessful non- **CLNTWGHT(0)** definitions are moved to the end of the list. **CLNTWGHT(0)** definitions remain at the start of the list and are selected first for each connection. For C, C++ and .NET (including fully managed .NET) clients the list is updated if the CCDT was modified since the list was created. Each client process with the same host name creates the same list.

NONE

The first connection in a process reading a CCDT creates a list of applicable definitions. All connections in a process select an applicable definition based on the weighting with any applicable **CLNTWGHT(0)** definitions selected first in alphabetic order. For C, C++ and .NET (including fully managed .NET) clients the list is updated if the CCDT was modified since the list was created.

For example, suppose that we had the following definitions in the CCDT:

```
CHLNAME(A) QMNAME (QM1) CLNTWGHT(3)
CHLNAME(B) QMNAME (QM1) CLNTWGHT(4)
CHLNAME(C) QMNAME (QM1) CLNTWGHT(4)
```

The first connection in a process creates its own ordered list based on the weightings. So it might, for example, create the ordered list CHLNAME(B), CHLNAME(A), CHLNAME(C).

For **AFFINITY(PREFFERED)**, each connection in the process attempts to connect using CHLNAME(B). If a connection is unsuccessful the definition is moved to the end of the list which now becomes CHLNAME(A), CHLNAME(C), CHLNAME(B). Each connection in the process then attempts to connect using CHLNAME(A).

For **AFFINITY(NONE)**, each connection in the process attempts to connect using one of the three definitions selected at random based on the weightings.

If sharing conversations is enabled with a non-zero channel weighting and **AFFINITY(NONE)**, multiple connections do not have to share an existing channel instance. They can connect to the same queue manager name using different applicable definitions rather than sharing an existing channel instance.

Multi **AMQPKA(*integer*)**

The keep alive time for an AMQP channel in milliseconds. If the **AMQPKA** property is Auto, it uses a value based on the negotiated heartbeat interval value.

If the AMQP client has not sent any frames within the keep alive interval, then the connection is closed with an amqp:resource-limit-exceeded AMQP error condition.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of AMQP

BATCHHB(*integer*)

Specifies whether batch heartbeats are to be used. The value is the length of the heartbeat in milliseconds.

Batch heartbeats allow a sending channel to verify that the receiving channel is still active just before committing a batch of messages. If the receiving channel is not active, the batch can be backed out rather than becoming in-doubt, as would otherwise be the case. By backing out the batch, the messages remain available for processing so they could, for example, be redirected to another channel.

If the sending channel received a communication from the receiving channel within the batch heartbeat interval, the receiving channel is assumed to be still active. If not, a 'heartbeat' is sent to the receiving channel to check.

The value must be in the range 0 - 999999. A value of zero indicates that batch heart beats are not used.

This parameter is valid for channels with a channel type (**CHLTYPE**) of only SDR, SVR, CLUSSDR, and CLUSRCVR.

BATCHINT(*integer*)

The minimum amount of time, in milliseconds, that a channel keeps a batch open.

The batch is terminated when one of the following conditions is met:

- **BATCHSZ** messages are sent.
- **BATCHLIM** kilobytes are sent.
- The transmission queue is empty and **BATCHINT** is exceeded.

The value must be in the range 0 - 999999999. Zero means that the batch is terminated as soon as the transmission queue becomes empty, or the **BATCHSZ** limit is reached.

This parameter is valid for channels with a channel type (**CHLTYPE**) of only SDR, SVR, CLUSSDR, and CLUSRCVR.

BATCHLIM(*integer*)

The limit, in kilobytes, of the amount of data that can be sent through a channel before taking a sync point. A sync point is taken after the message that caused the limit to be reached flows across the channel. A value of zero in this attribute means that no data limit is applied to batches over this channel.

The batch is terminated when one of the following conditions is met:

- **BATCHSZ** messages are sent.
- **BATCHLIM** kilobytes are sent.
- The transmission queue is empty and **BATCHINT** is exceeded.

This parameter is valid for channels with a channel type (**CHLTYPE**) of only SDR, SVR, CLUSSDR, and CLUSRCVR.

The value must be in the range 0 - 999999. The default value is 5000.

This parameter is supported on all platforms.

BATCHSZ(*integer*)

The maximum number of messages that can be sent through a channel before taking a sync point.

The maximum batch size used is the lowest of the following values:

- The **BATCHSZ** of the sending channel.
- The **BATCHSZ** of the receiving channel.
- z/OS On z/OS, three less than the maximum number of uncommitted messages allowed at the sending queue manager (or one if this value is zero or less).
- Multi On Multiplatforms, the maximum number of uncommitted messages allowed at the sending queue manager (or one if this value is zero or less).
- z/OS On z/OS, three less than the maximum number of uncommitted messages allowed at the receiving queue manager (or one if this value is zero or less).
- Multi On Multiplatforms, the maximum number of uncommitted messages allowed at the receiving queue manager (or one if this value is zero or less).

While non-persistent messages sent over an **NPMSPEED(FAST)** channel are delivered to a queue immediately (without waiting for a complete batch), the messages still contribute to the batch size for a channel and, therefore, cause confirm flows to occur when **BATCHSZ** messages have flowed.

If the batch flows are causing a performance impact when moving only non-persistent messages, and **NPMSPEED** is set to FAST, you should consider setting the **BATCHSZ** to the maximum permissible value of 9999, and **BATCHLIM** to zero.

Additionally, setting **BATCHINT** to a high value, for example, 999999999 keeps each batch "open" for longer, even if there are no new messages waiting on the transmission queue.

The above settings minimize the frequency of confirm flows, but be aware that if any persistent messages are moved over a channel with these settings, there will be significant delays in the delivery of those persistent messages only.

The maximum number of uncommitted messages is specified by the **MAXUMSGS** parameter of the **ALTER QMGR** command.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, RCVR, RQSTR, CLUSSDR, or CLUSRCVR.

The value must be in the range 1 - 9999.

CERTLABL

Certificate label for this channel to use.

The label identifies which personal certificate in the key repository is sent to the remote peer. If this attribute is blank, the certificate is determined by the queue manager **CERTLABL**, or z/OS on z/OS the **CERTQSGL** (if the queue manager is part of a queue sharing group) parameter.

Note that inbound channels (including receiver, requester, cluster-receiver, unqualified server, and server-connection channels) only send the configured certificate if the IBM MQ version of the remote peer fully supports certificate label configuration, and the channel is using a TLS CipherSpec. See Interoperability of Elliptic Curve and RSA CipherSpecs for further information.

An unqualified server channel is one that does not have the CONNAME field set.

In all other cases, the queue manager **CERTLABL** parameter determines the certificate sent. In particular, the following only ever receive the certificate configured by the **CERTLABL** parameter of the queue manager, regardless of the channel-specific label setting:

- All current Java and JMS clients.
- Versions of IBM MQ before IBM MQ 8.0.

You do not need to run the **REFRESH SECURITY TYPE(SSL)** command if you make any changes to **CERTLABL** on a channel. However, you must run a **REFRESH SECURITY TYPE(SSL)** command if you make any changes to **CERTLABL** on the queue manager.

Note: It is an error to inquire, or set, this attribute for cluster-sender channels. If you attempt to do so, you receive the error MQRCCF_WRONG_CHANNEL_TYPE. However, the attribute is present in cluster-sender channel objects (including MQCD structures) and a channel auto-definition (CHAD) exit might set it programmatically if required.

(channel-name)

The name of the new channel definition.

This parameter is required on all types of channel.

Multi On CLUSSDR channels, this parameter can take a different form to the other channel types. If your convention for naming CLUSSDR channels includes the name of the queue manager, you can define a CLUSSDR channel using the +QMNAME+ construction. After connection to the matching CLUSRCVR channel, IBM MQ substitutes the correct repository queue manager name in place of +QMNAME+ in the CLUSSDR channel definition. See Components of a cluster.

The name must not be the same as any existing channel defined on this queue manager, unless REPLACE or ALTER is specified.

z/OS On z/OS, CLNTCONN channel names can duplicate others.

The maximum length of the string is 20 characters, and the string must contain only valid characters; see Rules for naming IBM MQ objects.

V 9.2.0 Multi On CLUSRCVR channels when using automatic cluster setup, this parameter can use some additional inserts:

- +AUTOCL+ resolves to the automatic cluster name
- +QMNAME+ resolves to the local queue manager name.

When using these inserts, both the unexpanded string and the string with the replaced values must fit inside the maximum size of the field. If there are configured automatic cluster full repositories in the AutoCluster configuration, the channel name must also fit in the maximum channel name length when +QMNAME+ is replaced with each of the configured full repository names.

CHLTYPE

Channel type. This parameter is required.

Multi On Multiplatforms, it must follow immediately after the *(channel-name)* parameter.

SDR
Sender channel

SVR
Server channel

RCVR
Receiver channel

RQSTR
Requester channel

CLNTCONN
Client-connection channel

SVRCONN
Server-connection channel

CLUSSDR
CLUSSDR channel.

CLUSRCVR
Cluster-receiver channel.

AMQP
AMQP channel

Note: If you are using the REPLACE option, you cannot change the channel type.

CLNTWGHT
Set the client channel weighting attribute to select a client channel definition at random based on its weighting when more than one suitable definition is available. Specify a value in the range 0 - 99.

The special value 0 indicates that no random load balancing is performed and applicable definitions are selected in alphabetic order. To enable random load balancing the value can be in the range 1 - 99, where 1 is the lowest weighting and 99 is the highest.

If a client application issues MQCONN with a queue manager name of **name* a client channel definition can be selected at random. The chosen definition is randomly selected based on the weighting. Any applicable **CLNTWGHT(0)** definitions selected are selected first in alphabetic order. Randomness in the selection of client connection definitions is not guaranteed.

For example, suppose that we had the following two definitions in the CCDT:

```
CHLNAME(TO.QM1) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address1) CLNTWGHT(2)
CHLNAME(TO.QM2) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address2) CLNTWGHT(4)
```

A client MQCONN with queue manager name *GRP1 would choose one of the two definitions based on the weighting of the channel definition. (A random integer 1 - 6 would be generated. If the integer was in the range 1 through 2, address1 would be used otherwise address2 would be used). If this connection was unsuccessful the client would then use the other definition.

The CCDT might contain applicable definitions with both zero and non-zero weighting. In this situation, the definitions with zero weighting are chosen first and in alphabetic order. If these connections are unsuccessful the definitions with non-zero weighting are chosen based on their weighting.

For example, suppose that we had the following four definitions in the CCDT:

```
CHLNAME(TO.QM1) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address1) CLNTWGHT(1)
CHLNAME(TO.QM2) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address2) CLNTWGHT(2)
CHLNAME(TO.QM3) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address3) CLNTWGHT(0)
CHLNAME(TO.QM4) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address4) CLNTWGHT(0)
```

A client MQCONN with queue manager name *GRP1 would first choose definition TO.QM3. If this connection was unsuccessful the client would then choose definition TO.QM4. If this connection was

also unsuccessful the client would then randomly choose one of the remaining two definitions based on their weighting.

CLNTWGHT is supported for all transport protocols.

CLUSNL(*nlname*)
The name of the namelist that specifies a list of clusters to which the channel belongs. The maximum length is 48 characters conforming to the rules for naming IBM MQ objects.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of CLUSSDR and CLUSRCVR channels. Only one of the resultant values of **CLUSTER** or **CLUSNL** can be nonblank, the other must be blank.

CLUSTER(*clustername*)
The name of the cluster to which the channel belongs. The maximum length is 48 characters conforming to the rules for naming IBM MQ objects.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of CLUSSDR and CLUSRCVR channels. Only one of the resultant values of **CLUSTER** or **CLUSNL** can be nonblank, the other must be blank.

V 9.2.0 Multi On CLUSRCVR channels, when using automatic cluster setup, this parameter can use the value +AUTOCL+, which is automatically expanded to the name of the automatic cluster.

CLWLPRTY(*integer*)
Specifies the priority of the channel for the purposes of cluster workload distribution. The value must be in the range 0 - 9 where 0 is the lowest priority and 9 is the highest.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of CLUSSDR and CLUSRCVR channels.

For more information about this attribute, see **CLWLPRTY** channel attribute.

CLWLRANK(*integer*)
Specifies the rank of the channel for the purposes of cluster workload distribution. The value must be in the range 0 - 9 where 0 is the lowest rank and 9 is the highest.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of CLUSSDR and CLUSRCVR channels.

For more information about this attribute, see CLWLRANK channel attribute.

CLWLWGHT(*integer*)
Specifies the weighting to be applied to a channel so that the proportion of messages sent down the channel can be controlled by workload management. The value must be in the range 1 - 99 where 1 is the lowest rank and 99 is the highest.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of CLUSSDR and CLUSRCVR channels.

For more information about this attribute, see CLWLWGHT channel attribute.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must either be left blank, or if **QSGDISP** is set to GROUP, the local queue manager name.

' '
The command runs on the queue manager on which it was entered.

QmgrName
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name other than the queue manager on which the command was entered. To do so, you must be using a shared queue environment, and the command server must be enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of * is the same as entering the command on every queue manager in the queue sharing group.

COMPHDR
The list of header data compression techniques supported by the channel.

For SDR, SVR, CLUSSDR, CLUSRCVR, and CLNTCONN channels, the values must be specified in order of preference. The first compression technique in the list that is supported by the remote end of the channel is used.

The mutually supported compression techniques of the channel are passed to the message exit of the sending channel. The message exit can alter the compression technique on a per message basis. Compression alters the data passed to send and receive exits.

NONE
No header data compression is performed.

SYSTEM
Header data compression is performed.

COMPMSG
The list of message data compression techniques supported by the channel.

For SDR, SVR, CLUSSDR, CLUSRCVR, and CLNTCONN channels, the values must be specified in order of preference. The first compression technique in the list that is supported by the remote end of the channel is used.

The mutually supported compression techniques of the channel are passed to the message exit of the sending channel. The message exit can alter the compression technique on a per message basis. Compression alters the data passed to send and receive exits.

NONE
No message data compression is performed.

RLE
Message data compression is performed using run-length encoding.

ZLIBFAST
Message data compression is performed using ZLIB encoding with speed prioritized.

z/OS On z/OS systems with zEDC Express facility enabled, compression can be offloaded to zEDC Express.

ZLIBHIGH
Message data compression is performed using ZLIB encoding with compression prioritized.

ANY
Any compression technique supported by the queue manager can be used. This value is only valid for RCVR, RQSTR, and SVRCONN channels.

CONNAME(*string* <, *string* >)
Connection name.

For CLUSRCVR channels, **CONNAME** relates to the local queue manager, and for other channels it relates to the target queue manager.

V 9.2.0 ALW On CLUSRCVR channels, when using automatic cluster setup, this parameter can use any variable configured at queue manager create time surrounded by +; for example +CONNAME+.

V 9.2.0 ALW See the crtmqm **-iv** option for more information.

Note: When using these inserts, both the unexpanded inserts and the expanded values must fit inside the field maximum size.

z/OS On z/OS, **CONNAME** is mandatory for CLUSRCVR channels. In addition, whether you specify **CONNAME**, or the name is generated for you, the **CONNAME** produced must be a valid connection name for the local queue manager, otherwise the full repository is not able to make a connection back to the local queue manager.

z/OS On z/OS, the maximum length of the string is 48 characters.

Multi On Multiplatforms, the maximum length of the string is 264 characters

A workaround to the 48 character limit might be one of the following suggestions:

- Set up your DNS servers so that you use, for example, host name of `myserver` instead of `myserver.location.company.com`, ensuring you can use the short host name.
- Use IP addresses.

Specify **CONNAME** as a comma-separated list of names of machines for the stated **TRPTYPE**. Typically only one machine name is required. You can provide multiple machine names to configure multiple connections with the same properties. The connections are usually tried in the order they are specified in the connection list until a connection is successfully established. The order is modified for clients if the **CLNTWGHT** attribute is provided. If no connection is successful, the channel attempts the connection again, as determined by the attributes of the channel. With client channels, a connection-list provides an alternative to using queue manager groups to configure multiple connections. With message channels, a connection list is used to configure connections to the alternative addresses of a multi-instance queue manager.

CONNAME is required for channels with a channel type (**CHLTYPE**) of SDR, RQSTR, CLNTCONN, and CLUSSDR. It is optional for SVR channels, and for CLUSRCVR channels of **TRPTYPE(TCP)**, and is not valid for RCVR or SVRCONN channels.

Providing multiple connection names in a list was first supported in IBM WebSphere MQ 7.0.1. It changes the syntax of the **CONNAME** parameter. Earlier clients and queue managers connect using the first connection name in the list, and do not read the rest of the connection names in the list. In order for the earlier clients and queue managers to parse the new syntax, you must specify a port number on the first connection name in the list. Specifying a port number avoids problems when connecting to the channel from a client or queue manager that is running at a level earlier than IBM WebSphere MQ 7.0.1.

Multi On Multiplatforms, the TCP/IP connection name parameter of a cluster-receiver channel is optional. If you leave the connection name blank, IBM MQ generates a connection name for you, assuming the default port and using the current IP address of the system. You can override the default port number, but still use the current IP address of the system. For each connection name leave the IP name blank, and provide the port number in parentheses; for example:

```
(1415)
```

The generated **CONNAME** is always in the dotted decimal (IPv4) or hexadecimal (IPv6) form, rather than in the form of an alphanumeric DNS host name.

Tip: If you are using any of the special characters in your connection name (for example, parentheses) you must enclose the string in single quotation marks.

The value you specify depends on the transport type (**TRPTYPE**) to be used:

LU62

- z/OS On z/OS, there are two forms in which to specify the value:

  Logical unit name
  The logical unit information for the queue manager, comprising the logical unit name, TP name, and optional mode name. Logical unit name can be specified in one of three forms:

Table 144. Forms of logical unit name	
Form	**Example**
luname	IGY12355
luname/TPname	IGY12345/APING
luname/TPname/modename	IGY12345/APINGD/#INTER

For the first form, the TP name and mode name must be specified for the **TPNAME** and **MODENAME** parameters; otherwise these parameters must be blank.

Note: For CLNTCONN channels, only the first form is allowed.

Symbolic name
The symbolic destination name for the logical unit information for the queue manager, as defined in the side information data set. The **TPNAME** and **MODENAME** parameters must be blank.

Note: For CLUSRCVR channels, the side information is on the other queue managers in the cluster. Alternatively, it can be a name that a channel auto-definition exit can resolve into the appropriate logical unit information for the local queue manager.

The specified or implied LU name can be that of a VTAM generic resources group.

- Multi On IBM i, AIX, Linux, and Windows, **CONNAME** is the name of the CPI-C communications side object. Alternatively, if the **TPNAME** is not blank, **CONNAME** is the fully qualified name of the partner logical unit. See Configuration parameters for an LU 6.2 connection.

NetBIOS
A unique NetBIOS name (limited to 16 characters).

SPX
The 4-byte network address, the 6-byte node address, and the 2-byte socket number. These values must be entered in hexadecimal, with a period separating the network and node addresses. The socket number must be enclosed in brackets, for example:

```
CONNAME('0a0b0c0d.804abcde23a1(5e86)')
```

TCP
Either the host name, or the network address of the remote machine (or the local machine for CLUSRCVR channels). This address can be followed by an optional port number, enclosed in parentheses.

If the **CONNAME** is a host name, the host name is resolved to an IP address.

The IP stack used for communication depends on the value specified for **CONNAME** and the value specified for **LOCLADDR**. See **LOCLADDR** for information about how this value is resolved.

z/OS On z/OS, the connection name can include the IP_name of an z/OS dynamic DNS group or a Network Dispatcher input port. Do not include the IP_name or input port for channels with a channel type (**CHLTYPE**) of CLUSSDR.

On all platforms, , you do not always need to specify the network address of your queue manager. If you define a channel with a channel type (**CHLTYPE**) of CLUSRCVR that is using TCP/IP, IBM MQ generates a **CONNAME** for you. It assumes the default port and uses the current IPv4 address of the system. If the system does not have an IPv4 address, the current IPv6 address of the system is used.

Note: If you are using clustering between IPv6-only and IPv4-only queue managers, do not specify an IPv6 network address as the **CONNAME** for CLUSRCVR channels. A queue manager that is capable only of IPv4 communication is unable to start a CLUSSDR channel definition

that specifies the **CONNAME** in IPv6 hexadecimal form. Consider, instead, using host names in a heterogeneous IP environment.

CONVERT
Specifies whether the sending message channel agent attempts conversion of the application message data, if the receiving message channel agent cannot perform this conversion.

NO
No conversion by sender

YES
Conversion by sender

z/OS On z/OS, N and Y are accepted as synonyms of NO and YES.

This parameter is valid only for channels with a channel type (CHLTYPE) of SDR, SVR, CLUSSDR, or CLUSRCVR.

DEFCDISP
Specifies the default channel disposition of the channel.

PRIVATE
The intended disposition of the channel is as a private channel.

FIXSHARED
The intended disposition of the channel is as a shared channel associated with a specific queue manager.

SHARED
The intended disposition of the channel is as a shared channel.

This parameter does not apply to channels with a channel type (**CHLTYPE**) of CLNTCONN, CLUSSDR, or CLUSRCVR.

DEFRECON
Specifies whether a client connection automatically reconnects a client application if its connection breaks.

NO (default)
Unless overridden by **MQCONNX**, the client is not reconnected automatically.

YES
Unless overridden by **MQCONNX**, the client reconnects automatically.

QMGR
Unless overridden by **MQCONNX**, the client reconnects automatically, but only to the same queue manager. The QMGR option has the same effect as MQCNO_RECONNECT_Q_MGR.

DISABLED
Reconnection is disabled, even if requested by the client program using the **MQCONNX** MQI call.

Table 145. Automatic reconnection depends on the values set in the application and in the channel definition

DEFRECON	**Reconnection options set in the application**			
	MQCNO_RECONNECT	MQCNO_RECONNECT_Q_MGR	MQCNO_RECONNECT_AS_DEF	MQCNO_RECONNECT_DISABLED
NO (default)	YES	QMGR	NO	NO
YES	YES	QMGR	YES	NO
QMGR	YES	QMGR	QMGR	NO
DISABLED	NO	NO	NO	NO

DESCR(*string*)
Plain-text comment. It provides descriptive information about the channel when an operator issues the **DISPLAY CHANNEL** command.

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If the information is sent to another queue manager they might be translated incorrectly. The characters must be in the coded character set identifier (CCSID) of the local queue manager.

DISCINT(*integer*)
The minimum time in seconds for which the channel waits for a message to arrive on the transmission queue. The waiting period starts after a batch ends. After the end of the waiting period, if there are no more messages, the channel is ended. A value of zero causes the message channel agent to wait indefinitely.

The value must be in the range 0 - 999 999.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SVRCONN, SDR, SVR, CLUSSDR, CLUSRCVR.

For SVRCONN channels using the TCP protocol, **DISCINT** has a different interpretation. It is the minimum time in seconds for which the SVRCONN instance remains active without any communication from its partner client. A value of zero disables this disconnect processing. The SVRCONN inactivity interval applies only between IBM MQ API calls from a client, so no client is disconnected during an extended MQGET with wait call. This attribute is ignored for SVRCONN channels using protocols other than TCP.

HBINT(*integer*)

HBINT specifies the approximate time between heartbeat flows sent by a message channel agent (MCA). The flows are sent when there are no messages on the transmission queue.

Heartbeat flows unblock the receiving MCA, which is waiting for messages to arrive or for the disconnect interval to expire. When the receiving MCA is unblocked, it can disconnect the channel without waiting for the disconnect interval to expire. Heartbeat flows also free any storage buffers that are allocated for large messages. They also close any queues that are left open at the receiving end of the channel.

The value is in seconds and must be in the range 0 - 999999. A value of zero means that no heartbeat flows are to be sent. The default value is 300. To be most useful, the value needs to be less than the disconnect interval value.

For SVRCONN and CLNTCONN channels, heartbeats can flow from both the server side as well as the client side independently. If no data is transferred across the channel during the heartbeat interval, the CLNTCONN MQI agent sends a heartbeat flow. The SVRCONN MQI agent responds to it with another heartbeat flow. The flows happen irrespective of the state of the channel. For example, irrespective of whether it is inactive while making an API call, or is inactive waiting for client user input. The SVRCONN MQI agent is also capable of initiating a heartbeat to the client, again irrespective of the state of the channel. The SVRCONN and CLNTCONN MQI agents are prevented from heart beating to each other at the same time. The server heartbeat is flowed if no data is transferred across the channel for the heartbeat interval plus 5 seconds.

For server-connection and client-connection channels working in the channel mode before IBM WebSphere MQ 7.0, heartbeats flow only when a server MCA is waiting for an MQGET command with the WAIT option specified, which it has issued on behalf of a client application.

For more information, see Heartbeat interval (HBINT).

KAINT(*integer*)
The value passed to the communications stack for keepalive timing for this channel.

For this attribute to be effective, TCP/IP keepalive must be enabled both in the queue manager and in TCP/IP.

z/OS On z/OS, enable TCP/IP keepalive in the queue manager by issuing the **ALTER QMGR TCPKEEP(YES)** command. If the **TCPKEEP** queue manager parameter is NO, the value is ignored, and the keepalive facility is not used.

Multi On Multiplatforms, TCP/IP keepalive is enabled when the **KEEPALIVE=YES** parameter is specified in the TCP stanza. Modify the TCP stanza in the distributed queuing configuration file, `qm.ini`, or through the IBM MQ Explorer.

Keepalive must also be enabled within TCP/IP itself. Refer to your TCP/IP documentation for information about configuring keepalive:

- AIX On AIX, use the **no** command.
- Windows On Windows, edit the registry.
- z/OS On z/OS, update your TCP/IP `PROFILE` data set and add or change the **INTERVAL** parameter in the `TCPCONFIG` section.

z/OS Although the **KAINT** parameter is available on all platforms, its setting is implemented only on z/OS.

Multi On Multiplatforms, you can access and modify the parameter, but there is no functional implementation of the parameter, it is only stored and forwarded. This functionality is useful in a clustered environment where a value set in a cluster-receiver channel definition on AIX, for example, flows to (and is implemented by) z/OS queue managers that are in, or join, the cluster. On Multiplatforms, if you need the functionality provided by the **KAINT** parameter, use the Heartbeat Interval (**HBINT**) parameter, as described in **HBINT**.

(*integer*)
The `KeepAlive` interval to be used, in seconds, in the range 1 through 99999.

0
The value used is that specified by the **INTERVAL** statement in the TCP profile configuration data set.

AUTO
The KeepAlive interval is calculated based upon the negotiated heartbeat value as follows:

- If the negotiated **HBINT** is greater than zero, keepalive interval is set to that value plus 60 seconds.
- If the negotiated **HBINT** is zero, the keepalive value used is that specified by the **INTERVAL** statement in the TCP/IP `PROFILE` configuration data set.

If AUTO is specified for **KAINT**, and it is a server-connection channel, the **TCP INTERVAL** value is used instead for the keepalive interval.

In this case, **KAINT** is zero in **DISPLAY CHSTATUS**; it would be non-zero if an integer had been coded instead of AUTO.

This parameter is valid for all channel types. It is ignored for channels with a **TRPTYPE** other than TCP or SPX.

LIKE(*channel-name*)
The name of a channel. The parameters of this channel are used to model this definition.

If you do not set **LIKE**, and do not set a parameter field related to the command, its value is taken from one of the default channels. The default values depend upon the channel type:

SYSTEM.DEF.SENDER
Sender channel

SYSTEM.DEF.SERVER
Server channel

SYSTEM.DEF.RECEIVER
Receiver channel

SYSTEM.DEF.REQUESTER
Requester channel

SYSTEM.DEF.SVRCONN
Server-connection channel

SYSTEM.DEF.CLNTCONN
Client-connection channel

SYSTEM.DEF.CLUSSDR
CLUSSDR channel

SYSTEM.DEF.CLUSRCVR
Cluster-receiver channel

SYSTEM.DEF.AMQP
AMQP channel

This parameter is equivalent to defining the following object for a SDR channel, and similarly for other channel types:

```
LIKE(SYSTEM.DEF.SENDER)
```

These default channel definitions can be altered by the installation to the default values required.

z/OS On z/OS, the queue manager searches page set zero for an object with the name you specify and a disposition of QMGR or COPY. The disposition of the **LIKE** object is not copied to the object and channel type you are defining.

Note:

1. **QSGDISP(GROUP)** objects are not searched.
2. **LIKE** is ignored if **QSGDISP(COPY)** is specified. However, the group object defined is used as a **LIKE** object.

LOCLADDR(*string*)
LOCLADDR is the local communications address for the channel. For channels other than AMQP channels, use this parameter if you want a channel to use a particular IP address, port, or port range for outbound communications. **LOCLADDR** might be useful in recovery scenarios where a channel is restarted on a different TCP/IP stack. **LOCLADDR** is also useful to force a channel to use an IPv4 or IPv6 stack on a dual-stack system. You can also use **LOCLADDR** to force a channel to use a dual-mode stack on a single-stack system.

Note: AMQP channels do not support the same format of **LOCLADDR** as other IBM MQ channels. For the format supported by AMQ, see the next parameter **AMQP: LOCLADDR**.

For channels other than AMQP channels, the **LOCLADDR** parameter is valid only for channels with a transport type (**TRPTYPE**) of TCP. If **TRPTYPE** is not TCP, the data is ignored and no error message is issued.

The value is the optional IP address, and optional port or port range used for outbound TCP/IP communications. The format for this information is as follows:

```
LOCLADDR([ip-addr][(low-port[,high-port])][,[ip-addr][(low-port[,high-port])]])
```

The maximum length of **LOCLADDR**, including multiple addresses, is MQ_LOCAL_ADDRESS_LENGTH.

If you omit **LOCLADDR**, a local address is automatically allocated.

Note, that you can set **LOCLADDR** for a C client using the Client Channel Definition Table (CCDT).

All the parameters are optional. Omitting the `ip-addr` part of the address is useful to enable the configuration of a fixed port number for an IP firewall. Omitting the port number is useful to select a particular network adapter without having the identify a unique local port number. The TCP/IP stack generates a unique port number.

Specify *[,[ip-addr][(low-port[,high-port])]]* multiple times for each additional local address. Use multiple local addresses if you want to specify a specific subset of local network adapters. You can also use *[,[ip-addr][(low-port[,high-port])]]* to represent a particular local network address on different servers that are part of a multi-instance queue manager configuration.

ip-addr
`ip-addr` is specified in one of three forms:

IPv4 dotted decimal
For example, `192.0.2.1`

IPv6 hexadecimal notation
For example, `2001:DB8:0:0:0:0:0:0`

Alphanumeric host name form
For example `WWW.EXAMPLE.COM`

low-port and high-port
`low-port` and `high-port` are port numbers enclosed in parentheses.

The following table shows how the **LOCLADDR** parameter can be used:

*Table 146. Examples of how the **LOCLADDR** parameter can be used*

LOCLADDR	Meaning
9.20.4.98	Channel binds to this address locally
9.20.4.98, 9.20.4.99	Channel binds to either IP address. The address might be two network adapters on one server, or a different network adapter on two different servers in a multi-instance configuration.
9.20.4.98(1000)	Channel binds to this address and port 1000 locally
9.20.4.98(1000,2000)	Channel binds to this address and uses a port in the range 1000 - 2000 locally
(1000)	Channel binds to port 1000 locally
(1000,2000)	Channel binds to port in range 1000 - 2000 locally

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, RQSTR, CLNTCONN, CLUSSDR, OR CLUSRCVR.

On CLUSSDR channels, the IP address and port to which the outbound channel binds, is a combination of fields. It is a concatenation of the IP address, as defined in the **LOCLADDR** parameter, and the port range from the cluster cache. If there is no port range in the cache, the port range defined in the **LOCLADDR** parameter is used.

z/OS This port range does not apply to z/OS systems.

Even though this parameter is similar in form to **CONNAME**, it must not be confused with it. The **LOCLADDR** parameter specifies the characteristics of the local communications, whereas the **CONNAME** parameter specifies how to reach a remote queue manager.

When a channel is started, the values specified for **CONNAME** and **LOCLADDR** determine the IP stack to be used for communication; see Table 3 and Local Address (**LOCLADDR**).

If the TCP/IP stack for the local address is not installed or configured, the channel does not start and an exception message is generated.

z/OS For example, on z/OS systems, the message is "CSQO015E: Command issued but no reply received." The message indicates that the `connect()` request specifies an interface address that is not known on the default IP stack. To direct the connect() request to the alternative stack, specify the **LOCLADDR** parameter in the channel definition as either an interface on the alternative stack, or a DNS host name. The same specification also works for listeners that might not use the default stack. To find the value to code for **LOCLADDR**, run the **NETSTAT HOME** command on the IP stacks that you want to use as alternatives.

Table 147. How the IP stack to be used for communication is determined

Protocols supported	CONNAME	LOCLADDR	Action of channel
IPv4 only	IPv4 address [1]		Channel binds to IPv4 stack
	IPv6 address [2]		Channel fails to resolve **CONNAME**
	IPv4 and 6 host name [3]		Channel binds to IPv4 stack
	IPv4 address	IPv4 address	Channel binds to IPv4 stack
	IPv6 address	IPv4 address	Channel fails to resolve **CONNAME**
	IPv4 and 6 host name	IPv4 address	Channel binds to IPv4 stack
	Any address [4]	IPv6 address	Channel fails to resolve **LOCLADDR**
	IPv4 address	IPv4 and 6 host name	Channel binds to IPv4 stack
	IPv6 address	IPv4 and 6 host name	Channel fails to resolve **CONNAME**
	IPv4 and 6 host name	IPv4 and 6 host name	Channel binds to IPv4 stack

Table 147. How the IP stack to be used for communication is determined (continued)

Protocols supported	CONNAME	LOCLADDR	Action of channel
IPv4 and IPv6	IPv4 address		Channel binds to IPv4 stack
	IPv6 address		Channel binds to IPv6 stack
	IPv4 and 6 host name		Channel binds to stack determined by **IPADDRV**
	IPv4 address	IPv4 address	Channel binds to IPv4 stack
	IPv6 address	IPv4 address	Channel fails to resolve **CONNAME**
	IPv4 and 6 host name	IPv4 address	Channel binds to IPv4 stack
	IPv4 address	IPv6 address	Channel maps **CONNAME** to IPv6 [5]
	IPv6 address	IPv6 address	Channel binds IPv6 stack
	IPv4 and 6 host name	IPv6 address	Channel binds IPv6 stack
	IPv4 address	IPv4 and 6 host name	Channel binds to IPv4 stack
	IPv6 address	IPv4 and 6 host name	Channel binds to IPv6 stack
	IPv4 and 6 host name	IPv4 and 6 host name	Channel binds to stack determined by **IPADDRV**
IPv6 only	IPv4 address		Channel maps **CONNAME** to IPv6 [5]
	IPv6 address		Channel binds to IPv6 stack
	IPv4 and 6 host name		Channel binds to IPv6 stack
	Any address	IPv4 address	Channel fails to resolve **LOCLADDR**
	IPv4 address	IPv6 address	Channel maps **CONNAME** to IPv6 [5]
	IPv6 address	IPv6 address	Channel binds to IPv6 stack
	IPv4 and 6 host name	IPv6 address	Channel binds to IPv6 stack
	IPv4 address	IPv4 and 6 host name	Channel maps **CONNAME** to IPv6 [5]
	IPv6 address	IPv4 and 6 host name	Channel binds to IPv6 stack
	IPv4 and 6 host name	IPv4 and 6 host name	Channel binds to IPv6 stack

Table 147. How the IP stack to be used for communication is determined (continued)

Protocols supported	CONNAME	LOCLADDR	Action of channel

Notes:

1. IPv4 address. An IPv4 host name that resolves only to an IPv4 network address or a specific dotted notation IPv4 address, for example `1.2.3.4`. This note applies to all occurrences of ' IPv4 address' in this table.
2. IPv6 address. An IPv6 host name that resolves only to an IPv6 network address or a specific hexadecimal notation IPv6 address, for example `4321:54bc`. This note applies to all occurrences of ' IPv6 address' in this table.
3. IPv4 and 6 host name. A host name that resolves to both IPv4 and IPv6 network addresses. This note applies to all occurrences of ' IPv4 and 6 host name' in this table.
4. Any address. IPv4 address, IPv6 address, or IPv4 and 6 host name. This note applies to all occurrences of 'Any address' in this table.
5. Maps IPv4 **CONNAME** to IPv4 mapped IPv6 address. IPv6 stack implementations that do not support IPv4 mapped IPv6 addressing fail to resolve the **CONNAME**. Mapped addresses might require protocol translators in order to be used. The use of mapped addresses is not recommended.

AMQP: LOCLADDR(*ip-addr*)

Note: For the format of **LOCLADDR** that other IBM MQ channels use, see the previous parameter **LOCLADDR**.

For AMQP channels, **LOCLADDR** is the local communications address for the channel. Use this parameter if you want to force the client to use a particular IP address. **LOCLADDR** is also useful to force a channel to use an IPv4 or IPv6 address if a choice is available, or to use a particular network adapter on a system with multiple network adapters.

The maximum length of **LOCLADDR** is `MQ_LOCAL_ADDRESS_LENGTH`.

If you omit **LOCLADDR**, a local address is automatically allocated.

`ip-addr`
`ip-addr` is a single network address, specified in one of three forms:

IPv4 dotted decimal
For example, `192.0.2.1`

IPv6 hexadecimal notation
For example, `2001:DB8:0:0:0:0:0:0`

Alphanumeric host name form
For example, `WWW.EXAMPLE.COM`

If an IP address is entered, only the address format is validated. The IP address itself is not validated.

LONGRTY(*integer*)
The **LONGRTY** parameter specifies the maximum number of further attempts that are made by a SDR, SVR, or `CLUSSDR` channel to connect to a remote queue manager. The interval between attempts is specified by **LONGTMR**. The **LONGRTY** parameter takes effect if the count specified by **SHORTRTY** is exhausted.

If this count is exhausted without success, an error is logged to the operator, and the channel stops. In this circumstance, the channel must be restarted with a command. It is not started automatically by the channel initiator.

The **LONGRTY** value must be in the range `0` - `9999999`.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, `CLUSSDR`, or `CLUSRCVR`.

A channel attempts to reconnect if it fails to connect initially, whether it is started automatically by the channel initiator or by an explicit command. It also tries to connect again if the connection fails after the channel successfully connecting. If the cause of the failure is such that more attempts are unlikely to be successful, they are not attempted.

LONGTMR(*integer*)
For **LONGRTY**, **LONGTMR** is the maximum number of seconds to wait before reattempting connection to the remote queue manager.

The time is approximate; zero means that another connection attempt is made as soon as possible.

The interval between attempting to reconnect might be extended if the channel has to wait to become active.

The **LONGTMR** value must be in the range 0 - 9999999.

Note: For implementation reasons, the maximum **LONGTMR** value is 999,999; values exceeding this maximum are treated as 999,999. Similarly, the minimum interval between attempting to reconnect is 2 seconds. Values less than this minimum are treated as 2 seconds.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, CLUSSDR, or CLUSRCVR.

MAXINST(*integer*)

The maximum number of simultaneous instances of an individual SVRCONN channel or AMQP channel that can be started.

The value must be in the range 0 - 999999999.

A value of zero prevents all client access on this channel.

New instances of SVRCONN channels cannot start if the number of running instances equals or exceeds the value of this parameter. If **MAXINST** is changed to less than the number of instances of the SVRCONN channel that are currently running, the number of running instances is not affected.

If an AMQP client attempts to connect to an AMQP channel, and the number of connected clients has reached **MAXINST**, the channel closes the connection with a close frame. The close frame contains the following message: `amqp:resource-limit-exceeded`. If a client connects with an ID that is already connected (that is, it performs a client-takeover), and the client is permitted to take over the connection, the takeover will succeed regardless of whether the number of connected clients has reached **MAXINST**.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SVRCONN or AMQP.

MAXINSTC(*integer*)
The maximum number of simultaneous individual SVRCONN channels that can be started from a single client. In this context, connections that originate from the same remote network address are regarded as coming from the same client.

The value must be in the range 0 - 999999999.

A value of zero prevents all client access on this channel.

If you reduce the value of **MAXINSTC** to less than the number of instances of the SVRCONN channel that is currently running from an individual client, the running instances are not affected. New SVRCONN instances from that client cannot start until the client is running fewer instances than the value of **MAXINSTC**.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SVRCONN.

MAXMSGL(*integer*)
Specifies the maximum message length that can be transmitted on the channel. This parameter is compared with the value for the partner and the actual maximum used is the lower of the two values. The value is ineffective if the MQCB function is being executed and the channel type (**CHLTYPE**) is SVRCONN.

The value zero means the maximum message length for the queue manager; see ALTER QMGR MAXMSGL.

Multi On Multiplatforms, specify a value in the range zero to the maximum message length for the queue manager.

z/OS On z/OS, specify a value in the range 0 - 104857600 bytes (100 MB).

Note that by adding the digital signature and key to the message, Advanced Message Security increases the length of the message.

MCANAME(*string*)
Message channel agent name.

This parameter is reserved, and if specified must be set to blanks (maximum length 20 characters).

MCATYPE
Specifies whether the message-channel-agent program on an outbound message channel runs as a thread or a process.

PROCESS
The message channel agent runs as a separate process.

THREAD
The message channel agent runs as a separate thread

In situations where a threaded listener is required to service many incoming requests, resources can become strained. In this case, use multiple listener processes and target incoming requests at specific listeners though the port number specified on the listener.

Multi On Multiplatforms, this parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, RQSTR, CLUSSDR, or CLUSRCVR.

z/OS On z/OS, this parameter is supported only for channels with a channel type of CLUSRCVR. When specified in a CLUSRCVR definition, **MCATYPE** is used by a remote machine to determine the corresponding CLUSSDR definition.

MCAUSER(*string*)
Message channel agent user identifier.

Note: An alternative way of providing a user ID for a channel to run under is to use channel authentication records. With channel authentication records, different connections can use the same channel while using different credentials. If both **MCAUSER** on the channel is set and channel authentication records are used to apply to the same channel, the channel authentication records take precedence. The **MCAUSER** on the channel definition is only used if the channel authentication record uses **USERSRC(CHANNEL)**. For more details, see Channel authentication records

This parameter interacts with **PUTAUT**, see **PUTAUT**.

If **MCAUSER** is nonblank, a user identifier is used by the message channel agent for authorization to access IBM MQ resources. If **PUTAUT** is DEF, authorization includes authorization to put the message to the destination queue for RCVR or RQSTR channels.

If it is blank, the message channel agent uses its default user identifier.

The default user identifier is derived from the user ID that started the receiving channel. The possible values are:

z/OS **z/OS**
The user ID assigned to the channel-initiator started task by the z/OS started-procedures table.

TCP/IP, Multiplatforms
The user ID from the `inetd.conf` entry, or the user that started the listener.

SNA, Multiplatforms
The user ID from the SNA server entry. In the absence of the user ID from the SNA server entry, the user from the incoming attach request, or the user that started the listener.

NetBIOS or SPX
The user ID that started the listener.

The maximum length of the string is:

- Windows 64 characters on Windows.

  V 9.2.0 For channels with a **CHLTYPE** of AMQP, before IBM MQ 9.1.1, the MCAUSER user ID setting is only supported for user IDs up to 12 characters in length. From IBM MQ 9.1.1 Continuous Delivery, and from IBM MQ 9.2.0 Long Term Support, the 12 character limit is removed.
- 12 characters on platforms other than Windows.

Windows On Windows, you can optionally qualify a user identifier with the domain name in the format `user@domain`.

This parameter is not valid for channels with a channel type (**CHLTYPE**) of SDR, SVR, CLNTCONN, CLUSSDR.

MODENAME(*string*)
LU 6.2 mode name (maximum length 8 characters).

This parameter is valid only for channels with a transport type (**TRPTYPE**) of LU62. If **TRPTYPE** is not LU62, the data is ignored and no error message is issued.

If specified, this parameter must be set to the SNA mode name unless the **CONNAME** contains a side-object name. If **CONNAME** is a a side-object name it must be set to blanks. The actual name is then taken from the CPI-C Communications Side Object, or APPC side information data set, see Configuration parameters for an LU 6.2 connection.

This parameter is not valid for channels with a channel type (**CHLTYPE**) of RCVR or SVRCONN.

MONCHL
Controls the collection of online monitoring data for channels:

QMGR
Collect monitoring data according to the setting of the queue manager parameter **MONCHL**.

OFF
Monitoring data collection is turned off for this channel.

LOW
If the value of the queue manager **MONCHL** parameter is not NONE, online monitoring data is turned on. Data us collected at a low rate for this channel.

MEDIUM
If the value of the queue manager **MONCHL** parameter is not NONE, online monitoring data is turned on. Data us collected at a medium rate for this channel.

HIGH
If the value of the queue manager **MONCHL** parameter is not NONE, online monitoring data is turned on. Data us collected at a high rate for this channel.

Changes to this parameter take effect only on channels started after the change occurs.

For cluster channels, the value of this parameter is not replicated in the repository and, therefore, not used in the auto-definition of CLUSSDR channels. For auto-defined CLUSSDR channels, the value of this parameter is taken from the queue manager attribute **MONACLS**. This value might then be overridden in the channel auto-definition exit.

MRDATA(*string*)
Channel message-retry exit user data. The maximum length is 32 characters.

This parameter is passed to the channel message-retry exit when it is called.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of RCVR, RQSTR, or CLUSRCVR.

MREXIT(*string*)
Channel message-retry exit name.

The format and maximum length of the name is the same as for **MSGEXIT**, however you can specify only one message-retry exit.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of RCVR, RQSTR, or CLUSRCVR.

MRRTY(*integer*)
The number of times the channel tries again before it decides it cannot deliver the message.

This parameter controls the action of the MCA only if the message-retry exit name is blank. If the exit name is not blank, the value of **MRRTY** is passed to the exit to use. The number of attempts to redeliver the message is controlled by the exit, and not by this parameter.

The value must be in the range 0 - 999999999. A value of zero means that no attempts to redeliver the message are tried.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of RCVR, RQSTR, or CLUSRCVR.

MRTMR(*integer*)
The minimum interval of time that must pass before the channel can try the MQPUT operation again. The time interval is in milliseconds.

This parameter controls the action of the MCA only if the message-retry exit name is blank. If the exit name is not blank, the value of **MRTMR** is passed to the exit to use. The number of attempts to redeliver the message is controlled by the exit, and not by this parameter.

The value must be in the range 0 - 999999999. A value of zero means that if the value of **MRRTY** is greater than zero, the channel reattempts delivery as soon as possible.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of RCVR, RQSTR, or CLUSRCVR.

MSGDATA(*string*)
User data for the channel message exit. The maximum length is 32 characters.

This data is passed to the channel message exit when it is called.

ALW On AIX, Linux, and Windows, you can specify data for more than one exit program by specifying multiple strings separated by commas. The total length of the field must not exceed 999 characters.

IBM i On IBM i, you can specify up to 10 strings, each of length 32 characters. The first string of data is passed to the first message exit specified, the second string to the second exit, and so on.

z/OS On z/OS, you can specify up to eight strings, each of length 32 characters. The first string of data is passed to the first message exit specified, the second string to the second exit, and so on.

On other platforms, you can specify only one string of message exit data for each channel.

Note: This parameter is accepted but ignored for SVRCONN and CLNTCONN channels.

MSGEXIT(*string*)
Channel message exit name.

If **MSGEXIT** is nonblank the exit is called at the following times:

- Immediately after a SDR or SVR channel retrieves a message from the transmission queue.
- Immediately before a RQSTR channel puts a message on destination queue.
- When the channel is initialized or ended.

The exit is passed the entire application message and transmission queue header for modification.

MSGEXIT is accepted and ignored by CLNTCONN and SVRCONN channels. CLNTCONN or SVRCONN channels do not call message exits.

The format and maximum length of the exit name depends on the platform; see Table 148 on page 473.

If the **MSGEXIT**, **MREXIT**, **SCYEXIT**, **SENDEXIT**, and **RCVEXIT** parameters are all left blank, the channel user exit is not invoked. If any of these parameters is nonblank, the channel exit program is called. You can enter text string for these parameters. The maximum length of the string is 128 characters.

Table 148. Message exit format and length

Platform	Exit name format	Maximum length	Comment
AIX and Linux	*libraryname* (*functionname*)	128	You can specify the name of more than one exit program. Specify multiple strings separated by commas. However, the total number of characters specified must not exceed 999.
Windows	*dllname* (*functionname*)	128	1. You can specify the name of more than one exit program. Specify multiple strings separated by commas. However, the total number of characters specified must not exceed 999. 2. *dllname* is specified without the suffix (.DLL).
IBM i	*progname libname*	20	1. You can specify the names of up to 10 exit programs by specifying multiple strings separated by commas. 2. *program name* occupies the first 10 characters and *libname* the second 10 characters. If necessary, both fields are padded to the right with blanks.
z/OS	*loadModuleName*	8	1. You can specify the names of up to eight exit programs by specifying multiple strings separated by commas. 2. 128 characters are allowed for exit names for CLNTCONN channels, subject to a maximum total length including commas of 999.

NETPRTY(*integer*)
The priority for the network connection. Distributed queuing chooses the path with the highest priority if there are multiple paths available. The value must be in the range 0 - 9; 0 is the lowest priority.

This parameter is valid only for CLUSRCVR channels.

NPMSPEED
The class of service for nonpersistent messages on this channel:

FAST
Fast delivery for nonpersistent messages; messages might be lost if the channel is lost. Messages are retrieved using MQGMO_SYNCPOINT_IF_PERSISTENT and so are not included in the batch unit of work.

NORMAL
Normal delivery for nonpersistent messages.

If the value of **NPMSPEED** differs between the sender and receiver, or either one does not support it, NORMAL is used.

Notes:

1. If the active recovery logs for IBM MQ for z/OS are switching and archiving more frequently than expected, given that the messages being sent across a channel are non-persistent, setting NPMSPEED(FAST) on both the sending and receiving ends of the channel can minimize the SYSTEM.CHANNEL.SYNCQ updates.
2. If you are seeing high CPU usage relating to updates to the SYSTEM.CHANNEL.SYNCQ, setting NPMSPEED(FAST) can significantly reduce the CPU usage.

This parameter is valid only for channels with a **CHLTYPE** of SDR, SVR, RCVR, RQSTR, CLUSSDR, or CLUSRCVR.

PASSWORD(*string*)
Password used by the message channel agent when attempting to initiate a secure LU 6.2 session with a remote message channel agent. The maximum length is 12 characters.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, RQSTR, CLNTCONN, or CLUSSDR.

z/OS On z/OS, it is supported only for channels with a channel type (**CHLTYPE**) of CLNTCONN.

Although the maximum length of the parameter is 12 characters, only the first 10 characters are used.

PORT(*integer*)
The port number used to connect an AMQP channel. The default port for AMQP 1.0 connections is 5672. If you are already using port 5672, you can specify a different port.

PROPCTL
Property control attribute; see **PROPCTL** channel options.

PROPCTL specifies what happens to message properties when a message is sent to another queue manager; see

This parameter is applicable to SDR, SVR, CLUSSDR, and CLUSRCVR channels.

This parameter is optional.

Permitted values are:

COMPAT
COMPAT allows applications which expect JMS-related properties to be in an MQRFH2 header in the message data to continue to work unmodified.

Table 149. Range of results, depending on which mesage properties are set, when PROPCTL value is COMPAT

Message properties	Result
The message contains a property with a prefix of mcd., jms., usr. or mqext.	If the **Support** value is MQPD_SUPPORT_OPTIONAL, all optional message properties are placed in one or more MQRFH2 headers. This rule does not apply to properties in the message descriptor or extension, which remain in the same place. Optional message properties are moved into the message data before the message it sent to the remote queue manager.
The message does not contain a property with a prefix of mcd., jms., usr. or mqext.	All message properties, except properties in the message descriptor or extension, are removed from the message before the message is sent to the remote queue manager.

Table 149. Range of results, depending on which mesage properties are set, when PROPCTL value is COMPAT (continued)

Message properties	Result
The message contains a property where the **Support** field of the property descriptor is not set to MQPD_SUPPORT_OPTIONAL	The message is rejected with reason MQRC_UNSUPPORTED_PROPERTY and treated in accordance with its report options.
The message contains one or more properties where the **Support** field of the property descriptor is set to MQPD_SUPPORT_OPTIONAL. Other fields of the property descriptor are set to non-default values.	The properties with non-default values are removed from the message before the message is sent to the remote queue manager.
The MQRFH2 folder that would contain the message property needs to be assigned with the content='properties' attribute	The properties are removed to prevent MQRFH2 headers with unsupported syntax flowing to an IBM WebSphere MQ 6 or prior queue manager.

NONE
All properties of the message, except properties in the message descriptor or extension, are removed from the message. The properties are removed before the message is sent to the remote queue manager.

If the message contains a property where the **Support** field of the property descriptor is not set to MQPD_SUPPORT_OPTIONAL then the message is rejected with reason MQRC_UNSUPPORTED_PROPERTY. The error is reported in accordance with the report options set in the message header.

ALL
All properties of the message are included with the message when it is sent to the remote queue manager. The properties, except properties in the message descriptor (or extension), are placed in one or more MQRFH2 headers in the message data.

PUTAUT
PUTAUT specifies which user identifiers are used to establish authority for a channel. It specifies the user identifier to put messages to the destination queue using a message channel, or to run an MQI call using an MQI channel.

DEF
The default user ID is used.

z/OS On z/OS, DEF might involve using both the user ID received from the network and that derived from **MCAUSER**.

CTX
The user ID from the *UserIdentifier* field of the message descriptor is used.

z/OS On z/OS, CTX might involve also using the user ID received from the network or that derived from **MCAUSER**, or both.

z/OS **ONLYMCA**
The user ID derived from MCAUSER is used. Any user ID received from the network is not used. This value is supported only on z/OS.

z/OS **ALTMCA**
The user ID from the *UserIdentifier* field of the message descriptor is used. Any user ID received from the network is not used. This value is supported only on z/OS.

z/OS On z/OS, the user IDs that are checked, and how many user IDs are checked, depends on the setting of the MQADMIN RACF class hlq.RESLEVEL profile. Depending on the level of access the user ID of the channel initiator has to hlq.RESLEVEL, zero, one, or two user IDs are checked. To

see how many user IDs are checked, see RESLEVEL and the channel initiator connection. For more information about which user IDs are checked, see User IDs used by the channel initiator.

z/OS On z/OS, this parameter is valid only for channels with a channel type (**CHLTYPE**) of RCVR, RQSTR, CLUSRCVR, or SVRCONN. CTX and ALTMCA are not valid for SVRCONN channels.

Multi On Multiplatforms, this parameter is valid only for channels with a channel type (**CHLTYPE**) of RCVR, RQSTR, or CLUSRCVR.

QMNAME(*string*)
Queue manager name.

For CLNTCONN channels, **QMNAME** is the name of a queue manager to which an IBM MQ MQI client application can request connection. **QMNAME** is not necessarily the same as the name of the queue manager on which the channel is defined; see Queue manager groups in the CCDT.

For channels of other types, the **QMNAME** parameter is not valid.

z/OS **QSGDISP**
This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

*Table 150. Object dispositions for **QSGDISP** options*

QSGDISP	**DEFINE**

COPY	The object is defined on the page set of the queue manager that executes the command. It uses the **QSGDISP(GROUP)** object of the same name as the LIKE object.
	For example, if you issue the following command,
	`DEFINE CHANNEL(channel_name) CHLTYPE(channel_type)`
	`REPLACE QSGDISP(COPY)`
	the queue manager searches the shared configuration repository for a CHANNEL definition for *channel_name* and *channel_type*. If a matching CHANNEL definition is found, the queue manager creates a local copy of this definition on the queue manager page set.
	For local queues, messages are stored on the page sets of each queue manager and are available only through that queue manager.

GROUP	The object definition resides in the shared configuration repository. **QSGDISP(GROUP)** is allowed only if the queue manager is in a queue sharing group. If the DEFINE for the **QSGDISP(GROUP)** object is successful, the DEFINE CHANNEL(*channel_name*) CHLTYPE(*channel_type*) REPLACE QSGDISP(COPY) command is generated and sent to all active queue managers in the queue sharing group to make or refresh local copies on page set zero. The DEFINE for the group object takes effect regardless of whether the generated command with **QSGDISP(COPY)** fails.
PRIVATE	Not permitted.
QMGR	The object is defined on the page set of the queue manager that executes the command.

RCVDATA(*string*)
Channel receive exit user data (maximum length 32 characters).

This parameter is passed to the channel receive exit when it is called.

ALW On AIX, Linux, and Windows, you can specify data for more than one exit program by specifying multiple strings separated by commas. The total length of the field must not exceed 999 characters.

IBM i On IBM i, you can specify up to 10 strings, each of length 32 characters. The first string of data is passed to the first receive exit specified, the second string to the second exit, and so on.

z/OS On z/OS, you can specify up to eight strings, each of length 32 characters. The first string of data is passed to the first receive exit specified, the second string to the second exit, and so on.

On other platforms, you can specify only one string of receive exit data for each channel.

RCVEXIT(*string*)
Channel receive exit name.

If this name is nonblank, the exit is called at the following times:

- Immediately before the received network data is processed.

  The exit is given the complete transmission buffer as received. The contents of the buffer can be modified as required.
- At initialization and termination of the channel.

ALW On AIX, Linux, and Windows, you can specify the name of more than one exit program by specifying multiple strings separated by commas. However, the total number of characters specified must not exceed 999.

IBM i On IBM i, you can specify the names of up to 10 exit programs by specifying multiple strings separated by commas.

z/OS On z/OS, you can specify the names of up to eight exit programs by specifying multiple strings separated by commas.

On other platforms, you can specify only one receive exit name for each channel.

The format and maximum length of the name is the same as for **MSGEXIT**.

REPLACE and NOREPLACE
Replace the existing definition with this one, or not. This parameter is optional.

z/OS On z/OS it must have the same disposition. Any object with a different disposition is not changed.

REPLACE
The definition replaces any existing definition of the same name. If a definition does not exist, one is created. **REPLACE** does not alter the channel status.

NOREPLACE
The definition does not replace any existing definition of the same name.

SCYDATA(*string*)
Channel security exit user data (maximum length 32 characters).

This parameter is passed to the channel security exit when it is called.

SCYEXIT(*string*)
Channel security exit name.

If this name is nonblank, the exit is called at the following times:

- Immediately after establishing a channel.

Before any messages are transferred, the exit is able to instigate security flows to validate connection authorization.

- Upon receipt of a response to a security message flow.

  Any security message flows received from the remote processor on the remote queue manager are given to the exit.

- At initialization and termination of the channel.

The format and maximum length of the name is the same as for **MSGEXIT** but only one name is allowed.

SENDDATA(*string*)
Channel send exit user data. The maximum length is 32 characters.

This parameter is passed to the channel send exit when it is called.

ALW On AIX, Linux, and Windows, you can specify data for more than one exit program by specifying multiple strings separated by commas. The total length of the field must not exceed 999 characters.

IBM i On IBM i, you can specify up to 10 strings, each of length 32 characters. The first string of data is passed to the first send exit specified, the second string to the second exit, and so on.

z/OS On z/OS, you can specify up to eight strings, each of length 32 characters. The first string of data is passed to the first send exit specified, the second string to the second exit, and so on.

On other platforms, you can specify only one string of send exit data for each channel.

SENDEXIT(*string*)
Channel send exit name.

If this name is nonblank, the exit is called at the following times:

- Immediately before data is sent out on the network.

  The exit is given the complete transmission buffer before it is transmitted. The contents of the buffer can be modified as required.

- At initialization and termination of the channel.

ALW On AIX, Linux, and Windows, you can specify the name of more than one exit program by specifying multiple strings separated by commas. However, the total number of characters specified must not exceed 999.

IBM i On IBM i, you can specify the names of up to 10 exit programs by specifying multiple strings separated by commas.

z/OS On z/OS, you can specify the names of up to eight exit programs by specifying multiple strings separated by commas.

On other platforms, you can specify only one send exit name for each channel.

The format and maximum length of the name is the same as for **MSGEXIT**.

SEQWRAP(*integer*)
When this value is reached, sequence numbers wrap to start again at 1.

This value is nonnegotiable and must match in both the local and remote channel definitions.

The value must be in the range 100 - 999999999.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, RCVR, RQSTR, CLUSSDR, or CLUSRCVR.

SHARECNV(*integer*)
Specifies the maximum number of conversations that can be sharing each TCP/IP channel instance. A **SHARECNV** value of:

1
Specifies no sharing of conversations over a TCP/IP channel instance. Client heart beating is available whether in an MQGET call or not. Read ahead and client asynchronous consumption are also available, and channel quiescing is more controllable.

0
Specifies no sharing of conversations over a TCP/IP channel instance.

The value must be in the range zero through 999999999.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of CLNTCONN or SVRCONN. If the CLNTCONN **SHARECNV** value does not match the SVRCONN **SHARECNV** value, the lower of the two values is used. This parameter is ignored for channels with a transport type (**TRPTYPE**) other than TCP.

All the conversations on a socket are received by the same thread.

High **SHARECNV** limits have the advantage of reducing queue manager thread usage. If many conversations sharing a socket are all busy, there is a possibility of delays. The conversations contend with one another to use the receiving thread. In this situation, a lower **SHARECNV** value is better.

The number of shared conversations does not contribute to the **MAXINST** or **MAXINSTC** totals.

Note: You should restart the client for this change to take effect.

SHORTRTY(*integer*)
SHORTRTY specifies the maximum number of attempts that are made by a SDR, SVR, or CLUSSDR channel to connect to the remote queue manager, at intervals specified by **SHORTTMR**. After the number of attempts is exhausted, the channel tries to reconnect using to the schedule defined by **LONGRTY**.

The value must be in the range 0 - 999999999.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, CLUSSDR, or CLUSRCVR.

A channel attempts to reconnect if it fails to connect initially, whether it is started automatically by the channel initiator or by an explicit command. It also tries to connect again if the connection fails after the channel successfully connecting. If the cause of the failure is such that more attempts are unlikely to be successful, they are not attempted.

SHORTTMR(*integer*)
For **SHORTRTY**, **SHORTTMR** is the maximum number of seconds to wait before reattempting connection to the remote queue manager.

The time is approximate. From IBM MQ 8.0, zero means that another connection attempt is made as soon as possible.

The interval between attempting to reconnect might be extended if the channel has to wait to become active.

The value must be in the range 0 - 999999999.

Note: For implementation reasons, the maximum **SHORTTMR** value is 999,999; values exceeding this maximum are treated as 999,999. From IBM MQ 8.0, if SHORTTMR is set to 1 then the minimum interval between attempting to connect is 2 seconds.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, CLUSSDR, or CLUSRCVR.

SPLPROT
SPLPROT (Security Policy Protection) specifies how a server-to-server Message Channel Agent should deal with message protection when AMS is active and an applicable policy exists.

This parameter applies to z/OS only, from IBM MQ 9.1.3 onwards.

The permitted values are:

PASSTHRU
Pass through, unchanged, any messages sent or received by the message channel agent for this channel.

This value is valid for channels with a channel type (**CHLTYPE**) of SDR, SVR, RCVR, or RQSTR, and is the default value.

REMOVE
Remove any AMS protection from messages retrieved from the transmission queue by the message channel agent, and send the messages to the partner.

When the message channel agent gets a message from the transmission queue, if an AMS policy is defined for the transmission queue, it is applied to remove any AMS protection from the message prior to sending the message across the channel. If an AMS policy is not defined for the transmission queue, the message is sent as is.

This value is valid only for channels with a channel type of SDR or SVR.

ASPOLICY
Based on the policy defined for the target queue, apply AMS protection to inbound messages prior to putting them on to the target queue.

When the message channel agent receives an inbound message, if an AMS policy is defined for the target queue, AMS protection is applied to the message prior to the message being put to the target queue. If an AMS policy is not defined for the target queue, the message is put to the target queue as is.

This value is valid only for channels with a channel type of RCVR or RQSTR.

SSLCAUTH
SSLCAUTH defines whether IBM MQ requires a certificate from the TLS client. The TLS client is the initiating end of the channel. **SSLCAUTH** is applied to the TLS server, to determine the behavior required of the client. The TLS server is the end of the channel that receives the initiation flow.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of RCVR, SVRCONN, CLUSRCVR, SVR, OR RQSTR.

The parameter is used only for channels with **SSLCIPH** specified. If **SSLCIPH** is blank, the data is ignored and no error message is issued.

REQUIRED
IBM MQ requires and validates a certificate from the TLS client.

OPTIONAL
The peer TLS client system might still send a certificate. If it does, the contents of this certificate are validated as normal.

SSLCIPH*(string)*
Specifies the CipherSpec that is used on the channel. The maximum length is 32 characters.

Attention: IBM i z/OS On IBM MQ for z/OS, you can also specify the four digit hexadecimal code of a CipherSpec, whether or not it appears in the following table. On IBM i, you can also specify the two digit hexadecimal code of a CipherSpec, whether or not it appears in the following table. Also, on IBM i, installation of AC3 is a prerequisite for the use of TLS. You should not specify hexadecimal cipher values in SSLCIPH, because it is unclear from the value which cipher will be used, and the choice of which protocol to be used is indeterminate. Using hexadecimal cipher values can lead to CipherSpec mismatch errors.

The **SSLCIPH** values must specify the same CipherSpec on both ends of the channel.

This parameter is valid on all channel types that use transport type **TRPTYPE(TCP)**. If the parameter is blank, no attempt is made to use TLS on the channel.

V 9.2.4 ALW If SecureCommsOnly is enabled, plain text communication is not supported and the channel fails to start.

The value for this parameter is also used to set the value of SECPROT, which is an output field on the DISPLAY CHSTATUS command.

Note: When **SSLCIPH** is used with a telemetry channel, it means TLS Cipher Suite. See the **SSLCIPH** description for **DEFINE CHANNEL** (MQTT).

V 9.2.0 ALW From IBM MQ 9.1.1, you can specify a value of ANY_TLS12, which represents a subset of acceptable CipherSpecs that use the TLS 1.2 protocol; these CipherSpecs are listed in the following table. See Migrating existing security configurations to use the ANY_TLS12 CipherSpec for information on changing your existing security configurations to use the ANY_TLS12 value.

V 9.2.0 ALW From IBM MQ 9.1.4, on AIX, Linux, and Windows, IBM MQ provides an expanded set of alias CipherSpecs that includes ANY_TLS12_OR_HIGHER, and ANY_TLS13_OR_HIGHER. These alias CipherSpecs are listed in the following table.

Attention: If your enterprise needs to guarantee that a certain CipherSpec is negotiated and used, you must not use an alias CipherSpec value such as ANY_TLS12.

V 9.2.0 For information on changing your existing security configurations to use the ANY_TLS12_OR_HIGHER CipherSpec, see Migrating existing security configurations to use the ANY_TLS12_OR_HIGHER CipherSpec.

Table 151. CipherSpecs you can use with IBM MQ TLS support

Platform support "1" on page 483	CipherSpec name	Hex code	Protocol used	MAC algorithm	Encryption algorithm (encryption bits)	FIPS "2" on page 483	Suite B
Alias CipherSpecs							
All	ANY_TLS13_OR_HIGHER "3" on page 483 "4" on page 483 "5" on page 483	N/A	Negotiated	Negotiated	Negotiated	Negotiated	Negotiated
All	ANY_TLS13 "4" on page 483 "5" on page 483 "6" on page 483	N/A	TLS 1.3	Negotiated	Negotiated	Negotiated	Negotiated

All	ECDHE_RSA_AES_256_CBC_SHA384 "10" on page 483 "12" on page 483	C028	TLS 1.2	SHA-384	AES (256)	Yes	No
Multi	ECDHE_ECDSA_AES_128_GCM_SHA256 "12" on page 483 "13" on page 483	C02B	TLS 1.2	SHA-256 and AEAD GCM	AES (SHA384)	Yes	128 bit
Multi	ECDHE_ECDSA_AES_256_GCM_SHA384 "12" on page 483 "13" on page 483	C02C	TLS 1.2	SHA-384 and AEAD GCM	AES (SHA384)	Yes	192 bit
All	ECDHE_RSA_AES_128_GCM_SHA256 "13" on page 483	C02F	TLS 1.2	SHA-256 and AEAD GCM	AES (128)	Yes	No
All	ECDHE_RSA_AES_256_GCM_SHA384 "12" on page 483 "13" on page 483	C030	TLS 1.2	AEAD AES-128 GCM	AES (SHA384)	Yes	No

Table 151. CipherSpecs you can use with IBM MQ TLS support (continued)

Platform support "1" on page 483	CipherSpec name	Hex code	Protocol used	MAC algorithm	Encryption algorithm (encryption bits)	FIPS "2" on page 483	Suite B

Notes:

1. For a list of platforms covered by each platform icon, see Release and platform icons in the product documentation.
2. Specifies whether the CipherSpec is FIPS-certified on a FIPS-certified platform. See Federal Information Processing Standards (FIPS) for an explanation of FIPS.
3. ALW The ANY_TLS13_OR_HIGHER alias CipherSpec negotiates the highest level of security that the remote end will allow but will only connect using a TLS 1.3 or higher protocol.
4. z/OS To use TLS 1.3, or the ANY CipherSpec, on IBM MQ for z/OS, the operating system must be z/OS 2.4 or later.
5. IBM i To use TLS 1.3, or the ANY CipherSpec, on IBM i the underlying operating system version must support TLS 1.3. See System TLS support for TLSv1.3 for more information.
6. ALW The ANY_TLS13 alias CipherSpec represents a subset of acceptable CipherSpecs that use the TLS 1.3 protocol, as listed in this table for each platform.
7. ALW The ANY_TLS12_OR_HIGHER alias CipherSpec negotiates the highest level of security that the remote end will allow but will only connect using a TLS 1.2 or higher protocol.
8. The ANY_TLS12 CipherSpec represents a subset of acceptable CipherSpecs that use the TLS 1.2 protocol, as listed in this table for each platform.
9. ALW The ANY alias CipherSpec negotiates the highest level of security that the remote end will allow.
10. IBM i These CipherSpecs are not enabled on IBM i 7.4 systems that have System Value QSSLCSLCTL set to *OPSSYS.
11. ALW These CipherSpecs use an 8-octet Integrity Check Value (ICV) instead of a 16-octet ICV.
12. This CipherSpec cannot be used to secure a connection from the IBM MQ Explorer to a queue manager unless the appropriate unrestricted policy files are applied to the JRE used by the Explorer.
13. Linux Windows Following a recommendation by GSKit, TLS 1.2 GCM CipherSpecs have a restriction which means that after 2^24.5 TLS records are sent, using the same session key, the connection is terminated with message AMQ9288E. This GCM restriction is active, regardless of the FIPS mode being used.

    To prevent this error from happening, avoid using TLS 1.2 GCM Ciphers, enable secret key reset, or start your IBM MQ queue manager or client with the environment variable `GSK_ENFORCE_GCM_RESTRICTION=GSK_FALSE` set. For GSKit libraries, you must set this environment variable on both sides of the connection, and apply it to both client to queue manager connections and queue manager to queue manager connections. Note that this setting affects unmanaged .NET clients, but not Java or managed .NET clients. For more information, see AES-GCM cipher restriction.

    This restriction does not apply to IBM MQ for z/OS.

For more information about CipherSpecs, see Enabling CipherSpecs.

When you request a personal certificate, you specify a key size for the public and private key pair. The key size that is used during the SSL handshake can depend on the size stored in the certificate and on the CipherSpec:

- z/OS ALW On z/OS, AIX, Linux, and Windows, when a CipherSpec name includes _EXPORT, the maximum handshake key size is 512 bits. If either of the certificates exchanged during the SSL handshake has a key size greater than 512 bits, a temporary 512-bit key is generated for use during the handshake.
- z/OS For z/OS, System SSL state that if a TLS V1.3 connection is being negotiated:
  - The minimum key size for an RSA peer certificate is the larger of the following two values: 2048, or the value specified in the GSK_PEER_RSA_MIN_KEY_SIZE attribute.
  - The minimum key size for an ECC peer certificate is the larger of the following two values: 256, or the value specified in the GSK_PEER_ECC_MIN_KEY_SIZE attribute.
- ALW On UNIX, Linux, and Windows, when a CipherSpec name includes _EXPORT1024, the handshake key size is 1024 bits.
- Otherwise the handshake key size is the size stored in the certificate.

SSLPEER *(string)*

Specifies the certificate filter used by the peer queue manager or client at the other end of the channel. The filter is used to compare with the distinguished name of the certificate. A *distinguished name* is the identifier of the TLS certificate. If the distinguished name in the certificate received from the peer does not match the **SSLPEER** filter, the channel does not start.

Note: An alternative way of restricting connections into channels by matching against the TLS Subject distinguished name, is to use channel authentication records. With channel authentication records, different TLS subject distinguished name patterns can be applied to the same channel. Both **SSLPEER** and a channel authentication record can be applied to the same channel. If so, the inbound certificate must match both patterns in order to connect. For more information, see Channel authentication records.

SSLPEER is optional. If it is not specified, the distinguished name of the peer is not checked at channel startup. The distinguished name from the certificate is still written into the **SSLPEER** definition held in memory, and passed to the security exit. If **SSLCIPH** is blank, the data is ignored and no error message is issued.

This parameter is valid for all channel types.

The **SSLPEER** value is specified in the standard form used to specify a distinguished name. For example:

```
SSLPEER('SERIALNUMBER=4C:D0:49:D5:02:5F:38,CN="H1_C_FR1",O=IBM,C=GB')
```

You can use a semi-colon as a separator instead of a comma.

The possible attribute types supported are:

Table 152. Attribute types supported by SSLPEER

Attribute	Description
SERIALNUMBER	Certificate serial number
MAIL	Email address
E	Email address (Deprecated in preference to MAIL)
UID or USERID	User identifier
CN	Common Name
T	Title
OU	Organizational Unit name

Table 152. Attribute types supported by SSLPEER (continued)	
Attribute	**Description**
DC	Domain component
O	Organization name
STREET	Street / First line of address
L	Locality name
ST (or SP or S)	State or Province name
PC	Postal code / zipcode
C	Country
UNSTRUCTUREDNAME	Host name
UNSTRUCTUREDADDRESS	IP address
DNQ	Distinguished name qualifier

IBM MQ accepts only uppercase letters for the attribute types.

If any of the unsupported attribute types are specified in the **SSLPEER** string, an error is output either when the attribute is defined, or at run time. When the error is output depends on which platform you are running on. An error implies that the **SSLPEER** string does not match the distinguished name of the flowed certificate.

If the distinguished name of the flowed certificate contains multiple organizational unit (OU) attributes, and **SSLPEER** specifies that these attributes are to be compared, they must be defined in descending hierarchical order. For example, if the distinguished name of the flowed certificate contains the OUs `OU=Large Unit, OU=Medium Unit, OU=Small Unit`, specifying the following **SSLPEER** values works:

```
('OU=Large Unit,OU=Medium Unit')
('OU=*,OU=Medium Unit,OU=Small Unit')
('OU=*,OU=Medium Unit')
```

but specifying the following **SSLPEER** values fails:

```
('OU=Medium Unit,OU=Small Unit')
('OU=Large Unit,OU=Small Unit')
('OU=Medium Unit')
('OU=Small Unit, Medium Unit, Large Unit')
```

As indicated in these examples, attributes at the low end of the hierarchy can be omitted. For example, `('OU=Large Unit,OU=Medium Unit')` is equivalent to `('OU=Large Unit,OU=Medium Unit,OU=*')`

If two DNs are equal in all respects except for their domain component (DC)) values, almost the same matching rules apply as for OUs. The exception is that with DC values, the left-most DC is the lowest-level and most specific, and the comparison ordering differs accordingly.

Any or all the attribute values can be generic, either an asterisk `*` on its own, or a stem with initiating or trailing asterisks. Asterisks allow the **SSLPEER** to match any distinguished name value, or any value starting with the stem for that attribute. You can specify an asterisk at the beginning or end of any attribute value in the DN on the certificate. If you do so, you can still check for an exact match with **SSLPEER**. Specify `\*` to check for an exact match. For example, if you have an attribute of `CN='Test*'` in the DN of the certificate, you use the following command to check for an exact match:

```
SSLPEER('CN=Test\*')
```

Multi The maximum length of the parameter is 1024 bytes on Multiplatforms.

z/OS The maximum length of the parameter is 256 bytes on z/OS.

Channel authentication records provide greater flexibility when using SSLPEER and support 1024 bytes on all platforms.

STATCHL
Controls the collection of statistics data for channels:

QMGR
The value of the **STATCHL** parameter of the queue manager is inherited by the channel.

OFF
Statistics data collection is turned off for this channel.

LOW
If the value of the **STATCHL** parameter of the queue manager is not NONE, statistics data collection is turned on. Data is collected at a low rate for this channel.

MEDIUM
If the value of the **STATCHL** parameter of the queue manager is not NONE, statistics data collection is turned on.Data is collected at a medium rate for this channel.

HIGH
If the value of the **STATCHL** parameter of the queue manager is not NONE, statistics data collection is turned on.Data is collected at a high rate for this channel.

Changes to this parameter take effect only on channels started after the change occurs.

z/OS On z/OS systems, enabling this parameter simply turns on statistics data collection, regardless of the value you select. Specifying LOW, MEDIUM, or HIGH makes no difference to your results. This parameter must be enabled in order to collect channel accounting records.

For cluster channels, the value of this parameter is not replicated in the repository and therefore is not used in the auto-definition of CLUSSDR channels. For auto-defined CLUSSDR channels, the value of this parameter is taken from the attribute **STATACLS** of the queue manager. This value might then be overridden in the channel auto-definition exit.

Multi V 9.2.3 **TMPMODEL(*string*)**
The name of the model queue to be used while creating a temporary queue (maximum length 48 characters).

The default queue is SYSTEM.DEFAULT.MODEL.QUEUE.

Multi V 9.2.3 **TMPQPRFX(*string*?**
The temporary queue name prefix to add to the beginning of the model queue when deriving a temporary queue name (maximum length 48 characters).

The default is AMQP.*.

TPNAME(*string*)
LU 6.2 transaction program name (maximum length 64 characters).

This parameter is valid only for channels with a transport type (**TRPTYPE**) of LU62.

Set this parameter to the SNA transaction program name, unless the **CONNAME** contains a side-object name in which case set it to blanks. The actual name is taken instead from the CPI-C Communications Side Object, or the APPC side information data set. See Configuration parameters for an LU 6.2 connection

Windows z/OS On Windows SNA Server, and in the side object on z/OS, the TPNAME is wrapped to uppercase.

This parameter is not valid for channels with a channel type (**CHLTYPE**) of RCVR.

TPROOT
The topic root for an AMQP channel. The default value for TPROOT is SYSTEM.BASE.TOPIC. With this value, the topic string an AMQP client uses to publish or subscribe has no prefix, and the client can

exchange messages with other IBM MQ publish/subscribe applications. Alternatively, AMQP clients can publish and subscribe under a different topic prefix, specified in the TPROOT attribute.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of AMQP.

TRPTYPE
Transport type to be used:

LU62
SNA LU 6.2

NETBIOS
Windows Supported on Windows, and DOS.

z/OS Also used on z/OS for defining client-connection channels that connect to servers on the platforms supporting NetBIOS.

SPX
Sequenced packet exchange

Windows Supported on Windows, and DOS.

z/OS Also used on z/OS for defining client-connection channels that connect to servers on the platforms supporting SPX.

TCP
Transmission Control Protocol - part of the TCP/IP protocol suite.

If you do not enter a value for this parameter, the value specified in the SYSTEM.DEF.*channel-type* definition is used. If the channel is initiated from the other end, no check is made that the correct transport type is specified.

Multi On Multiplatforms, if the SYSTEM.DEF.*channel-type* definition does not exist, you must specify a value.

z/OS On z/OS, if the SYSTEM.DEF.*channel-type* definition does not exist, the default is LU62.

Multi **USECLTID**
Specifies that the client ID should be used for authorization checks for an AMQP channel, instead of the MCAUSER attribute value.

NO
The MCA user ID should be used for authorization checks.

YES
The client ID should be used for authorization checks.

USEDLQ
Determines whether the dead-letter queue is used when messages cannot be delivered by channels.

NO
Messages that cannot be delivered by a channel are treated as a failure. The channel either discards the message, or the channel ends, in accordance with the **NPMSPEED** setting.

YES
When the **DEADQ** queue manager attribute provides the name of a dead-letter queue, then it is used, else the behavior is as for NO. YES is the default value.

USERID(*string*)
Task user identifier. The maximum length is 12 characters.

This parameter is used by the message channel agent when attempting to initiate a secure LU 6.2 session with a remote message channel agent.

Multi On Multiplatforms, this parameter is valid only for channels with a channel type (CHLTYPE) of SDR, SVR, RQSTR, CLNTCONN, or CLUSSDR.

z/OS On z/OS, this parameter is supported only for CLNTCONN channels.

Although the maximum length of the parameter is 12 characters, only the first 10 characters are used.

At the receiving end, if passwords are encrypted and the LU 6.2 software is using a different encryption method, the channel does not start. The error is diagnosed as invalid security details. You can avoid invalid security details by modifying the receiving SNA configuration to either:

- Turn off password substitution, or
- Define a security user ID and password.

XMITQ(*string*)
Transmission queue name.

The name of the queue from which messages are retrieved. See Rules for naming IBM MQ objects.

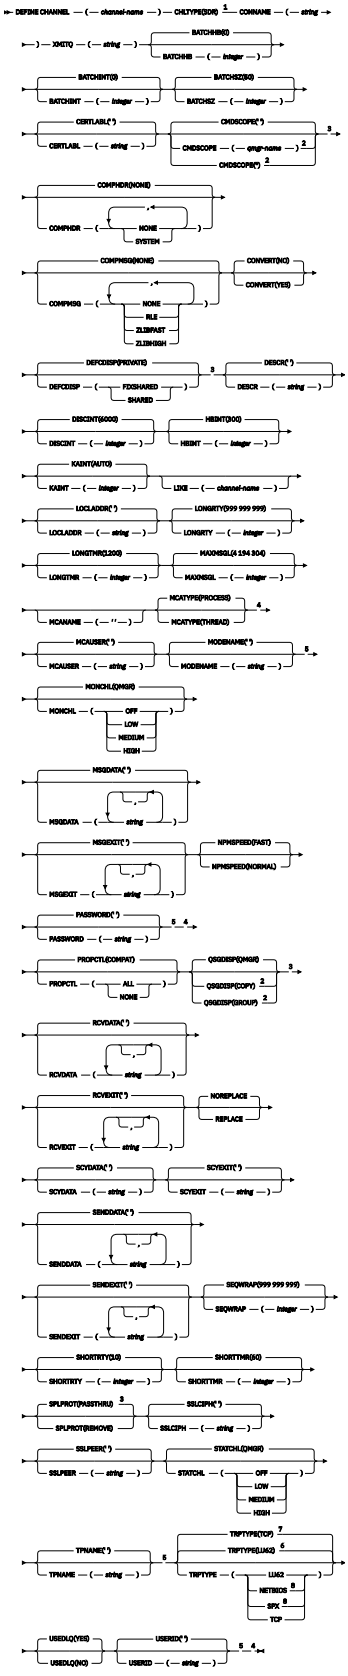
This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR or SVR. For these channel types, this parameter is required.

Sender channel

Syntax diagram for a sender channel when using the DEFINE CHANNEL command.

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See “Syntax diagrams” on page 236.

DEFINE CHANNEL



Notes:

1 This parameter must follow immediately after the channel name except on z/OS.

[2] Valid only on IBM MQ for z/OS when the queue manager is a member of a queue sharing group.
[3] Valid only on z/OS.
[4] Not valid on z/OS.
[5] Valid only if TRPTYPE is LU62.
[6] Default for z/OS.
[7] Default for Multiplatforms.
[8] Valid only on Windows.

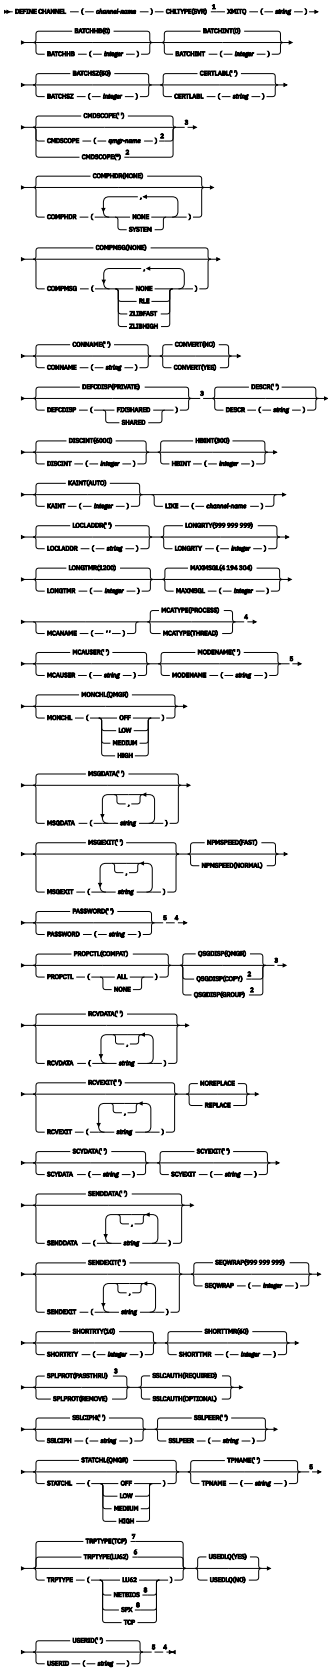
The parameters are described in "DEFINE CHANNEL (define a new channel)" on page 448.

Server channel

Syntax diagram for a server channel when using the DEFINE CHANNEL command.

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See "Syntax diagrams" on page 236.

DEFINE CHANNEL



Notes:

1 This parameter must follow immediately after the channel name except on z/OS.

[2] Valid only on IBM MQ for z/OS when the queue manager is a member of a queue sharing group.
[3] Valid only on z/OS.
[4] Not valid on z/OS.
[5] Valid only if TRPTYPE is LU62.
[6] Default for z/OS.
[7] Default for Multiplatforms.
[8] Valid only on Windows.

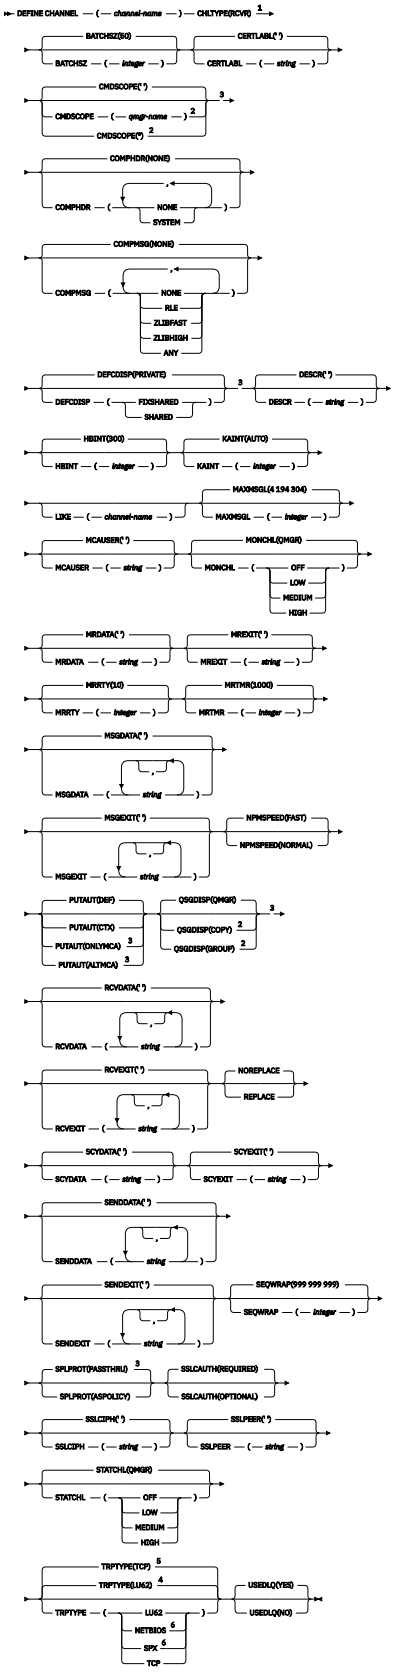
The parameters are described in "DEFINE CHANNEL (define a new channel)" on page 448.

Receiver channel

Syntax diagram for a receiver channel when using the DEFINE CHANNEL command.

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See "Syntax diagrams" on page 236.

DEFINE CHANNEL



Notes:

1 This parameter must follow immediately after the channel name except on z/OS.

[2] Valid only on IBM MQ for z/OS when the queue manager is a member of a queue sharing group.
[3] Valid only on z/OS.
[4] Default for z/OS.
[5] Default for Multiplatforms.
[6] Valid only on Windows.

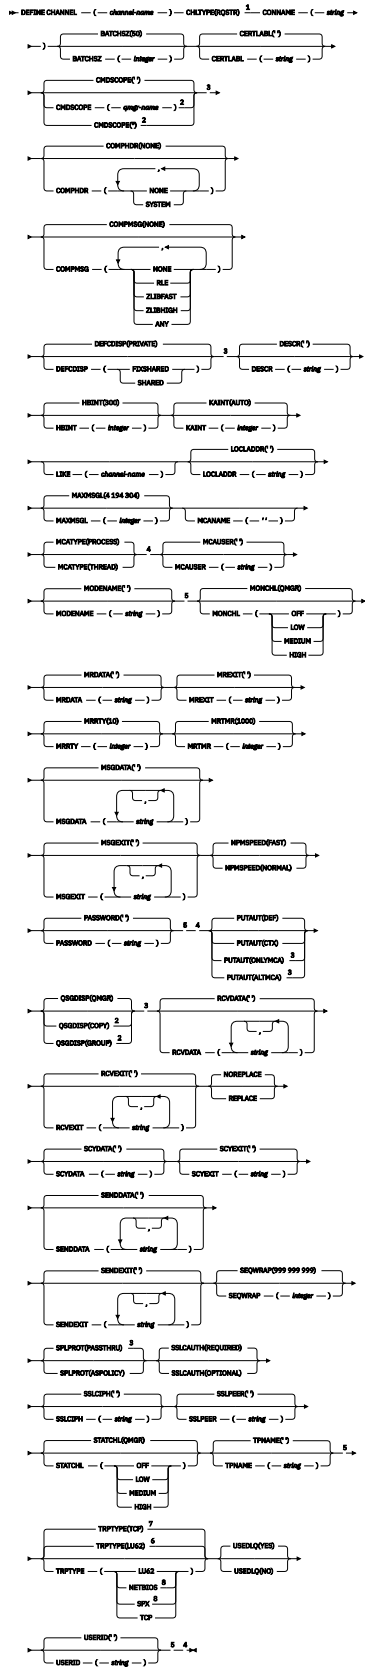
The parameters are described in "DEFINE CHANNEL (define a new channel)" on page 448.

Requester channel

Syntax diagram for a requester channel when using the DEFINE CHANNEL command.

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See "Syntax diagrams" on page 236.

DEFINE CHANNEL



Notes:

1 This parameter must follow immediately after the channel name except on z/OS.

[2] Valid only on IBM MQ for z/OS when the queue manager is a member of a queue sharing group.
[3] Valid only on z/OS.
[4] Not valid on z/OS.
[5] Valid only if TRPTYPE is LU62.
[6] Default for z/OS.
[7] Default for Multiplatforms.
[8] Valid only on Windows.

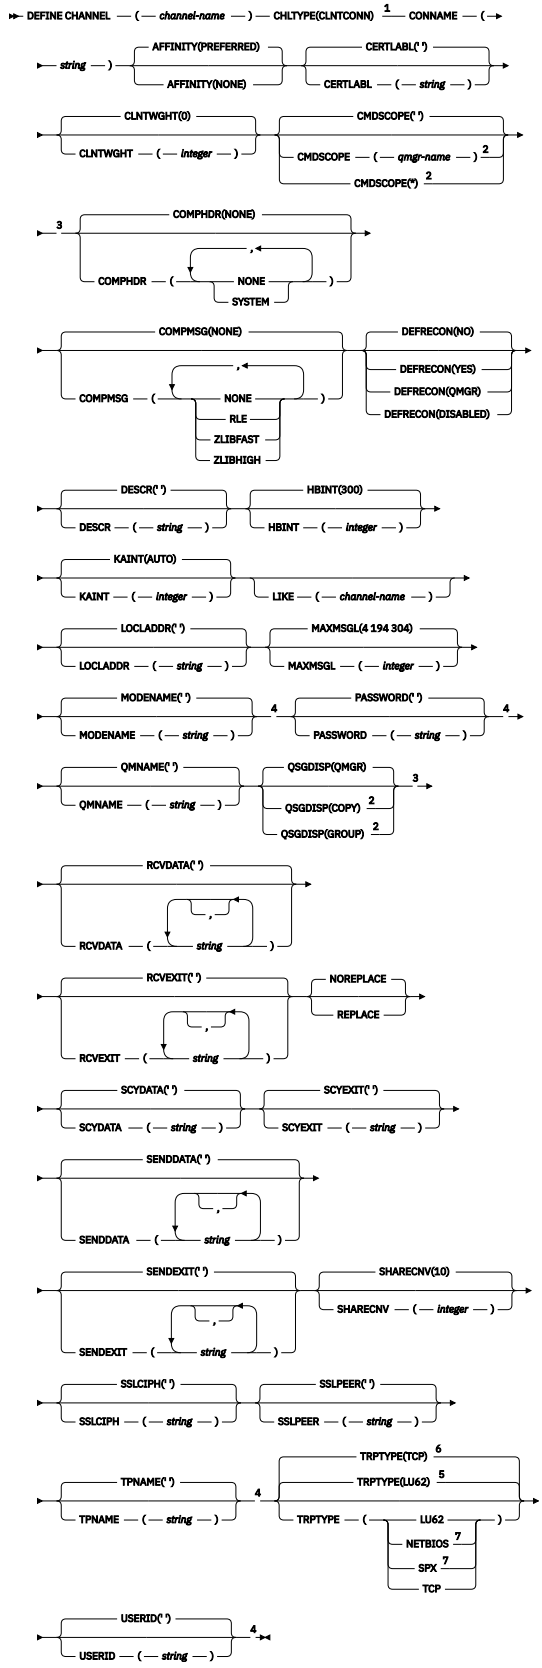
The parameters are described in "DEFINE CHANNEL (define a new channel)" on page 448.

Client-connection channel

Syntax diagram for a client-connection channel when using the DEFINE CHANNEL command.

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See "Syntax diagrams" on page 236.

DEFINE CHANNEL



Notes:

1 This parameter must follow immediately after the channel name except on z/OS.

[2] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[3] Valid only on z/OS.
[4] Valid only if TRPTYPE is LU62.
[5] Default for z/OS.
[6] Default for Multiplatforms.
[7] Valid only for clients to be run on DOS or Windows.

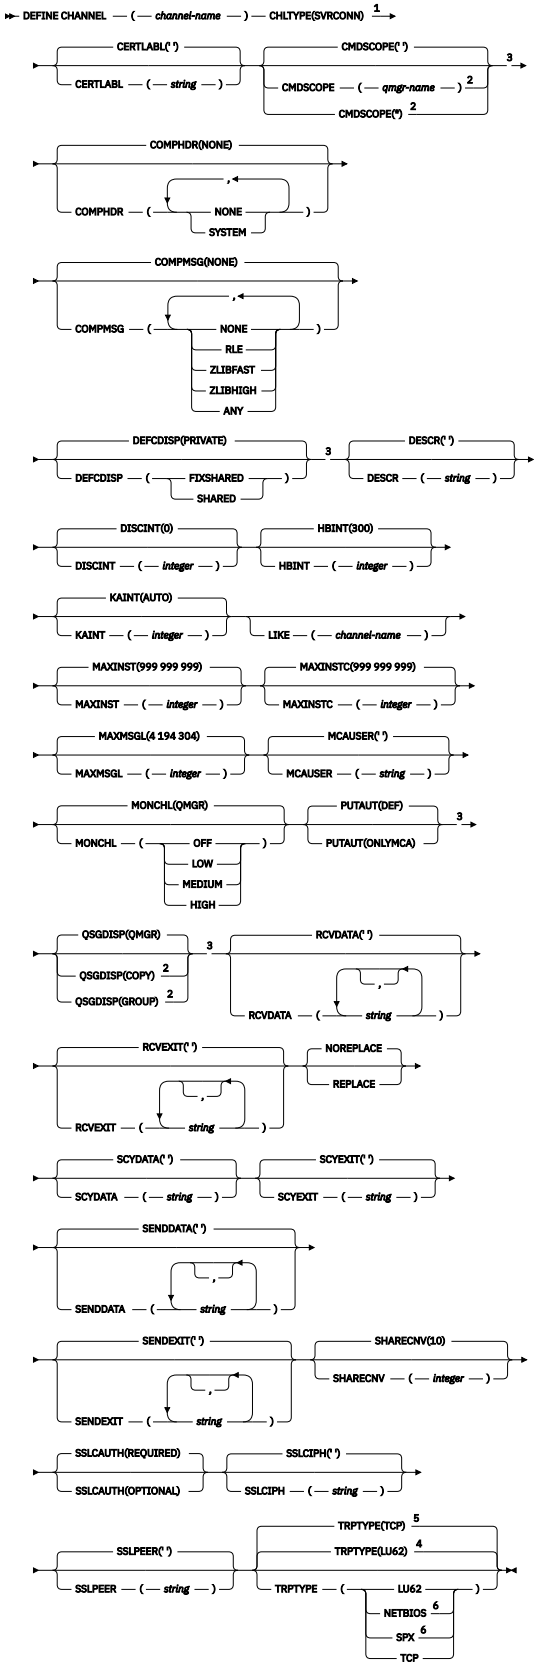
The parameters are described in "DEFINE CHANNEL (define a new channel)" on page 448.

Server-connection channel

Syntax diagram for a server-connection channel when using the DEFINE CHANNEL command.

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See "Syntax diagrams" on page 236.

DEFINE CHANNEL



Notes:

1 This parameter must follow immediately after the channel name except on z/OS.

[2] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[3] Valid only on z/OS.
[4] Default for z/OS.
[5] Default for Multiplatforms.
[6] Valid only for clients to be run on Windows.

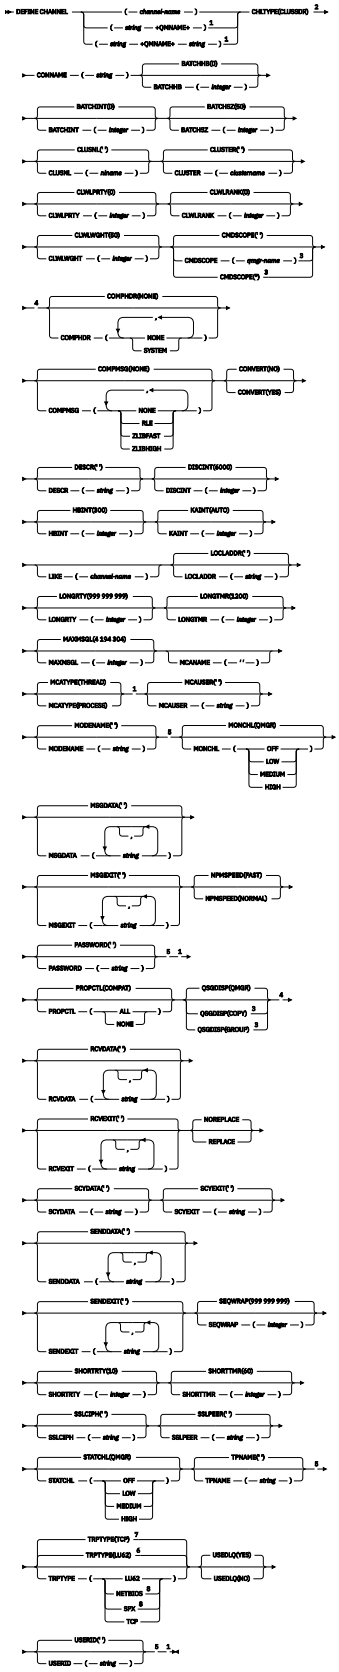
The parameters are described in "DEFINE CHANNEL (define a new channel)" on page 448.

Cluster-sender channel

Syntax diagram for a cluster-sender channel when using the DEFINE CHANNEL command.

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See "Syntax diagrams" on page 236.

DEFINE CHANNEL



Notes:

1 Not valid on z/OS.

[2] This parameter must follow immediately after the channel name except on z/OS.
[3] Valid only on IBM MQ for z/OS when the queue manager is a member of a queue sharing group.
[4] Valid only on z/OS.
[5] Valid only if TRPTYPE is LU62.
[6] Default for z/OS.
[7] Default for Multiplatforms.
[8] Valid only on Windows.

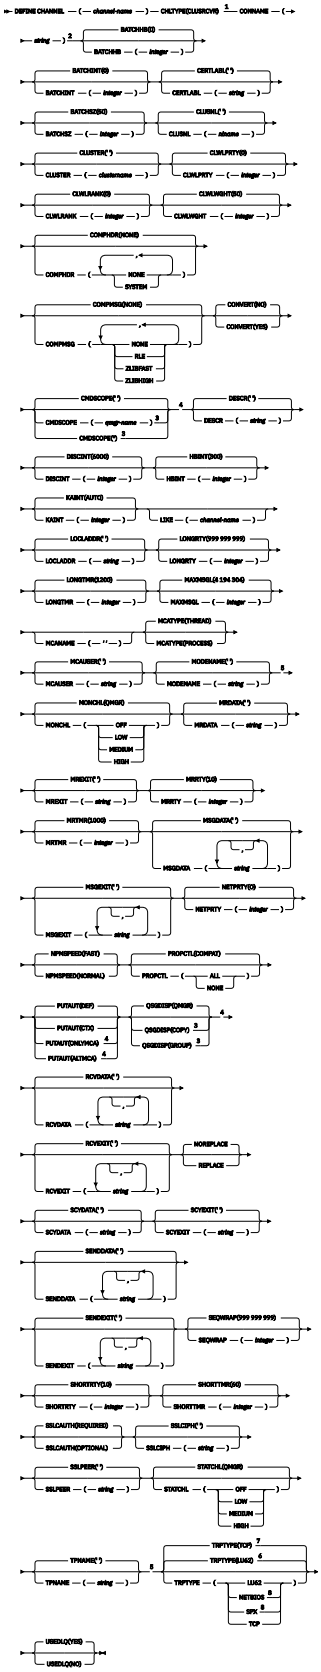
The parameters are described in "DEFINE CHANNEL (define a new channel)" on page 448.

Cluster-receiver channel

Syntax diagram for a cluster-receiver channel when using the DEFINE CHANNEL command.

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See "Syntax diagrams" on page 236.

DEFINE CHANNEL



Notes:

[1] This parameter must follow immediately after the channel name except on z/OS.

[2] This parameter is optional if TRPTYPE is TCP.
[3] Valid only on IBM MQ for z/OS when the queue manager is a member of a queue sharing group.
[4] Valid only on z/OS.
[5] Valid only if TRPTYPE is LU62.
[6] Default for z/OS.
[7] Default for Multiplatforms.
[8] Valid only on Windows.

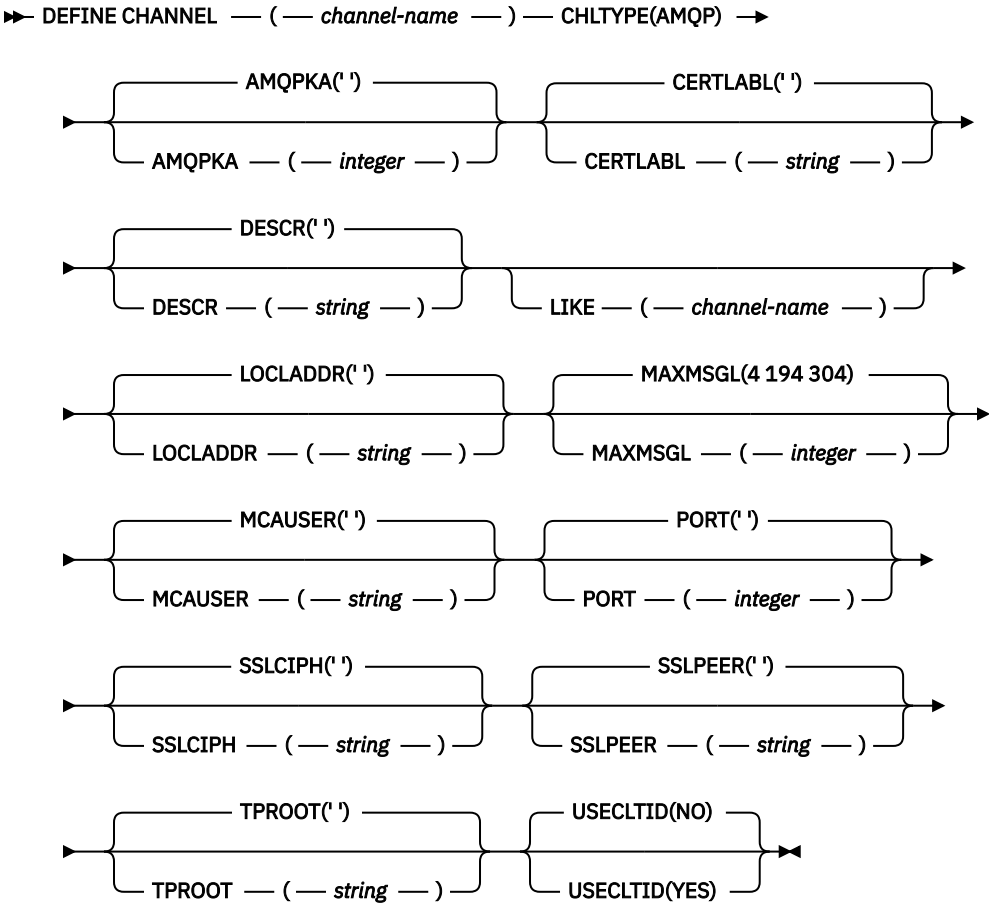
The parameters are described in "DEFINE CHANNEL (define a new channel)" on page 448.

ALW *AMQP channel*

Syntax diagram for an AMQP channel when using the DEFINE CHANNEL command.

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See "Syntax diagrams" on page 236.

DEFINE CHANNEL



The parameters are described in "DEFINE CHANNEL (define a new channel)" on page 448.

Windows Linux AIX DEFINE CHANNEL (define a new channel) for MQTT

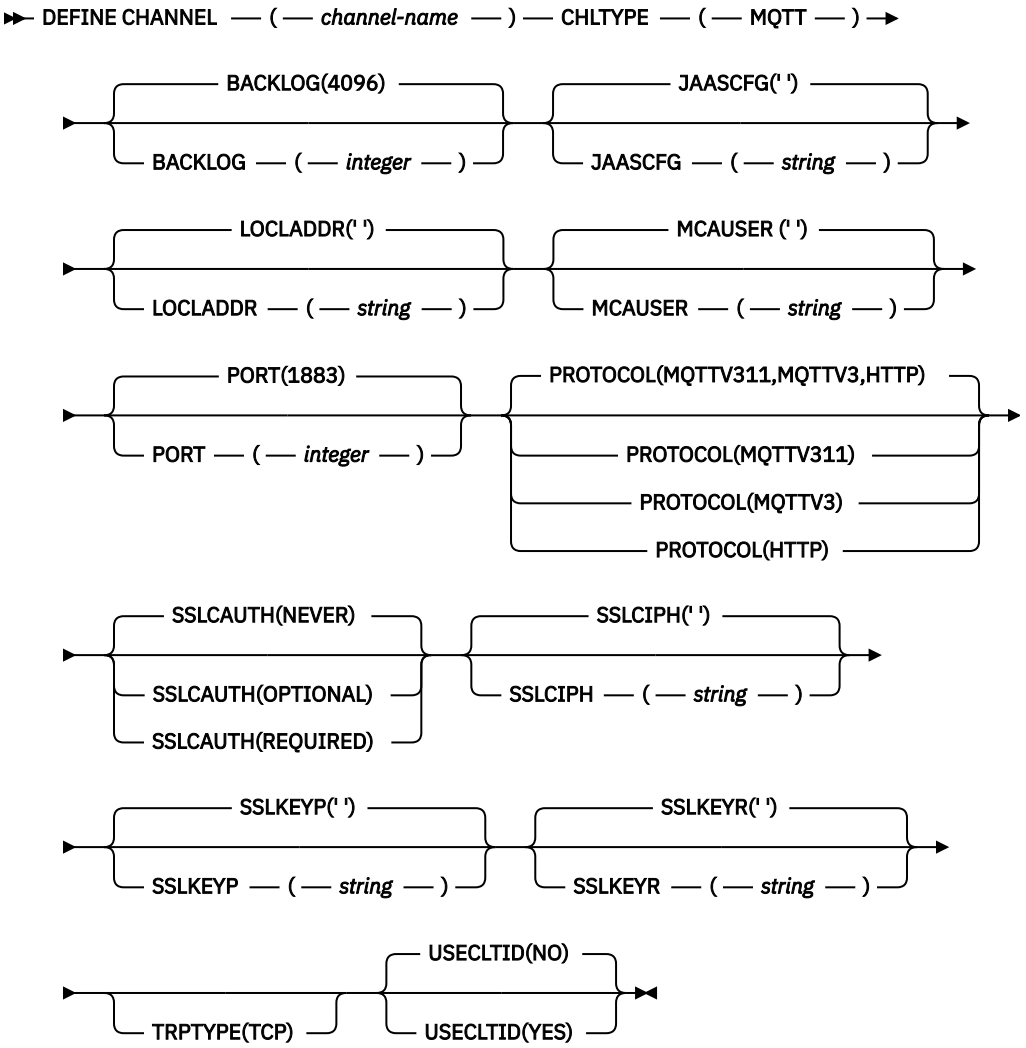
Syntax diagram for a telemetry channel when using the **DEFINE CHANNEL** command.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

Synonym: DEF CHL

DEFINE CHANNEL (MQTT)



Usage notes

The telemetry (MQXR) service must be running when you issue this command. For instructions on how to start the telemetry (MQXR) service, see Configuring a queue manager for telemetry on Linux or Configuring a queue manager for telemetry on Windows.

Note: After an MQTT channel is defined, the MQTT service attempts to start it automatically.

Parameter descriptions for DEFINE CHANNEL (MQTT)

(channel-name)

The name of the new channel definition.

The name must not be the same as any existing channel defined on this queue manager (unless REPLACE or ALTER is specified).

The maximum length of the string is 20 characters, and the string must contain only valid characters; see Rules for naming IBM MQ objects.

BACKLOG(*integer*)

The number of outstanding connection requests that the telemetry channel can support at any one time. When the backlog limit is reached, any further clients trying to connect will be refused connection until the current backlog is processed.

The value is in the range 0 - 999999999.

The default value is 4096.

CHLTYPE

Channel type. MQTT (telemetry) channel.

JAASCFG (*string*)

The name of a stanza in the JAAS configuration file.

See Authenticating an MQTT client Java app with JAAS

LOCLADDR (*ip-addr*)

LOCLADDR is the local communications address for the channel. Use this parameter if you want to force the client to use a particular IP address. LOCLADDR is also useful to force a channel to use an IPv4 or IPv6 address if a choice is available, or to use a particular network adapter on a system with multiple network adapters.

The maximum length of **LOCLADDR** is MQ_LOCAL_ADDRESS_LENGTH.

If you omit **LOCLADDR**, a local address is automatically allocated.

ip-addr
ip-addr is a single network address, specified in one of three forms:

IPv4 dotted decimal
For example 192.0.2.1

IPv6 hexadecimal notation
For example 2001:DB8:0:0:0:0:0:0

Alphanumeric host name form
For example WWW.EXAMPLE.COM

If an IP address is entered, only the address format is validated. The IP address itself is not validated.

MCAUSER(*string*)

Message channel agent user identifier.

The maximum length of the string is 12 characters. On Windows, you can optionally qualify a user identifier with the domain name in the format user@domain.

If this parameter is nonblank, and **USECLNTID** is set to NO, then this user identifier is used by the telemetry service for authorization to access IBM MQ resources.

If this parameter is blank, and **USECLNTID** is set to NO, then the user name flowed in the MQTT CONNECT Packet is used. See MQTT client identity and authorization.

PORT(*integer*)

The port number on which the telemetry (MQXR) service accepts client connections. The default port number for a telemetry channel is 1883; and the default port number for a telemetry channel secured using SSL is 8883. Specifying a port value of 0 causes MQTT to dynamically allocate an available port number.

PROTOCOL

The following communication protocols are supported by the channel:

MQTTV311
The channel accepts connections from clients using the protocol defined by the MQTT 3.1.1 Oasis standard. The functionality provided by this protocol is almost identical to that provided by the pre-existing MQTTV3 protocol.

MQTTV3
The channel accepts connections from clients using the MQTT V3.1 Protocol Specification from mqtt.org.

HTTP
The channel accepts HTTP requests for pages, or WebSockets connections to MQ Telemetry.

To accept connections from clients using different protocols, specify the acceptable values as a comma-delimited list. For example if you specify `MQTTV3,HTTP` the channel accepts connections from clients using either MQTTV3 or HTTP. If you specify no client protocols, the channel accepts connections from clients using any of the supported protocols.

If you are using IBM MQ 8.0.0 Fix Pack 3 or later, and your configuration includes an MQTT channel that was last modified in an earlier version of the product, you must explicitly change the protocol setting to prompt the channel to use the `MQTTV311` option. This is so even if the channel does not specify any client protocols, because the specific protocols to use with the channel are stored at the time the channel is configured, and previous versions of the product have no awareness of the `MQTTV311` option. To prompt a channel in this state to use the `MQTTV311` option, explicitly add the option then save your changes. The channel definition is now aware of the option. If you subsequently change the settings again, and specify no client protocols, the `MQTTV311` option is still included in the stored list of supported protocols.

SSLCAUTH

Defines whether IBM MQ requires a certificate from the TLS client. The initiating end of the channel acts as the TLS client, so this parameter applies to the end of the channel that receives the initiation flow, which acts as the TLS server.

NEVER
IBM MQ never requests a certificate from the TLS client.

REQUIRED
IBM MQ requires and validates a certificate from the TLS client.

OPTIONAL
IBM MQ lets the TLS client decide whether to provide a certificate. If the client sends a certificate, the contents of this certificate are validated as normal.

SSLCIPH*(string)*

When **SSLCIPH** is used with a telemetry channel, it means TLS Cipher Suite. The TLS cipher suite is the one supported by the JVM that is running the telemetry (MQXR) service. If the parameter is blank, no attempt is made to use TLS on the channel.

If you plan to use SHA-2 cipher suites, see System requirements for using SHA-2 cipher suites with MQTT channels.

SSLKEYP(*string*)

The passphrase for the TLS key repository.

V 9.2.4 If the MQXR service is configured for encryption of passphrases by specifying the **-sf** option in STARTARG for the service, then the pass phrase will be encrypted. For more information on encryption of passphrases, see Encryption of passphrases for MQTT TLS channels.

SSLKEYR(*string*)

The full path name of the TLS key repository file, the store for digital certificates and their associated private keys. If you do not specify a key file, TLS is not used.

The maximum length of the string is 256 characters;

- Linux AIX On AIX and Linux, the name is of the form *pathname/keyfile*.
- Windows On Windows, the name is of the form *pathname\keyfile*.

where *keyfile* is specified without the suffix `.jks`, and identifies a Java keystore file.

TRPTYPE (*string*)

The transmission protocol to be used:

TCP
TCP/IP.

USECLTID

Decide whether you want to use the MQTT client ID for the new connection as the IBM MQ user ID for that connection. If this property is specified, the user name supplied by the client is ignored.

If you set this parameter to YES, then **MCAUSER** must be blank.

If **USECLNTID** is set to NO, and **MCAUSER** is blank, then the user name flowed in the MQTT CONNECT Packet is used. See MQTT client identity and authorization.

Multi DEFINE COMMINFO (define a new communication information object) on Multiplatforms

Use the MQSC command **DEFINE COMMINFO** to define a new communication information object. These objects contain the definitions required for Multicast messaging.

Using MQSC commands

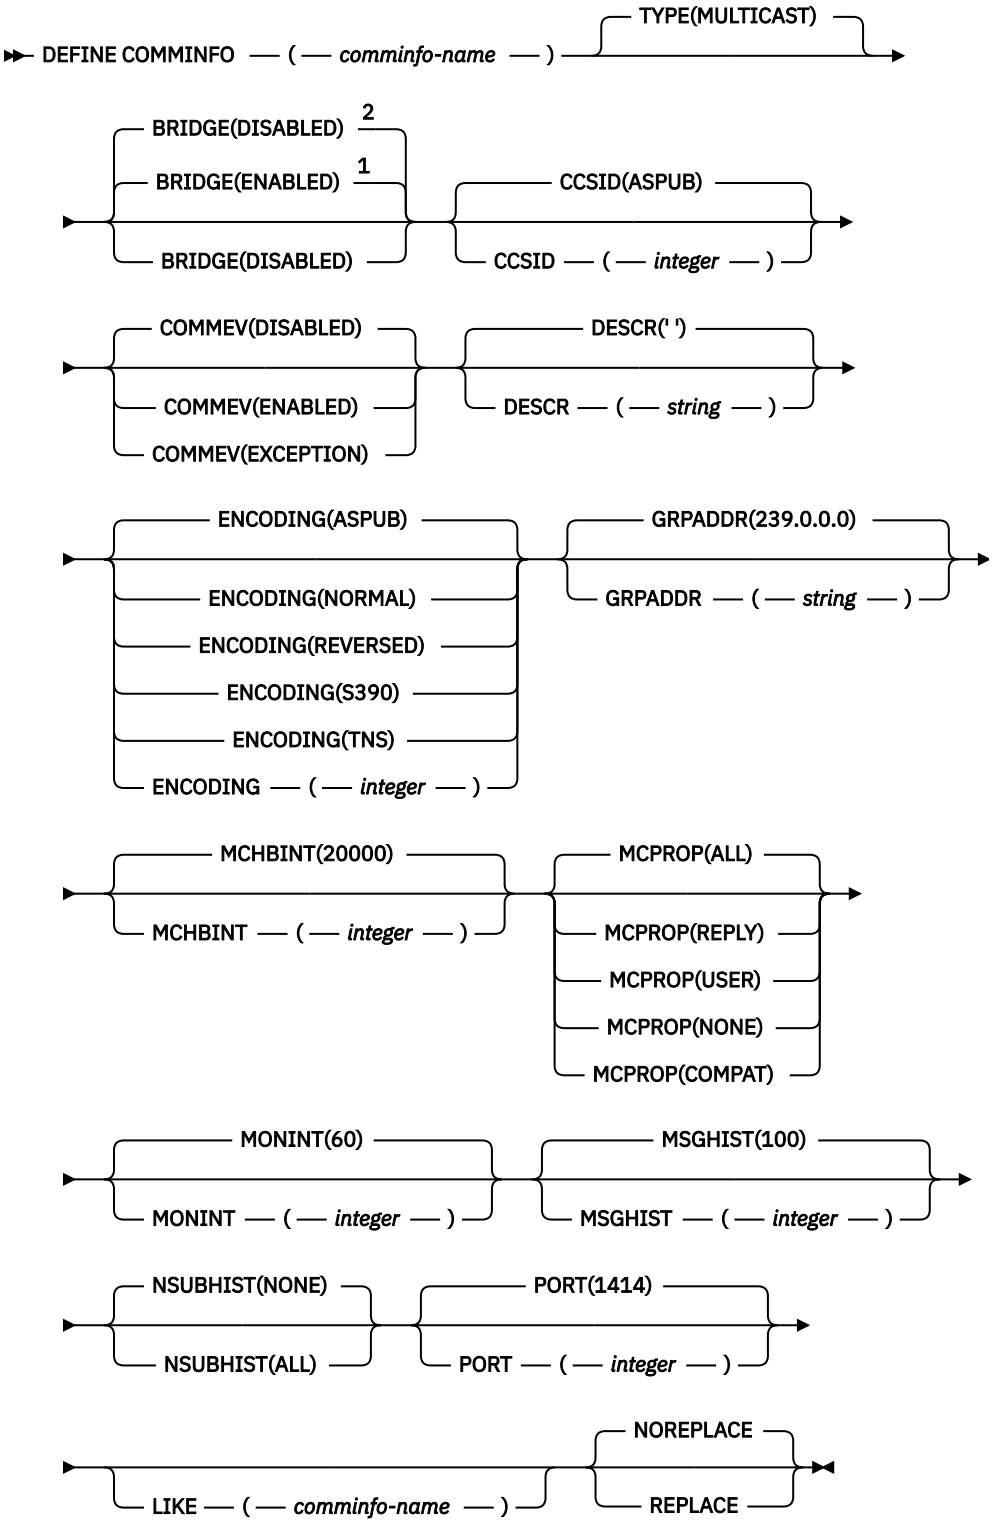
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

- Syntax diagram
- "Parameter descriptions for DEFINE COMMINFO" on page 510

Synonym: DEF COMMINFO

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See "Syntax diagrams" on page 236.

DEFINE COMMINFO



Notes:

[1] Default for platforms other than IBM i.
[2] Default for IBM i.

Parameter descriptions for DEFINE COMMINFO

(comminfo name)
Name of the communications information object. This is required.

The name must not be the same as any other communications information object name currently defined on this queue manager. See Rules for naming IBM MQ objects.

TYPE
The type of the communications information object. The only type supported is MULTICAST.

BRIDGE
Controls whether publications from applications not using Multicast are bridged to applications using Multicast. Bridging does not apply to topics that are marked as **MCAST(ONLY)**. As these topics can only be Multicast traffic, it is not applicable to bridge to the queue's publish/subscribe domain.

DISABLED
Publications from applications not using Multicast are not bridged to applications that do use Multicast.

This is the default for IBM i.

ENABLED
Publications from applications not using Multicast are bridged to applications that do use Multicast. This is the default for platforms other than IBM i.

CCSID(***integer*** **)**
The coded character set identifier that messages are transmitted on. Specify a value in the range 1 through 65535.

The CCSID must specify a value that is defined for use on your platform, and use a character set that is appropriate to the platform. If you use this parameter to change the CCSID, applications that are running when the change is applied continue to use the original CCSID. Because of this, you must stop and restart all running applications before you continue. This includes the command server and channel programs. To do this, stop and restart the queue manager after making the change.

The default value is ASPUB which means that the coded character set is taken from the one that is supplied in the published message.

COMMEV
Controls whether event messages are generated for Multicast handles that are created using this COMMINFO object. Events will only be generated if they are enabled using the **MONINT** parameter.

DISABLED
Event messages are not generated for Multicast handles that are created using the COMMINFO object. This is the default value.

ENABLED
Event messages are generated for Multicast handles that are created using the COMMINFO object.

EXCEPTION
Event messages are written if the message reliability is below the reliability threshold The reliability threshold is set to 90 by default.

DESCR(***string*** **)**
Plain-text comment. It provides descriptive information about the communication information object when an operator issues the DISPLAY COMMINFO command (see “DISPLAY COMMINFO (display communication information) on Multiplatforms” on page 704).

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

ENCODING
The encoding that the messages are transmitted in.

ASPUB
The encoding of the message is taken from the one that is supplied in the published message. This is the default value.

REVERSED

NORMAL

S390

TNS

encoding

GRPADDR
The group IP address or DNS name.

It is the administrator's responsibility to manage the group addresses. It is possible for all multicast clients to use the same group address for every topic; only the messages that match outstanding subscriptions on the client are delivered. Using the same group address can be inefficient because every client must examine and process every multicast packet in the network. It is more efficient to allocate different IP group addresses to different topics or sets of topics, but this requires careful management, especially if other non-MQ multicast applications are in use on the network. The default value is `239.0.0.0`.

MCHBINT
The heartbeat interval is measured in milliseconds, and specifies the frequency at which the transmitter notifies any receivers that there is no further data available. The value is in the range 0 to 999 999. The default value is `2000` milliseconds.

MCPROP
The multicast properties control how many of the MQMD properties and user properties flow with the message.

All
All user properties and all the fields of the MQMD are transported.

Reply
Only user properties, and MQMD fields that deal with replying to the messages, are transmitted. These properties are:

- MsgType
- MessageId
- CorrelId
- ReplyToQ
- ReplyToQmgr

User
Only the user properties are transmitted.

NONE
No user properties or MQMD fields are transmitted.

COMPAT
This value causes the transmission of the message to be done in a compatible mode to RMM. This allows some inter-operation with the current XMS applications and Broker RMM applications.

V 9.2.0 V 9.2.0 XMS .NET Multicast messaging (using RMM) was deprecated from IBM MQ 9.2 and will be removed in a future release of XMS .NET.

MONINT(*integer*)
How frequently, in seconds, that monitoring information is updated. If events messages are enabled, this parameter also controls how frequently event messages are generated about the status of the Multicast handles created using this COMMINFO object.

A value of 0 means that there is no monitoring.

The default value is 60.

MSGHIST
This value is the amount of message history in kilobytes that is kept by the system to handle retransmissions in the case of NACKs (negative acknowledgments).

The value is in the range 0 to 999 999 999. A value of 0 gives the least level of reliability. The default value is 100.

NSUBHIST
The new subscriber history controls whether a subscriber joining a publication stream receives as much data as is currently available, or receives only publications made from the time of the subscription.

NONE
A value of NONE causes the transmitter to transmit only publication made from the time of the subscription. This is the default value.

ALL
A value of ALL causes the transmitter to retransmit as much history of the topic as is known. In some circumstances this can give a similar behavior to retained publications.

Note: Using the value of ALL might have a detrimental effect on performance if there is a large topic history because all the topic history is retransmitted.

PORT(*integer*)
The port number to transmit on. The default port number is 1414.

LIKE(*authinfo-name*)
The name of a communication information object, with parameters that are used to model this definition.

If this field is not complete, and you do not complete the parameter fields related to the command, the values are taken from the default definition for an object of this type.

This default communication information object definition can be altered by the installation to the default values required.

REPLACE and NOREPLACE
Whether the existing definition is to be replaced with this one. This is optional. The default is NOREPLACE. Any object with a different disposition is not changed.

REPLACE
The definition replaces an existing definition of the same name. If a definition does not exist, one is created.

NOREPLACE
The definition does not replace an existing definition of the same name.

Related tasks
Getting started with multicast

Multi DEFINE LISTENER (define a new listener) on Multiplatforms

Use the MQSC command DEFINE LISTENER to define a new IBM MQ listener definition, and set its parameters.

Using MQSC commands

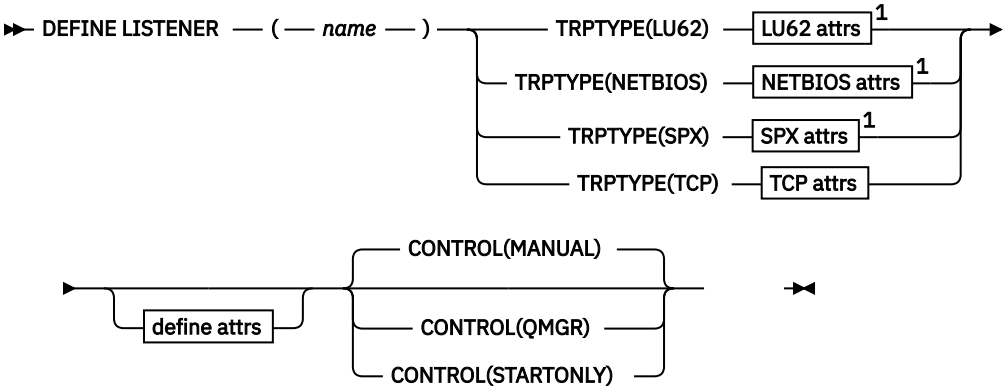
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

- Syntax diagram
- “Parameter descriptions for DEFINE LISTENER” on page 514

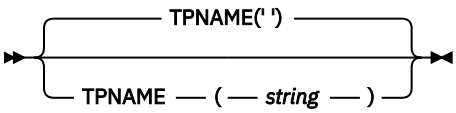
Synonym: DEF LSTR

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See “Syntax diagrams” on page 236.

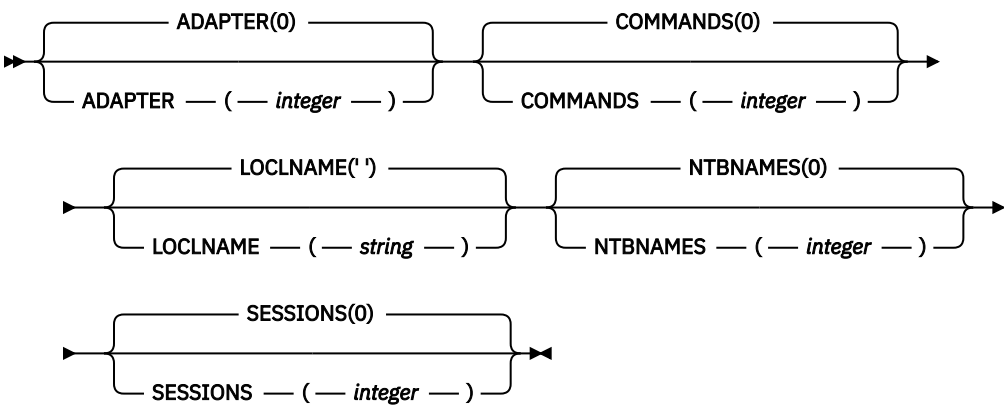
DEFINE LISTENER



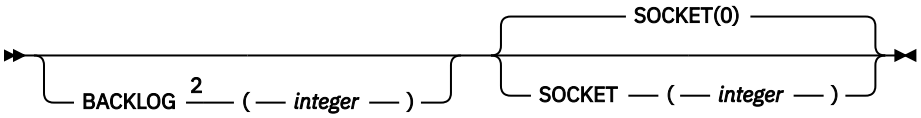
LU62 attrs



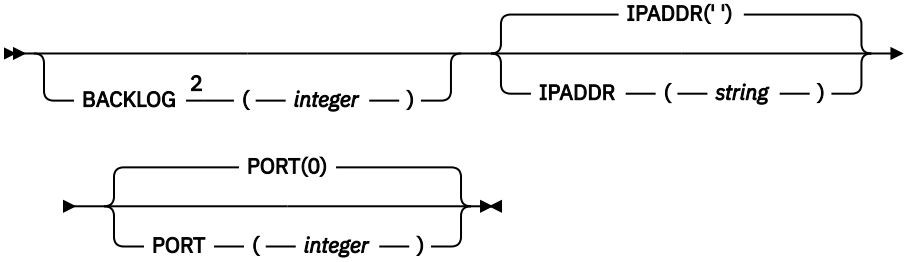
NETBIOS attrs



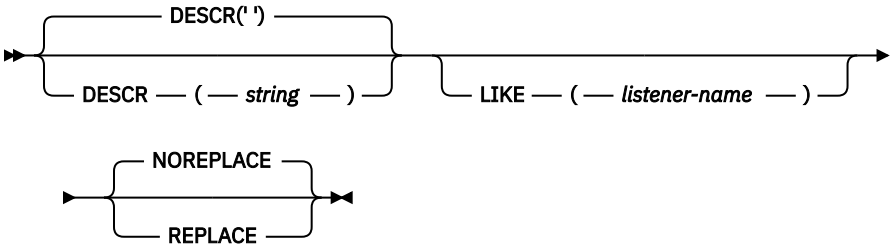
SPX attrs



TCP attrs



Define attrs



Notes:

[1] Valid only on Windows.

[2] When the BACKLOG attribute is left unchanged or when it is explicitly set to zero, the attribute is stored as zero by default in the listener object created by the **DEFINE LISTENER** command. However, when the listener is started, the default backlog value takes effect. For information about the default value of the BACKLOG attribute, see Using the TCP listener backlog option.

Parameter descriptions for DEFINE LISTENER

(listener-name)
Name of the IBM MQ listener definition (see Rules for naming IBM MQ objects). This is required.

The name must not be the same as any other listener definition currently defined on this queue manager (unless REPLACE is specified).

Windows **ADAPTER(*integer*)**
The adapter number on which NetBIOS listens. This parameter is valid only on Windows when TRPTYPE is NETBIOS.

BACKLOG(*integer*)
The number of concurrent connection requests that the listener supports.

Windows **COMMANDS(*integer*)**
The number of commands that the listener can use. This parameter is valid only on Windows when **TRPTYPE** is NETBIOS.

CONTROL(*string*)
Specifies how the listener is to be started and stopped.:

MANUAL
The listener is not to be started automatically or stopped automatically. It is to be controlled by use of the **START LISTENER** and **STOP LISTENER** commands.

QMGR
The listener being defined is to be started and stopped at the same time as the queue manager is started and stopped.

STARTONLY
The listener is to be started at the same time as the queue manager is started, but is not requested to stop when the queue manager is stopped.

DESCR(*string*)
Plain-text comment. It provides descriptive information about the listener when an operator issues the **DISPLAY LISTENER** command (see “DISPLAY LISTENER (display listener information) on Multiplatforms” on page 724).

It should contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

IPADDR(*string*)
IP address for the listener specified in IPv4 dotted decimal, IPv6 hexadecimal notation, or alphanumeric host name form. If you do not specify a value for this parameter, the listener listens on all configured IPv4 and IPv6 stacks.

LIKE(*listener-name*)
The name of a listener, with parameters that are used to model this definition.

This parameter applies only to the **DEFINE LISTENER** command.

If this field is not filled in, and you do not complete the parameter fields related to the command, the values are taken from the default definition for listeners on this queue manager. This is equivalent to specifying:

```
LIKE(SYSTEM.DEFAULT.LISTENER)
```

A default listener is provided but it can be altered by the installation of the default values required. See Rules for naming IBM MQ objects.

Windows **LOCLNAME(*string*)**
The NetBIOS local name that the listener uses. This parameter is valid only on Windows when **TRPTYPE** is NETBIOS.

Windows **NTBNAMES(*integer*)**
The number of names that the listener can use. This parameter is valid only on Windows when **TRPTYPE** is NETBIOS.

PORT(*integer*)
The port number for TCP/IP. This is valid only when TRPTYPE is TCP. It must not exceed 65535.

Windows **SESSIONS(*integer*)**
The number of sessions that the listener can use. This parameter is valid only on Windows when **TRPTYPE** is NETBIOS.

SOCKET(*integer*)
The SPX socket on which to listen. This is valid only if **TRPTYPE** is SPX.

Windows **TPNAME(*string*)**
The LU 6.2 transaction program name (maximum length 64 characters). This parameter is valid only on Windows when **TRPTYPE** is LU62.

TRPTYPE(*string*)
The transmission protocol to be used:

Windows **LU62**
SNA LU 6.2. This is valid only on Windows.

Windows **NETBIOS**
NetBIOS. This is valid only on Windows.

Windows **SPX**
Sequenced packet exchange. This is valid only on Windows.

TCP
TCP/IP.

z/OS DEFINE LOG (define a new active log) on z/OS

Use the MQSC command DEFINE LOG to add a new active log data set in the ring of active logs.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

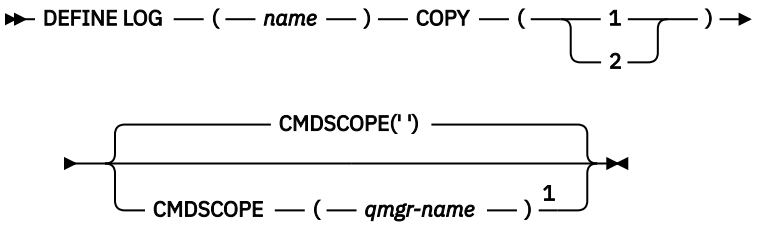
You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

The named data set is dynamically allocated to the running queue manager, added to either the COPY1 or COPY2 active log and the BSDS updated with the information so it is retained over a queue manager restart. The data set is added to the active log ring in a position such that it will be switched to after the last-added active log fills.

- Syntax diagram
- "Usage note for DEFINE LOG" on page 516
- "Parameter descriptions for DEFINE LOG" on page 516

Synonym: DEF LOG

DEFINE LOG



Notes:

[1] Valid only when the queue manager is a member of a queue sharing group.

Usage note for DEFINE LOG

If a log data set has to be added because there is no more log space and the queue manager is waiting, you must issue the command from the z/OS console, and not through the command server.

Parameter descriptions for DEFINE LOG

(name)

The name of the new log data set. This is required and is the name of a VSAM linear data set which will have already been defined by Access Method Services (and, optionally, formatted by utility CSQJUFMT). This is allocated dynamically to the queue manager.

The maximum length of the string is 44 characters. The string must conform to z/OS data set naming conventions.

COPY

Specifies the number of an active log ring to which to add the new log data set. This is either 1 or 2 and is required.

CMDSCOPE

This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

' '

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

z/OS DEFINE MAXSMSGS (define maximum messages setting) on z/OS

Use the MQSC command DEFINE MAXSMSGS to define the maximum number of messages that a task can get or put within a single unit of recovery.

Using MQSC commands

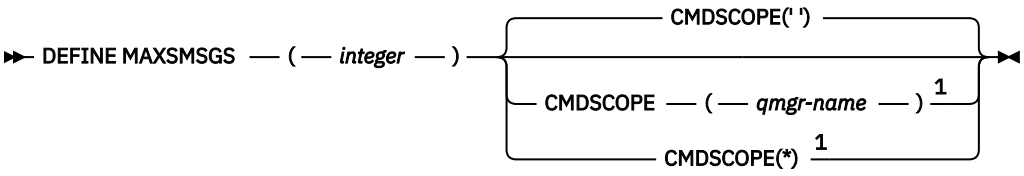
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Usage notes" on page 517
- "Parameter descriptions for DEFINE MAXSMSGS" on page 517

Synonym: DEF MAXSM

DEFINE MAXSMSGS



Notes:

1 Valid only when the queue manager is a member of a queue sharing group.

Usage notes

1. This command is valid only on z/OS and is retained for compatibility with earlier releases, although it can no longer be issued from the CSQINP1 initialization input data set. You should use the MAXUMSGS parameter of the ALTER QMGR command instead.
2. You can issue the DEFINE MAXSMSGS command to change the number of messages allowed. Once a value is set, it is preserved during a queue manager restart.

Parameter descriptions for DEFINE MAXSMSGS

(integer)
The maximum number of messages that a task can get or put within a single unit of recovery. This value must be an integer in the range 1 through 999999999. The default value is 10000.

The number includes any trigger messages and report messages generated within the same unit of recovery.

CMDSCOPE
This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

*
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

DEFINE NAMELIST (define a list of names)

Use the MQSC command **DEFINE NAMELIST** to define a list of names. This is most commonly a list of cluster names or queue names.

Using MQSC commands

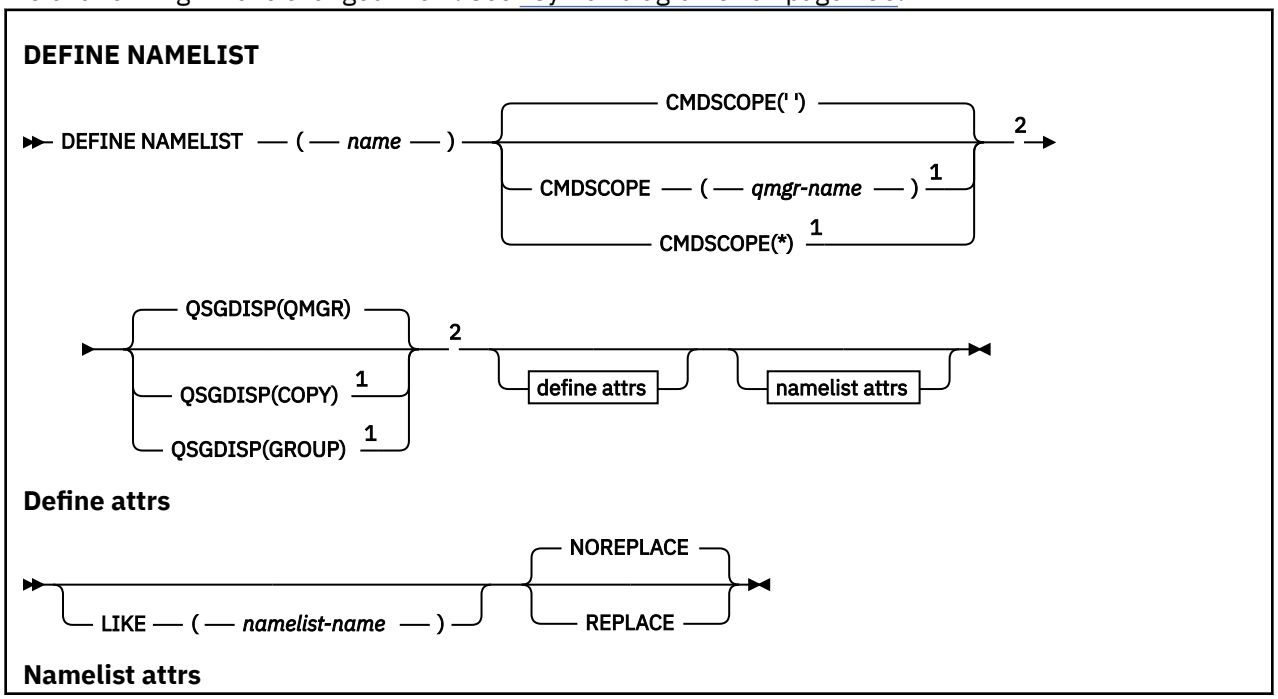
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

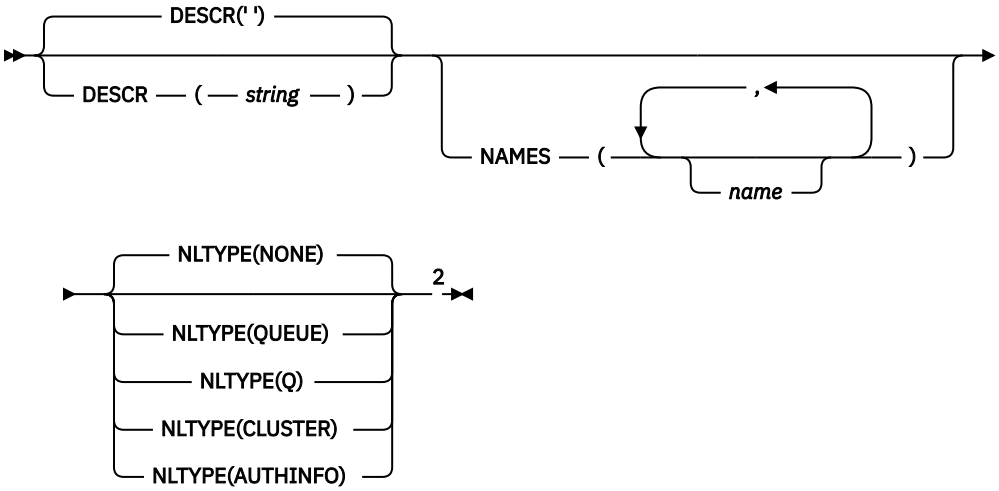
z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Usage notes" on page 519
- "Parameter descriptions for DEFINE NAMELIST" on page 519

Synonym: DEF NL

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See "Syntax diagrams" on page 236.





Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[2] Valid only on z/OS.

Usage notes

Successful completion of the command does not mean that the action completed. To check for true completion, see the DEFINE NAMELIST step in Checking that async commands for distributed networks have finished.

Parameter descriptions for DEFINE NAMELIST

(name)
Name of the list.

The name must not be the same as any other namelist name currently defined on this queue manager (unless REPLACE or ALTER is specified). See Rules for naming IBM MQ objects.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

' '
The command runs on the queue manager on which it was entered.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of specifying * is the same as entering the command on every queue manager in the queue sharing group.

DESCR(*string*)
Plain-text comment. It provides descriptive information about the namelist when an operator issues the **DISPLAY NAMELIST** command (see “DISPLAY NAMELIST (display a list of names)” on page 733).

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

LIKE(*namelist-name*)
The name of a namelist, with parameters that are used to model this definition.

If this field is not completed and you do not complete the parameter fields related to the command, the values are taken from the default definition for namelists on this queue manager.

Not completing this parameter is equivalent to specifying:

```
LIKE(SYSTEM.DEFAULT.NAMELIST)
```

A default namelist definition is provided, but it can be altered by the installation to the default values required. See Rules for naming IBM MQ objects.

z/OS On z/OS, the queue manager searches page set zero for an object with the name you specify and a disposition of QMGR or COPY. The disposition of the LIKE object is not copied to the object you are defining.

Note:

1. QSGDISP (GROUP) objects are not searched.
2. LIKE is ignored if QSGDISP(COPY) is specified.

NAMES(*name, ...*)
List of names.

The names can be of any type, but must conform to the rules for naming IBM MQ objects, with a maximum length of 48 characters.

An empty list is valid: specify NAMES( ). The maximum number of names in the list is 256.

z/OS **NLTYPE**
Indicates the type of names in the namelist.

This parameter is valid only on z/OS.

NONE
The names are of no particular type.

QUEUE or Q
A namelist that holds a list of queue names.

CLUSTER
A namelist that is associated with clustering, containing a list of the cluster names.

AUTHINFO
This namelist is associated with TLS and contains a list of authentication information object names.

Namelists used for clustering must have NLTYPE(CLUSTER) or NLTYPE(NONE).

Namelists used for TLS must have NLTYPE(AUTHINFO).

z/OS **QSGDISP**
This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

*Table 153. Object dispositions for **QSGDISP** options*	
QSGDISP	**DEFINE**

COPY	The object is defined on the page set of the queue manager that executes the command. It uses the **QSGDISP(GROUP)** object of the same name as the LIKE object.
	For example, if you issue the following command,
	`DEFINE NAMELIST(namelist_name)`
	`REPLACE QSGDISP(COPY)`
	the queue manager searches the shared configuration repository for a NAMELIST definition called *namelist_name*. If a matching NAMELIST definition is found, the queue manager creates a local copy of this definition on the queue manager page set.
	For local queues, messages are stored on the page sets of each queue manager and are available only through that queue manager.

GROUP	The object definition resides in the shared configuration repository. **QSGDISP(GROUP)** is allowed only if the queue manager is in a queue sharing group. If the DEFINE for the **QSGDISP(GROUP)** object is successful, the DEFINE NAMELIST(*namelist_name*) REPLACE QSGDISP(COPY) command is generated and sent to all active queue managers in the queue sharing group to make or refresh local copies on page set zero. The DEFINE for the group object takes effect regardless of whether the generated command with **QSGDISP(COPY)** fails.
PRIVATE	Not permitted.
QMGR	The object is defined on the page set of the queue manager that executes the command.

REPLACE and NOREPLACE

Whether the existing definition (and on z/OS, with the same disposition) is to be replaced with this one. Any object with a different disposition is not changed.

REPLACE

The definition replaces any existing definition of the same name. If a definition does not exist, one is created.

NOREPLACE

The definition does not replace any existing definition of the same name.

Related concepts

Namelists

Related tasks

Adding a new, interconnected cluster

DEFINE PROCESS (create a new process definition)

Use the MQSC command DEFINE PROCESS to define a new IBM MQ, process definition, and set its parameters.

Using MQSC commands

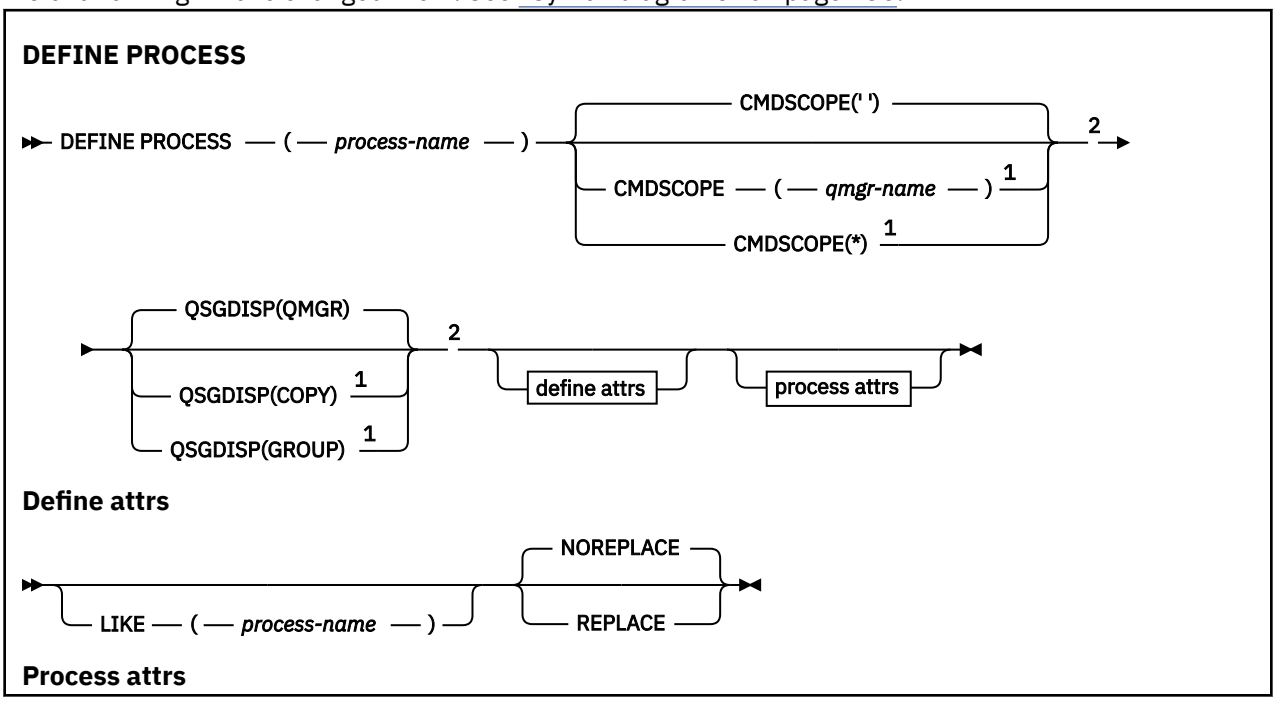
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

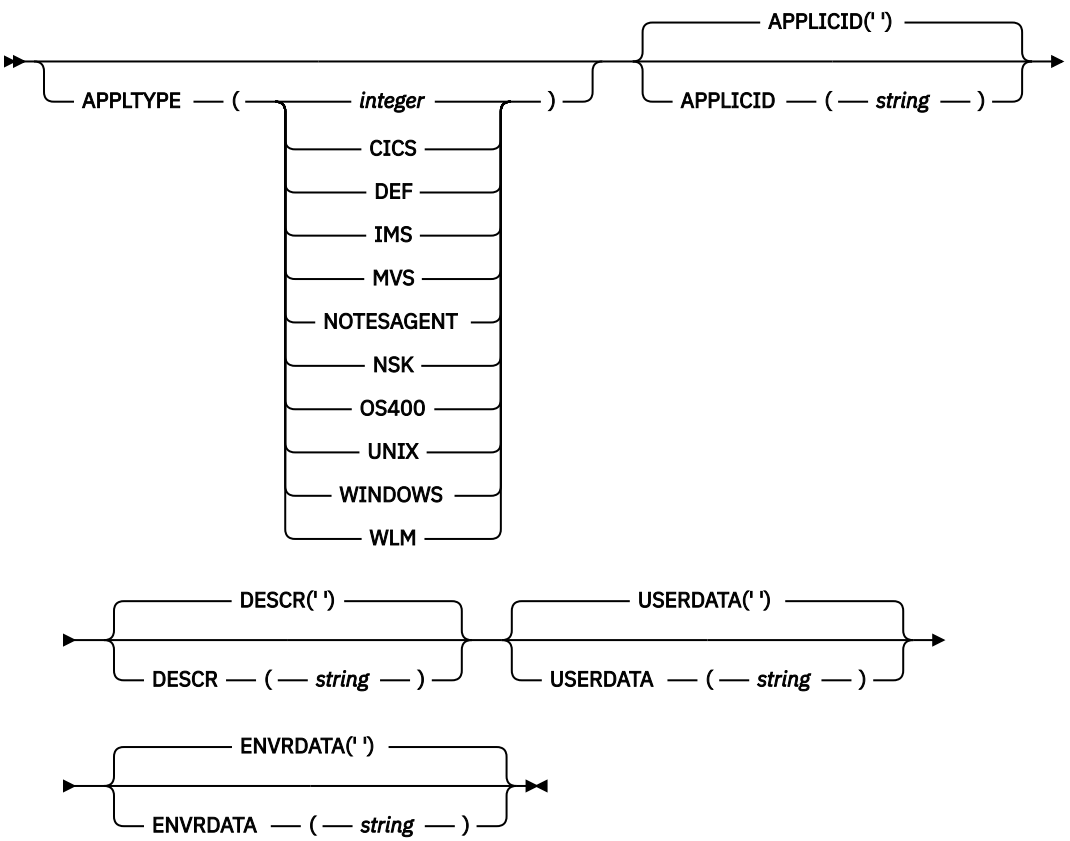
z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Parameter descriptions for DEFINE PROCESS" on page 523

Synonym: DEF PRO

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See "Syntax diagrams" on page 236.





Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[2] Valid only on z/OS.
[3] The default depends on the platform, and can be changed by your installation.

Parameter descriptions for DEFINE PROCESS

(process-name)
Name of the IBM MQ process definition (see Rules for naming IBM MQ objects). *process-name* is required.

The name must not be the same as any other process definition currently defined on this queue manager (unless REPLACE is specified).

APPLICID(*string*)
The name of the application to be started. The name might typically be a fully qualified file name of an executable object. Qualifying the file name is particularly important if you have multiple IBM MQ installations, to ensure the correct version of the application is run. The maximum length is 256 characters.

For a CICS application the name is a CICS transaction ID.

z/OS For an IMS application, it is an IMS transaction ID.

z/OS On z/OS, for distributed queuing, it must be **CSQX START**.

APPLTYPE(*string*)
The type of application to be started. Valid application types are:

integer
A system-defined application type in the range zero through 65 535 or a user-defined application type in the range 65 536 through 999 999 999.

For certain values in the system range, a parameter from the following list can be specified instead of a numeric value:

CICS
Represents a CICS transaction.

z/OS **IMS**
Represents an IMS transaction.

z/OS **MVS**
Represents a z/OS application (batch or TSO).

NOTESAGENT
Represents a Lotus Notes agent.

IBM i **OS400**
Represents an IBM i application.

UNIX
Represents a Linux or AIX application.

WINDOWS
Represents a Windows application.

z/OS **WLM**
Represents a z/OS workload manager application.

DEF
Specifying DEF causes the default application type for the platform at which the command is interpreted to be stored in the process definition. This default cannot be changed by the installation. If the platform supports clients, the default is interpreted as the default application type of the server.

Only use application types (other than user-defined types) that are supported on the platform at which the command is run:

- z/OS On z/OS, CICS, IMS, MVS, UNIX, WINDOWS, WLM, and DEF are supported.
- IBM i On IBM i, OS400, CICS, and DEF are supported.
- AIX On AIX and Linux, UNIX, WINDOWS, CICS, and DEF are supported.
- Windows On Windows, WINDOWS, UNIX, CICS, and DEF are supported.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' '
The command runs on the queue manager on which it was entered.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

In a shared queue environment, you can provide a different queue manager name from the one you are using to enter the command. The command server must be enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect is the same as entering the command on every queue manager in the queue sharing group.

DESCR(***string*** **)**
Plain-text comment. It provides descriptive information about the object when an operator issues the DISPLAY PROCESS command.

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: Use characters from the coded character set identifier (CCSID) for this queue manager. Other characters might be translated incorrectly if the information is sent to another queue manager.

ENVRDATA(***string*** **)**
A character string that contains environment information pertaining to the application to be started. The maximum length is 128 characters.

The meaning of ENVRDATA is determined by the trigger-monitor application. The trigger monitor provided by IBM MQ appends ENVRDATA to the parameter list passed to the started application. The parameter list consists of the MQTMC2 structure, followed by one blank, followed by ENVRDATA with trailing blanks removed.

Notes:

1. z/OS On z/OS, ENVRDATA is not used by the trigger-monitor applications provided by IBM MQ.
2. z/OS On z/OS, if APPLTYPE is WLM, the default values for the ServiceName and ServiceStep fields in the work information header (MQWIH) can be supplied in ENVRDATA. The format must be:

   ```
   SERVICENAME=servname,SERVICESTEP=stepname
   ```

   where:

   SERVICENAME=
   is the first 12 characters of ENVRDATA.

   servname
   is a 32-character service name. It can contain embedded blanks or any other data, and have trailing blanks. It is copied to the MQWIH as is.

   SERVICESTEP=
   is the next 13 characters of ENVRDATA.

   stepname
   is a 1 - 8 character service step name. It is copied as-is to the MQWIH, and padded to eight characters with blanks.

   If the format is incorrect, the fields in the MQWIH are set to blanks.
3. On AIX and Linux, ENVRDATA can be set to the ampersand character to make the started application run in the background.

LIKE(***process-name*** **)**
The name of an object of the same type, with parameters that are used to model this definition.

If this field is not provided, the values of fields you do not provide are taken from the default definition for this object.

Using LIKE is equivalent to specifying:

```
LIKE(SYSTEM.DEFAULT.PROCESS)
```

A default definition for each object type is provided. You can alter the provided defaults to the default values required. See Rules for naming IBM MQ objects.

z/OS On z/OS, the queue manager searches page set zero for an object with the name you specify and a disposition of QMGR or COPY. The disposition of the LIKE object is not copied to the object you are defining.

Note:

1. QSGDISP (GROUP) objects are not searched.
2. LIKE is ignored if QSGDISP(COPY) is specified.

z/OS QSGDISP

This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

*Table 154. Object dispositions for **QSGDISP** options*

QSGDISP	**DEFINE**

COPY	The object is defined on the page set of the queue manager that executes the command. It uses the **QSGDISP(GROUP)** object of the same name as the LIKE object.
	For example, if you issue the following command,
	`DEFINE PROCESS(process_name)`
	`REPLACE QSGDISP(COPY)`
	the queue manager searches the shared configuration repository for a PROCESS definition called *process_name*. If a matching PROCESS definition is found, the queue manager creates a local copy of this definition on the queue manager page set.
	For local queues, messages are stored on the page sets of each queue manager and are available only through that queue manager.

GROUP	The object definition resides in the shared configuration repository. **QSGDISP(GROUP)** is allowed only if the queue manager is in a queue sharing group. If the DEFINE for the **QSGDISP(GROUP)** object is successful, the DEFINE PROCESS(*process_name*) REPLACE QSGDISP(COPY) command is generated and sent to all active queue managers in the queue sharing group to make or refresh local copies on page set zero. The DEFINE for the group object takes effect regardless of whether the generated command with **QSGDISP(COPY)** fails.
PRIVATE	Not permitted.
QMGR	The object is defined on the page set of the queue manager that executes the command.

REPLACE and NOREPLACE

Whether the existing definition z/OS (and on z/OS, with the same disposition) is to be replaced with this one. REPLACE is optional. Any object with a different disposition is not changed.

REPLACE
The definition replaces any existing definition of the same name. If a definition does not exist, one is created.

NOREPLACE
The definition does not replace any existing definition of the same name.

USERDATA(***string*** **)**
A character string that contains user information pertaining to the application defined in the APPLICID that is to be started. The maximum length is 128 characters.

The meaning of USERDATA is determined by the trigger-monitor application. The trigger monitor provided by IBM MQ simply passes USERDATA to the started application as part of the parameter list. The parameter list consists of the MQTMC2 structure (containing USERDATA), followed by one blank, followed by ENVRDATA with trailing blanks removed.

For IBM MQ message channel agents, the format of this field is a channel name of up to 20 characters. See Managing objects for triggering for information about what APPLICID to provide to message channel agents.

For Microsoft Windows, the character string must not contain double quotation marks if the process definition is going to be passed to **runmqtrm**.

z/OS DEFINE PSID (define page set and buffer pool) on z/OS

Use the MQSC command DEFINE PSID to define a page set and associated buffer pool.

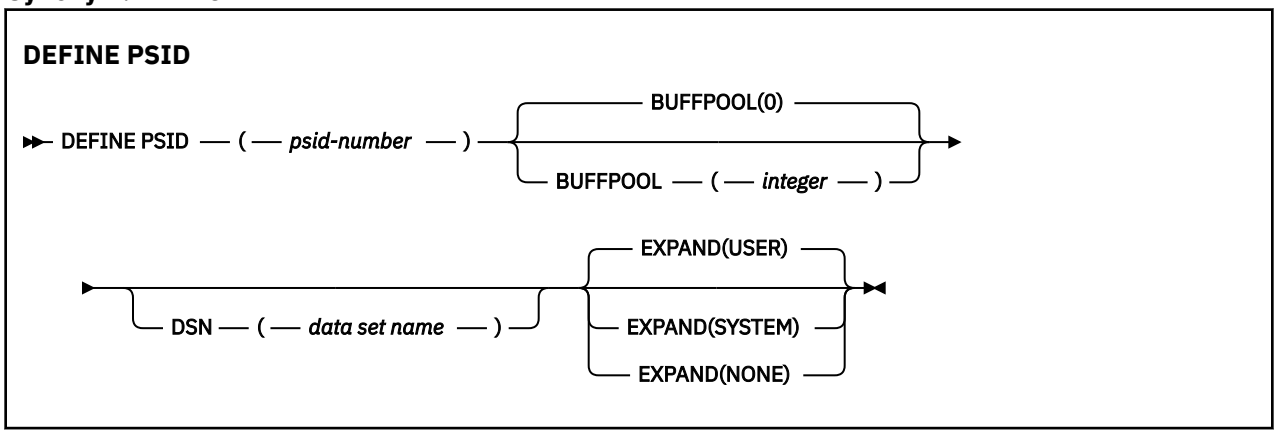
Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 1CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Usage notes for DEFINE PSID" on page 527
- "Parameter descriptions for DEFINE PSID" on page 528

Synonym: DEF PSID



Usage notes for DEFINE PSID

The command can be used in two ways:

1. **At restart, from the CSQINP1 initialization input data set, to specify your standard page sets:**
   - You cannot specify the DSN keyword if issuing the command from CSQINP1.

- If more than one DEFINE PSID command is issued for the same page set, only the last one is processed.

2. **While the queue manager is running, to dynamically add a page set:**
   - The command must specify the DSN keyword and can be issued from either of the following:
     - The z/OS console.
     - The command server and command queue by means of CSQUTIL, CSQINPX, or applications.
   - The page set identifier (that is the PSID number) may have previously been used by a queue manager. It should therefore be freshly formatted by a FORMAT(RECOVER) statement in CSQUTIL, or formatted by with a FORMAT(REPLACE) in CSQUTIL.
   - You cannot dynamically add page set zero.
   - The BUFFPOOL parameter can specify a currently unused buffer pool. If the buffer pool was defined in CSQINP1 but not used by any PSID, then the number of buffers specified there is created if the required virtual storage is available. If this is not available, or if the buffer pool was not defined in CSQINP1, the queue manager attempts to allocate 1000 buffers. If this is not possible, 100 buffers are allocated.
   - You should update your queue manager started task procedure JCL and your CSQINP1 initialization input data set to include the new page set.

One of the messages CSQP042I or CSQP041E is output when the command is complete.

You must use the ALTER PSID command to dynamically change the expansion method. For example, to change the EXPAND parameter from USER to SYSTEM, issue the following command:

```
ALTER PSID(page set id) EXPAND(SYSTEM)
```

You can use the DISPLAY USAGE TYPE(PAGESET) command to display information about page sets (see "DISPLAY USAGE (display usage information) on z/OS" on page 849).

Parameter descriptions for DEFINE PSID

(psid-number)
Identifier of the page set. This is required.

A one-to-one relationship exists between page sets and the VSAM data sets used to store the pages. The identifier consists of a number in the range 00 through 99. It is used to generate a *ddname*, which references the VSAM LDS data set, in the range CSQP0000 through CSQP0099.

The identifier must not be the same as any other page set identifier currently defined on this queue manager.

BUFFPOOL(*integer*)
The buffer pool number is in the range zero through 99. This is optional. The default is zero.

If the buffer pool has not already been created by a DEFINE BUFFPOOL command, the buffer pool is created with 1000 buffers, and a LOCATION value of BELOW.

If the psid-number is zero, the buffer pool number must be in the range 0 to 15, otherwise the command fails, and the queue manager does not start.

DSN(*data set name*)
The name of a cataloged VSAM LDS data set. This is optional. There is no default.

EXPAND
Controls how the queue manager should expand a page set when it becomes nearly full, and further pages are required in a page set.

USER
The secondary extent size that was specified when the page set was defined is used. If no secondary extent size was specified, or it was specified as zero, no dynamic page set expansion can take place if page set data set is non-striped.

At restart, if a previously used page set has been replaced with a data set that is smaller, it is expanded until it reaches the size of the previously used data set. Only one extent is required to reach this size.

SYSTEM

A secondary extent size that is approximately 10 per cent of the current size of the page set is used. It can be rounded up depending on the characteristics of the DASD.

NONE

No further page set expansion is to take place.

DEFINE queues

Use the MQSC **DEFINE** command to define a local, model, or remote queue, or a queue alias, reply-to queue alias, or a queue manager alias.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- "Syntax diagrams for DEFINE queues" on page 529
- "Usage notes for DEFINE queues" on page 529
- "Parameter descriptions for DEFINE QUEUE and ALTER QUEUE" on page 530

Syntax diagrams for DEFINE queues

There is a separate syntax diagram for each type of queue:

- Syntax diagram for DEFINE QALIAS
- Syntax diagram for DEFINE QLOCAL
- Syntax diagram for DEFINE QMODEL
- Syntax diagram for DEFINE QREMOTE

Usage notes for DEFINE queues

- Successful completion of the command does not mean that the action completed. To check for true completion, see the DEFINE queues step in Checking that async commands for distributed networks have finished.
- For local queues

1. z/OS You can define a local queue with QSGDISP(SHARED) even though another queue manager in the queue sharing group already has a local version of the queue. However, when you try to access the locally defined queue, it fails with reason code MQRC_OBJECT_NOT_UNIQUE (2343). A local version of the queue with the same name can be of type QLOCAL, QREMOTE, or QALIAS and has the disposition, QSGDISP(QMGR).

   To resolve the conflict, you must delete one of the queues using the **DELETE** command. If the queue you want to delete contains messages, use the PURGE option or remove the messages first using the **MOVE** command.

   For example, to delete the QSGDISP(LOCAL) version, which contains messages, and copy those messages to the QSGDISP(SHARED) version, then issue the following commands:

```
MOVE QLOCAL(QUEUE.1) QSGDISP(PRIVATE) TOQLOCAL(QUEUE.1) TYPE(ADD)
DELETE QLOCAL(QUEUE.1) QSGDISP(QMGR)
```

- For alias queues:
  1. DEFINE QALIAS(*aliasqueue*) TARGET(*otherqname*) CLUSTER(*c*) advertises the queue *otherqname* by the name *aliasqueue*.
  2. DEFINE QALIAS(*aliasqueue*) TARGET(*otherqname*) allows a queue advertised by the name *otherqname* to be used on this queue manager by the name *aliasqueue*.
  3. TARGTYPE and TARGET are not cluster attributes, that is, they are not shared in a cluster environment.
- For remote queues:
  1. DEFINE QREMOTE(*rqueue*) RNAME(*otherq*) RQMNAME(*otherqm*) CLUSTER(*cl*) advertises this queue manager as a store and forward gateway to which messages for queue *rqueue* can be sent. It has no effect as a reply-to queue alias, except on the local queue manager.

     DEFINE QREMOTE(*otherqm*) RNAME() RQMNAME(*anotherqm*) XMITQ(*xq*) CLUSTER advertises this queue manager as a store and forward gateway to which messages for *anotherqm* can be sent.
  2. RQMNAME can itself be the name of a cluster queue manager within the cluster. You can map the advertised queue manager name to another name locally. The pattern is the same as with QALIAS definitions.
  3. It is possible for the values of RQMNAME and QREMOTE to be the same if RQMNAME is itself a cluster queue manager. If this definition is also advertised using a CLUSTER attribute, do not choose the local queue manager in the cluster workload exit. If you do so, a cyclic definition results.
  4. Remote queues do not have to be defined locally. The advantage of doing so is that applications can refer to the queue by a simple, locally defined name. If you do then the queue name is qualified by the name of the queue manager on which the queue resides. Using a local definition means that applications do not need to be aware of the real location of the queue.
  5. A remote queue definition can also be used as a mechanism for holding a queue manager alias definition, or a reply-to queue alias definition. The name of the definition in these cases is:
     - The queue manager name being used as the alias for another queue manager name (queue manager alias), or
     - The queue name being used as the alias for the reply-to queue (reply-to queue alias).
  6. Define a reply-to queue or queue manager alias with the "DEFINE QREMOTE (create local definition of a remote queue)" on page 562 command.

Parameter descriptions for DEFINE QUEUE and ALTER QUEUE

Table 155 on page 530 shows the parameters that are relevant for each type of queue. There is a description of each parameter after the table.

queue-name
Local name of the queue, except the remote queue where it is the local definition of the remote queue.

See Rules for naming IBM MQ objects.

ACCTQ
Specifies whether accounting data collection is to be enabled for the queue. On z/OS, the data collected is class 3 accounting data (thread-level and queue-level accounting). In order for accounting data to be collected for this queue, accounting data for this connection must also be enabled. Turn on accounting data collection by setting either the **ACCTQ** queue manager attribute, or the options field in the MQCNO structure on the MQCONNX call.

QMGR
The collection of accounting data is based on the setting of the **ACCTQ** parameter on the queue manager definition.

ON
Accounting data collection is enabled for the queue unless the **ACCTQ** queue manager parameter has a value of NONE.

z/OS On z/OS systems, you must enable class 3 accounting using the **START TRACE** command.

OFF
Accounting data collection is disabled for the queue.

BOQNAME (*queue-name*)
The excessive backout requeue name.

This parameter is supported only on local and model queues.

Use this parameter to set or change the back out queue name attribute of a local or model queue. Apart from allowing its value to be queried, the queue manager does nothing based on the value of this attribute. IBM MQ classes for JMS transfers a message that is backed out the maximum number of times to this queue. The maximum is specified by the **BOTHRESH** attribute.

BOTHRESH(*integer*)
The backout threshold.

This parameter is supported only on local and model queues.

Use this parameter to set or change the value of the back out threshold attribute of a local or model queue. Apart from allowing its value to be queried, the queue manager does nothing based on the value of this attribute. IBM MQ classes for JMS use the attribute to determine how many times to allow a message to be backed out. When the value is exceeded, the message is transferred to the queue named by the **BOQNAME** attribute.

Specify a value in the range 0 - 999,999,999.

z/OS **CFSTRUCT(*structure-name*)**
Specifies the name of the coupling facility structure where you want messages stored when you use shared queues.

This parameter is supported only on z/OS for local and model queues.

The name:

- Cannot have more than 12 characters
- Must start with an uppercase letter (A - Z)
- Can include only the characters A - Z and 0 - 9

The name of the queue sharing group to which the queue manager is connected is prefixed to the name you supply. The name of the queue sharing group is always four characters, padded with @ symbols if necessary. For example, if you use a queue sharing group named NY03 and you supply the name PRODUCT7, the resultant coupling facility structure name is NY03PRODUCT7. The administrative structure for the queue sharing group (in this case NY03CSQ_ADMIN) cannot be used for storing messages.

For **ALTER QLOCAL**, **ALTER QMODEL**, **DEFINE QLOCAL** with **REPLACE**, and **DEFINE QMODEL** with **REPLACE** the following rules apply:

- On a local queue with **QSGDISP**(SHARED), **CFSTRUCT** cannot change.
- If you change either the **CFSTRUCT** or **QSGDISP** value you must delete and redefine the queue. To preserve any of the messages on the queue you must offload the messages before you delete the queue. Reload the messages after you redefine the queue, or move the messages to another queue.
- On a model queue with **DEFTYPE**(SHAREDYN), **CFSTRUCT** cannot be blank.
- On a local queue with a **QSGDISP** other than SHARED, or a model queue with a **DEFTYPE** other than SHAREDYN, the value of **CFSTRUCT** does not matter.

For **DEFINE QLOCAL** with **NOREPLACE** and **DEFINE QMODEL** with **NOREPLACE**, the coupling facility structure:

- On a local queue with **QSGDISP**(SHARED) or a model queue with a **DEFTYPE**(SHAREDYN), **CFSTRUCT** cannot be blank.
- On a local queue with a **QSGDISP** other than SHARED, or a model queue with a **DEFTYPE** other than SHAREDYN, the value of **CFSTRUCT** does not matter.

Note: Before you can use the queue, the structure must be defined in the coupling facility Resource Management (CFRM) policy data set.

CLCHNAME(*channel name*)

This parameter is supported only on transmission queues.

CLCHNAME is the generic name of the cluster-sender channels that use this queue as a transmission queue. The attribute specifies which cluster-sender channels send messages to a cluster-receiver channel from this cluster transmission queue.

You can also set the transmission queue attribute **CLCHNAME** attribute to a cluster-sender channel manually. Messages that are destined for the queue manager connected by the cluster-sender channel are stored in the transmission queue that identifies the cluster-sender channel. They are not stored in the default cluster transmission queue. If you set the **CLCHNAME** attribute to blanks, the channel switches to the default cluster transmission queue when the channel restarts. The default queue is either SYSTEM.CLUSTER.TRANSMIT.*ChannelName* or SYSTEM.CLUSTER.TRANSMIT.QUEUE, depending on the value of the queue manager **DEFCLXQ** attribute.

By specifying asterisks, "" * "", in **CLCHNAME**, you can associate a transmission queue with a set of cluster-sender channels. The asterisks can be at the beginning, end, or any number of places in the middle of the channel name string. **CLCHNAME** is limited to a length of 48 characters, MQ_OBJECT_NAME_LENGTH. A channel name is limited to 20 characters: MQ_CHANNEL_NAME_LENGTH. If you specify an asterisk you must also set the SHARE attribute so that multiple channels can concurrently access the transmission queue.

z/OS If you specify a "*" in **CLCHNAME**, to obtain a channel profile name, you must specify the channel profile name within quotation marks. If you do not specify the generic channel name within quotation marks you receive message CSQ9030E.

The default queue manager configuration is for all cluster-sender channels to send messages from a single transmission queue, SYSTEM.CLUSTER.TRANSMIT.QUEUE. The default configuration can be modified by changing the queue manager attribute, **DEFCLXQ**. The default value of the attribute is SCTQ. You can change the value to CHANNEL. If you set the **DEFCLXQ** attribute to CHANNEL, each cluster-sender channel defaults to using a specific cluster transmission queue, SYSTEM.CLUSTER.TRANSMIT.*ChannelName*.

z/OS On z/OS, if this parameter is set, the queue:

- Must be shareable, by specifying the queue attribute SHARE.
- Must be indexed on the correlation ID by specifying INDXTYPE(CORRELID).
- Must not be a dynamic or a shared queue.

z/OS ALW **CLUSNL(*namelist name*)**

The name of the namelist that specifies a list of clusters to which the queue belongs.

This parameter is supported only on alias, local, and remote queues.

Changes to this parameter do not affect instances of the queue that are already open.

Only one of the resultant values of **CLUSNL** or **CLUSTER** can be non-blank; you cannot specify a value for both.

On local queues, this parameter cannot be set for the following queues:

- Transmission queues
- SYSTEM.CHANNEL.*xx* queues
- SYSTEM.CLUSTER.*xx* queues
- SYSTEM.COMMAND.*xx* queues
- z/OS On z/OS only, SYSTEM.QSG.*xx* queues

This parameter is valid only on the following platforms:

- AIX, Linux, and Windows
- z/OS

z/OS ALW **CLUSTER(*cluster name*)**

The name of the cluster to which the queue belongs.

This parameter is supported only on alias, local, and remote queues.

The maximum length is 48 characters conforming to the rules for naming IBM MQ objects. Changes to this parameter do not affect instances of the queue that are already open.

Only one of the resultant values of **CLUSNL** or **CLUSTER** can be non-blank; you cannot specify a value for both.

On local queues, this parameter cannot be set for the following queues:

- Transmission queues
- SYSTEM.CHANNEL.*xx* queues
- SYSTEM.CLUSTER.*xx* queues
- SYSTEM.COMMAND.*xx* queues
- z/OS On z/OS only, SYSTEM.QSG.*xx* queues

This parameter is valid only on the following platforms:

- AIX, Linux, and Windows
- z/OS

CLWLPRTY(*integer*)
Specifies the priority of the queue for the purposes of cluster workload distribution. This parameter is valid only for local, remote, and alias queues. The value must be in the range zero through 9 where zero is the lowest priority and 9 is the highest. For more information about this attribute, see CLWLPRTY queue attribute.

CLWLRANK (*integer*)
Specifies the rank of the queue for the purposes of cluster workload distribution. This parameter is valid only for local, remote, and alias queues. The value must be in the range zero through 9 where zero is the lowest rank and 9 is the highest. For more information about this attribute, see CLWLRANK queue attribute.

CLWLUSEQ
Specifies the behavior of an MQPUT operation when the target queue has a local instance and at least one remote cluster instance. The parameter has no effect when the MQPUT originates from a cluster channel. This parameter is valid only for local queues.

QMGR
The behavior is as specified by the **CLWLUSEQ** parameter of the queue manager definition.

ANY
The queue manager is to treat the local queue as another instance of the cluster queue for the purposes of workload distribution.

LOCAL
The local queue is the only target of the MQPUT operation.

z/OS **CMDSCOPE**
This parameter applies to z/OS only. It specifies where the command is run when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP or SHARED.

''
The command runs on the queue manager on which it was entered.

QmgrName
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered. You can specify another name, only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of * is the same as entering the command on every queue manager in the queue sharing group.

CUSTOM(*string*)
The custom attribute for new features.

This attribute contains the values of attributes, as pairs of attribute name and value, separated by at least one space. The attribute name-value pairs have the form NAME(VALUE).

The maximum length is defined by the IBM MQ constant MQ_CUSTOM_LENGTH and is currently set to 128 on all platforms.

The CUSTOM attribute is intended to be used with the following IBM MQ attribute.

CAPEXPRY(*integer*)
The maximum time, expressed in tenths of a second, until a message put using an object handle with this object in the resolution path, becomes eligible for expiry processing.

For more information on message expiry processing, see Enforcing lower expiration times.

integer
The value must be in the range one through to 999 999 999.

NOLIMIT
There is no limit on the expiry time of messages put using this object. This is the default value.

Specifying a value for **CAPEXPRY** that is not valid, does not cause the command to fail. Instead the default value is used.

Note that existing messages in the queue, prior to a change in **CAPEXPRY**, are not affected by the change (that is, their expiry time remains intact). Only new messages that are put into the queue after the change in **CAPEXPRY** have the new expiry time.

DEFBIND
Specifies the binding to be used when the application specifies MQOO_BIND_AS_Q_DEF on the MQOPEN call, and the queue is a cluster queue.

OPEN
The queue handle is bound to a specific instance of the cluster queue when the queue is opened.

NOTFIXED
The queue handle is not bound to any instance of the cluster queue. The queue manager selects a specific queue instance when the message is put using MQPUT. It changes that selection later, if the need arises.

GROUP
Allows an application to request that a group of messages is allocated to the same destination instance.

Multiple queues with the same name can be advertised in a queue manager cluster. An application can send all messages to a single instance, MQOO_BIND_ON_OPEN. It can allow a workload management algorithm to select the most suitable destination on a per message basis, MQOO_BIND_NOT_FIXED. It can allow an application to request that a group of messages be all allocated to the same destination instance. The workload balancing reselects a destination between groups of messages, without requiring an MQCLOSE and MQOPEN of the queue.

The MQPUT1 call always behaves as if NOTFIXED is specified.

This parameter is valid on all platforms.

DEFPRESP
Specifies the behavior to be used by applications when the put response type, within the MQPMO options, is set to MQPMO_RESPONSE_AS_Q_DEF.

SYNC
Put operations to the queue specifying MQPMO_RESPONSE_AS_Q_DEF are issued as if MQPMO_SYNC_RESPONSE is specified instead.

ASYNC
Put operations to the queue specifying MQPMO_RESPONSE_AS_Q_DEF are issued as if MQPMO_ASYNC_RESPONSE is specified instead; see MQPMO options (MQLONG).

DEFPRTY(*integer*)
The default priority of messages put on the queue. The value must be in the range 0 - 9. Zero is the lowest priority, through to the **MAXPRTY** queue manager parameter. The default value of **MAXPRTY** is 9.

DEFPSIST
Specifies the message persistence to be used when applications specify the MQPER_PERSISTENCE_AS_Q_DEF option.

NO
Messages on this queue are lost across a restart of the queue manager.

YES
Messages on this queue survive a restart of the queue manager.

z/OS On z/OS, N and Y are accepted as synonyms of NO and YES.

DEFREADA
Specifies the default read ahead behavior for non-persistent messages delivered to the client. Enabling read ahead can improve the performance of client applications consuming non-persistent messages.

NO
Non-persistent messages are not read ahead unless the client application is configured to request read ahead.

YES
Non-persistent messages are sent to the client before an application requests them. Non-persistent messages can be lost if the client ends abnormally or if the client does not delete all the messages it is sent.

DISABLED
Read ahead of non-persistent messages in not enabled for this queue. Messages are not sent ahead to the client regardless of whether read ahead is requested by the client application.

DEFSOPT
The default share option for applications opening this queue for input:

EXCL
The open request is for exclusive input from the queue.

z/OS On z/OS, EXCL is the default value.

SHARED
The open request is for shared input from the queue.

Multi On Multiplatforms, SHARED is the default value.

DEFTYPE
Queue definition type.

This parameter is supported only on model queues.

PERMDYN
A permanent dynamic queue is created when an application issues an MQOPEN MQI call with the name of this model queue specified in the object descriptor (MQOD).

z/OS On z/OS, the dynamic queue has a disposition of QMGR.

z/OS **SHAREDYN**
This option is available on z/OS only.

A permanent dynamic queue is created when an application issues an MQOPEN API call with the name of this model queue specified in the object descriptor (MQOD).

The dynamic queue has a disposition of SHARED.

TEMPDYN
A temporary dynamic queue is created when an application issues an MQOPEN API call with the name of this model queue specified in the object descriptor (MQOD).

z/OS On z/OS, the dynamic queue has a disposition of QMGR.

z/OS Do not specify this value for a model queue definition with a **DEFPSIST** parameter of YES.

z/OS If you specify this option, do not specify **INDXTYPE**(MSGTOKEN).

DESCR(*string*)
Plain-text comment. It provides descriptive information about the object when an operator issues the **DISPLAY QUEUE** command.

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: Use characters that are in the coded character set identifier (CCSID) of this queue manager. If you do not do so and if the information is sent to another queue manager, they might be translated incorrectly.

ALW **DISTL**
Sets whether distribution lists are supported by the partner queue manager.

YES
Distribution lists are supported by the partner queue manager.

NO
Distribution lists are not supported by the partner queue manager.

Note: You do not normally change this parameter, because it is set by the MCA. However you can set this parameter when defining a transmission queue if the distribution list capability of the destination queue manager is known.

This parameter is valid only on AIX, Linux, and Windows.

FORCE
This parameter applies only to the **ALTER** command on alias, local and remote queues.

Specify this parameter to force completion of the command in the following circumstances.

For an alias queue, if both of the following statements are true:

- The **TARGET** parameter specifies a queue
- An application has this alias queue open

For a local queue, if both of the following statements are true:

- The **NOSHARE** parameter is specified
- More than one application has the queue open for input

FORCE is also needed if both of the following statements are true:

- The **USAGE** parameter is changed
- Either one or more messages are on the queue, or one or more applications have the queue open

Do not change the **USAGE** parameter while there are messages on the queue; the format of messages changes when they are put on a transmission queue.

For a remote queue, if both of the following statements are true:

- The **XMITQ** parameter is changed

- One or more applications has this queue open as a remote queue

FORCE is also needed if both of the following statements are true:

- Any of the **RNAME**, **RQMNAME**, or **XMITQ** parameters are changed
- One or more applications has a queue open that resolved through this definition as a queue manager alias

Note: FORCE is not required if this definition is in use as a reply-to queue alias only.

If **FORCE** is not specified in the circumstances described, the command is unsuccessful.

When you use the **ALTER QLOCAL** command with the **FORCE** parameter, IBM MQ force allows the changes with open handles on the queue. However, these existing open handles become invalid for some attributes and the next operation on these open handles will return the error message:

```
MQRC_OBJECT_CHANGED (2041)
```

Any of the following operations will fail with the error MQRC 2041:

- MQPUT
- MQGET
- MQINQ
- MQSET
- MQCTL
- MQCB

You can fix the applications that receive the error MQRC_OBJECT_CHANGED by the following steps:

1. Close the handle (MQCLOSE)
2. Reopen the object (MQOPEN) to select the new queue definition

GET
Specifies whether applications are to be permitted to get messages from this queue:

ENABLED
Messages can be retrieved from the queue, by suitably authorized applications.

DISABLED
Applications cannot retrieve messages from the queue.

This parameter can also be changed using the MQSET API call.

HARDENBO and NOHARDENBO
Specifies whether the count of the number of times that a message was backed out is hardened. When the count is hardened, the value of the **BackoutCount** field of the message descriptor is written to the log before the message is returned by an MQGET operation. Writing the value to the log ensures that the value is accurate across restarts of the queue manger.

This parameter is supported only on local and model queues.

When the backout count is hardened, the performance of MQGET operations for persistent messages on this queue is impacted.

HARDENBO
The message backout count for messages on this queue is hardened to ensure that the count is accurate.

NOHARDENBO
The message backout count for messages on this queue is not hardened and might not be accurate over queue manager restarts.

Note: z/OS This parameter affects only IBM MQ for z/OS. You can set this parameter on Multiplatforms but it is ineffective.

Multi **IMGRCOVQ**

Specifies whether a local or permanent dynamic queue object is recoverable from a media image, if linear logging is being used. Possible values are:

YES
These queue objects are recoverable.

NO
The “rcdmqimg (record media image)” on page 126 and“rcrmqobj (re-create object)” on page 129 commands are not permitted for these objects, and automatic media images, if enabled, are not written for these objects.

QMGR
If you specify QMGR, and the **IMGRCOVQ** attribute for the queue manager specifies YES, these queue objects are recoverable.

If you specify QMGR and the **IMGRCOVQ** attribute for the queue manager specifies NO, the “rcdmqimg (record media image)” on page 126 and“rcrmqobj (re-create object)” on page 129 commands are not permitted for these objects, and automatic media images, if enabled, are not written for these objects.

QMGR is the default value.

This parameter is not valid on z/OS.

z/OS **INDXTYPE**

The type of index maintained by the queue manager to expedite MQGET operations on the queue. For shared queues, the type of index determines the type of MQGET operations that can be used.

This parameter is supported only on z/OS.

This parameter is supported only on local and model queues.

Messages can be retrieved using a selection criterion only if an appropriate index type is maintained, as the following table shows:

Table 156. Index type required for different retrieval selection criteria

Retrieval selection criterion	**Index type required**	
	Shared queue	Other queue
None (sequential retrieval)	Any	Any
Message identifier	MSGID or NONE	Any
Correlation identifier	CORRELID	Any
Message and correlation identifiers	MSGID or CORRELID	Any
Group identifier	GROUPID	Any
Grouping	GROUPID	GROUPID
Message token	Not allowed	MSGTOKEN

where the value of **INDXTYPE** parameter has the following values:

NONE
No index is maintained. Use NONE when messages are typically retrieved sequentially or use both the message identifier and the correlation identifier as a selection criterion on the MQGET call.

MSGID
An index of message identifiers is maintained. Use MSGID when messages are typically retrieved using the message identifier as a selection criterion on the MQGET call with the correlation identifier set to NULL.

CORRELID
An index of correlation identifiers is maintained. Use CORRELID when messages are typically retrieved using the correlation identifier as a selection criterion on the MQGET call with the message identifier set to NULL.

GROUPID
An index of group identifiers is maintained. Use GROUPID when messages are retrieved using message grouping selection criteria.

Note:

1. You cannot set **INDXTYPE** to GROUPID if the queue is a transmission queue.
2. The queue must use a CF structure at CFLEVEL(3), to specify a shared queue with **INDXTYPE**(GROUPID).

z/OS **MSGTOKEN**
An index of message tokens is maintained. Use MSGTOKEN when the queue is a WLM-managed queue that you are using with the Workload Manager functions of z/OS.

Note: You cannot set **INDXTYPE** to MSGTOKEN if:

- The queue is a model queue with a definition type of SHAREDYN
- The queue is a temporary dynamic queue
- The queue is a transmission queue
- You specify **QSGDISP**(SHARED)

For queues that are not shared and do not use grouping or message tokens, the index type does not restrict the type of retrieval selection. However, the index is used to expedite **GET** operations on the queue, so choose the type that corresponds to the most common retrieval selection.

If you are altering or replacing an existing local queue, you can change the **INDXTYPE** parameter only in the cases indicated in the following table:

Table 157. Index type change permitted depending upon queue-sharing and presence of messages in the queue

Queue type		**NON-SHARED**			**SHARED**	
Queue state		Uncommitted activity	No uncommitted activity, messages present	No uncommitted activity, and empty	Open or messages present	Not open, and empty
Change **INDXTYPE** from:	To:	Change allowed?				
NONE	MSGID	No	Yes	Yes	No	Yes
NONE	CORRELID	No	Yes	Yes	No	Yes
NONE	MSGTOKEN	No	No	Yes	-	-
NONE	GROUPID	No	No	Yes	No	Yes
MSGID	NONE	No	Yes	Yes	No	Yes
MSGID	CORRELID	No	Yes	Yes	No	Yes
MSGID	MSGTOKEN	No	No	Yes	-	-
MSGID	GROUPID	No	No	Yes	No	Yes
CORRELID	NONE	No	Yes	Yes	No	Yes

Table 157. Index type change permitted depending upon queue-sharing and presence of messages in the queue (continued)

Queue type		NON-SHARED			SHARED	
CORRELID	MSGID	No	Yes	Yes	No	Yes
CORRELID	MSGTOKEN	No	No	Yes	-	-
CORRELID	GROUPID	No	No	Yes	No	Yes
MSGTOKEN	NONE	No	Yes	Yes	-	-
MSGTOKEN	MSGID	No	Yes	Yes	-	-
MSGTOKEN	CORRELID	No	Yes	Yes	-	-
MSGTOKEN	GROUPID	No	No	Yes	-	-
GROUPID	NONE	No	No	Yes	No	Yes
GROUPID	MSGID	No	No	Yes	No	Yes
GROUPID	CORRELID	No	No	Yes	No	Yes
GROUPID	MSGTOKEN	No	No	Yes	-	-

INITQ(*string*)
The local name of the initiation queue on this queue manager, to which trigger messages relating to this queue are written. See Rules for naming IBM MQ objects.

This parameter is supported only on local and model queues.

LIKE(*qtype-name*)
The name of a queue, with parameters that are used to model this definition.

If this field is not completed, the values of undefined parameter fields are taken from one of the following definitions. The choice depends on the queue type:

Table 158. Queue types and their corresponding definitions

Queue type	Definition
Alias queue	SYSTEM.DEFAULT.ALIAS.QUEUE
Local queue	SYSTEM.DEFAULT.LOCAL.QUEUE
Model queue	SYSTEM.DEFAULT.MODEL.QUEUE
Remote queue	SYSTEM.DEFAULT.REMOTE.QUEUE

For example, not completing this parameter is equivalent to defining the following value of **LIKE** for an alias queue:

```
LIKE(SYSTEM.DEFAULT.ALIAS.QUEUE)
```

If you require different default definitions for all queues, alter the default queue definitions instead of using the **LIKE** parameter.

z/OS On z/OS, the queue manager searches for an object with the name and queue type you specify with a disposition of QMGR, COPY, or SHARED. The disposition of the **LIKE** object is not copied to the object you are defining.

Note:

1. **QSGDISP**(GROUP) objects are not searched.
2. **LIKE** is ignored if **QSGDISP**(COPY) is specified.

z/OS ALW **MAXDEPTH(*integer*)**

The maximum number of messages allowed on the queue.

This parameter is supported only on local and model queues.

On the following platforms, specify a value in the range zero through 999999999:

- ALW AIX, Linux, and Windows
- z/OS z/OS

On any other IBM MQ platform, specify a value in the range zero through 640000.

Other factors can still cause the queue to be treated as full, for example, if there is no further hard disk space available.

If this value is reduced, any messages that are already on the queue that exceed the new maximum remain intact.

V 9.2.0 Multi **MAXFSIZE**

The maximum size, in megabytes, that a queue file can grow to. It is possible for a queue file to exceed this size if you have configured the value to be lower than the current queue file size.

If that happens the queue file no longer accepts new messages, but allows existing messages to be consumed. When the queue file size has dropped below the configured value, new messages can be put to the queue.

Note: This figure can differ from the value of the attribute configured on the queue, because internally the queue manager might need to use a larger block size to reach the chosen size. See Modifying IBM MQ queue files for more information on changing the size of queue files and block size and granularity.

When the granularity needs changing because this attribute has been increased, warning message AMQ7493W `Granularity changed` is written to the AMQERR logs. This gives you an indication that you need to plan for the queue to be emptied, in order for IBM MQ to adopt the new granularity.

Specify a value greater than or equal to 20, and less than or equal to 267,386,880.

The default value for this attribute is *DEFAULT*, which equates to a hard-coded value of 2,088,960 MB, the maximum for a queue in versions of IBM MQ prior to IBM MQ 9.1.5.

MAXMSGL(*integer*)

The maximum length (in bytes) of messages on this queue.

This parameter is supported only on local and model queues.

ALW On AIX, Linux, and Windows, specify a value in the range zero to the maximum message length for the queue manager. See the **MAXMSGL** parameter of the ALTER QMGR command, ALTER QMGR MAXMSGL.

z/OS On z/OS, specify a value in the range zero through 100 MB (104 857 600 bytes).

Message length includes the length of user data and the length of headers. For messages put on the transmission queue, there are additional transmission headers. Allow an additional 4000 bytes for all the message headers.

If this value is reduced, any messages that are already on the queue with length that exceeds the new maximum are not affected.

Applications can use this parameter to determine the size of buffer for retrieving messages from the queue. Therefore, the value can be reduced only if it is known that this reduction does not cause an application to operate incorrectly.

Note that by adding the digital signature and key to the message, Advanced Message Security increases the length of the message.

MONQ

Controls the collection of online monitoring data for queues.

This parameter is supported only on local and model queues.

QMGR
Collect monitoring data according to the setting of the queue manager parameter **MONQ**.

OFF
Online monitoring data collection is turned off for this queue.

LOW
If the value of the **MONQ** parameter of the queue manager is not NONE, online monitoring data collection is turned on for this queue.

MEDIUM
If the value of the **MONQ** parameter of the queue manager is not NONE, online monitoring data collection is turned on for this queue.

HIGH
If the value of the **MONQ** parameter of the queue manager is not NONE, online monitoring data collection is turned on for this queue.

There is no distinction between the values LOW, MEDIUM, and HIGH. These values all turn data collection on, but do not affect the rate of collection.

When this parameter is used in an **ALTER** queue command, the change is effective only when the queue is next opened.

MSGDLVSQ
Message delivery sequence.

This parameter is supported only on local and model queues.

PRIORITY
Messages are delivered (in response to MQGET API calls) in first-in-first-out (FIFO) order within priority.

FIFO
Messages are delivered (in response to MQGET API calls) in FIFO order. Priority is ignored for messages on this queue.

The message delivery sequence parameter can be changed from PRIORITY to FIFO while there are messages on the queue. The order of the messages already on the queue is not changed. Messages added to the queue later take the default priority of the queue, and so might be processed before some of the existing messages.

If the message delivery sequence is changed from FIFO to PRIORITY, the messages put on the queue while the queue was set to FIFO take the default priority.

Note: z/OS If **INDXTYPE**(GROUPID) is specified with **MSGDLVSQ**(PRIORITY), the priority in which groups are retrieved is based on the priority of the first message within each group. The priorities 0 and 1 are used by the queue manager to optimize the retrieval of messages in logical order. The first message in each group must not use these priorities. If it does, the message is stored as if it was priority two.

Multi **NPMCLASS**
The level of reliability to be assigned to non-persistent messages that are put to the queue:

NORMAL
Non-persistent messages are lost after a failure, or queue manager shutdown. These messages are discarded on a queue manager restart.

HIGH
The queue manager attempts to retain non-persistent messages on this queue over a queue manager restart or switch over.

z/OS You cannot set this parameter on z/OS.

PROCESS(*string*)
The local name of the IBM MQ process.

This parameter is supported only on local and model queues.

This parameter is the name of a process instance that identifies the application started by the queue manager when a trigger event occurs; see Rules for naming IBM MQ objects.

The process definition is not checked when the local queue is defined, but it must be available for a trigger event to occur.

If the queue is a transmission queue, the process definition contains the name of the channel to be started. This parameter is optional for transmission queues on the following platforms:

- IBM i
- AIX, Linux, and Windows
- z/OS

If you do not specify it, the channel name is taken from the value specified for the **TRIGDATA** parameter.

PROPCTL

Property control attribute. The attribute is optional. It is applicable to local, alias, and model queues.

Note: If your application is opening an alias queue you must set this value on both the alias and target queues.

PROPCTL options are as follows. The options do not affect message properties in the MQMD or MQMD extension.

ALL

Set ALL so that an application can read all the properties of the message either in MQRFH2 headers, or as properties of the message handle.

The ALL option enables applications that cannot be changed to access all the message properties from MQRFH2 headers. Applications that can be changed, can access all the properties of the message as properties of the message handle.

In some cases, the format of data in MQRFH2 headers in the received message might be different to the format in the message when it was sent.

COMPAT

Set COMPAT so that unmodified applications that expect JMS-related properties to be in an MQRFH2 header in the message data continue to work as before. Applications that can be changed, can access all the properties of the message as properties of the message handle.

If the message contains a property with a prefix of `mcd.`, `jms.`, `usr.`, or `mqext.`, all message properties are delivered to the application. If no message handle is supplied, properties are returned in an MQRFH2 header. If a message handle is supplied, all properties are returned in the message handle.

If the message does not contain a property with one of those prefixes, and the application does not provide a message handle, no message properties are returned to the application. If a message handle is supplied, all properties are returned in the message handle.

In some cases, the format of data in MQRFH2 headers in the received message might be different to the format in the message when it was sent.

FORCE

Force all applications to read message properties from MQRFH2 headers.

Properties are always returned in the message data in an MQRFH2 header regardless of whether the application specifies a message handle.

A valid message handle supplied in the `MsgHandle` field of the MQGMO structure on the MQGET call is ignored. Properties of the message are not accessible using the message handle.

In some cases, the format of data in MQRFH2 headers in the received message might be different to the format in the message when it was sent.

NONE
If a message handle is supplied, all the properties are returned in the message handle.

All message properties are removed from the message body before it is delivered to the application.

PUT
Specifies whether messages can be put on the queue.

ENABLED
Messages can be added to the queue (by suitably authorized applications).

DISABLED
Messages cannot be added to the queue.

This parameter can also be changed using the MQSET API call.

QDEPTHHI(*integer*)
The threshold against which the queue depth is compared to generate a Queue Depth High event.

This parameter is supported only on local and model queues.

z/OS For more information about the effect that shared queues on z/OS have on this event; see Shared queues and queue depth events on z/OS.

This event indicates that an application put a message on a queue resulting in the number of messages on the queue becoming greater than or equal to the queue depth high threshold. See the **QDPHIEV** parameter.

The value is expressed as a percentage of the maximum queue depth (**MAXDEPTH** parameter), and must be in the range zero through 100 and no less than **QDEPTHLO**.

QDEPTHLO(*integer*)
The threshold against which the queue depth is compared to generate a Queue Depth Low event.

This parameter is supported only on local and model queues.

z/OS For more information about the effect that shared queues on z/OS have on this event; see Shared queues and queue depth events on z/OS.

This event indicates that an application retrieved a message from a queue resulting in the number of messages on the queue becoming less than or equal to the queue depth low threshold. See the **QDPLOEV** parameter.

The value is expressed as a percentage of the maximum queue depth (**MAXDEPTH** parameter), and must be in the range zero through 100 and no greater than **QDEPTHHI**.

QDPHIEV
Controls whether Queue Depth High events are generated.

This parameter is supported only on local and model queues.

A Queue Depth High event indicates that an application put a message on a queue resulting in the number of messages on the queue becoming greater than or equal to the queue depth high threshold. See the **QDEPTHHI** parameter.

ENABLED
Queue Depth High events are generated.

DISABLED
Queue Depth High events are not generated.

Note: The value of this parameter can change implicitly.

z/OS On z/OS, shared queues affect the event.

For more information about this event, see Queue Depth High.

QDPLOEV
Controls whether Queue Depth Low events are generated.

This parameter is supported only on local and model queues.

A Queue Depth Low event indicates that an application retrieved a message from a queue resulting in the number of messages on the queue becoming less than or equal to the queue depth low threshold. See the **QDEPTHLO** parameter.

ENABLED
Queue Depth Low events are generated.

DISABLED
Queue Depth Low events are not generated.

Note: The value of this parameter can change implicitly.

z/OS On z/OS, shared queues affect the event.

For more information about this event, see Queue Depth Low.

QDPMAXEV
Controls whether Queue Full events are generated.

This parameter is supported only on local and model queues.

A Queue Full event indicates that a put to a queue was rejected because the queue is full. The queue depth reached its maximum value.

ENABLED
Queue Full events are generated.

DISABLED
Queue Full events are not generated.

Note: The value of this parameter can change implicitly.

z/OS On z/OS, shared queues affect the event.

For more information about this event, see Queue Full.

z/OS **QSGDISP**
This parameter applies to z/OS only.

Specifies the disposition of the object within the group.

*Table 159. Object dispositions for **QSGDISP** options*

QSGDISP	DEFINE

COPY	The object is defined on the page set of the queue manager that executes the command. It uses the **QSGDISP(GROUP)** object of the same name as the LIKE object.
	For example, if you issue the following command,
	`DEFINE QUEUE(q_name)`
	`REPLACE QSGDISP(COPY)`
	the queue manager searches the shared configuration repository for a QUEUE definition called *q_name*. If a matching QUEUE definition is found, the queue manager creates a local copy of this definition on the queue manager page set.
	For local queues, messages are stored on the page sets of each queue manager and are available only through that queue manager.

*Table 159. Object dispositions for **QSGDISP** options (continued)*	
QSGDISP	**DEFINE**
GROUP	The object definition resides in the shared configuration repository. **QSGDISP(GROUP)** is allowed only if the queue manager is in a queue sharing group. If the DEFINE for the **QSGDISP(GROUP)** object is successful, the DEFINE QUEUE(*q_name*) REPLACE QSGDISP(COPY) command is generated and sent to all active queue managers in the queue sharing group to make or refresh local copies on page set zero. The DEFINE for the group object takes effect regardless of whether the generated command with **QSGDISP(COPY)** fails.
PRIVATE	Not permitted.
QMGR	The object is defined on the page set of the queue manager that executes the command.
SHARED	This option applies only to local queues. The object is defined in the shared repository. Messages are stored in the coupling facility and are available to any queue manager in the queue sharing group. You can specify SHARED only if: • CFSTRUCT is nonblank • INDXTYPE is not MSGTOKEN • The queue is not: – SYSTEM.CHANNEL.INITQ – SYSTEM.COMMAND.INPUT If the queue is clustered, a command is generated. The command is sent to all active queue managers in the queue sharing group to notify them of this clustered, shared queue.

QSVCIEV
Controls whether Service Interval High or Service Interval OK events are generated.

This parameter is supported only on local and model queues and is ineffective if it is specified on a shared queue.

A Service Interval High event is generated when a check indicates that no messages were retrieved from the queue for at least the time indicated by the **QSVCINT** parameter.

A Service Interval OK event is generated when a check indicates that messages were retrieved from the queue within the time indicated by the **QSVCINT** parameter.

Note: The value of this parameter can change implicitly. For more information, see the description of the Service Interval High and Service Interval OK events in Queue Service Interval High and Queue Service Interval OK.

HIGH
Service Interval High events are generated

OK
Service Interval OK events are generated

NONE
No service interval events are generated

QSVCINT(*integer*)
The service interval used for comparison to generate Service Interval High and Service Interval OK events.

This parameter is supported only on local and model queues and is ineffective if it is specified on a shared queue.

See the **QSVCIEV** parameter.

The value is in units of milliseconds, and must be in the range zero through 999999999.

REPLACE & NOREPLACE

This option controls whether any existing definition is to be replaced with this one.

Note: z/OS On IBM MQ for z/OS, an existing definition is replaced only if it is of the same disposition. Any object with a different disposition is not changed.

REPLACE

If the object does exist, the effect is like issuing the **ALTER** command without the **FORCE** parameter and with all the other parameters specified. In particular, note that any messages that are on the existing queue are retained.

There is a difference between the **ALTER** command without the **FORCE** parameter, and the **DEFINE** command with the **REPLACE** parameter. The difference is that **ALTER** does not change unspecified parameters, but **DEFINE** with **REPLACE** sets all the parameters. If you use **REPLACE**, unspecified parameters are taken either from the object named on the **LIKE** parameter, or from the default definition, and the parameters of the object being replaced, if one exists, are ignored.

The command fails if both of the following statements are true:

- The command sets parameters that would require the use of the **FORCE** parameter if you were using the **ALTER** command
- The object is open

The **ALTER** command with the **FORCE** parameter succeeds in this situation.

ALW If **SCOPE(CELL)** is specified on AIX, Linux, and Windows, and there is already a queue with the same name in the cell directory, the command fails, even if **REPLACE** is specified.

NOREPLACE

The definition must not replace any existing definition of the object.

RETINTVL(*integer*)

The number of hours from when the queue was defined, after which the queue is no longer needed. The value must be in the range 0 - 999,999,999.

This parameter is supported only on local and model queues.

The **CRDATE** and **CRTIME** can be displayed using the **DISPLAY QUEUE** command.

This information is available for use by an operator or a housekeeping application to delete queues that are no longer required.

Note: The queue manager does not delete queues based on this value, nor does it prevent queues from being deleted if their retention interval is not expired. It is the responsibility of the user to take any required action.

RNAME(*string*)

Name of remote queue. This parameter is the local name of the queue as defined on the queue manager specified by **RQMNAME**.

This parameter is supported only on remote queues.

- If this definition is used for a local definition of a remote queue, **RNAME** must not be blank when the open occurs.
- If this definition is used for a queue manager alias definition, **RNAME** must be blank when the open occurs.

  In a queue manager cluster, this definition applies only to the queue manager that made it. To advertise the alias to the whole cluster, add the **CLUSTER** attribute to the remote queue definition.

- If this definition is used for a reply-to queue alias, this name is the name of the queue that is to be the reply-to queue.

The name is not checked to ensure that it contains only those characters normally allowed for queue names; see Rules for naming IBM MQ objects.

RQMNAME(*string*)
The name of the remote queue manager on which the queue **RNAME** is defined.

This parameter is supported only on remote queues.

- If an application opens the local definition of a remote queue, **RQMNAME** must not be blank or the name of the local queue manager. When the open occurs, if **XMITQ** is blank there must be a local queue of this name, which is to be used as the transmission queue.
- If this definition is used for a queue manager alias, **RQMNAME** is the name of the queue manager that is being aliased. It can be the name of the local queue manager. Otherwise, if **XMITQ** is blank, when the open occurs there must be a local queue of this name, which is to be used as the transmission queue.
- If **RQMNAME** is used for a reply-to queue alias, **RQMNAME** is the name of the queue manager that is to be the reply-to queue manager.

The name is not checked to ensure that it contains only those characters normally allowed for IBM MQ object names; see Rules for naming IBM MQ objects.

SCOPE
Specifies the scope of the queue definition.

This parameter is supported only on alias, local, and remote queues.

QMGR
The queue definition has queue manager scope. This means that the definition of the queue does not extend beyond the queue manager that owns it. You can open a queue for output that is owned by another queue manager in either of two ways:

1. Specify the name of the owning queue manager.
2. Open a local definition of the queue on the other queue manager.

CELL
The queue definition has cell scope. Cell scope means that the queue is known to all the queue managers in the cell. A queue with cell scope can be opened for output merely by specifying the name of the queue. The name of the queue manager that owns the queue need not be specified.

If there is already a queue with the same name in the cell directory, the command fails. The **REPLACE** option does not affect this situation.

This value is valid only if a name service supporting a cell directory is configured.

Restriction: The DCE name service is no longer supported.

This parameter is valid only on AIX, Linux, and Windows.

SHARE and NOSHARE
Specifies whether multiple applications can get messages from this queue.

This parameter is supported only on local and model queues.

SHARE
More than one application instance can get messages from the queue.

NOSHARE
Only a single application instance can get messages from the queue.

STATQ
Specifies whether statistics data collection is enabled:

QMGR
Statistics data collection is based on the setting of the **STATQ** parameter of the queue manager.

ON
If the value of the **STATQ** parameter of the queue manager is not NONE, statistics data collection for the queue is enabled.

OFF
Statistics data collection for the queue is disabled.

If this parameter is used in an **ALTER** queue command, the change is effective only for connections to the queue manager made after the change to the parameter.

This parameter is valid only on Multiplatforms.

z/OS **STGCLASS(*string*)**
The name of the storage class.

This parameter is supported only on local and model queues.

Note: You can change this parameter only if the queue is empty and closed.

This parameter is an installation-defined name. The first character of the name must be uppercase A through Z, and subsequent characters either uppercase A through Z or numeric 0 through 9.

This parameter is valid only on z/OS; see Storage classes.

Multi V 9.2.3 **STREAMQ**
The name of a secondary queue where a copy of each message is put.

This parameter is valid only on AIX, Linux, and Windows.

Attention: If the user setting the **STREAMQ** attribute does not have change authority on the chosen stream queue, the command fails with error message AMQ8135E `Not Authorized`.

In addition, if the stream queue does not exist, error message AMQ8135E is returned instead of AMQ8147E `IBM MQ object not found`.

Multi V 9.2.3 **STRMQOS**
The quality of service to use when delivering messages to the streaming queue.

The value can be one of:

BESTEF
If the original message can be delivered, but the streamed message cannot, the original message is still delivered to its queue.

This is the default value.

MUSTDUP
The queue manager ensures that both the original message and the streamed message are successfully delivered to their queues.

If, for some reason, the streamed message cannot be delivered to its queue, then the original message is not delivered to its queue either. The putting application receives an error reason code and must try to put the message again.

This parameter is valid only on AIX, Linux, and Windows.

TARGET(*string*)
The name of the queue or topic object being aliased; See Rules for naming IBM MQ objects. The object can be a queue or a topic as defined by **TARGTYPE**. The maximum length is 48 characters.

This parameter is supported only on alias queues.

This object needs to be defined only when an application process opens the alias queue.

The TARGQ parameter, defined in IBM WebSphere MQ 6.0, is renamed to TARGET from version 7.0 and generalized to allow you to specify the name of either a queue or a topic. The default value for TARGET is a queue, therefore TARGET(`my_queue_name`) is the same as TARGQ(`my_queue_name`). The TARGQ attribute is retained for compatibility with your existing programs. If you specify **TARGET**, you cannot also specify **TARGQ**.

TARGTYPE(*string*)
The type of object to which the alias resolves.

QUEUE
The alias resolves to a queue.

TOPIC
The alias resolves to a topic.

TRIGDATA(*string*)
The data that is inserted in the trigger message. The maximum length of the string is 64 bytes.

This parameter is supported only on local and model queues.

For a transmission queue, you can use this parameter to specify the name of the channel to be started.

This parameter can also be changed using the MQSET API call.

TRIGDPTH(*integer*)
The number of messages that have to be on the queue before a trigger message is written, if **TRIGTYPE** is DEPTH. The value must be in the range 1 - 999,999,999. The default value is 1.

This parameter is supported only on local and model queues.

This parameter can also be changed using the MQSET API call.

TRIGGER and NOTRIGGER
Specifies whether trigger messages are written to the initiation queue, named by the **INITQ** parameter, to trigger the application, named by the **PROCESS** parameter:

TRIGGER
Triggering is active, and trigger messages are written to the initiation queue.

NOTRIGGER
Triggering is not active, and trigger messages are not written to the initiation queue. This is the default value.

This parameter is supported only on local and model queues.

This parameter can also be changed using the MQSET API call.

TRIGMPRI(*integer*)
The message priority number that triggers this queue. The value must be in the range zero through to the **MAXPRTY** queue manager parameter; see "DISPLAY QMGR (display queue manager settings)" on page 747 for details. The default value is zero.

This parameter can also be changed using the MQSET API call.

TRIGTYPE
Specifies whether and under what conditions a trigger message is written to the initiation queue. The initiation queue is (named by the **INITQ** parameter.

This parameter is supported only on local and model queues.

FIRST
Whenever the first message of priority equal to or greater than the priority specified by the **TRIGMPRI** parameter of the queue arrives on the queue. This is the default value.

EVERY
Every time a message arrives on the queue with priority equal to or greater than the priority specified by the **TRIGMPRI** parameter of the queue.

DEPTH
When the number of messages with priority equal to or greater than the priority specified by **TRIGMPRI** is equal to the number indicated by the **TRIGDPTH** parameter.

NONE
No trigger messages are written.

This parameter can also be changed using the MQSET API call.

USAGE
Queue usage.

This parameter is supported only on local and model queues.

NORMAL
The queue is not a transmission queue.

XMITQ
The queue is a transmission queue, which is used to hold messages that are destined for a remote queue manager. When an application puts a message to a remote queue, the message is stored on the appropriate transmission queue. It stays there, awaiting transmission to the remote queue manager.

If you specify this option, do not specify values for **CLUSTER** and **CLUSNL**.

z/OS Additionally, on z/OS, do not specify **INDXTYPE**(MSGTOKEN) or **INDXTYPE**(GROUPID).

XMITQ(*string*)
The name of the transmission queue to be used for forwarding messages to the remote queue. **XMITQ** is used with either remote queue or queue manager alias definitions.

This parameter is supported only on remote queues.

If **XMITQ** is blank, a queue with the same name as **RQMNAME** is used as the transmission queue.

This parameter is ignored if the definition is being used as a queue manager alias and **RQMNAME** is the name of the local queue manager.

It is also ignored if the definition is used as a reply-to queue alias definition.

Related tasks
Copying a local queue definition

DEFINE QALIAS (define a new alias queue)
Use **DEFINE QALIAS** to define a new alias queue, and set its parameters.

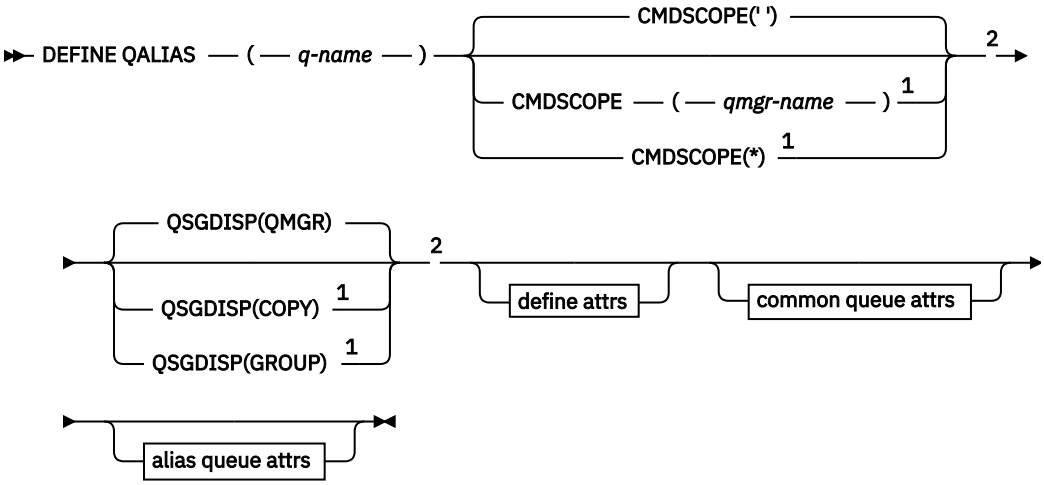
Note: An alias queue provides a level of indirection to another queue or a topic object. If the alias refers to a queue, it must be another local or remote queue, defined at this queue manager, or a clustered alias queue defined on another queue manager. It cannot be another alias queue on this queue manager. If the alias refers to a topic, it must be a topic object defined at this queue manager.

- Syntax diagram
- “Usage notes for DEFINE queues” on page 529
- “Parameter descriptions for DEFINE QUEUE and ALTER QUEUE” on page 530

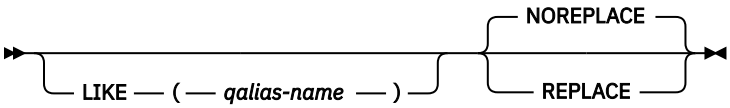
Synonym: DEF QA

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See “Syntax diagrams” on page 236.

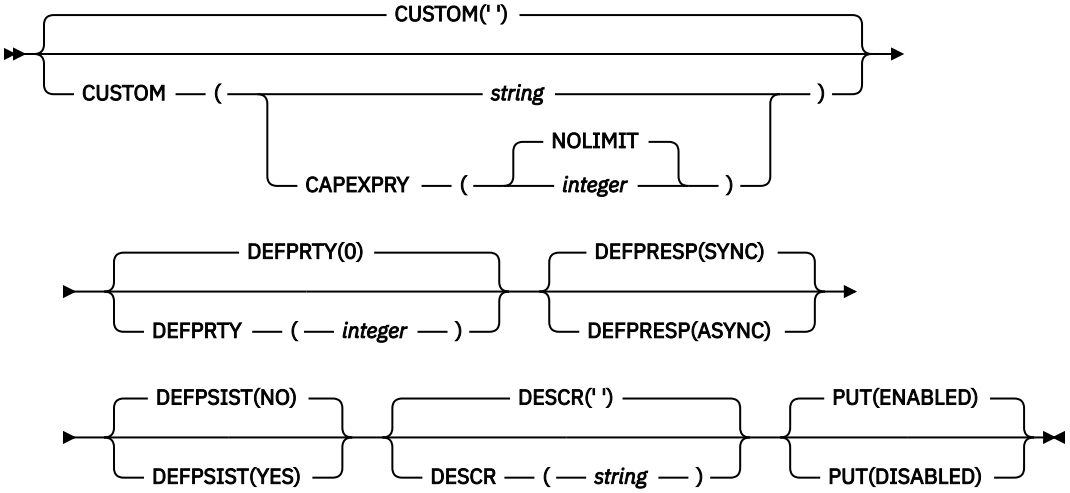
DEFINE QALIAS



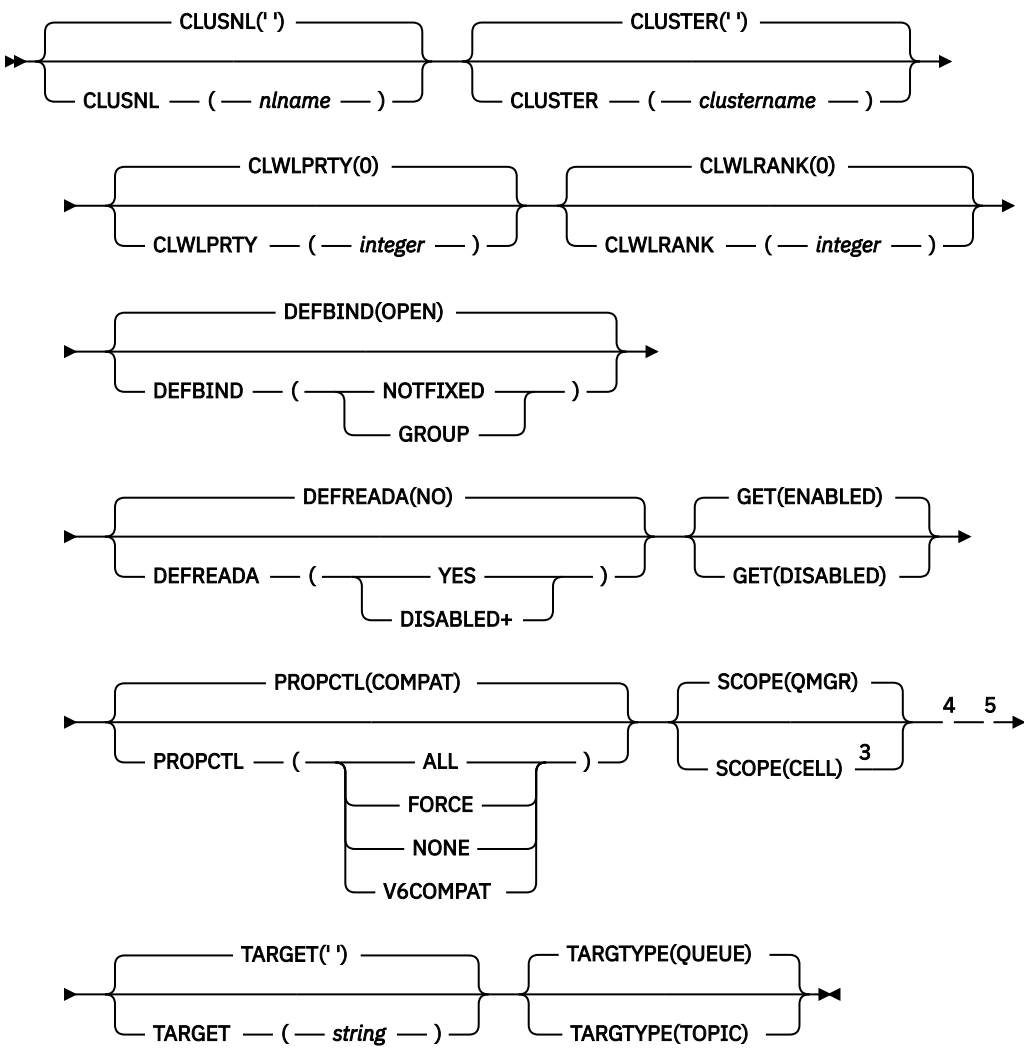
Define attrs



Common queue attrs



Alias queue attrs



Notes:

[1] Valid only on .z/OS

[2] Valid only on z/OS when the queue manager is a member of a queue sharing group.

[3] Valid only on AIX, Linux, and Windows.

[4] Not valid on z/OS.

[5] The TARGQ parameter, defined in IBM WebSphere MQ 6.0, is renamed to TARGET from version 7.0 and generalized to allow you to specify the name of either a queue or a topic. The default value for TARGET is a queue, therefore TARGET(my_queue_name) is the same as TARGQ(my_queue_name). The TARGQ attribute is retained for compatibility with your existing programs.

DEFINE QLOCAL (define a new local queue)

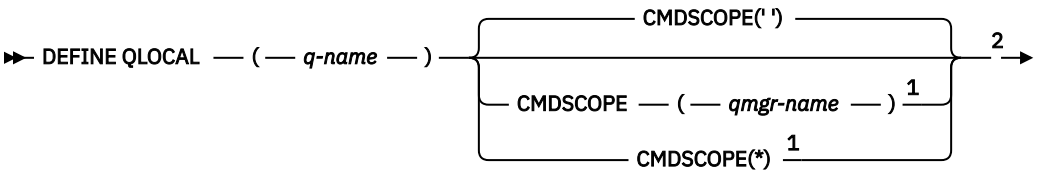
Use **DEFINE QLOCAL** to define a new local queue, and set its parameters.

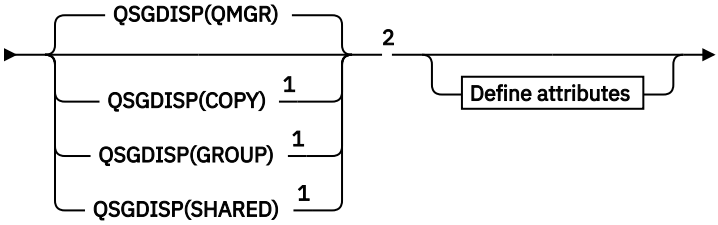
- Syntax diagram
- "Usage notes for DEFINE queues" on page 529
- "Parameter descriptions for DEFINE QUEUE and ALTER QUEUE" on page 530

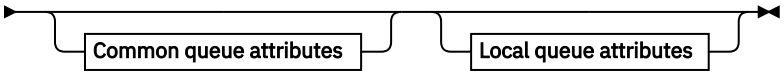
Synonym: **DEF QL**

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See “Syntax diagrams” on page 236.

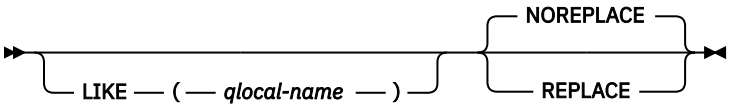
DEFINE QLOCAL



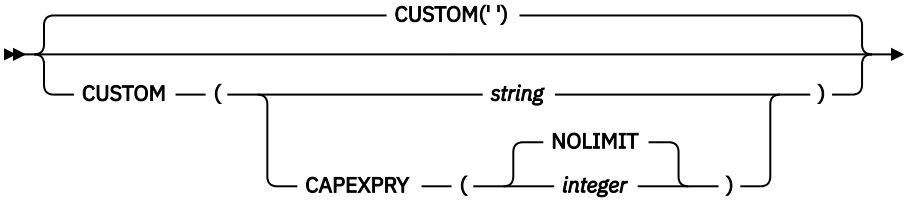


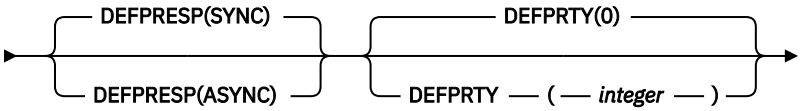


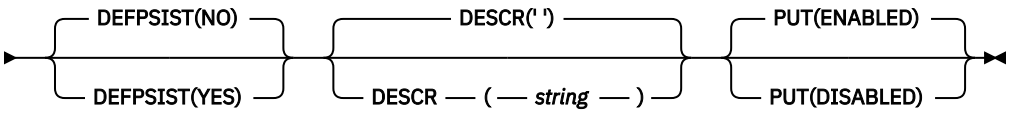
Define attributes



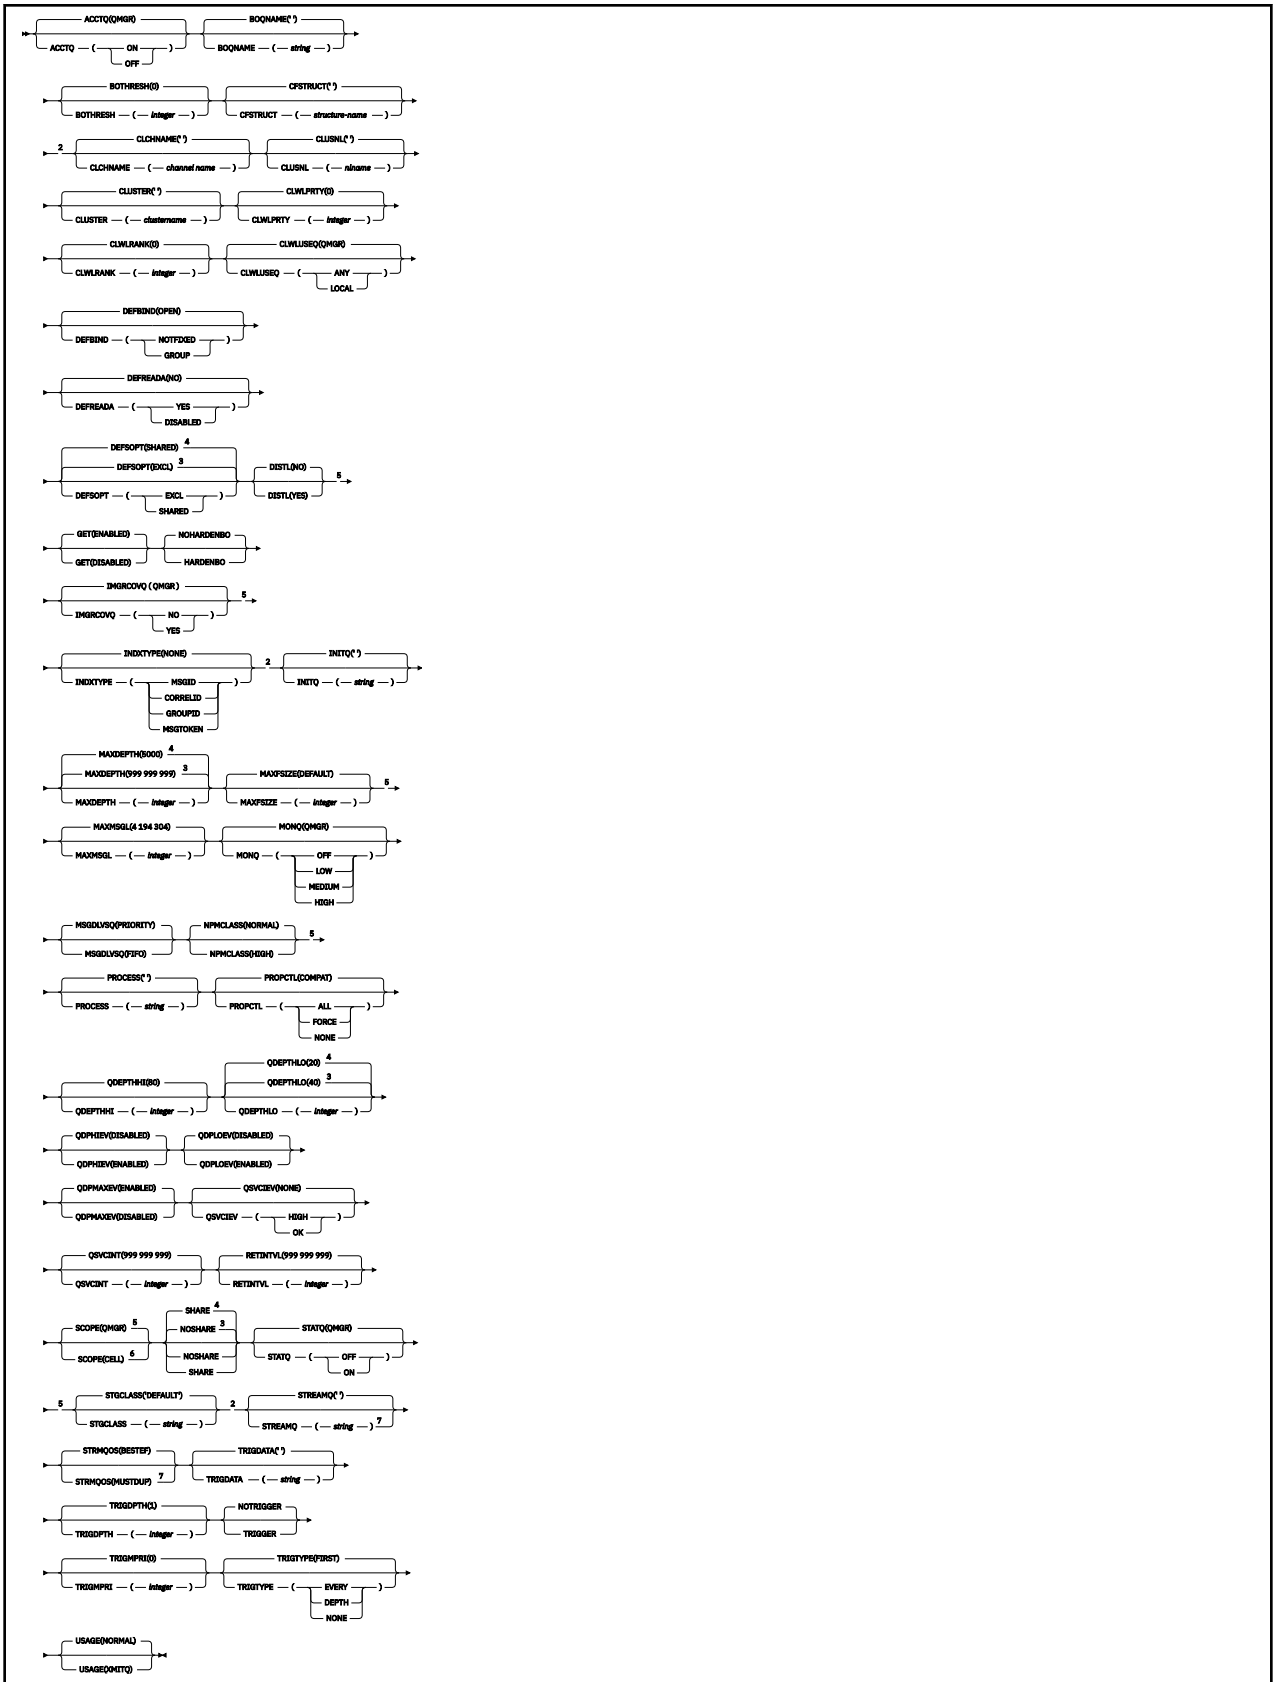
Common queue attributes







Local queue attributes



Notes:

1 Valid only on z/OS and when the queue manager is a member of a queue sharing group.

2 Valid only on z/OS.

[3] Default for z/OS.
[4] Default for Multiplatforms.
[5] Not valid on z/OS.
[6] Valid only on AIX, Linux, and Windows systems.
[7] Valid only on Multiplatforms.

Related tasks
Defining a local queue
Changing local queue attributes

DEFINE QMODEL (define a new model queue)

Use **DEFINE QMODEL** to define a new model queue, and set its parameters.

A model queue is not a real queue, but a collection of attributes that you can use when creating dynamic queues with the MQOPEN API call.

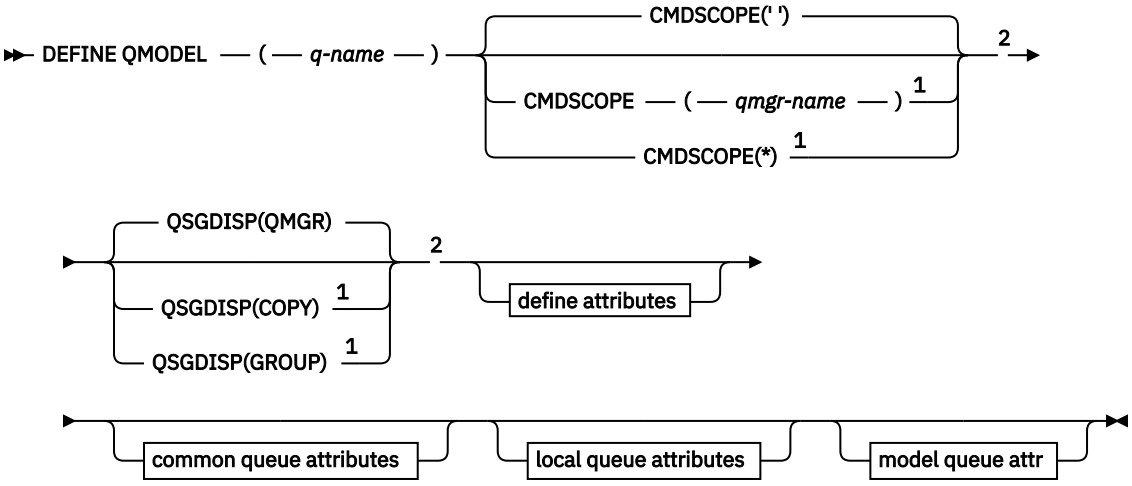
When it has been defined, a model queue (like any other queue) has a complete set of applicable attributes, even if some of these are defaults.

- Syntax diagram
- “Usage notes for DEFINE queues” on page 529
- “Parameter descriptions for DEFINE QUEUE and ALTER QUEUE” on page 530

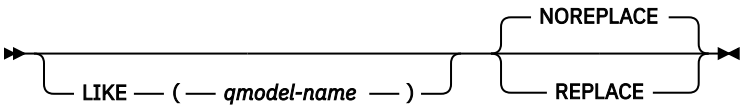
Synonym: **DEF QM**

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See “Syntax diagrams” on page 236.

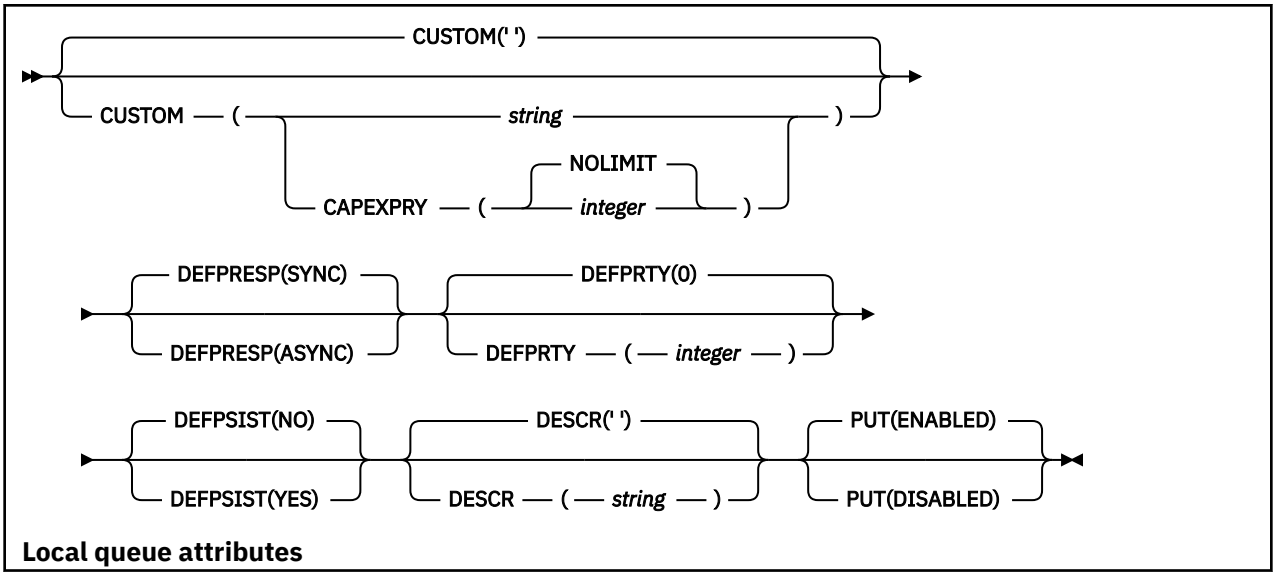
DEFINE QMODEL



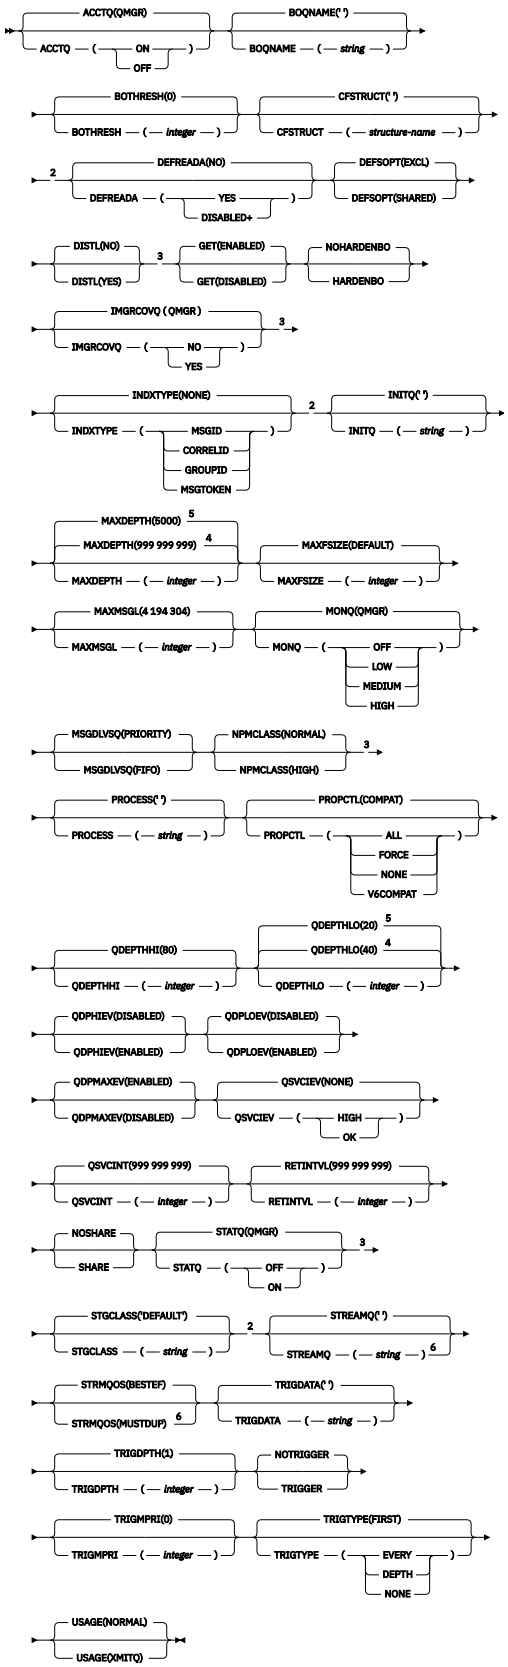
Define attributes



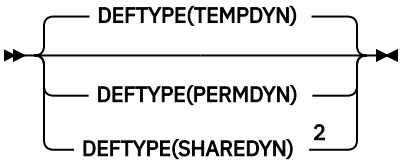
Common queue attributes



Local queue attributes



Model queue attr



Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[2] Used only on z/OS.
[3] Not valid on z/OS.
[4] Default for z/OS.
[5] Default for Multiplatforms.
[6] Valid only on AIX, Linux, and Windows.

Related concepts
Working with model queues

DEFINE QREMOTE (create local definition of a remote queue)

Use DEFINE QREMOTE to define a new local definition of a remote queue, a queue manager alias, or a reply-to queue alias, and to set its parameters.

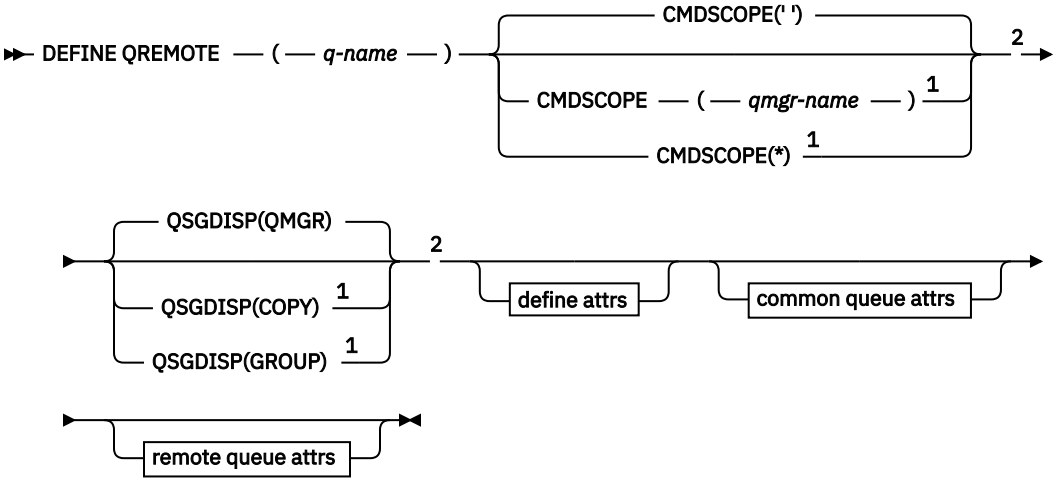
A remote queue is one that is owned by another queue manager that application processes connected to this queue manager need to access.

- Syntax diagram
- "Usage notes for DEFINE queues" on page 529
- "Parameter descriptions for DEFINE QUEUE and ALTER QUEUE" on page 530

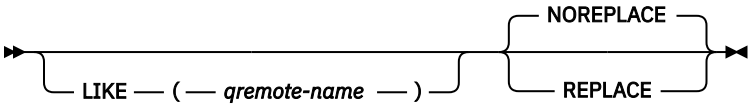
Synonym: DEF QR

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See "Syntax diagrams" on page 236.

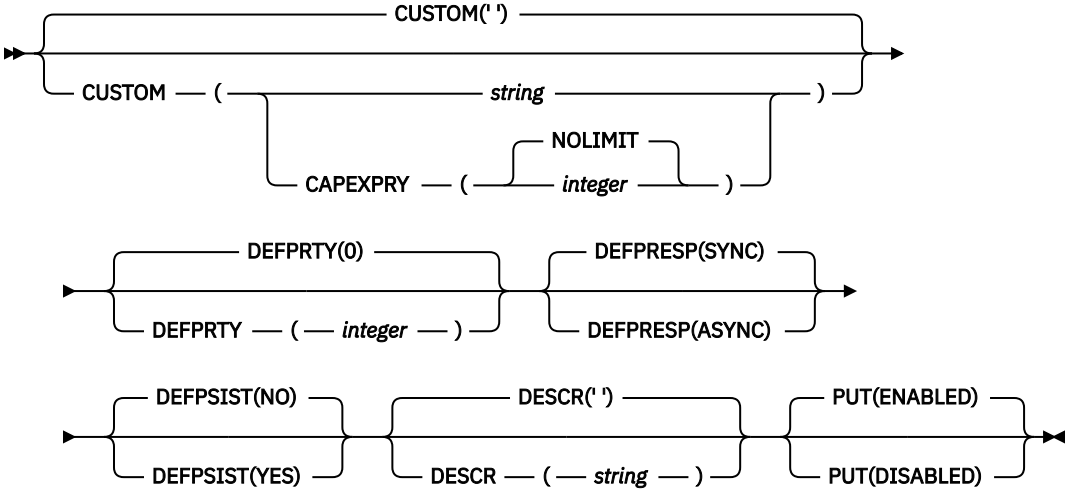
DEFINE QREMOTE



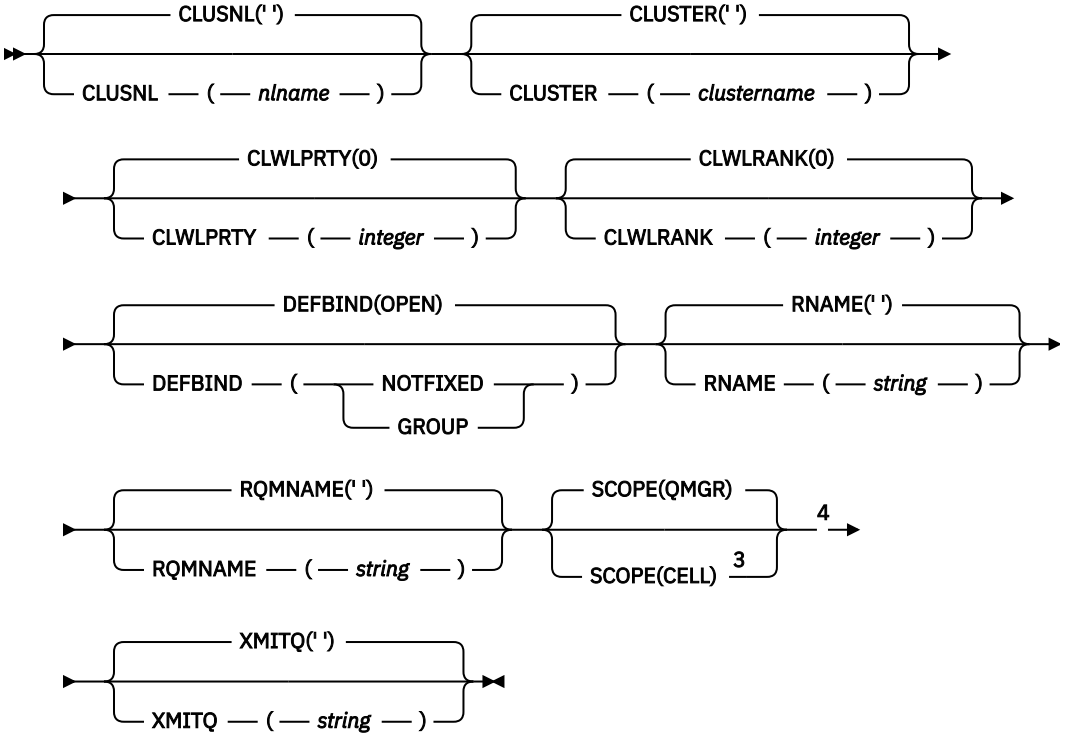
Define attrs



Common queue attrs



Remote queue attrs



Notes:

1 Valid only on z/OS when the queue manager is a member of a queue sharing group.
2 Valid only on z/OS.
3 Valid only on AIX, Linux, and Windows.
4 Not valid on z/OS.

Multi DEFINE SERVICE (create a new service definition) on Multiplatforms

Use the MQSC command **DEFINE SERVICE** to define a new IBM MQ service definition, and set its parameters.

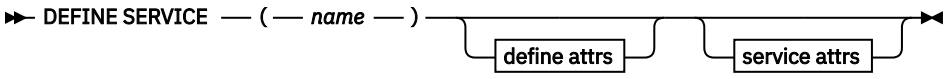
Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

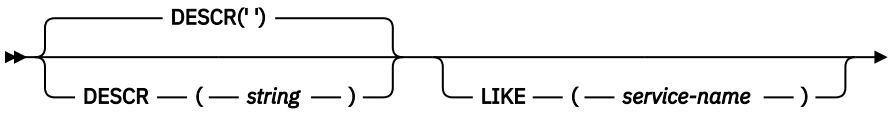
- Syntax diagram
- "Usage notes" on page 565
- "Parameter descriptions for DEFINE SERVICE" on page 565

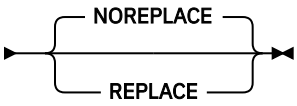
Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See "Syntax diagrams" on page 236.

DEFINE SERVICE

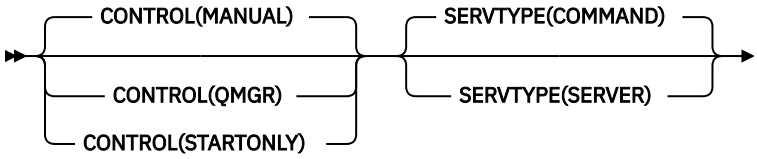


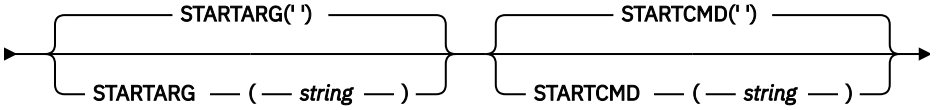
Define attrs

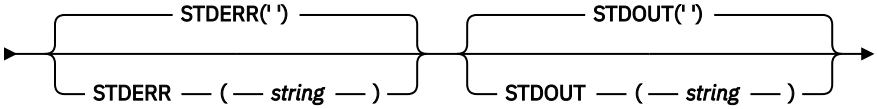


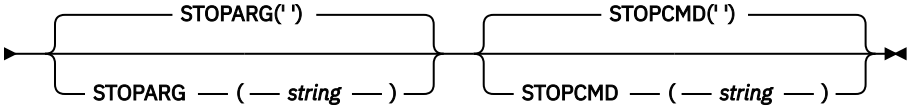


Service attrs









Usage notes

A service is used to define the user programs that are to be started and stopped when the queue manager is started and stopped. You can also start and stop these programs by issuing the **START SERVICE** and **STOP SERVICE** commands.

Attention: This command allows a user to run an arbitrary command with mqm authority. If granted rights to use this command, a malicious or careless user could define a service which damages your systems or data, for example, by deleting essential files.

For more information about services, see Services.

Parameter descriptions for DEFINE SERVICE

The parameter descriptions apply to the **ALTER SERVICE** and **DEFINE SERVICE** commands, with the following exceptions:

- The **LIKE** parameter applies only to the **DEFINE SERVICE** command.
- The **NOREPLACE** and **REPLACE** parameter applies only to the **DEFINE SERVICE** command.

(service-name)
Name of the IBM MQ service definition (see Rules for naming IBM MQ objects).

The name must not be the same as any other service definition currently defined on this queue manager (unless **REPLACE** is specified).

CONTROL(*string*)
Specifies how the service is to be started and stopped:

MANUAL
The service is not to be started automatically or stopped automatically. It is to be controlled by use of the **START SERVICE** and **STOP SERVICE** commands.

QMGR
The service being defined is to be started and stopped at the same time as the queue manager is started and stopped.

STARTONLY
The service is to be started at the same time as the queue manager is started, but is not requested to stop when the queue manager is stopped.

DESCR(*string*)
Plain-text comment. It provides descriptive information about the service when an operator issues the **DISPLAY SERVICE** command (see “DISPLAY SERVICE (display service information) on Multiplatforms” on page 799).

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

LIKE(*service-name*)
The name of a service the parameters of which are used to model this definition.

This parameter applies only to the **DEFINE SERVICE** command.

If this field is not completed, and you do not complete the parameter fields related to the command, the values are taken from the default definition for services on this queue manager. Not completing this parameter is equivalent to specifying:

```
LIKE(SYSTEM.DEFAULT.SERVICE)
```

A default service is provided but it can be altered by the installation of the default values required. See Rules for naming IBM MQ objects.

REPLACE and NOREPLACE
Whether the existing definition is to be replaced with this one.

This parameter applies only to the **DEFINE SERVICE** command.

REPLACE
The definition must replace any existing definition of the same name. If a definition does not exist, one is created.

NOREPLACE
The definition should not replace any existing definition of the same name.

SERVTYPE
Specifies the mode in which the service is to run:

COMMAND
A command service object. Multiple instances of a command service object can be executed concurrently. You cannot monitor the status of command service objects.

SERVER
A server service object. Only one instance of a server service object can be executed at a time. The status of server service objects can be monitored using the **DISPLAY SVSTATUS** command.

STARTARG(*string*)
Specifies the arguments to be passed to the user program at queue manager startup.

STARTCMD(*string*)
Specifies the name of the program which is to run. You must specify a fully qualified path name to the executable program.

STDERR(*string*)
Specifies the path to a file to which the standard error (stderr) of the service program is redirected. If the file does not exist when the service program is started, the file is created. If this value is blank then any data written to stderr by the service program is discarded.

STDOUT(*string*)
Specifies the path to a file to which the standard output (stdout) of the service program is redirected. If the file does not exist when the service program is started, the file is created. If this value is blank then any data written to stdout by the service program is discarded.

STOPARG(*string*)
Specifies the arguments to be passed to the stop program when instructed to stop the service.

STOPCMD(*string*)
Specifies the name of the executable program to run when the service is requested to stop. You must specify a fully qualified path name to the executable program.

Replaceable inserts can be used for any of the **STARTCMD**, **STARTARG**, **STOPCMD**, **STOPARG**, **STDOUT** or **STDERR** strings, for more information, see Replaceable inserts on service definitions.

Related concepts
Working with services
Related tasks
Defining a service object
Related reference
“ALTER SERVICE (alter a service definition) on Multiplatforms” on page 398
Use the MQSC command **ALTER SERVICE** to alter the parameters of an existing IBM MQ service definition.

“DISPLAY SVSTATUS (display services status) on Multiplatforms” on page 819
Use the MQSC command **DISPLAY SVSTATUS** to display status information for one or more services. Only services with a **SERVTYPE** of SERVER are displayed.

“START SERVICE (start a service) on Multiplatforms” on page 932

Use the MQSC command **START SERVICE** to start a service. The identified service definition is started within the queue manager and inherits the environment and security variables of the queue manager.

"STOP SERVICE (stop a service) on Multiplatforms" on page 951
Use the MQSC command **STOP SERVICE** to stop a service.

Examples of using service objects

z/OS DEFINE STGCLASS (define storage class to page set mapping) on z/OS

Use the MQSC command DEFINE STGCLASS to define a storage class to page set mapping.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

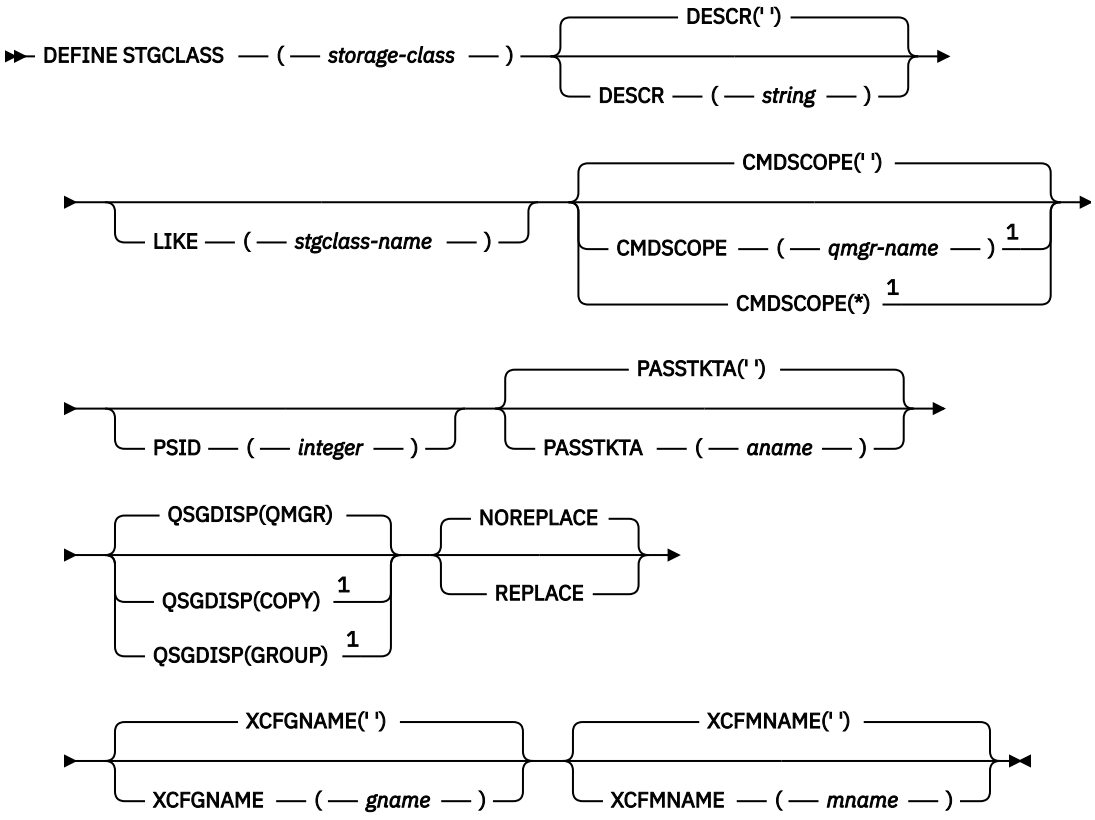
You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Usage notes for DEFINE STGCLASS" on page 568
- "Parameter descriptions for DEFINE STGCLASS" on page 568

Synonym: DEF STC

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See "Syntax diagrams" on page 236.

DEFINE STGCLASS



Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.

Usage notes for DEFINE STGCLASS

1. The resultant values of XCFGNAME and XCFMNAME must either both be blank or both be nonblank.
2. You can change a storage class only if it is not being used by any queues. To determine whether any queues are using the storage class, you can use the following command:

   ```
   DISPLAY QUEUE(*) STGCLASS(ABC) PSID(n)
   ```

   where 'ABC' is the name of the storage class, and *n* is the identifier of the page set that the storage class is associated with.

   This command gives a list of all queues that reference the storage class, and have an active association to page set *n*, and therefore identifies the queues that are actually preventing the change to the storage class. If you do not specify the PSID, you just get a list of queues that are potentially stopping the change.

   See the DISPLAY QUEUE PSID command for more information about active association of a queue to a page set.

Parameter descriptions for DEFINE STGCLASS

(storage-class)
Name of the storage class.

This name is one to 8 characters. The first character is in the range A through Z; subsequent characters are A through Z or 0 through 9.

Note: Exceptionally, certain all numeric storage class names are allowed, but are reserved for the use of IBM service personnel.

The storage class must not be the same as any other storage class currently defined on this queue manager.

CMDSCOPE
This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' '
The command runs on the queue manager on which it was entered.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of * is the same as entering the command on every queue manager in the queue sharing group.

DESCR(*description*)
Plain-text comment. It provides descriptive information about the object when an operator issues the DISPLAY STGCLASS command.

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager

LIKE(*stgclass-name*)
The name of an object of the same type, with parameters that are used to model this definition.

If this field is not completed, and you do not complete the parameter fields related to the command, the values are taken from the default definition for this object.

Not completing this parameter is equivalent to specifying:

```
LIKE(SYSTEMST)
```

This default storage class definition can be altered by your installation to the default values required.

The queue manager searches for an object with the name you specify and a disposition of QMGR or COPY. The disposition of the LIKE object is not copied to the object you are defining.

Note:

1. QSGDISP (GROUP) objects are not searched.
2. LIKE is ignored if QSGDISP(COPY) is specified.

PASSTKTA(*application name*)
The application name that is passed to RACF when authenticating the PassTicket specified in the MQIIH header.

PSID(*integer*)
The page set identifier that this storage class is to be associated with.

Note: No check is made that the page set has been defined; an error is raised only when you try to put a message to a queue that specifies this storage class (MQRC_PAGESET_ERROR).

The string consists of two numeric characters, in the range 00 through 99. See “DEFINE PSID (define page set and buffer pool) on z/OS” on page 527.

QSGDISP
Specifies the disposition of the object in the group.

*Table 160. Object dispositions for **QSGDISP** options*

QSGDISP	**DEFINE**

COPY	The object is defined on the page set of the queue manager that executes the command. It uses the **QSGDISP(GROUP)** object of the same name as the LIKE object.
	For example, if you issue the following command,
	`DEFINE STGCLASS(storage_class_name)`
	`REPLACE QSGDISP(COPY)`
	the queue manager searches the shared configuration repository for an STGCLASS definition called *storage_class_name*. If a matching STGCLASS definition is found, the queue manager creates a local copy of this definition on the queue manager page set.
	For local queues, messages are stored on the page sets of each queue manager and are available only through that queue manager.

*Table 160. Object dispositions for **QSGDISP** options (continued)*	
QSGDISP	**DEFINE**
GROUP	The object definition resides in the shared configuration repository. **QSGDISP(GROUP)** is allowed only if the queue manager is in a queue sharing group. If the DEFINE for the **QSGDISP(GROUP)** object is successful, the DEFINE STGCLASS(*storage_class_name*) REPLACE QSGDISP(COPY) command is generated and sent to all active queue managers in the queue sharing group to make or refresh local copies on page set zero. The DEFINE for the group object takes effect regardless of whether the generated command with **QSGDISP(COPY)** fails.
PRIVATE	Not permitted.
QMGR	The object is defined on the page set of the queue manager that executes the command.

REPLACE and NOREPLACE
Whether the existing definition, and with the same disposition, is to be replaced with this one. Any object with a different disposition is not changed.

REPLACE
The definition replaces any existing definition of the same name. If a definition does not exist, one is created.

If you use the REPLACE option, all queues that use this storage class must be temporarily altered to use another storage class while the command is issued.

NOREPLACE
The definition does not replace any existing definition of the same name.

XCFGNAME(*group name*)
If you are using the IMS bridge, this name is the name of the XCF group to which the IMS system belongs. (This name is the group name specified in the IMS parameter list.)

This name is 1 - 8 characters. The first character is in the range A through Z; subsequent characters are A through Z or 0 - 9.

XCFMNAME(*member name*)
If you are using the IMS bridge, this name is the XCF member name of the IMS system within the XCF group specified in XCFGNAME. (This name is the member name specified in the IMS parameter list.)

This name is 1 - 16 characters. The first character is in the range A through Z; subsequent characters are A through Z or 0 - 9.

DEFINE SUB (create a durable subscription)

Use **DEFINE SUB** to allow an existing application to participate in a publish/subscribe application by allowing the administrative creation of a durable subscription.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

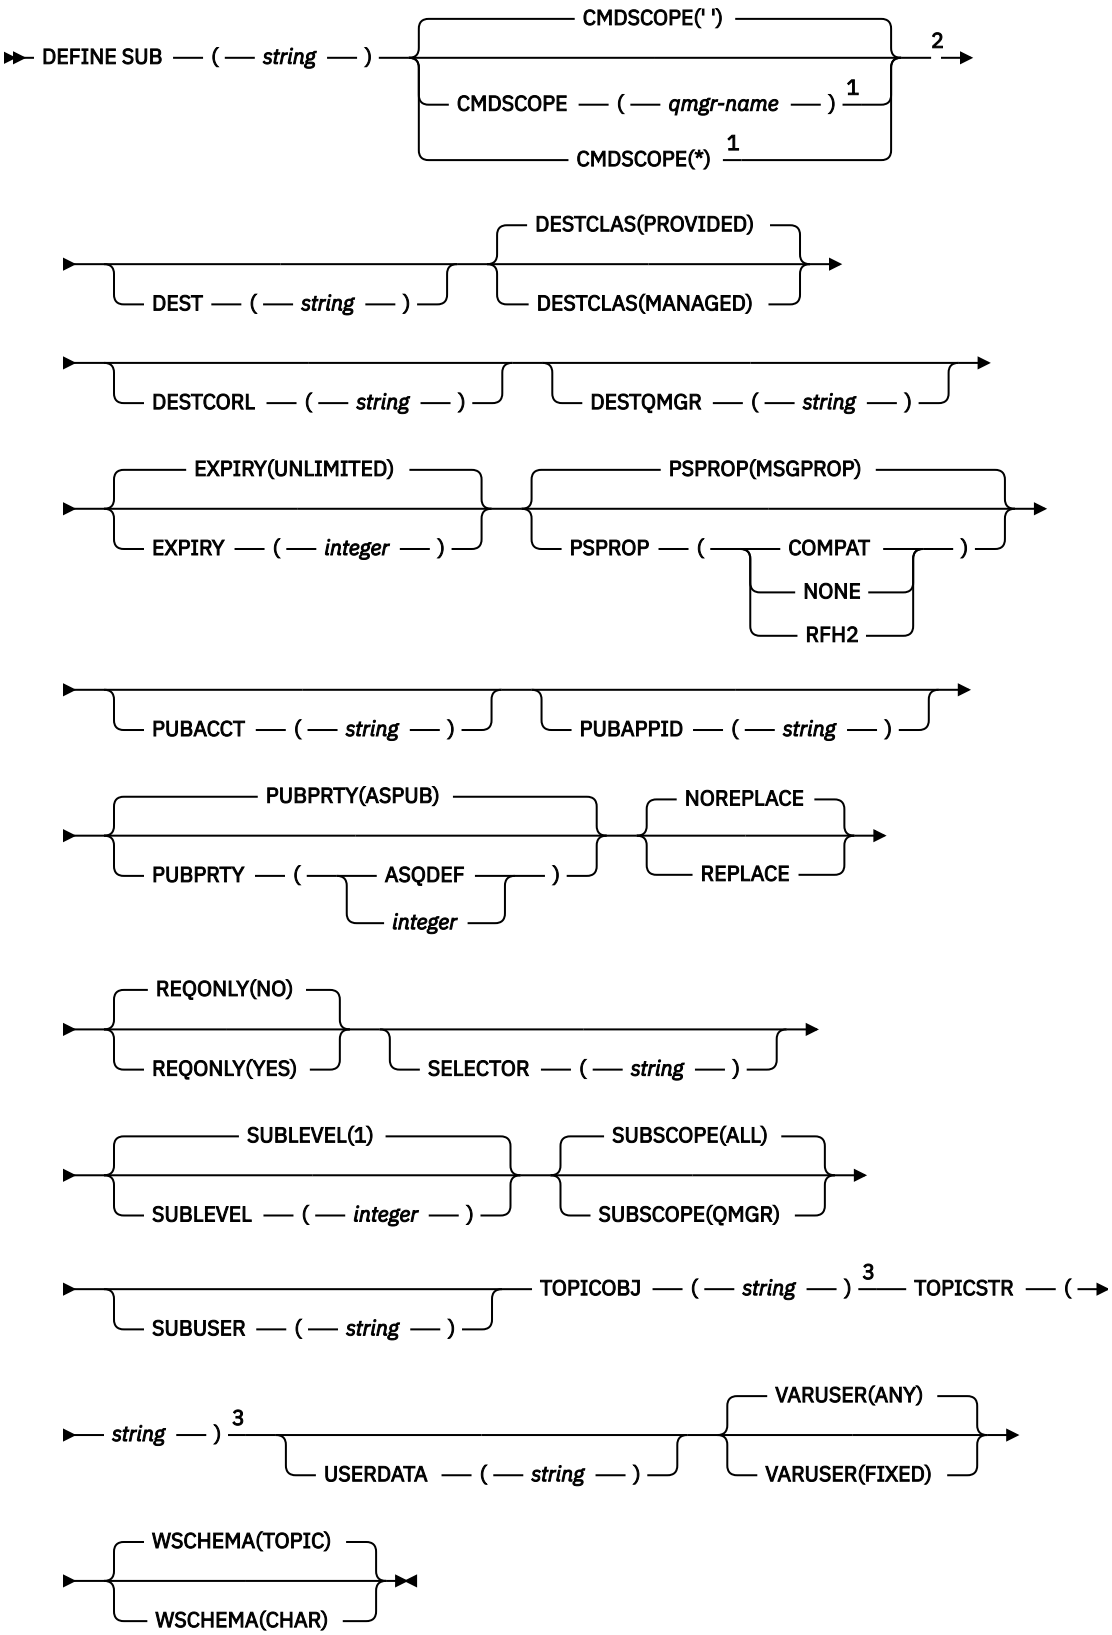
- Syntax diagram

- “Usage notes for DEFINE SUB” on page 573
- “Parameter descriptions for DEFINE SUB” on page 573

Synonym: **DEF SUB**

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See “Syntax diagrams” on page 236.

DEFINE SUB



Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.

[2] Valid only on z/OS.
[3] At least one of **TOPICSTR** and **TOPICOBJ** must be present on **DEFINE**.

Usage notes for DEFINE SUB

- You must provide the following information when you define a subscription:
  - The **SUBNAME**
  - A destination for messages
  - The topic to which the subscription applies
- You can provide the topic name in the following ways:

  TOPICSTR
  The topic is fully specified as the **TOPICSTR** attribute.

  TOPICOBJ
  The topic is obtained from the **TOPICSTR** attribute of the named topic object. The named topic object is retained as the **TOPICOBJ** attribute of the new subscription. This method is provided to help you enter long topic strings through an object definition.

  TOPICSTR and TOPICOBJ
  The topic is obtained by the concatenation of the **TOPICSTR** attribute of the named topic object and the value of **TOPICSTR** (see the MQSUB API specification for concatenation rules). The named topic object is retained as the **TOPICOBJ** attribute of the new subscription.
- If you specify **TOPICOBJ**, the parameter must name an IBM MQ topic object. The existence of the named topic object is checked at the time the command processes.
- You can explicitly specify the destination for messages through the use of the **DEST** and **DESTQMGR** keywords.

  You must provide the **DEST** keyword for the default option of **DESTCLAS(PROVIDED)**; if you specify **DESTCLAS(MANAGED)**, a managed destination is created on the local queue manager, so you cannot specify either the **DEST** or **DESTQMGR** attribute. For more information, see Managed queues and publish/subscribe.
- z/OS On z/OS only, at the time the **DEF SUB** command processes, no check is performed that the named **DEST** or **DESTQMGR** exists.

  These names are used at publishing time as the `ObjectName` and `ObjectQMgrName` for an MQOPEN call. These names are resolved according to the IBM MQ name resolution rules.
- When a subscription is defined administratively using MQSC or PCF commands, the selector is not validated for invalid syntax. The **DEFINE SUB** command has no equivalent to the MQRC_SELECTION_NOT_AVAILABLE reason code that can be returned by the MQSUB API call.
- **TOPICOBJ**, **TOPICSTR**, **WSCHEMA**, **SELECTOR**, **SUBSCOPE**, **SUBLEVEL**, and **DESTCLAS** cannot be changed with **DEFINE REPLACE**.
- When a publication has been retained, it is no longer available to subscribers at higher levels because it is republished at PubLevel 1.
- Successful completion of the command does not mean that the action completed. To check for true completion, see the DEFINE SUB step in Checking that async commands for distributed networks have finished.

Parameter descriptions for DEFINE SUB

(string)
A mandatory parameter. Specifies the unique name for this subscription, see **SUBNAME** property.

z/OS **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

' '

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of setting this value is the same as entering the command on every queue manager in the queue sharing group.

You cannot use CMDSCOPE as a filter keyword.

DEST(*string*)

The destination for messages published to this subscription; this parameter is the name of a queue.

DESTCLAS

System managed destination.

PROVIDED

The destination is a queue.

MANAGED

The destination is managed.

DESTCORL(*string*)

The **CorrelId** used for messages published to this subscription.

A blank value (default) results in a system generated correlation identifier being used.

If set to ' `00000000000000000000000000000000000000000000000000000000` ' (48 zeros) the **CorrelId** set by the publishing application will be maintained in the copy of the message delivered to the subscription, unless messages are propagated across a publish/subscribe hierarchy.

If this byte string is enclosed in quotation marks, characters in the range A-F must be specified in uppercase.

Note: It is not possible to set the DESTCORL property programmatically with JMS.

DESTQMGR(*string*)

The destination queue manager for messages published to this subscription. You must define the channels to the remote queue manager, for example, the XMITQ, and a sender channel. If you do not, messages do not arrive at the destination.

EXPIRY

The time to expiry of the subscription object from the creation date and time.

(*integer*)

The time to expiry, in tenths of a second, from the creation date and time.

UNLIMITED

There is no expiry time. This is the default option supplied with the product.

LIKE(*subscription-name*)

The name of a subscription, the parameters of which are used as a model for this definition.

This parameter applies only to the **DEFINE SUB** command.

If this field is not supplied, and you do not complete the parameter fields related to the command, the values are taken from the default definition for subscriptions on this queue manager. Not completing this parameter is equivalent to specifying:

```
LIKE (SYSTEM.DEFAULT.SUB)
```

PSPROP
The manner in which publish subscribe related message properties are added to messages sent to this subscription.

NONE
Do not add publish subscribe properties to the message.

COMPAT
Publish/subscribe properties are added within an MQRFH version 1 header unless the message was published in PCF format.

MSGPROP
Publish/subscribe properties are added as message properties.

RFH2
Publish/subscribe properties are added within an MQRFH version 2 header.

PUBACCT(*string*)
Accounting token passed by the subscriber, for propagation into messages published to this subscription in the `AccountingToken` field of the MQMD.

If this byte string is enclosed in quotation marks, characters in the range A-F must be specified in uppercase.

PUBAPPID(*string*)
Identity data passed by the subscriber, for propagation into messages published to this subscription in the `ApplIdentityData` field of the MQMD.

PUBPRTY
The priority of the message sent to this subscription.

ASPUB
Priority of the message sent to this subscription is taken from the priority supplied in the published message.

ASQDEF
Priority of the message sent to this subscription is taken from the default priority of the queue defined as a destination.

(integer)
An integer providing an explicit priority for messages published to this subscription.

REPLACE and NOREPLACE
This parameter controls whether any existing definition is to be replaced with this one.

REPLACE
The definition replaces any existing definition of the same name. If a definition does not exist, one is created.

You cannot change **TOPICOBJ**, **TOPICSTR**, **WSCHEMA**, **SELECTOR**, **SUBSCOPE**, or **DESTCLAS** with **DEFINE REPLACE**.

NOREPLACE
The definition does not replace any existing definition of the same name.

REQONLY
Indicates whether the subscriber polls for updates using the MQSUBRQ API call, or whether all publications are delivered to this subscription.

NO
All publications on the topic are delivered to this subscription. This is the default value.

YES
Publications are only delivered to this subscription in response to an MQSUBRQ API call.

This parameter is equivalent to the subscribe option MQSO_PUBLICATIONS_ON_REQUEST.

SELECTOR(*string*)
A selector that is applied to messages published to the topic.

SUBLEVEL(*integer*)
The level within the subscription hierarchy at which this subscription is made. The range is zero through 9.

SUBSCOPE
Determines whether this subscription is forwarded to other queue managers, so that the subscriber receives messages published at those other queue managers.

ALL
The subscription is forwarded to all queue managers directly connected through a publish/subscribe collective or hierarchy.

QMGR
The subscription forwards messages published on the topic only within this queue manager.

Note: Individual subscribers can only restrict **SUBSCOPE**. If the parameter is set to ALL at topic level, then an individual subscriber can restrict it to QMGR for this subscription. However, if the parameter is set to QMGR at topic level, then setting an individual subscriber to ALL has no effect.

SUBNAME
The application's unique subscription name that is associated with the handle. This parameter is relevant only for handles of subscriptions to topics. It is not returned for other handles. Not all subscriptions will have a subscription name.

SUBUSER(*string*)
Specifies the user ID that is used for security checks that are performed to ensure that publications can be put to the destination queue associated with the subscription. This ID is either the user ID associated with the creator of the subscription or, if subscription takeover is permitted, the user ID that last took over the subscription. The length of this parameter must not exceed 12 characters.

TOPICOBJ(*string*)
The name of a topic object used by this subscription.

TOPICSTR(*string*)
Specifies a fully qualified topic name, or a topic set using wildcard characters for the subscription.

USERDATA(*string*)
Specifies the user data associated with the subscription. The string is a variable length value that can be retrieved by the application on an MQSUB API call and passed in a message sent to this subscription as a message property. The **USERDATA** is stored in the RFH2 header in the mqps folder with the key Sud.

An IBM MQ classes for JMS application can retrieve the subscription user data from the message by using the constant JMS_IBM_SUBSCRIPTION_USER_DATA. For more information, see Retrieval of user subscription data.

VARUSER
Specifies whether a user other than the subscription creator can connect to and take over ownership of the subscription.

ANY
Any user can connect to and takeover ownership of the subscription.

FIXED
Takeover by another USERID is not permitted.

WSCHEMA
The schema to be used when interpreting any wildcard characters in the topic string.

CHAR
Wildcard characters represent portions of strings.

TOPIC
Wildcard characters represent portions of the topic hierarchy.

Related tasks
Defining an administrative subscription
Changing local subscription attributes

DEFINE TOPIC (define a new administrative topic)

Use **DEFINE TOPIC** to define a new IBM MQ administrative topic in a topic tree, and set its parameters.

Using MQSC commands

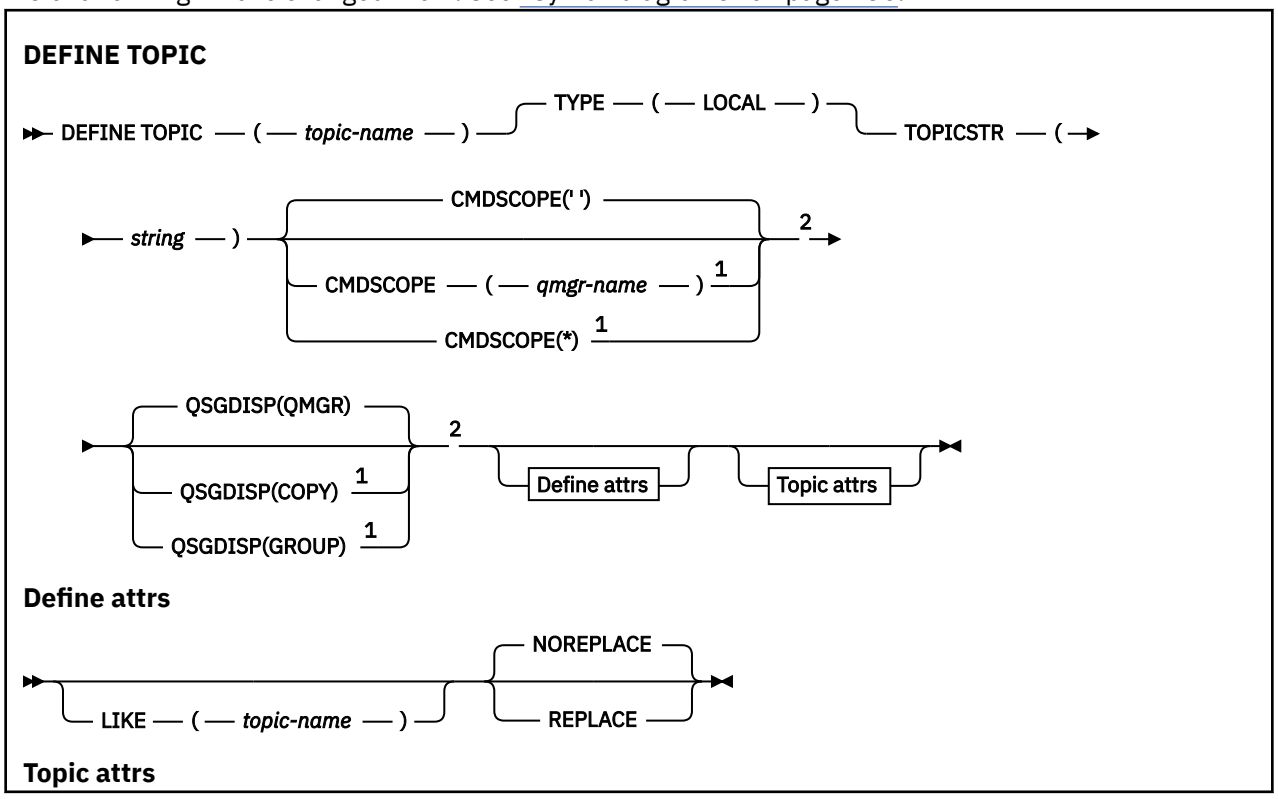
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

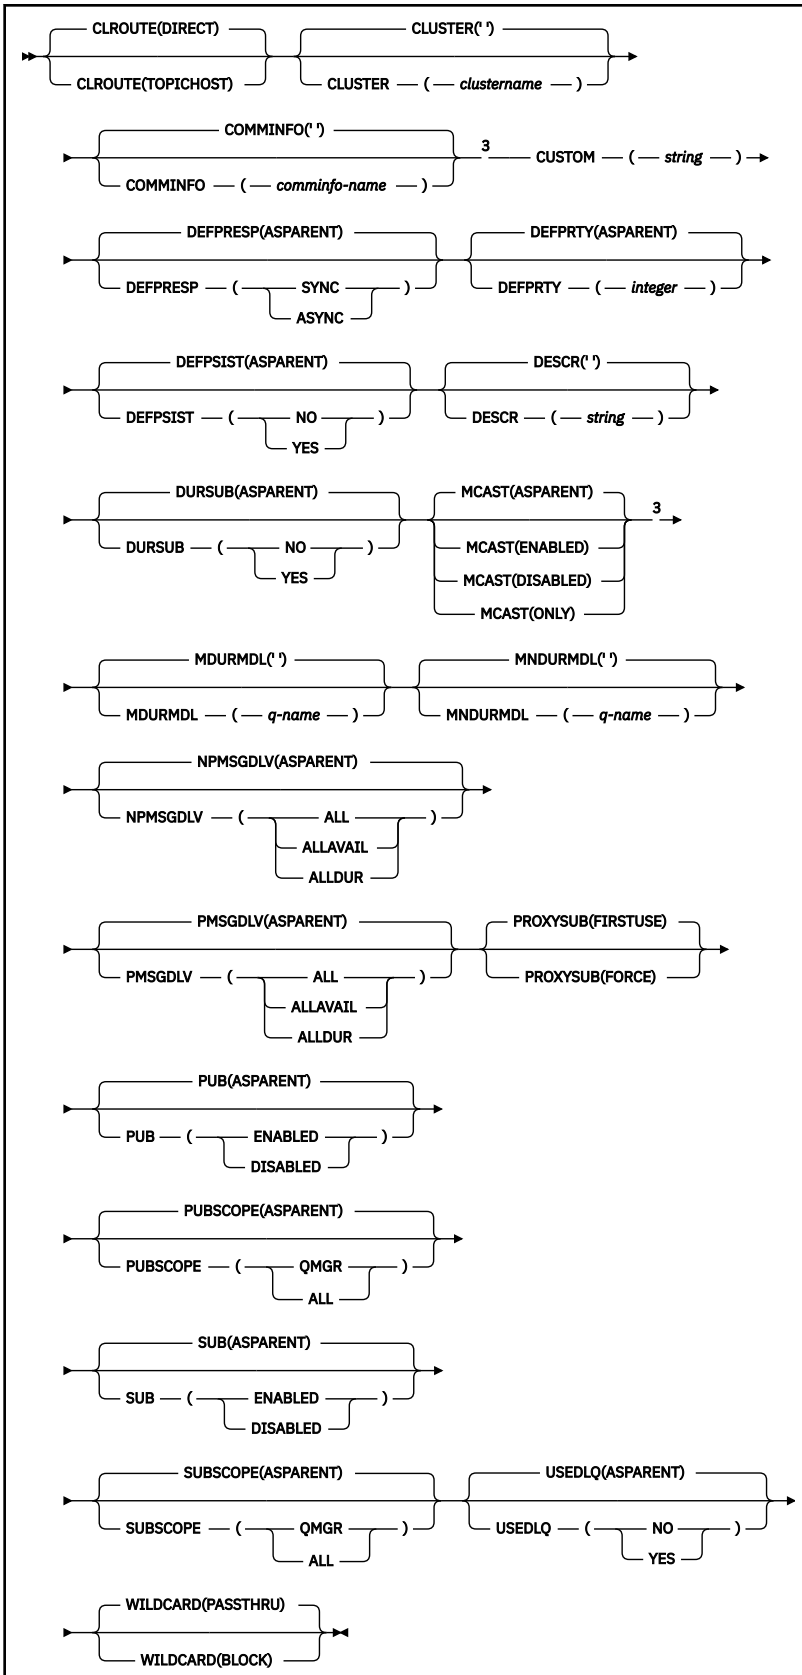
z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Usage notes for DEFINE TOPIC" on page 579
- "Parameter descriptions for DEFINE TOPIC" on page 579

Synonym: DEF TOPIC

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See "Syntax diagrams" on page 236.





Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.

[2] Valid only on z/OS.

[3] Not valid on z/OS.

Usage notes for DEFINE TOPIC

- When an attribute has the value ASPARENT, the value is taken from the setting of the first parent administrative node that is found in the topic tree. Administered nodes are based on either locally defined topic objects or remotely defined cluster topics when participating in a publish/subscribe cluster. If the first parent topic object also has the value ASPARENT, the next object is looked for. If every object that is found, when looking up the tree, uses ASPARENT, the values are taken from the SYSTEM.BASE.TOPIC, if it exists. If SYSTEM.BASE.TOPIC does not exist, the values are the same as the values supplied with IBM MQ in the definition of the SYSTEM.BASE.TOPIC.
- The ASPARENT attribute is applied at each queue manager in the cluster collective by inspecting the set of local definitions and cluster definitions that is visible in the queue manager at the time.
- When a publication is sent to multiple subscribers, the attributes used from the topic object are used consistently for all subscribers that receive the publication. For example, inhibiting publication on a topic is applied for the next application MQPUT to the topic. A publication that is in progress to multiple subscribers completes to all subscribers. This publication does not take note of a change that has happened, part of the way through, to any attribute on the topic.
- Successful completion of the command does not mean that the action completed. To check for true completion, see the DEFINE TOPIC step in Checking that async commands for distributed networks have finished.

Parameter descriptions for DEFINE TOPIC

(topic-name)
Name of the IBM MQ topic definition (see Rules for naming IBM MQ objects). The maximum length is 48 characters.

The name must not be the same as any other topic definition currently defined on this queue manager (unless REPLACE is specified).

CLROUTE
The routing behavior to use for topics in the cluster defined by the **CLUSTER** parameter.

DIRECT
When you configure a direct routed clustered topic on a queue manager, all queue managers in the cluster become aware of all other queue managers in the cluster. When performing publish and subscribe operations, each queue manager can connect direct to any other queue manager in the cluster.

TOPICHOST
When you use topic host routing, all queue managers in the cluster become aware of the cluster queue managers that host the routed topic definition (that is, the queue managers on which you have defined the topic object). When performing publish and subscribe operations, queue managers in the cluster connect only to these topic host queue managers, and not directly to each other. The topic host queue managers are responsible for routing publications from queue managers on which publications are published to queue managers with matching subscriptions.

After a topic object has been clustered (through setting the **CLUSTER** property) you cannot change the value of the **CLROUTE** property. The object must be un-clustered (**CLUSTER** set to `' '`) before you can change the value. Un-clustering a topic converts the topic definition to a local topic, which results in a period during which publications are not delivered to subscriptions on remote queue managers; this should be considered when performing this change. See The effect of defining a non-cluster topic with the same name as a cluster topic from another queue manager. If you try to change the value of the **CLROUTE** property while it is clustered, the system generates an `MQRCCF_CLROUTE_NOT_ALTERABLE` exception.

See also Routing for publish/subscribe clusters: Notes on behavior and Designing publish/subscribe clusters.

CLUSTER
The name of the cluster to which this topic belongs. Setting this parameter to a cluster that this queue manager is a member of makes all queue managers in the cluster aware of this topic. Any publication to this topic or a topic string below it put to any queue manager in the cluster is propagated to subscriptions on any other queue manager in the cluster. For more details, see Distributed publish/subscribe networks.

' '
If no topic object above this topic in the topic tree has set this parameter to a cluster name, then this topic does not belong to a cluster. Publications and subscriptions for this topic are not propagated to publish/subscribe cluster-connected queue managers. If a topic node higher in the topic tree has a cluster name set, publications and subscriptions to this topic are also propagated throughout the cluster.

string
The topic belongs to this cluster. It is not recommended that this is set to a different cluster from a topic object above this topic object in the topic tree. Other queue managers in the cluster will honor this object's definition unless a local definition of the same name exists on those queue managers.

To prevent all subscriptions and publications being propagated throughout a cluster, leave this parameter blank on the system topics SYSTEM.BASE.TOPIC and SYSTEM.DEFAULT.TOPIC, except in special circumstances, for example to support migration.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' '
The command runs on the queue manager on which it was entered.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

***
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of * is the same as entering the command on every queue manager in the queue sharing group.

COMMINFO(*comminfo-name*)
The name of the Multicast communication information object associated with this topic object.

CUSTOM(*string*)
The custom attribute for new features.

This attribute contains the values of attributes, as pairs of attribute name and value, separated by at least one space. The attribute name-value pairs have the form `NAME(VALUE)`.

CAPEXPRY(*integer*)
The maximum time, expressed in tenths of a second, until a message published to a topic which inherits properties from this object, remains in the system until it becomes eligible for expiry processing.

For more information on message expiry processing, see Enforcing lower expiration times.

integer
The value must be in the range one through to 999 999 999.

NOLIMIT
There is no limit on the expiry time of messages put to this topic.

ASPARENT
The maximum message expiry time is based on the setting of the closest parent administrative topic object in the topic tree. This is the default value.

Specifying a value for CAPEXPRY that is not valid, does not cause the command to fail. Instead, the default value is used.

DEFPRESP
Specifies the put response to be used when applications specify the MQPMO_RESPONSE_AS_DEF option.

ASPARENT
The default put response is based on the setting of the closest parent administrative topic object in the topic tree.

SYNC
Put operations to the queue that specify MQPMO_RESPONSE_AS_Q_DEF are issued as if MQPMO_SYNC_RESPONSE had been specified instead. Fields in the MQMD and MQPMO are returned by the queue manager to the application.

ASYNC
Put operations to the queue that specify MQPMO_RESPONSE_AS_Q_DEF are always issued as if MQPMO_ASYNC_RESPONSE had been specified instead. Some fields in the MQMD and MQPMO are not returned by the queue manager to the application; but an improvement in performance might be seen for messages put in a transaction and any non-persistent messages

DEFPRTY(*integer*)
The default priority of messages published to the topic.

(*integer*)
The value must be in the range zero (the lowest priority), through to the MAXPRTY queue manager parameter (MAXPRTY is 9).

ASPARENT
The default priority is based on the setting of the closest parent administrative topic object in the topic tree.

DEFPSIST
Specifies the message persistence to be used when applications specify the MQPER_PERSISTENCE_AS_TOPIC_DEF option.

ASPARENT
The default persistence is based on the setting of the closest parent administrative topic object in the topic tree.

NO
Messages on this queue are lost during a restart of the queue manager.

YES
Messages on this queue survive a restart of the queue manager.

On z/OS, N and Y are accepted as synonyms of NO and YES.

DESCR(*string*)
Plain-text comment. It provides descriptive information about the object when an operator issues the DISPLAY TOPIC command.

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

DURSUB
Specifies whether applications are permitted to make durable subscriptions on this topic.

ASPARENT
Whether durable subscriptions can be made on this topic is based on the setting of the closest parent administrative topic object in the topic tree.

NO
Durable subscriptions cannot be made on this topic.

YES
Durable subscriptions can be made on this topic.

LIKE(*topic-name*)
The name of a topic. The topic parameters are used to model this definition.

If this field is not completed, and you do not complete the parameter fields related to the command, the values are taken from the default definition for topics on this queue manager.

Not completing this field is equivalent to specifying:

```
LIKE(SYSTEM.DEFAULT.TOPIC)
```

A default topic definition is provided, but it can be altered by the installation to the default values required. See Rules for naming IBM MQ objects.

z/OS On z/OS, the queue manager searches page set zero for an object with the name you specify and a disposition of QMGR or COPY. The disposition of the LIKE object is not copied to the object you are defining.

Note:

1. QSGDISP (GROUP) objects are not searched.
2. LIKE is ignored if QSGDISP(COPY) is specified.

MCAST
Specifies whether multicast is allowable in the topic tree. The values are:

ASPARENT
The multicast attribute of the topic is inherited from the parent.

DISABLED
No multicast traffic is allowed at this node.

ENABLED
Multicast traffic is allowed at this node.

ONLY
Only subscriptions from a multicast capable client are allowed.

MDURMDL(*string*)
The name of the model queue to be used for durable subscriptions that request that the queue manager manages the destination of its publications (see Rules for naming IBM MQ objects). The maximum length is 48 characters.

If **MDURMDL** is blank, it operates in the same way as ASPARENT values on other attributes. The name of the model queue to be used is based on the closest parent administrative topic object in the topic tree with a value set for **MDURMDL**.

If you use **MDURMDL** to specify a model queue for a clustered topic, you must ensure that the queue is defined on every queue manager in the cluster where a durable subscription using this topic can be made.

The dynamic queue created from this model has a prefix of SYSTEM.MANAGED.DURABLE

MNDURMDL(*string*)
The name of the model queue to be used for non-durable subscriptions that request that the queue manager manages the destination of its publications (see Rules for naming IBM MQ objects). The maximum length is 48 characters.

If **MNDURMDL** is blank, it operates in the same way as ASPARENT values on other attributes. The name of the model queue to be used is based on the closest parent administrative topic object in the topic tree with a value set for **MNDURMDL**.

If you use **MNDURMDL** to specify a model queue for a clustered topic, you must ensure that the queue is defined on every queue manager in the cluster where a non-durable subscription using this topic can be made.

The dynamic queue created from this model has a prefix of SYSTEM.MANAGED.NDURABLE.

NPMSGDLV
The delivery mechanism for non-persistent messages published to this topic:

ASPARENT
The delivery mechanism used is based on the setting of the first parent administrative node found in the topic tree relating to this topic.

ALL
Non-persistent messages must be delivered to all subscribers, irrespective of durability for the MQPUT call to report success. If a delivery failure to any subscriber occurs, no other subscribers receive the message and the MQPUT call fails.

ALLAVAIL
Non-persistent messages are delivered to all subscribers that can accept the message. Failure to deliver the message to any subscriber does not prevent other subscribers from receiving the message.

ALLDUR
Non-persistent messages must be delivered to all durable subscribers. Failure to deliver a non-persistent message to any non-durable subscribers does not return an error to the MQPUT call. If a delivery failure to a durable subscriber occurs, no subscribers receive the message and the MQPUT calls fails.

PMSGDLV
The delivery mechanism for persistent messages published to this topic:

ASPARENT
The delivery mechanism used is based on the setting of the first parent administrative node found in the topic tree relating to this topic.

ALL
Persistent messages must be delivered to all subscribers, irrespective of durability for the MQPUT call to report success. If a delivery failure to any subscriber occurs, no other subscribers receive the message and the MQPUT call fails.

ALLAVAIL
Persistent messages are delivered to all subscribers that can accept the message. Failure to deliver the message to any subscriber does not prevent other subscribers from receiving the message.

ALLDUR
Persistent messages must be delivered to all durable subscribers. Failure to deliver a persistent message to any non-durable subscribers does not return an error to the MQPUT call. If a delivery failure to a durable subscriber occurs, no subscribers receive the message and the MQPUT calls fails.

PROXYSUB
Controls when a proxy subscription is sent for this topic, or topic strings below this topic, to neighboring queue managers when in a publish/subscribe cluster or hierarchy. For more details, see Subscription performance in publish/subscribe networks.

FIRSTUSE
For each unique topic string at or below this topic object, a proxy subscription is asynchronously sent to all neighboring queue managers in the following scenarios:

- When a local subscription is created.

- When a proxy subscription is received that must be propagated to further directly connected queue managers.

FORCE
A wildcard proxy subscription that matches all topic strings at and below this point in the topic tree is sent to neighboring queue managers even if no local subscriptions exist.

Note: The proxy subscription is sent when this value is set on DEFINE or ALTER. When set on a clustered topic, all queue managers in the cluster issue the wildcard proxy subscription to all other queue managers in the cluster.

PUB
Controls whether messages can be published to this topic.

ASPARENT
Whether messages can be published to the topic is based on the setting of the closest parent administrative topic object in the topic tree.

ENABLED
Messages can be published to the topic (by suitably authorized applications).

DISABLED
Messages cannot be published to the topic.

See also Special handling for the **PUB** parameter.

PUBSCOPE
Determines whether this queue manager propagates publications to queue managers as part of a hierarchy or as part of a publish/subscribe cluster.

Note: You can restrict the behavior on a publication-by-publication basis, using MQPMO_SCOPE_QMGR on the Put Message options.

ASPARENT
Determines whether this queue manager propagates publications to queue managers as part of a hierarchy or as part of a publish/subscribe cluster. This is based on the setting of the first parent administrative node found in the topic tree that relates to this topic.

QMGR
Publications for this topic are not propagated to connected queue managers.

ALL
Publications for this topic are propagated to hierarchically connected queue managers and to publish/subscribe cluster-connected queue managers.

z/OS **QSGDISP**
This parameter applies to z/OS only.

Specifies the disposition of the object within the group.

*Table 161. Object dispositions for **QSGDISP** options*	
QSGDISP	**DEFINE**

COPY	The object is defined on the page set of the queue manager that executes the command. It uses the **QSGDISP(GROUP)** object of the same name as the LIKE object.
	For example, if you issue the following command,
	`DEFINE TOPIC(topic_name)`
	`REPLACE QSGDISP(COPY)`
	the queue manager searches the shared configuration repository for a TOPIC definition called *topic_name*. If a matching TOPIC definition is found, the queue manager creates a local copy of this definition on the queue manager page set.
	For local queues, messages are stored on the page sets of each queue manager and are available only through that queue manager.

GROUP	The object definition resides in the shared configuration repository. **QSGDISP(GROUP)** is allowed only if the queue manager is in a queue sharing group. If the DEFINE for the **QSGDISP(GROUP)** object is successful, the DEFINE TOPIC(*topic_name*) REPLACE QSGDISP(COPY) command is generated and sent to all active queue managers in the queue sharing group to make or refresh local copies on page set zero. The DEFINE for the group object takes effect regardless of whether the generated command with **QSGDISP(COPY)** fails.
PRIVATE	Not permitted.
QMGR	The object is defined on the page set of the queue manager that executes the command.

REPLACE and NOREPLACE

Determines whether the existing definition (and on z/OS, with the same disposition) is to be replaced with this one. Any object with a different disposition is not changed.

REPLACE

If the object does exist, the effect is like issuing the **ALTER** command without the **FORCE** option and with *all* the other parameters specified.

(The difference between the **ALTER** command without the **FORCE** option, and the **DEFINE** command with the **REPLACE** option, is that **ALTER** does not change unspecified parameters, but **DEFINE** with **REPLACE** sets *all* the parameters. When you use **REPLACE**, unspecified parameters are taken either from the object named on the **LIKE** option, or from the default definition, and the parameters of the object being replaced, if one exists, are ignored.)

The command fails if both of the following statements are true:

- The command sets parameters that would require the use of the **FORCE** option if you were using the **ALTER** command.
- The object is open.

The ALTER command with the FORCE option succeeds in this situation.

Note: The REPLACE option does not replace the TOPICSTR properties of a topic. TOPICSTR is a property that is usefully varied in the example to test different topic trees. To change topics, delete the topic first.

NOREPLACE
The definition must not replace any existing definition of the object.

SUB
Controls whether applications are to be permitted to subscribe to this topic.

ASPARENT
Whether applications can subscribe to the topic is based on the setting of the closest parent administrative topic object in the topic tree.

ENABLED
Subscriptions can be made to the topic (by suitably authorized applications).

DISABLED
Applications cannot subscribe to the topic.

SUBSCOPE
Determines whether this queue manager subscribes to publications in this queue manager or in the network of connected queue managers. If subscribing to all queue managers, the queue manager propagates subscriptions to them as part of a hierarchy or as part of a publish/subscribe cluster.

Note: You can restrict the behavior on a subscription-by-subscription basis, using **MQPMO_SCOPE_QMGR** on the Subscription Descriptor or **SUBSCOPE(QMGR)** on **DEFINE SUB**. Individual subscribers can override the **SUBSCOPE** setting of ALL by specifying the **MQSO_SCOPE_QMGR** subscription option when creating a subscription.

ASPARENT
Whether this queue manager subscribes to publications in the same way as the setting of the first parent administrative node found in the topic tree relating to this topic.

QMGR
Only publications that are published on this queue manager reach the subscriber.

ALL
A publication made on this queue manager or on another queue manager reaches the subscriber. Subscriptions for this topic are propagated to hierarchically connected queue managers and to publish/subscribe cluster-connected queue managers.

TOPICSTR(*string*)
The topic string represented by this topic object definition. This parameter is required and cannot contain the empty string.

The topic string must not be the same as any other topic string already represented by a topic object definition.

The maximum length of the string is 10,240 characters.

Note: The REPLACE option does not replace the TOPICSTR properties of a topic. TOPICSTR is a property that is usefully varied in the example to test different topic trees. To change topics, delete the topic first.

TYPE(*topic-type*)
If this parameter is used it must follow immediately after the *topic-name* parameter on all platforms z/OS except z/OS.

LOCAL
A local topic object.

USEDLQ
Determines whether the dead-letter queue is used when publication messages cannot be delivered to their correct subscriber queue.

ASPARENT
Determines whether to use the dead-letter queue using the setting of the closest administrative topic object in the topic tree. This value is the default supplied with IBM MQ, but your installation might have changed it.

NO
Publication messages that cannot be delivered to their correct subscriber queue are treated as a failure to put the message. The MQPUT of an application to a topic fails in accordance with the settings of **NPMSGDLV** and **PMSGDLV**.

YES
When the **DEADQ** queue manager attribute provides the name of a dead-letter queue, then it is used. If the queue manager does not provide the name of a dead-letter queue, then the behavior is as for NO.

WILDCARD
The behavior of wildcard subscriptions with respect to this topic.

PASSTHRU
Subscriptions made to a wildcarded topic less specific than the topic string at this topic object receive publications made to this topic and to topic strings more specific than this topic.

BLOCK
Subscriptions made to a wildcarded topic less specific than the topic string at this topic object do not receive publications made to this topic or to topic strings more specific than this topic.

The value of this attribute is used when subscriptions are defined. If you alter this attribute, the set of topics covered by existing subscriptions is not affected by the modification. This scenario applies also if the topology is changed when topic objects are created or deleted; the set of topics matching subscriptions created following the modification of the **WILDCARD** attribute is created using the modified topology. If you want to force the matching set of topics to be re-evaluated for existing subscriptions, you must restart the queue manager.

Related tasks
Defining an administrative topic

DELETE AUTHINFO (delete authentication information)

Use MQSC command **DELETE AUTHINFO** to delete an authentication information object.

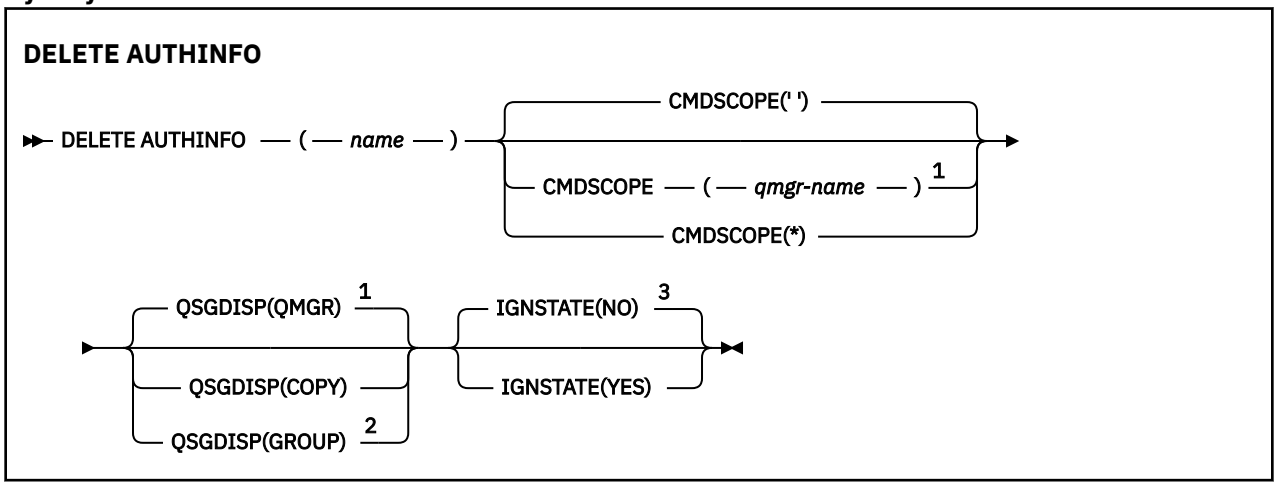
Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Parameter descriptions for DELETE AUTHINFO" on page 588

Synonym: None



Notes:

[1] Valid only on z/OS.
[2] Valid only when the queue manager is a member of a queue sharing group. You can use queue sharing groups only on IBM MQ for z/OS.
[3] Valid only on AIX, Linux, and Windows.

Parameter descriptions for DELETE AUTHINFO

(name)
Name of the authentication information object. This is required.

The name must be that of an existing authentication information object.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

z/OS **QSGDISP**
This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

COPY
The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters **QSGDISP(COPY)**. Any object residing in the shared repository, or any object defined using a command that had the parameters QSGDISP(QMGR), is not affected by this command.

GROUP
The object definition resides in the shared repository. The object was defined using a command that had the parameters **QSGDISP(GROUP)**. Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command.

If the command is successful, the following command is generated and sent to all active queue managers in the queue sharing group to delete local copies on page set zero:

```
DELETE AUTHINFO(name) QSGDISP(COPY)
```

The deletion of the group object takes effect even if the generated command with **QSGDISP(COPY)** fails.

QMGR
The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters **QSGDISP(QMGR)**. Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

This is the default value.

V 9.2.1 ALW **IGNSTATE**
This parameter allows you to specify whether you want the command to return an error code if the object is already in the state the command moves it to.

A value of YES means the return code and message are the same as if the MQSC object has not been deleted.

A value of NO means that the return code is zero, even if the object has been deleted. This is the default value.

Note that, when running in **runmqsc -n** mode, that is, not connected to a queue manager, the **DELETE AUTHINFO** command accepts the **IGNSTATE** parameter, but there is no difference in behavior between YES and NO options. If **runmqsc** is run normally, **DELETE AUTHINFO** acts like other objects.

Multi DELETE AUTHREC (delete authority records) on Multiplatforms

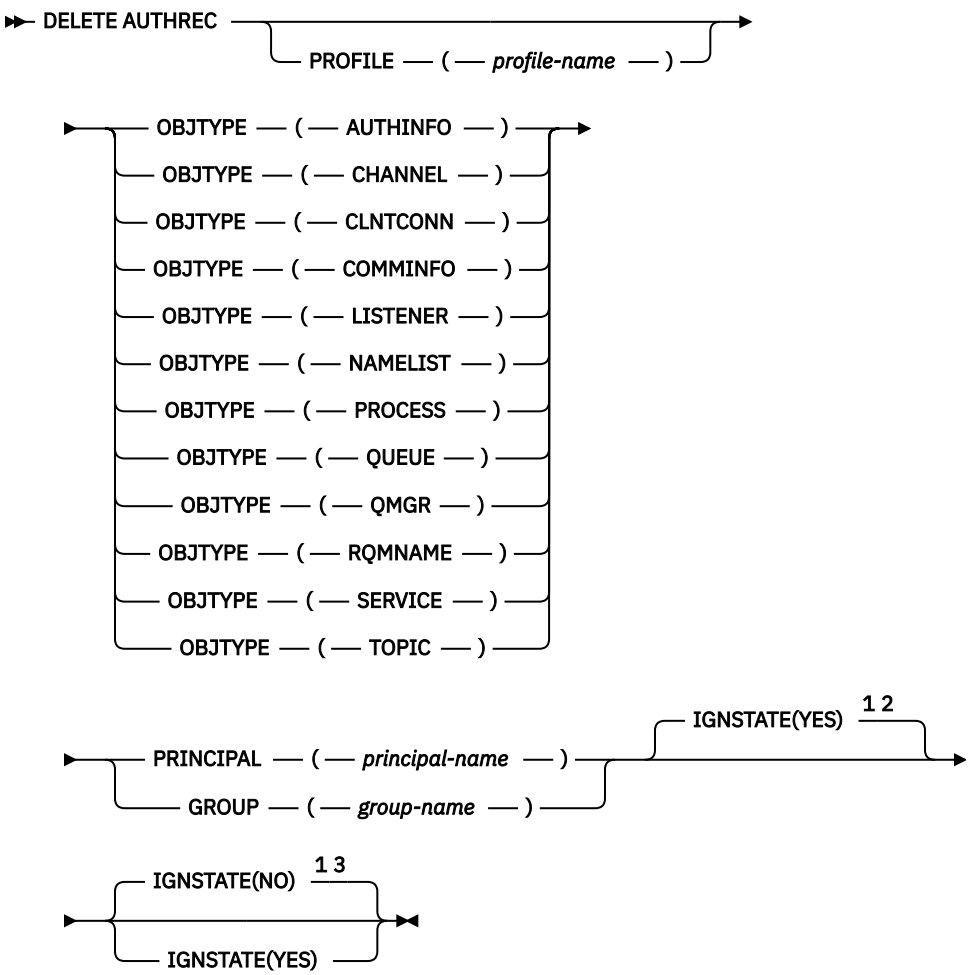
Use the MQSC command DELETE AUTHREC to delete authority records associated with a profile name.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

- Syntax diagram
- "Parameter descriptions" on page 590

DELETE AUTHREC



Notes:

[1] Valid only on AIX, Linux, and Windows.

[2] Default value is YES for QMGR, TOPIC, RQMNAME and QUEUE objects when set using the OBJTYPE parameter. Setting IGNSTATE to NO is not valid for these objects.

[3] Default value is NO for objects apart from QMGR, TOPIC, RQMNAME and QUEUE.

Parameter descriptions

PROFILE(*profile-name*)
The name of the object or generic profile for which to remove the authority record. This parameter is required unless the **OBJTYPE** parameter is QMGR, in which case it can be omitted.

OBJTYPE
The type of object referred to by the profile. Specify one of the following values:

AUTHINFO
Authentication information record

CHANNEL
Channel

CLNTCONN
Client connection channel

COMMINFO
Communication information object

LISTENER
Listener

NAMELIST
Namelist

PROCESS
Process

QUEUE
Queue

QMGR
Queue manager

RQMNAME
Remote queue manager

SERVICE
Service

TOPIC
Topic

PRINCIPAL(*principal-name*)
A principal name. This is the name of a user for whom to remove authority records for the specified profile. On IBM MQ for Windows, the name of the principal can optionally include a domain name, specified in this format: `user@domain`.

You must specify either PRINCIPAL or GROUP.

GROUP(*group-name*)
A group name. This is the name of the user group for which to remove authority records for the specified profile. You can specify one name only and it must be the name of an existing user group.

Windows For IBM MQ for Windows only, the group name can optionally include a domain name, specified in the following formats:

```
GroupName@domain
domain\GroupName
```

You must specify either PRINCIPAL or GROUP.

V 9.2.1 ALW **IGNSTATE**
This parameter allows you to specify whether you want the command to return an error code if the object is already in the state the command moves it to.

A value of YES means the return code and message are the same as if the MQSC object has not been deleted.

A value of NO means that the return code is zero, even if the object has been deleted.

Attention: You can only set the value to YES for QMGR, TOPIC, RQMNAME and QUEUE objects. For these objects, the value NO is not valid. For all other objects the default value is NO.

z/OS DELETE BUFFPOOL (delete a buffer pool) on z/OS

Use the MQSC command DELETE BUFFPOOL to delete a buffer pool that is used for holding messages in main storage.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Usage note for DELETE BUFFPOOL" on page 592
- "Parameter descriptions for DELETE BUFFPOOL" on page 592

Synonym: DEL BP

DELETE BUFFPOOL

Usage note for DELETE BUFFPOOL

- Ensure there are no current page set definitions using the named buffer pool, otherwise the command will fail.
- DELETE BUFFPOOL cannot be issued from CSQINPT.

Parameter descriptions for DELETE BUFFPOOL

(integer)

This is the number of the buffer pool to be deleted. The value is an integer in the range zero through 99.

z/OS DELETE CFSTRUCT (delete CF application structure) on z/OS

Use the MQSC command DELETE CFSTRUCT to delete a CF application structure definition.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Usage notes for DELETE CFSTRUCT" on page 592
- "Keyword and parameter descriptions for DELETE CFSTRUCT" on page 593

Synonym: None

DELETE CFSTRUCT

Usage notes for DELETE CFSTRUCT

1. This command is valid only z/OS when the queue manager is a member of a queue sharing group.
2. The command fails if there are any queues in existence that reference this CF structure name that are not both empty and closed.
3. The command cannot specify the CF administration structure (CSQ_ADMIN).
4. The command deletes the Db2 CF structure record only. It does **not** delete the CF structure definition from the CFRM policy data set.
5. CF structures at CFLEVEL(1) are automatically deleted when the last queue on that structure is deleted.

Keyword and parameter descriptions for DELETE CFSTRUCT

(structure-name)

The name of the CF structure definition to be deleted. The name must be defined within the queue sharing group.

DELETE CHANNEL (delete a channel)

Use the MQSC command DELETE CHANNEL to delete a channel definition.

Using MQSC commands

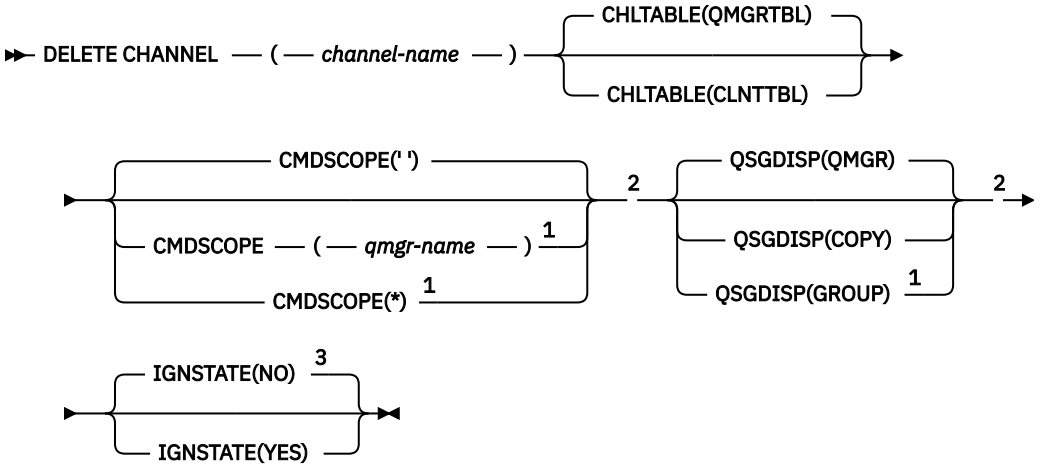
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Usage notes" on page 593
- "Parameter descriptions" on page 594

Synonym: DELETE CHL

DELETE CHANNEL



Notes:

1 Valid only on z/OS when the queue manager is a member of a queue sharing group.
2 Valid only on z/OS.
3 Valid only on AIX, Linux, and Windows.

Usage notes

- Successful completion of the command does not mean that the action completed. To check for true completion, see the DELETE CHANNEL step in Checking that async commands for distributed networks have finished.
- z/OS On z/OS systems, the command fails if the channel initiator and command server have not been started, or the channel status is RUNNING, except client-connection channels, which can be deleted without the channel initiator or command server running.

- z/OS On z/OS systems, you can only delete cluster-sender channels that have been created manually.

Parameter descriptions

(channel-name)
The name of the channel definition to be deleted. This is required. The name must be that of an existing channel.

CHLTABLE
Specifies the channel definition table that contains the channel to be deleted. This is optional.

QMGRTBL
The channel table is that associated with the target queue manager. This table does not contain any channels of type CLNTCONN. This is the default.

CLNTTBL
The channel table for CLNTCONN channels. On z/OS, this is associated with the target queue manager, but separate from the main channel table. On all other platforms, this channel table is normally associated with a queue manager, but can be a system-wide, queue manager independent channel table if you set up a number of environment variables. For more information about setting up environment variables, see Using IBM MQ environment variables.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

z/OS **QSGDISP**
This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

COPY
The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(COPY). Any object residing in the shared repository, or any object defined using a command that had the parameters QSGDISP(QMGR), is not affected by this command.

GROUP
The object definition resides in the shared repository. The object was defined using a command that had the parameters QSGDISP(GROUP). Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command.

If the command is successful, the following command is generated and sent to all active queue managers in the queue sharing group to delete local copies on page set zero:

```
DELETE CHANNEL(channel-name) QSGDISP(COPY)
```

The deletion of the group object takes effect even if the generated command with QSGDISP(COPY) fails.

QMGR
The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(QMGR). Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

This is the default value.

V 9.2.1 ALW **IGNSTATE**
This parameter allows you to specify whether you want the command to return an error code if the object is already in the state the command moves it to.

A value of YES means the return code and message are the same as if the MQSC object has not been deleted.

A value of NO means that the return code is zero, even if the object has been deleted. This is the default value.

Note that, when running in **runmqsc -n** mode, that is, not connected to a queue manager, the **DELETE CHANNEL** command accepts the **IGNSTATE** parameter, but there is no difference in behavior between YES and NO options. If **runmqsc** is run normally, **DELETE CHANNEL** acts like other objects.

Windows Linux AIX

DELETE CHANNEL ((delete a channel) MQTT

Use the MQSC command DELETE CHANNEL to delete an MQ Telemetry channel definition.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

The DELETE CHANNEL (MQTT) command is only valid for MQ Telemetry channels.

Synonym: DELETE CHL

DELETE CHANNEL

Parameter descriptions

(channel-name)
The name of the channel definition to be deleted. This is required. The name must be that of an existing channel.

CHLTYPE
This parameter is required. There is only one possible value: MQTT.

Multi DELETE COMMINFO (delete communications information) on Multiplatforms

Use the MQSC command DELETE COMMINFO to delete a communication information object.

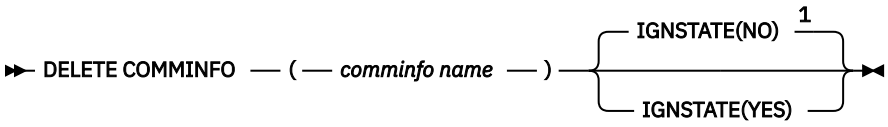
Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

- Syntax diagram
- "Parameter descriptions for DELETE COMMINFO" on page 596

Synonym: DEL COMMINFO

DELETE COMMINFO



Notes:

[1] Valid only on AIX, Linux, and Windows.

Parameter descriptions for DELETE COMMINFO

(comminfo name)
The name of the communications information object to be deleted. This is required.

V 9.2.1 ALW **IGNSTATE**
This parameter allows you to specify whether you want the command to return an error code if the object is already in the state the command moves it to.

A value of YES means the return code and message are the same as if the MQSC object has not been deleted.

A value of NO means that the return code is zero, even if the object has been deleted. This is the default value.

Multi DELETE LISTENER (delete a listener) on Multiplatforms

Use the MQSC command DELETE LISTENER to delete a listener definition.

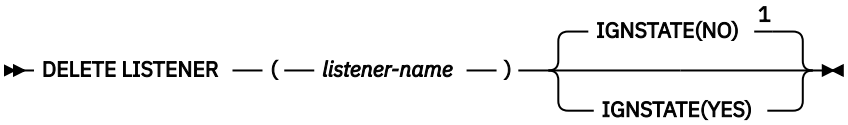
Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

- Syntax diagram
- "Usage notes for DELETE LISTENER" on page 597
- "Keyword and parameter descriptions for DELETE LISTENER" on page 597

Synonym: DELETE LSTR

DELETE LISTENER



Notes:

[1] Valid only on AIX, Linux, and Windows.

Usage notes for DELETE LISTENER

1. The command fails if an application has the specified listener object open, or if the listener is currently running.

Keyword and parameter descriptions for DELETE LISTENER

(listener-name)

The name of the listener definition to be deleted. This is required. The name must be that of an existing listener defined on the local queue manager.

V 9.2.1 ALW **IGNSTATE**

This parameter allows you to specify whether you want the command to return an error code if the object is already in the state the command moves it to.

A value of YES means the return code and message are the same as if the MQSC object has not been deleted.

A value of NO means that the return code is zero, even if the object has been deleted. This is the default value.

DELETE NAMELIST (delete a name list)

Use the MQSC command DELETE NAMELIST to delete a namelist definition.

Using MQSC commands

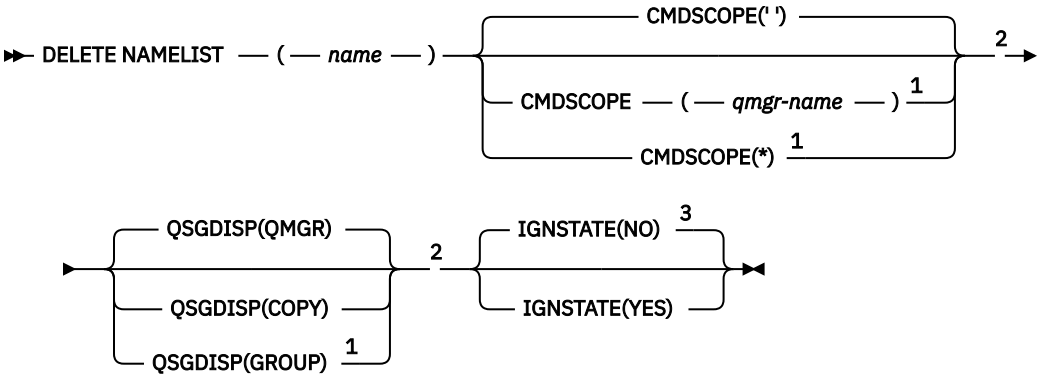
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- “Usage notes” on page 598
- “Parameter descriptions for DELETE NAMELIST” on page 598

Synonym: DELETE NL

DELETE NAMELIST



Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[2] Valid only on z/OS.
[3] Valid only on AIX, Linux, and Windows.

Usage notes

Successful completion of the command does not mean that the action completed. To check for true completion, see the DELETE NAMELIST step in Checking that async commands for distributed networks have finished.

Parameter descriptions for DELETE NAMELIST

You must specify which namelist definition you want to delete.

(name)
The name of the namelist definition to be deleted. The name must be defined to the local queue manager.

If an application has this namelist open, the command fails.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

z/OS **QSGDISP**
This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

COPY
The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(COPY). Any object residing in the shared repository, or any object defined using a command that had the parameters QSGDISP(QMGR), is not affected by this command.

GROUP
The object definition resides in the shared repository. The object was defined using a command that had the parameters QSGDISP(GROUP). Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command.

If the command is successful, the following command is generated and sent to all active queue managers in the queue sharing group to delete local copies on page set zero:

```
DELETE NAMELIST(name) QSGDISP(COPY)
```

The deletion of the group object takes effect even if the generated command with QSGDISP(COPY) fails.

QMGR
The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(QMGR). Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

This is the default value.

V 9.2.1 ALW **IGNSTATE**
This parameter allows you to specify whether you want the command to return an error code if the object is already in the state the command moves it to.

A value of YES means the return code and message are the same as if the MQSC object has not been deleted.

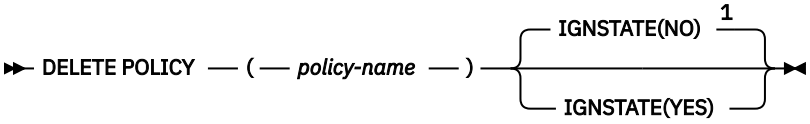
A value of NO means that the return code is zero, even if the object has been deleted. This is the default value.

Multi DELETE POLICY (delete a security policy) on Multiplatforms

Use the MQSC command DELETE POLICY to delete a security policy.

- Syntax diagram
- “Parameter descriptions for DELETE POLICY” on page 600

DELETE POLICY



Notes:

[1] Valid only on AIX, Linux, and Windows.

Parameter descriptions for DELETE POLICY

(policy-name)

Specifies the policy name to be deleted.

The name of the policy, or policies, to delete are the same as the name of the queue, or queues, that the policies control.

V 9.2.1 ALW **IGNSTATE**

This parameter allows you to specify whether you want the command to return an error code if the object is already in the state the command moves it to.

A value of YES means the return code and message are the same as if the MQSC object has not been deleted.

A value of NO means that the return code is zero, even if the object has been deleted. This is the default value.

DELETE PROCESS (delete a process definition)

Use the MQSC command DELETE PROCESS to delete a process definition.

Using MQSC commands

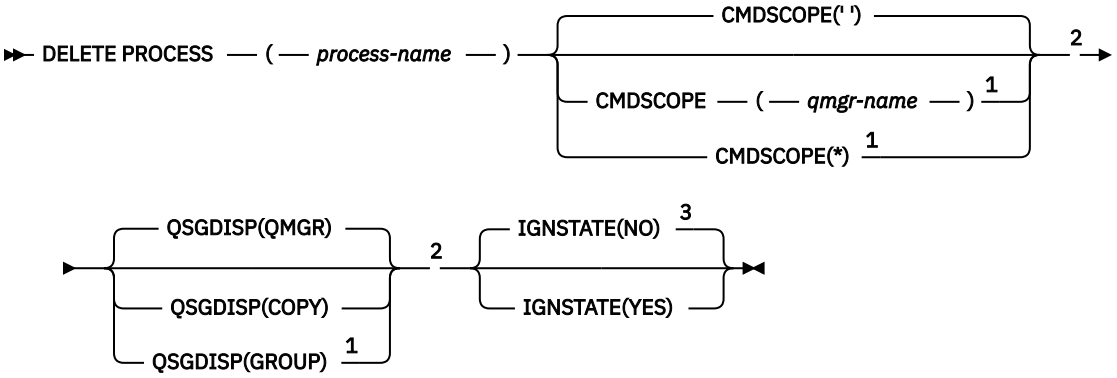
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Parameter descriptions for DELETE PROCESS" on page 600

Synonym: DELETE PRO

DELETE PROCESS



Notes:

1 Valid only on z/OS when the queue manager is a member of a queue sharing group.
2 Valid only on z/OS.
3 Valid only on AIX, Linux, and Windows.

Parameter descriptions for DELETE PROCESS

You must specify which process definition you want to delete.

(process-name)
The name of the process definition to be deleted. The name must be defined to the local queue manager.

If an application has this process open, the command fails.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

z/OS **QSGDISP**
This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

COPY
The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(COPY). Any object residing in the shared repository, or any object defined using a command that had the parameters QSGDISP(QMGR), is not affected by this command.

GROUP
The object definition resides in the shared repository. The object was defined using a command that had the parameters QSGDISP(GROUP). Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command.

If the command is successful, the following command is generated and sent to all active queue managers in the queue sharing group to delete local copies on page set zero:

```
DELETE PROCESS(process-name) QSGDISP(COPY)
```

The deletion of the group object takes effect even if the generated command with QSGDISP(COPY) fails.

QMGR
The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(QMGR). Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

This is the default value.

V 9.2.1 ALW **IGNSTATE**
This parameter allows you to specify whether you want the command to return an error code if the object is already in the state the command moves it to.

A value of YES means the return code and message are the same as if the MQSC object has not been deleted.

A value of NO means that the return code is zero, even if the object has been deleted. This is the default value.

z/OS DELETE PSID (delete a page set) on z/OS

Use the MQSC command DELETE PSID to delete a page set. This command closes the page set and de-allocates it from the queue manager.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Usage notes for DELETE PSID" on page 602
- "Parameter descriptions for DELETE PSID" on page 602

Synonym: DEL PSID

DELETE PSID

Usage notes for DELETE PSID

1. The identified page set must have no storage class (STGCLASS) referencing it.
2. If the page set still has buffers in the buffer pool when you issue this command, the command fails and an error message is issued. You cannot delete the page set until 3 checkpoints have been completed since the page set was emptied.
3. If the page set is not to be used again by the queue manager, update the queue manager started task procedure JCL, and remove the corresponding DEFINE PSID command from the CSQINP1 initialization data set. If the page set had a dedicated buffer pool, remove its definitions also from CSQINP1.
4. If you want to reuse the data set again as a page set, format it before doing so.

Parameter descriptions for DELETE PSID

(psid-number)
Identifier of the page set. This is required. You cannot delete page set 0.

DELETE queues

Use the MQSC **DELETE** command to delete a queue definition for a local, model, or remote queue, or a queue alias.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

This section contains the following commands:

- "DELETE QALIAS (delete an alias queue definition)" on page 605

- "DELETE QLOCAL (delete a local queue definition)" on page 605
- "DELETE QMODEL (delete a model queue definition)" on page 606
- "DELETE QREMOTE (delete local definition of remote queue)" on page 607

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

Usage notes for DELETE queues

- Successful completion of the command does not mean that the action completed. To check for true completion, see the DELETE queues step in Checking that async commands for distributed networks have finished.

Parameter descriptions for DELETE queues

(q-name)
The name of the queue must be defined to the local queue manager for all the queue types.

For an alias queue this is the local name of the alias queue to be deleted.

For a model queue this is the local name of the model queue to be deleted.

For a remote queue this is the local name of the remote queue to be deleted.

For a local queue this is the name of the local queue to be deleted. You must specify which queue you want to delete.

Note: A queue cannot be deleted if it contains uncommitted messages.

If an application has this queue open, or has open a queue that eventually resolves to this queue, the command fails. The command also fails if this queue is a transmission queue, and any queue that is, or resolves to, a remote queue that references this transmission queue, is open.

If this queue has a SCOPE attribute of CELL, the entry for the queue is also deleted from the cell directory.

AUTHREC
This parameter does not apply to z/OS.

Specifies whether the associated authority record is also deleted:

YES
The authority record associated with the object is deleted. This is the default.

NO
The authority record associated with the object is not deleted.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP or SHARED.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

PURGE and NOPURGE

Specifies whether any existing committed messages on the queue named by the DELETE command are to be purged for the delete command to work. The default is NOPURGE.

PURGE

The deletion is to go ahead even if there are committed messages on the named queue, and these messages are also to be purged.

NOPURGE

The deletion is not to go ahead if there are any committed messages on the named queue.

z/OS **QSGDISP**

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves). If the object definition is shared, you do not need to delete it on every queue manager that is part of a queue sharing group. (Queue sharing groups are available only on IBM MQ for z/OS.)

COPY

The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(COPY). Any object residing in the shared repository, or any object defined using a command that had the parameters QSGDISP(QMGR), is not affected by this command.

GROUP

The object definition resides in the shared repository. The object was defined using a command that had the parameters QSGDISP(GROUP). Any object residing on the page set of the queue manager that executes the command, or any object defined using a command that had the parameters QSGDISP(SHARED), is not affected by this command.

If the deletion is successful, the following command is generated and sent to all active queue managers in the queue sharing group to make, or delete, local copies on page set zero:

```
DELETE queue(q-name) QSGDISP(COPY)
```

or, for a local queue only:

```
DELETE QLOCAL(q-name) NOPURGE QSGDISP(COPY)
```

The deletion of the group object takes effect even if the generated command with QSGDISP(COPY) fails.

Note: You always get the NOPURGE option even if you specify PURGE. To delete messages on local copies of the queues, you must explicitly issue the command:

```
DELETE QLOCAL(q-name) QSGDISP(COPY) PURGE
```

for each copy.

QMGR

The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(QMGR). Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

This is the default value.

SHARED

This option applies only to local queues.

The object definition resides in the shared repository. The object was defined using a command that had the parameters QSGDISP(SHARED). Any object residing on the page set of the queue manager that executes the command, or any object defined using a command that had the parameters QSGDISP(GROUP), is not affected by this command.

V 9.2.1 ALW **IGNSTATE**

This parameter allows you to specify whether you want the command to return an error code if the object is already in the state the command moves it to.

A value of YES means the return code and message are the same as if the MQSC object has not been deleted.

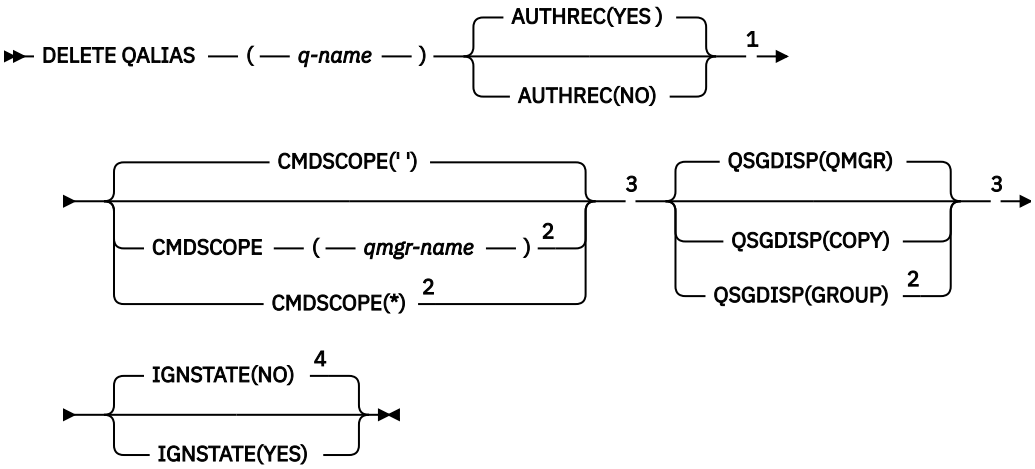
A value of NO means that the return code is zero, even if the object has been deleted. This is the default value.

DELETE QALIAS (delete an alias queue definition)

Use DELETE QALIAS to delete an alias queue definition.

Synonym: DELETE QA

DELETE QALIAS



Notes:

1 Not valid on z/OS.
2 Valid only on z/OS when the queue manager is a member of a queue sharing group.
3 Valid only on z/OS.
4 Valid only on AIX, Linux, and Windows.

The parameters are described in "DELETE queues" on page 602.

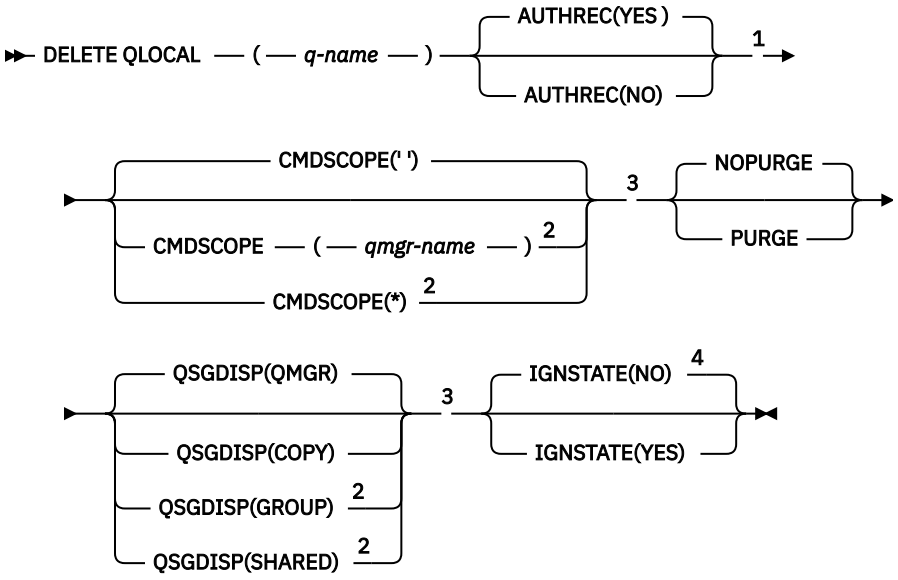
Related concepts
Working with alias queues

DELETE QLOCAL (delete a local queue definition)

Use DELETE QLOCAL to delete a local queue definition. You can specify that the queue must not be deleted if it contains messages, or that it can be deleted even if it contains messages.

Synonym: DELETE QL

DELETE QLOCAL



Notes:

1 Not valid on z/OS.
2 Valid only on z/OS when the queue manager is a member of a queue sharing group.
3 Valid only on z/OS.
4 Valid only on AIX, Linux, and Windows.

The parameters are described in "DELETE queues" on page 602.

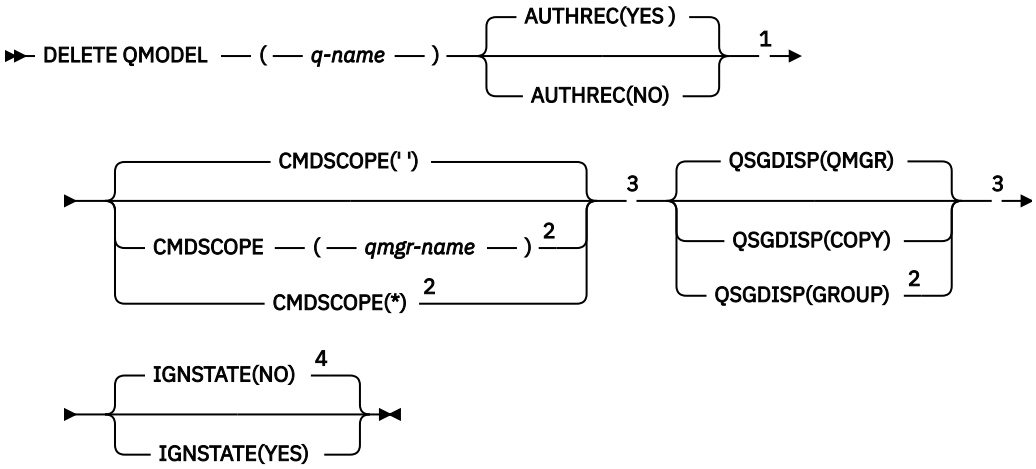
Related tasks
Deleting a local queue

DELETE QMODEL (delete a model queue definition)

Use **DELETE QMODEL** to delete a model queue definition.

Synonym: DELETE QM

DELETE QMODEL



Notes:

[1] Not valid on z/OS.
[2] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[3] Valid only on z/OS.
[4] Valid only on AIX, Linux, and Windows.

The parameters are described in "DELETE queues" on page 602.

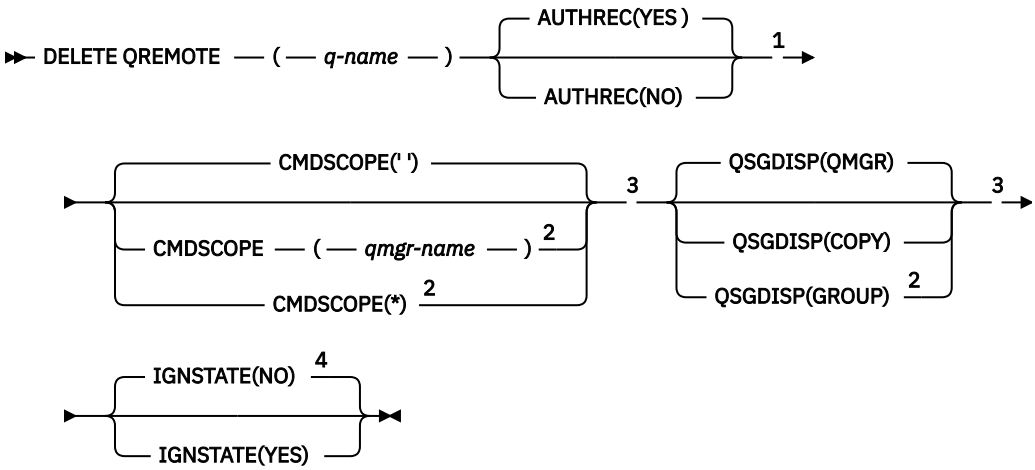
Related concepts
Working with model queues

DELETE QREMOTE (delete local definition of remote queue)

Use DELETE QREMOTE to delete a local definition of a remote queue. It does not affect the definition of that queue on the remote system.

Synonym: DELETE QR

DELETE QREMOTE



Notes:

[1] Not valid on z/OS.
[2] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[3] Valid only on z/OS.
[4] Valid only on AIX, Linux, and Windows.

The parameters are described in "DELETE queues" on page 602.

Multi DELETE SERVICE (delete a service definition) on Multiplatforms

Use the MQSC command DELETE SERVICE to delete a service definition.

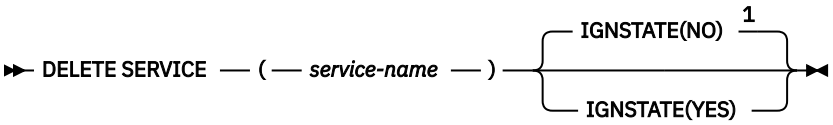
Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

- Syntax diagram
- "Usage notes for DELETE SERVICE" on page 608
- "Keyword and parameter descriptions for DELETE SERVICE" on page 608

Synonym:

DELETE SERVICE



Notes:

[1] Valid only on AIX, Linux, and Windows.

Usage notes for DELETE SERVICE

1. The command fails if an application has the specified service object open, or if the service is currently running.

Keyword and parameter descriptions for DELETE SERVICE

(service-name)

The name of the service definition to be deleted. This is required. The name must be that of an existing service defined on the local queue manager.

V 9.2.1 ALW **IGNSTATE**

This parameter allows you to specify whether you want the command to return an error code if the object is already in the state the command moves it to.

A value of YES means the return code and message are the same as if the MQSC object has not been deleted.

A value of NO means that the return code is zero, even if the object has been deleted. This is the default value.

z/OS DELETE STGCLASS (delete a storage class) on z/OS

Use the MQSC command DELETE STGCLASS to delete a storage class definition.

Using MQSC commands

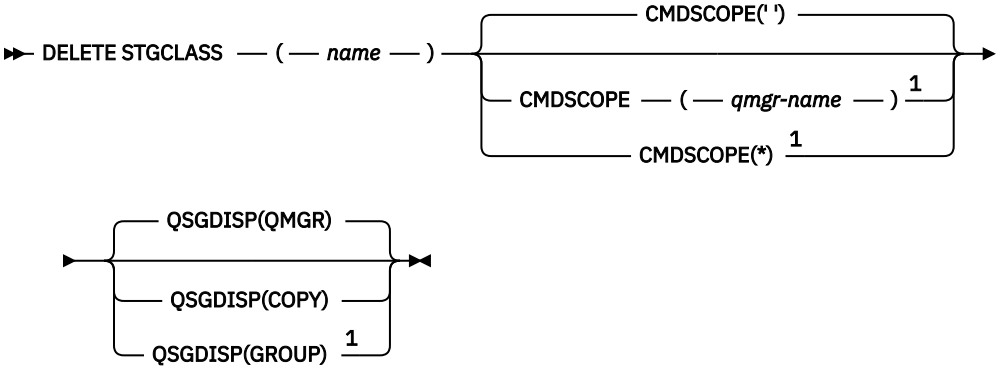
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- “Parameter descriptions for DELETE STGCLASS” on page 609

Synonym: DELETE STC

DELETE STGCLASS



Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.

Parameter descriptions for DELETE STGCLASS

You must specify which storage class definition you want to delete.

All queues that use this storage class must be altered to use another storage class.

(name)
The name of the storage class definition to be deleted. The name must be defined to the local queue manager.

The command fails unless all queues referencing the storage class are empty and closed.

CMDSCOPE
This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

QSGDISP
Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

COPY
The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(COPY). Any object residing in the shared repository, or any object defined using a command that had the parameters QSGDISP(QMGR), is not affected by this command.

GROUP
The object definition resides in the shared repository. The object was defined using a command that had the parameters QSGDISP(GROUP). Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command.

If the command is successful, the following command is generated and sent to all active queue managers in the queue sharing group to delete local copies on page set zero:

```
DELETE STGCLASS(name) QSGDISP(COPY)
```

The deletion of the group object takes effect even if the generated command with QSGDISP(COPY) fails.

QMGR
The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(QMGR). Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

This is the default value.

DELETE SUB (delete a durable subscription)

Use the MQSC command **DELETE SUB** to remove a durable subscription from the system. For a managed destination, any unprocessed messages left on the destination are removed.

Using MQSC commands

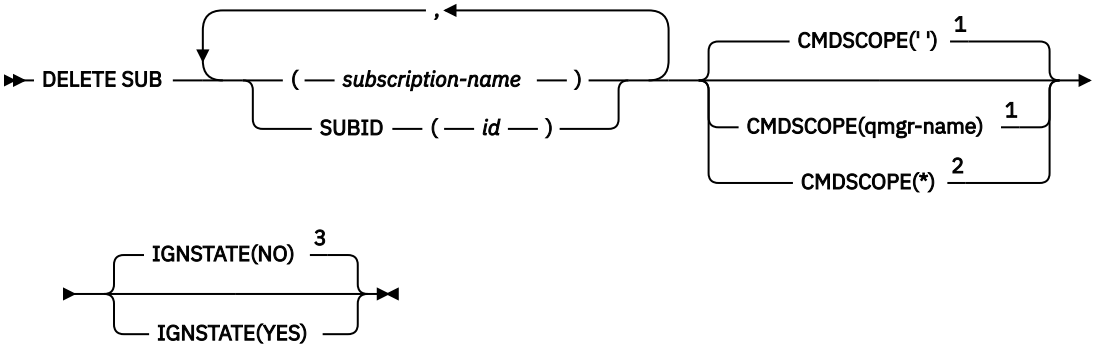
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- Usage notes for DELETE SUB
- “Parameter descriptions for DELETE SUB” on page 611

Synonym: **DEL SUB**

DELETE SUB



Notes:

1 Valid only on z/OS.
2 Valid only on z/OS when the queue manager is a member of a queue sharing group.
3 Valid only on AIX, Linux, and Windows.

Usage notes for DELETE SUB

- You can specify either the name, the identifier, or both, of the subscription you want to delete.

  Examples of valid forms:

```
DELETE SUB(xyz)
DELETE SUB SUBID(123)
DELETE SUB(xyz) SUBID(123)
```

- Successful completion of the command does not mean that the action completed. To check for true completion, see the DELETE SUB step in Checking that async commands for distributed networks have finished.

Parameter descriptions for DELETE SUB

subscription-name
The local name of the subscription definition to be deleted.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

You cannot use **CMDSCOPE** as a filter keyword.

SUBID(***string*** **)**
The internal, unique key identifying a subscription.

V 9.2.1 ALW **IGNSTATE**
This parameter allows you to specify whether you want the command to return an error code if the object is already in the state the command moves it to.

A value of YES means the return code and message are the same as if the MQSC object has not been deleted.

A value of NO means that the return code is zero, even if the object has been deleted. This is the default value.

Related tasks
Deleting a subscription

DELETE TOPIC (delete an administrative topic node)

Use **DELETE TOPIC** to delete an IBM MQ administrative topic node.

Using MQSC commands

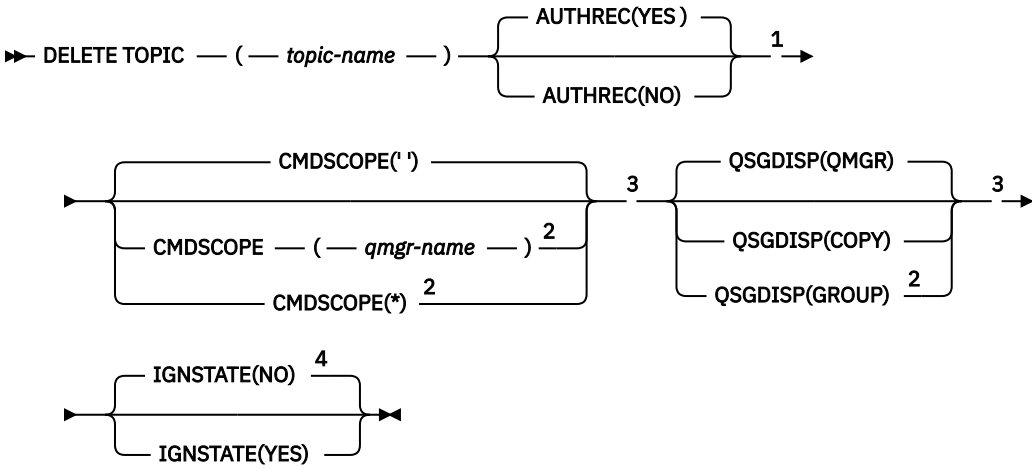
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Usage notes for DELETE TOPIC" on page 612
- "Parameter descriptions for DELETE TOPIC" on page 612

Synonym: None

DELETE TOPIC



Notes:

1 Not valid on z/OS
2 Valid only on z/OS when the queue manager is a member of a queue sharing group.
3 Valid only on z/OS.
4 Valid only on AIX, Linux, and Windows.

Usage notes for DELETE TOPIC

- Successful completion of the command does not mean that the action completed. To check for true completion, see the DELETE TOPIC step in Checking that async commands for distributed networks have finished.

Parameter descriptions for DELETE TOPIC

(topic-name)
The name of the administrative topic object to be deleted. This parameter is required.

The name must be that of an existing administrative topic object.

AUTHREC
This parameter does not apply to z/OS

Specifies whether the associated authority record is also deleted:

YES
The authority record associated with the object is deleted. This is the default.

NO
The authority record associated with the object is not deleted.

z/OS **CMDSCOPE**

This parameter applies to only z/OS and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

z/OS **QSGDISP**

This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

COPY
The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(COPY). Any object residing in the shared repository, or any object defined using a command that had the parameters QSGDISP(QMGR), is not affected by this command.

GROUP
The object definition resides in the shared repository. The object was defined using a command that had the parameters QSGDISP(GROUP). Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command.

If the command is successful, the following command is generated and sent to all active queue managers in the queue sharing group to make, or delete, local copies on page set zero:

```
DELETE TOPIC(topic-name) QSGDISP(COPY)
```

The deletion of the group object takes effect even if the generated command with QSGDISP(COPY) fails.

QMGR
The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(QMGR). Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

This is the default value.

V 9.2.1 ALW **IGNSTATE**

This parameter allows you to specify whether you want the command to return an error code if the object is already in the state the command moves it to.

A value of YES means the return code and message are the same as if the MQSC object has not been deleted.

A value of NO means that the return code is zero, even if the object has been deleted. This is the default value.

Deleting an administrative topic definition

V 9.2.0 Multi DISPLAY APSTATUS (display application status)

Use the MQSC command **DISPLAY APSTATUS** to display the status of one or more applications and application instances connected to a queue manager or a uniform cluster.

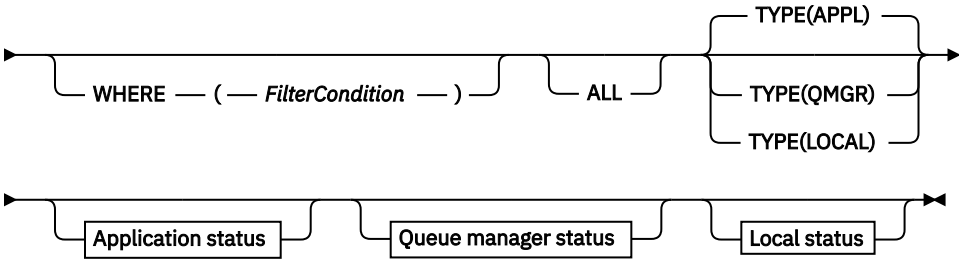
Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

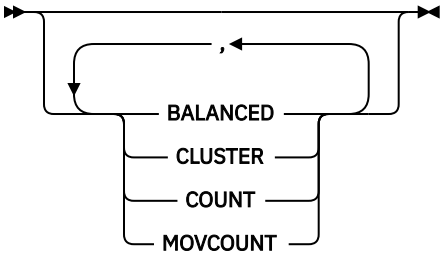
- Syntax diagram
- "Usage notes for DISPLAY APSTATUS" on page 615
- "Parameter descriptions for DISPLAY APSTATUS" on page 615
- "Application status" on page 617
- "Queue manager status" on page 617
- "Local status" on page 618

Synonym: DIS APS

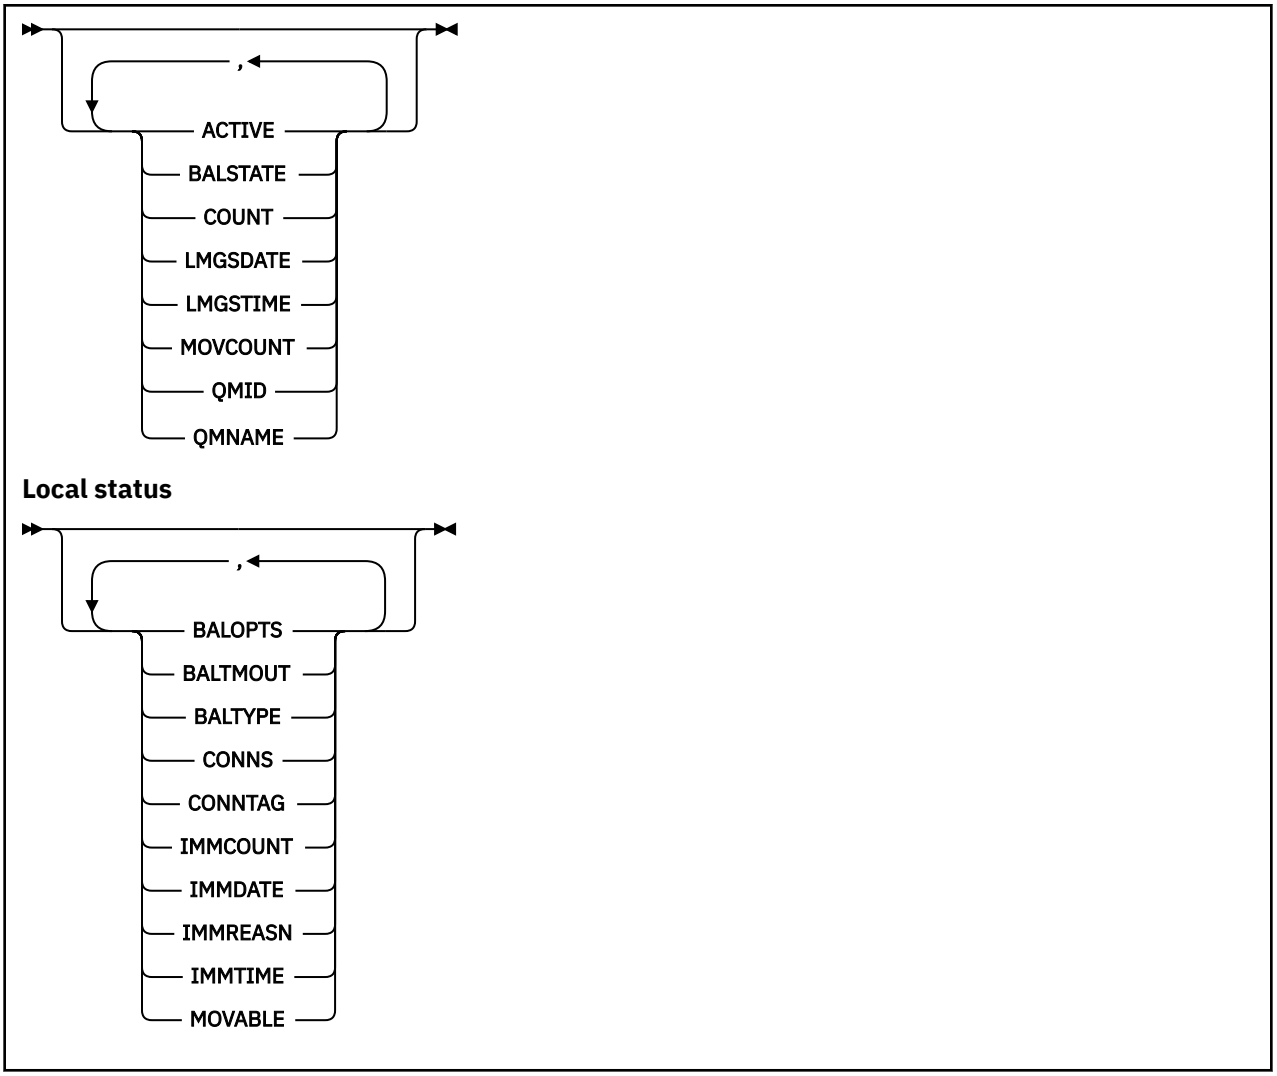
DISPLAY APSTATUS



Application status



Queue manager status



Usage notes for DISPLAY APSTATUS

The application name parameter of the **DISPLAY APSTATUS** command matches against application names set by applications. See using the application name in supported programming languages for more information.

Parameter descriptions for DISPLAY APSTATUS

The **DISPLAY APSTATUS** command requires an application name string value to determine which application details to return.

applicationnamestr

The application name string can have one of the following values:

- A specific application name string value. For example, `DIS APSTATUS('myapp')` returns details of just the `'myapp'` application
- A string containing one or more wildcard characters. For example, `DIS APSTATUS('*put*')` returns all applications which have `'put'` in their application names.

To return a list of all user applications, use `DIS APSTATUS('*')`

To filter the list of applications returned, use the WHERE parameter. For example, `DIS APSTATUS('*put*') TYPE(APPL) WHERE(BALANCED eq NO)` returns application information about all unbalanced applications with `'put'` in their name.

WHERE

Specifies a filter condition to match only those applications or application instances that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

Any parameter that you can use with this DISPLAY command based on the TYPE option.

operator

Determines whether a keywords value satisfies a condition on the given filter value. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

CT

Contains a specified item. If the *filter-keyword* is a list, you can use this filter to display objects whose attributes contain the specified item.

EX

Does not contain a specified item. If the *filter-keyword* is a list, you can use this filter to display objects whose attributes do not contain the specified item.

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this value can be:

- An explicit value, that is a valid value for the attribute being tested.

  You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter, you can only use EQ or NE.

- A generic value. This value is a character string with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed.

  You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

ALL

Use this parameter to display all attributes.

If you specify this parameter, any attributes that you request additionally have no effect; the command displays all attributes.

This value is the default, if you do not specify a generic name, and do not request any specific parameters.

TYPE
Specifies the type of status information required:

APPL
The command displays status information relating to each unique application name, which is the default if you do not provide a TYPE parameter. This represents a summary of the details from the local queue manager and any queue manager in the same uniform cluster.

QMGR
The command displays status information relating to applications at a queue manager level, including the local queue manager and any queue manager in the same uniform cluster.

LOCAL
The command displays status information for applications, for each application instance connected to the local queue manager.

Application status

Application status parameters define the data that the command displays. You can specify these parameters in any order, but you must not specify the same parameter more than once:

BALANCED
If the local queue manager is a member of a uniform cluster, this field gives an indication as to whether the number of application instances across the cluster is currently balanced, based on the last information received from the other queue managers in the cluster.

If the queue manager is not a member of a uniform cluster, this field shows NOTAPPLIC.

The value can be any of the following values:

NO
This application is not considered balanced in the uniform cluster.

YES
This application is considered balanced in the uniform cluster.

NOTAPPLIC
This application is not shared across a uniform cluster.

UNKNOWN
This is a temporary state, representing an application that has not yet undergone a scan to calculate whether it is balanced or not, on at least one queue manager, across the uniform cluster.

CLUSTER
If the application details are being sent around a uniform cluster, this field displays the name of the uniform cluster, otherwise it shows a blank.

COUNT
This displays the sum of the number of application instances for this application from the local queue manager, and all queue managers in the uniform cluster that have shared their application instance counts.

A queue manager not in a uniform cluster displays the count of local application instances.

MOVCOUNT
This displays the sum of the number of movable application instances for this application from the local queue manager and all queue managers in the uniform cluster that have shared their application instance counts.

A queue manager not in a uniform cluster displays the count of local application instances that would be movable if put in a uniform cluster.

Queue manager status

Queue manager status parameters define the data that the command displays. You can specify these parameters in any order, but you must not specify the same parameter more than once.

ACTIVE
Displays if the queue manager is considered active when balancing applications, which indicates whether information from that queue manager has been received recently.

YES
The queue manager is communicating with the uniform cluster, and actively participating in balancing for this application.

NO
No status has recently been received from this queue manager. This could indicate a communication problem, or that the queue manager has been suspended from the uniform cluster.

BALSTATE
Indicates the state of the application instances on this queue manager, compared to the other queue managers in a uniform cluster. The value can be :

HIGH
There is a surplus of application instances.

OK
There is a balanced number of application instances.

LOW
There are not enough application instances.

NOTAPPLIC
The queue manager is not in a uniform cluster.

UNKNOWN
This is a temporary state representing an application that is new to the uniform cluster, and which has not yet undergone a scan to calculate whether it is balanced or not.

COUNT
Represents the count of application instances for this application on the queue manager.

LMSGDATE
The local date on which the local queue manager last received a published message from this queue manager, containing its application instance details.

LMSGTIME
The local time on which the local queue manager last received a published message from this queue manager, containing its application instance details.

MOVCOUNT
This represents the count of movable application instances for this application on the queue manager. Only application instances which are movable will be considered for rebalancing in a uniform cluster.

QMID
The queue manager identifier of the queue manager, that this information originated from.

QMNAME
The queue manager name that this information originated from. There will be one entry for the local queue manager, and one from each queue manager that has distributed information about this application in a uniform cluster.

Local status

Local status parameters define the data that the command displays. You can specify these parameters in any order, but you must not specify the same parameter more than once.

V 9.2.4 **BALOPTS**
The balancing options in effect for this application instance. Possible values are:

MQBNO_OPTIONS_NONE
No options are set.

MQBNO_OPTIONS_IGNORE_TRANS
This option allows applications to be rebalanced even if in the middle of a transaction.

V 9.2.5 **BALTMOUT**
The time out value in effect for this application instance. Possible values are:

NEVER
No time out occurs.

IMMEDIATE
Time out occurs immediately

Set value
The timeout value in seconds, up to a maximum of 999999999 seconds.

V 9.2.4 **BALTYPE**
The application type in effect for this application instance. Possible values are:

MQBNO_BALTYPE_SIMPLE
No specific rules should be applied beyond the defaults described in Configuring the balancing behavior.

MQBNO_BALTYPE_REQREP
After each MQPUT call, a matching MQGET call is expected for a response message. Balancing is delayed until such a message is received, or the request message EXPIRY has been exceeded.

MQBNO_BALTYPE_RAMANAGED
Re-balancing requests are always dispatched immediately to the client, which re-balances at a point the client considers appropriate.

Note that different instances of the same application can provide different balancing options without causing any error.

CONNS
The number of connections (HCONNS) the application instance currently has.

CONNTAG
The connection tag of this application instance.

IMMCOUNT
The number of times this application instance has been asked to reconnect but has stayed connected. Any value higher than one indicates the application is not moving when requested.

IMMDATE
If the application instance is immovable for a fixed period, this indicates the date at which the instance will be eligible for moving again. If this has a value, the **IMMREASN** field should indicate why the connection is temporarily immovable. If the connection is not temporarily immovable, the value is blank.

IMMREASN
If the application instance is immovable, this indicates a reason as to why. If the application instance is movable, the value is blank. Only one IMMREASN is displayed even though multiple might apply; note that permanent statuses (such as NOTRECONN, NOTCLIENT) are displayed in preference to temporary values (such as MOVING, INTRANS).

The value can be any of the following values:

APPNAMECHG
This application instance cannot be moved as it is sharing a socket with a connection from an application instance which has a different application name.

V 9.2.4 **INTRANS**
The application instance has successfully performed at least one MQI operation within syncpoint, and the timeout specified to forcibly rebalance an instance has not been reached.

MOVING
This application instance cannot be moved as it has recently been requested to move, and has not yet disconnected.

This status should be temporary. IMMDATE and IMMTIME indicate when this application instance is considered eligible to move again if this state unexpectedly persists.

NONE
This application instance is currently considered movable.

V 9.2.5 **NOREDIRECT**
The client application has indicated that it cannot process redirect hints from the queue manager. This might be because the application isn't using a CCDT to connect to the queue manager.

NOTCLIENT
This application instance cannot be moved as it is not a client connection.

NOTRECONN
This application instance cannot be moved as it is not a reconnectable client connection.

V 9.2.4 **REPLY**
The application instance is of type REQREP and has sent at least one request message for which a corresponding response has not been received. The timeout specified to forcibly rebalance an instance has not been reached.

IMMTIME
If the application instance is immovable for a fixed period, this indicates the time at which the instance will be eligible for moving again. If this has a value, the IMMREASN field should indicate why the connection is temporarily immovable. If the connection is not temporarily immovable, the value is blank.

MOVABLE
This indicates whether this application instance is considered movable or not.

Related tasks
Monitoring application balancing
Related reference
“MQCMD_INQUIRE_APPL_STATUS (inquire application status) Response on Multiplatforms” on page 1131
The response to the Inquire Application Status (**MQCMD_INQUIRE_APPL_STATUS**) PCF command consists of the response header followed by the *ApplicationName* structure and the requested combination of attribute parameter structures (where applicable) for the requested *ApplicationStatusInfoType*.

z/OS DISPLAY ARCHIVE (display archive system information) on z/OS

Use the MQSC command DISPLAY ARCHIVE to display archive system parameters and information.

Using MQSC commands

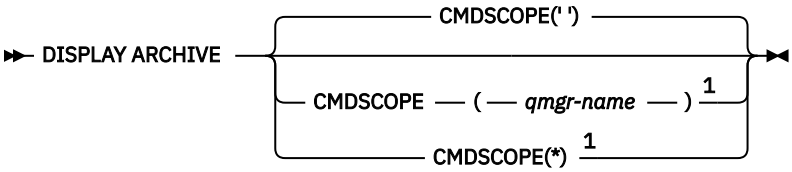
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 12CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- “Usage notes for DISPLAY ARCHIVE” on page 621
- “Parameter descriptions for DISPLAY ARCHIVE” on page 621

Synonym: DIS ARC

DISPLAY ARCHIVE



Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.

Usage notes for DISPLAY ARCHIVE

1. DISPLAY ARCHIVE returns a report that shows the initial values for the archiving parameters, and the current values as changed by the SET ARCHIVE command.
   - Units in which primary and secondary space allocations are made (ALCUNIT).
   - Prefix for first archive log data set name (ARCPFX1).
   - Prefix for second archive log data set name (ARCPFX2).
   - The retention period of the archive log data set in days (ARCRETN).
   - List of route codes for messages to the operator about archive log data sets (ARCWRTC).
   - Whether to send message to operator and wait for reply before trying to mount an archive log data set (ARCWTOR).
   - Block size of archive log data set (BLKSIZE).
   - Whether archive log data sets are cataloged in the ICF (CATALOG).
   - Whether archive log data sets should be compacted (COMPACT).
   - Primary space allocation for DASD data sets (PRIQTY).
   - Whether archive log data sets are protected by ESM profiles when the data sets are created (PROTECT).
   - Maximum time, in seconds, allowed for quiesce when ARCHIVE LOG with MODE(QUIESCE) specified (QUIESCE).
   - Secondary space allocation for DASD data sets. See the ALCUNIT parameter for the units to be used (SECQTY).
   - Whether the archive data set name should include a time stamp (TSTAMP).
   - Device type or unit name on which the first copy of archive log data sets is stored (UNIT).
   - Device type or unit name on which the second copy of archive log data sets is stored (UNIT2).

   It also reports the status of tape units used for archiving.

   For more details of these parameters, see "SET ARCHIVE (change archive system settings) on z/OS" on page 892.
2. This command is issued internally by IBM MQ at the end of queue manager startup.

Parameter descriptions for DISPLAY ARCHIVE

CMDSCOPE

This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE cannot be used for commands issued from the first initialization input data set CSQINP1.

' '

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

DISPLAY AUTHINFO (display authentication information)

Use the MQSC command DISPLAY AUTHINFO to display the attributes of an authentication information object.

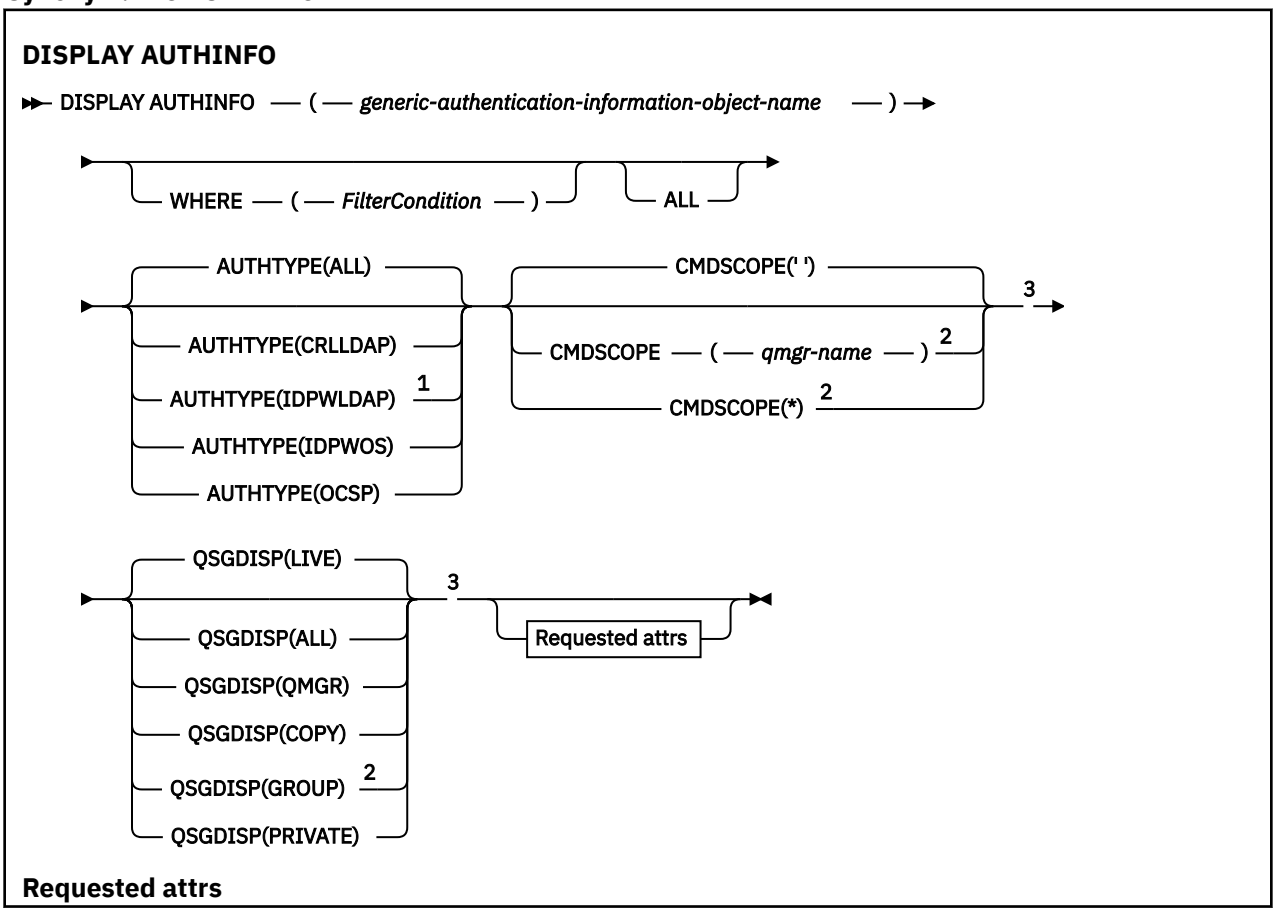
Using MQSC commands

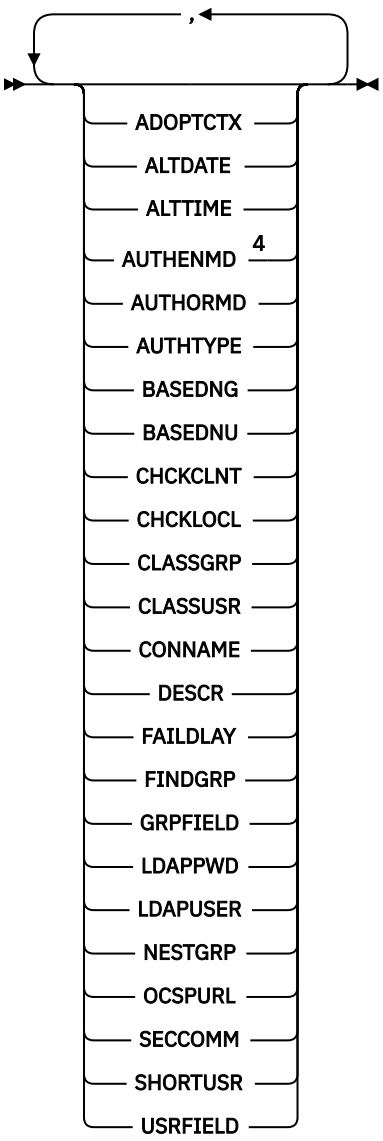
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Parameter descriptions for DISPLAY AUTHINFO" on page 623
- "Requested parameters" on page 626

Synonym: DIS AUTHINFO





Notes:

[1] Not valid on IBM MQ for z/OS.

[2] Valid only when the queue manager is a member of a queue sharing group. You can use queue sharing groups only on IBM MQ for z/OS.

[3] Valid only on z/OS.

[4] Not valid on z/OS and AUTHENMD PAM value valid only on AIX and Linux.

Parameter descriptions for DISPLAY AUTHINFO

(generic-authentication-information-object-name)

The name of the authentication information object to be displayed (see Rules for naming IBM MQ objects). A trailing asterisk (*) matches all authentication information objects with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all authentication information objects.

WHERE

Specify a filter condition to display only those authentication information objects that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword
Almost any parameter that can be used to display attributes for this DISPLAY command. However, you cannot use the CMDSCOPE or QSGDISP parameters as filter keywords.

operator
This is used to determine whether an authentication information object satisfies the filter value on the given filter keyword. The operators are:

LT
Less than

GT
Greater than

EQ
Equal to

NE
Not equal to

LE
Less than or equal to

GE
Greater than or equal to

LK
Matches a generic string that you provide as a *filter-value*

NL
Does not match a generic string that you provide as a *filter-value*

filter-value
The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

  You can use any of the operators except LK and NL.

- A generic value. This is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC*. The characters must be valid for the attribute you are testing. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. You cannot use a generic filter-value with numeric values. Only a single trailing wildcard character (asterisk) is permitted.

  You can only use operators LK or NL for generic values on the DISPLAY AUTHINFO command.

ALL
Specify this to display all the parameters. If this parameter is specified, any parameters that are requested specifically have no effect; all parameters are still displayed.

This is the default if you do not specify a generic name and do not request any specific parameters.

z/OS On z/OS this is also the default if you specify a filter condition using the WHERE parameter, but on other platforms only requested attributes are displayed.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

You cannot use CMDSCOPE as a filter keyword.

AUTHTYPE
Specifies the authentication information type of the objects for which information is to be displayed. Values are:

ALL
This is the default value and displays information for objects defined with AUTHTYPE(CRLLDAP) and with AUTHTYPE(OCSP).

CRLLDAP
Displays information only for objects defined with AUTHTYPE(CRLLDAP).

IDPWLDAP
Displays information only for objects defined with AUTHTYPE(IDPWLDAP).

IDPWOS
Displays information only for objects defined with AUTHTYPE(IDPWOS).

OCSP
Displays information only for objects defined with AUTHTYPE(OCSP).

z/OS **QSGDISP**
Specifies the disposition of the objects for which information is to be displayed. Values are:

LIVE
This is the default value and displays information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

ALL
Displays information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

If there is a shared queue manager environment, and the command is being executed on the queue manager where it was issued, this option also displays information for objects defined with QSGDISP(GROUP).

If QSGDISP(LIVE) is specified or defaulted, or if QSGDISP(ALL) is specified in a shared queue manager environment, the command might give duplicated names (with different dispositions).

COPY
Displays information only for objects defined with QSGDISP(COPY).

GROUP
Displays information only for objects defined with QSGDISP(GROUP). This is allowed only if there is a shared queue manager environment.

PRIVATE
Displays information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY). Note that QSGDISP(PRIVATE) displays the same information as QSGDISP(LIVE).

QMGR
Displays information only for objects defined with QSGDISP(QMGR).

QSGDISP displays one of the following values:

QMGR
The object was defined with QSGDISP(QMGR).

GROUP
The object was defined with QSGDISP(GROUP).

COPY
The object was defined with QSGDISP(COPY).

You cannot use QSGDISP as a filter keyword.

Requested parameters

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

The default, if no parameters are specified (and the ALL parameter is not specified) is that the object names and their AUTHTYPEs, and, on z/OS, their QSGDISPs, are displayed.

ADOPTCTX
Displays the presented credentials as the context for this application.

ALTDATE
The date on which the definition was last altered, in the form `yyyy-mm-dd`

ALTTIME
The time at which the definition was last altered, in the form `hh.mm.ss`

AUTHENMD
Authentication method. Possible values are:

OS
Displays the traditional UNIX password verification method permissions.

PAM
Displays the Pluggable Authentication Method permissions.

You can set the PAM value only on AIX and Linux platforms.

AUTHORMD
Displays the authorization method. Possible values are:

OS
Use operating system groups to determine permissions associated with a user.

SEARCHGRP
A group entry in the LDAP repository contains an attribute listing the Distinguished Name of all users belonging to that group.

SEARCHUSR
A user entry in the LDAP repository contains an attribute listing the Distinguished Name of all the groups to which the specified user belongs.

SRCHGRPSN
A group entry in the LDAP repository contains an attribute listing the short user name of all users belonging to that group.

AUTHTYPE
The type of the authentication information

BASEDNG
Displays the Base DN for groups.

BASEDNU
Displays the base distinguished name to search for users within the LDAP server.

CHCKLOCL or CHCKCLNT
These attributes are valid only for an **AUTHTYPE** of *IDPWOS* or *IDPWLDAP*. The possible values are:

NONE
Displays all locally bound applications that have no user ID and password authentication.

OPTIONAL
Displays the user IDs and passwords provided by an application. Note that it is not mandatory to provide these attributes. This option might be useful during migration, for example.

REQUIRED
Displays all applications providing a valid user ID and password.

REQDADM
Displays privileged users supplying a valid user ID and password, Non-privileged users are treated as with the OPTIONAL setting. See also the following note. z/OS (This setting is not allowed on z/OS systems.)

CLASSGRP
Displays the LDAP object class for group records.

CLASSUSR
Displays the LDAP object class for user records within the LDAP repository.

CONNAME
The host name, IPv4 dotted decimal address, or IPv6 hexadecimal notation of the host on which the LDAP server is running. Applies only to objects with AUTHTYPE(CRLLDAP) or AUTHTYPE(IDPWLDAP).

DESCR
Description of the authentication information object.

FAILDLAY
Delay in seconds before an authentication failure is returned to an application.

FINDGRP
Displays the name of the attribute within an LDAP entry to determine group membership.

GRPFIELD
Displays the LDAP attribute that represents a simple name for the group.

LDAPPWD
Password associated with the Distinguished Name of the user on the LDAP server. If nonblank, this is displayed as asterisks z/OS on all platforms except z/OS. Applies only to objects with AUTHTYPE(CRLLDAP) or AUTHTYPE(IDPWLDAP).

LDAPUSER
Distinguished Name of the user on the LDAP server. Applies only to objects with AUTHTYPE(CRLLDAP) or AUTHTYPE(IDPWLDAP).

NESTGRP
Displays whether a group is a member of another group..

OCSPURL
The URL of the OCSP responder used to check for certificate revocation. Applies only to objects with AUTHTYPE(OCSP).

SECCOMM
Displays the method used to connect the LDAP server.

SHORTUSR
Displays the user record being used as a short name.

USRFIELD
Displays the user record being used in the LDAP user record, only if the user ID does not contain a qualifier.

See "Usage notes for DEFINE AUTHINFO" on page 430 for more information about individual parameters.

Multi DISPLAY AUTHREC (display authority records) on Multiplatforms

Use the MQSC command DISPLAY AUTHREC to display the authority records associated with a profile name.

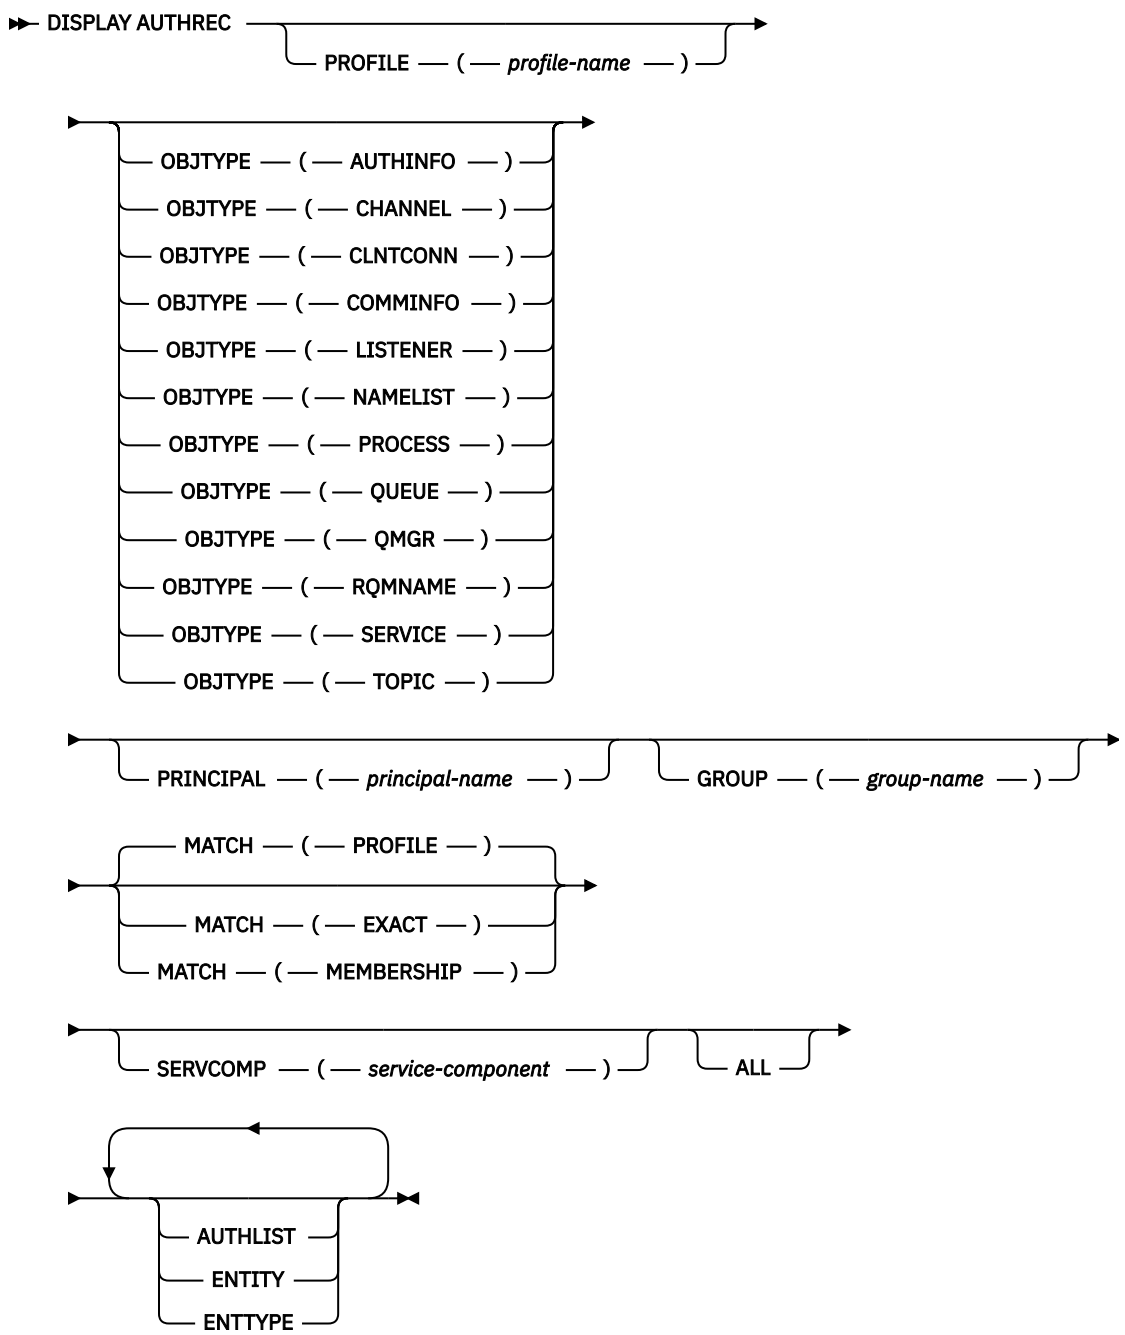
Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

- Syntax diagram
- "Parameter descriptions" on page 629
- "Requested parameters" on page 631

Synonym: DIS AUTHREC

DISPLAY AUTHREC



Parameter descriptions

PROFILE(*profile-name*)
The name of the object or generic profile for which to display the authority records. If you omit this parameter, all authority records that satisfy the values of the other parameters are displayed.

OBJTYPE
The type of object referred to by the profile. Specify one of the following values:

AUTHINFO
Authentication information record

CHANNEL
Channel

CLNTCONN
Client connection channel

COMMINFO
Communication information object

LISTENER
Listener

NAMELIST
Namelist

PROCESS
Process

QUEUE
Queue

QMGR
Queue manager

RQMNAME
Remote queue manager

SERVICE
Service

TOPIC
Topic

If you omit this parameter, authority records for all object types are displayed.

PRINCIPAL(*principal-name*)
A principal name. This is the name of a user for whom to retrieve authorizations to the specified object. On IBM MQ for Windows, the name of the principal can optionally include a domain name, specified in this format: `user@domain`.

This parameter cannot be specified with GROUP.

GROUP(*group-name*)
A group name. This is the name of the user group on which to make the inquiry. You can specify one name only and it must be the name of an existing user group.

Windows For IBM MQ for Windows only, the group name can optionally include a domain name, specified in the following formats:

```
GroupName@domain
domain\GroupName
```

This parameter cannot be specified with PRINCIPAL.

MATCH
Specify this parameter to control the set of authority records that is displayed. Specify one of the following values:

PROFILE
Return only those authority records which match the specified profile, principal, and group names. This means that a profile of ABCD results in the profiles ABCD, ABC*, and AB* being returned (if ABC* and AB* have been defined as profiles). If the profile name is a generic profile, only authority records which exactly match the specified profile name are returned. If a principal is specified, no profiles are returned for any group in which the principal is a member; only the profiles defined for the specified principal or group.

This is the default value.

MEMBERSHIP
Return only those authority records which match the specified profile, and the entity field of which matches the specified principal and the profiles pertaining to any groups in which the principal is a member that contribute to the cumulative authority for the specified entity.

If this option is specified, the PROFILE and OBJTYPE parameters must also be specified. In addition, either the PRINCIPAL or GROUP parameter must also be supplied. If OBJTYPE(QMGR) is specified, the profile name is optional.

EXACT
Return only those authority records which exactly match the specified profile name and EntityName. No matching generic profiles are returned unless the profile name is, itself, a generic profile. If a principal is specified, no profiles are returned for any group in which the principal is a member; only the profile defined for the specified principal or group.

SERVCOMP(*service-component*)
The name of the authorization service for which information is to be displayed.

If you specify this parameter, it specifies the name of the authorization service to which the authorizations apply. If you omit this parameter, the inquiry is made to the registered authorization services in turn in accordance with the rules for chaining authorization services.

ALL
Specify this parameter to display all of the authorization information available for the entity and the specified profile.

Requested parameters

You can request the following information about the authorizations:

AUTHLIST
Specify this parameter to display the list of authorizations.

ENTITY
Specify this parameter to display the entity name.

ENTTYPE
Specify this parameter to display the entity type.

Related reference

“dmpmqaut (dump MQ authorizations)” on page 45
Dump a list of current authorizations for a range of IBM MQ object types and profiles.

“setmqaut (grant or revoke authority)” on page 178
Change the authorizations to a profile, object, or class of objects. Authorizations can be granted to, or revoked from, any number of principals or groups.

“SET AUTHREC (set authority records) on Multiplatforms” on page 897
Use the MQSC command SET AUTHREC to set authority records associated with a profile name.

ALW DISPLAY AUTHSERV (display authorization services information)

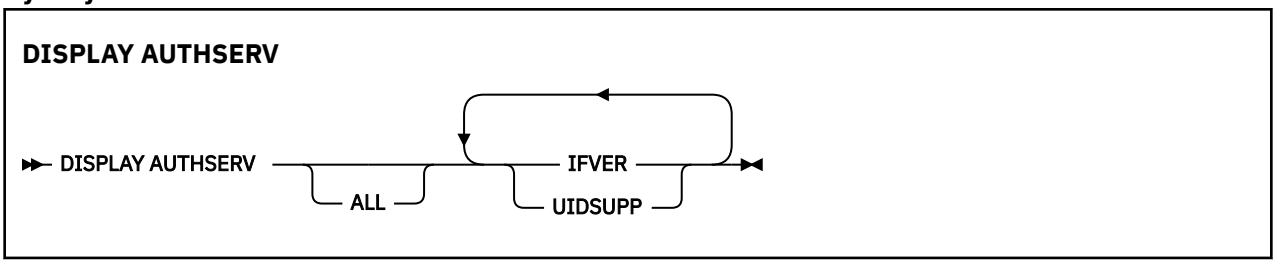
Use the MQSC command DISPLAY AUTHSERV to display information about the level of function supported by the installed authorization services.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

- Syntax diagram
- “Parameter descriptions” on page 632
- “Requested parameters” on page 632

Synonym: DIS AUTHSERV



Parameter descriptions

ALL
Specify this parameter to display all the information for each authorization service.

Requested parameters

You can request the following information for the authorization service:

IFVER
Specify this parameter to display the current interface version of the authorization service.

UIDSUPP
Specify this parameter to display whether the authorization service supports user IDs.

z/OS DISPLAY CFSTATUS (display CF application structure status) on z/OS

Use the MQSC command DISPLAY CFSTATUS to display the status of one or more CF application structures. This command is valid only on IBM MQ for z/OS when the queue manager is a member of a queue sharing group.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

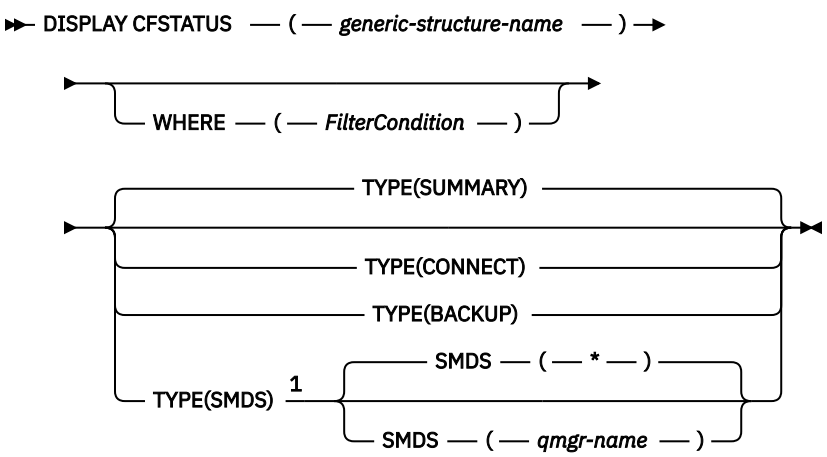
- “Keyword and parameter descriptions for DISPLAY CFSTATUS” on page 633
- “Summary status” on page 635
- “Connection status” on page 636
- “Backup status” on page 637
- “SMDS status” on page 638

Synonym: DIS CFSTATUS

DISPLAY CFSTATUS



Notes:

[1] This option is only supported when the CFSTRUCT is defined with OFFLOAD(SMDS).

Keyword and parameter descriptions for DISPLAY CFSTATUS

The name of the application structure for the status information to be displayed must be specified. This can be a specific application structure name or a generic name. By using a generic name, it is possible to display either:

- status information for all application structure definitions
- status information for one or more application structures that match the specified name

The type of status information to be returned can also be specified. This can be:

- summary status information for the application structure in the queue sharing group
- connection status information for each queue manager in the queue sharing group for each matching application structure name
- backup status information for each backup taken for each matching application structure defined in the queue sharing group

(generic-structure-name)
The 12-character name of the CF application structure to be displayed. A trailing asterisk (*) matches all structure names with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all structure names.

The CF structure name must be defined within the queue sharing group.

The CFSTATUS generic name can be the administration CF structure name (CSQ_ADMIN) or any generic form of this name. Data for this structure, however, is only displayed when TYPE is set to SUMMARY.

WHERE
Specify a filter condition to display status information for those CF application structures that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword
Almost any parameter that is returned by this DISPLAY command. However, you cannot use the TYPE parameter as a filter keyword.

operator
This is used to determine whether a CF application structure satisfies the filter value on the given filter keyword. The operators are:

LT
Less than

GT
Greater than

EQ
Equal to

NE
Not equal to

LE
Less than or equal to

GE
Greater than or equal to

LK
Matches a generic string that you provide as a *filter-value*

NL
Does not match a generic string that you provide as a *filter-value*

CT
Contains a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which contain the specified item.

EX
Does not contain a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which do not contain the specified item.

CTG
Contains an item which matches a generic string that you provide as a *filter-value*. If the *filter-keyword* is a list, you can use this to display objects the attributes of which match the generic string.

EXG
Does not contain any item which matches a generic string that you provide as a *filter-value*. If the *filter-keyword* is a list, you can use this to display objects the attributes of which do not match the generic string.

filter-value
The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

  You can use operators LT, GT, EQ, NE, LE, GE, only. However, if the value is one from a possible set of values returnable on a parameter (for example, the value ACTIVE on the STATUS parameter), you can only use EQ or NE.
- A generic value. This is a character string (such as the character string in the QMNAME parameter) with an asterisk at the end, for example ABC*. The characters must be valid for the attribute you are testing. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed.

  You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.
- An item in a list of values. The value can be explicit or, if it is a character value, it can be explicit or generic. If it is explicit, use CT or EX as the operator. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed. If it is generic, use CTG or EXG as the operator. If ABC* is specified with the operator CTG, all items where one of the attribute values begins with ABC are listed.

TYPE
Specifies the type of status information required to be displayed. Values are:

SUMMARY
Display summary status information for each application structure. This is the default.

CONNECT
Display connection status information for each application structure for each active queue manager.

BACKUP
Display backup status information for each application structure.

SMDS
Display shared message data set information.

SMDS

qmgr-name
Specifies the queue manager for which the shared message data set status is to be displayed.

*****
Displays the status for all shared message data sets associated with the specified CFSTRUCT except those which have both STATUS(NOTFOUND) and ACCESS(ENABLED).

Summary status

For summary status, the following information is returned for each structure that satisfies the selection criteria:

- The name of the application structure matching the generic name.
- The type of information returned.

CFTYPE
The CF structure type. This is one of the following:

ADMIN
This is the CF administration structure.

APPL
This is a CF application structure.

STATUS
The status of the CF application structure. This is one of the following:

ACTIVE
The structure is active.

FAILED
The structure has failed.

NOTFOUND
The structure is not allocated in the CF, but has been defined to Db2. Check and resolve any messages in the job log about this structure.

INBACKUP
The structure is in the process of being backed-up.

INRECOVER
The structure is in the process of being recovered.

UNKNOWN
The status of the CF structure is not known because, for example, Db2 might be unavailable.

SIZEMAX *(size)*
The size in kilobytes of the application structure.

SIZEUSED *(integer)*
The percentage of the size of the application structure that is in use. Therefore SIZEUSED(25) would indicate that a quarter of the space allocated to this application structure is in use.

ENTSMAX *(integer)*
The number of CF list entries defined for this application structure.

Note: The number does not include any entries that are in storage class memory (SCM), and which might have been allocated to the structure.

ENTSUSED ***(integer)***
The number of CF list entries for this application structure that are in use.

Note: The number does not include any entries that are in storage class memory (SCM), and which might have been allocated to the structure.

FAILTIME ***(time)***
The time that this application structure failed. The format of this field is `hh.mm.ss`. This parameter is only applicable when the CF structure is in FAILED or INRECOVER state. If the structure is not in a failed state, this is displayed as FAILTIME().

FAILDATE ***(date)***
The date that this application-structure failed. The format of this field is `yyyy-mm-dd`. This parameter is only applicable when the CF structure is in FAILED or INRECOVER state. If the structure is not in a failed state, then this is displayed as FAILDATE().

OFFLDUSE
This indicates whether offloaded large message data potentially exists in shared message data sets, Db2 or both.

When the offload method is switched, the previous offload method needs to remains available for retrieving and deleting old messages, so the OFFLDUSE status is changed to indicate BOTH. When a queue manager disconnects normally from a structure that has OFFLDUSE(BOTH) it checks whether there still are any messages which were stored using the old offload method. If not, it changes the OFFLDUSE status to match the current offload method and issues message CSQE245I to indicate that the switch is complete.

This parameter is one of the following:

NONE
No offloaded large messages are present.

SMDS
Offloaded large messages can exist in shared message data sets.

Db2
Offloaded large messages can exist in Db2.

BOTH
Offloaded large messages can exist both in shared message data sets and in Db2.

Connection status

For connection status, the following information is returned for each connection to each structure that satisfies the selection criteria:

- The name of the application structure matching the generic name.
- The type of information returned.

QMNAME ***(qmgrname)***
The queue manager name.

SYSNAME ***(systemname)***
The name of the z/OS image of the queue manager that last connected to the application structure. These can be different across queue managers depending on the customer configuration setup.

STATUS
A status indicating whether this queue manager is connected to this application structure. This is one of the following:

ACTIVE
The structure is connected to this queue manager.

FAILED
The queue manager connection to this structure has failed.

NONE
The structure has never been connected to this queue manager.

UNKNOWN
The status of the CF structure is not known.

FAILTIME ***(time)***
The time that this queue manager lost connectivity to this application structure. The format of this field is `hh.mm.ss`. This parameter is only applicable when the CF structure is in FAILED state. If the structure is not in a failed state, this is displayed as FAILTIME().

FAILDATE ***(date)***
The date that this queue manager lost connectivity to this application structure. The format of this field is `yyyy-mm-dd`. This parameter is only applicable when the CF structure is in FAILED state. If the structure is not in a failed state, this is displayed as FAILDATE().

Backup status

For backup status, the following information is returned for each structure that satisfies the selection criteria:

- The name of the application structure matching the generic name.
- The type of information returned.

STATUS
The status of the CF application structure. This is one of the following:

ACTIVE
The structure is active.

FAILED
The structure has failed.

NONE
The structure is defined as RECOVER(YES), but has never been backed up.

INBACKUP
The structure is in the process of being backed-up.

INRECOVER
The structure is in the process of being recovered.

UNKNOWN
The status of the CF structure is not known.

QMNAME ***(qmgrname)***
The name of the queue manager that took the last successful backup for this application structure.

BKUPTIME ***(time)***
The end time of the last successful backup taken for this application structure. The format of this field is `hh.mm.ss`.

BKUPDATE ***(date)***
The date of the last successful backup taken for this application structure. The format of this field is `yyyy-mm-dd`.

BKUPSIZE ***(size)***
The size in megabytes of the last successful backup taken for this application structure.

BKUPSRBA ***(hexadecimal)***
This is the backup data set start RBA for the start of the last successful backup taken for this application structure.

BKUPERBA ***(hexadecimal)***
This is the backup data set end RBA for the end of the last successful backup taken for this application structure.

LOGS ***(qmgrname-list)***
This is the list of queue managers, the logs of which are required to perform a recovery.

FAILTIME ***(time)***
The time that this CF structure failed. The format of this field is `hh.mm.ss`. This parameter is only applicable when the CF structure is in FAILED state. If the structure is not in a failed state, this is displayed as FAILTIME().

FAILDATE ***(date)***
The date that this CF structure failed. The format of this field is `yyyy-mm-dd`. This parameter is only applicable when the CF structure is in FAILED state. If the structure is not in a failed state, this is displayed as FAILDATE().

SMDS status

The DISPLAY CFSTATUS command with TYPE(SMDS) displays status information relating to one or more shared message data sets associated with a specific application structure.

The following data is returned for each selected data set:

SMDS
The queue manager name which owns the shared message data set for which properties are being displayed

STATUS
The current status of the shared message data set. This is one of the following:

NOTFOUND
The data set has never been used, or the attempt to open it for the first time failed. Check and resolve any messages in the job log about this structure.

NEW
The data set is being opened and initialized for the first time, ready to be made active.

ACTIVE
The data set is available for normal use.

FAILED
The data set is in an unusable state and probably requires recovery.

INRECOVER
Data set recovery (using RECOVER CFSTRUCT) is in progress.

RECOVERED
The data set has been recovered or otherwise repaired, and is ready for use again, but requires some restart processing the next time it is opened. This restart processing ensures that obsolete references to any deleted messages have been removed from the coupling facility structure before the data set is made available again. The restart processing also rebuilds the data set space map.

EMPTY
The data set contains no messages. The data set is put into this state if it is closed normally by the owning queue manager at a time when it does not contain any messages. It can also be put into EMPTY state when the previous data set contents are to be discarded because the application structure has been emptied (using **RECOVER CFSTRUCT** with TYPE PURGE or, for a nonrecoverable structure only, by deleting the previous instance of the structure). The next time the data set is opened by its owning queue manager, the space map is reset to empty, and the status is changed to ACTIVE. As the previous data set contents are no longer required, a data set in this state can be replaced with a newly allocated data set, for example to change the space allocation or move it to another volume.

ACCESS
The current availability state of the shared message data set. This parameter is one of the following:

ENABLED
The data set can be used, and no error has been detected since the time that it was enabled. If the data set has STATUS(RECOVERED) it can only be opened by the owning queue manager for restart purposes, but if it has STATUS(ACTIVE) all queue managers can open it.

SUSPENDED
The data set is unavailable because of an error.

This occurs specifically when the STATUS is set to FAILED either because of an error accessing the data set, or using the ALTER SMDS command.

The queue manager can try to enable access again automatically if the error might no longer be present, for example when recovery completes, or if the status is manually set to RECOVERED. Otherwise, it can be enabled again by a command in order to retry the action which originally failed.

DISABLED
The shared message data set cannot be used because it has been explicitly disabled using a command. It can only be enabled again by using another command to enable it. For more information, see "RESET SMDS (reset shared message data sets) on z/OS" on page 882.

RCVDATE
The recovery start date.

If recovery is currently enabled for the data set, this indicates the date when it was activated, in the form yyyy-mm-dd. If recovery is not enabled, this is displayed as RCVDATE().

RCVTIME
The recovery start time.

If recovery is currently enabled for the data set, this indicates the time when it was activated, in the form hh.mm.ss. If recovery is not enabled, this is displayed as RCVTIME().

FAILDATE
The failure date.

If the data set was put into a failed state, and has not yet been restored to the active state, this indicates the date when the failure was indicated, in the form yyyy-mm-dd. If the data set is in the active state, this is displayed as FAILDATE().

FAILTIME
The failure time.

If the data set was put into a failed state and has not yet been restored to the active state, this indicates the time when the failure was indicated, in the form hh.mm.ss. If the data set is in the active state, this is displayed as FAILTIME().

z/OS DISPLAY CFSTRUCT (display CF application structure settings) on z/OS

Use the MQSC command DISPLAY CFSTRUCT to display the attributes of one or more CF application structures. This command is valid only on z/OS when the queue manager is a member of a queue sharing group.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

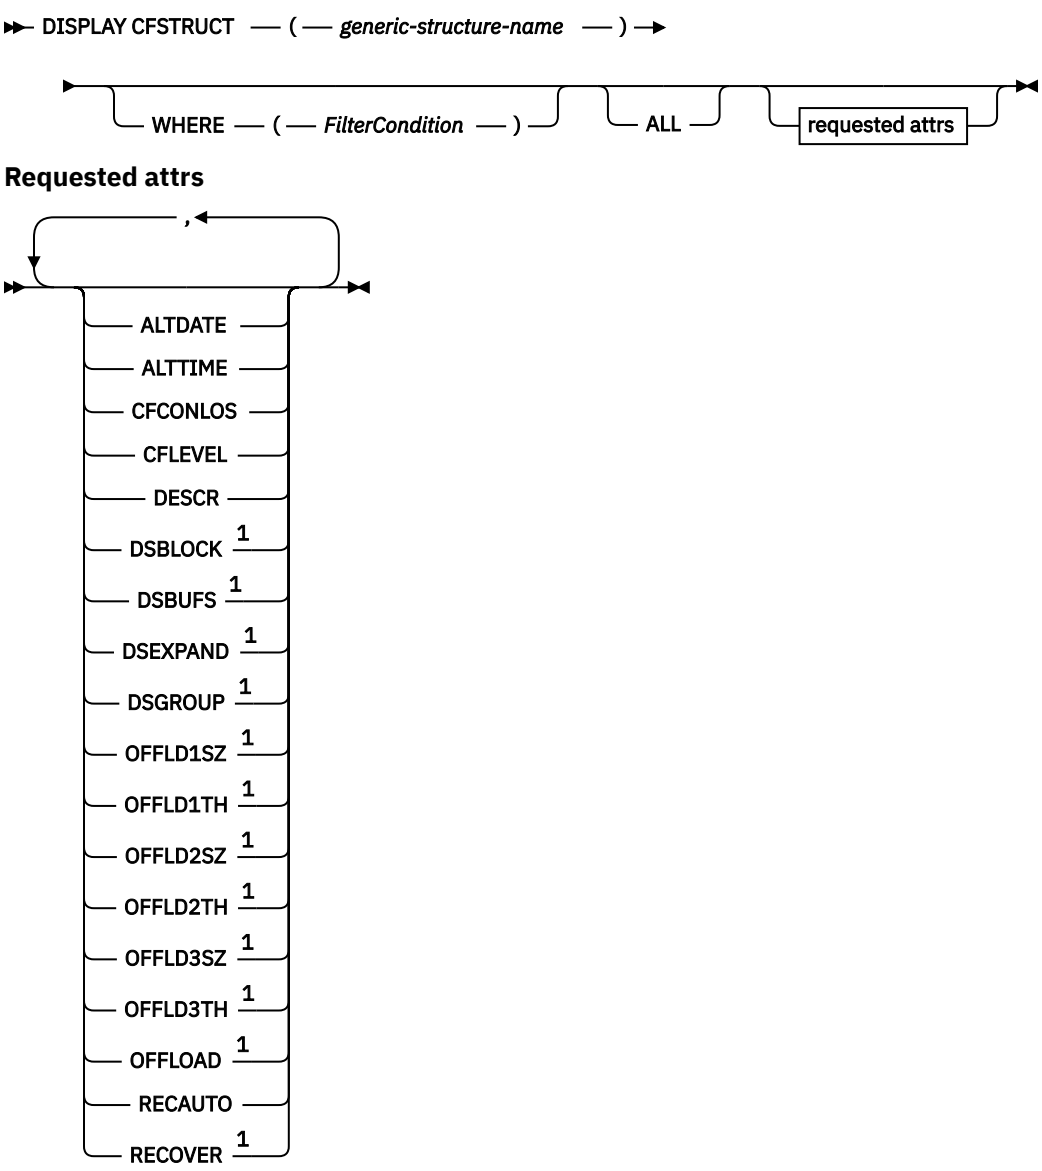
You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Usage notes for DISPLAY CFSTRUCT" on page 640

- “Keyword and parameter descriptions for DISPLAY CFSTRUCT” on page 640
- “Requested parameters” on page 642

Synonym: DIS CFSTRUCT

DISPLAY CFSTRUCT



Notes:

[1] For more information about this parameter, see Planning your coupling facility and offload storage environment.

Usage notes for DISPLAY CFSTRUCT

1. The command cannot specify the CF administration structure (CSQ_ADMIN).

Keyword and parameter descriptions for DISPLAY CFSTRUCT

The name of the application structure to be displayed must be specified. This can be a specific application structure name or a generic name. By using a generic name, it is possible to display either:

- all application structure definitions
- one or more application structures that match the specified name

(*generic-structure-name*)
The 12-character name of the CF application structure to be displayed. A trailing asterisk (*) matches all structure names with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all structure names.

The CF structure name must be defined within the queue sharing group.

WHERE
Specify a filter condition to display only those CF application structures that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword
Any parameter that can be used to display attributes for this DISPLAY command.

operator
This is used to determine whether a CF application structure satisfies the filter value on the given filter keyword. The operators are:

LT
Less than

GT
Greater than

EQ
Equal to

NE
Not equal to

LE
Less than or equal to

GE
Greater than or equal to

LK
Matches a generic string that you provide as a *filter-value*

NL
Does not match a generic string that you provide as a *filter-value*

filter-value
The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

  You can use any of the operators except LK and NL. However, if the value is one from a possible set of values returnable on a parameter (for example, the value YES on the RECOVER parameter), you can only use EQ or NE.
- A generic value. This is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC*. The characters must be valid for the attribute you are testing. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

  You can only use operators LK or NL for generic values on the DISPLAY CFSTRUCT command.

ALL
Specify this to display all attributes. If this keyword is specified, any attributes that are requested specifically have no effect; all attributes are still displayed.

This is the default behavior if you do not specify a generic name and do not request any specific attributes.

Requested parameters

Specify one or more attributes that define the data to be displayed. The attributes can be specified in any order. Do not specify the same attribute more than once.

The default, if no parameters are specified (and the ALL parameter is not specified) is that the structure names are displayed.

ALTDATE
The date on which the definition was last altered, in the form `yyyy-mm-dd`.

ALTTIME
The time at which the definition was last altered, in the form `hh.mm.ss`.

CFCONLOS
The action to be taken when the queue manager loses connectivity to the CF application structure.

CFLEVEL
Indicates the functional capability level for this CF application structure.

DESCR
Descriptive comment.

DSBLOCK
The logical block size, which is the unit in which shared message data set space is allocated to individual queues.

DSBUFS
The number of buffers allocated in each queue manager for accessing shared message data sets.

DSEXPAND
Whether the queue manager expands a shared message data set.

DSGROUP
The generic data set name to be used for the group of shared message data sets.

OFFLD1SZ
Offload rule 1: The message size value specifying an integer followed by K, giving the number of kilobytes.

OFFLD1TH
Offload rule 1: The coupling facility structure percentage usage threshold value as an integer.

OFFLD2SZ
Offload rule 2: The message size value specifying an integer followed by K, giving the number of kilobytes.

OFFLD2TH
Offload rule 2: The coupling facility structure percentage usage threshold value as an integer.

OFFLD3SZ
Offload rule 3: The message size value specifying an integer followed by K, giving the number of kilobytes.

OFFLD3TH
Offload rule 3: The coupling facility structure percentage usage threshold value as an integer.

OFFLOAD
If the CFLEVEL is less than 4, the only value you can display is NONE.

If the CFLEVEL is 4, the only value can display is Db2.

If the CFLEVEL is 5, the values displayed are Db2, SMDS, or BOTH. These values depict whether offloaded message data is stored in a group of shared message data sets, or in Db2, or both.

In addition, the offload rules parameter values for OFFLD1SZ, OFFLD1TH, OFFLD2SZ, OFFLD2TH, OFFLD3SZ, and OFFLD3TH are displayed.

RECAUTO
Indicates whether automatic recovery action is taken when a queue manager detects that the structure is failed, or when a queue manager loses connectivity to the structure and no systems in the SysPlex have connectivity to the Coupling Facility that the structure is allocated in. Values are:

YES
The structure and associated shared message data sets which also need recovery are automatically recovered.

NO
The structure is not automatically recovered.

RECOVER
Indicates whether CF recovery for the application structure is supported. Values are:

NO
CF application structure recovery is not supported.

YES
CF application structure recovery is supported.

DISPLAY CHANNEL (display channel definition)

Use the MQSC command DISPLAY CHANNEL to display a channel definition.

Using MQSC commands

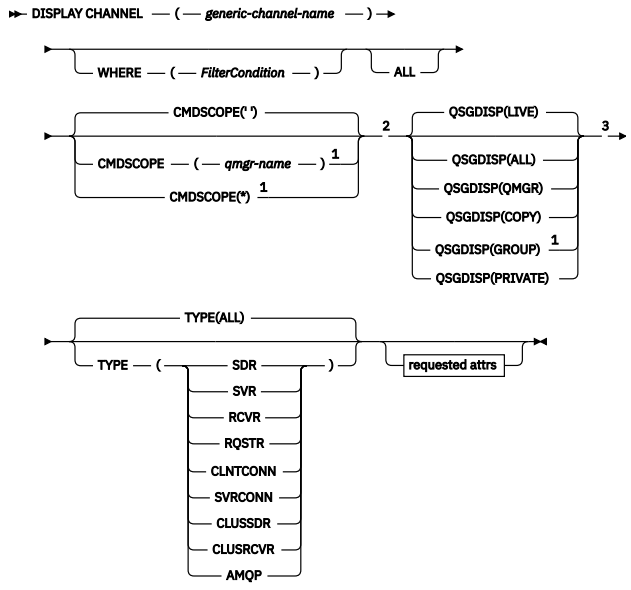
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

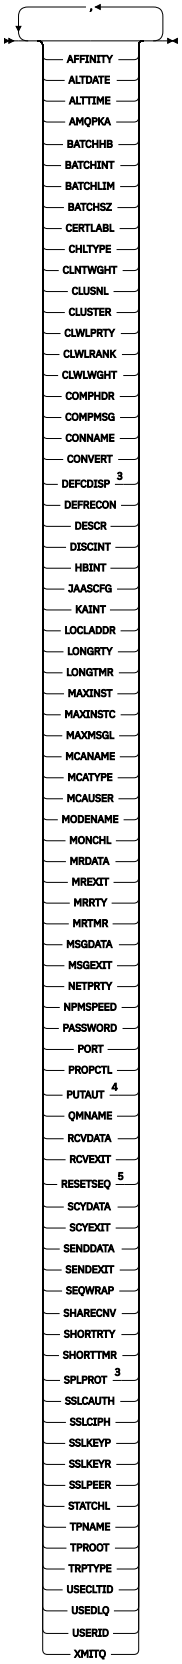
- Syntax diagram
- “Usage notes” on page 645
- “Parameter descriptions for DISPLAY CHANNEL” on page 645
- “Requested parameters” on page 648

Synonym: DIS CHL

DISPLAY CHANNEL



Requested attrs



Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.

[2] Not valid for z/OS client-connection channels.

[3] Valid only on z/OS.
[4] Valid only for RCVR, RQSTR, CLUSRCVR and (for z/OS only) SVRCONN channel types.
[5] Not valid on z/OS.

Usage notes

You can only display cluster-sender channels if they were created manually. See Cluster channels.

The values shown describe the current definition of the channel. If the channel has been altered since it was started, any currently running instance of the channel object might not have the same values as the current definition.

Parameter descriptions for DISPLAY CHANNEL

You must specify the name of the channel definition you want to display. It can be a specific channel name or a generic channel name. By using a generic channel name, you can display either:

- All channel definitions
- One or more channel definitions that match the specified name

(generic-channel-name)
The name of the channel definition to be displayed (see Rules for naming IBM MQ objects). A trailing asterisk (*) matches all channel definitions with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all channel definitions.

WHERE
Specify a filter condition to display only those channels that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword
Almost any parameter that can be used to display attributes for this DISPLAY command. However, you cannot use the CMDSCOPE, QSGDISP, or MCANAME parameters as filter keywords. You cannot use TYPE (or CHLTYPE) if it is also used to select channels. Channels of a type for which the filter keyword is not a valid attribute are not displayed.

operator
This is used to determine whether a channel satisfies the filter value on the given filter keyword. The operators are:

LT
Less than

GT
Greater than

EQ
Equal to

NE
Not equal to

LE
Less than or equal to

GE
Greater than or equal to

LK
Matches a generic string that you provide as a *filter-value*

NL
Does not match a generic string that you provide as a *filter-value*

CT
Contains a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which contain the specified item.

EX
Does not contain a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which do not contain the specified item.

CTG
Contains an item which matches a generic string that you provide as a *filter-value*. If the *filter-keyword* is a list, you can use this to display objects the attributes of which match the generic string.

EXG
Does not contain any item which matches a generic string that you provide as a *filter-value*. If the *filter-keyword* is a list, you can use this to display objects the attributes of which do not match the generic string.

filter-value
The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

  You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value SDR on the TYPE parameter), you can only use EQ or NE.
- A generic value. This is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC*. The characters must be valid for the attribute you are testing. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

  You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.
- An item in a list of values. The value can be explicit or, if it is a character value, it can be explicit or generic. If it is explicit, use CT or EX as the operator. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed. If it is generic, use CTG or EXG as the operator. If ABC* is specified with the operator CTG, all items where one of the attribute values begins with ABC are listed.

ALL
Specify ALL to display the results of querying all the parameters. If ALL is specified, any request for a specific parameter is ignored. The result of querying with ALL is to return the results for all of the possible parameters.

This is the default, if you do not specify a generic name and do not request any specific parameters.

z/OS On z/OS this is also the default if you specify a filter condition using the WHERE parameter, but on other platforms, only requested attributes are displayed.

If no parameters are specified (and the ALL parameter is not specified or defaulted), the default is that the channel names only are displayed.

z/OS On z/OS, the CHLTYPE and QSGDISP values are also displayed.

z/OS **CMDSCOPE**
This parameter specifies how the command is executed when the queue manager is a member of a queue sharing group.

' '
The command is executed on the queue manager on which it was entered. This is the default value.

qmgr-name
The command is executed on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command is executed on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

z/OS **QSGDISP**

Specifies the disposition of the objects for which information is to be displayed. Values are:

LIVE
This is the default value and displays information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

ALL
Displays information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

If there is a shared queue manager environment, and the command is being executed on the queue manager where it was issued, this option also displays information for objects defined with QSGDISP(GROUP).

If QSGDISP(ALL) is specified in a shared queue manager environment, the command might give duplicated names (with different dispositions).

Note: In the QSGDISP(LIVE) case, this occurs only where a shared and a non-shared queue have the same name; such a situation should not occur in a well-managed system.

In a shared queue manager environment, use

```
DISPLAY CHANNEL(name) CMDSCOPE(*) QSGDISP(ALL)
```

to list ALL objects matching

```
name
```

in the queue sharing group without duplicating those in the shared repository.

COPY
Display information only for objects defined with QSGDISP(COPY).

GROUP
Display information only for objects defined with QSGDISP(GROUP). This is allowed only if there is a shared queue manager environment.

PRIVATE
Display information only for objects defined with QSGDISP(QMGR) or QSGDISP(COPY). Note that QSGDISP(PRIVATE) displays the same information as QSGDISP(LIVE).

QMGR
Display information only for objects defined with QSGDISP(QMGR).

QSGDISP displays one of the following values:

QMGR
The object was defined with QSGDISP(QMGR).

GROUP
The object was defined with QSGDISP(GROUP).

COPY
The object was defined with QSGDISP(COPY).

You cannot use QSGDISP as a filter keyword.

TYPE
This is optional. It can be used to restrict the display to channels of one type.

The value is one of the following:

ALL
Channels of all types are displayed (this is the default).

SDR
Sender channels only are displayed.

SVR
Server channels only are displayed.

RCVR
Receiver channels only are displayed.

RQSTR
Requester channels only are displayed.

CLNTCONN
Client-connection channels only are displayed.

SVRCONN
Server-connection channels only are displayed.

CLUSSDR
Cluster-sender channels only are displayed.).

CLUSRCVR
Cluster-receiver channels only are displayed.).

AMQP
AMQP channels only are displayed.

CHLTYPE(*type*) can be used as a synonym for this parameter. ,

Requested parameters

Specify one or more DISPLAY CHANNEL parameters that define the data to be displayed. You can specify the parameters in any order, but do not specify the same parameter more than once.

Some parameters are relevant only for channels of a particular type or types. Attributes that are not relevant for a particular type of channel cause no output, nor is an error raised. The following table shows the parameters that are relevant for each type of channel. There is a description of each parameter after the table. Parameters are optional unless the description states that they are required.

Note:

1. PUTAUT is valid for a channel type of SVRCONN on z/OS only.

AFFINITY
The channel affinity attribute.

PREFERRED
Subsequent connections in a process attempt to use the same channel definition as the first connection.

NONE
All connections in a process select an applicable definition based on the weighting with any applicable CLNTWGHT(0) definitions selected first in alphabetical order.

ALTDATE
The date on which the definition was last altered, in the form `yyyy-mm-dd`.

ALTTIME
The time at which the definition was last altered, in the form `hh.mm.ss`.

AMQPKA
The keep alive time for an AMQP channel in milliseconds.

AUTOSTART
Whether an LU 6.2 responder process should be started for the channel.

BATCHHB
The batch heartbeating value being used.

BATCHINT
Minimum batch duration.

BATCHLIM
Batch data limit.

The limit of the amount of data that can be sent through a channel.

BATCHSZ
Batch size.

CERTLABL
Certificate label.

CHLTYPE
Channel type.

The channel type is always displayed if you specify a generic channel name and do not request any other parameters. On z/OS, the channel type is always displayed.

Multi On Multiplatforms, TYPE can be used as a synonym for this parameter.

CLNTWGHT
The client channel weighting.

The special value 0 indicates that no random load balancing is performed and applicable definitions are selected in alphabetical order. If random load balancing is performed the value is in the range 1 - 99 where 1 is the lowest weighting and 99 is the highest.

CLUSTER
The name of the cluster to which the channel belongs.

CLUSNL
The name of the namelist that specifies the list of clusters to which the channel belongs.

CLWLPRTY
The priority of the channel for the purposes of cluster workload distribution.

CLWLRANK
The rank of the channel for the purposes of cluster workload distribution.

CLWLWGHT
The weighting of the channel for the purposes of cluster workload distribution.

COMPHDR
The list of header data compression techniques supported by the channel. For sender, server, cluster-sender, cluster-receiver, and client-connection channels, the values specified are in order of preference.

COMPMSG
The list of message data compression techniques supported by the channel. For sender, server, cluster-sender, cluster-receiver, and client-connection channels, the values specified are in order of preference.

CONNAME
Connection name.

CONVERT
Whether sender should convert application message data.

DEFCDISP
Specifies the default channel disposition of the channels for which information is to be returned. If this keyword is not present, channels of all default channel dispositions are eligible.

ALL
Channels of all default channel dispositions are displayed.

This is the default setting.

PRIVATE
Only channels where the default channel disposition is PRIVATE are displayed.

SHARED
Only channels where the default channel disposition is FIXSHARED or SHARED are displayed.

Note: This does not apply to client-connection channel types on z/OS.

DESCR
Default client reconnection option.

DESCR
Description.

DISCINT
Disconnection interval.

HBINT
Heartbeat interval.

KAINT
KeepAlive timing for the channel.

LOCLADDR
Local communications address for the channel.

LONGRTY
Long retry count.

LONGTMR
Long retry timer.

MAXINST(***integer*** **)**
The maximum number of instances of a server-connection channel that are permitted to run simultaneously.

MAXINSTC(***integer*** **)**
The maximum number of instances of a server-connection channel, started from a single client, that are permitted to run simultaneously.

Note: In this context, connections originating from the same remote network address are regarded as coming from the same client.

MAXMSGL
Maximum message length for channel.

MCANAME
Message channel agent name.

You cannot use MCANAME as a filter keyword.

MCATYPE
Whether message channel agent runs as a separate process or a separate thread.

MCAUSER
Message channel agent user identifier.

MODENAME
LU 6.2 mode name.

MONCHL
Online monitoring data collection.

MRDATA
Channel message-retry exit user data.

MREXIT
Channel message-retry exit name.

MRRTY
Channel message-retry count.

MRTMR
Channel message-retry time.

MSGDATA
Channel message exit user data.

MSGEXIT
Channel message exit names.

NETPRTY
The priority for the network connection.

NPMSPEED
Nonpersistent message speed.

PASSWORD

Password for initiating LU 6.2 session. If nonblank, this is displayed as asterisks z/OS on all platforms except z/OS.

PORT

The port number used to connect an AMQP channel.

PROPCTL

Message property control.

Specifies what happens to properties of messages when the message is about to be sent to a V6 or prior queue manager (a queue manager that does not understand the concept of a property descriptor).

This parameter is applicable to Sender, Server, Cluster Sender, and Cluster Receiver channels.

This parameter is optional.

Permitted values are:

COMPAT

This is the default value.

Table 163. Range of results, depending on which mesage properties are set, when PROPCTL value is COMPAT

Message properties	Result
The message contains a property with a prefix of **mcd.**, **jms.**, **usr.** or **mqext.**	All optional message properties (where the **Support** value is MQPD_SUPPORT_OPTIONAL), except those in the message descriptor or extension, are placed in one or more MQRFH2 headers in the message data before the message it sent to the remote queue manager.
The message does not contain a property with a prefix of **mcd.**, **jms.**, **usr.** or **mqext.**	All message properties, except those in the message descriptor or extension, are removed from the message before the message is sent to the remote queue manager.
The message contains a property where the **Support** field of the property descriptor is not set to MQPD_SUPPORT_OPTIONAL	The message is rejected with reason MQRC_UNSUPPORTED_PROPERTY and treated in accordance with its report options.
The message contains one or more properties where the **Support** field of the property descriptor is set to MQPD_SUPPORT_OPTIONAL but other fields of the property descriptor are set to non-default values	The properties with non-default values are removed from the message before the message is sent to the remote queue manager.
The MQRFH2 folder that would contain the message property needs to be assigned with the *content='properties'* attribute	The properties are removed to prevent MQRFH2 headers with unsupported syntax flowing to a V6 or prior queue manager.

NONE

All properties of the message, except those in the message descriptor or extension, are removed from the message before the message is sent to the remote queue manager.

If the message contains a property where the **Support** field of the property descriptor is not set to MQPD_SUPPORT_OPTIONAL then the message is rejected with reason MQRC_UNSUPPORTED_PROPERTY and treated in accordance with its report options.

ALL

All properties of the message are included with the message when it is sent to the remote queue manager. The properties, except those in the message descriptor (or extension), are placed in one or more MQRFH2 headers in the message data.

PUTAUT
Put authority.

QMNAME
Queue manager name.

RESETSEQ
Pending reset sequence number.

This is the sequence number from an outstanding request and it indicates a user RESET CHANNEL command request is outstanding.

A value of zero indicates that there is no outstanding RESET CHANNEL. The value can be in the range 1 - 999999999.

This parameter is not applicable on z/OS.

RCVDATA
Channel receive exit user data.

RCVEXIT
Channel receive exit names.

SCYDATA
Channel security exit user data.

SCYEXIT
Channel security exit names.

SENDDATA
Channel send exit user data.

SENDEXIT
Channel send exit names.

SEQWRAP
Sequence number wrap value.

SHARECNV
Sharing conversations value.

SHORTRTY
Specifies the maximum number of times that the channel is to try allocating a session to its partner.

SHORTTMR
Short retry timer.

V 9.2.0 z/OS **SPLPROT**
SPLPROT (Security Policy Protection) specifies how a server-to-server Message Channel Agent should deal with message protection when AMS is active and an applicable policy exists.

SSLCAUTH
Whether TLS client authentication is required.

SSLCIPH
Cipher specification for the TLS connection.

SSLPEER
Filter for the Distinguished Name from the certificate of the peer queue manager or client at the other end of the channel.

STATCHL
Statistics data collection.

TPNAME
LU 6.2 transaction program name.

TPROOT
The topic root for an AMQP channel.

TRPTYPE
Transport type.

USECLTID
Specifies that the client ID should be used for authorization checks for an AMQP channel, instead of the MCAUSER attribute value.

USEDLQ
Determines whether the dead-letter queue is used when messages cannot be delivered by channels.

USERID
User identifier for initiating LU 6.2 session.

XMITQ
Transmission queue name.

For more details of these parameters, see "DEFINE CHANNEL (define a new channel)" on page 448.

Windows Linux AIX DISPLAY CHANNEL (display channel definition) MQTT

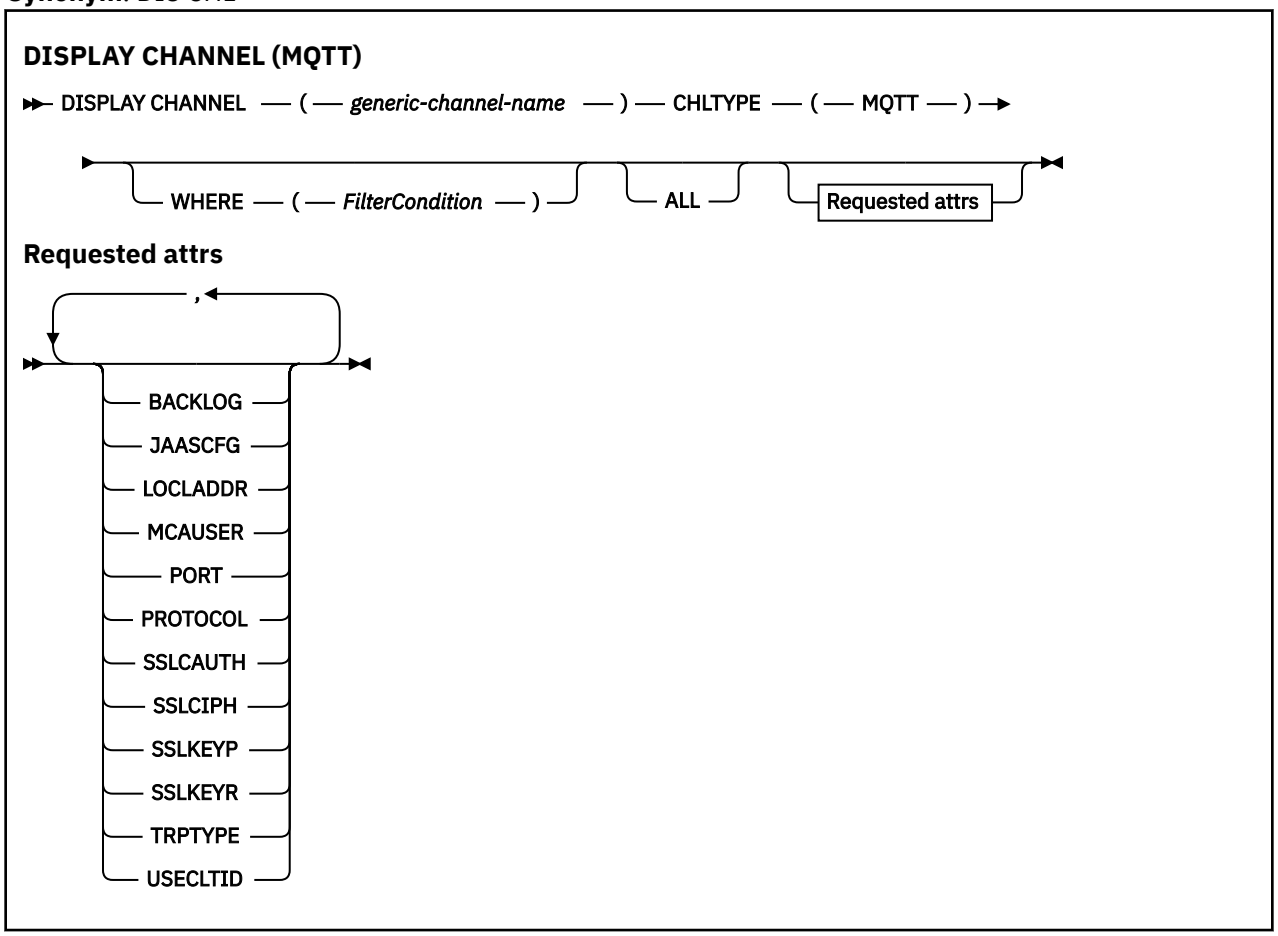
Use the MQSC command DISPLAY CHANNEL (MQTT) to display an MQ Telemetry channel definition.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

- Syntax diagram
- "Parameter descriptions for DISPLAY CHANNEL (MQTT)" on page 658
- "Requested parameters" on page 659

Synonym: DIS CHL



DISPLAY CHANNEL (MQTT) command is only valid for MQ Telemetry channels.

Parameter descriptions for DISPLAY CHANNEL (MQTT)

You must specify the name of the channel definition you want to display. This can be a specific channel name or a generic channel name. By using a generic channel name, you can display either:

- All channel definitions
- One or more channel definitions that match the specified name

(generic-channel-name)

The name of the channel definition to be displayed (see Rules for naming IBM MQ objects). A trailing asterisk (*) matches all channel definitions with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all channel definitions.

CHLTYPE(*type*)

The value is always MQTT.

TYPE can be used as a synonym for this parameter.

WHERE

Specify a filter condition to display only those channels that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword
Almost any parameter that can be used to display attributes for this DISPLAY command. However, you cannot use the CMDSCOPE, QSGDISP, or MCANAME parameters as filter keywords. You cannot use TYPE (or CHLTYPE) if it is also used to select channels. Channels of a type for which the filter keyword is not a valid attribute are not displayed.

operator
This is used to determine whether a channel satisfies the filter value on the given filter keyword. The operators are:

LT
Less than

GT
Greater than

EQ
Equal to

NE
Not equal to

LE
Less than or equal to

GE
Greater than or equal to

LK
Matches a generic string that you provide as a *filter-value*

NL
Does not match a generic string that you provide as a *filter-value*

CT
Contains a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which contain the specified item.

EX
Does not contain a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which do not contain the specified item.

CTG
Contains an item which matches a generic string that you provide as a *filter-value*. If the *filter-keyword* is a list, you can use this to display objects the attributes of which match the generic string.

EXG
Does not contain any item which matches a generic string that you provide as a *filter-value*. If the *filter-keyword* is a list, you can use this to display objects the attributes of which do not match the generic string.

filter-value
The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

  You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value SDR on the TYPE parameter), you can only use EQ or NE.
- A generic value. This is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC*. The characters must be valid for the attribute you are testing. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

  You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.
- An item in a list of values. The value can be explicit or, if it is a character value, it can be explicit or generic. If it is explicit, use CT or EX as the operator. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed. If it is generic, use CTG or EXG as the operator. If ABC* is specified with the operator CTG, all items where one of the attribute values begins with ABC are listed.

ALL

Specify ALL to display the results of querying all the parameters. If ALL is specified, any request for a specific parameter is ignored. The result of querying with ALL is to return the results for all of the possible parameters.

This is the default, if you do not specify a generic name and do not request any specific parameters.

If no parameters are specified (and the ALL parameter is not specified or defaulted), the default is that the channel names only are displayed.

Requested parameters

Specify one or more DISPLAY CHANNEL parameters that define the data to be displayed. You can specify the parameters in any order, but do not specify the same parameter more than once.

Some parameters are relevant only for channels of a particular type or types. Attributes that are not relevant for a particular type of channel cause no output, nor is an error raised. The following table shows the parameters that are relevant for each type of channel. There is a description of each parameter after the table. Parameters are optional unless the description states that they are required.

BACKLOG

The number of outstanding connection requests that the telemetry channel can support at any one time. When the backlog limit is reached, any further clients trying to connect will be refused connection until the current backlog is processed. The value is in the range 0 - 999999999. The default value is 4096.

CHLTYPE

Channel type.

There is only one valid value for this parameter: MQTT.

JAASCFG

The name of a stanza in the JAAS configuration file.

LOCLADDR

The local communications address for the channel.

MCAUSER

The message channel agent user identifier.

PORT

The port number on which the telemetry (MQXR) service accepts client connections.

PROTOCOL

The communication protocol supported by the channel.

SSLCAUTH

Defines whether IBM MQ requires a certificate from the TLS client.

SSLCIPH

When **SSLCIPH** is used with a telemetry channel, it means TLS Cipher Suite.

SSLKEYP

The password for the key repository. If no passphrase is entered, you must use unencrypted connections.

SSLKEYR

The name of the TLS key repository. For full details, see the SSLKEYR parameter of the ALTER QMGR command.

TRPTYPE

The transmission protocol to be used. For a Telemetry channel, this is always TCP (that is, the TCP/IP protocol).

USECLTID

Indicates whether you want to use the MQTT client ID for the connection as the IBM MQ user ID for that connection.

For more details of these parameters, see “DEFINE CHANNEL (define a new channel) for MQTT” on page 505.

z/OS DISPLAY CHINIT (display channel initiator information) on z/OS

Use the MQSC command DISPLAY CHINIT to display information about the channel initiator. The command server must be running.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

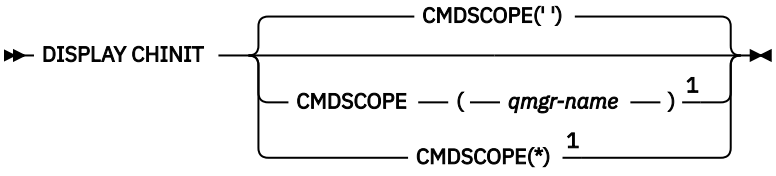
You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram

- "Usage notes for DISPLAY CHINIT" on page 661
- "Parameter descriptions for DISPLAY CHINIT" on page 661

Synonym: DIS CHI or DIS DQM

DISPLAY CHINIT



Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.

Usage notes for DISPLAY CHINIT

1. The response to this command is a series of messages showing the current status of the channel initiator. This includes the following:
   - Whether the channel initiator is running or not
   - Which listeners are started, and information about them.
   - How many dispatchers are started, and how many were requested
   - How many adapter subtasks are started, and how many were requested
   - How many TLS subtasks are started, and how many were requested
   - The TCP system name
   - How many channel connections are current, and whether they are active, stopped, or retrying
   - The maximum number of current connections

Parameter descriptions for DISPLAY CHINIT

CMDSCOPE

This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

' '

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

DISPLAY CHLAUTH (display channel authentication record)

Use the MQSC command DISPLAY CHLAUTH to display the attributes of a channel authentication record.

Using MQSC commands

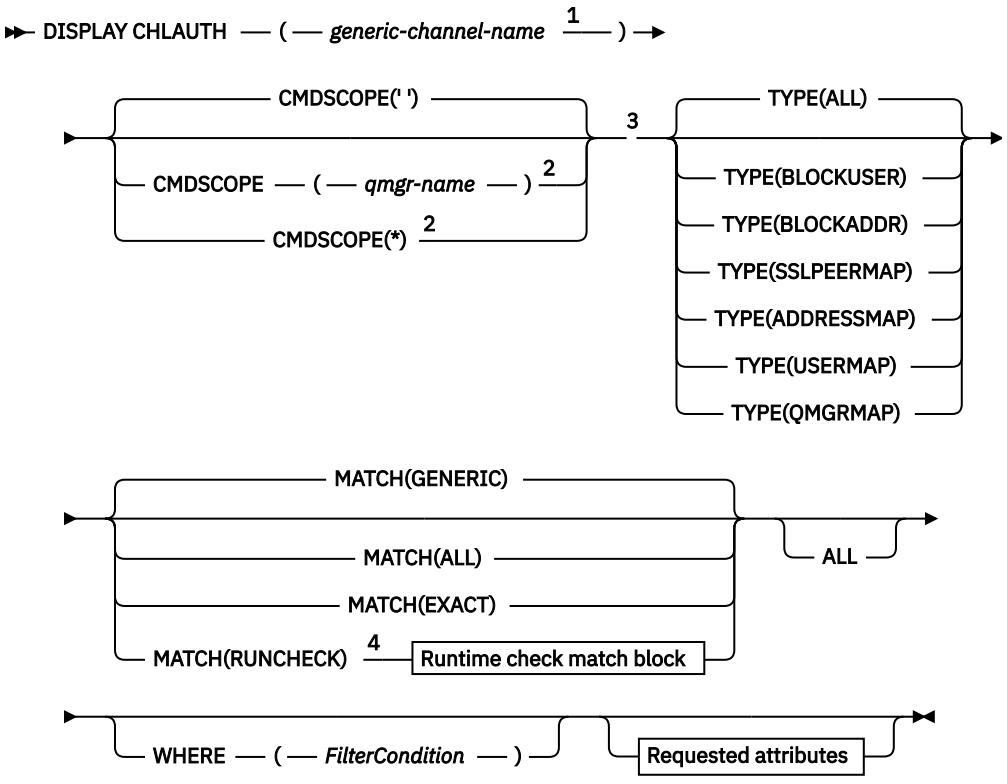
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

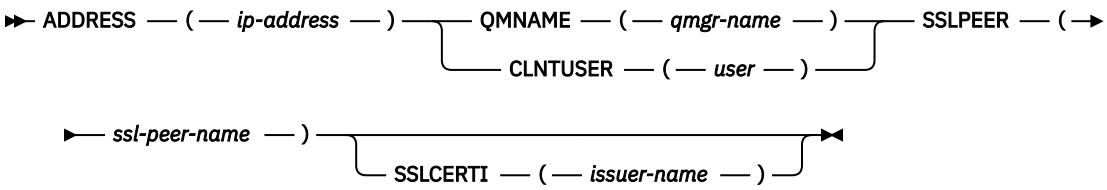
- Syntax diagram
- Parameters

Synonym: DIS CHLAUTH

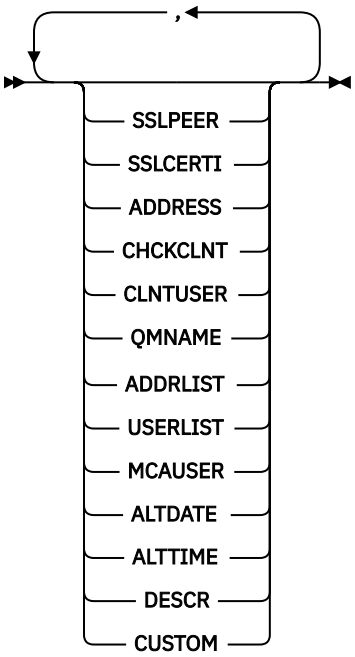
DISPLAY CHLAUTH



Runtime check match block



Requested attributes



Notes:

[1] Must be * with TYPE(BLOCKADDR) and cannot be generic with MATCH(RUNCHECK)
[2] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[3] Valid only on z/OS.
[4] Must be combined with TYPE(ALL)

Parameters

generic-channel-name
The name of the channel or set of channels to display. You can use the asterisk (*) as a wildcard to specify a set of channels. When an asterisk is used on z/OS, single quotes must be used around the whole value. When **MATCH** is RUNCHECK this parameter must not be generic.

ADDRESS
The IP address to be matched.

This parameter is valid only when **MATCH** is RUNCHECK, must not be generic and must not be a host name.

ALL
Specify this parameter to display all attributes. If this keyword is specified, any attributes that are requested specifically have no effect; all attributes are still displayed.

This is the default behavior if you do not specify a generic name and do not request any specific attributes.

CLNTUSER
The client asserted user ID to be mapped to a new user ID, allowed through unchanged, or blocked.

This can be the user ID flowed from the client indicating the user ID the client side process is running under, or the user ID presented by the client on an MQCONNX call using MQCSP.

This parameter is valid only with TYPE(USERMAP) and when **Match** is RUNCHECK.

The maximum length of the string is MQ_CLIENT_USER_ID_LENGTH.

z/OS **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command is run when the queue manager is a member of a queue sharing group.

' '

The command is run on the queue manager on which it was entered. This is the default value.

qmgr-name

The command is run on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****

The command is run on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect is the same as entering the command on every queue manager in the queue sharing group.

MATCH

Indicates the type of matching to be applied.

RUNCHECK

Returns the record that is matched by a specific inbound channel at run time if it connects to this queue manager. The specific inbound channel is described by providing values that are not generic:

- Channel name.
- **ADDRESS** attribute containing an IP address, that is then reverse looked up as part of running the command to discover the host name, if the queue manager is configured with **REVDNS(ENABLED)**.
- **SSLCERTI** attribute, only if the inbound channel uses TLS.
- **SSLPEER** attribute, only if the inbound channel uses TLS.
- **QMNAME** or **CLNTUSER** attribute, depending on whether the inbound channel is a client or queue manager channel.

If the record discovered has **WARN** set to YES, a second record might also be displayed to show the actual record the channel will use at run time. This parameter must be combined with **TYPE(ALL)**.

EXACT

Return only those records which exactly match the channel profile name supplied. If there are no asterisks in the channel profile name, this option returns the same output as MATCH(GENERIC).

GENERIC

Any asterisks in the channel profile name are treated as wildcards. If there are no asterisks in the channel profile name, this returns the same output as MATCH(EXACT). For example, a profile of ABC* could result in records for ABC, ABC*, and ABCD being returned.

ALL

Return all possible records that match the channel profile name supplied. If the channel name is generic in this case, all records that match the channel name are returned even if more specific matches exist. For example, a profile of SYSTEM.*.SVRCONN could result in records for SYSTEM.*, SYSTEM.DEF.*, SYSTEM.DEF.SVRCONN, and SYSTEM.ADMIN.SVRCONN being returned.

QMNAME

The name of the remote partner queue manager to be matched

This parameter is valid only when **MATCH** is RUNCHECK and must not be generic.

SSLCERTI

The Certificate issuer Distinguished Name of the certificate to be matched.

The **SSLCERTI** field, if not blank, is matched in addition to the **SSLPEER** value.

This parameter is valid only when **MATCH** is RUNCHECK and must not be generic.

SSLPEER

The Subject Distinguished Name of the certificate to be matched.

The **SSLPEER** value is specified in the standard form used to specify a Distinguished Name.

This parameter is valid only when **MATCH** is RUNCHECK and must not be generic.

TYPE

The type of Channel Authentication Record for which to display details. Possible values are:

- ALL
- BLOCKUSER
- BLOCKADDR
- SSLPEERMAP
- ADDRESSMAP
- USERMAP
- QMGRMAP

WHERE

Specify a filter condition to display only those channel authentication records that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

Any parameter that can be used to display attributes for this DISPLAY command.

operator

This is used to determine whether a channel authentication record satisfies the filter value on the given filter keyword. The operators are as follows:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

CT

Contains a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which contain the specified item.

EX

Does not contain a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which do not contain the specified item.

CTG
Contains an item which matches a generic string that you provide as a *filter-value*. If the *filter-keyword* is a list, you can use this to display objects the attributes of which match the generic string.

EXG
Does not contain any item which matches a generic string that you provide as a *filter-value*. If the *filter-keyword* is a list, you can use this to display objects the attributes of which do not match the generic string.

filter-value
The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, the value can be either explicit or generic:

- An explicit value, that is a valid value for the attribute being tested.

  You can use any of the operators except LK and NL. However, if the value is one from a possible set of values returnable on a parameter (for example, the value ALL on the MATCH parameter), you can only use EQ or NE.
- A generic value. This is a character string with an asterisk at the end, for example ABC*. The characters must be valid for the attribute you are testing. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

  You can only use operators LK or NL for generic values.
- An item in a list of values. The value can be explicit or, if it is a character value, it can be explicit or generic. If it is explicit, use CT or EX as the operator. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed. If it is generic, use CTG or EXG as the operator. If ABC* is specified with the operator CTG, all items where one of the attribute values begins with ABC are listed.

Note: z/OS On z/OS there is a 256 character limit for the filter-value of the MQSC **WHERE** clause. This limit is not in place for other platforms.

Requested parameters

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

TYPE
The type of channel authentication record

SSLPEER
The Distinguished Name of the certificate.

ADDRESS
The IP address

CHCKCLNT
Whether a user ID and password are to be supplied by connections which match this rule.

CLNTUSER
The client asserted user ID

QMNAME
The name of the remote partner queue manager

MCAUSER
The user identifier to be used when the inbound connection matches the TLS DN, IP address, client asserted user ID or remote queue manager name supplied.

ADDRLIST
A list of IP address patterns which are banned from connecting into this queue manager on any channel.

USERLIST
A list of user IDs which are banned from use of this channel or set of channels.

ALTDATE
The date on which the channel authentication record was last altered, in the format *yyyy-mm-dd*.

ALTTIME
The time on which the channel authentication record was last altered, in the form *hh.mm.ss*.

DESCR
Descriptive information about the channel authentication record.

SSLCERTI
The Certificate issuer Distinguished Name of the certificate to be matched.

CUSTOM
Reserved for future use.

Related concepts
Channel authentication records

Related reference
"Generic IP addresses for channel authentication records" on page 910
In the various commands that create and display channel authentication records, you can specify certain parameters as either a single IP address or a pattern to match a set of IP addresses.

DISPLAY CHSTATUS (display channel status)

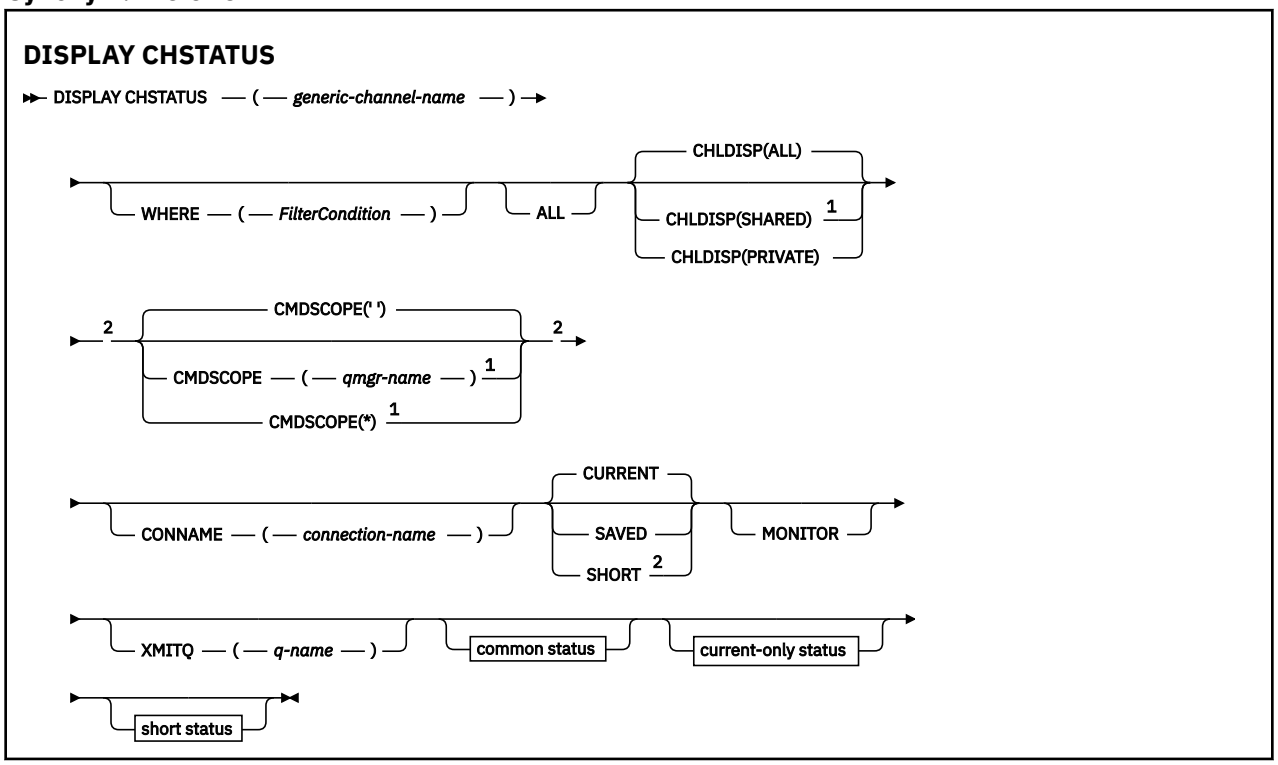
Use the MQSC command **DISPLAY CHSTATUS** to display the status of one or more channels.

Using MQSC commands

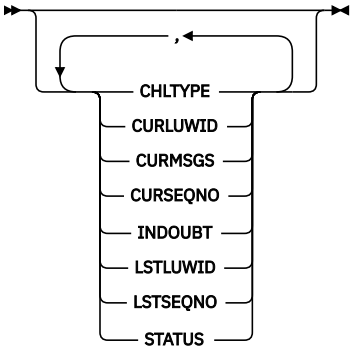
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

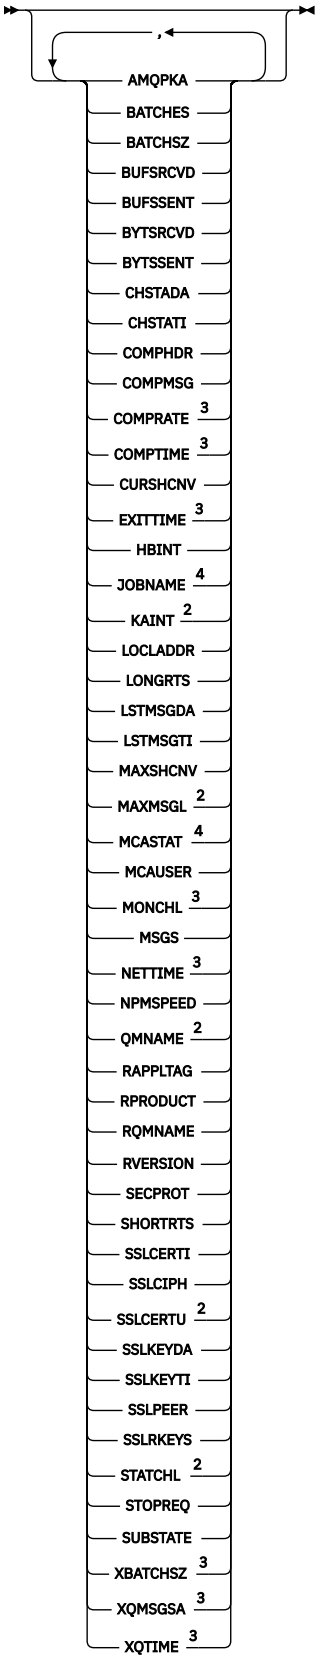
Synonym: DIS CHS



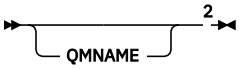
Common status



Current-only status



Short status



Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[2] Valid only on z/OS.
[3] Also displayed by selection of the MONITOR parameter.
[4] Ignored if specified on z/OS.

Usage notes for DISPLAY CHSTATUS on z/OS

z/OS

1. The command fails if the channel initiator has not been started.
2. The command server must be running.
3. If you want to see the overall status of the channel (that is, the status of the queue sharing group) use the command **DISPLAY CHSTATUS SHORT**, which obtains the status information of the channel from Db2.
4. If any numeric parameter exceeds 999,999,999, it is displayed as 999999999.
5. The status information that is returned for various combinations of **CHLDISP**, **CMDSCOPE**, and status type are summarized in Table 164 on page 670, Table 165 on page 670, and Table 166 on page 671.

Table 164. CHLDISP and CMDSCOPE for DISPLAY CHSTATUS CURRENT

CHLDISP	CMDSCOPE( ) or CMDSCOPE (local-qmgr)	CMDSCOPE (qmgr-name)	CMDSCOPE(*)
PRIVATE	Common and current-only status for current private channels on the local queue manager	Common and current-only status for current private channels on the named queue manager	Common and current-only status for current private channels on all queue managers
SHARED	Common and current-only status for current shared channels on the local queue manager	Common and current-only status for current shared channels on the named queue manager	Common and current-only status for current shared channels on all queue managers
ALL	Common and current-only status for current private and shared channels on the local queue manager	Common and current-only status for current private and shared channels on the named queue manager	Common and current-only status for current private and shared channels on all active queue managers

Table 165. CHLDISP and CMDSCOPE for DISPLAY CHSTATUS SHORT

CHLDISP	CMDSCOPE( ) or CMDSCOPE (local-qmgr)	CMDSCOPE (qmgr-name)	CMDSCOPE(*)
PRIVATE	STATUS and short status for current private channels on the local queue manager	STATUS and short status for current private channels on the named queue manager	STATUS and short status for current private channels on all active queue managers
SHARED	STATUS and short status for current shared channels on all active queue managers in the queue sharing group	Not permitted	Not permitted

Table 165. CHLDISP and CMDSCOPE for DISPLAY CHSTATUS SHORT (continued)			
CHLDISP	**CMDSCOPE( ) or CMDSCOPE (local-qmgr)**	**CMDSCOPE (qmgr-name)**	**CMDSCOPE(*)**
ALL	STATUS and short status for current private channels on the local queue manager and current shared channels in the queue sharing group (“5.a” on page 671)	STATUS and short status for current private channels on the named queue manager	STATUS and short status for current private, and shared, channels on all active queue managers in the queue sharing group (“5.a” on page 671)

Note:

a. In this case you get two separate sets of responses to the command on the queue manager where it was entered; one for PRIVATE and one for SHARED.

Table 166. CHLDISP and CMDSCOPE for DISPLAY CHSTATUS SAVED			
CHLDISP	**CMDSCOPE( ) or CMDSCOPE (local-qmgr)**	**CMDSCOPE (qmgr-name)**	**CMDSCOPE(*)**
PRIVATE	Common status for saved private channels on the local queue manager	Common status for saved private channels on the named queue manager	Common status for saved private channels on all active queue managers
SHARED	Common status for saved shared channels on all active queue managers in the queue sharing group	Not permitted	Not permitted
ALL	Common status for saved private channels on the local queue manager and saved shared channels in the queue sharing group	Common status for saved private channels on the named queue manager	Common status for saved private, and shared, channels on all active queue managers in the queue sharing group

Parameter descriptions for DISPLAY CHSTATUS on all platforms

You must specify the name of the channel for which you want to display status information. This can be a specific channel name or a generic channel name. By using a generic channel name, you can display either the status information for all channels, or status information for one or more channels that match the specified name.

You can also specify whether you want the current status data (of current channels only), or the saved status data of all channels.

Status for all channels that meet the selection criteria is displayed, whether the channels were defined manually or automatically.

The classes of data available for channel status are **saved** and **current**, and (on z/OS only) **short**.

The status fields available for saved data are a subset of the fields available for current data and are called **common** status fields. Note that although the common data *fields* are the same, the data *values* might be different for saved and current status. The rest of the fields available for current data are called **current-only** status fields.

- **Saved** data consists of the common status fields noted in the syntax diagram.
  - For a sending channel data is updated before requesting confirmation that a batch of messages has been received and when confirmation has been received

  - For a receiving channel data is reset just before confirming that a batch of messages has been received
  - For a server connection channel no data is saved.
  - Therefore, a channel that has never been current cannot have any saved status.

    Note: Status is not saved until a persistent message is transmitted across a channel, or a nonpersistent message is transmitted with a NPMSPEED of NORMAL. Because status is saved at the end of each batch, a channel does not have any saved status until at least one batch has been transmitted.
- **Current** data consists of the common status fields and current-only status fields as noted in the syntax diagram. The data fields are continually updated as messages are sent/received.
- z/OS **Short** data consists of the STATUS current data item and the short status field as noted in the syntax diagram.

This method of operation has the following consequences:

- An inactive channel might not have any saved status - if it has never been current or has not yet reached a point where saved status is reset.
- The "common" data fields might have different values for saved and current status.
- A current channel always has current status and might have saved status.

Channels can either be current or inactive:

Current channels
: These are channels that have been started, or on which a client has connected, and that have not finished or disconnected normally. They might not yet have reached the point of transferring messages, or data, or even of establishing contact with the partner. Current channels have **current** status and might also have **saved** status.

  The term **Active** is used to describe the set of current channels that are not stopped.

Inactive channels
: These are channels that either:

  - Have not been started
  - On which a client has not connected
  - Have finished
  - Have disconnected normally

  (Note that if a channel is stopped, it is not yet considered to have finished normally - and is, therefore, still current.) Inactive channels have either **saved** status or no status at all.

There can be more than one instance of the same named receiver, requester, cluster-receiver, or server-connection channel current at the same time (the requester is acting as a receiver). This occurs if several senders, at different queue managers, each initiate a session with this receiver, using the same channel name. For channels of other types, there can only be one instance current at any time.

For all channel types, however, there can be more than one set of saved status information available for a channel name. At most one of these sets relates to a current instance of the channel, the rest relate to previously current instances. Multiple instances arise if different transmission queue names or connection names have been used with the same channel. This can happen in the following cases:

- At a sender or server:
  - If the same channel has been connected to by different requesters (servers only)
  - If the transmission queue name has been changed in the definition
  - If the connection name has been changed in the definition
- At a receiver or requester:
  - If the same channel has been connected to by different senders or servers

– If the connection name has been changed in the definition (for requester channels initiating connection)

The number of sets that are displayed for a channel can be limited by using the XMITQ, CONNAME, and CURRENT parameters on the command.

(*generic-channel-name*)
The name of the channel definition for which status information is to be displayed. A trailing asterisk (*) matches all channel definitions with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all channel definitions. A value is required for all channel types.

WHERE
Specify a filter condition to display status information for those channels that satisfy the selection criterion of the filter condition.

The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword
The parameter to be used to display attributes for this DISPLAY command.

Multi You cannot use the following parameters as filter keywords on Multiplatforms: COMPRATE, COMPTIME, CURRENT, EXITTIME, JOBNAME, NETTIME, SAVED, SHORT, XBATCHSZ, or XQTIME.

z/OS You cannot use the following parameters as filter keywords on z/OS: CHLDISP, CMDSCOPE, MCASTAT, or MONITOR.

You cannot use CONNAME or XMITQ as filter keywords if you also use them to select channel status.

Status information for channels of a type for which the filter keyword is not valid is not displayed.

operator
This is used to determine whether a channel satisfies the filter value on the filter keyword. The operators are:

LT
Less than

GT
Greater than

EQ
Equal to

NE
Not equal to

LE
Less than or equal to

GE
Greater than or equal to

LK
Matches a generic string that you provide as a *filter-value*

NL
Does not match a generic string that you provide as a *filter-value*

CT
Contains a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which contain the specified item.

EX
Does not contain a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which do not contain the specified item.

filter-value
The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

  You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value SDR on the CHLTYPE parameter), you can only use EQ or NE.
- A generic value. This is a character string with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

  You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.
- An item in a list of values. Use CT or EX as the operator. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed.

ALL
Specify this to display all the status information for each relevant instance.

If SAVED is specified, this causes only common status information to be displayed, not current-only status information.

If this parameter is specified, any parameters requesting specific status information that are also specified have no effect; all the information is displayed.

z/OS **CHLDISP**
This parameter applies to z/OS only and specifies the disposition of the channels for which information is to be displayed, as used in the START and STOP CHANNEL commands, and **not** that set by QSGDISP for the channel definition. Values are:

ALL
This is the default value and displays requested status information for private channels.

If there is a shared queue manager environment and the command is being executed on the queue manager where it was issued, or if CURRENT is specified, this option also displays the requested status information for shared channels.

PRIVATE
Display requested status information for private channels.

SHARED
Display requested status information for shared channels. This is allowed only if there is a shared queue manager environment, and either:

- CMDSCOPE is blank or the local queue manager
- CURRENT is specified

CHLDISP displays the following values:

PRIVATE
The status is for a private channel.

SHARED
The status is for a shared channel.

FIXSHARED
The status is for a shared channel, tied to a specific queue manager.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which it was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

You cannot use CMDSCOPE as a filter keyword.

Note: See Table 1, Table 2, and Table 3 for the permitted combinations of CHLDISP and CMDSCOPE.

CONNAME(*connection-name*)
The connection name for which status information is to be displayed, for the specified channel or channels.

This parameter can be used to limit the number of sets of status information that is displayed. If it is not specified, the display is not limited in this way.

The value returned for CONNAME might not be the same as in the channel definition, and might differ between the current channel status and the saved channel status. (Using CONNAME for limiting the number of sets of status is therefore not recommended.)

For example, when using TCP, if CONNAME in the channel definition:

- Is blank or is in "host name" format, the channel status value has the resolved IP address.
- Includes the port number, the current channel status value includes the port number (except on z/OS), but the saved channel status value does not.

V 9.2.0 z/OS For SAVED or SHORT status, this value could also be the queue manager name, or queue sharing group name, on the remote system.

V 9.2.0 Multi For SAVED status, this value could also be:

1. The queue manager name on the remote system.
2. A combination of the queue manager name and QMID of the queue manager name on the remote system.

   For the second option, the format is ALW QMNAME@QMID or IBM i QMNAME&QMID, where QMNAME is the queue manager name, blank padded to the right, up to 48 characters.

   To show this, in the following example there are 45 blank spaces between the character 2 (in QM2) and the @ character.

```
CONNAME(QM2                                             @QM2_2023-07-18_12.24.06)
```

CURRENT
This is the default, and indicates that current status information as held by the channel initiator for current channels only is to be displayed.

Both common and current-only status information can be requested for current channels.

Short status information is not displayed if this parameter is specified.

SAVED
Specify this to display saved status information for both current and inactive channels.

Only common status information can be displayed. Short and current-only status information is not displayed for current channels if this parameter is specified.

z/OS **SHORT**
This indicates that short status information and the STATUS item for current channels only is to be displayed.

Other common status and current-only status information is not displayed for current channels if this parameter is specified.

MONITOR
Specify this to return the set of online monitoring parameters. These are COMPRATE, COMPTIME, EXITTIME, MONCHL, NETTIME, XBATCHSZ, XQMSGSA, and XQTIME. If you specify this parameter, any of the monitoring parameters that you request specifically have no effect; all monitoring parameters are still displayed.

XMITQ(*q-name*)
The name of the transmission queue for which status information is to be displayed, for the specified channel or channels.

This parameter can be used to limit the number of sets of status information that is displayed. If it is not specified, the display is not limited in this way.

The following information is always returned, for each set of status information:

- The channel name
- The transmission queue name (for sender and server channels)
- The connection name
- The remote queue manager, or queue sharing group, name (only for current status, and for all channel types except server-connection channels)
- The remote partner application name (for server-connection channels)
- The type of status information returned (CURRENT, or SAVED, or on z/OS only, SHORT)
- STATUS (except SAVED on z/OS)
- On z/OS, CHLDISP
- STOPREQ (only for current status)
- SUBSTATE

If no parameters requesting specific status information are specified (and the ALL parameter is not specified), no further information is returned.

If status information is requested that is not relevant for the particular channel type, this is not an error.

Common status

The following information applies to sets of current status data and also to sets of saved status data. Some of this information does not apply to server-connection channels.

CHLTYPE
The channel type. This is one of the following:

SDR
A sender channel

SVR
A server channel

RCVR
A receiver channel

RQSTR
A requester channel

CLUSSDR
A cluster-sender channel

CLUSRCVR
A cluster-receiver channel

SVRCONN
A server-connection channel

AMQP
An AMQP channel

CURLUWID
The logical unit of work identifier associated with the current batch, for a sending or a receiving channel.

For a sending channel, when the channel is in doubt it is the LUWID of the in-doubt batch.

For a saved channel instance, this parameter has meaningful information only if the channel instance is in doubt. However, the parameter value is still returned when requested, even if the channel instance is not in doubt.

It is updated with the LUWID of the next batch when this is known.

This parameter does not apply to server-connection channels.

CURMSGS
For a sending channel, this is the number of messages that have been sent in the current batch. It is incremented as each message is sent, and when the channel becomes in doubt it is the number of messages that are in doubt.

For a saved channel instance, this parameter has meaningful information only if the channel instance is in doubt. However, the parameter value is still returned when requested, even if the channel instance is not in doubt.

For a receiving channel, it is the number of messages that have been received in the current batch. It is incremented as each message is received.

The value is reset to zero, for both sending and receiving channels, when the batch is committed.

This parameter does not apply to server-connection channels.

CURSEQNO
For a sending channel, this is the message sequence number of the last message sent. It is updated as each message is sent, and when the channel becomes in doubt it is the message sequence number of the last message in the in-doubt batch.

For a saved channel instance, this parameter has meaningful information only if the channel instance is in doubt. However, the parameter value is still returned when requested, even if the channel instance is not in doubt.

For a receiving channel, it is the message sequence number of the last message that was received. It is updated as each message is received.

This parameter does not apply to server-connection channels.

INDOUBT
Whether the channel is currently in doubt.

This is only YES while the sending Message Channel Agent is waiting for an acknowledgment that a batch of messages that it has sent has been successfully received. It is NO at all other times, including the period during which messages are being sent, but before an acknowledgment has been requested.

For a receiving channel, the value is always NO.

This parameter does not apply to server-connection channels.

LSTLUWID
The logical unit of work identifier associated with the last committed batch of messages transferred.

This parameter does not apply to server-connection channels.

LSTSEQNO
Message sequence number of the last message in the last committed batch. This number is not incremented by nonpersistent messages using channels with a NPMSPEED of FAST.

This parameter does not apply to server-connection channels.

STATUS
Current status of the channel. This is one of the following:

BINDING
Channel is performing channel negotiation and is not yet ready to transfer messages.

INITIALIZING
The channel initiator is attempting to start a channel.

On z/OS, this is displayed as INITIALIZI.

PAUSED
The channel is waiting for the message-retry interval to complete before retrying an MQPUT operation.

REQUESTING
A local requester channel is requesting services from a remote MCA.

RETRYING
A previous attempt to establish a connection has failed. The MCA will reattempt connection after the specified time interval.

RUNNING
The channel is either transferring messages at this moment, or is waiting for messages to arrive on the transmission queue so that they can be transferred.

STARTING
A request has been made to start the channel but the channel has not yet begun processing. A channel is in this state if it is waiting to become active.

STOPPED
This state can be caused by one of the following:

- Channel manually stopped

  A user has entered a stop channel command against this channel.

- Retry limit reached

  The MCA has reached the limit of retry attempts at establishing a connection. No further attempt will be made to establish a connection automatically.

A channel in this state can be restarted only by issuing the START CHANNEL command, or starting the MCA program in an operating-system dependent manner.

STOPPING
Channel is stopping or a close request has been received.

SWITCHING
The channel is switching transmission queues.

On z/OS, STATUS is not displayed if saved data is requested.

Multi On Multiplatforms, the value of the STATUS field returned in the saved data is the status of the channel at the time the saved status was written. Normally, the saved status value is RUNNING. To see the current status of the channel, the user can use the DISPLAY CHSTATUS CURRENT command.

Note: For an inactive channel, CURMSGS, CURSEQNO, and CURLUWID have meaningful information only if the channel is INDOUBT. However they are still displayed and returned if requested.

Current-only status

The following information applies only to current channel instances. The information applies to all channel types, except where stated.

AMQPKA
The keep alive time for an AMQP channel in milliseconds. If the AMQP client has not sent any frames within the keep alive interval, then the connection is closed with a `amqp:resource-limit-exceeded` AMQP error condition.

This parameter is valid only for channels with a channel type (`CHLTYPE`) of `AMQP`

BATCHES
Number of completed batches during this session (since the channel was started).

BATCHSZ
The batch size being used for this session.

This parameter does not apply to server-connection channels, and no values are returned; if specified on the command, this is ignored.

BUFSRCVD
Number of transmission buffers received. This includes transmissions to receive control information only.

BUFSSENT
Number of transmission buffers sent. This includes transmissions to send control information only.

BYTSRCVD
Number of bytes received during this session (since the channel was started). This includes control information received by the message channel agent.

If the value for BYTSSENT or BYTSRCVD exceeds 999999999, it wraps to zero.

BYTSSENT
Number of bytes sent during this session (since the channel was started). This includes control information sent by the message channel agent.

If the value for BYTSSENT or BYTSRCVD exceeds 999999999, it wraps to zero.

CHSTADA
Date when this channel was started (in the form yyyy-mm-dd).

CHSTATI
Time when this channel was started (in the form hh.mm.ss).

COMPHDR
The technique used to compress the header data sent by the channel. Two values are displayed:

- The default header data compression value negotiated for this channel.
- The header data compression value used for the last transmission segment that was eligible for compression, which might or might not carry a message. The header data compression value can be altered in a sending channels message exit. If no eligible transmission segment has been sent, the second value is blank.

COMPMSG
The technique used to compress the message data sent by the channel. Two values are displayed:

- The default message data compression value negotiated for this channel.
- The message data compression value used for the last message sent. The message data compression value can be altered in a sending channels message exit. If no message has been sent, the second value is blank.

COMPRATE
The compression rate achieved displayed to the nearest percentage; that is, a rate of 25 indicates messages are being compressed to 75% of their original length.

Two values are displayed:

- The first value based on recent activity over a short period.
- The second value based on activity over a longer period.

These values are reset every time the channel is started and are displayed only when the STATUS of the channel is RUNNING. If monitoring data is not being collected, or if no messages have been sent by the channel, the values are shown as blank.

A value is only displayed for this parameter if MONCHL is set for this channel. See "Setting monitor values" on page 687.

COMPTIME
The amount of time for each message, displayed in microseconds, spent on compression or decompression. Two values are displayed:

- The first value based on recent activity over a short period.
- The second value based on activity over a longer period.

Note:

On z/OS, COMPTIME is the amount of time for each message, provided that the message does not have to be processed in segments. This segmenting of the message on z/OS occurs when the message is:

- 32 KB or larger, or
- 16 KB or larger, and the channel has TLS encryption.

If the message is split into segments, COMPTIME is the time spent compressing each segment. This means that a message that is split into 8 segments actually spends (COMPTIME * 8) microseconds during compression or decompression.

A value is only displayed for this parameter if MONCHL is set for this channel. See "Setting monitor values" on page 687.

CURSHCNV
The CURSHCNV value is blank for all channel types other than server-connection channels. For each instance of a server-connection channel, the CURSHCNV output gives a count of the number of conversations currently running over that channel instance.

A value of zero indicates that the channel is running as it did in versions of the product earlier than IBM WebSphere MQ 7.0, regarding:

- Administrator stop-quiesce
- Heartbeating
- Read ahead
- Sharing conversations
- Client Asynchronous consumption

EXITTIME
Amount of time, displayed in microseconds, spent processing user exits per message. Two values are displayed:

- The first value based on recent activity over a short period.
- The second value based on activity over a longer period.

These values depend on the configuration and behavior of your system, as well as the levels of activity within it, and serve as an indicator that your system is performing normally. A significant variation in these values may indicate a problem with your system. They are reset every time the channel is started and are displayed only when the STATUS of the channel is RUNNING.

This parameter is also displayed when you specify the MONITOR parameter.

A value is only displayed for this parameter if MONCHL is set for this channel. See "Setting monitor values" on page 687.

HBINT
The heartbeat interval being used for this session.

JOBNAME
A name that identifies the MQ process that is currently providing and hosting the channel.

Multi On Multiplatforms, this name is the concatenation of the process identifier and the thread identifier of the MCA program, displayed in hexadecimal.

z/OS This information is not available on z/OS. The parameter is ignored if specified.

z/OS You cannot use JOBNAME as a filter keyword on z/OS.

z/OS **KAINT**
The keepalive interval being used for this session. This is valid only on z/OS.

LOCLADDR
Local communications address for the channel. The value returned depends on the TRPTYPE of the channel (currently only TCP/IP is supported).

LONGRTS
Number of long retry wait start attempts left. This applies only to sender or server channels.

LSTMSGDA
Date when the last message was sent or MQI call was handled, see LSTMSGTI.

LSTMSGTI
Time when the last message was sent or MQI call was handled.

For a sender or server, this is the time the last message (the last part of it if it was split) was sent. For a requester or receiver, it is the time the last message was put to its target queue. For a server-connection channel, it is the time when the last MQI call completed.

In the case of a server-connection channel instance on which conversations are being shared, this is the time when the last MQI call completed on any of the conversations running on the channel instance.

z/OS **MAXMSGL**
The maximum message length being used for this session (valid only on z/OS).

MAXSHCNV
The MAXSHCNV value is blank for all channel types other than server-connection channels. For each instance of a server-connection channel, the MAXSHCNV output gives the negotiated maximum of the number of conversations that can run over that channel instance.

A value of zero indicates that the channel is running as it did in versions earlier than IBM WebSphere MQ 7.0, regarding:

- Administrator stop-quiesce
- Heartbeating
- Read ahead
- Sharing conversations
- Client asynchronous consumption

Multi **MCASTAT**
Whether the Message Channel Agent is currently running. This is either "running" or "not running". Note that it is possible for a channel to be in stopped state, but for the program still to be running.

z/OS This information is not available on z/OS. The parameter is ignored if specified.

z/OS You cannot use MCASTAT as a filter keyword on z/OS.

MCAUSER
The user ID used by the MCA. This can be the user ID set in the channel definition, the default user ID for message channels, a user ID transferred from a client if this is a server-connection channel, or a user ID specified by a security exit.

This parameter applies only to server-connection, receiver, requester, and cluster-receiver channels.

On server connection channels that share conversations, the MCAUSER field contains a user ID if all the conversations have the same MCA user ID value. If the MCA user ID in use varies across these conversations, the MCAUSER field contains a value of *.

Multi The maximum length on Multiplatforms is 64 characters.

z/OS The maximum length on z/OS is 12 characters.

MONCHL
Current level of monitoring data collection for the channel.

This parameter is also displayed when you specify the MONITOR parameter.

MSGS
Number of messages sent or received (or, for server-connection channels, the number of MQI calls handled) during this session (since the channel was started).

In the case of a server-connection channel instance on which conversations are being shared, this is the total number of MQI calls handled on all of the conversations running on the channel instance.

NETTIME
Amount of time, displayed in microseconds, to send a request to the remote end of the channel and receive a response. This time only measures the network time for such an operation. Two values are displayed:

- The first value based on recent activity over a short period.
- The second value based on activity over a longer period.

These values depend on the configuration and behavior of your system, as well as the levels of activity within it, and serve as an indicator that your system is performing normally. A significant variation in these values may indicate a problem with your system. They are reset every time the channel is started and are displayed only when the STATUS of the channel is RUNNING.

This parameter applies only to sender, server, and cluster-sender channels.

This parameter is also displayed when you specify the MONITOR parameter.

A value is only displayed for this parameter if MONCHL is set for this channel. See “Setting monitor values” on page 687.

NPMSPEED
The nonpersistent message handling technique being used for this session.

PORT
The port number used to connect an AMQP channel. The default port for AMQP 1.0 connections is 5672.

RAPPLTAG
The remote partner application name. This is the name of the client application at the remote end of the channel.

For Managed File Transfer, **RAPPLTAG** displays `Managed File Transfer Agent` *`agent name`*.

This parameter applies only to server-connection channels.

Note: If multiple IBM MQ connections use the same channel instance, that is, the channel is defined with SHARECNV > 1 and the same process makes multiple connections to the queue manager, if the connections specify different application names the RAPPLTAG field displays an asterisk: `RAPPLTAG(*)`.

RPRODUCT
The remote partner product identifier. This is the product identifier of the IBM MQ code running at the remote end of the channel. The possible values are shown in Table 167 on page 683.

Table 167. Product Identifier values

Product Identifier	Description
MQMM	Queue manager on a distributed platform
z/OS z/OS MQMV	Queue manager on z/OS
MQCC	IBM MQ C client
MQNM	IBM MQ .NET fully managed client
MQJB	IBM MQ Classes for JAVA
MQJF	Managed File Transfer Agent
MQJM	IBM MQ Classes for JMS (normal mode)
MQJN	IBM MQ Classes for JMS (migration mode)
MQJU	Common Java interface to the MQI
MQXC	XMS client C/C++ (normal mode)
MQXD	XMS client C/C++ (migration mode)
MQXN	XMS client .NET (normal mode)
MQXM	XMS client .NET (migration mode)
MQXU	IBM MQ .NET XMS client (unmanaged/XA)
MQNU	IBM MQ .NET unmanaged client

RQMNAME
The queue manager name, or queue sharing group name, of the remote system. This parameter does not apply to server-connection channels.

RVERSION
The remote partner version. This is the version of the IBM MQ code running at the remote end of the channel.

The remote version is displayed as **VVRRMMFF**, where

VV
Version

RR
Release

MM
Maintenance level

FF
Fix level

SECPROT
Defines the security protocol currently in use.

Does not apply to client-connection channels.

Set automatically, based on the value you set for SSLCIPH in **DEFINE CHANNEL**.

V 9.2.0 z/OS From IBM MQ 9.2.0, **SECPROT** is supported on z/OS.

Possible values are:

NONE
No security protocol

SSLV3
SSL 3.0

This protocol is deprecated. See Deprecated CipherSpecs

TLSV1
TLS 1.0

TLSV12
TLS 1.2

TLSV13
TLS 1.3

From IBM MQ 9.2.0, the product supports the TLS 1.3 security protocol on all platforms.

V 9.2.0 V 9.2.0 z/OS On IBM MQ for z/OS, TLS 1.3 is supported only on z/OS 2.4 or later.

SHORTRTS
Number of short retry wait start attempts left. This applies only to sender or server channels.

SSLCERTI
The full Distinguished Name of the issuer of the remote certificate. The issuer is the Certificate Authority that issued the certificate.

The maximum length is 256 characters, so longer Distinguished Names are truncated.

z/OS **SSLCERTU**
The local user ID associated with the remote certificate. This is valid on z/OS only.

SSLCIPH
The CipherSpec being used by the connection.

V 9.2.0 This parameter, which already existed in **DEFINE CHANNEL**, is displayed by **DISPLAY CHSTATUS** from IBM MQ 9.1.1 on Continuous Delivery, and from IBM MQ 9.2.0 on Long Term Support.

For more information, see the SSLCIPH property in DEFINE CHANNEL.

The value for this parameter is also used to set the value of SECPROT.

SSLKEYDA
Date on which the previous successful TLS secret key reset was issued.

Note: TLS 1.3 key resets are integral to TLS 1.3, and not communicated to applications. As a result, on z/OS queue managers, for receiver channels, this value will not be set when the channel is communicating using a TLS 1.3 CipherSpec. On distributed queue managers this value will not be accurate, and might even be set to zero at either end of a channel, when the channel is communicating using a TLS 1.3 CipherSpec.

SSLKEYTI
Time at which the previous successful TLS secret key reset was issued.

Note: TLS 1.3 key resets are integral to TLS 1.3, and not communicated to applications. As a result, on z/OS queue managers, for receiver channels, this value will not be set when the channel is communicating using a TLS 1.3 CipherSpec. On distributed queue managers this value will not be accurate, and might even be set to zero at either end of a channel, when the channel is communicating using a TLS 1.3 CipherSpec.

SSLPEER
Distinguished Name of the peer queue manager or client at the other end of the channel.

The maximum length is 256 characters, so longer Distinguished Names are truncated.

SSLRKEYS
Number of successful TLS key resets. The count of TLS secret key resets is reset when the channel instance ends.

Note: TLS 1.3 key resets are integral to TLS 1.3, and not communicated to applications. As a result, on z/OS queue managers, for receiver channels, this value will not be set when the channel is communicating using a TLS 1.3 CipherSpec. On distributed queue managers this value will not be accurate, and might even be set to zero at either end of a channel, when the channel is communicating using a TLS 1.3 CipherSpec.

STOPREQ
Whether a user stop request is outstanding. This is either YES or NO.

z/OS **STATCHL**
Current level of statistics data collection for the channel.

SUBSTATE
Action being performed by the channel when this command is issued. The following substates are listed in precedence order, starting with the substate of the highest precedence:

ENDBATCH
Channel is performing end-of-batch processing.

SEND
A request has been made to the underlying communication subsystem to send some data.

RECEIVE
A request has been made to the underlying communication subsystem to receive some data.

z/OS **SERIALIZE**
Channel is serializing its access to the queue manager. Valid on z/OS only.

RESYNCH
Channel is resynchronizing with the partner.

HEARTBEAT
Channel is heartbeating with the partner.

SCYEXIT
Channel is running the security exit.

RCVEXIT
Channel is running one of the receive exits.

SENDEXIT
Channel is running one of the send exits.

MSGEXIT
Channel is running one of the message exits.

MREXIT
Channel is running the message retry exit.

CHADEXIT
Channel is running through the channel auto-definition exit.

NETCONNECT
A request has been made to the underlying communication subsystem to connect a partner machine.

SSLHANDSHK
Channel is processing a TLS handshake.

NAMESERVER
A request has been made to the name server.

MQPUT
A request has been made to the queue manager to put a message on the destination queue.

MQGET
A request has been made to the queue manager to get a message from the transmission queue (if this is a message channel) or from an application queue (if this is an MQI channel).

MQICALL
A MQ API call, other than MQPUT and MQGET, is being executed.

COMPRESS
Channel is compressing or extracting data.

Not all substates are valid for all channel types or channel states. There are occasions when no substate is valid, at which times a blank value is returned.

For channels running on multiple threads, this parameter displays the substate of the highest precedence.

TPROOT
The topic root for an AMQP channel. The default value for TPROOT is SYSTEM.BASE.TOPIC. With this value, the topic string an AMQP client uses to publish or subscribe has no prefix, and the client can exchange messages with other MQ pub/sub applications. To have AMQP clients publish and subscribe under a topic prefix, first create an MQ topic object with a topic string set to the prefix you want, then set TPROOT to the name of the MQ topic object you created.

This parameter is valid only for channels with a channel type (CHLTYPE) of AMQP

XBATCHSZ
Size of the batches transmitted over the channel. Two values are displayed:

- The first value based on recent activity over a short period.
- The second value based on activity over a longer period.

These values depend on the configuration and behavior of your system, as well as the levels of activity within it, and serve as an indicator that your system is performing normally. A significant variation in these values might indicate a problem with your system. They are reset every time the channel is started and are displayed only when the STATUS of the channel is RUNNING.

This parameter does not apply to server-connection channels.

This parameter is also displayed when you specify the MONITOR parameter.

A value is only displayed for this parameter if MONCHL is set for this channel. See "Setting monitor values" on page 687.

USECLTID
Specifies that the client ID should be used for authorization checks for an AMQP channel, instead of the MCAUSER attribute value.

XQMSGSA
Number of messages queued on the transmission queue available to the channel for MQGETs.

This parameter has a maximum displayable value of 999. If the number of messages available exceeds 999, a value of 999 is displayed.

On z/OS, if the transmission queue is not indexed by *CorrelId* , this value is shown as blank.

This parameter applies to cluster-sender channels only.

This parameter is also displayed when you specify the MONITOR parameter.

A value is only displayed for this parameter if MONCHL is set for this channel. See "Setting monitor values" on page 687.

XQTIME
The time, in microseconds, that messages remained on the transmission queue before being retrieved. The time is measured from when the message is put onto the transmission queue until it is retrieved to be sent on the channel and, therefore, includes any interval caused by a delay in the putting application.

Two values are displayed:

- The first value based on recent activity over a short period.

- The second value based on activity over a longer period.

These values depend on the configuration and behavior of your system, as well as the levels of activity within it, and serve as an indicator that your system is performing normally. A significant variation in these values might indicate a problem with your system. They are reset every time the channel is started and are displayed only when the STATUS of the channel is RUNNING.

This parameter applies only to sender, server, and cluster-sender channels.

This parameter is also displayed when you specify the MONITOR parameter.

A value is only displayed for this parameter if MONCHL is set for this channel. See "Setting monitor values" on page 687.

Short status

z/OS

The following information applies only to current channel instances.

QMNAME
The name of the queue manager that owns the channel instance.

Setting monitor values

For auto-defined cluster sender channels, these are controlled with the queue manager MONACLS parameter. See "ALTER QMGR (alter queue manager settings)" on page 331 for more information. You cannot display or alter auto-defined cluster sender channels. However you can get their status, or issue DISPLAY CLUSQMGR, as described here: Working with auto-defined cluster-sender channels.

For other channels, including manually-defined cluster sender channels, these are controlled with the channel MONCHL parameter. See "ALTER CHANNEL (alter channel settings)" on page 256 for more information.

The response to the Inquire Channel Status (MQCMD_INQUIRE_CHANNEL_STATUS) PCF command consists of the response header followed by several structures.

ALW DISPLAY CHSTATUS (display channel status) AMQP

Use the MQSC command DISPLAY CHSTATUS (AMQP) to display the status of one or more AMQP channels.

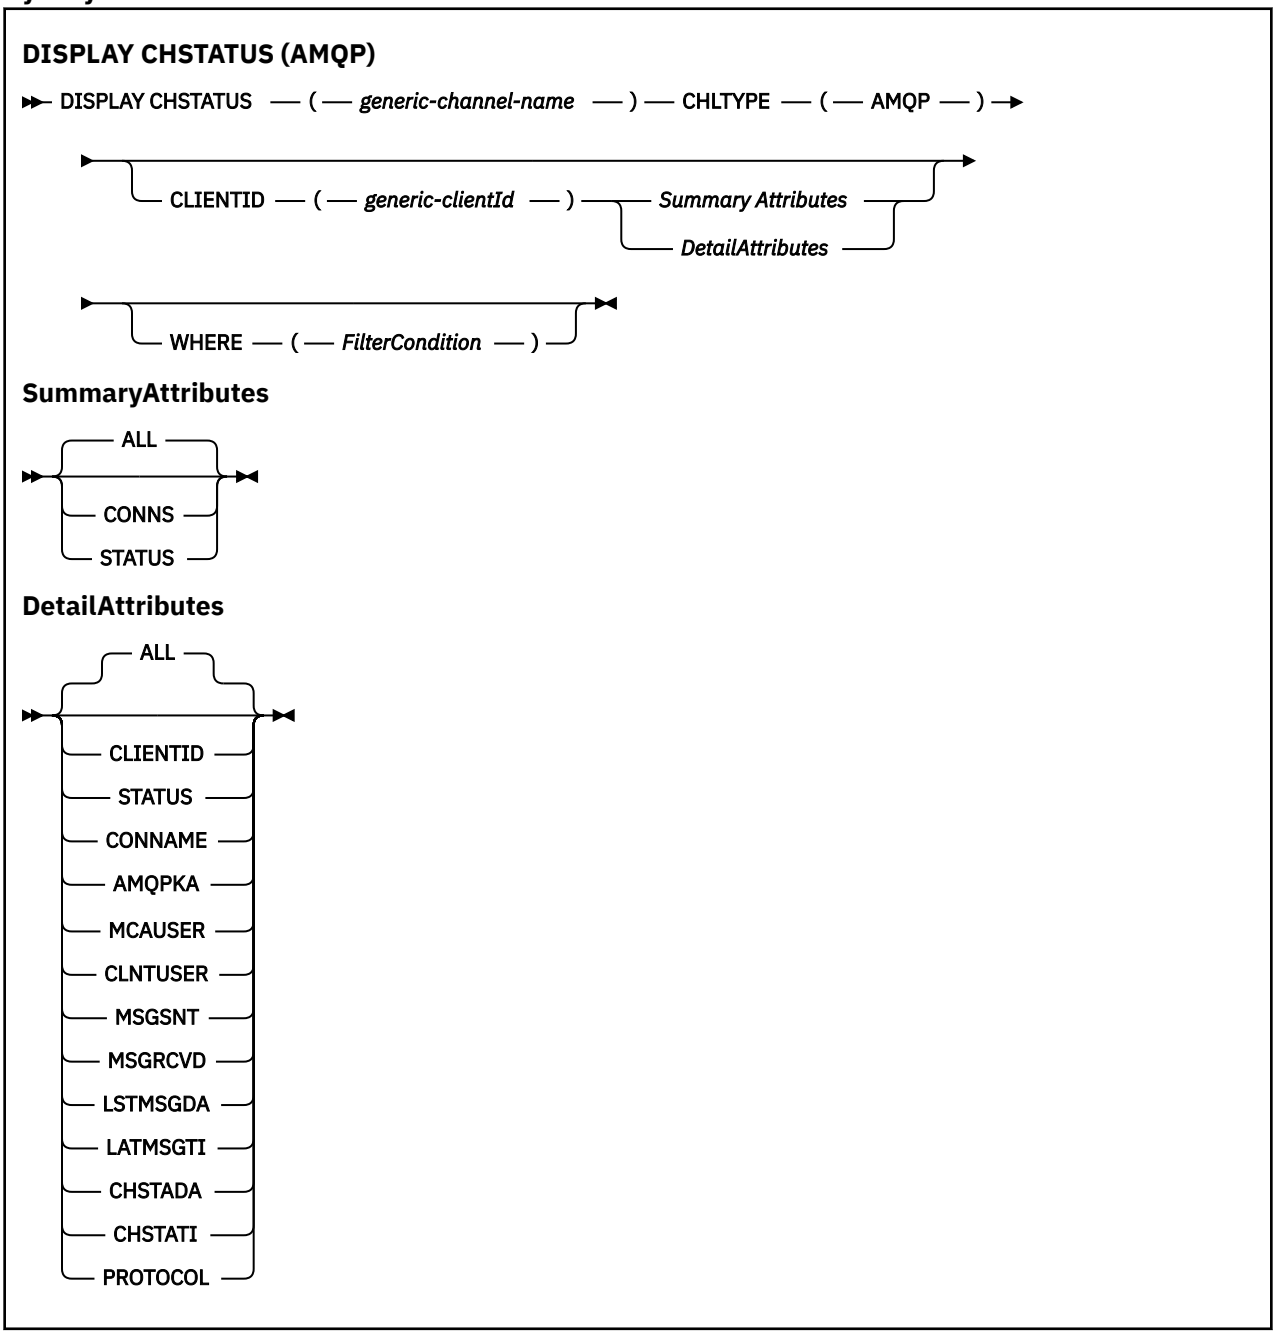
Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

- "Syntax diagram" on page 688
- "Parameter descriptions for DISPLAY CHSTATUS" on page 688
- "Summary attributes" on page 690
- "Client details mode" on page 690
- "Examples" on page 691

Syntax diagram

Synonym: DIS CHS



Note:

- The default behavior is for **RUNMQSC** to return a summary of the connections to the channel. If **CLIENTID** is specified then **RUNMQSC** returns details of each client connected to the channel.

Parameter descriptions for DISPLAY CHSTATUS

You must specify the name of the channel for which you want to display status information. This parameter can be a specific channel name or a generic channel name. By using a generic channel name, you can display either the status information for all channels, or status information for one or more channels that match the specified name.

(*generic-channel-name*)

The name of the channel definition for which status information is to be displayed. A trailing asterisk (*) matches all channel definitions with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all channel definitions. A value is required for all channel types.

WHERE

Specify a filter condition to display status information for those channels that satisfy the selection criterion of the filter condition.

The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword
The parameter to be used to display attributes for this DISPLAY command.

Status information for channels of a type for which the filter keyword is not valid is not displayed.

operator
This is used to determine whether a channel satisfies the filter value on the filter keyword. The operators are:

LT
Less than

GT
Greater than

EQ
Equal to

NE
Not equal to

LE
Less than or equal to

GE
Greater than or equal to

LK
Matches a generic string that you provide as a *filter-value*

NL
Does not match a generic string that you provide as a *filter-value*

CT
Contains a specified item. If the *filter-keyword* is a list, you can use this operator to display objects the attributes of which contain the specified item.

EX
Does not contain a specified item. If the *filter-keyword* is a list, you can use this operator to display objects the attributes of which do not contain the specified item.

filter-value
The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this value can be:

- An explicit value, that is a valid value for the attribute that is being tested.

  You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value SDR on the CHLTYPE parameter), you can use EQ or NE only.
- A generic value. This value is a character string with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

- An item in a list of values. Use CT or EX as the operator. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed.

ALL

Specify this parameter to display all the status information for each relevant instance.

If this parameter is specified, any parameters that request specific status information which are also specified have no effect; all the information is displayed.

Summary attributes

When no CLIENTID parameter is added to the MQSC command DISPLAY CHSTATUS (AMQP), a summary of AMQP channel information is displayed. The number of connections is displayed as the CONNS attribute. The following attributes display a summary for each channel.

ALL

Specify this parameter to display all the status information for each relevant instance. This attribute is the default value if no attributes are requested.

This parameter is valid for AMQP channels.

If this parameter is specified, any specified parameters that are requesting specific status information have no effect; and all the information is displayed.

CONNS

The number of current connections to this channel.

STATUS

The status of this channel.

Client details mode

CLIENTID

The identifier of the client.

STATUS

The status of the client.

CONNAME

The name of the remote connection (IP address)

AMQPKA

The client's keep alive interval.

MCAUSER

The user ID that the client is using to access IBM MQ resources.

CLNTUSER

The user ID that the client provided when it connected.

MSGSNT

Number of messages sent by the client since it connected last.

MSGRCVD

Number of messages received by the client since it connected last.

LSTMSGDA

Date last message was received or sent.

LSTMSGTI

Time last message was received or sent.

CHSTADA

Date channel started.

CHSTATI

Time channel was started.

PROTOCOL

The communication protocol used by the client. The value is AMQP.

Examples

The following command retrieves a status summary for the AMQP channel named MYAMQP:

```
dis chstatus(MYAMQP) chltype(AMQP) all
```

The command outputs the following status:

```
AMQ8417: Display Channel Status details.
   CHANNEL(MYAMQP)                         CHLTYPE(AMQP)
   CONNECTIONS(1)                          STATUS(RUNNING)
```

The following command retrieves a full status for the AMQP channel named MYAMQP:

```
dis chstatus(*) chltype(AMQP) clientid(*) all
```

The command outputs the following status:

```
AMQ8417: Display Channel Status details.
   CHANNEL(MYAMQP)                         CHLTYPE(AMQP)
   CLIENTID(recv_cc2022b)                  STATUS(RUNNING)
   CONNAME(192.168.60.1)                   AMQPKA(0)
   MCAUSER(matt)                           CLNTUSER( )
   MSGSNT(0)                               MSGRCVD(0)
   LSTMSGDA( )                             LSTMSGTI( )
   CHSTADA(2015-09-18)                     CHSTATI(06.23.30)
   PROTOCOL(AMQP)
```

Windows Linux AIX DISPLAY CHSTATUS (display channel status) MQTT

Use the MQSC command DISPLAY CHSTATUS (MQTT) to display the status of one or more MQ Telemetry channels.

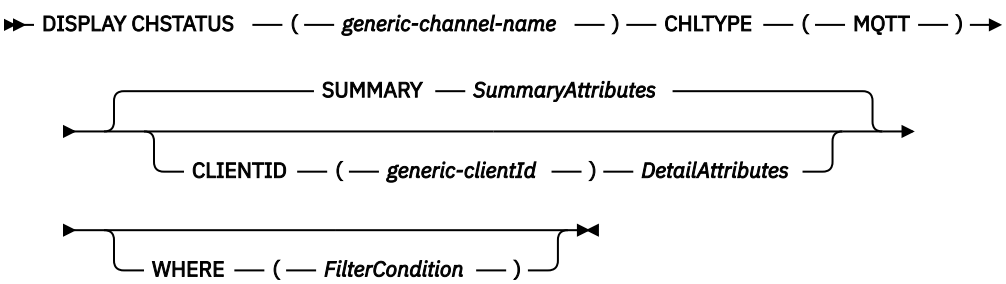
Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

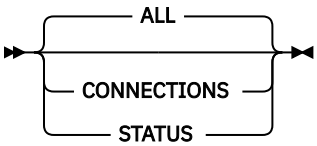
- Syntax diagram
- “Parameter descriptions for DISPLAY CHSTATUS” on page 693
- “Summary attributes” on page 694

Synonym: DIS CHS

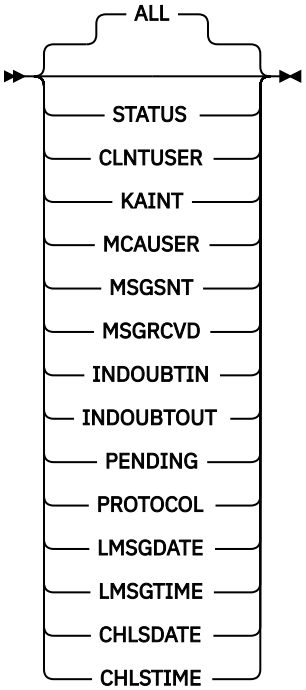
DISPLAY CHSTATUS (MQTT)



SummaryAttributes



DetailAttributes



Notes:

- The default behavior is for **RUNMQSC** to return a summary of the connections to the channel. If **CLIENTID** is specified then **RUNMQSC** returns details of each client connected to the channel.
- Either **CLIENTID**, **SUMMARY**, or neither may be specified, but not both at the same time.
- The **DISPLAY CHSTATUS** command for MQ Telemetry has the potential to return a far larger number of responses than if the command was run for an IBM MQ channel. For this reason, the MQ Telemetry server does not return more responses than fit on the reply-to queue. The number of responses is limited to the value of MAXDEPTH parameter of the SYSTEM.MQSC.REPLY.QUEUE queue. When RUNMQSC processes an MQ Telemetry command that is truncated by the MQ Telemetry server, the AMQ8492 message is displayed specifying how many responses are returned based on the size of MAXDEPTH.
- You can use this command to list disconnected clients. As these clients are not associated with a particular channel, you list them using the wildcard character. For example,

```
DIS CHS(*) CHLTYPE(MQTT) CLIENTID(*) WHERE(STATUS EQ DISCONNECTED).
```

You should take care using this command when there could be a large number of disconnected clients.

Parameter descriptions for DISPLAY CHSTATUS

You must specify the name of the channel for which you want to display status information. This parameter can be a specific channel name or a generic channel name. By using a generic channel name, you can display either the status information for all channels, or status information for one or more channels that match the specified name.

(*generic-channel-name*)

The name of the channel definition for which status information is to be displayed. A trailing asterisk (*) matches all channel definitions with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all channel definitions. A value is required for all channel types.

WHERE

Specify a filter condition to display status information for those channels that satisfy the selection criterion of the filter condition.

The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword
The parameter to be used to display attributes for this DISPLAY command.

Status information for channels of a type for which the filter keyword is not valid is not displayed.

operator
This is used to determine whether a channel satisfies the filter value on the filter keyword. The operators are:

LT
Less than

GT
Greater than

EQ
Equal to

NE
Not equal to

LE
Less than or equal to

GE
Greater than or equal to

LK
Matches a generic string that you provide as a *filter-value*

NL
Does not match a generic string that you provide as a *filter-value*

CT
Contains a specified item. If the *filter-keyword* is a list, you can use this operator to display objects the attributes of which contain the specified item.

EX
Does not contain a specified item. If the *filter-keyword* is a list, you can use this operator to display objects the attributes of which do not contain the specified item.

filter-value
The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this value can be:

- An explicit value, that is a valid value for the attribute that is being tested.

  You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value SDR on the CHLTYPE parameter), you can use EQ or NE only.
- A generic value. This value is a character string with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

  You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.
- An item in a list of values. Use CT or EX as the operator. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed.

ALL

Specify this parameter to display all the status information for each relevant instance.

If this parameter is specified, any parameters that request specific status information which are also specified have no effect; all the information is displayed.

Summary attributes

When SUMMARY is added to the MQSC command DISPLAY CHSTATUS (MQTT), the number of connections is displayed as the CONNECTIONS attribute. The following attributes display a summary for each channel.

ALL

Specify this parameter to display all the status information for each relevant instance. This attribute is the default value if no attributes are requested.

This parameter is valid for MQTT channels.

If this parameter is specified, any specified parameters that are requesting specific status information have no effect; and all the information is displayed.

CONNECTIONS

The number of current connections to this channel.

STATUS

The status of this channel.

Client details mode

STATUS

The status of the client.

CLNTUSER

The user ID that the client provided when it connected.

CONNAME

The name of the remote connection (IP address)

KAINT

The client's keep alive interval.

MCAUSER

The user ID that the client is using to access IBM MQ resources. This is the client user ID selected by the process described in MQTT client identity and authorization.

MSGSNT

Number of messages sent by the client since it connected last.

MSGRCVD

Number of messages received by the client since it connected last.

INDOUBTIN

Number of in doubt, inbound messages to the client.

INDOUBTOUT

Number of in doubt, outbound messages to the client.

PENDING

Number of outbound pending messages.

PROTOCOL

The communication protocol used by the client. This is MQTTV311, MQTTV3, or HTTP.

LMSGDATE

Date last message was received or sent.

LMSGTIME

Time last message was received or sent.

CHLSDATE

Date channel started.

CHLSTIME

Time channel was started.

DISPLAY CLUSQMGR (display channel information for cluster queue managers)

Use the MQSC command **DISPLAY CLUSQMGR** to display information about cluster channels for queue managers in a cluster.

Using MQSC commands

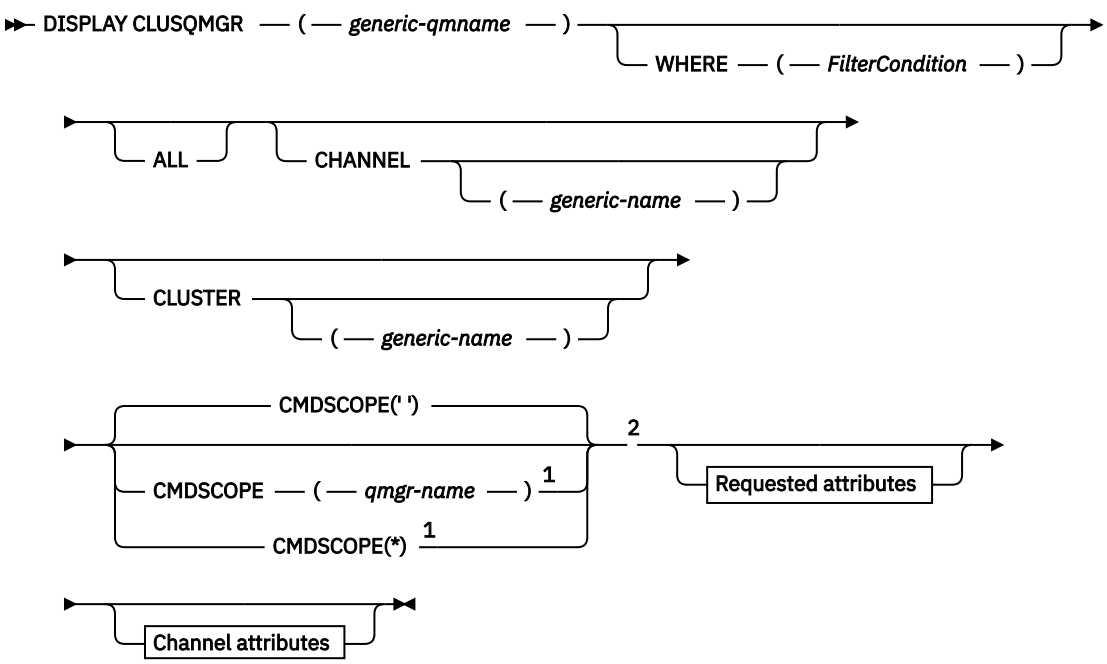
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

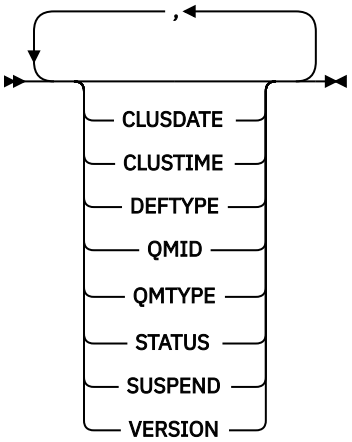
- Syntax diagram
- “Usage notes” on page 698
- “Parameter descriptions for DISPLAY CLUSQMGR” on page 698
- “Requested parameters” on page 700
- “Channel parameters” on page 701

Synonym: `DIS CLUSQMGR`

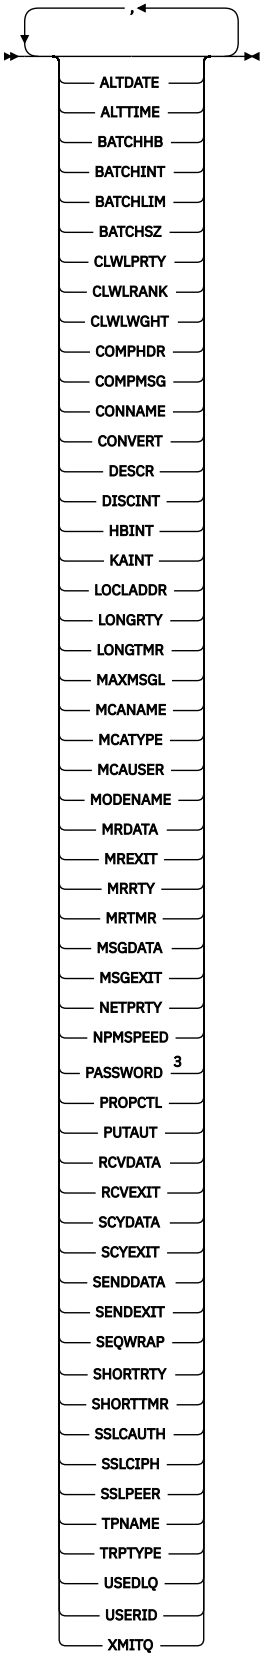
DISPLAY CLUSQMGR



Requested attributes



Channel attributes



Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.

[2] Valid only on z/OS.

[3] Not valid on z/OS.

Usage notes

Unlike the **DISPLAY CHANNEL** command, this command includes information about cluster channels that are auto-defined, and the status of cluster channels.

Note: On z/OS, the command fails if the channel initiator is not started.

Parameter descriptions for DISPLAY CLUSQMGR

(*generic-qmgr-name*)
The name of the cluster queue manager for which information is to be displayed.

A trailing asterisk "*" matches all cluster queue managers with the specified stem followed by zero or more characters. An asterisk "*" on its own specifies all cluster queue managers.

WHERE
Specify a filter condition to display only those cluster channels that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword
Almost any parameter that can be used to display attributes for this **DISPLAY** command. However, you cannot use the CMDSCOPE or MCANAME parameters as filter keywords. You cannot use CHANNEL or CLUSTER as filter keywords if you use them to select cluster queue managers.

operator
The operators are:

LT
Less than

GT
Greater than

EQ
Equal to

NE
Not equal to

LE
Less than or equal to

GE
Greater than or equal to

LK
Matches a generic string that you provide as a *filter-value*

NL
Does not match a generic string that you provide as a *filter-value*

CT
Contains a specified item. If the *filter-keyword* is a list, you can use CT to display objects the attributes of which contain the specified item.

EX
Does not contain a specified item. If the *filter-keyword* is a list, you can use EX to display objects the attributes of which do not contain the specified item.

CTG
Contains an item which matches a generic string that you provide as a *filter-value*. If the *filter-keyword* is a list, you can use CTG to display objects the attributes of which match the generic string.

EXG
Does not contain any item which matches a generic string that you provide as a *filter-value*. If the *filter-keyword* is a list, you can use EXG to display objects the attributes of which do not match the generic string.

filter-value
The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, *filter-value* can be:

- An explicit value, that is a valid value for the attribute being tested.

  You can use operators LT, GT, EQ, NE, LE,, or GE only. If the attribute value is a value from a possible set of values, you can use only EQ or NE. For example, the value STARTING on the **STATUS** parameter.
- A generic value. *filter-value* is a character string. An example is ABC*. If the operator is LK, all items where the attribute value begins with the string, ABC in the example, are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

  You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.
- An item in a list of values. The value can be explicit or, if it is a character value, it can be explicit or generic. If it is explicit, use CT or EX as the operator. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed. If it is generic, use CTG or EXG as the operator. If ABC* is specified with the operator CTG, all items where one of the attribute values begins with ABC are listed.

ALL
Specify ALL to display all the parameters. If this parameter is specified, any parameters that are also requested specifically have no effect; all parameters are still displayed.

ALL is the default if you do not specify a generic name and do not request any specific parameters.

z/OS On z/OS ALL is also the default if you specify a filter condition using the WHERE parameter, but on other platforms, only requested attributes are displayed.

CHANNEL (*generic-name*)
This is optional, and limits the information displayed to cluster channels with the specified channel name. The value can be a generic name.

CLUSTER (*generic-name*)
This is optional, and limits the information displayed to cluster queue managers with the specified cluster name. The value can be a generic name.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

''
The command runs on the queue manager on which it was entered. '' is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered. You can enter a different queue manager name, if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of * is the same as entering the command on every queue manager in the queue sharing group.

You cannot use CMDSCOPE as a filter keyword.

Requested parameters

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

Some parameters are relevant only for cluster channels of a particular type or types. Attributes that are not relevant for a particular type of channel cause no output, and do not cause an error.

CLUSDATE
The date on which the definition became available to the local queue manager, in the form yyyy-mm-dd.

CLUSTIME
The time at which the definition became available to the local queue manager, in the form hh.mm.ss.

DEFTYPE
How the cluster channel was defined:

CLUSSDR
As a cluster-sender channel from an explicit definition.

CLUSSDRA
As a cluster-sender channel by auto-definition alone.

CLUSSDRB
As a cluster-sender channel by auto-definition and an explicit definition.

CLUSRCVR
As a cluster-receiver channel from an explicit definition.

QMID
The internally generated unique name of the cluster queue manager.

QMTYPE
The function of the cluster queue manager in the cluster:

REPOS
Provides a full repository service.

NORMAL
Does not provide a full repository service.

STATUS
The status of the channel for this cluster queue manager is one of the following values:

STARTING
The channel was started and is waiting to become active.

BINDING
The channel is performing channel negotiation and is not yet ready to transfer messages.

INACTIVE
The channel is not active.

INITIALIZING
The channel initiator is attempting to start a channel.

On z/OS, INITIALIZING is displayed as INITIALIZI.

RUNNING
The channel is either transferring messages at this moment, or is waiting for messages to arrive on the transmission queue so that they can be transferred.

STOPPING
The channel is stopping, or received a close request.

RETRYING
A previous attempt to establish a connection failed. The MCA attempts to connect again after the specified time interval.

PAUSED
The channel is waiting for the message-retry interval to complete before trying an MQPUT operation again.

STOPPED
This state can be caused by one of the following events:

- Channel manually stopped.

  A user entered a stop channel command for this channel.
- The number of attempts to establish a connection reached the maximum number of attempts allowed for the channel.

  No further attempt is made to establish a connection automatically.

A channel in this state can be restarted only by issuing the **START CHANNEL** command, or starting the MCA program in an operating-system dependent manner.

REQUESTING
A local requester channel is requesting services from a remote MCA.

SWITCHING
The channel is switching transmission queues.

SUSPEND
Specifies whether this cluster queue manager is suspended from the cluster or not (as a result of the **SUSPEND QMGR** command). The value of SUSPEND is either YES or NO.

VERSION
The version of the IBM MQ installation that the cluster queue manager is associated with.

The version has the format VVRRMMFF:

- VV: Version
- RR: Release
- MM: Maintenance level
- FF: Fix level

XMITQ
The cluster transmission queue.

Channel parameters

ALTDATE
The date on which the definition or information was last altered, in the form yyyy-mm-dd

ALTTIME
The time at which the definition or information was last altered, in the form hh.mm.ss

BATCHHB
The batch heartbeat value being used.

BATCHINT
Minimum batch duration.

BATCHLIM
Batch data limit.

The limit of the amount of data that can be sent through a channel.

BATCHSZ
Batch size.

CLWLPRTY
The priority of the channel for the purposes of cluster workload distribution.

CLWLRANK
The rank of the channel for the purposes of cluster workload distribution.

CLWLWGHT
The weighting of the channel for the purposes of cluster workload distribution.

COMPHDR
The list of header data compression techniques supported by the channel.

COMPMSG
The list of message data compression techniques supported by the channel.

CONNAME
Connection name.

CONVERT
Specifies whether the sender converts application message data.

DESCR
Description.

DISCINT
Disconnection interval.

HBINT
Heartbeat interval.

KAINT
KeepAlive timing for the channel.

LOCLADDR
Local communications address for the channel.

LONGRTY
Limit of number of attempts to connect using the long duration timer.

LONGTMR
Long duration timer.

MAXMSGL
Maximum message length for channel.

MCANAME
Message channel agent name.

You cannot use MCANAME as a filter keyword.

MCATYPE
Specifies whether the message channel agent runs as a separate process or a separate thread.

MCAUSER
Message channel agent user identifier.

MODENAME
LU 6.2 mode name.

MRDATA
Channel message-retry exit user data.

MREXIT
Channel message-retry exit name.

MRRTY
Channel message-retry count.

MRTMR
Channel message-retry time.

MSGDATA
Channel message exit user data.

MSGEXIT
Channel message exit names.

NETPRTY
The priority for the network connection.

NPMSPEED
Nonpersistent message speed.

PASSWORD
Password for initiating LU 6.2 session (if nonblank, PASSWORD is displayed as asterisks).

PROPCTL
Message property control.

PUTAUT
Put authority.

RCVDATA
Channel receive exit user data.

RCVEXIT
Channel receive exit names.

SCYDATA
Channel security exit user data.

SCYEXIT
Channel security exit name.

SENDDATA
Channel send exit user data.

SENDEXIT
Channel send exit names.

SEQWRAP
Sequence number wrap value.

SHORTRTY
Limit of number of attempts to connect using the short duration timer.

SHORTTMR
Short duration timer.

SSLCAUTH
Specifies whether TLS client authentication is required.

SSLCIPH
Cipher specification for the TLS connection.

SSLPEER
Filter for the Distinguished Name from the certificate of the peer queue manager or client at the other end of the channel.

TRPTYPE
Transport type.

TPNAME
LU 6.2 transaction program name.

USEDLQ
Determines whether the dead-letter queue is used when messages cannot be delivered by channels.

USERID
User identifier for initiating LU 6.2 session.

For more information about channel parameters, see "DEFINE CHANNEL (define a new channel)" on page 448

z/OS DISPLAY CMDSERV (display command server status) on z/OS

Use the MQSC command DISPLAY CMDSERV to display the status of the command server.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 12CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Usage notes for DISPLAY CMDSERV" on page 704

Synonym: DIS CS

DISPLAY CMDSERV

Usage notes for DISPLAY CMDSERV

1. The command server takes messages from the system command input queue, and commands using CMDSCOPE, and processes them. DISPLAY CMDSERV displays the status of the command server.
2. The response to this command is a message showing the current status of the command server, which is one of the following:

   ENABLED
   Available to process commands

   DISABLED
   Not available to process commands

   STARTING
   START CMDSERV in progress

   STOPPING
   STOP CMDSERV in progress

   STOPPED
   STOP CMDSERV completed

   RUNNING
   Available to process commands, currently processing a message

   WAITING
   Available to process commands, currently waiting for a message

Multi DISPLAY COMMINFO (display communication information) on Multiplatforms

Use the MQSC command DISPLAY COMMINFO to display the attributes of a communication information object.

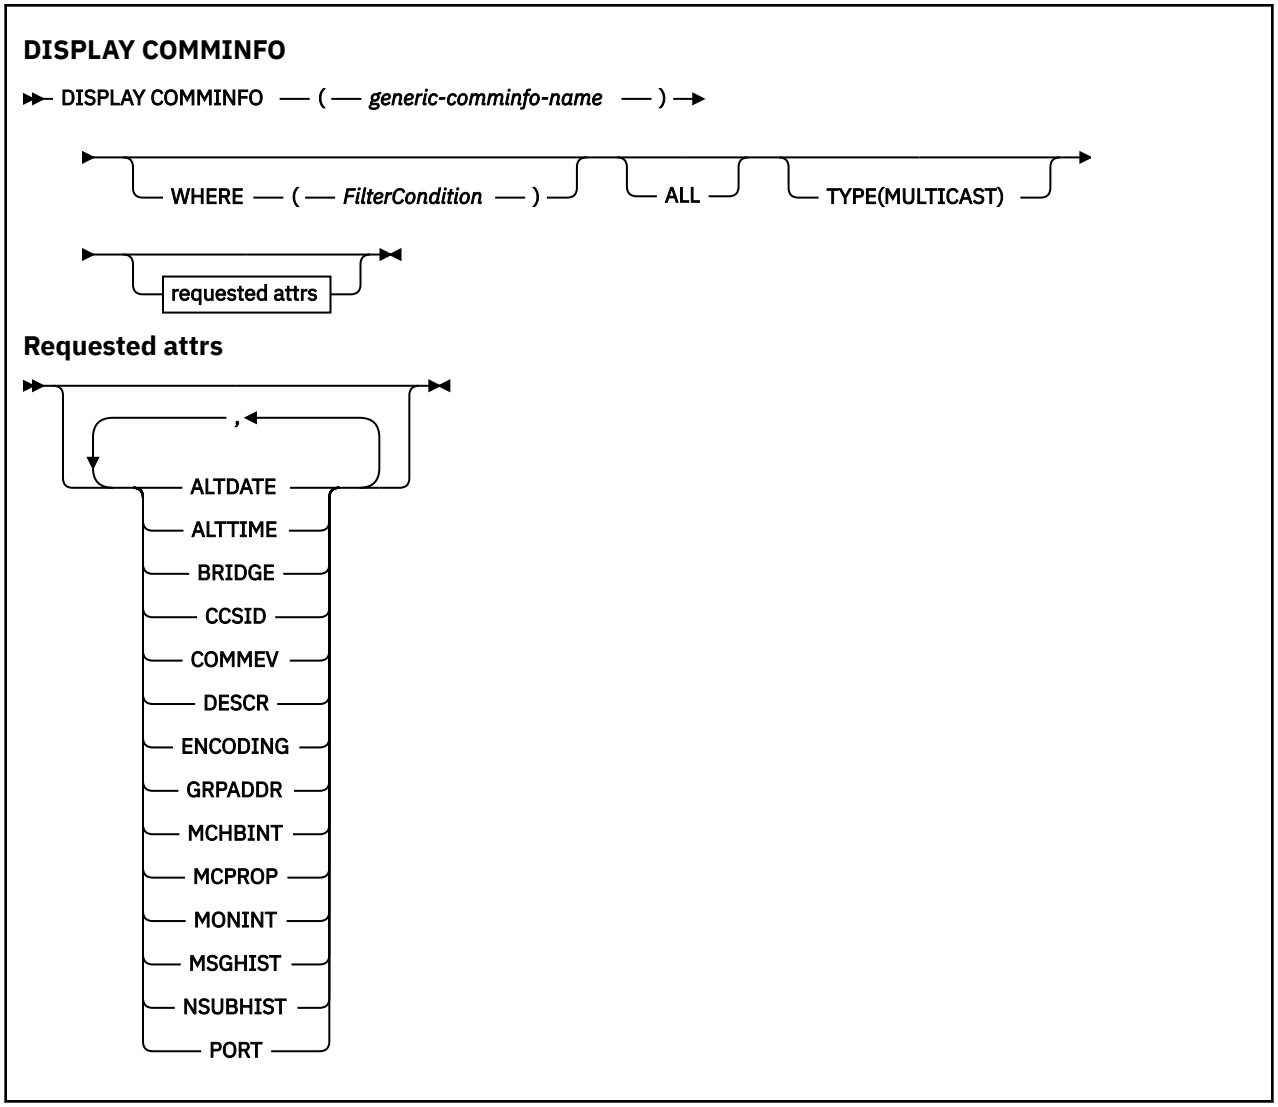
Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

- Syntax diagram
- "Parameter descriptions for DISPLAY COMMINFO" on page 705

- “Requested parameters” on page 706

Synonym: DIS COMMINFO



Parameter descriptions for DISPLAY COMMINFO

You must specify the name of the communication information object you want to display. This can be a specific communication information object name or a generic communication information object name. By using a generic communication information object name, you can display either:

- All communication information object definitions
- One or more communication information objects that match the specified name

(generic-comminfo-name)
The name of the communication information object definition to be displayed (see Rules for naming IBM MQ objects). A trailing asterisk (*) matches all communication information objects with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all communication information objects. The names must all be defined to the local queue manager.

WHERE
Specify a filter condition to display only those communication information object definitions that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword
Almost any parameter that can be used to display attributes for this DISPLAY command.

operator
This is used to determine whether a communication information object definition satisfies the filter value on the given filter keyword. The operators are:

LT
Less than

GT
Greater than

EQ
Equal to

NE
Not equal to

LE
Less than or equal to

GE
Greater than or equal to

LK
Matches a generic string that you provide as a *filter-value*

NL
Does not match a generic string that you provide as a *filter-value*

filter-value
The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

  You can use operators LT, GT, EQ, NE, LE or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value DISABLED on the COMMEV parameter), you can only use EQ or NE.
- A generic value. This is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

ALL
Specify this to display all the parameters. If this parameter is specified, any parameters that are requested specifically have no effect; all parameters are still displayed.

TYPE
Indicates the type of namelist to be displayed.

MULTICAST
Displays multicast communication information objects. This is the default.

Requested parameters

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

The default, if no parameters are specified (and the ALL parameter is not specified) is that the object names and TYPE parameters are displayed.

ALTDATE
The date on which the definition was last altered, in the form `yyyy-mm-dd`

ALTTIME
The time at which the definition was last altered, in the form hh.mm.ss

BRIDGE
Multicast bridging

CCSID
The coded character set identifier that messages are transmitted on.

COMMEV
Whether event messages are generated for Multicast.

DESCR(*string*)
Description

ENCODING
The encoding that the messages are transmitted in.

GRPADDR
The group IP address or DNS name.

MCHBINT
Multicast heartbeat interval.

MCPROP
Multicast property control

MONINT
Monitoring frequency.

MSGHIST
The amount of message history in kilobytes that is kept by the system to handle retransmissions in the case of NACKs (negative acknowledgments).

NSUBHIST
How much history a new subscriber joining a publication stream receives.

PORT
The port number to transmit on.

DISPLAY CONN (display application connection information)

Use the MQSC command **DISPLAY CONN** to display connection information about the applications connected to the queue manager. This is a useful command because it enables you to identify applications with long-running units of work.

Using MQSC commands

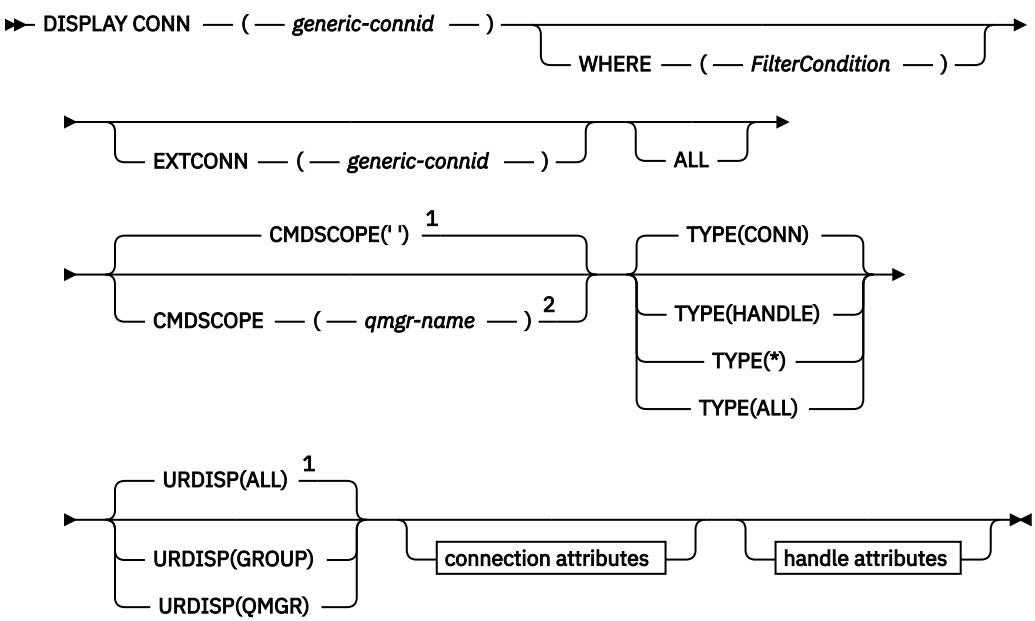
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

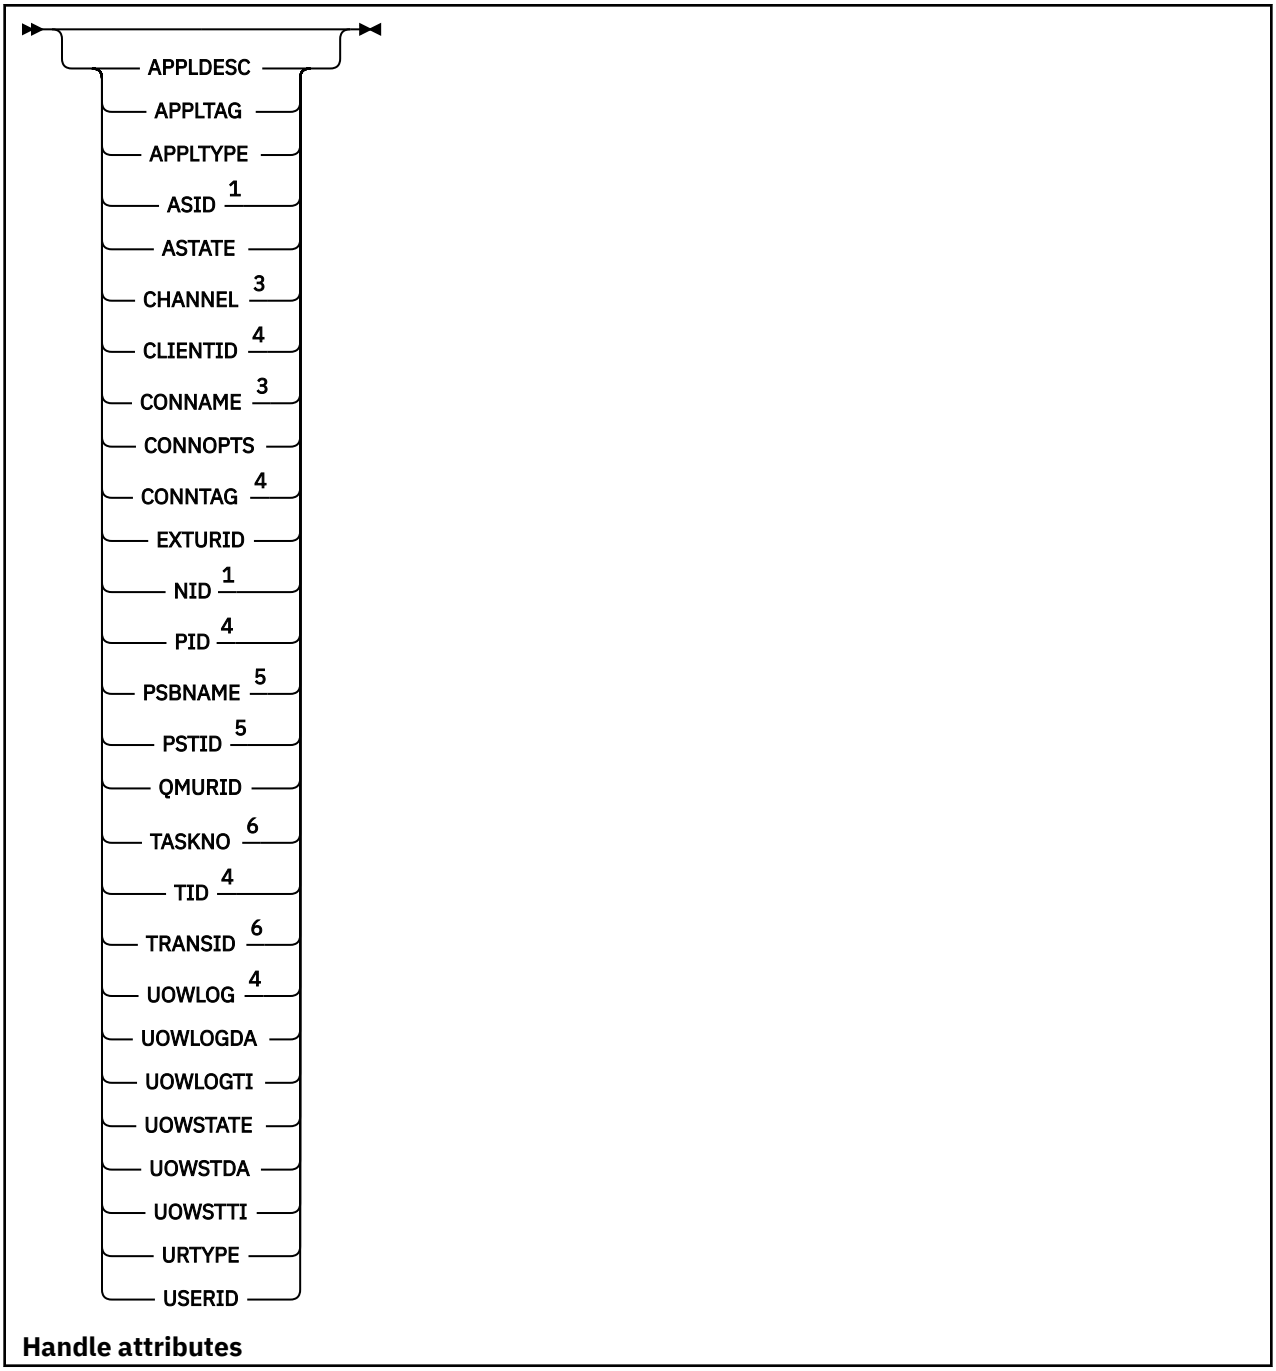
- "Usage notes for DISPLAY CONN" on page 710
- "Parameter descriptions for DISPLAY CONN" on page 710
- "Connection attributes" on page 713
- "Handle attributes" on page 717
- "Full attributes" on page 721

Synonym: DIS CONN

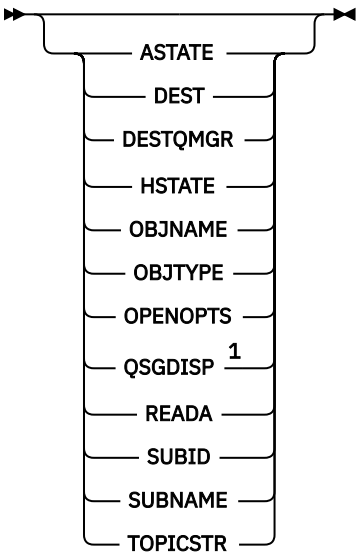
DISPLAY CONN



Connection attributes



Handle attributes



Notes:

[1] Valid only on z/OS.
[2] Valid only when the queue manager is a member of a queue sharing group.
[3] Valid only when the connection is associated with a channel.
[4] Not valid on z/OS.
[5] IMS only.
[6] CICS for z/OS only.

Usage notes for DISPLAY CONN

1. z/OS This command is issued internally by IBM MQ on z/OS when taking a checkpoint, and when the queue manager is starting and stopping, so that a list of units of work that are in doubt at the time is written to the z/OS console log.
2. The TOPICSTR parameter might contain characters that cannot be translated into printable characters when the command output is displayed.

   z/OS On z/OS, these non-printable characters will be displayed as blanks.

   Multi On Multiplatforms platforms using **runmqsc**, these non-printable characters will be displayed as dots.
3. The state of asynchronous consumers, ASTATE, reflects that of the server-connection proxy on behalf of the client application; it does not reflect the client application state.

From IBM MQ 8.0, there is a change to the data that is returned in the EXTURID field on the results shown for the **DISPLAY CONN runmqsc** command when there is no XA transaction associated with the connection. Prior to IBM MQ 8.0, if there is no XA transaction associated with the connection then within the EXTURID attribute the XA_FORMATID field would be show as [00000000]. From IBM MQ 8.0, if there is no XA transaction associated with the connection, then the XA_FORMATID value is shown as the empty string [].

Parameter descriptions for DISPLAY CONN

You must specify a connection for which you want to display information. This can be a specific connection identifier or a generic connection identifier. A single asterisk (*) can be used as a generic connection identifier to display information for all connections.

(*generic-connid*)
The identifier of the connection definition for which information is to be displayed. A single asterisk (*) specifies that information for all connection identifiers is to be displayed.

When an application connects to IBM MQ, it is given a unique 24-byte connection identifier (ConnectionId). The value for CONN is formed by converting the last eight bytes of the ConnectionId to its 16 -character hexadecimal equivalent.

WHERE
Specify a filter condition to display only those connections that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword
Almost any parameter that can be used to display attributes for this **DISPLAY** command. However, you cannot use the **CMDSCOPE**, **EXTCONN**, **QSGDISP**, **TYPE**, and **EXTURID** parameters as filter keywords.

operator
This is used to determine whether a connection satisfies the filter value on the given filter keyword. The operators are:

LT
Less than

GT
Greater than

EQ
Equal to

NE
Not equal to

LE
Less than or equal to

GE
Greater than or equal to

LK
Matches a generic string that you provide as a *filter-value*

NL
Does not match a generic string that you provide as a *filter-value*

CT
Contains a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which contain the specified item. You cannot use the **CONNOPTS** value MQCNO_STANDARD_BINDING with this operator.

EX
Does not contain a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which do not contain the specified item. You cannot use the **CONNOPTS** value MQCNO_STANDARD_BINDING with this operator.

filter-value
The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

  You can use operators LT, GT, EQ, NE, LE or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value NONE on the **UOWSTATE** parameter), you can only use EQ or NE.
- A generic value. This is a character string (such as the character string in the **APPLTAG** parameter) with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL,

all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

- An item in a list of values. Use CT or EX as the operator. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed.

ALL
Specify this to display all the connection information of the requested type for each specified connection. This is the default if you do not specify a generic identifier, and do not request any specific parameters.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which it was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

You cannot use **CMDSCOPE** as a filter keyword.

EXTCONN
The value for **EXTCONN** is based on the first sixteen bytes of the ConnectionId converted to its 32 -character hexadecimal equivalent.

Connections are identified by a 24-byte connection identifier. The connection identifier comprises a prefix, which identifies the queue manager, and a suffix which identifies the connection to that queue manager. By default, the prefix is for the queue manager currently being administered, but you can specify a prefix explicitly by using the **EXTCONN** parameter. Use the **CONN** parameter to specify the suffix.

When connection identifiers are obtained from other sources, specify the fully qualified connection identifier (both **EXTCONN** and **CONN**) to avoid possible problems related to non-unique **CONN** values.

Do not specify both a generic value for **CONN** and a non-generic value for **EXTCONN**.

You cannot use **EXTCONN** as a filter keyword.

TYPE
Specifies the type of information to be displayed. Values are:

CONN
Connection information for the specified connection.

z/OS On z/OS, this includes threads which may be logically or actually disassociated from a connection, together with those that are in-doubt and for which external intervention is needed to resolve them. These latter threads are those that **DIS THREAD TYPE(INDOUBT)** would show.

HANDLE
Information relating to any objects opened by the specified connection.

*****
Display all available information relating to the connection.

ALL
Display all available information relating to the connection.

z/OS On z/OS, if you specify **TYPE**(*ALL*/*) and **WHERE**(*xxxxx*) you only get CONN or HANDLE information returned, based on the **WHERE** specification. That is, if the *xxxxx* is a condition relating to handle attributes then only handle attributes for the connection are returned.

URDISP
Specifies the unit of recovery disposition of connections to be displayed. Values are:

ALL
Display all connections. This is the default option.

GROUP
Display only those connections with a GROUP unit of recovery disposition.

QMGR
Display only those connections with a QMGR unit of recovery disposition.

Connection attributes

If **TYPE** is set to CONN, the following information is always returned for each connection that satisfies the selection criteria, except where indicated:

- Connection identifier (**CONN** parameter)
- Type of information returned (**TYPE** parameter)

The following parameters can be specified for **TYPE(CONN)** to request additional information for each connection. If a parameter is specified that is not relevant for the connection, operating environment, or type of information requested, that parameter is ignored.

APPLDESC
A string containing a description of the application connected to the queue manager, where it is known. If the application is not recognized by the queue manager the description returned is blank.

APPLTAG
A string containing the tag of the application connected to the queue manager. It is one of the following:

- z/OS z/OS batch job name
- z/OS TSO USERID
- CICS APPLID
- z/OS IMS region name
- Channel initiator job name
- IBM i IBM i job name
- Linux AIX UNIX process

  Notes:

  – Linux On Linux, if the process name exceeds 15 characters, only the first 15 characters are shown.

  – AIX On AIX, if the process name exceeds 28 characters, only the first 28 characters are shown.
- Windows Windows process

  Note: This consists of the full program path and executable file name. If it is more than 28 characters long, only the last 28 characters are shown.
- Internal queue manager process name

APPLTYPE
A string indicating the type of the application that is connected to the queue manager. It is one of the following:

BATCH
Application using a batch connection

RRSBATCH
RRS-coordinated application using a batch connection

CICS
CICS transaction

IMS
IMS transaction

CHINIT
Channel initiator

OS400
An IBM i application

SYSTEM
Queue manager

SYSTEMEXT
Application performing an extension of function that is provided by the queue manager

UNIX
A Linux or AIX application

USER
A user application

WINDOWSNT
A Windows application

ASID
A 4-character address-space identifier of the application identified by **APPLTAG**. It distinguishes duplicate values of **APPLTAG**.

This parameter is returned only on z/OS when the **APPLTYPE** parameter does not have the value SYSTEM.

This parameter is valid only on z/OS.

ASTATE
The state of asynchronous consumption on this connection handle.

Possible values are:

SUSPENDED
An MQCTL call with the Operation parameter set to MQOP_SUSPEND has been issued against the connection handle so that so that asynchronous message consumption is temporarily suspended on this connection.

STARTED
An MQCTL call with the Operation parameter set to MQOP_START has been issued against the connection handle so that asynchronous message consumption can proceed on this connection.

STARTWAIT
An MQCTL call with the Operation parameter set to MQOP_START_WAIT has been issued against the connection handle so that asynchronous message consumption can proceed on this connection.

STOPPED
An MQCTL call with the Operation parameter set to MQOP_STOP has been issued against the connection handle so that asynchronous message consumption cannot currently proceed on this connection.

NONE
No MQCTL call has been issued against the connection handle. Asynchronous message consumption cannot currently proceed on this connection.

CHANNEL
The name of the channel that owns the connection. If there is no channel associated with the connection, this parameter is blank.

Multi **CLIENTID**
The client ID of the client that is using the connection. If there is no client ID associated with the connection, this parameter is blank.

CONNAME
The connection name associated with the channel that owns the connection. If there is no channel associated with the connection, this parameter is blank.

CONNOPTS
The connect options currently in force for this application connection. Possible values are:

- MQCNO_ACCOUNTING_MQI_DISABLED
- MQCNO_ACCOUNTING_MQI_ENABLED
- MQCNO_ACCOUNTING_Q_DISABLED
- MQCNO_ACCOUNTING_Q_ENABLED
- MQCNO_FASTPATH_BINDING
- MQCNO_HANDLE_SHARE_BLOCK
- MQCNO_HANDLE_SHARE_NO_BLOCK
- MQCNO_HANDLE_SHARE_NONE
- MQCNO_ISOLATED_BINDING
- MQCNO_RECONNECT
- MQCNO_RECONNECT_Q_MGR
- MQCNO_RESTRICT_CONN_TAG_Q_MGR
- MQCNO_RESTRICT_CONN_TAG_QSG
- MQCNO_SERIALIZE_CONN_TAG_Q_MGR
- MQCNO_SERIALIZE_CONN_TAG_QSG
- MQCNO_SHARED_BINDING
- MQCNO_STANDARD_BINDING

V 9.2.0 If you are using an IBM MQ 9.1.2 or later client, the values displayed for MQCNO_RECONNECT and MQCNO_RECONNECT_Q_MGR are the effective reconnect options. If you are using an earlier client version, the values displayed are whatever the application specifies, whether they are currently taking effect or not.

You cannot use the value MQCNO_STANDARD_BINDING as a filter value with the CT and EX operators on the **WHERE** parameter.

V 9.2.0 ALW **CONNTAG**
The connection tag associated with this connection, formatted as a readable string in the local codepage for the RUNMQSC.

Note: The *CONNTAG* is treated as string data, so it can be filtered using the syntax `WHERE(CONNTAG LK 'generic_tag*')`.

EXTURID
The external unit of recovery identifier associated with this connection. Its format is determined by the value of **URTYPE**.

You cannot use **EXTURID** as a filter keyword.

z/OS **NID**
Origin identifier, set only if the value of **UOWSTATE** is UNRESOLVED. This is a unique token identifying the unit of work within the queue manager. It is of the form `origin-node.origin-urid` where

- `origin-node` identifies the originator of the thread, except in the case where **APPLTYPE** is set to RRSBATCH, when it is omitted.
- `origin-urid` is the hexadecimal number assigned to the unit of recovery by the originating system for the specific thread to be resolved.

This parameter is valid only on z/OS.

PID
Number specifying the process identifier of the application that is connected to the queue manager.

z/OS This parameter is not valid on z/OS.

z/OS **PSBNAME**
The 8-character name of the program specification block (PSB) associated with the running IMS transaction. You can use the **PSBNAME** and **PSTID** to purge the transaction using IMS commands. It is valid on z/OS only.

This parameter is returned only when the **APPLTYPE** parameter has the value IMS.

z/OS **PSTID**
The 4-character IMS program specification table (PST) region identifier for the connected IMS region. It is valid on z/OS only.

This parameter is returned only when the **APPLTYPE** parameter has the value IMS.

QMURID
The queue manager unit of recovery identifier.

z/OS On z/OS, this is an 8-byte log RBA, displayed as 16 hexadecimal characters.

Multi On Multiplatforms, this is an 8-byte transaction identifier, displayed as `m.n` where `m` and `n` are the decimal representation of the first and last 4 bytes of the transaction identifier.

z/OS You can use **QMURID** as a filter keyword. On z/OS, you must specify the filter value as a hexadecimal string.

Multi On platforms other than z/OS, you must specify the filter value as a pair of decimal numbers separated by a period (.). You can only use the EQ, NE, GT, LT, GE, or LE filter operators.

z/OS However, on z/OS, if log shunting has taken place, as indicated by message CSQR026I, instead of the RBA you have to use the URID from the message.

z/OS **TASKNO**
A 7-digit CICS task number. This number can be used in the CICS command "CEMT SET TASK(taskno) PURGE" to end the CICS task. This parameter is valid on z/OS only.

This parameter is returned only when the **APPLTYPE** parameter has the value CICS.

TID
Number specifying the thread identifier within the application process that has opened the specified queue.

z/OS This parameter is not valid on z/OS.

z/OS **TRANSID**
A 4-character CICS transaction identifier. This parameter is valid only on z/OS.

This parameter is returned only when the **APPLTYPE** parameter has the value CICS.

Multi **UOWLOG**
The file name of the extent to which the transaction associated with this connection first wrote.

Multi This parameter is valid only on Multiplatforms.

UOWLOGDA
The date that the transaction associated with the current connection first wrote to the log.

UOWLOGTI
The time that the transaction associated with the current connection first wrote to the log.

UOWSTATE
The state of the unit of work. It is one of the following:

NONE
There is no unit of work.

ACTIVE
The unit of work is active.

PREPARED
The unit of work is in the process of being committed.

z/OS **UNRESOLVED**
The unit of work is in the second phase of a two-phase commit operation. IBM MQ holds resources on its behalf and external intervention is required to resolve it. This might be as simple as starting the recovery coordinator (such as CICS, IMS, or RRS) or it might involve a more complex operation such as using the **RESOLVE INDOUBT** command. The UNRESOLVED value can occur only on z/OS.

UOWSTDA
The date that the transaction associated with the current connection was started.

UOWSTTI
The time that the transaction associated with the current connection was started.

URTYPE
The type of unit of recovery as seen by the queue manager. It is one of the following:

- z/OS CICS (valid only on z/OS)
- XA
- z/OS RRS (valid only on z/OS)
- z/OS IMS (valid only on z/OS)
- QMGR

URTYPE identifies the **EXTURID** type and not the type of the transaction coordinator. When **URTYPE** is QMGR, the associated identifier is in **QMURID** (and not **EXTURID**).

USERID
The user identifier associated with the connection.

This parameter is not returned when **APPLTYPE** has the value SYSTEM.

Handle attributes

If **TYPE** is set to HANDLE, the following information is always returned for each connection that satisfies the selection criteria, except where indicated:

- Connection identifier (**CONN** parameter)

- Read ahead status (**DEFREADA** parameter)
- Type of information returned (**TYPE** parameter)
- Handle status (**HSTATE**)
- Object name (**OBJNAME** parameter)
- Object type (**OBJTYPE** parameter)

The following parameters can be specified for **TYPE(HANDLE)** to request additional information for each queue. If a parameter is specified that is not relevant for the connection, operating environment, or type of status information requested, that parameter is ignored.

ASTATE
The state of the asynchronous consumer on this object handle.

Possible values are:

ACTIVE
An MQCB call has set up a function to call back to process messages asynchronously and the connection handle has been started so that asynchronous message consumption can proceed.

INACTIVE
An MQCB call has set up a function to call back to process messages asynchronously but the connection handle has not yet been started, or has been stopped or suspended, so that asynchronous message consumption cannot currently proceed.

SUSPENDED
The asynchronous consumption callback has been suspended so that asynchronous message consumption cannot currently proceed on this object handle. This can be either because an MQCB call with Operation MQOP_SUSPEND has been issued against this object handle by the application, or because it has been suspended by the system. If it has been suspended by the system, as part of the process of suspending asynchronous message consumption the callback function will be called with the reason code that describes the problem resulting in suspension. This will be reported in the Reason field in the MQCBC structure that is passed to the callback function.

For asynchronous message consumption to proceed, the application must issue an MQCB call with the Operation parameter set to MQOP_RESUME.

SUSPTEMP
The asynchronous consumption callback has been temporarily suspended by the system so that asynchronous message consumption cannot currently proceed on this object handle. As part of the process of suspending asynchronous message consumption, the callback function will be called with the reason code that describes the problem resulting in suspension. This will be reported in the Reason field in the MQCBC structure passed to the callback function.

The callback function will be called again when asynchronous message consumption is resumed by the system, when the temporary condition has been resolved.

NONE
An MQCB call has not been issued against this handle, so no asynchronous message consumption is configured on this handle.

DEST
The destination queue for messages that are published to this subscription. This parameter is only relevant for handles of subscriptions to topics. It is not returned for other handles.

DESTQMGR
The destination queue manager for messages that are published to this subscription. This parameter is relevant only for handles of subscriptions to topics. It is not returned for other handles. If DEST is a queue that is hosted on the local queue manager, this parameter will contain the local queue manager name. If DEST is a queue that is hosted on a remote queue manager, this parameter will contain the name of the remote queue manager.

HSTATE
The state of the handle.

Possible values are:

ACTIVE
An API call from this connection is currently in progress for this object. If the object is a queue, this condition can arise when an MQGET WAIT call is in progress.

If there is an MQGET SIGNAL outstanding, then this does not mean, by itself, that the handle is active.

INACTIVE
No API call from this connection is currently in progress for this object. If the object is a queue, this condition can arise when no MQGET WAIT call is in progress.

OBJNAME
The name of an object that the connection has open.

OBJTYPE
The type of the object that the connection has open. If this handle is that of a subscription to a topic, then the **SUBID** parameter identifies the subscription. You can then use the **DISPLAY SUB** command to find all the details about the subscription.

It is one of the following:

- QUEUE
- PROCESS
- QMGR
- z/OS STGCLASS (valid only on z/OS)
- NAMELIST
- CHANNEL
- AUTHINFO
- TOPIC

OPENOPTS
The open options currently in force for the connection for the object. This parameter is not returned for a subscription. Use the value in the **SUBID** parameter and the **DISPLAY SUB** command to find the details about the subscription.

Possible values are:

MQOO_INPUT_AS_Q_DEF
Open queue to get messages using queue-defined default.

MQOO_INPUT_SHARED
Open queue to get messages with shared access.

MQOO_INPUT_EXCLUSIVE
Open queue to get messages with exclusive access.

MQOO_BROWSE
Open queue to browse messages.

MQOO_OUTPUT
Open queue or topic to put messages.

MQOO_INQUIRE
Open queue to inquire attributes.

MQOO_SET
Open queue to set attributes.

MQOO_BIND_ON_OPEN
Bind handle to destination when queue is found.

MQOO_BIND_NOT_FIXED
Do not bind to a specific destination.

MQOO_SAVE_ALL_CONTEXT
Save context when message retrieved.

MQOO_PASS_IDENTITY_CONTEXT
Allow identity context to be passed.

MQOO_PASS_ALL_CONTEXT
Allow all context to be passed.

MQOO_SET_IDENTITY_CONTEXT
Allow identity context to be set.

MQOO_SET_ALL_CONTEXT
Allow all context to be set.

MQOO_ALTERNATE_USER_AUTHORITY
Validate with specified user identifier.

MQOO_FAIL_IF_QUIESCING
Fail if queue manager is quiescing.

z/OS **QSGDISP**
Indicates the disposition of the object. It is valid on z/OS only. The value is one of the following:

QMGR
The object was defined with **QSGDISP(QMGR)**.

COPY
The object was defined with **QSGDISP(COPY)**.

SHARED
The object was defined with **QSGDISP(SHARED)**.

You cannot use **QSGDISP** as a filter keyword.

READA
The read ahead connection status.

Possible values are:

NO
Read ahead of non-persistent messages is not enabled for this object.

YES
Read ahead of non-persistent message is enabled for this object and is being used efficiently.

BACKLOG
Read ahead of non-persistent messages is enabled for this object. Read ahead is not being used efficiently because the client has been sent a large number of messages which are not being consumed.

INHIBITED
Read ahead was requested by the application but has been inhibited because of incompatible options specified on the first MQGET call.

SUBID
The internal, all-time unique identifier of the subscription. This parameter is relevant only for handles of subscriptions to topics. It is not returned for other handles.

Not all subscriptions show up in **DISPLAY CONN**; only those that have current handles open to the subscription show up. You can use the **DISPLAY SUB** command to see all subscriptions.

SUBNAME
The application's unique subscription name that is associated with the handle. This parameter is relevant only for handles of subscriptions to topics. It is not returned for other handles. Not all subscriptions will have a subscription name.

TOPICSTR
The resolved topic string. This parameter is relevant for handles with **OBJTYPE(TOPIC)**. For any other object type, this parameter is not returned.

Full attributes

If **TYPE** is set to *, or ALL, both Connection attributes and Handle attributes are returned for each connection that satisfies the selection criteria.

Multi DISPLAY ENTAUTH (display entity authorizations) on Multiplatforms

Use the MQSC command DISPLAY ENTAUTH to display the authorizations an entity has to a specified object.

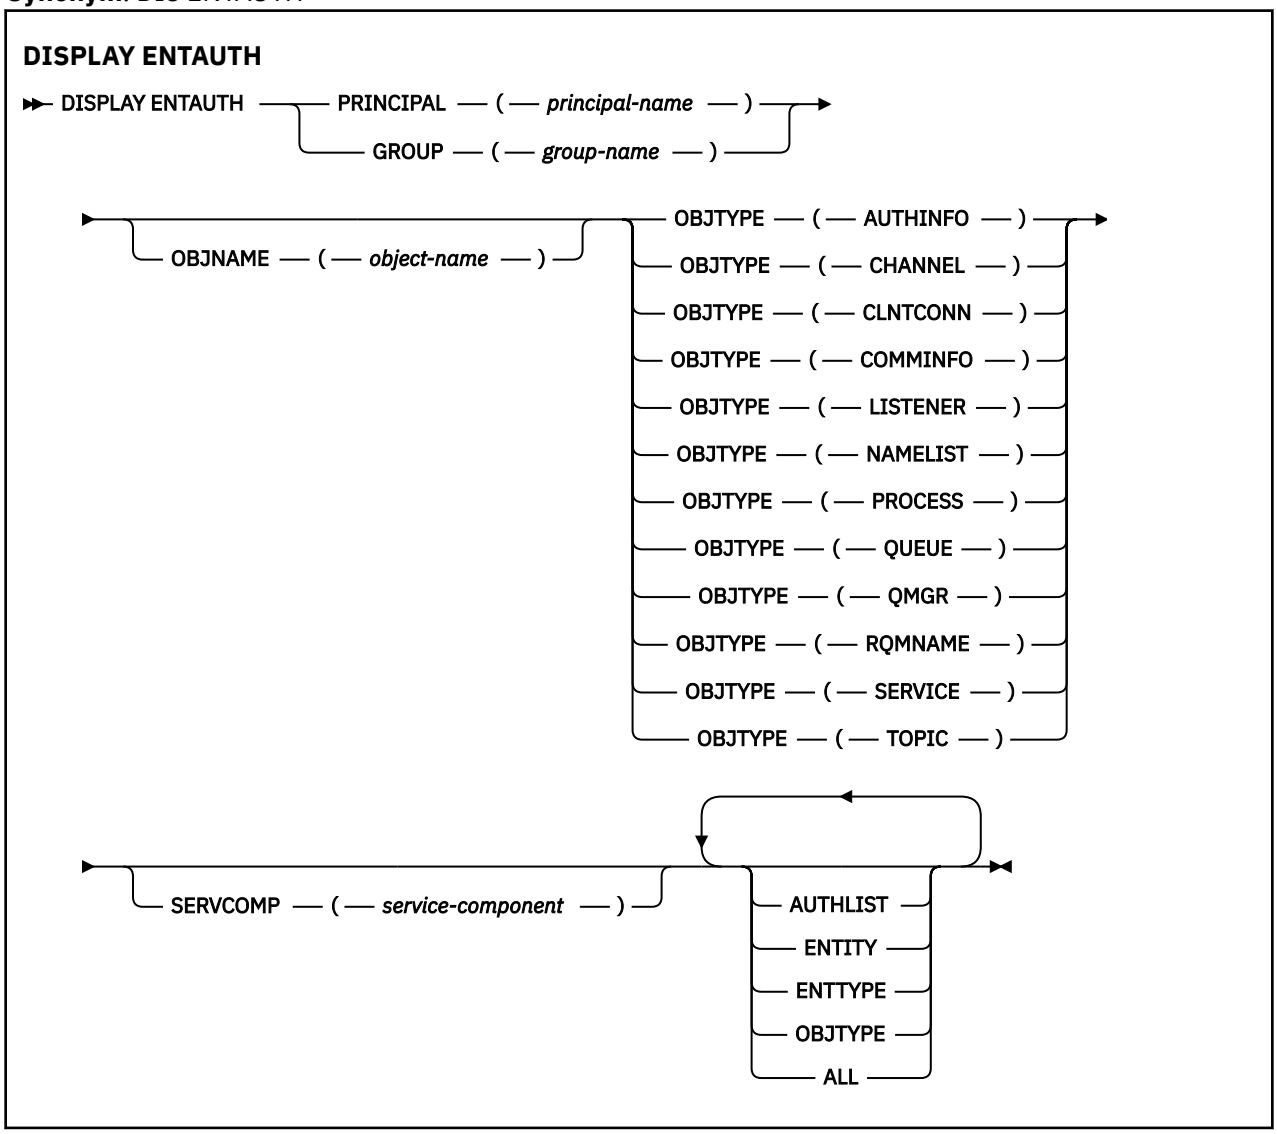
Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

- Syntax diagram
- "Parameter descriptions" on page 722
- "Requested parameters" on page 723

Synonym: DIS ENTAUTH

DISPLAY ENTAUTH



Parameter descriptions

PRINCIPAL(*principal-name*)
A principal name. This is the name of a user for whom to retrieve authorizations to the specified object. On IBM MQ for Windows, the name of the principal can optionally include a domain name, specified in this format: `user@domain`.

You must specify either PRINCIPAL or GROUP.

GROUP(*group-name*)
A group name. This is the name of the user group on which to make the inquiry. You can specify one name only and it must be the name of an existing user group.

For IBM MQ for Windows only, the group name can optionally include a domain name, specified in the following formats:

```
GroupName@domain
domain\GroupName
```

You must specify either PRINCIPAL or GROUP.

OBJNAME(*object-name*)
The name of the object or generic profile for which to display the authorizations.

This parameter is required unless the OBJTYPE parameter is QMGR. This parameter can be omitted if the OBJTYPE parameter is QMGR.

OBJTYPE
The type of object referred to by the profile. Specify one of the following values:

AUTHINFO
Authentication information record

CHANNEL
Channel

CLNTCONN
Client connection channel

COMMINFO
Communication information object

LISTENER
Listener

NAMELIST
Namelist

PROCESS
Process

QUEUE
Queue

QMGR
Queue manager

RQMNAME
Remote queue manager

SERVICE
Service

TOPIC
Topic

SERVCOMP(*service-component*)
The name of the authorization service for which information is to be displayed.

If you specify this parameter, it specifies the name of the authorization service to which the authorizations apply. If you omit this parameter, the inquiry is made to the registered authorization services in turn in accordance with the rules for chaining authorization services.

ALL
Specify this value to display all of the authorization information available for the entity and the specified profile.

Requested parameters

You can request the following information about the authorizations:

AUTHLIST
Specify this parameter to display the list of authorizations.

ENTITY
Specify this parameter to display the entity name.

ENTTYPE
Specify this parameter to display the entity type.

OBJTYPE
Specify this parameter to display the object type.

z/OS DISPLAY GROUP (display QSG information) on z/OS

Use the MQSC command DISPLAY GROUP to display information about the queue sharing group to which the queue manager is connected. This command is valid only when the queue manager is a member of a queue sharing group.

Using MQSC commands

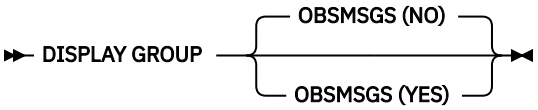
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Usage notes for DISPLAY GROUP" on page 723
- "Parameter descriptions for DISPLAY GROUP" on page 724

Synonym: DIS GROUP

DISPLAY GROUP



Usage notes for DISPLAY GROUP

1. The response to the DISPLAY GROUP command is a series of messages containing information about the queue sharing group to which the queue manager is connected.

   The following information is returned:

   - The name of the queue sharing group
   - Whether all the queue managers that belong to the group are active or inactive
   - The names of all the queue managers that belong to the group.

- If you specify OBSMSGS (YES), whether queue managers in the group contain obsolete messages in Db2

Parameter descriptions for DISPLAY GROUP

OBSMSGS
Specifies whether the command additionally looks for obsolete messages in Db2. This is optional. Possible values are:

NO
Obsolete messages in Db2 are not looked for. This is the default value.

YES
Obsolete messages in Db2 are looked for and messages containing information about any found are returned.

Multi DISPLAY LISTENER (display listener information) on Multiplatforms

Use the MQSC command DISPLAY LISTENER to display information about a listener.

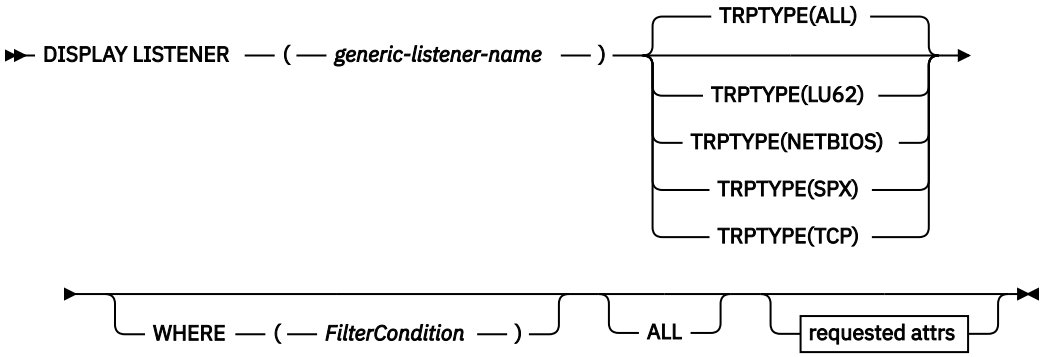
Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

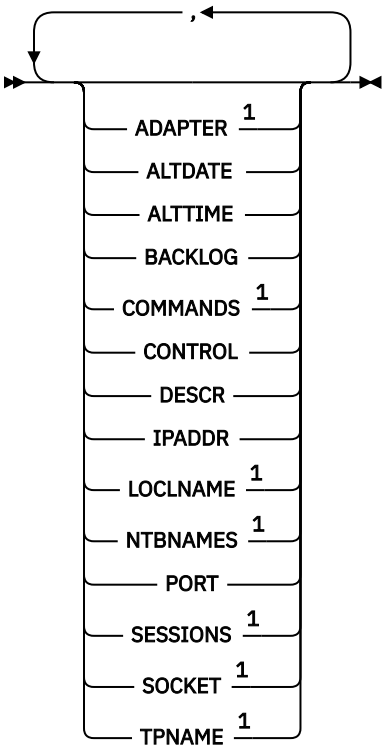
- Syntax diagram
- "Usage notes" on page 725
- "Keyword and parameter descriptions for DISPLAY LISTENER" on page 725
- "Requested parameters" on page 726

Synonym: DIS LSTR

DISPLAY LISTENER



Requested attrs



Notes:

[1] Valid only on Windows.

Usage notes

The values displayed describe the current definition of the listener. If the listener has been altered since it was started, the currently running instance of the listener object may not have the same values as the current definition.

Keyword and parameter descriptions for DISPLAY LISTENER

You must specify a listener for which you want to display information. You can specify a listener by using either a specific listener name or a generic listener name. By using a generic listener name, you can display either:

- Information about all listener definitions, by using a single asterisk (*), or
- Information about one or more listeners that match the specified name.

(*generic-listener-name*)
The name of the listener definition for which information is to be displayed. A single asterisk (*) specifies that information for all listener identifiers is to be displayed. A character string with an asterisk at the end matches all listeners with the string followed by zero or more characters.

TRPTYPE
Transmission protocol. If you specify this parameter, it must follow directly after the *generic-listener-name* parameter. If you do not specify this parameter, a default of ALL is assumed. Values are:

ALL
This is the default value and displays information for all listeners.

LU62
Displays information for all listeners defined with a value of LU62 in their TRPTYPE parameter.

NETBIOS
Displays information for all listeners defined with a value of NETBIOS in their TRPTYPE parameter.

SPX
Displays information for all listeners defined with a value of SPX in their TRPTYPE parameter.

TCP
Displays information for all listeners defined with a value of TCP in their TRPTYPE parameter.

WHERE
Specify a filter condition to display information for those listeners that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword
Any parameter that can be used to display attributes for this DISPLAY command.

operator
This is used to determine whether a listener satisfies the filter value on the given filter keyword. The operators are:

LT
Less than

GT
Greater than

EQ
Equal to

NE
Not equal to

LE
Less than or equal to

GE
Greater than or equal to

LK
Matches a generic string that you provide as a *filter-value*

NL
Does not match a generic string that you provide as a *filter-value*

filter-value
The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.
- A generic value. This is a character string. with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed.

  You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

ALL
Specify this to display all the listener information for each specified listener. If this parameter is specified, any parameters that are requested specifically have no effect; all parameters are still displayed.

This is the default if you do not specify a generic identifier, and do not request any specific parameters.

Requested parameters

Specify one or more attributes that define the data to be displayed. The attributes can be specified in any order. Do not specify the same attribute more than once.

ADAPTER
The adapter number on which NetBIOS listens.

ALTDATE
The date on which the definition was last altered, in the form `yyyy-mm-dd`.

ALTTIME
The time at which the definition was last altered, in the form `hh.mm.ss`.

BACKLOG
The number of concurrent connection requests that the listener supports.

COMMANDS
The number of commands that the listener can use.

CONTROL
How the listener is to be started and stopped:

MANUAL
The listener is not to be started automatically or stopped automatically. It is to be controlled by use of the START LISTENER and STOP LISTENER commands.

QMGR
The listener being defined is to be started and stopped at the same time as the queue manager is started and stopped.

STARTONLY
The listener is to be started at the same time as the queue manager is started, but is not requested to stop when the queue manager is stopped.

DESCR
Descriptive comment.

IPADDR
The listener's IP address.

LOCLNAME
The NetBIOS local name that the listener uses.

NTBNAMES
The number of names that the listener can use.

PORT
The port number for TCP/IP.

SESSIONS
The number of sessions that the listener can use.

SOCKET
SPX socket.

TPNAME
The LU6.2 transaction program name.

For more information on these parameters, see "DEFINE LISTENER (define a new listener) on Multiplatforms" on page 512.

z/OS DISPLAY LOG (display log information) on z/OS

Use the MQSC command **DISPLAY LOG** to display log system parameters and information.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

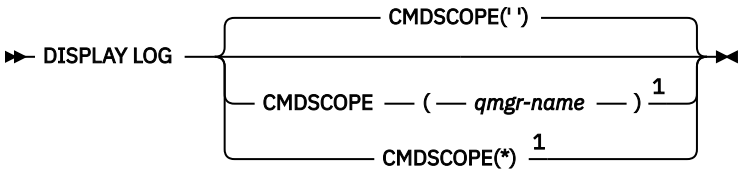
You can issue this command from sources 12CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- "Usage notes for DISPLAY LOG" on page 728

- "Parameter descriptions for DISPLAY LOG" on page 728

Synonym: DIS LOG

DISPLAY LOG



Notes:

[1] Valid only when the queue manager is a member of a queue sharing group.

Usage notes for DISPLAY LOG

1. **DISPLAY LOG** returns a report that shows the initial log parameters, and the current values as changed by the **SET LOG** command:
   - Whether log compression is active (COMPLOG).
   - V 9.2.0 Whether writes to the active logs are made with zHyperWrite being enabled (ZHYWRITE)
   - Length of time that an allowed archive read tape unit remains unused before it is deallocated (DEALLCT).
   - Size of input buffer storage for active and archive log data sets (INBUFF).
   - Size of output buffer storage for active and archive log data sets (OUTBUFF).
   - Maximum number of dedicated tape units that can be set to read archive log tape volumes (MAXRTU).
   - Maximum number of archive log volumes that can be recorded (MAXARCH).
   - Maximum number of concurrent log offload tasks (MAXCNOFF)
   - Whether archiving is on or off (OFFLOAD).
   - Whether single or dual active logging is being used (TWOACTV).
   - Whether single or dual archive logging is being used (TWOARCH).
   - Whether single or dual BSDS is being used (TWOBSDS).
   - Number of output buffers to be filled before they are written to the active log data sets (WRTHRSH).

   It also returns a report about the status of the logs.
2. This command is issued internally by IBM MQ at the end of queue manager startup.

Parameter descriptions for DISPLAY LOG

CMDSCOPE

This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE cannot be used for commands issued from the first initialization input data set CSQINP1.

' '

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

Multi DISPLAY LSSTATUS (display listener status) on Multiplatforms

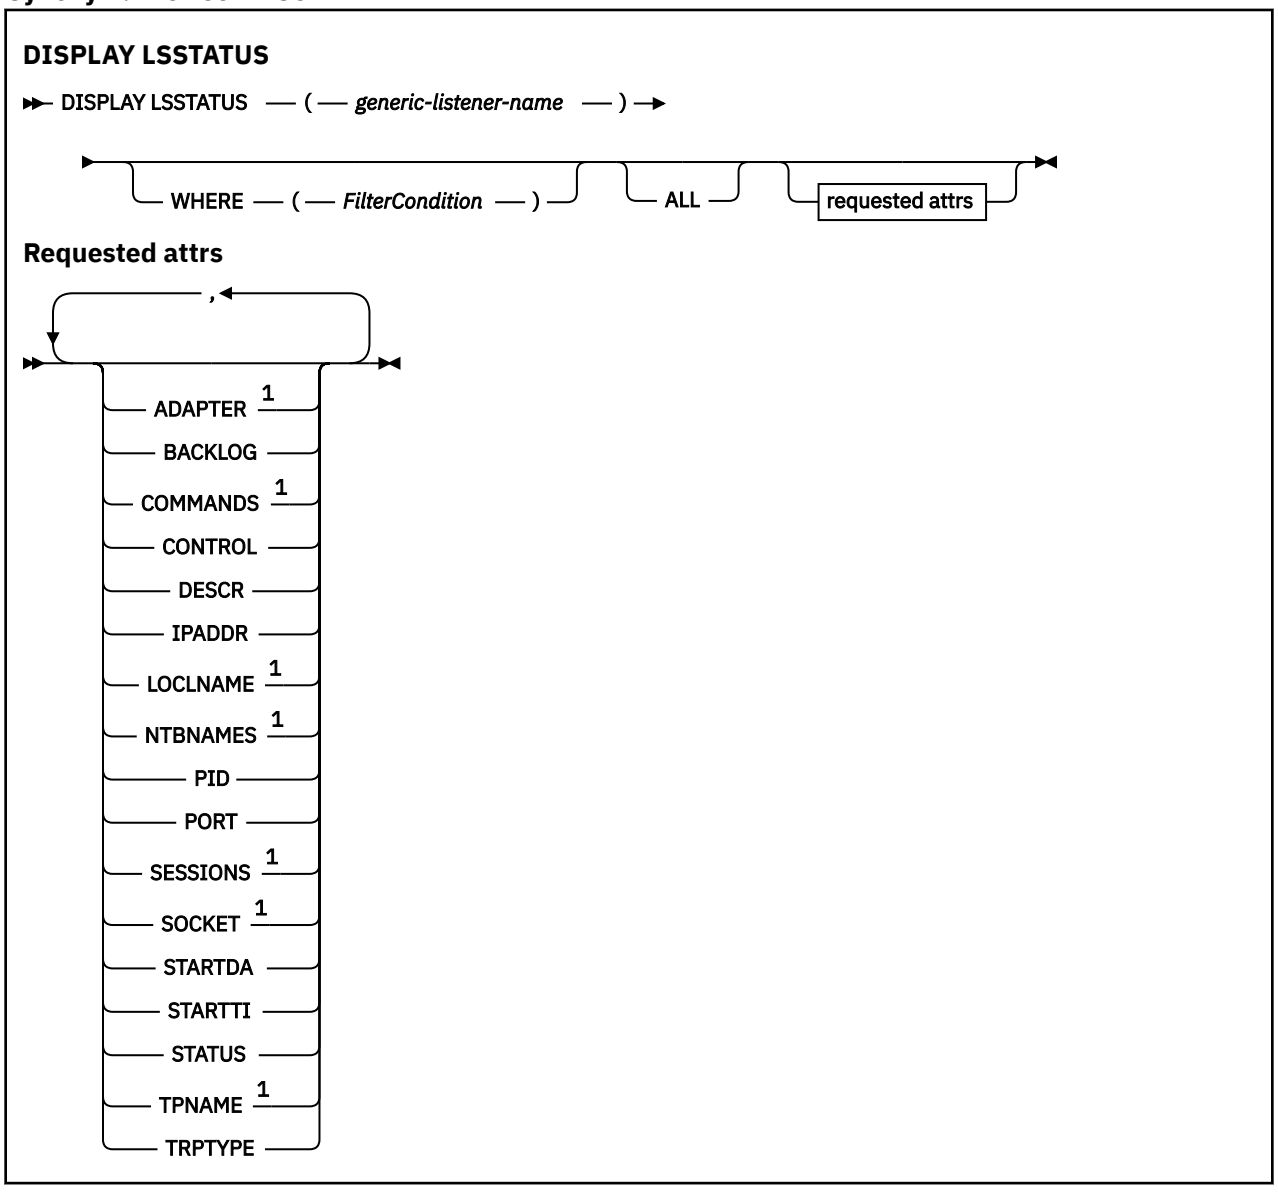
Use the MQSC command DISPLAY LSSTATUS to display status information for one or more listeners.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

- "Keyword and parameter descriptions for DISPLAY LSSTATUS" on page 730
- "Requested parameters" on page 731

Synonym: DIS LSSTATUS



Notes:

[1] Valid only on Windows.

Keyword and parameter descriptions for DISPLAY LSSTATUS

You must specify a listener for which you want to display status information. You can specify a listener by using either a specific listener name or a generic listener name. By using a generic listener name, you can display either:

- Status information for all listener definitions, by using a single asterisk (*), or
- Status information for one or more listeners that match the specified name.

(*generic-listener-name*)
The name of the listener definition for which status information is to be displayed. A single asterisk (*) specifies that information for all connection identifiers is to be displayed. A character string with an asterisk at the end matches all listeners with the string followed by zero or more characters.

WHERE
Specify a filter condition to display information for those listeners that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword
Any parameter that can be used to display attributes for this DISPLAY command.

operator
This is used to determine whether a listener satisfies the filter value on the given filter keyword. The operators are:

LT
Less than

GT
Greater than

EQ
Equal to

NE
Not equal to

LE
Less than or equal to

GE
Greater than or equal to

LK
Matches a generic string that you provide as a *filter-value*

NL
Does not match a generic string that you provide as a *filter-value*

filter-value
The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.
- A generic value. This is a character string. with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed.

  You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

ALL
Display all the status information for each specified listener. This is the default if you do not specify a generic name, and do not request any specific parameters.

Requested parameters

Specify one or more attributes that define the data to be displayed. The attributes can be specified in any order. Do not specify the same attribute more than once.

ADAPTER
The adapter number on which NetBIOS listens.

BACKLOG
The number of concurrent connection requests that the listener supports.

CONTROL
How the listener is to be started and stopped:

MANUAL
The listener is not to be started automatically or stopped automatically. It is to be controlled by use of the START LISTENER and STOP LISTENER commands.

QMGR
The listener being defined is to be started and stopped at the same time as the queue manager is started and stopped.

STARTONLY
The listener is to be started at the same time as the queue manager is started, but is not requested to stop when the queue manager is stopped.

DESCR
Descriptive comment.

IPADDR
The listener's IP address.

LOCLNAME
The NetBIOS local name that the listener uses.

NTBNAMES
The number of names that the listener can use.

PID
The operating system process identifier associated with the listener.

PORT
The port number for TCP/IP.

SESSIONS
The number of sessions that the listener can use.

SOCKET
SPX socket.

STARTDA
The date on which the listener was started.

STARTTI
The time at which the listener was started.

STATUS
The current status of the listener. It can be one of:

RUNNING
The listener is running.

STARTING
The listener is in the process of initializing.

STOPPING
The listener is stopping.

TPNAME
The LU6.2 transaction program name.

TRPTYPE
Transport type.

For more information on these parameters, see "DEFINE LISTENER (define a new listener) on Multiplatforms" on page 512.

z/OS DISPLAY MAXSMSGS (display maximum messages setting) on z/OS

Use the MQSC command DISPLAY MAXSMSGS to see the maximum number of messages that a task can get or put within a single unit of recovery.

Using MQSC commands

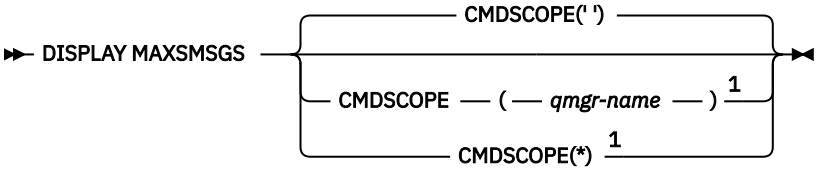
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Usage notes" on page 732
- "Parameter descriptions for DISPLAY MAXSMSGS" on page 732

Synonym: DIS MAXSM

DISPLAY MAXSMSGS



Notes:

1 Valid only on full function IBM MQ for z/OS when the queue manager is a member of a queue sharing group.

Usage notes

This command is valid only on z/OS and is retained for compatibility with earlier releases, although it can no longer be issued from the CSQINP1 initialization data set. You should use the MAXUMSGS parameter of the DISPLAY QMGR command instead.

Parameter descriptions for DISPLAY MAXSMSGS

CMDSCOPE
This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

DISPLAY NAMELIST (display a list of names)

Use the MQSC command DISPLAY NAMELIST to display the names in a namelist.

Using MQSC commands

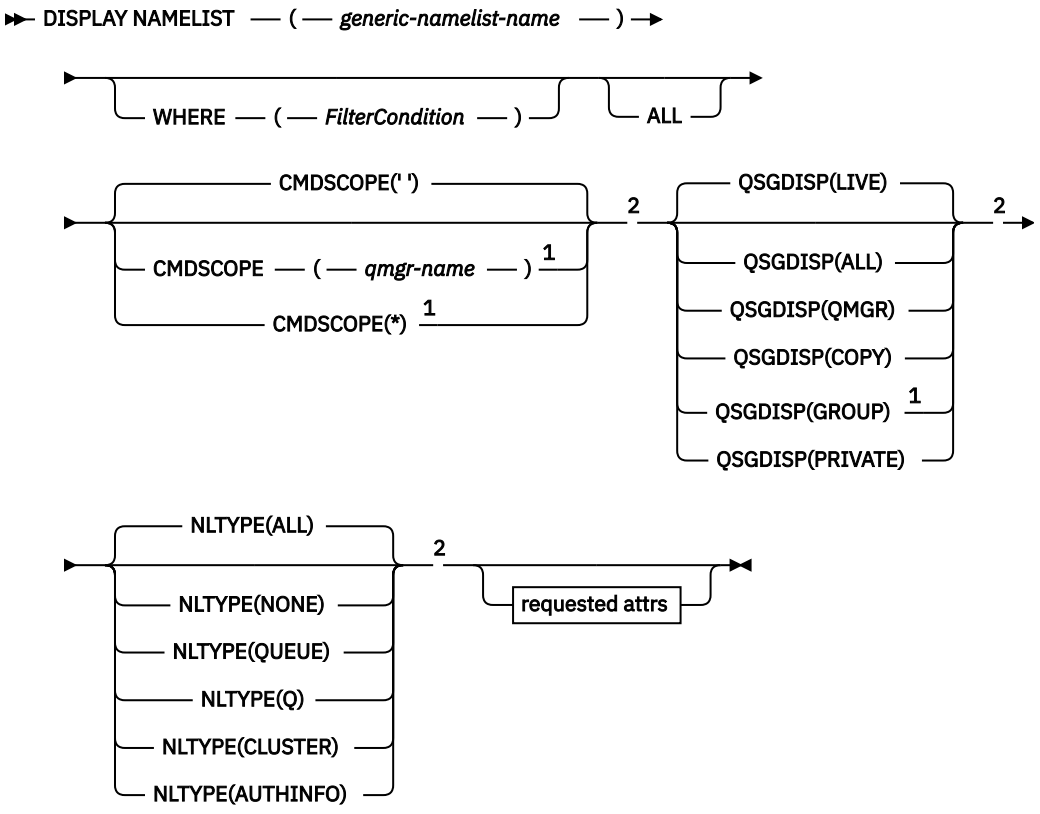
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

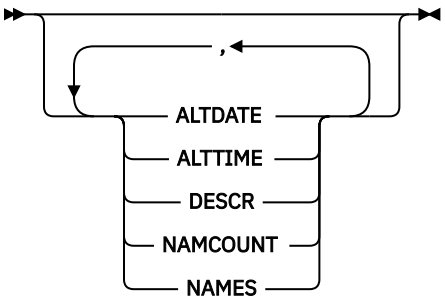
- Syntax diagram
- "Parameter descriptions for DISPLAY NAMELIST" on page 734
- "Requested parameters" on page 737

Synonym: DIS NL

DISPLAY NAMELIST



Requested attrs



Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[2] Valid only on z/OS.

Parameter descriptions for DISPLAY NAMELIST

You must specify the name of the namelist definition you want to display. This can be a specific namelist name or a generic namelist name. By using a generic namelist name, you can display either:

- All namelist definitions
- One or more namelists that match the specified name

(*generic-namelist-name*)
The name of the namelist definition to be displayed (see Rules for naming IBM MQ objects). A trailing asterisk (*) matches all namelists with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all namelists.

WHERE
Specify a filter condition to display only those namelists that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword
Almost any parameter that can be used to display attributes for this DISPLAY command. However, you cannot use the CMDSCOPE or QSGDISP parameters as filter keywords. You cannot use NLTYPE as a filter keyword if you also use it to select namelists.

operator
This is used to determine whether a namelist satisfies the filter value on the given filter keyword. The operators are:

LT
Less than

GT
Greater than

EQ
Equal to

NE
Not equal to

LE
Less than or equal to

GE
Greater than or equal to

LK
Matches a generic string that you provide as a *filter-value*

NL
Does not match a generic string that you provide as a *filter-value*

CT
Contains a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which contain the specified item.

EX
Does not contain a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which do not contain the specified item.

CTG
Contains an item which matches a generic string that you provide as a *filter-value*. If the *filter-keyword* is a list, you can use this to display objects the attributes of which match the generic string.

EXG
Does not contain any item which matches a generic string that you provide as a *filter-value*. If the *filter-keyword* is a list, you can use this to display objects the attributes of which do not match the generic string.

filter-value
The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

  You can use operators LT, GT, EQ, NE, LE or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value NONE on the NLTYPE parameter), you can only use EQ or NE.
- A generic value. This is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC*. The characters must be valid for the attribute you are testing. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

  You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.
- An item in a list of values. The value can be explicit or, if it is a character value, it can be explicit or generic. If it is explicit, use CT or EX as the operator. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed. If it is generic, use CTG or EXG as the operator. If ABC* is specified with the operator CTG, all items where one of the attribute values begins with ABC are listed.

ALL
Specify this to display all the parameters. If this parameter is specified, any parameters that are requested specifically have no effect; all the parameters are displayed.

This is the default if you do not specify a generic name, and do not request any specific parameters.

z/OS On z/OS this is also the default if you specify a filter condition using the WHERE parameter, but on other platforms only requested attributes are displayed.

z/OS **CMDSCOPE**
This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

z/OS **QSGDISP**

Specifies the disposition of the objects for which information is to be displayed. Values are:

LIVE
This is the default value and displays information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

ALL
Displays information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

If there is a shared queue manager environment, and the command is being executed on the queue manager where it was issued, this option also displays information for objects defined with QSGDISP(GROUP).

If QSGDISP(ALL) is specified in a shared queue manager environment, the command might give duplicated names (with different dispositions).

In a shared queue manager environment, use

```
DISPLAY NAMELIST(name) CMDSCOPE(*) QSGDISP(ALL)
```

to list ALL objects matching

```
name
```

in the queue sharing group without duplicating those in the shared repository.

COPY
Display information only for objects defined with QSGDISP(COPY).

GROUP
Display information only for objects defined with QSGDISP(GROUP). This is allowed only if there is a shared queue manager environment.

PRIVATE
Display information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY). Note that QSGDISP(PRIVATE) displays the same information as QSGDISP(LIVE).

QMGR
Display information only for objects defined with QSGDISP(QMGR).

QSGDISP displays one of the following values:

QMGR
The object was defined with QSGDISP(QMGR).

GROUP
The object was defined with QSGDISP(GROUP).

COPY
The object was defined with QSGDISP(COPY).

You cannot use QSGDISP as a filter keyword.

z/OS **NLTYPE**

Indicates the type of namelist to be displayed.

This parameter is valid only on z/OS.

ALL
Displays namelists of all types. This is the default.

NONE
Displays namelists of type NONE.

QUEUE or Q
Displays namelists that hold lists of queue names.

CLUSTER
Displays namelists that are associated with clustering.

AUTHINFO
Displays namelists that contain lists of authentication information object names.

Requested parameters

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

The default, if no parameters are specified (and the ALL parameter is not specified) is that the object names, and, on z/OS, their NLTYPEs and QSGDISP are displayed.

ALTDATE
The date on which the definition was last altered, in the form `yyyy-mm-dd`

ALTTIME
The time at which the definition was last altered, in the form `hh.mm.ss`

DESCR
Description

NAMCOUNT
Number of names in the list

NAMES
List of names

See "DEFINE NAMELIST (define a list of names)" on page 518 for more information about the individual parameters.

Multi DISPLAY POLICY (display a security policy) on Multiplatforms

Use the MQSC command DISPLAY POLICY to display a security policy.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

- Syntax diagram
- "Parameter descriptions for DISPLAY POLICY" on page 737

DISPLAY POLICY

Parameter descriptions for DISPLAY POLICY

(policy-name)
Specifies the policy name to be displayed.

The name of the policy to display is the same as the name of the queue that the policy controls. You can specify an asterisk to display all policy names.

Note: *policy-name* does not support wildcard characters to return multiple policies.

Display policy behavior with specific policy names

When executing a **DISPLAY POLICY** command for a specific policy, for example `DISPLAY POLICY(QUEUE.1)`, a policy object is always returned even if one does not exist. When a policy object does not exist, the policy object returned is a default policy object that specifies plain text protection, that is, no signing or encryption of message data.

To view policy objects that exist, a `DISPLAY POLICY(*)` command must be run. This command returns all policy objects that exist.

Related reference

"SET POLICY (set security policy) on Multiplatforms" on page 915
Use the MQSC command SET POLICY to set a security policy.

"setmqspl (set security policy)" on page 201
Use the **setmqspl** command to define a new security policy, replace an already existing one, or remove an existing policy.

"dspmqspl (display security policy)" on page 88
Use the **dspmqspl** command to display a list of all policies and details of a named policy.

Managing security policies in AMS

DISPLAY PROCESS (display process information)

Use the MQSC command DISPLAY PROCESS to display the attributes of one or more IBM MQ processes.

Using MQSC commands

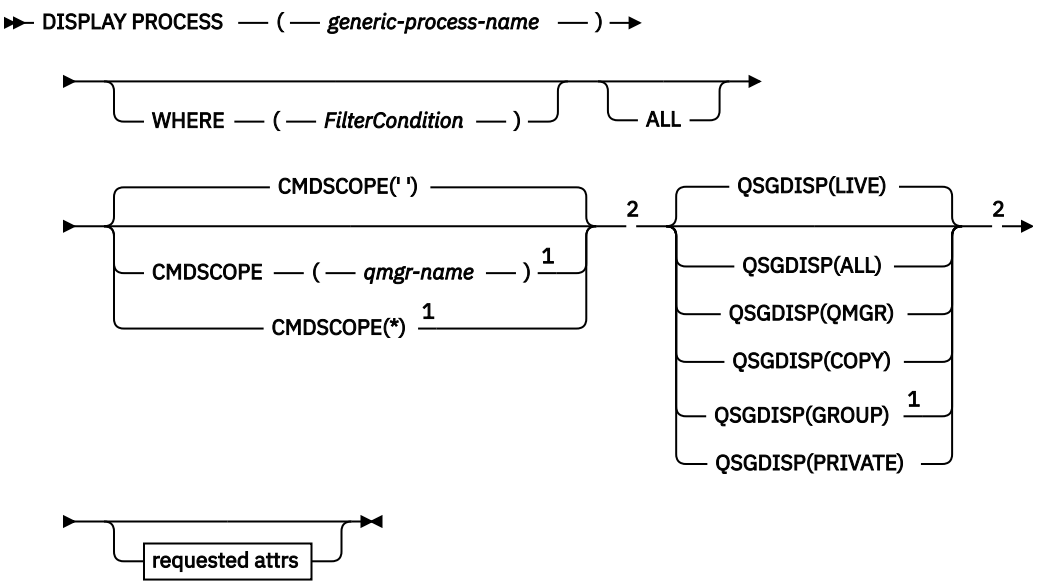
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

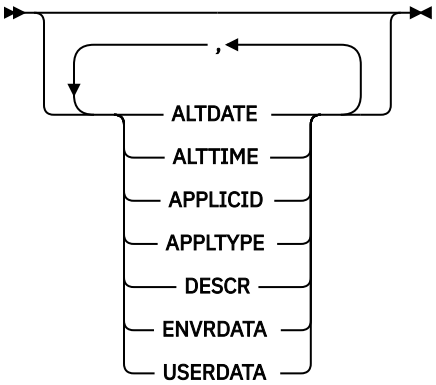
- Syntax diagram
- "Parameter descriptions for DISPLAY PROCESS" on page 739
- "Requested parameters" on page 742

Synonym: DIS PRO

DISPLAY PROCESS



Requested attrs



Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[2] Valid only on z/OS.

Parameter descriptions for DISPLAY PROCESS

You must specify the name of the process you want to display. This can be a specific process name or a generic process name. By using a generic process name, you can display either:

- All process definitions
- One or more processes that match the specified name

(generic-process-name)
The name of the process definition to be displayed (see Rules for naming IBM MQ objects). A trailing asterisk (*) matches all processes with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all processes. The names must all be defined to the local queue manager.

WHERE
Specify a filter condition to display only those process definitions that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword
Almost any parameter that can be used to display attributes for this DISPLAY command.

z/OS However, on z/OS, you cannot use the CMDSCOPE or QSGDISP parameters as filter keywords.

operator
This is used to determine whether a process definition satisfies the filter value on the given filter keyword. The operators are:

LT
Less than

GT
Greater than

EQ
Equal to

NE
Not equal to

LE
Less than or equal to

GE
Greater than or equal to

LK
Matches a generic string that you provide as a *filter-value*

NL
Does not match a generic string that you provide as a *filter-value*

filter-value
The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

  You can use operators LT, GT, EQ, NE, LE or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value DEF on the APPLTYPE parameter), you can only use EQ or NE.
- A generic value. This is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

ALL
Specify this to display all the parameters. If this parameter is specified, any parameters that are requested specifically have no effect; all parameters are still displayed.

On the following platforms, this is the default if you do not specify a generic name and do not request any specific parameters:

- AIX AIX
- IBM i IBM i
- Linux Linux
- Windows Windows
- z/OS z/OS

z/OS On z/OS this is also the default if you specify a filter condition using the WHERE parameter, but on other platforms only requested attributes are displayed.

z/OS **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' '

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

You cannot use CMDSCOPE as a filter keyword.

z/OS **QSGDISP**

Specifies the disposition of the objects for which information is to be displayed. Values are:

LIVE

This is the default value and displays information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

ALL

Displays information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

If there is a shared queue manager environment, and the command is being executed on the queue manager where it was issued, this option also displays information for objects defined with QSGDISP(GROUP).

If QSGDISP(LIVE) is specified or defaulted, or if QSGDISP(ALL) is specified in a shared queue manager environment, the command might give duplicated names (with different dispositions).

COPY

Display information only for objects defined with QSGDISP(COPY).

GROUP

Display information only for objects defined with QSGDISP(GROUP). This is allowed only if there is a shared queue manager environment.

PRIVATE

Display information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY). Note that QSGDISP(PRIVATE) displays the same information as QSGDISP(LIVE).

QMGR

Display information only for objects defined with QSGDISP(QMGR).

QSGDISP displays one of the following values:

QMGR

The object was defined with QSGDISP(QMGR).

GROUP

The object was defined with QSGDISP(GROUP).

COPY

The object was defined with QSGDISP(COPY).

You cannot use QSGDISP as a filter keyword.

Requested parameters

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

The default, if no parameters are specified and the **ALL** parameter is not specified, is that:

- Multi On Multiplatforms, that is, on platforms other than z/OS, the object names are displayed.
- z/OS On z/OS only, the object names and QSGDISP are displayed.

ALTDATE
The date on which the definition was last altered, in the form `yyyy-mm-dd`

ALTTIME
The time at which the definition was last altered, in the form `hh.mm.ss`

APPLICID
Application identifier

APPLTYPE
Application type. In addition to the values listed for this parameter in "Parameter descriptions for DEFINE PROCESS" on page 523, the value SYSTEM can be displayed. This indicates that the application type is a queue manager.

DESCR
Description

ENVRDATA
Environment data

USERDATA
User data

See "DEFINE PROCESS (create a new process definition)" on page 522 for more information about individual parameters.

DISPLAY PUBSUB (display publish/subscribe status information)

Use the MQSC command DISPLAY PUBSUB to display publish/subscribe status information for a queue manager.

Using MQSC commands

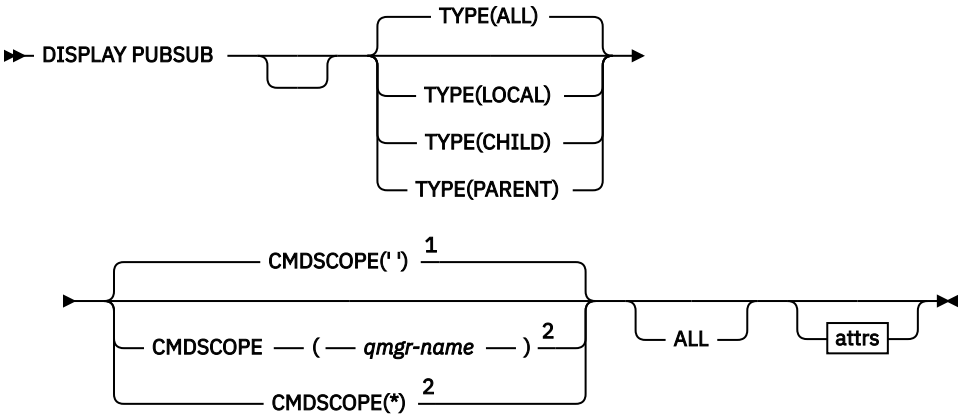
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

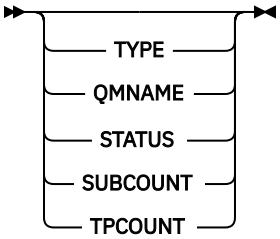
- Syntax diagram
- "Parameter descriptions for DISPLAY PUBSUB" on page 743
- "Returned parameters" on page 744

Synonym: None

DISPLAY PUBSUB



Attrs



Notes:

1 Valid only on z/OS.
2 Valid only on z/OS when the queue manager is a member of a queue sharing group.

Parameter descriptions for DISPLAY PUBSUB

TYPE
The type of publish/subscribe connections.

ALL
Display the publish/subscribe status for this queue manager and for parent and child hierarchical connections.

CHILD
Display the publish/subscribe status for child connections.

LOCAL
Display the publish/subscribe status for this queue manager.

PARENT
Display the publish/subscribe status for the parent connection.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

You cannot use CMDSCOPE as a filter keyword.

Returned parameters

A group of parameters is returned, containing the attributes TYPE, QMNAME, STATUS, SUBCOUNT, and TPCOUNT. This group is returned for the current queue manager if you set TYPE to LOCAL or ALL, for the parent queue manager if you set TYPE to PARENT or ALL, and for each child queue manager if you set TYPE to CHILD or ALL.

TYPE

CHILD
A child connection.

LOCAL
Information for this queue manager.

PARENT
The parent connection.

QMNAME
The name of the current queue manager or the remote queue manager connected as a parent or a child.

STATUS
The status of the publish/subscribe engine or the hierarchical connection. The publish/subscribe engine is initializing and is not yet operational. If the queue manager is a member of a cluster (has at least one CLUSRCVR defined), it remains in this state until the cluster cache is available.

z/OS On IBM MQ for z/OS, this requires that the Channel Initiator is running.

When TYPE is CHILD, the following values can be returned:

ACTIVE
The connection with the child queue manager is active.

ERROR
This queue manager is unable to initialize a connection with the child queue manager because of a configuration error. A message is produced in the queue manager logs to indicate the specific error. If you receive error message AMQ5821 or on z/OS systems CSQT821E, possible causes include:

- Transmit queue is full.
- Transmit queue put is disabled.

If you receive error message AMQ5814 or on z/OS systems CSQT814E, take the following actions:

- Check that the child queue manager is correctly specified.
- Ensure that broker is able to resolve the queue manager name of the child broker.

To resolve the queue manager name, at least one of the following resources must be configured:

- A transmission queue with the same name as the child queue manager name.
- A queue manager alias definition with the same name as the child queue manager name.
- A cluster with the child queue manager a member of the same cluster as this queue manager.

- A cluster queue manager alias definition with the same name as the child queue manager name.
- A default transmission queue.

After you have set up the configuration correctly, modify the child queue manager name to blank. Then set with the child queue manager name.

STARTING
Another queue manager is attempting to request that this queue manager become its parent.

If the child status remains in STARTING without progressing to ACTIVE, take the following actions:

- Check that the sender channel to child queue manager is running
- Check that the receiver channel from child queue manager is running

STOPPING
The queue manager is disconnecting.

If the child status remains in STOPPING, take the following actions:

- Check that the sender channel to child queue manager is running
- Check that the receiver channel from child queue manager is running

When TYPE is LOCAL, the following values can be returned:

ACTIVE
The publish/subscribe engine and the queued publish/subscribe interface are running. It is therefore possible to publish or subscribe using the application programming interface and the queues that are monitored by the queued publish/subscribe interface.

COMPAT
The publish/subscribe engine is running. It is therefore possible to publish or subscribe by using the application programming interface. The queued publish/subscribe interface is not running. Therefore, any message that is put to the queues that are monitored by the queued publish/subscribe interface are not acted upon by IBM MQ.

ERROR
The publish/subscribe engine has failed. Check your error logs to determine the reason for the failure.

INACTIVE
The publish/subscribe engine and the queued publish/subscribe interface are not running. It is therefore not possible to publish or subscribe using the application programming interface. Any publish/subscribe messages that are put to the queues that are monitored by the queued publish/subscribe interface are not acted upon by IBM MQ.

If inactive and you want to start the publish/subscribe engine use the command **ALTER QMGR PSMODE(ENABLED)**.

STARTING
The publish/subscribe engine is initializing and is not yet operational. If the queue manager is a member of a cluster, that is, it has at least one CLUSRCVR defined, it remains in this state until the cluster cache is available.

z/OS On IBM MQ for z/OS, this requires that the Channel Initiator is running.

STOPPING
The publish/subscribe engine is stopping.

When TYPE is PARENT, the following values can be returned:

ACTIVE
The connection with the parent queue manager is active.

ERROR
This queue manager is unable to initialize a connection with the parent queue manager because of a configuration error. A message is produced in the queue manager logs to indicate the specific

error. If you receive error message AMQ5821, z/OS or on z/OS systems CSQT821E, possible causes include:

- Transmit queue is full.
- Transmit queue put is disabled.

If you receive error message AMQ5814, z/OS or error message CSQT814E on z/OS systems, take the following actions:

- Check that the parent queue manager is correctly specified.
- Ensure that broker is able to resolve the queue manager name of the parent broker.

To resolve the queue manager name, at least one of the following resources must be configured:

- A transmission queue with the same name as the parent queue manager name.
- A queue manager alias definition with the same name as the parent queue manager name.
- A cluster with the parent queue manager a member of the same cluster as this queue manager.
- A cluster queue manager alias definition with the same name as the parent queue manager name.
- A default transmission queue.

After you have set up the configuration correctly, modify the parent queue manager name to blank. Then set with the parent queue manager name.

REFUSED
The connection has been refused by the parent queue manager. This might be caused by the following:

- The parent queue manager already has a child queue manager with the same name as this queue manager.
- The parent queue manager has used the command RESET QMGR TYPE(PUBSUB) CHILD to remove this queue manager as one of its children.

STARTING
The queue manager is attempting to request that another queue manager become its parent.

If the parent status remains in STARTING without progressing to ACTIVE, take the following actions:

- Check that the sender channel to parent queue manager is running
- Check that the receiver channel from parent queue manager is running

STOPPING
The queue manager is disconnecting from its parent.

If the parent status remains in STOPPING, take the following actions:

- Check that the sender channel to parent queue manager is running
- Check that the receiver channel from parent queue manager is running

SUBCOUNT
When TYPE is LOCAL, the total number of subscriptions against the local tree is returned. When TYPE is CHILD or PARENT, queue manager relations are not inquired and the value NONE is returned.

TPCOUNT
When TYPE is LOCAL, the total number of topic nodes in the local tree is returned. When TYPE is CHILD or PARENT, queue manager relations are not inquired and the value NONE is returned.

DISPLAY QMGR (display queue manager settings)

Use the MQSC command **DISPLAY QMGR** to display the queue manager parameters for this queue manager.

Using MQSC commands

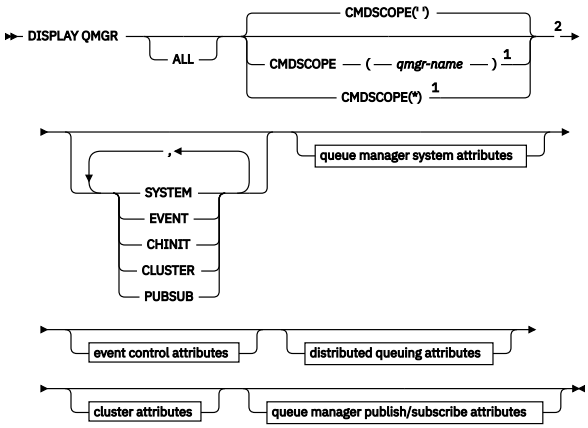
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

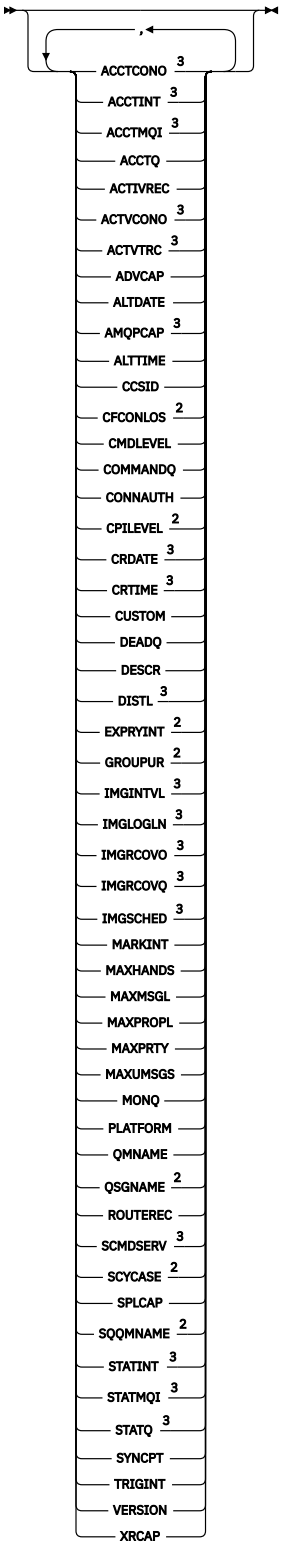
- Syntax diagram
- "Parameter descriptions for DISPLAY QMGR" on page 751
- "Requested parameters" on page 752

Synonym: **DIS QMGR**

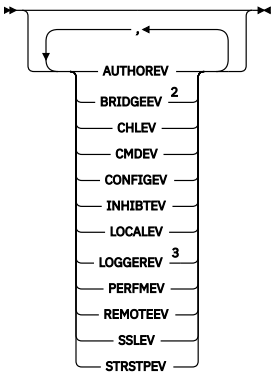
DISPLAY QMGR



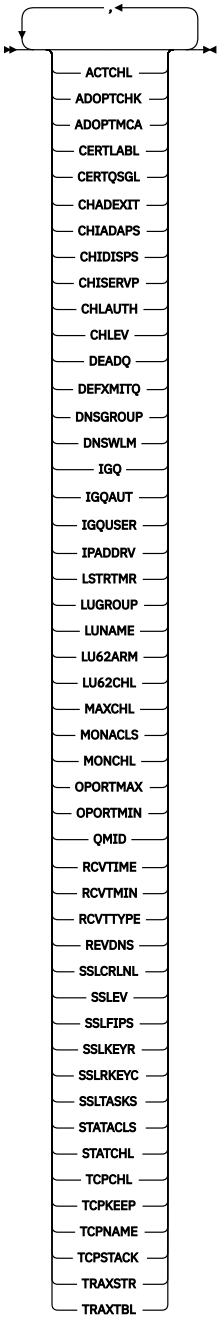
Queue manager system attributes



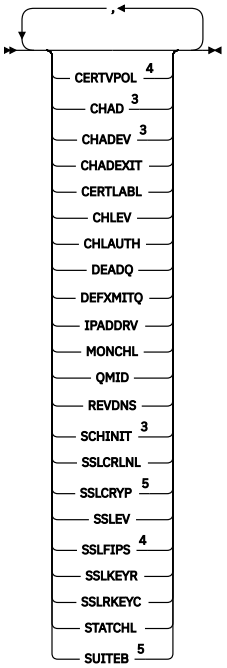
Event control attributes



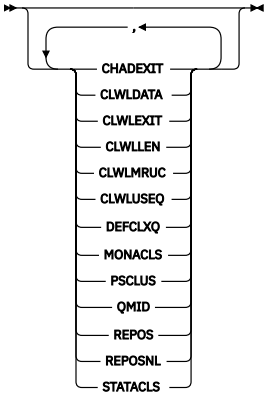
Distributed queuing attributes for z/OS



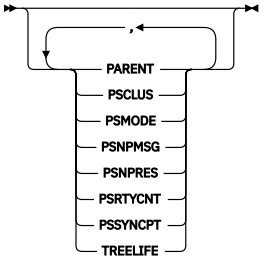
Distributed queuing attributes for other platforms



Cluster attributes



Queue manager publish/subscribe attributes



Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[2] Valid only on z/OS.
[3] Not valid on z/OS.
[4] Not valid on IBM i.
[5] Valid only on AIX, Linux, and Windows.

Parameter descriptions for DISPLAY QMGR

ALL
Specify this parameter to display all the parameters. If this parameter is specified, any parameters that are requested specifically are ineffective; all parameters are still displayed.

Multi On Multiplatforms, this parameter is the default if you do not request any specific parameters.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

' '
The command runs on the queue manager on which it was entered. This command is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of running this command is the same as entering the command on every queue manager in the queue sharing group.

SYSTEM
Specify this parameter to display the set of queue manager system attributes that are available in the Queue manager system attrs list. See "Requested parameters" on page 752 for information about these parameters.

If you specify this parameter, any request you make to display individual parameters within this set is ineffective.

EVENT
Specify this parameter to display the set of event control attributes that are available in the Event control attrs list. See "Requested parameters" on page 752 for information about these parameters.

If you specify this parameter, any request you make to display individual parameters within this set is ineffective.

CHINIT
Specify this parameter to display the set of attributes relating to distributed queuing that are available in the Distributed queuing attrs list. You can also specify DQM to display the same set of attributes. See "Requested parameters" on page 752 for information about these parameters.

If you specify this parameter, any request you make to display individual parameters within this set is ineffective.

CLUSTER
Specify this parameter to display the set of attributes relating to clustering that are available in the Cluster attrs list. See "Requested parameters" on page 752 for information about these parameters.

If you specify this parameter, any request you make to display individual parameters within this set is ineffective.

PUBSUB
Specify this parameter to display the set of attributes relating to publish/subscribe that are available in the Queue manager pub/sub attrs list. See "Requested parameters" on page 752 for information about these parameters.

If you specify this parameter, any request you make to display individual parameters within this set is ineffective.

Requested parameters

Note: If no parameters are specified (and the **ALL** parameter is not specified or defaulted), the queue manager name is returned.

You can request the following information for the queue manager:

Multi **ACCTCONO**
Whether the settings of the **ACCTQMQI** and **ACCTQ** queue manager parameters can be overridden. This parameter is valid only on Multiplatforms.

Multi **ACCTINT**
The interval at which intermediate accounting records are written. This parameter is valid only on Multiplatforms.

Multi **ACCTMQI**
Whether accounting information is to be collected for MQI data. This parameter is valid only on Multiplatforms.

ACCTQ
Whether accounting data collection is to be enabled for queues.

z/OS **ACTCHL**
The maximum number of channels that can be active at any time.

This parameter is valid only on z/OS.

ACTIVREC
Whether activity reports are to be generated if requested in the message.

Multi **ACTVCONO**
Whether the settings of the **ACTVTRC** queue manager parameter can be overridden. This parameter is valid only on Multiplatforms.

Multi **ACTVTRC**
Whether IBM MQ MQI application activity tracing information is to be collected. See Setting ACTVTRC to control collection of activity trace information. This parameter is valid only on Multiplatforms.

z/OS **ADOPTCHK**
Which elements are checked to determine whether an MCA is adopted when a new inbound channel is detected with the same name as an already active MCA.

This parameter is valid only on z/OS.

z/OS **ADOPTMCA**
Whether an orphaned MCA instance is to be restarted when a new inbound channel request matching the **ADOPTCHK** parameters is detected.

This parameter is valid only on z/OS.

MQ Adv. **ADVCAP**
Whether IBM MQ Advanced extended capabilities are available for a queue manager.

z/OS On z/OS, the queue manager sets the value to be ENABLED, only if the value of **QMGRPROD** is ADVANCEDVUE. For any other value of **QMGRPROD**, or if **QMGRPROD** is not set, the queue manager sets the value to DISABLED. If **ADVCAP** is ENABLED you must be entitled to IBM MQ Advanced for z/OS Value Unit Edition (VUE). See “START QMGR (start queue manager) on z/OS” on page 929 and Installing IBM MQ Advanced for z/OS Value Unit Edition for more information.

Multi On other platforms, the queue manager sets the value to be ENABLED, only if you have installed Managed File Transfer, XR, Advanced Message Security or RDQM. If you have not installed Managed File Transfer, XR, Advanced Message Security or RDQM, **ADVCAP** is set to DISABLED. If **ADVCAP** is ENABLED, you must be entitled to IBM MQ Advanced. The list of installable components that enable **ADVCAP** might change in future releases. for more information, see IBM MQ components and features and Installing IBM MQ Advanced for Multiplatforms.

ALTDATE
The date on which the definition was last altered, in the form *yyyy-mm-dd*.

ALTTIME
The time at which the definition was last altered, in the form *hh.mm.ss*.

AMQPCAP
Whether AMQP capabilities are available for a queue manager.

AUTHOREV
Whether authorization events are generated.

z/OS **BRIDGEEV**
On z/OS only, whether IMS bridge events are generated.

CCSID
Coded character set identifier. This parameter applies to all character string fields defined by the application programming interface (API), including the names of objects, and the creation date and time of each queue. It does not apply to application data carried as the text of messages.

CERTLABL
Specifies the certificate label that this queue manager used.

z/OS **CERTQSGL**
Specifies the queue sharing group (QSG) certificate label.

This parameter is valid only on z/OS.

ALW **CERTVPOL**
Specifies which TLS certificate validation policy is used to validate digital certificates received from remote partner systems. This attribute can be used to control how strictly the certificate chain validation conforms to industry security standards. For more information about certificate validation policies, see Certificate validation policies in IBM MQ.

This parameter is valid only on AIX, Linux, and Windows.

z/OS **CFCONLOS**
Specifies the action to be taken when the queue manager loses connectivity to the administration structure, or any CF structure with **CFCONLOS** set to ASQMGR.

This parameter is valid only on z/OS.

Multi **CHAD**
Whether auto-definition of receiver and server-connection channels is enabled.

z/OS This parameter is not valid on z/OS.

Multi **CHADEV**
Whether auto-definition events are enabled.

z/OS This parameter is not valid on z/OS.

CHADEXIT
The name of the channel auto-definition exit.

z/OS **CHIADAPS**
The number of adapter subtasks to use to process IBM MQ calls.

This parameter is valid only on z/OS.

z/OS **CHIDISPS**
The number of dispatchers to use for the channel initiator.

This parameter is valid only on z/OS.

CHISERVP
This field is reserved for IBM use only.

CHLAUTH
Whether channel authentication records are checked.

CHLEV
Whether channel events are generated.

CLWLEXIT
The name of the cluster workload exit.

CLWLDATA
The data passed to the cluster workload exit.

CLWLLEN
The maximum number of bytes of message data that is passed to the cluster workload exit.

CLWLMRUC
The maximum number of outbound cluster channels.

CLWLUSEQ
The behavior of MQPUTs for queues where **CLWLUSEQ** has a value of QMGR.

CMDEV
Whether command events are generated.

CMDLEVEL
Command level. This indicates the level of system control commands supported by the queue manager.

COMMANDQ
The name of the system-command input queue. Suitably authorized applications can put commands on this queue.

CONFIGEV
Whether configuration events are generated.

CONNAUTH
The name of an authentication information object that is used to provide the location of user ID and password authentication.

CPILEVEL
Reserved, this value has no significance.

CRDATE
The date on which the queue manager was created (in the form *yyyy-mm-dd*).

CRTIME
The time at which the queue manager was created (in the form *hh.mm.ss*).

CUSTOM
This attribute is reserved for the configuration of new features before separate attributes have been introduced. It can contain the values of zero or more attributes as pairs of attribute name and value in the form NAME(VALUE).

DEADQ
The name of the queue to which messages are sent if they cannot be routed to their correct destination (the dead-letter queue or undelivered-message queue). The default is blanks.

For example, messages are put on this queue when:

- A message arrives at a queue manager, destined for a queue that is not yet defined on that queue manager

- A message arrives at a queue manager, but the queue for which it is destined cannot receive it because, possibly:
  - The queue is full
  - The queue is inhibited for puts
  - The sending node does not have authority to put the message on the queue
- An exception message must be generated, but the queue named is not known to that queue manager

Note: Messages that have passed their expiry time are not transferred to this queue when they are discarded.

If the dead-letter queue is not defined, or full, or unusable for some other reason, a message that would have been transferred to it by a message channel agent is retained instead on the transmission queue.

If a dead-letter queue or undelivered-message queue is not specified, all blanks are returned for this parameter.

DEFCLXQ
The **DEFCLXQ** attribute controls which transmission queue is selected by default by cluster-sender channels to get messages from, to send the messages to cluster-receiver channels.

SCTQ

All cluster-sender channels send messages from `SYSTEM.CLUSTER.TRANSMIT.QUEUE`. The `correlID` of messages placed on the transmission queue identifies which cluster-sender channel the message is destined for.

`SCTQ` is set when a queue manager is defined. This behavior is implicit in versions of IBM WebSphere MQ, earlier than IBM WebSphere MQ 7.5. In earlier versions, the queue manager attribute **DEFCLXQ** was not present.

CHANNEL
Each cluster-sender channel sends messages from a different transmission queue. Each transmission queue is created as a permanent dynamic queue from the model queue `SYSTEM.CLUSTER.TRANSMIT.MODEL.QUEUE`.

If the queue manager attribute, **DEFCLXQ**, is set to `CHANNEL`,the default configuration is changed to cluster-sender channels being associated with individual cluster transmission queues. The transmission queues are permanent-dynamic queues created from the model queue `SYSTEM.CLUSTER.TRANSMIT.MODEL.QUEUE`. Each transmission queue is associated with one cluster-sender channel. As one cluster-sender channel services a cluster transmission queue, the transmission queue contains messages for only one queue manager in one cluster. You can configure clusters so that each queue manager in a cluster contains only one cluster queue. In this case, the message traffic from a queue manager to each cluster queue is transferred separately from messages to other queues.

DEFXMITQ
Default transmission queue name. This parameter is the transmission queue on which messages, destined for a remote queue manager, are put if there is no other suitable transmission queue defined.

DESCR
Description.

DISTL
Whether distribution lists are supported by the queue manager.

This parameter is not valid on z/OS.

DNSGROUP
This parameter is no longer used. See z/OS: WLM/DNS no longer supported. This parameter is valid only on z/OS

z/OS **DNSWLM**
This parameter is no longer used. See z/OS: WLM/DNS no longer supported. This parameter is valid only on z/OS.

z/OS **EXPRYINT**
On z/OS only, the approximate interval between scans for expired messages.

z/OS **GROUPUR**
On z/OS only, whether XA client applications are allowed to connect to this queue manager with a GROUP unit of recovery disposition.

IMGINTVL
The target frequency with which the queue manager automatically writes media images.

z/OS This parameter is not valid on z/OS.

IMGLOGLN
The target amount of recovery log written by which the queue manager automatically writes media images.

z/OS This parameter is not valid on z/OS.

IMGRCOVO
Whether specified objects are recoverable from a media image, if linear logging is being used.

z/OS This parameter is not valid on z/OS.

IMGRCOVQ
Whether a local or permanent dynamic queue object is recoverable from a media image, if linear logging is being used.

z/OS This parameter is not valid on z/OS.

IMGSCHED
Whether the queue manager automatically writes media images.

z/OS This parameter is not valid on z/OS.

z/OS **IGQ**
On z/OS only, whether intra-group queuing is to be used.

z/OS **IGQAUT**
On z/OS only, displays the type of authority checking used by the intra-group queuing agent.

z/OS **IGQUSER**
On z/OS only, displays the user ID used by the intra-group queuing agent.

INHIBTEV
Whether inhibit events are generated.

IPADDRV
Whether to use an IPv4 or IPv6 IP address for a channel connection in ambiguous cases.

LOCALEV
Whether local error events are generated.

Multi **LOGGEREV**
Whether recovery log events are generated. This parameter is valid only on Multiplatforms.

z/OS **LSTRTMR**
The time interval, in seconds, between attempts by IBM MQ to restart the listener after an APPC or TCP/IP failure.

This parameter is valid only on z/OS.

z/OS **LUGROUP**
The generic LU name to be used by the LU 6.2 listener that handles inbound transmissions for the queue sharing group.

This parameter is valid only on z/OS.

z/OS **LUNAME**
The name of the LU to use for outbound LU 6.2 transmissions.

This parameter is valid only on z/OS.

z/OS **LU62ARM**
The suffix of the APPCPM member of SYS1.PARMLIB. This suffix nominates the LUADD for this channel initiator. When automatic restart manager (ARM) restarts the channel initiator, the z/OS command SET APPC= xx is issued.

This parameter is valid only on z/OS.

z/OS **LU62CHL**
The maximum number of channels that can be current, or clients that can be connected, that use the LU 6.2 transmission protocol. If the value of LU62CHL is zero, the LU 6.2 transmission protocol is not used.

This parameter is valid only on z/OS.

MARKINT
The mark browse interval in milliseconds.

Attention: This value should not be below the default of 5000.

z/OS **MAXCHL**
The maximum number of channels that can be current (including server-connection channels with connected clients).

This parameter is valid only on z/OS.

MAXHANDS
The maximum number of open handles that any one connection can have at any one time.

MAXMSGL
The maximum message length that can be handled by the queue manager. Individual queues or channels might have a smaller maximum than the value of this parameter.

MAXPROPL (*integer*)
The maximum length of property data in bytes that can be associated with a message.

MAXPRTY
The maximum priority. This value is 9.

MAXUMSGS
Maximum number of uncommitted messages within one sync point. The default value is 10000.

MAXUMSGS has no effect on MQ Telemetry. MQ Telemetry tries to batch requests to subscribe, unsubscribe, send, and receive messages from multiple clients into batches of work within a transaction.

MONACLS
Whether online monitoring data is to be collected for auto-defined cluster-sender channels, and, if so, the rate of data collection.

MONCHL
Whether online monitoring data is to be collected for channels, and, if so, the rate of data collection.

MONQ
Whether online monitoring data is to be collected for queues, and, if so, the rate of data collection.

z/OS OPORTMAX
The maximum value in the range of port numbers to be used when binding outgoing channels.

This parameter is valid only on z/OS.

z/OS OPORTMIN
The minimum value in the range of port numbers to be used when binding outgoing channels.

This parameter is valid only on z/OS.

PARENT
The name of the queue manager to which this queue manager is connected hierarchically as its child.

PERFMEV
Whether performance-related events are generated.

PLATFORM
The architecture of the platform on which the queue manager is running. The value of this parameter is:

- z/OS MVS (for z/OS platforms)
- NSK
- OS2
- OS400
- APPLIANCE
- UNIX
- WINDOWSNT

PSCLUS
Controls whether this queue manager participates in publish subscribe activity across any clusters in which it is a member. No clustered topic objects can exist in any cluster when modifying from ENABLED to DISABLED.

PSMODE
Controls whether the publish/subscribe engine and the queued publish/subscribe interface are running, and therefore controls whether applications can publish or subscribe by using the application programming interface and the queues that are monitored by the queued publish/subscribe interface.

PSNPMSG
If the queued publish/subscribe interface cannot process a non-persistent input message it might attempt to write the input message to the dead-letter queue (depending on the report options of the input message). If the attempt to write the input message to the dead-letter queue fails, and the MQRO_DISCARD_MSG report option was specified on the input message or PSNPMSG=DISCARD, the broker discards the input message. If PSNPMSG=KEEP is specified, the interface only discards the input message if the MQRO_DISCARD_MSG report option was set in the input message.

PSNPRES
If the queued publish/subscribe interface attempts to generate a response message in response to a non-persistent input message, and the response message cannot be delivered to the reply-to queue, this attribute indicates whether the interface tries to write the undeliverable message to the dead-letter queue or whether to discard the message.

PSRTYCNT
When the queued publish/subscribe interface fails to process a command message under sync point (for example a publish message that cannot be delivered to a subscriber because the subscriber queue is full and it is not possible to put the publication on the dead letter queue), the unit of work is backed out and the command tries this number of times again before the broker attempts to process the command message according to its report options instead.

PSSYNCPT
If this attribute is set to IFPER, when the queued publish/subscribe interface reads a publish or delete publication messages from a stream queue during normal operation then it specifies

MQGMO_SYNCPOINT_IF_PERSISTENT. This value makes the queued pubsub daemon receive non-persistent messages outside sync point. If the daemon receives a publication outside sync point, the daemon forwards that publication to subscribers known to it outside sync point.

QMID
The internally generated unique name of the queue manager.

QMNAME
The name of the local queue manager. See Rules for naming IBM MQ objects.

z/OS **QSGNAME**
The name of the queue sharing group to which the queue manager belongs, or blank if the queue manager is not a member of a queue sharing group. You can use queue sharing groups only on z/OS.

z/OS **RCVTIME**
The approximate length of time that a TCP/IP channel waits to receive data, including heartbeats, from its partner before returning to an inactive state. The value of this parameter is the numeric value qualified by **RCVTTYPE**.

This parameter is valid only on z/OS.

z/OS **RCVTMIN**
The minimum length of time that a TCP/IP channel waits to receive data, including heartbeats, from its partner before returning to an inactive state.

This parameter is valid only on z/OS.

z/OS **RCVTTYPE**
The qualifier to apply to the value in **RCVTIME**.

This parameter is valid only on z/OS.

REMOTEEV
Whether remote error events are generated.

REPOS
The name of a cluster for which this queue manager is to provide a repository manager service.

REPOSNL
The name of a list of clusters for which this queue manager is to provide a repository manager service.

REVDNS
Whether reverse lookup of the host name from a Domain Name Server (DNS) is done for the IP address from which a channel has connected.

ROUTEREC
Whether trace-route information is to be recorded if requested in the message.

Multi **SCHINIT**
Whether the channel initiator is to be started automatically when the queue manager starts.

z/OS This parameter is not valid on z/OS.

Multi **SCMDSERV**
Whether the command server is to be started automatically when the queue manager starts.

z/OS This parameter is not valid on z/OS.

z/OS **SCYCASE**
Whether the security profiles are uppercase or mixed case.

This parameter is valid only on z/OS.

If this parameter has been altered but the **REFRESH SECURITY** command has not yet been issued, the queue manager might not be using the case of profiles you expect. Use **DISPLAY SECURITY** to verify which case of profiles is actually in use.

SPLCAP

Indicates if Advanced Message Security (AMS) capabilities are available to the queue manager. If the AMS component is installed for the version of IBM MQ that the queue manager is running under, the attribute has a value ENABLED. If the AMS component is not installed, the value is DISABLED.

z/OS **SQQMNAME**

When a queue manager makes an MQOPEN call for a shared queue and the queue manager that is specified in the **ObjectQmgrName** parameter of the MQOPEN call is in the same queue sharing group as the processing queue manager, the **SQQMNAME** attribute specifies whether the **ObjectQmgrName** is used or whether the processing queue manager opens the shared queue directly.

This parameter is valid only on z/OS.

SSLCRLNL

Indicates the namelist of AUTHINFO objects being used for the queue manager for certificate revocation checking.

Only authentication information objects with types of CRLLDAP or OCSP are allowed in the namelist referred to by **SSLCRLNL**. Any other type results in an error message when the list is processed and is subsequently ignored.

ALW **SSLCRYP**

Indicates the name of the parameter string being used to configure the cryptographic hardware present on the system. The PKCS #11 password appears as xxxxxx. This is valid only on AIX, Linux, and Windows.

SSLEV

Whether TLS events are generated.

SSLFIPS

Whether only FIPS-certified algorithms are to be used if cryptography is processed in IBM MQ rather than in the cryptographic hardware itself.

SSLKEYR

Indicates the name of the Secure Sockets Layer key repository.

SSLRKEYC

Indicates the number of bytes to be sent and received within an TLS conversation before the secret key is renegotiated.

z/OS **SSLTASKS**

On z/OS only, indicates the number of server subtasks to use for processing TLS calls.

STATACLS

Whether statistics data is to be collected for auto-defined cluster-sender channels, and, if so, the rate of data collection.

STATCHL

It determines whether statistics data is to be collected for channels, and, if so, the rate of data collection.

Multi **STATINT**

The interval at which statistics monitoring data is written to the monitoring queue. This parameter is valid only on Multiplatforms.

Multi **STATMQI**

Whether statistics monitoring data is to be collected for the queue manager. This parameter is valid only on Multiplatforms.

Multi **STATQ**

Whether statistics data is to be collected for queues. This parameter is valid only on Multiplatforms.

STRSTPEV
Whether start and stop events are generated.

SUITEB
Whether Suite B compliant cryptography is used. For more information about Suite B configuration and its effect on TLS channels, see NSA Suite B Cryptography in IBM MQ .

SYNCPT
Whether sync point support is available with the queue manager. This is a read only queue manager attribute.

z/OS **TCPCHL**
The maximum number of channels that can be current, or clients that can be connected, that use the TCP/IP transmission protocol. If zero, the TCP/IP transmission protocol is not used.

This parameter is valid only on z/OS.

z/OS **TCPKEEP**
Whether the KEEPALIVE facility is to be used to check that the other end of the connection is still available. If it is unavailable, the channel is closed.

This parameter is valid only on z/OS.

z/OS **TCPNAME**
The name of the preferred TCP/IP stack to be used in a CINET multiple stack environment. In INET single stack environments the channel initiator uses the only available TCP/IP stack.

This parameter is valid only on z/OS.

z/OS **TCPSTACK**
Whether the channel initiator uses only the TCP/IP stack specified in TCPNAME, or can optionally bind to any of the TCP/IP stacks defined in a CINET multiple stack environment.

This parameter is valid only on z/OS.

z/OS **TRAXSTR**
Whether channel initiator trace starts automatically.

This parameter is valid only on z/OS.

z/OS **TRAXTBL**
The size, in megabytes, of the trace data space of the channel initiator.

This parameter is valid only on z/OS.

TREELIFE
The lifetime of non-administrative topics.

TRIGINT
The trigger interval.

VERSION
The version of the IBM MQ installation that the queue manager is associated with. The version has the format VVRRMMFF:

VV: Version

RR: Release

MM: Maintenance level

FF: Fix level

XRCAP
Whether MQ Telemetry capability is supported by the queue manager.

For more information about these parameters, see “ALTER QMGR (alter queue manager settings)” on page 331.

Related tasks

Displaying and altering queue manager attributes

Multi DISPLAY QMSTATUS (display queue manager status) on Multiplatforms

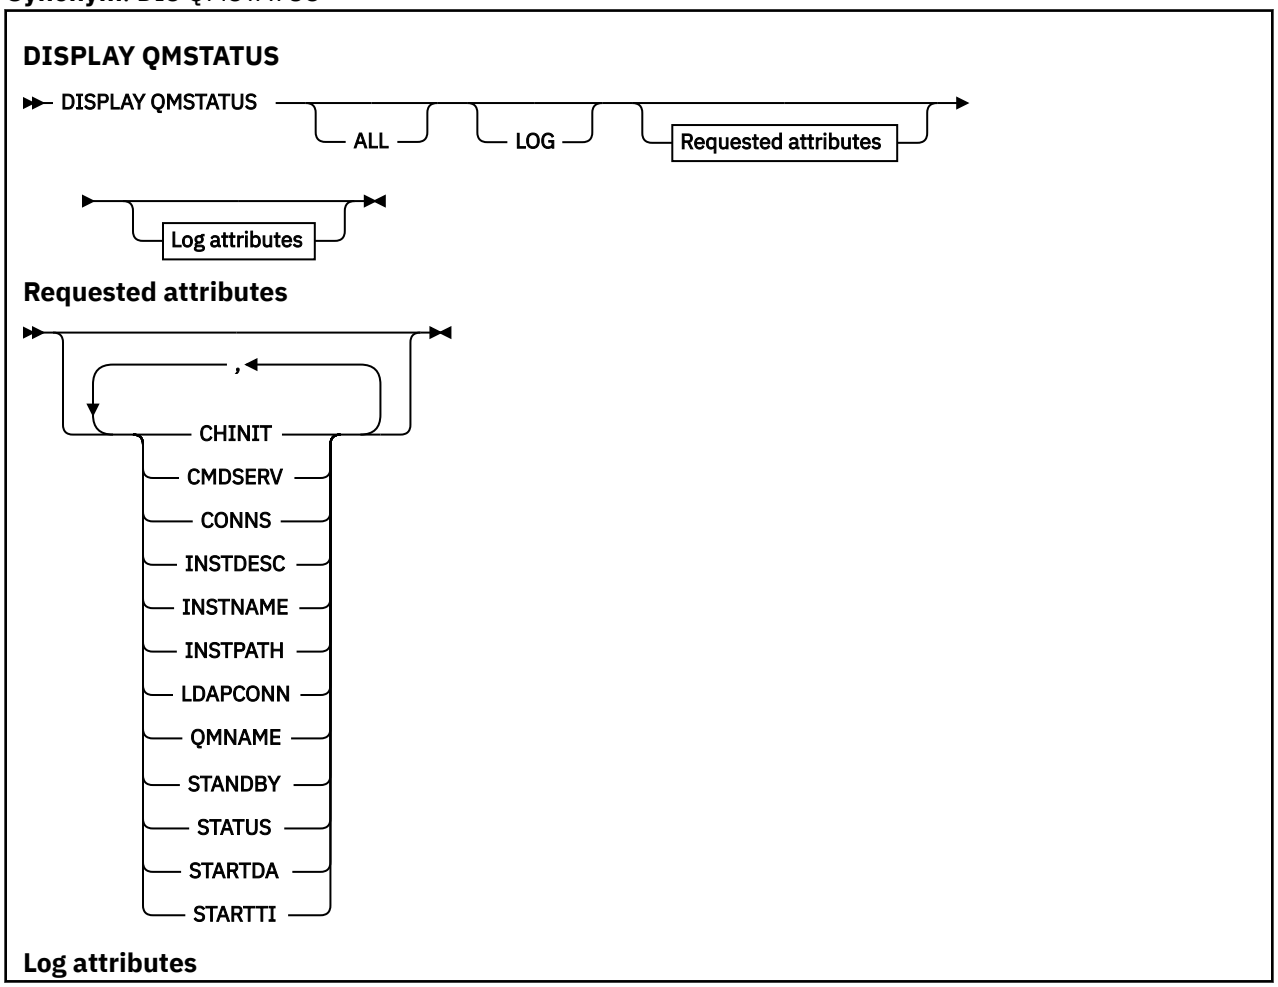
Use the MQSC command **DISPLAY QMSTATUS** to display status information associated with this queue manager.

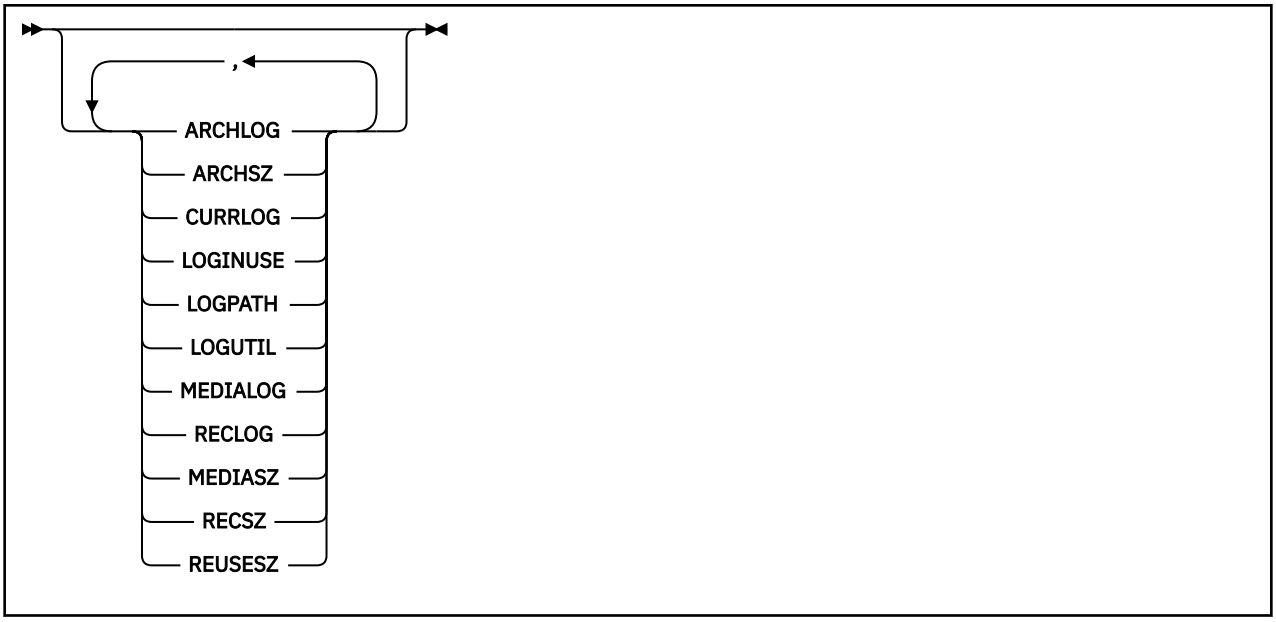
Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

- Syntax diagram
- "Parameter descriptions for DISPLAY QMSTATUS" on page 763
- "Requested parameters" on page 763

Synonym: DIS QMSTATUS





Parameter descriptions for DISPLAY QMSTATUS

ALL
Specify this parameter to display all the parameters. If this parameter is specified, any parameters that are requested specifically have no effect; all parameters are still displayed.

This parameter is the default if you do not request any specific parameters.

Requested parameters

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

ARCHLOG
Name of the oldest log extent for which the queue manager is waiting for archive notification. This parameter is:

- Available only on queue managers using archive log management.
- Blank, if the queue manager is not using archive log management, or if the queue manager has no extents waiting for notification.

IBM i This parameter is not valid on IBM i.

ARCHSZ

The amount of space occupied, in megabytes, by log extents no longer required for restart or media recovery, but waiting to be archived.

Note that this value impacts the total space used by the queue manager for log extents.

This parameter is available only on queue managers using archive log management. If the queue manager is not using archive log management, this parameter is zero.

IBM i This parameter is not valid on IBM i.

CHINIT
The status of the channel initiator reading SYSTEM.CHANNEL.INITQ. It is one of the following:

STOPPED
The channel initiator is not running.

STARTING
The channel initiator is in the process of initializing and is not yet operational.

RUNNING
The channel initiator is fully initialized and is running.

STOPPING
The channel initiator is stopping.

CMDSERV
The status of the command server. It is one of the following:

STOPPED
The command server is not running.

STARTING
The command server is in the process of initializing and is not yet operational.

RUNNING
The command server is fully initialized and is running.

STOPPING
The command server is stopping.

CONNS
The current number of connections to the queue manager.

CURRLOG
The name of the log extent being written to at the time that the **DISPLAY QMSTATUS** command is processed. If the queue manager is using circular logging, and this parameter is explicitly requested, a blank string is displayed.

INSTDESC
Description of the installation associated with the queue manager.

INSTNAME
Name of the installation associated with the queue manager.

INSTPATH
Path of the installation associated with the queue manager.

LDAPCONN
The status of the connection to the LDAP server. It is one of the following:

CONNECTED
The queue manager currently has a connection to the LDAP server.

ERROR
The queue manager attempted to make a connection to the LDAP server and failed.

INACTIVE
The queue manager is not configured to use an LDAP server or has not yet made a connection to the LDAP server.

Note: The **LDAPCONN** status within **DISPLAY QMSTATUS** is a single status for the whole queue manager, reflecting only the most recent actions performed with the LDAP server. There are multiple connections to the LDAP server, one per queue manager agent process. **LDAPCONN** reflects the status from the most recent LDAP connection across the agents of the whole queue manager. If the error is temporary, and quickly clears, then the ERROR status will be short-lived. Always look in the queue manager error logs to see more details of any LDAP connectivity failures.

LOG
Specify this parameter to display all the **LOG** parameters. If this parameter is specified, any **LOG** parameters that are requested specifically have no effect; all parameters are still displayed.

LOGINUSE
The percentage of the primary log space in use for restart recovery at this point in time.

A value of 100 or greater indicates the queue manager might have allocated, and be using, secondary log files, probably due to long-lived transactions at this point in time.

This parameter is not valid on IBM i.

LOGPATH
Identifies the directory where log files are created by the queue manager.

LOGUTIL

A percentage estimate of how well the queue manager workload is contained within the primary log space.

If the value is consistently above 100 you might want to investigate whether there are long-lived transactions, or if the number of primary files is not sufficient for the workload.

If the utilization continues to rise, eventually requests for most further operations requiring log activity will be refused, together with an MQRC_RESOURCE_PROBLEM return code being returned to the application. Transactions might be backed out.

This parameter is not valid on IBM i.

MEDIALOG
The name of the oldest log extent required by the queue manager to perform media recovery. If the queue manager is using circular logging, and this parameter is explicitly requested, a blank string is displayed.

MEDIASZ

Size of the log data required for media recovery in megabytes.

This value shows how much log that must be read for media recovery and directly impacts the time taken for this operation.

This is zero for a circular logging queue manager. The size is typically reduced by taking more frequent media images of objects.

This parameter is not valid on IBM i.

QMNAME
The name of the queue manager. This parameter is always returned.

RECLOG
The name of the oldest log extent required by the queue manager to perform restart recovery. If the queue manager is using circular logging, and this parameter is explicitly requested, a blank string is displayed.

RECSZ
Size of the log data required for restart recovery in megabytes.

This value shows how much log that must be read for restart recovery and directly impacts the time taken for this operation.

This parameter is not valid on IBM i.

REUSESZ
This attribute is valid only on automatic or archive log management queue managers.

The amount of space occupied, in megabytes, by log extents available to be reused.

This value impacts the total space used by the queue manager for log extents.

The size is automatically managed by the queue manager, but if necessary you can request reductions using the **RESET QMGR TYPE(REDUCELOG)** command.

IBM i This parameter is not valid on IBM i.

STANDBY
Whether a standby instance is permitted. It is one of the following:

NOPERMIT
Standby instances are not permitted.

PERMIT
Standby instances are permitted.

STATUS
The status of the queue manager. It is one of the following:

STARTING
The queue manager is in the process of initializing.

RUNNING
The queue manager is fully initialized and is running.

QUIESCING
The queue manager is quiescing.

STARTDA
The date on which the queue manager was started (in the form yyyy-mm-dd).

STARTTI
The time at which the queue manager was started (in the form hh.mm.ss).

DISPLAY QSTATUS (display queue status)

Use the MQSC command DISPLAY QSTATUS to display the status of one or more queues.

Using MQSC commands

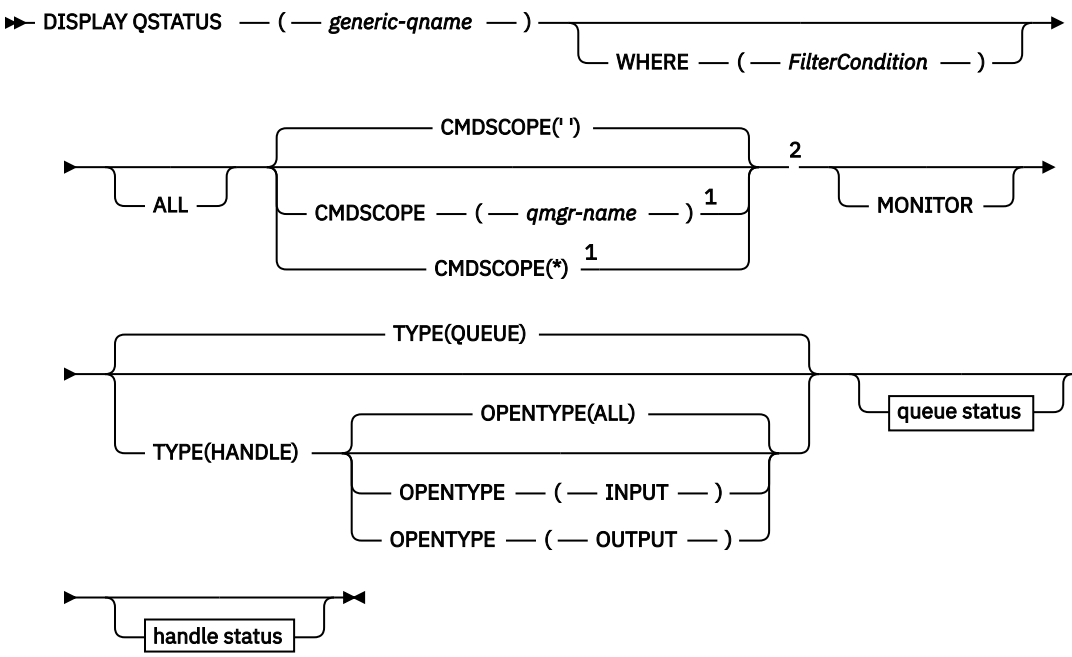
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

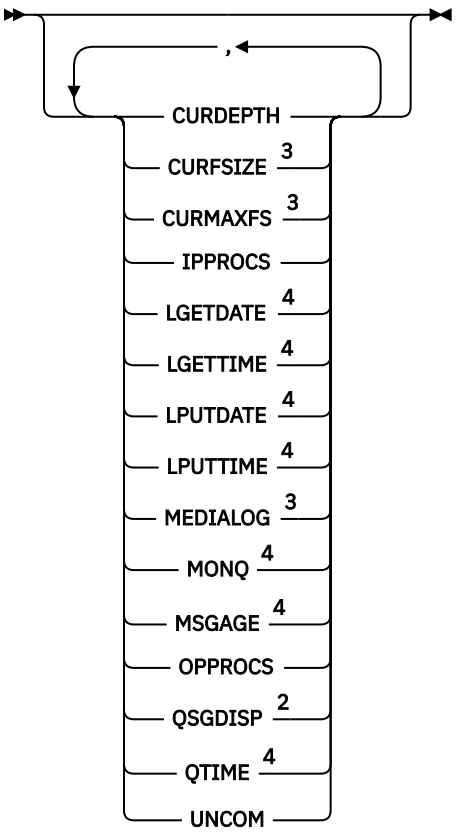
- Syntax diagram
- “Usage notes for DISPLAY QSTATUS” on page 768
- “Parameter descriptions for DISPLAY QSTATUS” on page 769
- “Queue status” on page 771
- “Handle status” on page 774

Synonym: DIS QS

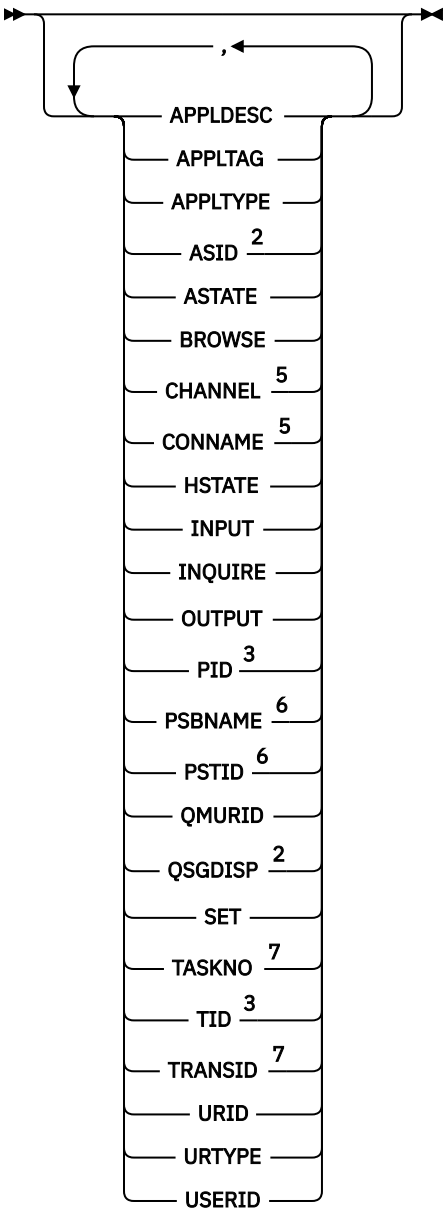
DISPLAY QSTATUS



Queue status



Handle status



Notes:

1 Valid only on z/OS when the queue manager is a member of a queue sharing group.
2 Valid on z/OS only.
3 Not valid on z/OS.
4 Also displayed by selection of the MONITOR parameter.
5 Channel initiator only
6 IMS only
7 CICS only

Usage notes for DISPLAY QSTATUS

The state of asynchronous consumers, ASTATE, reflects that of the server-connection proxy on behalf of the client application; it does not reflect the client application state.

Parameter descriptions for DISPLAY QSTATUS

You must specify the name of the queue for which you want to display status information. This name can either be a specific queue name or a generic queue name. By using a generic queue name you can display either:

- Status information for all queues, or
- Status information for one or more queues that match the specified name and other selection criteria

You must also specify whether you want status information about:

- Queues
- Handles that are accessing the queues

Note: You cannot use the DISPLAY QSTATUS command to display the status of an alias queue or remote queue. If you specify the name of one of these types of queue, no data is returned. You can, however, specify the name of the local queue or transmission queue to which the alias queue or remote queue resolves.

(*generic-qname*)
The name of the queue for which status information is to be displayed. A trailing asterisk (*) matches all queues with the specified stem followed by zero or more characters. An asterisk (*) on its own matches all queues.

WHERE
Specify a filter condition to display status information for queues that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword
Almost any parameter that can be used to display attributes for this DISPLAY command. However, you cannot use the CMDSCOPE, MONITOR, OPENTYPE, QSGDISP, QTIME, TYPE, or URID parameters as filter keywords.

operator
The operator is used to determine whether a queue satisfies the filter value on the given filter keyword. The operators are:

LT
Less than

GT
Greater than

EQ
Equal to

NE
Not equal to

LE
Less than or equal to

GE
Greater than or equal to

LK
Matches a generic string that you provide as a *filter-value*

NL
Does not match a generic string that you provide as a *filter-value*

CT
Contains a specified item. If the *filter-keyword* is a list, you can use this filter to display objects whose attributes contain the specified item.

EX
Does not contain a specified item. If the *filter-keyword* is a list, you can use this filter to display objects whose attributes do not contain the specified item.

filter-value
The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this value can be:

- An explicit value, that is a valid value for the attribute being tested.

  You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value NO on the UNCOM parameter), you can only use EQ or NE.

- A generic value. This value is a character string (such as the character string in the APPLTAG parameter) with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

  You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

- An item in a list of values. The operator must be CT or EX. If it is a character value, it can be explicit or generic. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed. If ABC* is specified, all items where one of the attribute values begins with ABC are listed.

ALL
Display all the status information for each specified queue.

This value is the default if you do not specify a generic name, and do not request any specific parameters.

z/OS On z/OS, this value is also the default if you specify a filter condition using the WHERE parameter, but on other platforms only the requested attributes are displayed.

z/OS **CMDSCOPE**
This parameter specifies how the command runs when the queue manager is a member of a queue sharing group. It is valid on z/OS only.

' '
The command runs on the queue manager on which it was entered. This value is the default.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this value is the same as entering the command on every queue manager in the queue sharing group.

You cannot use CMDSCOPE as a filter keyword.

MONITOR
Specify this value to return the set of online monitoring parameters. These are LGETDATE, LGETTIME, LPUTDATE, LPUTTIME, MONQ, MSGAGE, and QTIME. If you specify this parameter, any of the monitoring parameters that you request specifically have no effect; all monitoring parameters are still displayed.

OPENTYPE
Restricts the queues selected to queues which have handles with the specified type of access:

ALL
Selects queues that are open with any type of access. This value is the default if the OPENTYPE parameter is not specified.

INPUT
Selects queues that are open for input only. This option does not select queues that are open for browse.

OUTPUT
Selects queues that are open only for output.

The OPENTYPE parameter is valid only if TYPE(HANDLE) is also specified.

You cannot use OPENTYPE as a filter keyword.

TYPE
Specifies the type of status information required:

QUEUE
Status information relating to queues is displayed. This value is the default if the TYPE parameter is not specified.

HANDLE
Status information relating to the handles that are accessing the queues is displayed.

You cannot use TYPE as a filter keyword.

Queue status

For queue status, the following information is always returned for each queue that satisfies the selection criteria, except where indicated:

- Queue name
- Type of information returned (TYPE parameter)
- Multi Current queue depth (CURDEPTH parameter)
- z/OS On z/OS only, the queue sharing group disposition (QSGDISP parameter)

The following parameters can be specified for TYPE(QUEUE) to request additional information for each queue. If a parameter is specified that is not relevant for the queue, operating environment, or type of status information requested, that parameter is ignored.

CURDEPTH
The current depth of the queue.

Messages put on a queue count toward the current depth as they are put. Messages got from a queue do not count toward the current depth. This is true whether operations are done under syncpoint or not. Commit has no effect on current depth. Therefore:

- Messages put under syncpoint (but not yet committed) are included in the current depth.
- Messages got under syncpoint (but not yet committed) are not included in the current depth.

V 9.2.0 Multi **CURFSIZE**
Indicates the current size of the queue file in megabytes, rounded up to the nearest megabyte.

For a new queue with default attributes, the value of CURFSIZE is 1.

V 9.2.0 Multi **CURMAXFS**
Indicates the current maximum size the queue file can grow to, rounded up to the nearest megabyte, given the current block size in use on a queue.

The use of this field is two fold:

- If you set MAXFSIZE(DEFAULT) for the current block size, CURMAXFS shows the actual value that DEFAULT equates to.

- If CURMAXFS does not match MAXFSIZE, you know the queue must be drained in order to adopt a bigger granularity.

IPPROCS
The number of handles that are currently open for input for the queue (either input-shared or input-exclusive). This number does not include handles that are open for browse.

For shared queues, the number returned applies only to the queue manager generating the reply. The number is not the total for all the queue managers in the queue sharing group.

LGETDATE
The date on which the last message was retrieved from the queue since the queue manager started. A message being browsed does not count as a message being retrieved. When no get date is available, perhaps because no message has been retrieved from the queue since the queue manager was started, the value is shown as a blank.

z/OS For queues with QSGDISP(SHARED), the value shown is for measurements collected on this queue manager only.

This parameter is also displayed when you specify the MONITOR parameter.

A value is only displayed for this parameter if MONQ is set to a value other than OFF for this queue.

LGETTIME
The time at which the last message was retrieved from the queue since the queue manager started. A message being browsed does not count as a message being retrieved. When no get time is available, perhaps because no message has been retrieved from the queue since the queue manager was started, the value is shown as a blank.

z/OS For queues with QSGDISP(SHARED), the value shown is for measurements collected on this queue manager only.

This parameter is also displayed when you specify the MONITOR parameter.

A value is only displayed for this parameter if MONQ is set to a value other than OFF for this queue.

LPUTDATE
The date on which the last message was put to the queue since the queue manager started. When no put date is available, perhaps because no message has been put to the queue since the queue manager was started, the value is shown as a blank.

z/OS For queues with QSGDISP(SHARED), the value shown is for measurements collected on this queue manager only.

This parameter is also displayed when you specify the MONITOR parameter.

A value is only displayed for this parameter if MONQ is set to a value other than OFF for this queue.

LPUTTIME
The time at which the last message was put to the queue since the queue manager started. When no put time is available, perhaps because no message has been put to the queue since the queue manager was started, the value is shown as a blank.

z/OS For queues with QSGDISP(SHARED), the value shown is for measurements collected on this queue manager only.

This parameter is also displayed when you specify the MONITOR parameter.

A value is only displayed for this parameter if MONQ is set to a value other than OFF for this queue.

Note: Moving the system clock backwards should be avoided in case the LPUTTIME is being used to monitor the messages. The LPUTTIME of a queue is only updated when a message that arrives on the queue has a PutTime greater than the existing value of LPUTTIME. Because the PutTime of the message is less than the existing LPUTTIME of the queue in this case, the time is left unchanged.

Multi **MEDIALOG**
The log extent or journal receiver needed for media recovery of the queue. On queue managers on which circular logging is in place, MEDIALOG is returned as a null string.

This parameter is valid only on Multiplatforms.

MONQ
Current level of monitoring data collection for the queue.

This parameter is also displayed when you specify the MONITOR parameter.

MSGAGE
Age, in seconds, of the oldest message on the queue. The maximum displayable value is 999999999; if the age exceeds this value, 999999999 is displayed.

This parameter is also displayed when you specify the MONITOR parameter.

A value is only displayed for this parameter if MONQ is set to a value other than OFF for this queue.

OPPROCS
This is the number of handles that are currently open for output for the queue.

For shared queues, the number returned applies only to the queue manager generating the reply. The number is not the total for all the queue managers in the queue sharing group.

z/OS **QSGDISP**
Indicates the disposition of the queue. The value displayed is one of the following:

QMGR
The object was defined with QSGDISP(QMGR).

COPY
The object was defined with QSGDISP(COPY).

SHARED
The object was defined with QSGDISP(SHARED).

This parameter is valid on z/OS only.

For shared queues, if the CF structure used by the queue is unavailable or has failed, the status information might be unreliable.

You cannot use QSGDISP as a filter keyword.

QTIME
Interval, in microseconds, between messages being put on the queue and then being destructively read. The maximum displayable value is 999999999; if the interval exceeds this value, 999999999 is displayed.

The interval is measured from the time that the message is placed on the queue until it is destructively retrieved by an application and, therefore, includes any interval caused by a delay in committing by the putting application.

Two values are displayed and these are recalculated only when messages are processed:

- A value based on the last few messages processed
- A value based on a larger sample of the recently processed messages

These values depend on the configuration and behavior of your system, as well as the levels of activity within it, and serve as an indicator that your system is performing normally. A significant variation in these values might indicate a problem with your system. For queues with QSGDISP(SHARED), the values shown are for measurements collected on this queue manager only.

This parameter is also displayed when you specify the MONITOR parameter.

A value is only displayed for this parameter if MONQ is set to a value other than OFF for this queue.

UNCOM
Indicates whether there are any uncommitted changes (puts and gets) pending for the queue. The value displayed is one of the following:

YES
On z/OS, there are one or more uncommitted changes pending.

NO
There are no uncommitted changes pending.

n
Multi On Multiplatforms, an integer value indicating how many uncommitted changes are pending.

For shared queues, the value returned applies only to the queue manager generating the reply. The value does not apply to all the queue managers in the queue sharing group.

Handle status

For handle status, the following information is always returned for each queue that satisfies the selection criteria, except where indicated:

- Queue name
- Type of information returned (TYPE parameter)
- Multi User identifier (USERID parameter) - not returned for APPLTYPE(SYSTEM)

  Note: z/OS Returned only if requested on z/OS
- Multi Application tag (APPLTAG parameter)
- Application type (APPLTYPE parameter)
- z/OS On z/OS only, the queue sharing group disposition (QSGDISP parameter)

The following parameters can be specified for TYPE(HANDLE) to request additional information for each queue. If a parameter that is not relevant is specified for the queue, operating environment, or type of status information requested, that parameter is ignored.

APPLDESC
A string containing a description of the application connected to the queue manager, where it is known. If the application is not recognized by the queue manager the description returned is blank.

APPLTAG
A string containing the tag of the application connected to the queue manager. It is one of the following:

- z/OS z/OS batch job name
- z/OS TSO USERID
- CICS APPLID
- IMS region name
- Channel initiator job name
- IBM i IBM i job name
- Linux AIX Linux or AIX process
- Windows Windows process

  Note: The returned value consists of the full program path and executable file name. If it is more than 28 characters long, only the first 28 characters are shown.

- Internal queue manager process name

Application name represents the name of the process or job that has connected to the queue manager. In the instance that this process or job is connected via a channel, the application name represents the remote process or job rather than the local channel process or job name.

APPLTYPE
A string indicating the type of the application that is connected to the queue manager. It is one of the following:

BATCH
Application using a batch connection

RRSBATCH
RRS-coordinated application using a batch connection

CICS
CICS transaction

IMS
IMS transaction

CHINIT
Channel initiator

SYSTEM
Queue manager

SYSTEMEXT
Application performing an extension of function that is provided by the queue manager

USER
A user application

z/OS **ASID**
A four-character address-space identifier of the application identified by APPLTAG. It distinguishes duplicate values of APPLTAG.

This parameter is returned only when the queue manager owning the queue is running on z/OS, and the APPLTYPE parameter does not have the value SYSTEM.

ASTATE
The state of the asynchronous consumer on this queue.

Possible values are:

ACTIVE
An MQCB call has set up a function to call back to process messages asynchronously and the connection handle has been started so that asynchronous message consumption can proceed.

INACTIVE
An MQCB call has set up a function to call back to process messages asynchronously but the connection handle has not yet been started, or has been stopped or suspended, so that asynchronous message consumption cannot currently proceed.

SUSPENDED
The asynchronous consumption call-back has been suspended so that asynchronous message consumption cannot currently proceed on this queue. This can be either because an MQCB call with Operation MQOP_SUSPEND has been issued against this object handle by the application, or because it has been suspended by the system. If it has been suspended by the system, as part of the process of suspending asynchronous message consumption the call-back function is initiated with the reason code that describes the problem resulting in suspension. This code is reported in the Reason field in the MQCBC structure that is passed to the call-back function.

For asynchronous message consumption to proceed, the application must issue an MQCB call with the Operation parameter set to MQOP_RESUME.

SUSPTEMP
The asynchronous consumption call-back has been temporarily suspended by the system so that asynchronous message consumption cannot currently proceed on this queue. As part of the process of suspending asynchronous message consumption, the call-back function is called with the reason code that describes the problem resulting in suspension. This code is reported in the Reason field in the MQCBC structure passed to the call-back function.

The call-back function is initiated again when asynchronous message consumption is resumed by the system, when the temporary condition has been resolved.

NONE
An MQCB call has not been issued against this handle, so no asynchronous message consumption is configured on this handle.

BROWSE
Indicates whether the handle is providing browse access to the queue. The value is one of the following:

YES
The handle is providing browse access.

NO
The handle is not providing browse access.

CHANNEL
The name of the channel that owns the handle. If there is no channel associated with the handle, this parameter is blank.

This parameter is returned only when the handle belongs to the channel initiator.

CONNAME
The connection name associated with the channel that owns the handle. If there is no channel associated with the handle, this parameter is blank.

This parameter is returned only when the handle belongs to the channel initiator.

HSTATE
Whether an API call is in progress.

Possible values are:

ACTIVE
An API call from a connection is currently in progress for this object. For a queue, this condition can arise when an MQGET WAIT call is in progress.

If there is an MQGET SIGNAL outstanding, then this value does not mean, by itself, that the handle is active.

INACTIVE
No API call from a connection is currently in progress for this object. For a queue, this condition can arise when no MQGET WAIT call is in progress.

INPUT
Indicates whether the handle is providing input access to the queue. The value is one of the following:

SHARED
The handle is providing shared-input access.

EXCL
The handle is providing exclusive-input access.

NO
The handle is not providing input access.

INQUIRE
Indicates whether the handle currently provides inquire access to the queue. The value is one of the following:

YES
The handle provides inquire access.

NO
The handle does not provide inquire access.

OUTPUT
Indicates whether the handle is providing output access to the queue. The value is one of the following:

YES
The handle is providing output access.

NO
The handle is not providing output access.

PID
Number specifying the process identifier of the application that has opened the specified queue.

This parameter is not valid on z/OS.

PSBNAME
The eight characters long name of the program specification block (PSB) associated with the running IMS transaction. You can use the PSBNAME and PSTID to purge the transaction using IMS commands. It is valid on z/OS only.

This parameter is returned only when the APPLTYPE parameter has the value IMS.

PSTID
The four character IMS program specification table (PST) region identifier for the connected IMS region. It is valid on z/OS only.

This parameter is returned only when the APPLTYPE parameter has the value IMS.

QMURID
The queue manager unit of recovery identifier. On z/OS, this value is an 8-byte log RBA, displayed as 16 hexadecimal characters. On platforms other than z/OS, this value is an 8-byte transaction identifier, displayed as `m.n` where `m` and n are the decimal representation of the first and last 4 bytes of the transaction identifier.

You can use QMURID as a filter keyword. On z/OS, you must specify the filter value as a hexadecimal string. On platforms other than z/OS, you must specify the filter value as a pair of decimal numbers separated by a period (.). You can only use the EQ, NE, GT, LT, GE, or LE filter operators.

QSGDISP
Indicates the disposition of the queue. It is valid on z/OS only. The value is one of the following:

QMGR
The object was defined with QSGDISP(QMGR).

COPY
The object was defined with QSGDISP(COPY).

SHARED
The object was defined with QSGDISP(SHARED).

You cannot use QSGDISP as a filter keyword.

SET
Indicates whether the handle is providing set access to the queue. The value is one of the following:

YES
The handle is providing set access.

NO
The handle is not providing set access.

z/OS **TASKNO**
A seven-digit CICS task number. This number can be used in the CICS command "CEMT SET TASK(taskno) PURGE" to end the CICS task. This parameter is valid on z/OS only.

This parameter is returned only when the APPLTYPE parameter has the value CICS.

TID
Number specifying the thread identifier within the application process that has opened the specified queue.

z/OS This parameter is not valid on z/OS.

An asterisk indicates that this queue was opened using a shared connection.

For further information about shared connections see Shared (thread independent) connections with MQCONNX .

z/OS **TRANSID**
A four-character CICS transaction identifier. This parameter is valid on z/OS only.

This parameter is returned only when the APPLTYPE parameter has the value CICS.

URID
The external unit of recovery identifier associated with the connection. It is the recovery identifier known in the external syncpoint coordinator. Its format is determined by the value of URTYPE.

You cannot use URID as a filter keyword.

URTYPE
The type of unit of recovery as seen by the queue manager. It is one of the following:

- CICS (valid only on z/OS)
- XA
- RRS (valid only on z/OS)
- IMS (valid only on z/OS)
- QMGR

URTYPE identifies the EXTURID type and not the type of the transaction coordinator. When URTYPE is QMGR, the associated identifier is in QMURID (and not URID).

USERID
The user identifier associated with the handle.

This parameter is not returned when APPLTYPE has the value SYSTEM.

DISPLAY QUEUE (display queue attributes)

Use the MQSC command **DISPLAY QUEUE** to display the attributes of one or more queues of any type.

Using MQSC commands

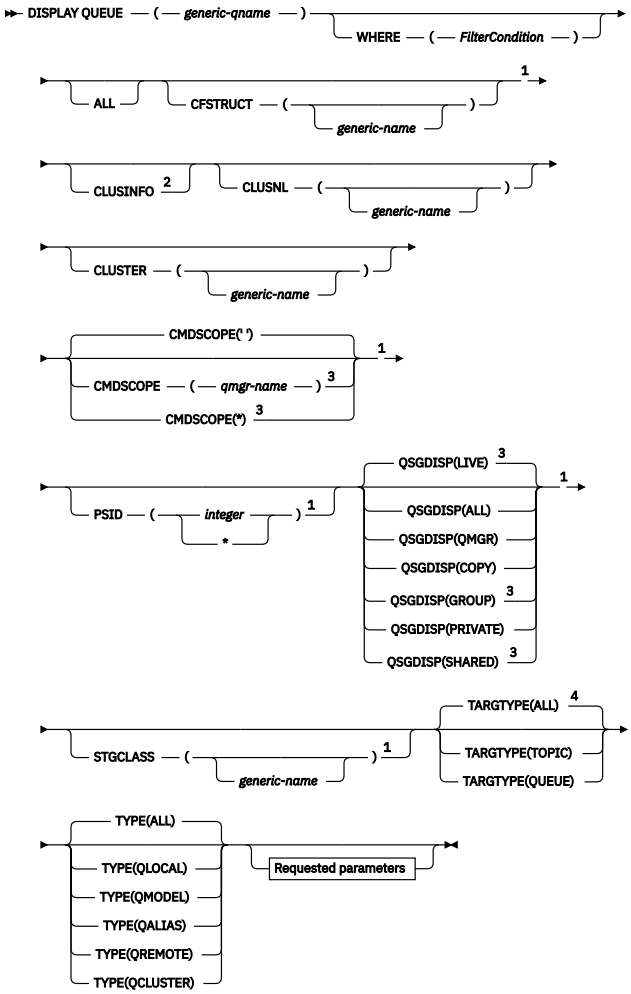
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

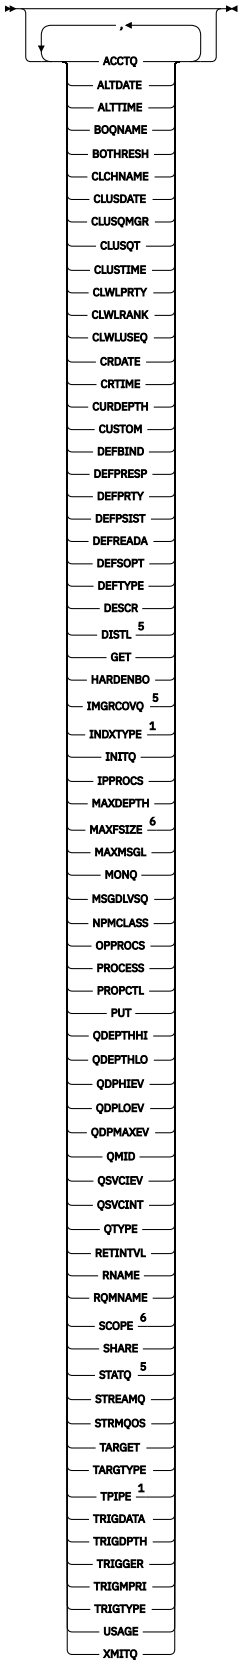
- Syntax diagram
- “Usage notes” on page 781
- “Parameter descriptions for DISPLAY QUEUE” on page 781
- “Requested parameters” on page 785

Synonym: **DIS Q**

DISPLAY QUEUE



Requested parameters



Notes:

1 Valid only on z/OS.

2 On z/OS, you cannot issue this from CSQINP2.

[3] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[4] Valid only on an alias queue.
[5] Not valid on z/OS.
[6] Not valid on z/OS or IBM i.

Usage notes

1. You can use the following commands (or their synonyms) as an alternative way to display these attributes.
   - **DISPLAY QALIAS**
   - **DISPLAY QCLUSTER**
   - **DISPLAY QLOCAL**
   - **DISPLAY QMODEL**
   - **DISPLAY QREMOTE**

   These commands produce the same output as the DISPLAY QUEUE TYPE(*queue-type*) command. If you enter the commands this way, do not use the **TYPE** parameter.
2. z/OS On z/OS, the channel initiator must be running before you can display information about cluster queues (using TYPE(QCLUSTER) or the CLUSINFO parameter).
3. The command might not show every clustered queue in the cluster when issued on a partial repository, because the partial repository only knows about a queue once it has tried to use it.

Parameter descriptions for DISPLAY QUEUE

You must specify the name of the queue definition you want to display. This can be a specific queue name or a generic queue name. By using a generic queue name, you can display either:

- All queue definitions
- One or more queues that match the specified name

queue-name
The local name of the queue definition to be displayed (see Rules for naming IBM MQ objects). A trailing asterisk * matches all queues with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all queues.

WHERE
Specify a filter condition to display only those queues that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword
Almost any parameter that can be used to display attributes for this **DISPLAY** command. However, you cannot use the z/OS CMDSCOPE, QDPHIEV, QDPLOEV, QDPMAXEV, z/OS QSGDISP, or QSVCIEV parameters as filter keywords. You cannot use z/OS CFSTRUCT, CLUSTER, z/OS PSID, z/OS STGCLASS,, or CLUSNLif these are also used to select queues. Queues of a type for which the filter keyword is not a valid attribute are not displayed.

operator
This is used to determine whether a queue satisfies the filter value on the given filter keyword. The operators are:

LT
Less than

GT
Greater than

EQ
Equal to

NE
Not equal to

LE
Less than or equal to

GE
Greater than or equal to

LK
Matches a generic string that you provide as a *filter-value*

NL
Does not match a generic string that you provide as a *filter-value*

filter-value
The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

  You can use operators LT, GT, EQ, NE, LE or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value QALIAS on the CLUSQT parameter), you can only use EQ or NE. For the parameters HARDENBO, SHARE, and TRIGGER, use either EQ YES or EQ NO.
- A generic value. This is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

  You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

ALL
Specify this to display all the attributes. If this parameter is specified, any attributes that are also requested specifically have no effect; all attributes are still displayed.

On all platforms, this is the default if you do not specify a generic name and do not request any specific attributes.

z/OS On z/OS this is also the default if you specify a filter condition using the WHERE parameter, but on other platforms only requested attributes are displayed.

z/OS **CFSTRUCT (*generic-name)***
This parameter is optional and limits the information displayed to those queues where the value of the coupling facility structure is specified in brackets.

The value can be a generic name. If you do not enter a value for this parameter, **CFSTRUCT** is treated as a requested parameter.

CLUSINFO
This requests that, in addition to information about attributes of queues defined on this queue manager, information about these and other queues in the cluster that match the selection criteria is displayed. In this case, there might be multiple queues with the same name displayed. The cluster information is obtained from the repository on this queue manager.

z/OS Note that, on z/OS, you cannot issue `DISPLAY QUEUE CLUSINFO` commands from `CSQINP2`.

CLUSNL (*generic-name*)
This is optional, and limits the information displayed if entered with a value in brackets:

- For queues defined on the local queue manager, only those with the specified cluster list. The value can be a generic name. Only queue types for which **CLUSNL** is a valid parameter are restricted in this way; other queue types that meet the other selection criteria are displayed.
- For cluster queues, only those belonging to clusters in the specified cluster list if the value is not a generic name. If the value is a generic name, no restriction is applied to cluster queues.

If you do not enter a value to qualify this parameter, it is treated as a requested parameter, and cluster list information is returned about all the queues displayed.

Note: z/OS If the disposition requested is SHARED, CMDSCOPE must be blank or the local queue manager.

CLUSTER (*generic-name*)
This is optional, and limits the information displayed to queues with the specified cluster name if entered with a value in brackets. The value can be a generic name. Only queue types for which **CLUSTER** is a valid parameter are restricted in this way by this parameter; other queue types that meet the other selection criteria are displayed.

If you do not enter a value to qualify this parameter, it is treated as a requested parameter, and cluster name information is returned about all the queues displayed.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP or SHARED.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

You cannot use **CMDSCOPE** as a filter keyword.

z/OS **PSID (*integer*)**
The identifier of the page set where a queue resides. This is optional. Specifying a value limits the information displayed to queues that have an active association to the specified page set. The value consists of two numeric characters, in the range 00 - 99. An asterisk * on its own specifies all page set identifiers. If you do not enter a value, page set information is returned about all the queues displayed.

The page set identifier is displayed only if there is an active association of the queue to a page set, that is, after the queue has been the target of an MQPUT request. The association of a queue to a page set is not active when:

- The queue is just defined
- The STGCLASS attribute of the queue is altered, and there is no subsequent MQPUT request to the queue
- The queue manager is restarted and there are no messages on the queue

This parameter is valid only on z/OS.

z/OS **QSGDISP**

Specifies the disposition of the objects for which information is to be displayed. Values are:

LIVE
This is the default value and displays information for objects defined with `QSGDISP(QMGR)` or `QSGDISP(COPY)`. If there is a shared queue manager environment, and the command is being executed on the queue manager where it was issued, also display information for objects defined with `QSGDISP(SHARED)`.

ALL
Display information for objects defined with `QSGDISP(QMGR)` or `QSGDISP(COPY)`.

If there is a shared queue manager environment, and the command is being executed on the queue manager where it was issued, this option also displays information for objects defined with `QSGDISP(GROUP)` or `QSGDISP(SHARED)`.

In a shared queue manager environment:

```
DISPLAY QUEUE(name) CMDSCOPE(*) QSGDISP(ALL)
```

The command lists objects matching `name` in the queue sharing group, without duplicating those in the shared repository.

COPY
Display information only for objects defined with `QSGDISP(COPY)`.

GROUP
Display information only for objects defined with `QSGDISP(GROUP)`. This is allowed only if there is a shared queue manager environment.

PRIVATE
Display information only for objects defined with `QSGDISP(QMGR)` or `QSGDISP(COPY)`.

QMGR
Display information only for objects defined with `QSGDISP(QMGR)`.

SHARED
Display information only for objects defined with `QSGDISP(SHARED)`. This is allowed only in a shared queue manager environment.

Note: For cluster queues, this is always treated as a requested parameter. The value returned is the disposition of the real queue that the cluster queue represents.

If `QSGDISP(LIVE)` is specified or defaulted, or if `QSGDISP(ALL)` is specified in a shared queue manager environment, the command might give duplicated names (with different dispositions) .

Note: In the `QSGDISP(LIVE)` case, this occurs only where a shared and a non-shared queue have the same name; such a situation should not occur in a well-managed system.

QSGDISP displays one of the following values:

QMGR
The object was defined with `QSGDISP(QMGR)`.

GROUP
The object was defined with `QSGDISP(GROUP)`.

COPY
The object was defined with `QSGDISP(COPY)`.

SHARED
The object was defined with `QSGDISP(SHARED)`.

You cannot use **QSGDISP** as a filter keyword.

z/OS **STGCLASS (*generic-name)***

This is optional, and limits the information displayed to queues with the storage class specified if entered with a value in brackets. The value can be a generic name.

If you do not enter a value to qualify this parameter, it is treated as a requested parameter, and storage class information is returned about all the queues displayed.

This parameter is valid only on z/OS.

TARGTYPE (*target-type*)
This is optional and specifies the target type of the alias queue you want to be displayed.

TYPE (*queue-type*)
This is optional, and specifies the type of queues you want to be displayed. If you specify ALL, which is the default value, all queue types are displayed; this includes cluster queues if CLUSINFO is also specified.

As well as ALL, you can specify any of the queue types allowed for a **DEFINE** command: QALIAS, QLOCAL, QMODEL, QREMOTE, or their synonyms, as follows:

QALIAS
Alias queues

QLOCAL
Local queues

QMODEL
Model queues

QREMOTE
Remote queues

You can specify a queue type of QCLUSTER to display only cluster queue information. If QCLUSTER is specified, any selection criteria specified by the CFSTRUCT, STGCLASS, or PSID parameters are ignored. Note that you cannot issue **DISPLAY QUEUE TYPE(QCLUSTER)** commands from CSQINP2.

Multi On Multiplatforms, QTYPE (*type*) can be used as a synonym for this parameter.

The queue name and queue type z/OS (and, on z/OS, the queue disposition) are always displayed.

Requested parameters

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

Most parameters are relevant only for queues of a particular type or types. Parameters that are not relevant for a particular type of queue cause no output, nor is an error raised.

The following table shows the parameters that are relevant for each type of queue. There is a brief description of each parameter after the table, but for more information, see the **DEFINE** command for each queue type.

ACCTQ
Whether accounting (on z/OS, thread-level and queue-level accounting) data collection is to be enabled for the queue.

ALTDATE
The date on which the definition or information was last altered, in the form `yyyy-mm-dd`.

ALTTIME
The time at which the definition or information was last altered, in the form `hh.mm.ss`.

BOQNAME
Backout requeue name.

BOTHRESH
Backout threshold.

CLCHNAME
CLCHNAME is the generic name of the cluster-sender channels that use this queue as a transmission queue. The attribute specifies which cluster-sender channels send messages to a cluster-receiver channel from this cluster transmission queue.

CLUSDATE
The date on which the definition became available to the local queue manager, in the form `yyyy-mm-dd`.

CLUSNL
The namelist that defines the cluster that the queue is in.

CLUSQMGR
The name of the queue manager that hosts the queue.

CLUSQT
Cluster queue type. This can be:

QALIAS
The cluster queue represents an alias queue.

QLOCAL
The cluster queue represents a local queue.

QMGR
The cluster queue represents a queue manager alias.

QREMOTE
The cluster queue represents a remote queue.

CLUSTER
The name of the cluster that the queue is in.

CLUSTIME
The time at which the definition became available to the local queue manager, in the form `hh.mm.ss`.

CLWLPRTY
The priority of the queue for the purposes of cluster workload distribution.

CLWLRANK
The rank of the queue for the purposes of cluster workload distribution.

CLWLUSEQ
Whether puts are allowed to other queue definitions apart from local ones.

CRDATE
The date on which the queue was defined (in the form `yyyy-mm-dd`).

CRTIME
The time at which the queue was defined (in the form `hh.mm.ss`).

CURDEPTH
Current depth of queue.

On z/OS, CURDEPTH is returned as zero for queues defined with a disposition of GROUP. It is also returned as zero for queues defined with a disposition of SHARED if the CF structure that they use is unavailable or has failed.

Messages put on a queue count toward the current depth as they are put. Messages got from a queue do not count toward the current depth. This is true whether operations are done under syncpoint or not. Commit has no effect on current depth. Therefore:

- Messages put under syncpoint (but not yet committed) are included in the current depth.
- Messages got under syncpoint (but not yet committed) are not included in the current depth.

CUSTOM
This attribute is reserved for the configuration of new features before separate attributes have been introduced. It can contain the values of zero or more attributes as pairs of attribute name and value in the form `NAME(VALUE)`.

DEFBIND
Default message binding.

DEFPRESP
Default put response; defines the behavior that should be used by applications when the put response type in the MQPMO options has been set to MQPMO_RESPONSE_AS_Q_DEF.

DEFPRTY
Default priority of the messages put on the queue.

DEFPSIST
Whether the default persistence of messages put on this queue is set to NO or YES. NO means that messages are lost across a restart of the queue manager.

DEFREADA
This specifies the default read ahead behavior for non-persistent messages delivered to the client.

DEFSOPT
Default share option on a queue opened for input.

DEFTYPE
Queue definition type. This can be:

- PREDEFINED (Predefined)

  The queue was created with a DEFINE command, either by an operator or by a suitably authorized application sending a command message to the service queue.

- PERMDYN (Permanent dynamic)

  Either the queue was created by an application issuing MQOPEN with the name of a model queue specified in the object descriptor (MQOD), or (if this is a model queue) this determines the type of dynamic queue that can be created from it.

  On z/OS the queue was created with QSGDISP(QMGR).

- TEMPDYN (Temporary dynamic)

  Either the queue was created by an application issuing MQOPEN with the name of a model queue specified in the object descriptor (MQOD), or (if this is a model queue) this determines the type of dynamic queue that can be created from it.

  On z/OS the queue was created with QSGDISP(QMGR).

- SHAREDYN

  A permanent dynamic queue was created when an application issued an MQOPEN API call with the name of this model queue specified in the object descriptor (MQOD).

  On z/OS, in a queue sharing group environment, the queue was created with QSGDISP(SHARED).

DESCR
Descriptive comment.

DISTL
Whether distribution lists are supported by the partner queue manager. Supported only on Multiplatforms.

GET
Whether the queue is enabled for gets.

HARDENBO
Whether the back out count is hardened to ensure that the count of the number of times that a message has been backed out is accurate.

Note: This parameter affects only IBM MQ for z/OS. It can be set and displayed on other platforms but has no effect.

IMGRCOVQ
Whether a local or permanent dynamic queue object is recoverable from a media image if linear logging is being used.

Note: This parameter is not valid on IBM MQ for z/OS.

INDXTYPE
Index type (supported only on z/OS).

INITQ
Initiation queue name.

IPPROCS
Number of applications that are currently connected to the queue to get messages from the queue.

On z/OS, IPPROCS is returned as zero for queues defined with a disposition of GROUP. With a disposition of SHARED, only the handles for the queue manager sending back the information are returned, not the information for the whole group.

MAXDEPTH
Maximum depth of queue.

V 9.2.0 Multi **MAXFSIZE**
The size, in megabytes, of the queue file displayed.

The default value for this attribute is *DEFQFS*, which stands for *default queue file size* and equates to a hard-coded value of 2,088,960 MB.

MAXMSGL
Maximum message length.

MONQ
Online monitoring data collection.

MSGDLVSQ
Message delivery sequence.

NPMCLASS
Level of reliability assigned to non-persistent messages that are put to the queue.

OPPROCS
Number of applications that are currently connected to the queue to put messages on the queue.

On z/OS, OPPROCS is returned as zero for queues defined with a disposition of GROUP. With a disposition of SHARED, only the handles for the queue manager sending back the information are returned, not the information for the whole group.

PROCESS
Process name.

PROPCTL
Property control attribute.

This parameter is applicable to Local, Alias and Model queues.

This parameter is optional.

Specifies how message properties are handled when messages are retrieved from queues using the MQGET call with the MQGMO_PROPERTIES_AS_Q_DEF option.

Permissible values are:

ALL
To contain all the properties of the message, except those contained in the message descriptor (or extension), select All. The All value enables applications that cannot be changed to access all the message properties from MQRFH2 headers.

COMPAT
If the message contains a property with a prefix of **mcd.**, **jms.**, **usr.**, or **mqext.**, all message properties are delivered to the application in an MQRFH2 header. Otherwise all properties of the message, except those contained in the message descriptor (or extension), are discarded and are no longer accessible to the application.

This is the default value; it allows applications which expect JMS related properties to be in an MQRFH2 header in the message data to continue to work unmodified.

FORCE
Properties are always returned in the message data in an MQRFH2 header regardless of whether the application specifies a message handle.

A valid message handle supplied in the `MsgHandle` field of the `MQGMO` structure on the `MQGET` call is ignored. Properties of the message are not accessible via the message handle.

NONE
All properties of the message, except those in the message descriptor (or extension), are removed from the message before the message is delivered to the application.

PUT
Whether the queue is enabled for puts.

QDEPTHHI
Queue Depth High event generation threshold.

QDEPTHLO
Queue Depth Low event generation threshold.

QDPHIEV
Whether Queue Depth High events are generated.

You cannot use QDPHIEV as a filter keyword.

QDPLOEV
Whether Queue Depth Low events are generated.

You cannot use QDPLOEV as a filter keyword.

QDPMAXEV
Whether Queue Full events are generated.

You cannot use QDPMAXEV as a filter keyword.

QMID
The internally generated unique name of the queue manager that hosts the queue.

QSVCIEV
Whether service interval events are generated.

You cannot use QSVCIEV as a filter keyword.

QSVCINT
Service interval event generation threshold.

QTYPE
Queue type.

The queue type is always displayed.

Multi On Multiplatforms, TYPE(*type*) can be used as a synonym for this parameter.

RETINTVL
Retention interval.

RNAME
Name of the local queue, as known by the remote queue manager.

RQMNAME
Remote queue manager name.

SCOPE
Scope of queue definition (not supported on z/OS).

SHARE
Whether the queue can be shared.

STATQ
Whether statistics data information is to be collected.

STGCLASS
Storage class.

Multi V 9.2.3 **STREAMQ**
The name of a secondary queue where a copy of each message is put.

Multi V 9.2.3 **STRMQOS**
The quality of service to use when delivering messages to the duplicate queue.

TARGET
This parameter requests that the base object name of an aliased queue is displayed.

TARGTYPE
This parameter requests that the target (base) type of an aliased queue is displayed.

TPIPE
The TPIPE names used for communication with OTMA using the IBM MQ - IMS bridge if the bridge is active. This parameter is supported only on z/OS.

z/OS For more information about TPIPEs, see Controlling the IMS bridge.

TRIGDATA
Trigger data.

TRIGDPTH
Trigger depth.

TRIGGER
Whether triggers are active.

TRIGMPRI
Threshold message priority for triggers.

TRIGTYPE
Trigger type.

USAGE
Whether the queue is a transmission queue.

XMITQ
Transmission queue name.

For more details of these parameters, see “DEFINE queues” on page 529.

Displaying default object attributes

DISPLAY SBSTATUS (display subscription status)

Use the MQSC command **DISPLAY SBSTATUS** to display the status of a subscription.

Using MQSC commands

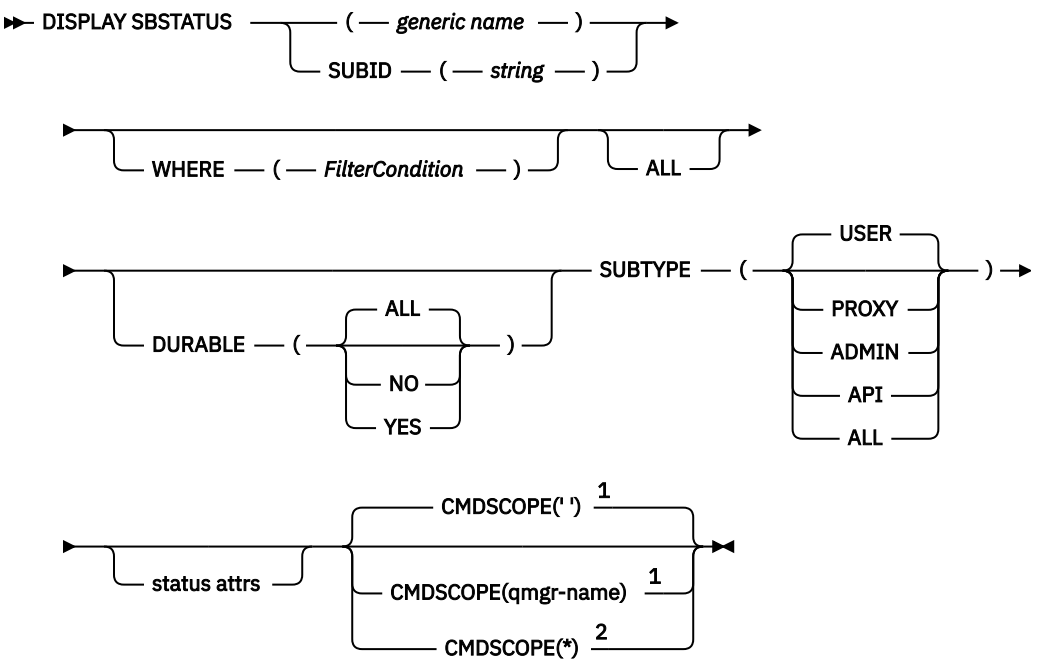
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

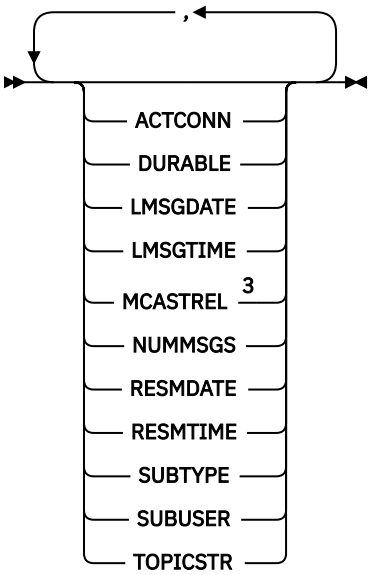
- Syntax diagram
- “Parameter descriptions for DISPLAY SBSTATUS” on page 794
- “Requested parameters” on page 796

Synonym: **DIS SBSTATUS**

DISPLAY SBSTATUS



Status attributes



Notes:

[1] Valid only on z/OS.
[2] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[3] Not valid on z/OS.

Parameter descriptions for DISPLAY SBSTATUS

You must specify the name of the subscription definition for which you want to display status information. This can be a specific subscription name or a generic subscription name. By using a generic subscription name, you can display either:

- All subscription definitions

- One or more subscriptions that match the specified name

(generic-name)
The local name of the subscription definition to be displayed. A trailing asterisk (*) matches all subscriptions with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all subscriptions.

WHERE
Specify a filter condition to display only those subscriptions that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword
Almost any parameter that can be used to display attributes for this **DISPLAY** command.

However, you cannot use the **CMDSCOPE** parameter as a filter keyword.

Subscriptions of a type for which the filter keyword is not a valid attribute are not displayed.

operator
This is used to determine whether a subscription satisfies the filter value on the given filter keyword. The operators are:

LT
Less than

GT
Greater than

EQ
Equal to

NE
Not equal to

LE
Less than or equal to

GE
Greater than or equal to

LK
Matches a generic string that you provide as a *filter-value*

NL
Does not match a generic string that you provide as a *filter-value*

filter-value
The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

  You can use operators LT, GT, EQ, NE, LE or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value USER on the **SUBTYPE** parameter), you can only use EQ or NE.
- A generic value. This is a character string (such as the character string you supply for the **SUBUSER** parameter) with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed.

  You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

ALL
Display all the status information for each specified subscription definition. This is the default if you do not specify a generic name, and do not request any specific parameters.

z/OS On z/OS this is also the default if you specify a filter condition using the **WHERE** parameter, but on other platforms only, requested attributes are displayed.

z/OS **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

' '

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

You cannot use **CMDSCOPE** as a filter keyword.

DURABLE

Specify this attribute to restrict the type of subscriptions which are displayed.

ALL

Display all subscriptions.

NO

Only information about nondurable subscriptions is displayed.

YES

Only information about durable subscriptions is displayed.

SUBTYPE

Specify this attribute to restrict the type of subscriptions which are displayed.

USER

Displays only **API** and **ADMIN** subscriptions.

PROXY

Only system created subscriptions relating to inter-queue manager subscriptions are selected.

ADMIN

Only subscriptions that have been created by an administration interface or modified by an administration interface are selected.

API

Only subscriptions created by applications using an IBM MQ API call are selected.

ALL

All subscription types are displayed (no restriction).

Requested parameters

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

ACTCONN

Returns the *ConnId* of the *HConn* that currently has this subscription open.

DURABLE

A durable subscription is not deleted when the creating application closes its subscription handle.

NO
The subscription is removed when the application that created it is closed or disconnected from the queue manager.

YES
The subscription persists even when the creating application is no longer running or has been disconnected. The subscription is reinstated when the queue manager restarts.

LMSGDATE
The date on which a message was last published to the destination specified by this subscription.

LMSGTIME
The time on which a message was last published to the destination specified by this subscription.

MCASTREL
Indicator of the reliability of the multicast messages.

The values are expressed as a percentage. A value of 100 indicates that all messages are being delivered without problems. A value less than 100 indicates that some of the messages are experiencing network issues. To determine the nature of these issues you can enable event message generation, using the **COMMEV** parameter of the COMMINFO objects, and examine the generated event messages.

The following two values are returned:

- The first value is based on recent activity over a short period.
- The second value is based on activity over a longer period.

If no measurement is available the values are shown as blanks.

NUMMSGS
The number of messages put to the destination specified by this subscription since it was created, or since the queue manager was restarted, whichever is more recent. This number might not reflect the total number of messages that are, or have been, available to the consuming application. This is because it might also include publications that were partially processed but then undone by the queue manager due to a publication failure, or publications that were made within syncpoint that were rolled-back by the publishing application.

RESMDATE
The date of the most recent **MQSUB** API call that connected to the subscription.

RESMTIME
The time of the most recent **MQSUB** API call that connected to the subscription.

SUBID(***string*** **)**
The internal, unique key identifying a subscription.

SUBUSER(***string*** **)**
The owing user ID of the subscription.

SUBTYPE
Indicates how the subscription was created.

PROXY
An internally created subscription used for routing publications through a queue manager.

ADMIN
Created using the **DEF SUB** MQSC or PCF command. This **SUBTYPE** also indicates that a subscription has been modified using an administrative command.

API
Created using an **MQSUB** API call.

TOPICSTR
Returns the fully resolved topic string of the subscription.

For more details of these parameters, see "DEFINE SUB (create a durable subscription)" on page 570.

Checking messages on a subscription

z/OS DISPLAY SECURITY (display security settings) on z/OS

Use the MQSC command DISPLAY SECURITY to display the current settings for the security parameters.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

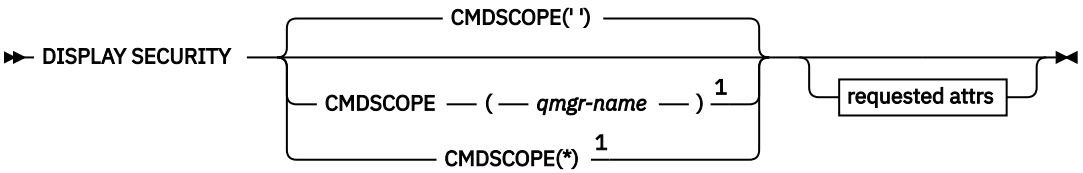
You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Parameter descriptions for DISPLAY SECURITY" on page 798

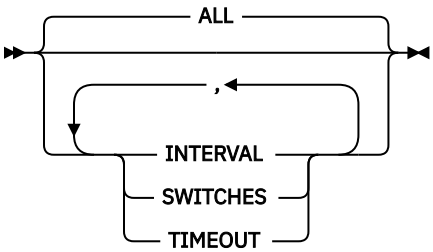
Note: From IBM WebSphere MQ 7.0 onwards, this command is no longer allowed to be issued from CSQINP1 or CSQINP2 on z/OS.

Synonym: DIS SEC

DISPLAY SECURITY



Requested attrs



Notes:

[1] Valid only when the queue manager is a member of a queue sharing group.

Parameter descriptions for DISPLAY SECURITY

CMDSCOPE

This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE cannot be used for commands issued from the first initialization input data set CSQINP1.

' '

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

ALL
Display the TIMEOUT, INTERVAL, and SWITCHES parameters. This is the default if no requested parameters are specified.

The command also outputs an additional message, either CSQH037I or CSQH038I, stating whether security is currently using upper or mixed case security classes.

The command also outputs messages CSQH040I through CSQH042I showing the connection authentication settings currently in use.

INTERVAL
Time interval between checks.

SWITCHES
Display the current setting of the switch profiles.

If the subsystem security switch is off, no other switch profile settings are displayed.

TIMEOUT
Timeout value.

See "ALTER SECURITY (alter security options) on z/OS" on page 396 for details of the TIMEOUT and INTERVAL parameters.

Multi DISPLAY SERVICE (display service information) on Multiplatforms

Use the MQSC command DISPLAY SERVICE to display information about a service.

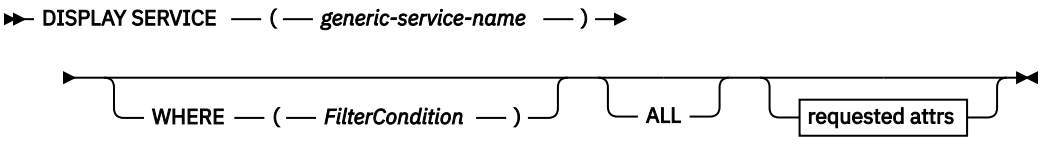
Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

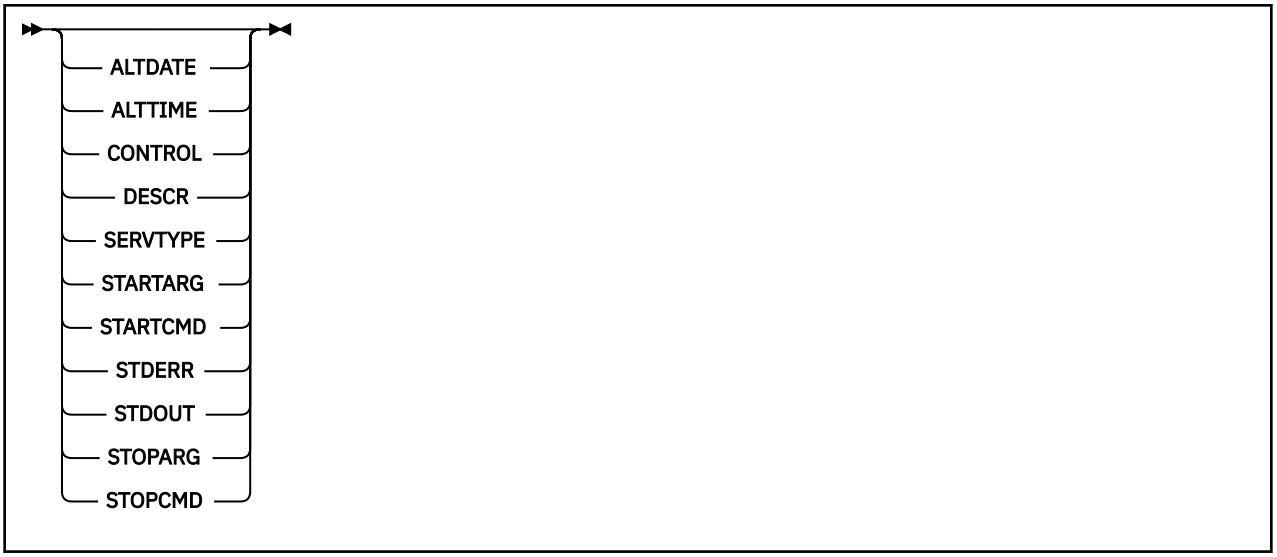
- Syntax diagram
- "Keyword and parameter descriptions for DISPLAY SERVICE" on page 800
- "Requested parameters" on page 801

Synonym:

DISPLAY SERVICE



Requested attrs



Keyword and parameter descriptions for DISPLAY SERVICE

You must specify a service for which you want to display information. You can specify a service by using either a specific service name or a generic service name. By using a generic service name, you can display either:

- Information about all service definitions, by using a single asterisk (*), or
- Information about one or more service that match the specified name.

(*generic-service-name*)
The name of the service definition for which information is to be displayed. A single asterisk (*) specifies that information for all service identifiers is to be displayed. A character string with an asterisk at the end matches all services with the string followed by zero or more characters.

WHERE
Specify a filter condition to display information for those listeners that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword
Any parameter that can be used to display attributes for this DISPLAY command.

operator
This is used to determine whether a listener satisfies the filter value on the given filter keyword. The operators are:

LT
Less than

GT
Greater than

EQ
Equal to

NE
Not equal to

LE
Less than or equal to

GE
Greater than or equal to

LK
Matches a generic string that you provide as a *filter-value*

NL
Does not match a generic string that you provide as a *filter-value*

filter-value
The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

  You can use operators LT, GT, EQ, NE, LE or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value MANUAL on the CONTROL parameter), you can only use EQ or NE.

  .

- A generic value. This is a character string. with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed.

  You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

ALL
Specify this to display all the service information for each specified service. If this parameter is specified, any parameters that are requested specifically have no effect; all parameters are still displayed.

This is the default if you do not specify a generic identifier, and do not request any specific parameters.

On z/OS this is also the default if you specify a filter condition using the WHERE parameter, but on other platforms only requested attributes are displayed.

Requested parameters

Specify one or more attributes that define the data to be displayed. The attributes can be specified in any order. Do not specify the same attribute more than once.

ALTDATE
The date on which the definition was last altered, in the form `yyyy-mm-dd`.

ALTTIME
The time at which the definition was last altered, in the form `hh.mm.ss`.

CONTROL
How the service is to be started and stopped:

MANUAL
The service is not to be started automatically or stopped automatically. It is to be controlled by use of the START SERVICE and STOP SERVICE commands.

QMGR
The service is to be started and stopped at the same time as the queue manager is started and stopped.

STARTONLY
The service is to be started at the same time as the queue manager is started, but is not requested to stop when the queue manager is stopped.

DESCR
Descriptive comment.

SERVTYPE
Specifies the mode in which the service is to run:

COMMAND
A command service object. Multiple instances of a command service object can be executed concurrently. You cannot monitor the status of command service objects.

SERVER
A server service object. Only one instance of a server service object can be executed at a time. The status of server service objects can be monitored using the DISPLAY SVSTATUS command.

STARTARG
Specifies the arguments to be passed to the user program at queue manager startup.

STARTCMD
Specifies the name of the program which is to run.

STDERR
Specifies the path to the file to which the standard error (stderr) of the service program is to be redirected.

STDOUT
Specifies the path to the file to which the standard output (stdout) of the service program is to be redirected.

STOPARG
Specifies the arguments to be passed to the stop program when instructed to stop the service.

STOPCMD
Specifies the name of the executable program to run when the service is requested to stop.

For more details of these parameters, see "DEFINE SERVICE (create a new service definition) on Multiplatforms" on page 564.

z/OS DISPLAY SMDS (display shared message data sets information) on z/OS

Use the MQSC command DISPLAY SMDS to display the parameters of existing IBM MQ shared message data sets associated with a specified application structure.

Using MQSC commands

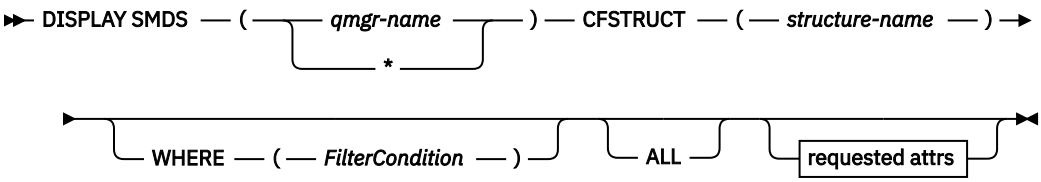
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

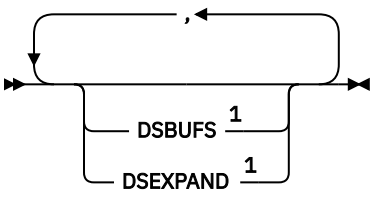
- Syntax diagram
- "Parameter descriptions for DISPLAY SMDS" on page 803
- "Usage notes for DISPLAY SMDSCONN" on page 806

Synonym:

DISPLAY SMDS



Requested attrs



Notes:

[1] For more information about this parameter, see Planning your coupling facility and offload storage environment.

Parameter descriptions for DISPLAY SMDS

The parameter descriptions for the DISPLAY SMDS command.

SMDS(*qmgr-name*|*)
Specifies the queue manager for which the shared message data set properties are to be displayed, or an asterisk to display the properties for all shared message data sets associated with the specified CFSTRUCT.

CFSTRUCT(*structure-name*)
Specify the coupling facility application structure for which the properties of one or more shared message data sets are to be displayed.

WHERE
Specify a filter condition to display only the SMDS information that satisfies the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword
Any parameter that can be used to display attributes for this DISPLAY command.

operator
This is used to determine whether a CF application structure satisfies the filter value on the given filter keyword. The operators are:

LT
Less than

GT
Greater than

EQ
Equal to

NE
Not equal to

LE
Less than or equal to

GE
Greater than or equal to

LK
Matches a generic string that you provide as a *filter-value*

NL
Does not match a generic string that you provide as a *filter-value*

filter-value
The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use any of the operators except LK and NL. However, if the value is one from a possible set of values returnable on a parameter (for example, the value YES on the RECOVER parameter), you can only use EQ or NE.

- A generic value. This is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC*. The characters must be valid for the attribute you are testing. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

  You can only use operators LK or NL for generic values on the DISPLAY SMDS command.

ALL
Specify this keyword to display all attributes. If this keyword is specified, any attributes that are requested specifically have no effect; all attributes are still displayed.

This is the default behavior if you do not specify a generic name and do not request any specific attributes.

Requested parameters for DISPLAY SMDS

The following information is returned for each selected data set:

SMDS
The queue manager name which owns the shared message data set for which properties are being displayed.

CFSTRUCT
The coupling facility application structure name.

DSBUFS
Displays the override value for the number of buffers to be used by the owning queue manager for accessing shared message data sets for this structure, or DEFAULT if the group value from the CFSTRUCT definition is being used.

DSEXPAND
Displays the override value (YES or NO) for the data set expansion option, or DEFAULT if the group value from the CFSTRUCT definition is being used.

z/OS DISPLAY SMDSCONN (display shared message data sets connection information) on z/OS

Use the MQSC command DISPLAY SMDSCONN to display status and availability information about the connection between the queue manager and the shared message data sets for the specified CFSTRUCT.

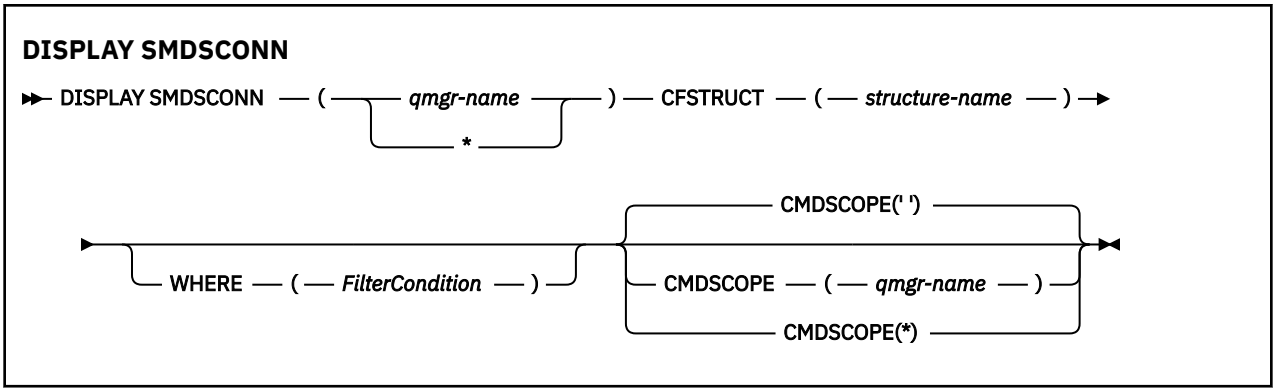
Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- “Parameter descriptions for DISPLAY SMDSCONN” on page 805
- “Usage notes for DISPLAY SMDSCONN” on page 806

Synonym:



Parameter descriptions for DISPLAY SMDSCONN

The parameter descriptions for the DISPLAY SMDS command.

SMDSCONN(*qmgr-name*|*)
Specify the queue manager which owns the SMDS for which the connection information is to be displayed, or an asterisk to display the connection information for all shared message data sets associated with the specified CFSTRUCT.

CFSTRUCT(*structure-name*)
Specify the structure name for which the shared message data set connection information is required.

WHERE
Specify a filter condition to display only the SMDS connection information that satisfies the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword
Any parameter that can be used to display attributes for this DISPLAY command.

operator
This is used to determine whether a CF application structure satisfies the filter value on the given filter keyword. The operators are:

LT
Less than

GT
Greater than

EQ
Equal to

NE
Not equal to

LE
Less than or equal to

GE
Greater than or equal to

LK
Matches a generic string that you provide as a *filter-value*

NL
Does not match a generic string that you provide as a *filter-value*

filter-value
The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use any of the operators except LK and NL. However, if the value is one from a possible set of values returnable on a parameter (for example, the value YES on the RECOVER parameter), you can only use EQ or NE.

- A generic value. This is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC*. The characters must be valid for the attribute you are testing. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

  You can only use operators LK or NL for generic values on the DISPLAY SMDSCONN command.

CMDSCOPE
This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

' '
The command runs on the queue manager on which it was entered.

This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group. You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

Usage notes for DISPLAY SMDSCONN

This command is only supported when the CFSTRUCT definition is currently using the option OFFLOAD(SMDS).

This information indicates whether the queue manager is currently able to allocate and open the data set.

The following results are returned for each selected connection:

SMDSCONN
The name of the queue manager which owns the shared message data set for this connection.

CFSTRUCT
The name of the coupling facility application structure.

OPENMODE
The mode in which the data set is currently open by this queue manager. This is one of the following:

NONE
The data set is not currently open.

READONLY
The data set is owned by another queue manager and is open for read-only access.

UPDATE
The data set is owned by this queue manager and is open for update access.

RECOVERY
The data set is open for recovery processing.

STATUS
The connection status as seen by this queue manager. This is one of the following:

CLOSED
This data set is not currently open.

OPENING
This queue manager is currently in the process of opening and validating this data set (including space map restart processing when necessary).

OPEN
This queue manager has successfully opened this data set and it is available for normal use.

CLOSING
This queue manager is currently in the process of closing this data set, including quiescing normal I/O activity and storing the saved space map if necessary.

NOTENABLED
The SMDS definition is not in the ACCESS(ENABLED) state so the data set is not currently available for normal use. This status is only set when the SMDSCONN status does not already indicate some other form of failure.

ALLOCFAIL
This queue manager was unable to locate or allocate this data set.

OPENFAIL
This queue manager was able to allocate the data set but was unable to open it, so it has now been deallocated.

STGFAIL
The data set could not be used because the queue manager was unable to allocate associated storage areas for control blocks, or for space map or header record processing.

DATAFAIL
The data set was successfully opened but the data was found to be invalid or inconsistent, or a permanent I/O error occurred, so it has now been closed and deallocated.

This may result in the shared message data set itself being marked as STATUS(FAILED).

AVAIL
The availability of this data set connection as seen by this queue manager. This is one of the following:

NORMAL
The connection can be used and no error has been detected.

ERROR
The connection is unavailable because of an error.

The queue manager may try to enable access again automatically if the error may no longer be present, for example when recovery completes or the status is manually set to RECOVERED. Otherwise, it can be enabled again using the START SMDSCONN command in order to retry the action which originally failed.

STOPPED
The connection cannot be used because it has been explicitly stopped using the STOP SMDSCONN command. It can only be made available again by using a START SMDSCONN command to enable it.

EXPANDST
The data set automatic expansion status. This is one of the following:

NORMAL
No problem has been noted which would affect automatic expansion.

FAILED
A recent expansion attempt failed, causing the DSEXPAND option to be set to NO for this specific data set. This status is cleared when ALTER SMDS is used to set the DSEXPAND option back to YES or DEFAULT

MAXIMUM
The maximum number of extents has been reached, so future expansion is not possible (except by taking the data set out of service and copying it to larger extents).

Note, that the command works only if the structure is currently connected, that is, some shared queues allocated to that structure have been opened.

Related reference

"START SMDSCONN (restart a shared message data set connection) on z/OS" on page 933
Use the MQSC command START SMDSCONN to enable a previously stopped connection from this queue manager to the specified shared message data sets, allowing them to be allocated and opened again.

"STOP SMDSCONN (stop shared message data sets connection) on z/OS" on page 952
Use the MQSC command STOP SMDSCONN to terminate the connection from this queue manager to one or more specified shared message data sets (causing them to be closed and deallocated) and to mark the connection as STOPPED.

z/OS DISPLAY STGCLASS (display storage class information) on z/OS

Use the MQSC command DISPLAY STGCLASS to display information about storage classes.

Using MQSC commands

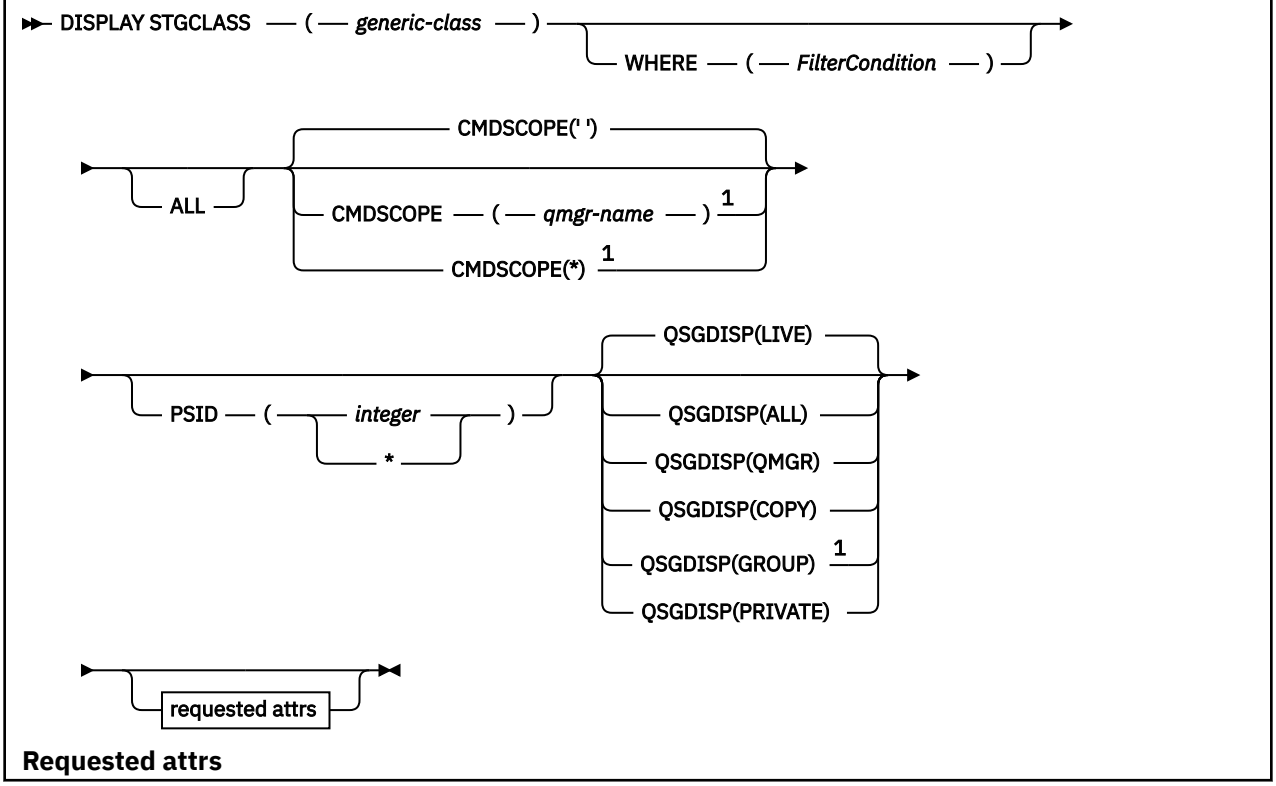
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

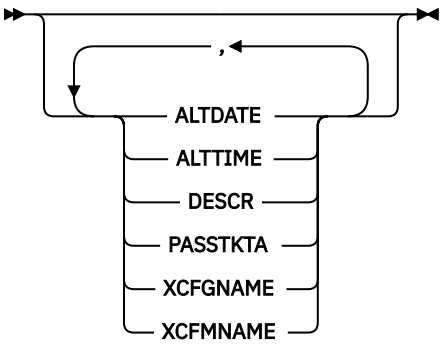
- Syntax diagram
- "Parameter descriptions for DISPLAY STGCLASS" on page 809
- "Requested parameters" on page 811

Synonym: DIS STC

DISPLAY STGCLASS



Requested attrs



Notes:

[1] Valid only on IBM MQ for z/OS when the queue manager is a member of a queue sharing group.

Parameter descriptions for DISPLAY STGCLASS

You use DISPLAY STGCLASS to show the page set identifiers that are associated with each storage class.

(generic-class)
Name of the storage class. This is required.

This is 1 through 8 characters. The first character is in the range A through Z; subsequent characters are A through Z or 0 through 9.

A trailing asterisk (*) matches all storage classes with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all storage classes.

WHERE
Specify a filter condition to display only those storage classes that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword
Almost any parameter that can be used to display attributes for this DISPLAY command. However, you cannot use the CMDSCOPE or QSGDISP parameters as filter keywords. You cannot use PSID as a filter keyword if you also use it to select storage classes.

operator
This is used to determine whether a connection satisfies the filter value on the given filter keyword. The operators are:

LT
Less than

GT
Greater than

EQ
Equal to

NE
Not equal to

LE
Less than or equal to

GE
Greater than or equal to

LK
Matches a generic string that you provide as a *filter-value*

NL
Does not match a generic string that you provide as a *filter-value*

filter-value
The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

  You can use operators LT, GT, EQ, NE, LE or GE only. However, if the attribute value is one from a possible set of values on a parameter, you can only use EQ or NE.

- A generic value. This is a character string (such as the character string in the DESCR parameter) with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string ABC are listed. Only a single trailing wildcard character (asterisk) is permitted.

  You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

ALL
Specify this to display all the parameters. If this parameter is specified, any parameters that are also requested specifically have no effect; all parameters are still displayed.

This is the default if you do not specify a generic name, and do not request any specific parameters.

On z/OS this is also the default if you specify a filter condition using the WHERE parameter, but on other platforms only requested attributes are displayed.

CMDSCOPE
This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

If QSGDISP is set to GROUP, CMDSCOPE must be blank or the local queue manager.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

You cannot use CMDSCOPE as a filter keyword.

PSID(*integer*)
The page set identifier that a storage class maps to. This is optional.

The string consists of two numeric characters, in the range 00 through 99. An asterisk (*) on its own specifies all page set identifiers. See "DEFINE PSID (define page set and buffer pool) on z/OS" on page 527.

QSGDISP
Specifies the disposition of the objects for which information is to be displayed. Values are:

LIVE
This is the default value and displays information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

ALL
Displays information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

If there is a shared queue manager environment, and the command is being executed on the queue manager where it was issued, this option also displays information for objects defined with QSGDISP(GROUP).

If QSGDISP(ALL) is specified in a shared queue manager environment, the command might give duplicated names (with different dispositions).

In a shared queue manager environment, use

```
DISPLAY STGCLASS(generic-class) CMDSCOPE(*) QSGDISP(ALL)
```

to list ALL objects matching

```
name
```

in the queue sharing group without duplicating those in the shared repository.

COPY
Display information only for objects defined with QSGDISP(COPY).

GROUP
Display information only for objects defined with QSGDISP(GROUP). This is allowed only if there is a shared queue manager environment.

PRIVATE
Display information only for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

QMGR
Display information only for objects defined with QSGDISP(QMGR).

QSGDISP displays one of the following values:

QMGR
The object was defined with QSGDISP(QMGR).

GROUP
The object was defined with QSGDISP(GROUP).

COPY
The object was defined with QSGDISP(COPY).

You cannot use QSGDISP as a filter keyword.

Requested parameters

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

The default, if no parameters are specified (and the ALL parameter is not specified) is the storage class names, their page set identifiers and queue sharing group dispositions are displayed.

ALTDATE
The date on which the definition was last altered, in the form `yyyy-mm-dd`.

ALTTIME
The time at which the definition was last altered, in the form `hh.mm.ss`.

DESCR
Descriptive comment.

PASSTKTA
The application name used to authenticate IMS bridge passtickets. A blank value indicates that the default batch job profile name is to be used.

XCFGNAME
The name of the XCF group that IBM MQ is a member of.

XCFMNAME
The XCF member name of the IMS system within the XCF group specified in XCFGNAME.

For more details of these parameters, see “DEFINE STGCLASS (define storage class to page set mapping) on z/OS” on page 567.

DISPLAY SUB (display subscription information)

Use the MQSC command **DISPLAY SUB** to display the attributes associated with a subscription.

Using MQSC commands

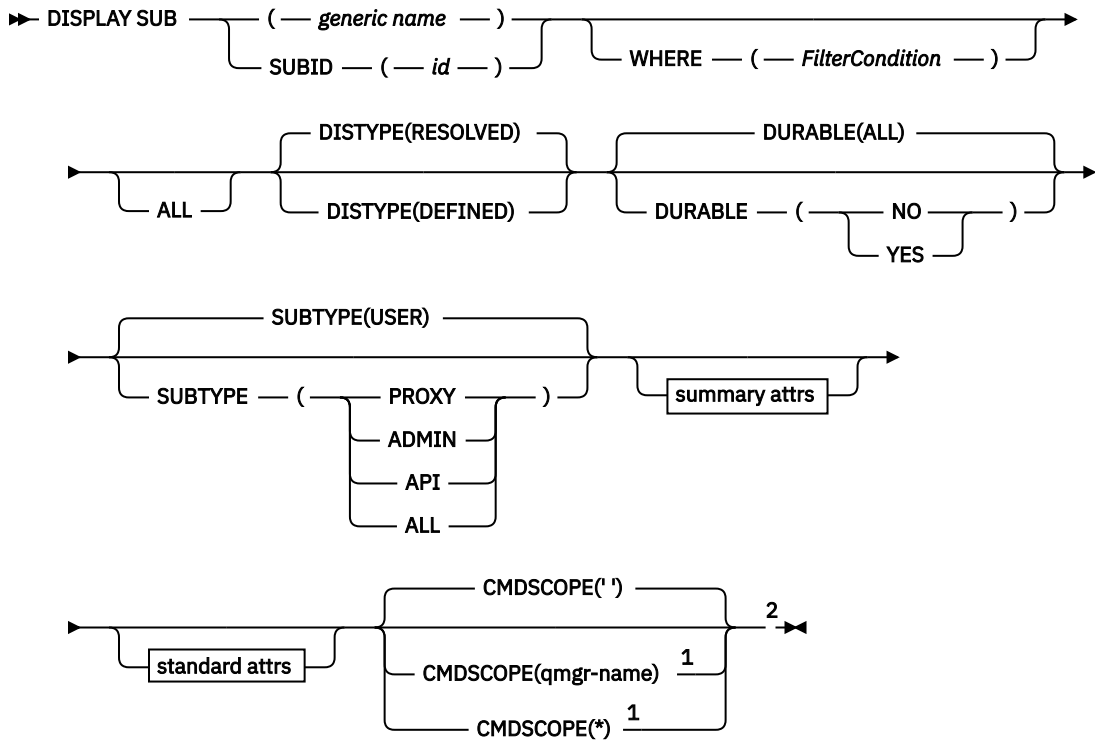
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

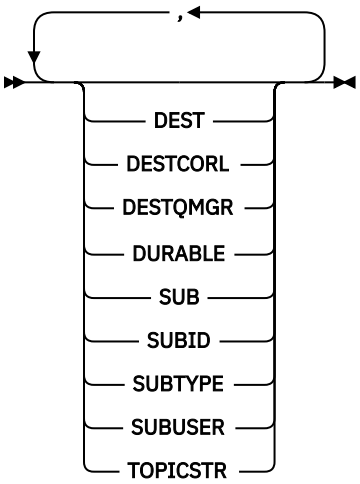
- Syntax diagram
- “Usage notes for DISPLAY SUB” on page 813
- “Parameter descriptions for DISPLAY SUB” on page 814

Synonym: **DIS SUB**

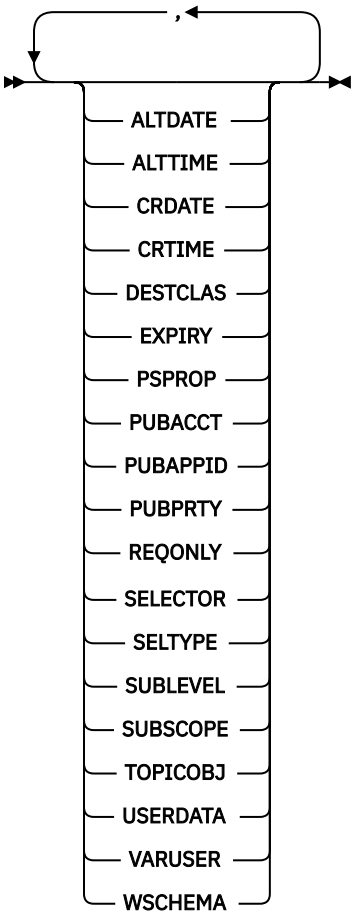
DISPLAY SUB



summary attributes



standard attributes



Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[2] Valid only on z/OS.

Usage notes for DISPLAY SUB

The **TOPICSTR** parameter might contain characters that cannot be translated into printable characters when the command output is displayed.

z/OS On z/OS, these non-printable characters are displayed as blanks.

Multi On Multiplatforms using runmqsc, these non-printable characters are displayed as dots.

Parameter descriptions for DISPLAY SUB

You must specify either the name or the identifier of subscription you want to display. This can be a specific subscription name, or SUBID, or a generic subscription name. By using a generic subscription name, you can display either:

- All subscription definitions
- One or more subscriptions that match the specified name

The following forms are valid:

```
DIS SUB(xyz)
DIS SUB SUBID(123)
DIS SUB(xyz*)
```

(generic-name)
The local name of the subscription definition to be displayed. A trailing asterisk (*) matches all subscriptions with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all subscriptions.

WHERE
Specify a filter condition to display only those subscriptions that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword
Almost any parameter that can be used to display attributes for this DISPLAY command. However, you cannot use the CMDSCOPE parameter as a filter keyword. Subscriptions of a type for which the filter keyword is not a valid attribute are not displayed.

operator
This is used to determine whether a subscription satisfies the filter value on the given filter keyword. The operators are:

LT
Less than

GT
Greater than

EQ
Equal to

NE
Not equal to

LE
Less than or equal to

GE
Greater than or equal to

LK
Matches a generic string that you provide as a *filter-value*

NL
Does not match a generic string that you provide as a *filter-value*

filter-value
The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use operators LT, GT, EQ, NE, LE or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value QALIAS on the CLUSQT parameter), you can only use EQ or NE. For the parameters HARDENBO, SHARE, and TRIGGER, use either EQ YES or EQ NO.

- A generic value. This is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

  You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

Note: z/OS On z/OS there is a 256 character limit for the filter-value of the MQSC WHERE clause. This limit is not in place for other platforms.

SUMMARY
Specify this to display the set of summary attributes that you want displayed.

ALL
Specify this to display all the attributes.

If this parameter is specified, any attributes that are also requested specifically have no effect; all attributes are still displayed.

This is the default if you do not specify a generic name and do not request any specific attributes.

ALTDATE(***string*** **)**
The date of the most recent **MQSUB** or **ALTER SUB** command that modified the properties of the subscription.

ALTTIME(***string*** **)**
The time of the most recent **MQSUB** or **ALTER SUB** command that modified the properties of the subscription.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of setting this value is the same as entering the command on every queue manager in the queue sharing group.

You cannot use CMDSCOPE as a filter keyword.

CRDATE(***string*** **)**
The date of the first **MQSUB** or **DEF SUB** command that created this subscription.

CRTIME(***string*** **)**
The time of the first **MQSUB** or **DEF SUB** command that created this subscription.

DEST(*string*)
The destination for messages published to this subscription; this parameter is the name of a queue.

DESTCLAS
System managed destination.

PROVIDED
The destination is a queue.

MANAGED
The destination is managed.

DESTCORL(*string*)
The **CorrelId** used for messages published to this subscription.

A blank value (default) results in a system generated correlation identifier being used.

If set to ' `00000000000000000000000000000000000000000000000000000000` ' (48 zeros) the **CorrelId** set by the publishing application will be maintained in the copy of the message delivered to the subscription, unless messages are propagated across a publish/subscribe hierarchy.

If this byte string is enclosed in quotation marks, characters in the range A-F must be specified in uppercase.

Note: It is not possible to set the DESTCORL property programmatically with JMS.

DESTQMGR(*string*)
The destination queue manager for messages published to this subscription.

DISTYPE
Controls the output returned in the **TOPICSTR** and **TOPICOBJ** attributes.

RESOLVED
Returns the resolved (full) topic string in the **TOPICSTR** attribute. The value of the **TOPICOBJ** attribute is also returned. This is the default value.

DEFINED
Returns the values of the **TOPICOBJ** and **TOPICSTR** attributes provided when the subscription was created. The **TOPICSTR** attribute will contain the application part of the topic string only. You can use the values returned with **TOPICOBJ** and **TOPICSTR** to fully re-create the subscription by using **DISTYPE(DEFINED)**.

DURABLE
A durable subscription is not deleted when the creating application closes its subscription handle.

ALL
Display all subscriptions.

NO
The subscription is removed when the application that created it, is closed or disconnected from the queue manager.

YES
The subscription persists even when the creating application is no longer running or has been disconnected. The subscription is reinstated when the queue manager restarts.

EXPIRY
The time to expiry of the subscription object from the creation date and time.

(*integer*)
The time to expiry, in tenths of a second, from the creation date and time.

UNLIMITED
There is no expiry time. This is the default option supplied with the product.

PSPROP
The manner in which publish subscribe related message properties are added to messages sent to this subscription.

NONE
Do not add publish subscribe properties to the message.

COMPAT
Publish/subscribe properties are added within an MQRFH version 1 header unless the message was published in PCF format.

MSGPROP
Publish/subscribe properties are added as message properties.

RFH2
Publish/subscribe properties are added within an MQRFH version 2 header.

PUBACCT(*string*)
Accounting token passed by the subscriber, for propagation into messages published to this subscription in the `AccountingToken` field of the MQMD.

If this byte string is enclosed in quotation marks, characters in the range A-F must be specified in uppercase.

PUBAPPID(*string*)
Identity data passed by the subscriber, for propagation into messages published to this subscription in the `ApplIdentityData` field of the MQMD.

PUBPRTY
The priority of the message sent to this subscription.

ASPUB
Priority of the message sent to this subscription is taken from the priority supplied in the published message.

ASQDEF
Priority of the message sent to this subscription is taken from the default priority of the queue defined as a destination.

(integer)
An integer providing an explicit priority for messages published to this subscription.

REQONLY
Indicates whether the subscriber polls for updates using the MQSUBRQ API call, or whether all publications are delivered to this subscription.

NO
All publications on the topic are delivered to this subscription. This is the default value.

YES
Publications are only delivered to this subscription in response to an MQSUBRQ API call.

This parameter is equivalent to the subscribe option MQSO_PUBLICATIONS_ON_REQUEST.

SELECTOR(*string*)
A selector that is applied to messages published to the topic.

SELTYPE
The type of selector string that has been specified.

NONE
No selector has been specified.

STANDARD
The selector references only the properties of the message, not its content, using the standard IBM MQ selector syntax. Selectors of this type are to be handled internally by the queue manager.

EXTENDED
The selector uses extended selector syntax, typically referencing the content of the message. Selectors of this type cannot be handled internally by the queue manager; extended selectors can be handled only by another program such as IBM Integration Bus.

SUB(*string*)
The application's unique identifier for a subscription.

SUBID(*string*)
The internal, unique key identifying a subscription.

SUBLEVEL(*integer*)
The level within the subscription hierarchy at which this subscription is made. The range is zero through 9.

SUBSCOPE
Determines whether this subscription is forwarded to other queue managers, so that the subscriber receives messages published at those other queue managers.

ALL
The subscription is forwarded to all queue managers directly connected through a publish/subscribe collective or hierarchy.

QMGR
The subscription forwards messages published on the topic only within this queue manager.

Note: Individual subscribers can only restrict **SUBSCOPE**. If the parameter is set to ALL at topic level, then an individual subscriber can restrict it to QMGR for this subscription. However, if the parameter is set to QMGR at topic level, then setting an individual subscriber to ALL has no effect.

SUBTYPE
Indicates how the subscription was created.

USER
Displays only **API** and **ADMIN** subscriptions.

PROXY
An internally created subscription used for routing publications through a queue manager.

Subscriptions of type PROXY are not modified to ADMIN when alterations are attempted.

ADMIN
Created using **DEF SUB** MQSC or PCF command. This **SUBTYPE** also indicates that a subscription has been modified using an administrative command.

API
Created using an **MQSUB** API request.

ALL
All.

SUBUSER(*string*)
Specifies the user ID that is used for security checks that are performed to ensure that publications can be put to the destination queue associated with the subscription. This ID is either the user ID associated with the creator of the subscription or, if subscription takeover is permitted, the user ID that last took over the subscription. The length of this parameter must not exceed 12 characters.

TOPICOBJ(*string*)
The name of a topic object used by this subscription.

TOPICSTR(*string*)
Returns a topic string, that can contain wildcard characters to match a set of topic strings, for the subscription. The topic string is either the application provided portion only, or fully qualified, depending on the value of **DISTYPE**.

USERDATA(*string*)
Specifies the user data associated with the subscription. The string is a variable length value that can be retrieved by the application on an MQSUB API call and passed in a message sent to this subscription as a message property. The **USERDATA** is stored in the RFH2 header in the mqps folder with the key Sud.

An IBM MQ classes for JMS application can retrieve the subscription user data from the message by using the constant JMS_IBM_SUBSCRIPTION_USER_DATA. For more information, see Retrieval of user subscription data.

VARUSER
Specifies whether a user other than the subscription creator can connect to and take over ownership of the subscription.

ANY
Any user can connect to and takeover ownership of the subscription.

FIXED
Takeover by another USERID is not permitted.

WSCHEMA
The schema to be used when interpreting any wildcard characters in the topic string.

CHAR
Wildcard characters represent portions of strings.

TOPIC
Wildcard characters represent portions of the topic hierarchy.

Multi DISPLAY SVSTATUS (display services status) on Multiplatforms

Use the MQSC command **DISPLAY SVSTATUS** to display status information for one or more services. Only services with a **SERVTYPE** of SERVER are displayed.

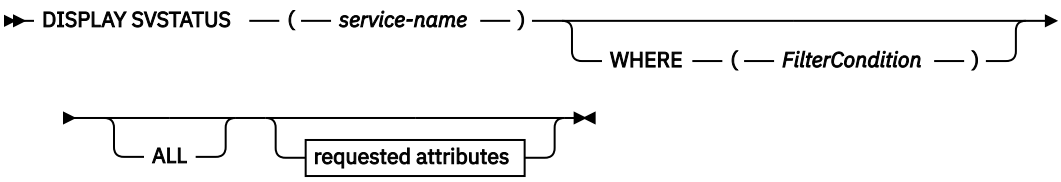
Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

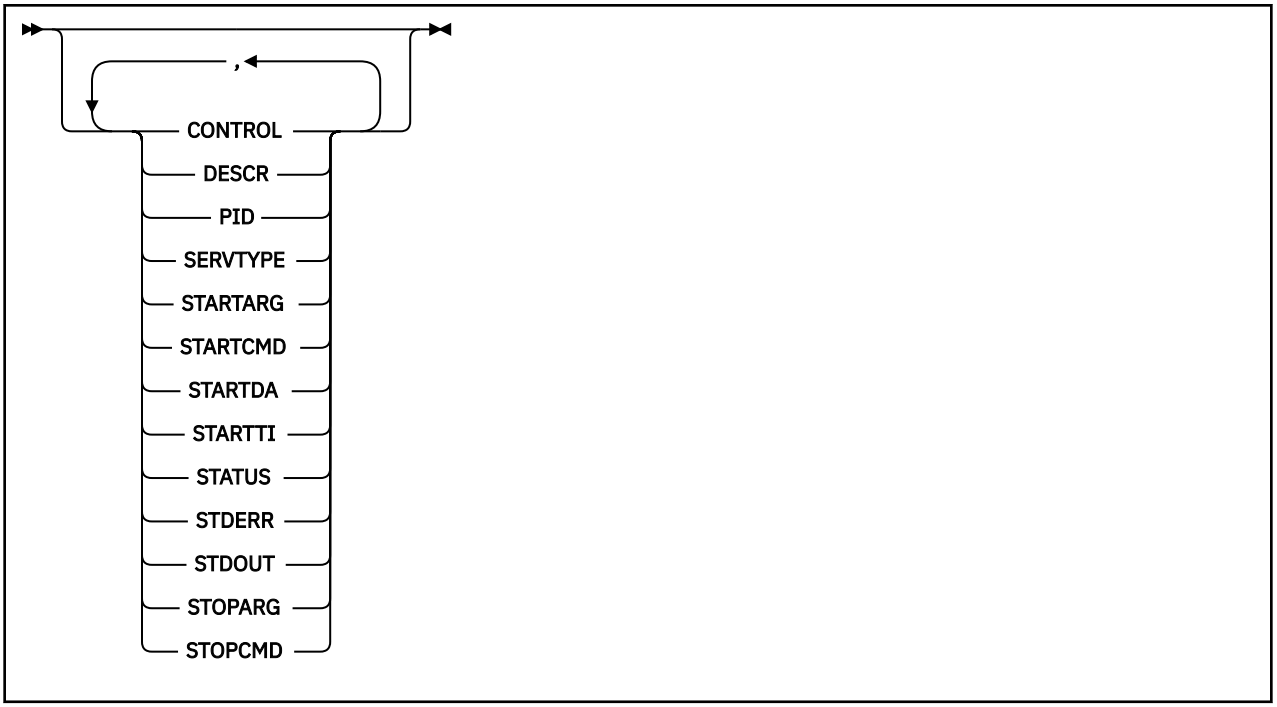
- Syntax diagram
- “Keyword and parameter descriptions for DISPLAY SVSTATUS” on page 820
- “Requested parameters” on page 821

Synonym:

DISPLAY SVSTATUS



Requested attributes



Keyword and parameter descriptions for DISPLAY SVSTATUS

You must specify a service for which you want to display status information. You can specify a service by using either a specific service name or a generic service name. By using a generic service name, you can display either:

- Status information for all service definitions, by using a single asterisk (*), or
- Status information for one or more services that match the specified name.

(*generic-service-name*)
The name of the service definition for which status information is to be displayed. A single asterisk (*) specifies that information for all connection identifiers is to be displayed. A character string with an asterisk at the end matches all services with the string followed by zero or more characters.

WHERE
Specify a filter condition to display status information for those services that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword
Any parameter that can be used to display attributes for this **DISPLAY** command.

operator
This is used to determine whether a service satisfies the filter value on the given filter keyword. The operators are:

LT
Less than

GT
Greater than

EQ
Equal to

NE
Not equal to

LE
Less than or equal to

GE
Greater than or equal to

filter-value
The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

  You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value MANUAL on the **CONTROL** parameter), you can only use EQ or NE.
- A generic value. This is a character string. with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed.

  You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

ALL
Display all the status information for each specified service. This is the default if you do not specify a generic name, and do not request any specific parameters.

Requested parameters

Specify one or more attributes that define the data to be displayed. The attributes can be specified in any order. Do not specify the same attribute more than once.

CONTROL
How the service is to be started and stopped:

MANUAL
The service is not to be started automatically or stopped automatically. It is to be controlled by use of the **START SERVICE** and **STOP SERVICE** commands.

QMGR
The service is to be started and stopped at the same time as the queue manager is started and stopped.

STARTONLY
The service is to be started at the same time as the queue manager is started, but is not requested to stop when the queue manager is stopped.

DESCR
Descriptive comment.

PID
The operating system process identifier associated with the service.

SERVTYPE
The mode in which the service runs. A service can have a **SERVTYPE** of SERVER or COMMAND, but only services with **SERVTYPE(SERVER)** are displayed by this command.

STARTARG
The arguments passed to the user program at startup.

STARTCMD
The name of the program being run.

STARTDA
The date on which the service was started.

STARTTI
The time at which the service was started.

STATUS
The status of the process:

RUNNING
The service is running.

STARTING
The service is in the process of initializing.

STOPPING
The service is stopping.

STDERR
Destination of the standard error (stderr) of the service program.

STDOUT
Destination of the standard output (stdout) of the service program.

STOPARG
The arguments to be passed to the stop program when instructed to stop the service.

STOPCMD
The name of the executable program to run when the service is requested to stop.

For more information about these parameters, see "DEFINE SERVICE (create a new service definition) on Multiplatforms" on page 564.

Examples of using service objects

z/OS DISPLAY SYSTEM (display system information) on z/OS

Use the MQSC command DISPLAY SYSTEM to display general system parameters and information.

Using MQSC commands

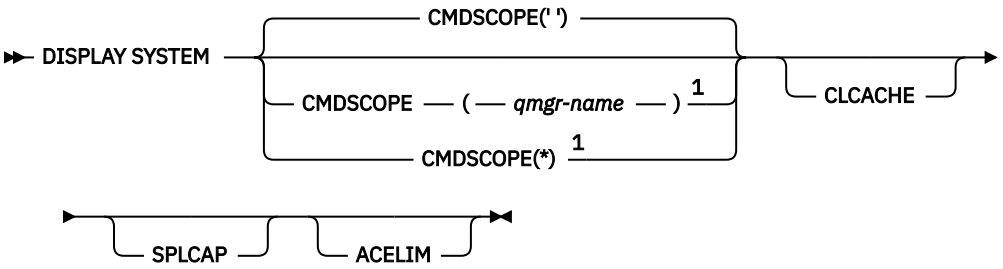
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 12CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Usage notes for DISPLAY SYSTEM" on page 823
- "Parameter descriptions for DISPLAY SYSTEM" on page 823

Synonym: DIS SYSTEM

DISPLAY SYSTEM



Notes:

[1] Valid only when the queue manager is a member of a queue sharing group.

Usage notes for DISPLAY SYSTEM

1. DISPLAY SYSTEM returns a report that shows the initial values of the system parameters and the current values as changed by the SET SYSTEM command:
   - Default user ID for command security checks (CMDUSER).
   - Time in seconds for which queue manager exits can execute during each invocation (EXITLIM).
   - How many started server tasks to use to run queue manager exits (EXITTCB).
   - Number of log records written by IBM MQ between the start of one checkpoint and the next (LOGLOAD).
   - The Measured Usage Pricing property for this queue manager (MULCCAPT). This property is only displayed if the MULCCAPT property is set to REFINED.
   - The OTMA connection parameters (OTMACON).
   - Whether queue manager restart waits until all indexes are built, or completes before all indexes are built (QINDXBLD).
   - Coded character set identifier for the queue manager (QMCCSID).
   - The queue sharing group parameters (QSGDATA).
   - The RESLEVEL auditing parameter (RESAUDIT).
   - The message routing code assigned to messages not solicited from a specific console (ROUTCDE).
   - Whether SMF accounting data is collected when IBM MQ is started (SMFACCT).
   - Whether SMF statistics are collected when IBM MQ is started (SMFSTAT).
   - LTS From IBM MQ for z/OS 9.2.0 to 9.2.3, the time, in minutes, between each gathering of statistics data (STATIME).
   - V 9.2.4 From IBM MQ for z/OS 9.2.4, the time, in minutes and seconds, between consecutive gatherings of statistics data (STATIME). This value is also used for accounting data if ACCTIME is set to -1.
   - V 9.2.4 Time, in minutes and seconds, between each gathering of accounting data (ACCTIME).
   - Whether tracing is started automatically (TRACSTR).
   - Size of trace table, in 4 KB blocks, to be used by the global trace facility (TRACTBL).
   - Time between scanning the queue index for WLM-managed queues (WLMTIME).
   - WLMTIMU indicates whether WLMTIME is given in seconds or minutes.
   - A list of messages excluded from being written to any log (EXCLMSG).
   - It might also return a report about system status.
2. This command is issued internally by IBM MQ at the end of queue manager startup.

Parameter descriptions for DISPLAY SYSTEM

CMDSCOPE

This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE cannot be used for commands issued from the first initialization input data set CSQINP1.

' '

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect is the same as entering the command on every queue manager in the queue sharing group.

ACELIM
The maximum size of the ACE storage pool in kilobytes .

CLCACHE
The type of the cluster cache .

SPLCAP
Whether the AMS component is installed .

DISPLAY TCLUSTER (display cluster topic attributes)

Use the MQSC command DISPLAY TCLUSTER to display the attributes of the IBM MQ cluster topic object.

Using MQSC commands

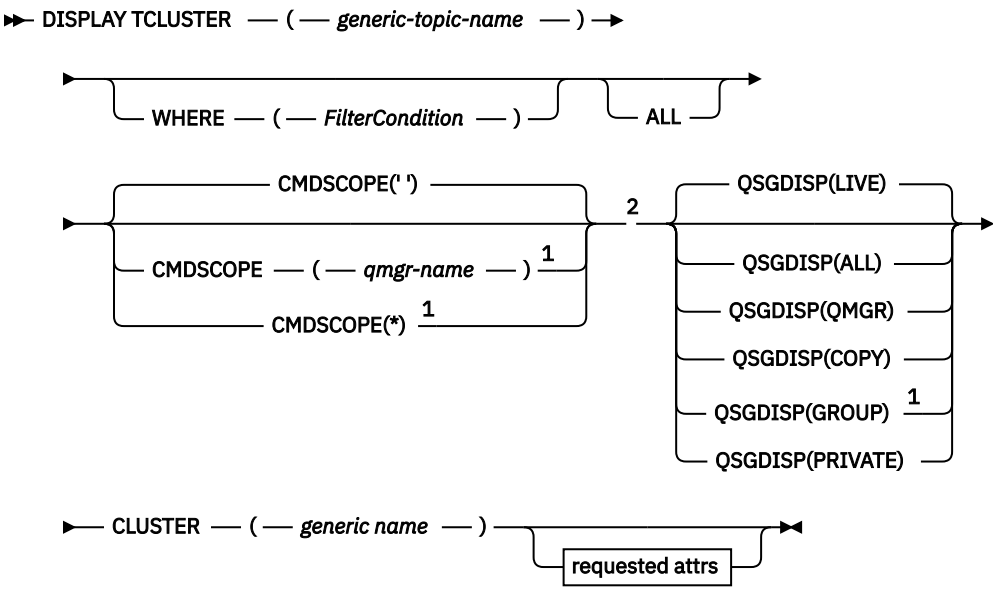
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

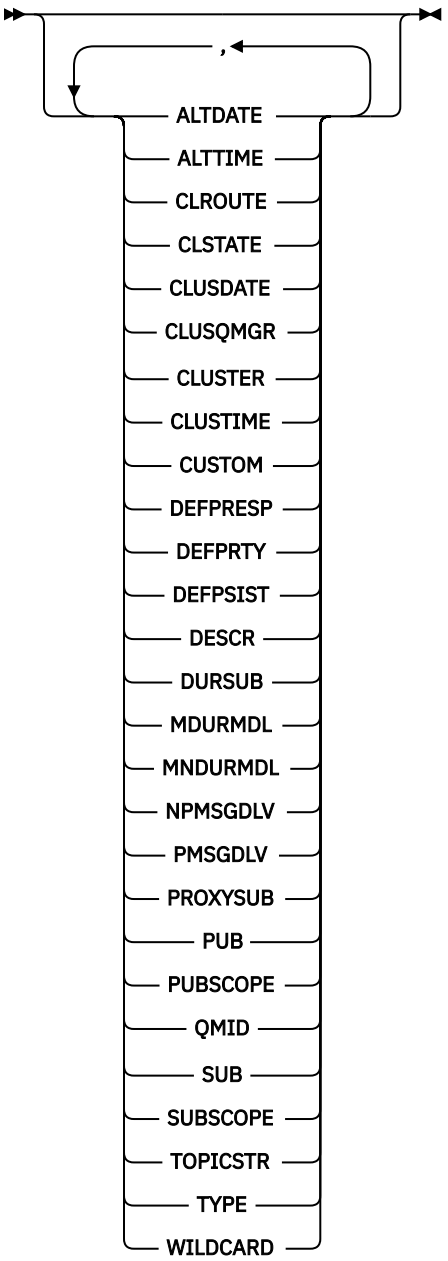
Attention: The **DISPLAY TCLUSTER** command produces the same output as the **DISPLAY TOPIC TYPE(CLUSTER)** command. See "DISPLAY TOPIC (display topic information)" on page 831 for further information.

Synonym: DIS TCLUSTER

DISPLAY TCLUSTER



Requested attrs



Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[2] Valid only on z/OS.

Parameter descriptions for DISPLAY TCLUSTER

You must specify the name of the cluster topic definition you want to display. This name can be a specific cluster topic name or a generic cluster topic name. By using a generic topic name, you can display either:

(generic-topic-name)
The name of the administrative cluster topic definition to be displayed (see Rules for naming IBM MQ objects). A trailing asterisk (*) matches all administrative topic objects with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all administrative topic objects.

WHERE

Specify a filter condition to display only those administrative topic object definitions that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

Almost any parameter that can be used to display attributes for this DISPLAY command.

z/OS However, you cannot use the CMDSCOPE, or QSGDISP parameters as filter keywords.

operator

This part is used to determine whether a topic object satisfies the filter value on the given filter keyword. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this value can be:

- An explicit value, that is a valid value for the attribute being tested.

  You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter, you can use only EQ or NE.

- A generic value. This value is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

  You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

Note: z/OS On z/OS there is a 256 character limit for the filter-value of the MQSC **WHERE** clause. This limit is not in place for other platforms.

ALL

Specify this parameter to display all the attributes. If this parameter is specified, any attributes that are requested specifically have no effect; all attributes are still displayed.

This is the default if you do not specify a generic name, and do not request any specific attributes.

z/OS CMDSCOPE

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' '

The command runs on the queue manager on which it was entered. This value is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this process is the same as entering the command on every queue manager in the queue sharing group.

You cannot use CMDSCOPE as a filter keyword.

z/OS QSGDISP

Specifies the disposition of the objects for which information is to be displayed. Values are:

LIVE

LIVE is the default value and displays information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

ALL

Display information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

If there is a shared queue manager environment, and the command is being executed on the queue manager where it was issued, this option also displays information for objects defined with QSGDISP(GROUP).

If QSGDISP(ALL) is specified in a shared queue manager environment, the command might give duplicated names (with different dispositions).

In a shared queue manager environment, use

```
DISPLAY TOPIC(name) CMDSCOPE(*) QSGDISP(ALL)
```

to list ALL objects matching name in the queue sharing group without duplicating those objects in the shared repository.

COPY

Display information only for objects defined with QSGDISP(COPY).

GROUP

Display information only for objects defined with QSGDISP(GROUP). This is allowed only if there is a shared queue manager environment.

PRIVATE

Display information only for objects defined with QSGDISP(QMGR) or QSGDISP(COPY). QSGDISP(PRIVATE) displays the same information as QSGDISP(LIVE).

QMGR

Display information only for objects defined with QSGDISP(QMGR).

QSGDISP

QSGDISP displays one of the following values:

QMGR

The object was defined with QSGDISP(QMGR).

GROUP
The object was defined with QSGDISP(GROUP).

COPY
The object was defined with QSGDISP(COPY).

You cannot use QSGDISP as a filter keyword.

CLUSTER
Displays topics with the specified cluster name. The value can be a generic name.

Requested attributes

CLROUTE
The routing behavior to use for topics in the cluster defined by the **CLUSTER** parameter.

CLSTATE
The current state of this topic in the cluster defined by the **CLUSTER** parameter. The values can be as follows:

ACTIVE
The cluster topic is correctly configured and being adhered to by this queue manager.

PENDING
Only seen by a hosting queue manager, this state is reported when the topic has been created but the full repository has not yet propagated it to the cluster. This might be because the host queue manager is not connected to a full repository, or because the full repository has deemed the topic to be invalid.

INVALID
This clustered topic definition conflicts with an earlier definition in the cluster and is therefore not currently active.

ERROR
An error has occurred with respect to this topic object.

This parameter is typically used to aid diagnosis when multiple definitions of the same clustered topic are defined on different queue managers, and the definitions are not identical. See Routing for publish/subscribe clusters: Notes on behavior.

CLUSDATE
The date on which the information became available to the local queue manager, in the form `yyyy-mm-dd`.

CLUSQMGR
The name of the queue manager that hosts the topic.

CLUSTIME
The time at which the information became available to the local queue manager, in the form `hh.mm.ss`.

QMID
The internally generated unique name of the queue manager that hosts the topic.

Usage notes for DISPLAY TCLUSTER

1. On z/OS, the channel initiator must be running before you can display information about cluster topics.
2. The TOPICSTR parameter might contain characters that cannot be translated into printable characters when the command output is displayed.

   z/OS On z/OS, these non-printable characters are displayed as blanks.

   Multi On Multiplatforms using the **runmqsc** command, these non-printable characters are displayed as dots.

Related reference

"DISPLAY TPSTATUS (display topic status)" on page 839
Use the MQSC command **DISPLAY TPSTATUS** to display the status of one or more topics in a topic tree.

"DISPLAY TOPIC (display topic information)" on page 831
Use the MQSC command **DISPLAY TOPIC** to display the attributes of one or more IBM MQ topic objects of any type.

z/OS DISPLAY THREAD (display thread information) on z/OS

Use the MQSC command DISPLAY THREAD to display information about active and in-doubt threads.

Using MQSC commands

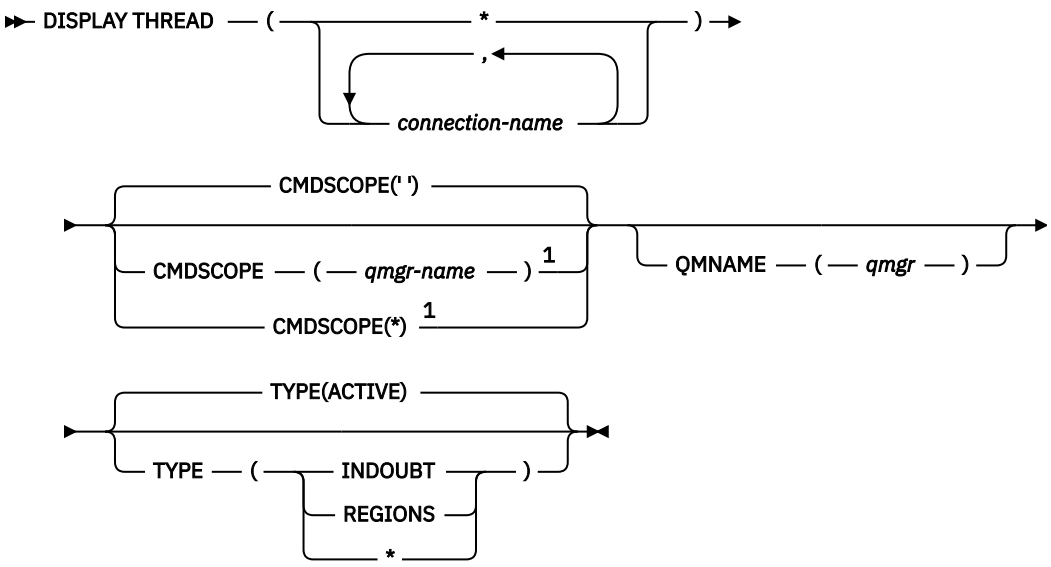
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Usage notes" on page 829
- "Parameter descriptions for DISPLAY THREAD" on page 830

Synonym: DIS THD

DISPLAY THREAD



Notes:

[1] Valid only when the queue manager is a member of a queue sharing group.

Usage notes

Threads shown as in doubt on one invocation of this command will probably be resolved for subsequent invocations.

This command is retained for compatibility with earlier release of IBM MQ. It has been superseded by the DISPLAY CONN command which is preferable to use.

Parameter descriptions for DISPLAY THREAD

(connection-name)
List of one or more *connection-name* s (of 1 through 8 characters each).

- For batch connections, this name is the batch job name
- For CICS connections, this name is the CICS applid
- For IMS connections, this name is the IMS job name
- For TSO connections, this name is the TSO user ID
- For RRS connections, this is RRSBATCH for all RRSBATCH-type connections, or the batch job name

Threads are selected from the address spaces associated with these connections only.

(*)
Displays threads associated with all connections to IBM MQ.

CMDSCOPE
This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

TYPE
The type of thread to display. This parameter is optional.

ACTIVE
Display only active threads.

An active thread is one for which a unit of recovery has started but not completed. Resources are held in IBM MQ on its behalf.

This is the default if TYPE is omitted.

INDOUBT
Display only in-doubt threads.

An in-doubt thread is one that is in the second phase of the two-phase commit operation. Resources are held in IBM MQ on its behalf. External intervention is needed to resolve the status of in-doubt threads. You might only have to start the recovery coordinator (CICS, IMS, or RRS), or you might need to do more. They might have been in doubt at the last restart, or they might have become in doubt since the last restart.

REGIONS
Display a summary of active threads for each active connection.

Note: Threads used internally by IBM MQ are excluded.

*****
Display both active and in-doubt threads, but not regions.

If, during command processing, an active thread becomes in doubt, it might appear twice: once as active and once as in doubt.

QMNAME
Specifies that IBM MQ should check whether the designated queue manager is INACTIVE, and if so, report any shared units of work that were in progress on the designated and inactive queue manager.

This option is valid only for TYPE(INDOUBT).

z/OS For more information about the DISPLAY THREAD command and in-doubt recovery, see Recovering units of recovery on another queue manager in the queue sharing group. Also, see messages CSQV401I through CSQV406I, and CSQV432I, in Agent services messages (CSQV...).

DISPLAY TOPIC (display topic information)

Use the MQSC command **DISPLAY TOPIC** to display the attributes of one or more IBM MQ topic objects of any type.

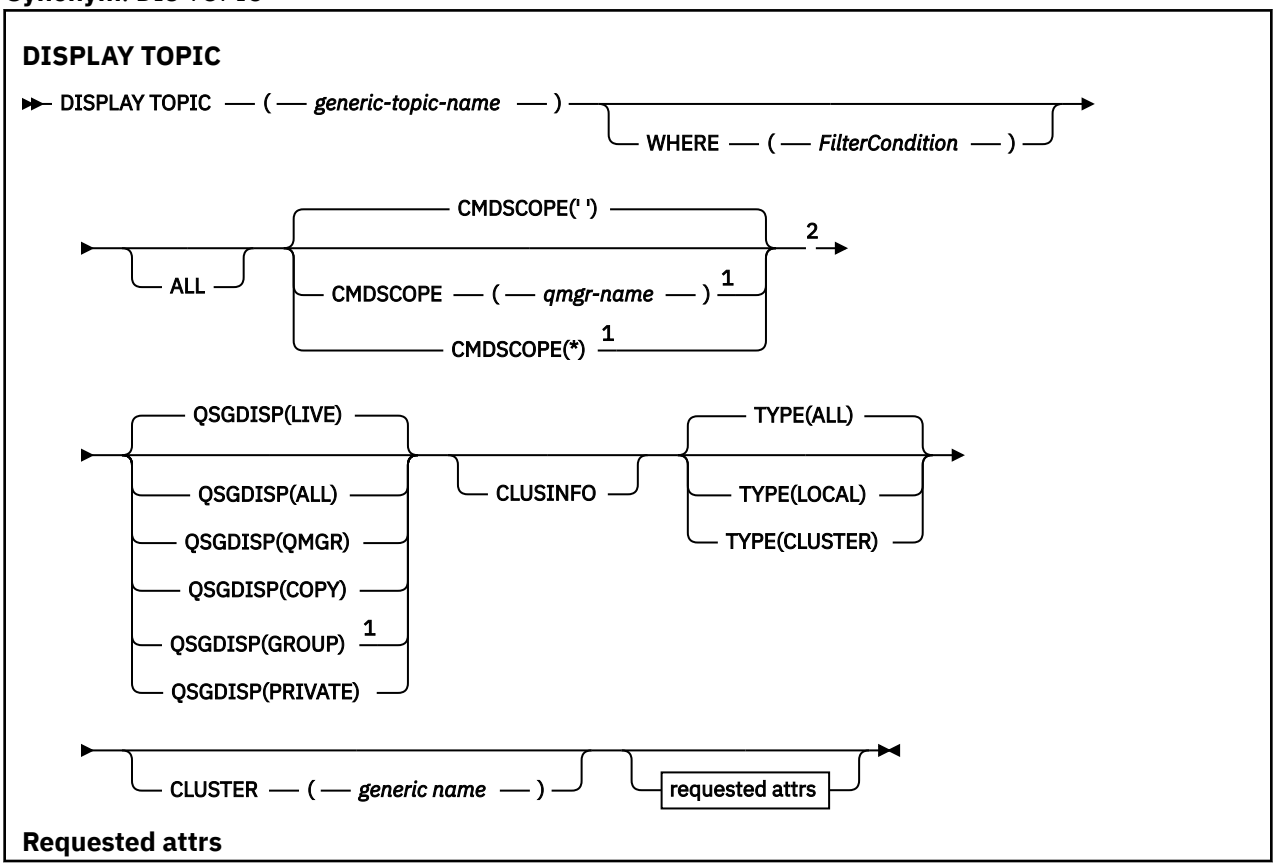
Using MQSC commands

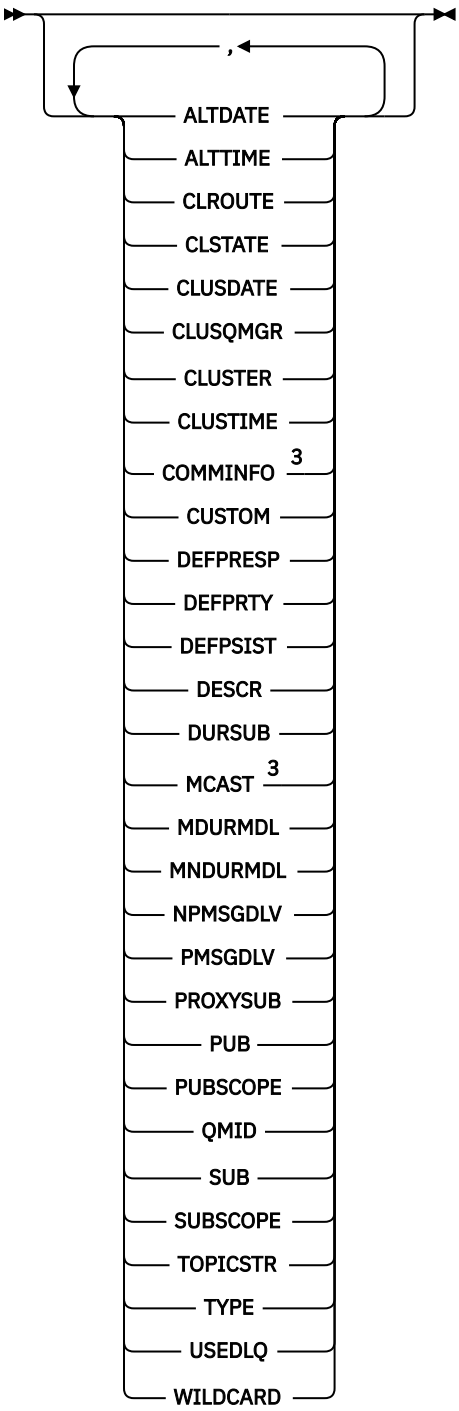
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Usage notes for DISPLAY TOPIC" on page 832
- "Parameter descriptions for DISPLAY TOPIC" on page 833
- "Requested parameters" on page 836

Synonym: DIS TOPIC





Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[2] Valid only on z/OS.
[3] Not valid on z/OS.

Usage notes for DISPLAY TOPIC

1. z/OS On z/OS, the channel initiator must be running before you can display information about cluster topics, using **TYPE(CLUSTER)** or the **CLUSINFO** parameter.

2. The **TOPICSTR** parameter might contain characters that cannot be translated into printable characters when the command output is displayed.

   z/OS On z/OS, these non-printable characters are displayed as blanks.

   Multi On Multiplatforms using the runmqsc command, these non-printable characters are displayed as dots

3. You can use the following command (or synonym) as an alternative way to display these attributes.

   ```
   DISPLAY TCLUSTER
   ```

   This command produces the same output as the following command:

   ```
   DISPLAY TOPIC TYPE(CLUSTER)
   ```

   If you enter the command in this way, do not use the **TYPE** parameter.

Parameter descriptions for DISPLAY TOPIC

You must specify the name of the topic definition you want to display. This name can be a specific topic name or a generic topic name. By using a generic topic name, you can display either:

- All topic definitions
- One or more topic definitions that match the specified name

(generic-topic-name)
The name of the administrative topic definition to be displayed (see Rules for naming IBM MQ objects). A trailing asterisk (*) matches all administrative topic objects with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all administrative topic objects.

WHERE
Specify a filter condition to display only those administrative topic object definitions that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword
Almost any parameter that can be used to display attributes for this **DISPLAY** command. However, you cannot use the **CMDSCOPE**, or **QSGDISP** parameters as filter keywords.

operator
This part is used to determine whether a topic object satisfies the filter value on the given filter keyword. The operators are:

LT
Less than

GT
Greater than

EQ
Equal to

NE
Not equal to

LE
Less than or equal to

GE
Greater than or equal to

LK
Matches a generic string that you provide as a *filter-value*

NL
Does not match a generic string that you provide as a *filter-value*

filter-value
The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this value can be:

- An explicit value, that is a valid value for the attribute being tested.

  You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter, you can use only EQ or NE.

- A generic value. This value is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

  You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

Note: z/OS On z/OS there is a 256 character limit for the filter-value of the MQSC **WHERE** clause. This limit is not in place for other platforms.

ALL
Specify this parameter to display all the attributes. If this parameter is specified, any attributes that are requested specifically have no effect; all attributes are still displayed.

This is the default if you do not specify a generic name, and do not request any specific attributes.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' '
The command runs on the queue manager on which it was entered. This value is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this process is the same as entering the command on every queue manager in the queue sharing group.

You cannot use CMDSCOPE as a filter keyword.

z/OS **QSGDISP**
Specifies the disposition of the objects for which information is to be displayed. Values are:

LIVE
LIVE is the default value and displays information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

ALL
Display information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

If there is a shared queue manager environment, and the command is being processed on the queue manager where it was issued, this option also displays information for objects defined with QSGDISP(GROUP).

If QSGDISP(ALL) is specified in a shared queue manager environment, the command might give duplicated names (with different dispositions).

In a shared queue manager environment, use

```
DISPLAY TOPIC(name) CMDSCOPE(*) QSGDISP(ALL)
```

to list ALL objects matching name in the queue sharing group without duplicating those objects in the shared repository.

COPY
Display information only for objects defined with QSGDISP(COPY).

GROUP
Display information only for objects defined with QSGDISP(GROUP). This is allowed only if there is a shared queue manager environment.

PRIVATE
Display information only for objects defined with QSGDISP(QMGR) or QSGDISP(COPY). QSGDISP(PRIVATE) displays the same information as QSGDISP(LIVE).

QMGR
Display information only for objects defined with QSGDISP(QMGR).

QSGDISP
QSGDISP displays one of the following values:

QMGR
The object was defined with QSGDISP(QMGR).

GROUP
The object was defined with QSGDISP(GROUP).

COPY
The object was defined with QSGDISP(COPY).

You cannot use QSGDISP as a filter keyword.

CLUSINFO
Requests that, in addition to information about attributes of topics defined on this queue manager, information about these and other topics in the cluster, that match the selection criteria, is displayed. In this case, there might be multiple topics with the same topic string displayed. The cluster information is obtained from the repository on this queue manager.

z/OS On z/OS, the channel initiator must be running before you can use the CLUSINFO parameter to display information about cluster topics.

CLUSTER
Limits the information displayed to topics with the specified cluster name if entered with a value in brackets. The value can be a generic name.

If you do not enter a value to qualify this parameter, it is treated as a requested parameter, and cluster name information is returned about all the topics displayed.

z/OS On z/OS, the channel initiator must be running before you can use the CLUSINFO parameter to display information about cluster topics.

TYPE
Specifies the type of topics that you want to be displayed. Values are:

ALL
Display all topic types, including cluster topics if you also specify CLUSINFO.

LOCAL
Display locally defined topics.

CLUSTER
Display topics that are defined in publish/subscribe clusters. Cluster attributes include:

CLUSDATE
The date on which the definition became available to the local queue manager, in the form `yyyy-mm-dd`.

CLUSQMGR
The name of the queue manager hosting the topic.

CLUSTIME
The time at which the definition became available to the local queue manager, in the form `hh.mm.ss`.

QMID
The internally generated, unique name of the queue manager hosting the topic.

Requested parameters

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

Most of the parameters are relevant for both types of topics, but parameters that are not relevant for a particular type of topic cause no output, nor is an error raised.

The following table shows the parameters that are relevant for each type of topic. There is a brief description of each parameter after the table, but for more information, see "DEFINE TOPIC (define a new administrative topic)" on page 577.

Table 169. Parameters that can be returned by the DISPLAY TOPIC command

WILDCARD	✓	✓

ALTDATE
The date on which the definition or information was last altered, in the form `yyyy-mm-dd`.

ALTTIME
The time at which the definition or information was last altered, in the form `hh.mm.ss`.

CLROUTE
The routing behavior to use for topics in the cluster defined by the **CLUSTER** parameter.

CLSTATE
The current state of this topic in the cluster defined by the **CLUSTER** parameter. The values can be as follows:

ACTIVE
The cluster topic is correctly configured and being adhered to by this queue manager.

PENDING
Only seen by a hosting queue manager, this state is reported when the topic has been created but the full repository has not yet propagated it to the cluster. This might be because the host queue manager is not connected to a full repository, or because the full repository has deemed the topic to be invalid.

INVALID
This clustered topic definition conflicts with an earlier definition in the cluster and is therefore not currently active.

ERROR
An error has occurred with respect to this topic object.

This parameter is typically used to aid diagnosis when multiple definitions of the same clustered topic are defined on different queue managers, and the definitions are not identical. See Routing for publish/subscribe clusters: Notes on behavior.

CLUSDATE
The date on which the information became available to the local queue manager, in the form `yyyy-mm-dd`.

CLUSQMGR
The name of the queue manager that hosts the topic.

CLUSTER
The name of the cluster that the topic is in.

CLUSTIME
The time at which the information became available to the local queue manager, in the form `hh.mm.ss`.

COMMINFO
The communication information object name.

CUSTOM
This attribute is reserved for the configuration of new features before separate attributes have been introduced. It can contain the values of zero or more attributes as pairs of attribute name and value in the form `NAME(VALUE)`.

DEFPRTY
Default priority of the messages published to this topic.

DEFPSIST
Default persistence of messages published to this topic.

DEFPRESP
Default put response for this topic. This attribute defines the behavior that must be used by applications when the put response type in the MQPMO options has been set to MQPMO_RESPONSE_AS_TOPIC_DEF.

DESCR
Description of this administrative topic object.

DURSUB
Determines whether the topic permits durable subscriptions to be made.

MCAST
Specifies whether the topic is enabled for multicast.

MDURMDL
The name of the model queue for durable managed subscriptions.

MNDURMDL
The name of the model queue for non-durable managed subscriptions.

NPMSGDLV
The delivery mechanism for non-persistent messages.

PMSGDLV
The delivery mechanism for persistent messages.

PROXYSUB
Determines whether a proxy subscription is forced for this subscription, even if no local subscriptions exist.

PUB
Determines whether the topic is enabled for publication.

PUBSCOPE
Determines whether this queue manager propagates publications to queue managers as part of a hierarchy or as part of a publish/subscribe cluster.

QMID
The internally generated unique name of the queue manager that hosts the topic.

SUB
Determines whether the topic is enabled for subscription.

SUBSCOPE
Determines whether this queue manager propagates subscriptions to queue managers as part of a hierarchy or as part of a publish/subscribe cluster.

TOPICSTR
The topic string.

TYPE
Specifies whether this object is a local topic or cluster topic.

USEDLQ
Determines whether the dead-letter queue is used when publication messages cannot be delivered to their correct subscriber queue.

WILDCARD
The behavior of wildcard subscriptions with respect to this topic.

For more details of these parameters, except the **CLSTATE** parameter, see "DEFINE TOPIC (define a new administrative topic)" on page 577.

Displaying administrative topic object attributes

Changing administrative topic attributes

Related reference

"DISPLAY TPSTATUS (display topic status)" on page 839

Use the MQSC command **DISPLAY TPSTATUS** to display the status of one or more topics in a topic tree.

DISPLAY TPSTATUS (display topic status)

Use the MQSC command **DISPLAY TPSTATUS** to display the status of one or more topics in a topic tree.

Using MQSC commands

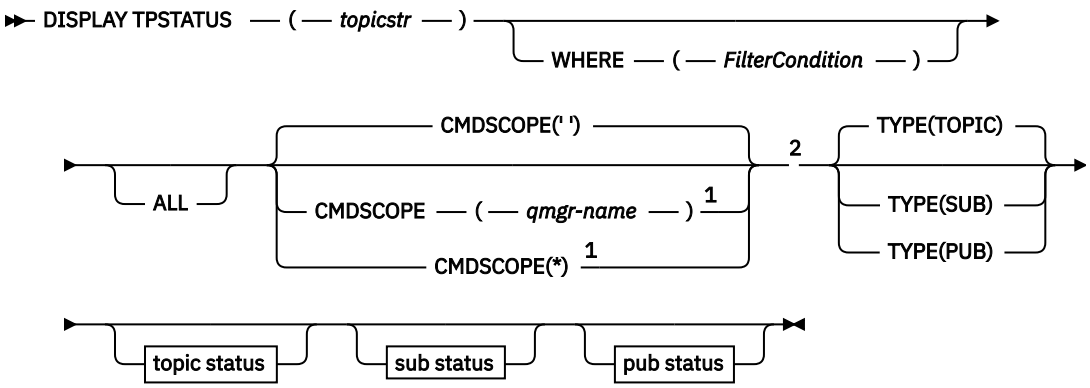
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

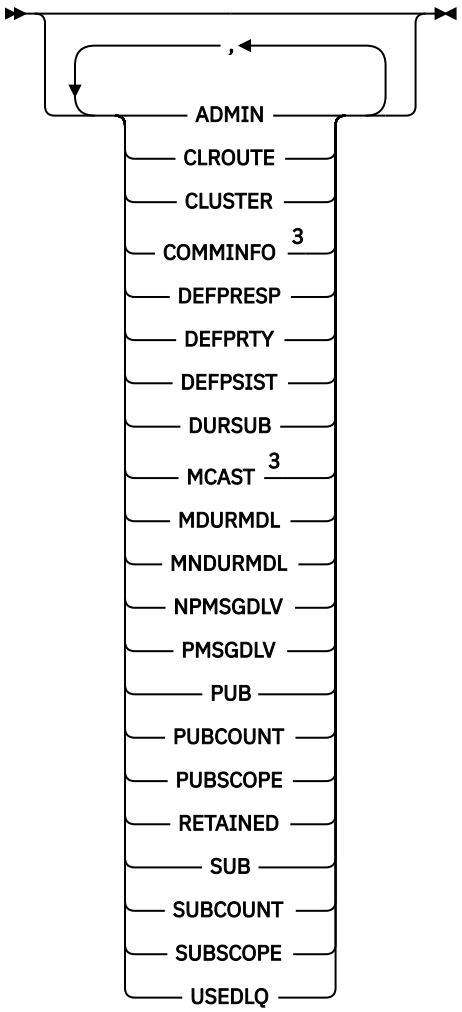
- Syntax diagram
- "Usage notes for DISPLAY TPSTATUS" on page 841
- "Parameter descriptions for DISPLAY TPSTATUS" on page 841
- "Topic status parameters" on page 843
- "Sub status parameters" on page 845
- "Pub status parameters" on page 846

Synonym: DIS TPS

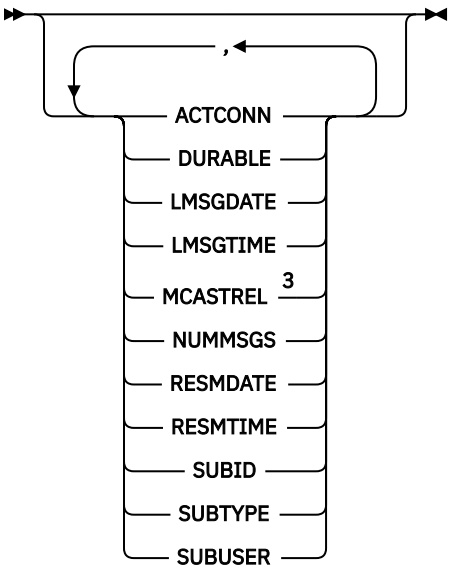
DISPLAY TPSTATUS



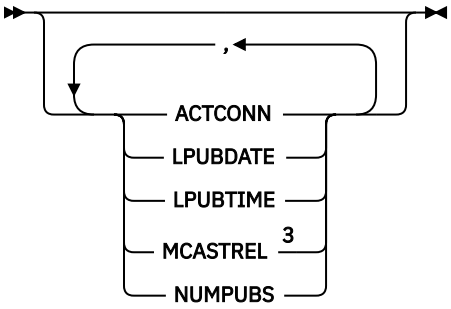
Topic status



Sub status



Pub status



Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[2] Valid only on z/OS.
[3] Not valid on z/OS.

Usage notes for DISPLAY TPSTATUS

1. The TOPICSTR parameter might contain characters that cannot be translated into printable characters when the command output is displayed.
   - Multi On Multiplatforms using the **runmqsc** command, these non-printable characters are displayed as dots.
   - z/OS On z/OS, these non-printable characters are displayed as blanks.
2. The topic-string input parameter on this command must match the topic you want to act on. Keep the character strings in your topic strings as characters that can be used from the location issuing the command. If you issue commands using MQSC, you have fewer characters available to you than if you are using an application that submits PCF messages, such as the IBM MQ Explorer.

Parameter descriptions for DISPLAY TPSTATUS

The **DISPLAY TPSTATUS** command requires a topic string value to determine which topic nodes the command returns.

topicstr)

The value of the topic string for which you want to display status information. You cannot specify the name of an IBM MQ topic object.

The topic string can have one of the following values:

- A specific topic string value. For example, `DIS TPS('Sports/Football')` returns just the 'Sports/Football' node.
- A topic string containing a "+" wildcard character. For example, `DIS TPS('Sports/Football/+')` returns all direct child nodes of the 'Sports/Football' node.
- A topic string containing a "#" wildcard character. For example, `DIS TPS('Sports/Football/#')` returns the 'Sports/Football' node and all its descendant nodes.
- A topic string containing more than one wildcard. For example, `DIS TPS('Sports/+/Teams/#')` returns any direct child node of 'Sports' that also has a 'teams' child, with all descendants of the latter nodes.

The **DISPLAY TPSTATUS** command does not support the '*' wildcard. For more information about using wildcards, see the related topic.

- To return a list of all root-level topics, use `DIS TPS('+')`
- To return a list of all topics in the topic tree, use `DIS TPS('#')`, but note that this command might return a large amount of data.
- To filter the list of topics returned, use the **WHERE** parameter. For example, `DIS TPS('Sports/Football/+') WHERE(TOPICSTR LK 'Sports/Football/L*')` returns all direct child nodes of the 'Sports/Football' node, that begin with the letter "L".

WHERE

Specifies a filter condition to display only those administrative topic definitions that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

Except for the CMDSCOPE parameter, any parameter that you can use with this DISPLAY command.

operator

Determines whether a topic string satisfies the filter value on the given filter keyword. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *topicstr*

NL

Does not match a generic string that you provide as a *topicstr*

filter-value
The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this value can be:

- An explicit value that is a valid value for the attribute being tested.

  You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter, you can use only EQ or NE.

- A generic value. This value is a character string with an asterisk at the end, for example ABC*. If the operator is LK, the command lists all topic nodes that begin with the string (ABC in the example). If the operator is NL, the command lists all topic nodes that do not begin with the string.

  You cannot use a generic *filter-value* for parameters with numeric values or with one of a set of values.

ALL
Use this parameter to display all attributes.

If this parameter is specified, any attributes that you request specifically have no effect; the command displays all attributes.

This parameter is the default parameter if you do not specify a generic name, and do not request any specific attributes.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

' '
The command runs on the queue manager on which it was entered. This value is the default value.

qmgr-name
The command runs on the named queue manager, if the queue manager is active within the queue sharing group.

You can specify a queue manager name other than the queue manager on which you enter the command, but only if you are using a queue sharing group environment and the command server is enabled.

***
The command runs on the local queue manager and on every active queue manager in the queue sharing group. The effect of this option is equivalent to entering the command on every queue manager in the queue sharing group.

TYPE

TOPIC
The command displays status information relating to each topic node, which is the default if you do not provide a **TYPE** parameter.

PUB
The command displays status information relating to applications that have topic nodes open for publish.

SUB
The command displays status information relating to applications that subscribe to the topic node or nodes. The subscribers that the command returns are not necessarily the subscribers that would receive a message published to this topic node. The value of **SelectionString** or **SubLevel** determines which subscribers receive such messages.

Topic status parameters

Topic status parameters define the data that the command displays. You can specify these parameters in any order but must not specify the same parameter more than once.

Topic objects can be defined with attributes that have a value of *ASPARENT*. Topic status shows the resolved values that result in finding the setting of the closest parent administrative topic object in the topic tree, and so will never display a value of *ASPARENT*.

ADMIN
If the topic node is an admin-node, the command displays the associated topic object name containing the node configuration. If the field is not an admin-node the command displays a blank.

CLROUTE
The routing behavior to use for topics in the cluster defined by the **CLUSTER** parameter. The values can be as follows:

DIRECT
A publication on this topic string, originating from this queue manager, is sent direct to any queue manager in the cluster with a matching subscription.

TOPICHOST
A publication on this topic string, originating from this queue manager, is sent to one of the queue managers in the cluster that hosts a definition of the corresponding clustered topic object, and from there to any queue manager in the cluster with a matching subscription.

NONE
This topic node is not clustered.

CLUSTER
The name of the cluster to which this topic belongs.

' '
This topic does not belong to a cluster. Publications and subscriptions for this topic are not propagated to publish/subscribe cluster-connected queue managers.

COMMINFO
Displays the resolved value of the name of the communication information object to be used for ths topic node.

DEFPRESP
Displays the resolved default put response of messages published to the topic. The value can be *SYNC* or *ASYNC*

DEFPRTY
Displays the resolved default priority of messages published to the topic.

DEFPSIST
Displays the resolved default persistence for this topic string. The value can be *YES* or *NO*.

DURSUB
Displays the resolved value that shows whether applications can make durable subscriptions. The value can be *YES* or *NO*.

MCAST
Displays the resolved value that shows whether the topic could be transmittable via multicast or not. The value can be *ENABLED*, *DISABLED*, or *ONLY*.

MDURMDL
Displays the resolved value of the name of the model queue to be used for durable subscriptions.

MNDURMDL
Displays the resolved value of the name of the model queue used for non-durable subscriptions.

NPMSGDLV
Displays the resolved value for the delivery mechanism for non-persistent messages published to this topic. The value can be *ALL*, *ALLDUR*, or *ALLAVAIL*.

PMSGDLV
Displays the resolved value for the delivery mechanism for persistent messages published to this topic. The value can be *ALL*, *ALLDUR*, or *ALLAVAIL*.

PUB
Displays the resolved value that shows whether publications are allowed for this topic. The values can be *ENABLED* or *DISABLED*.

PUBCOUNT
Displays the number of handles that are open for publish on this topic node.

PUBSCOPE
Determines whether this queue manager propagates publications, for this topic node, to other queue managers as part of a hierarchy or a cluster, or whether it restricts them to only subscriptions defined on the local queue manager. The value can be *QMGR* or *ALL*.

RETAINED
Displays whether there is a retained publication associated with this topic. The value can be *YES* or *NO*.

SUB
Displays the resolved value that shows whether subscriptions are allowed for this topic. The values can be *ENABLED* or *DISABLED*.

SUBCOUNT
Displays the number of subscribers to this topic node, including durable subscribers that are not currently connected.

SUBSCOPE
Determines whether this queue manager propagates subscriptions, for this topic node, to other queue managers as part of a cluster or hierarchy, or whether it restricts the subscriptions to only the local queue manager. The value can be *QMGR* or *ALL*.

USEDLQ
Determines whether the dead-letter queue is used when publication messages cannot be delivered to their correct subscriber queue. The value can be *YES* or *NO*.

Sub status parameters

Sub status parameters define the data that the command displays. You can specify these parameters in any order but must not specify the same parameter more than once.

ACTCONN
Detects local publications, returning the currently active ConnectionId (CONNID) that opened this subscription.

DURABLE
Indicates whether a durable subscription is not deleted when the creating application closes its subscription handle, and persists over queue manager restart. The value can be *YES* or *NO*.

LMSGDATE
The date on which an MQPUT call last sent a message to this subscription. The MQPUT call updates the date field only when the call successfully puts a message to the destination specified by this subscription. An MQSUBRQ call causes an update to this value.

LMSGTIME
The time at which an MQPUT call last sent a message to this subscription. The MQPUT call updates the time field only when the call successfully puts a message to the destination specified by this subscription. An MQSUBRQ call causes an update to this value.

MCASTREL
Indicator of the reliability of the multicast messages.

The values are expressed as a percentage. A value of 100 indicates that all messages are being delivered without problems. A value less than 100 indicates that some of the messages are experiencing network issues. To determine the nature of these issues you can enable event message generation, use the **COMMEV** parameter of the COMMINFO objects, and examine the generated event messages.

The following two values are returned:

- The first value is based on recent activity over a short period.
- The second value is based on activity over a longer period.

If no measurement is available the values are shown as blanks.

NUMMSGS
Number of messages put to the destination specified by this subscription. An MQSUBRQ call causes an update to this value.

RESMDATE
Date of the most recent MQSUB call that connected to this subscription.

RESMTIME
Time of the most recent MQSUB call that connected to this subscription.

SUBID
An all time unique identifier for this subscription, assigned by the queue manager. The format of **SUBID** matches that of a CorrelId. For durable subscriptions, the command returns the **SUBID** even if the subscriber is not currently connected to the queue manager.

SUBTYPE
The type of subscription, indicating how it was created. The value can be *ADMIN*, *API*, or *PROXY*.

SUBUSER
The user ID that owns this subscription, which can be either the user ID associated with the creator of the subscription or, if subscription takeover is permitted, the user ID that last took over the subscription.

Pub status parameters

Pub status parameters define the data that the command displays. You can specify these parameters in any order but must not specify the same parameter more than once.

ACTCONN
The currently active ConnectionId (CONNID) associated with the handle that has this topic node open for publish.

LPUBDATE
The date on which this publisher last sent a message.

LPUBTIME
The time at which this publisher last sent a message.

MCASTREL
Indicator of the reliability of the multicast messages.

The values are expressed as a percentage. A value of 100 indicates that all messages are being delivered without problems. A value less than 100 indicates that some of the messages are experiencing network issues. To determine the nature of these issues you can enable event message generation, using the **COMMEV** parameter of the COMMINFO objects, and examine the generated event messages.

The following two values are returned:

- The first value is based on recent activity over a short period.
- The second value is based on activity over a longer period.

If no measurement is available the values are shown as blanks.

NUMPUBS
Number of publishes by this publisher. This value records the actual number of publishes, not the total number of messages published to all subscribers.

"DISPLAY TOPIC (display topic information)" on page 831

Use the MQSC command **DISPLAY TOPIC** to display the attributes of one or more IBM MQ topic objects of any type.

z/OS DISPLAY TRACE (display active traces list) on z/OS

Use the MQSC command DISPLAY TRACE to display a list of active traces.

Using MQSC commands

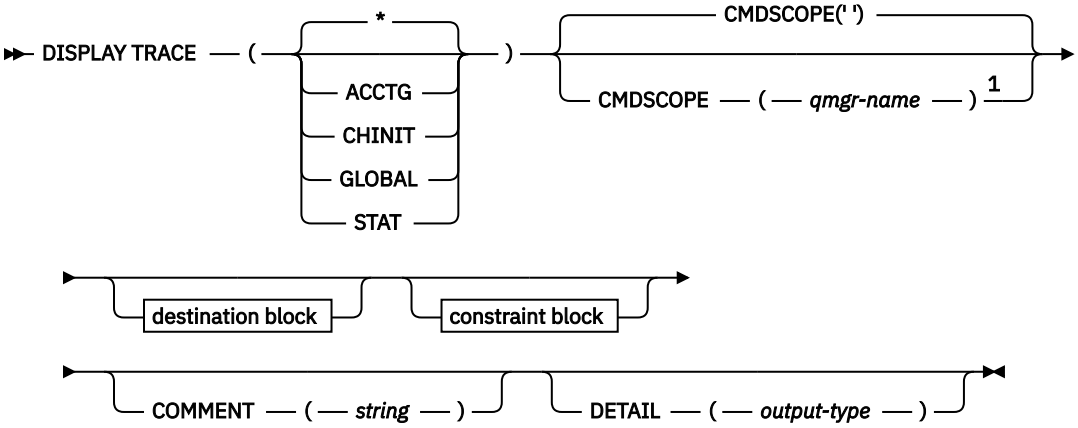
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 12CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

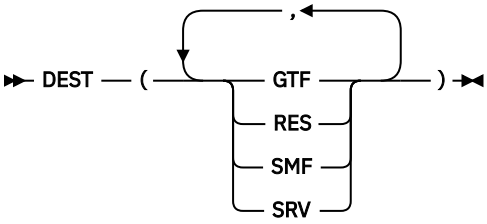
- Syntax diagram
- "Parameter descriptions for DISPLAY TRACE" on page 848
- "Destination block" on page 849
- "Constraint block" on page 849

Synonym: DIS TRACE

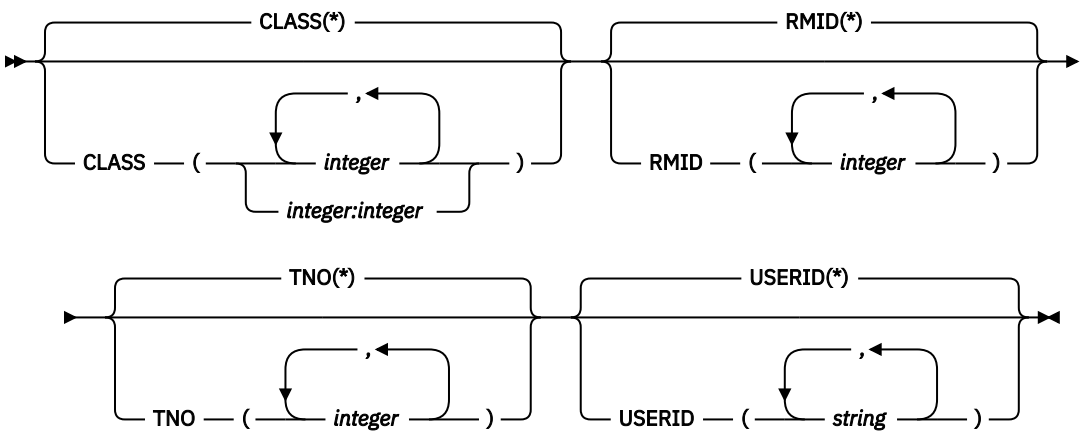
DISPLAY TRACE



Destination block



Constraint block



Notes:

[1] Valid only when the queue manager is a member of a queue sharing group.

Parameter descriptions for DISPLAY TRACE

All parameters are optional. Each option that is used limits the effect of the command to active traces that were started using the same option, either explicitly or by default, with exactly the same parameter values.

*****

Does not limit the list of traces. This is the default. The CLASS option cannot be used with DISPLAY TRACE(*).

Each remaining parameter in this section limits the list to traces of the corresponding type:

ACCTG
Accounting data (the synonym is A)

CHINIT
Service data from the channel initiator. The synonym is CHI or DQM.

GLOBAL
Service data from the entire queue manager except the channel initiator. The synonym is G.

STAT
Statistical data (the synonym is S)

COMMENT(*string*)
Specifies a comment. This does not appear in the display, but it might be recorded in trace output.

DETAIL(*output-type*)
This parameter is ignored; it is retained only for compatibility with earlier releases.

Possible values for *output-type* are *, 1, or 2.

CMDSCOPE
This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE cannot be used for commands issued from the first initialization input data set CSQINP1.

' '

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

Destination block

DEST
Limits the list to traces started for particular destinations. More than one value can be specified, but do not use the same value twice. If no value is specified, the list is not limited.

Possible values and their meanings are:

GTF
The Generalized Trace Facility

RES
A wraparound table residing in the ECSA (extended common service area)

SMF
The System Management Facility

SRV
A serviceability routine designed for IBM for problem diagnosis

Constraint block

CLASS(*integer*)
Limits the list to traces started for particular classes. See "START TRACE (start trace) on z/OS" on page 934 for a list of allowed classes.

The default is CLASS(*), which does not limit the list.

RMID(*integer*)
Limits the list to traces started for particular resource managers. See "START TRACE (start trace) on z/OS" on page 934 for a list of allowed resource manager identifiers. Do not use this option with the STAT or CHINIT trace type.

The default is RMID(*), which does not limit the list.

TNO(*integer*)
Limits the list to particular traces, identified by their trace number (0 to 32). Up to 8 trace numbers can be used. If more than one number is used, only one value for USERID can be used. The default is TNO(*), which does not limit the list.

0 is the trace that the channel initiator can start automatically. Traces 1 to 32 are those for queue manager or the channel initiator that can be started automatically by the queue manager, or manually, using the START TRACE command.

USERID(*string*)
Limits the list to traces started for particular user IDs. Up to 8 user IDs can be used. If more than one user ID is used, only one value can be used for TNO. Do not use this option with STAT. The default is USERID(*), which does not limit the list.

z/OS DISPLAY USAGE (display usage information) on z/OS

Use the MQSC command DISPLAY USAGE to display information about the current state of a page set, to display information about the log data sets, or to display information about the shared message data sets.

Using MQSC commands

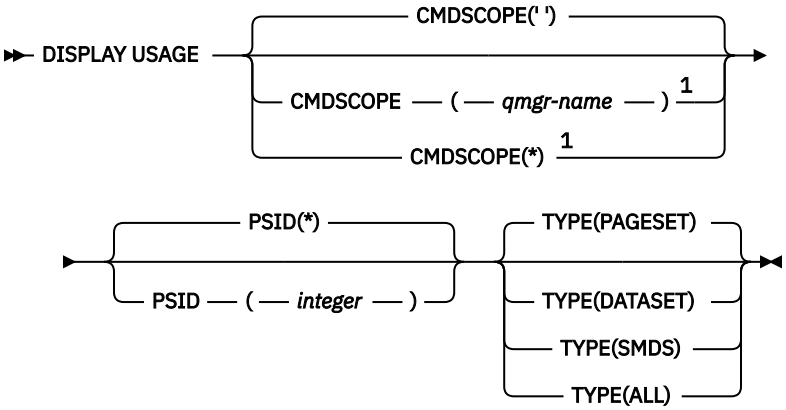
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Parameter descriptions for DISPLAY USAGE" on page 850

Synonym: DIS USAGE

DISPLAY USAGE



Notes:

[1] Valid only when the queue manager is a member of a queue sharing group.

Parameter descriptions for DISPLAY USAGE

CMDSCOPE

This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

' '

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

PSID(*integer*)

The page-set identifier. This is optional.

*****

An asterisk (*) on its own specifies all page set identifiers. This is the default value.

integer

This is a number, in the range 00 through 99.

The command fails if PSID has been specified together with TYPE(DATASET), or TYPE(SMDS).

If the command is running at the same time as an ALTER BUFFPOOL command the buffer pool attributes might not be entirely consistent. For example, the value of the location parameter might be

BELOW, but the number of available buffers value might be more than can fit below the bar. If this occurs, run the display command again when the ALTER BUFFPOOL command has completed.

TYPE
Defines the type of information to be displayed. Values are:

PAGESET
Display page set and buffer pool information. This is the default.

DATASET
Display data set information for log data sets. This returns messages containing 44-character data set names for the following:

- The log data set containing the BEGIN_UR record for the oldest incomplete unit of work for this queue manager, or if there are no incomplete units of work, the log data set containing the current highest written RBA.
- The log data set containing the oldest restart_RBA of any page set owned by this queue manager.
- The log data set with a timestamp range that includes the timestamp of the last successful backup of any application structure known within the queue sharing group.

SMDS
Display data set space usage information and buffer pool information for shared message data sets owned by this queue manager. Space usage information is only available when the data set is open. Buffer pool information is only available when the queue manager is connected to the structure. For more information about the displayed information, see the descriptions of messages CSQE280I and CSQE285I.

ALL
Display page set, data set, and SMDS information.

Note: This command is issued internally by IBM MQ:

- During queue manager shutdown so that the restart RBA is recorded on the z/OS console log.
- At queue manager startup so that page set information can be recorded.
- When DEFINE PSID is used to dynamically define the first page set in the queue manager that uses the buffer pool specified on the DEFINE PSID command.

Related reference
“ALTER PSID (change page set expansion method) on z/OS” on page 329
Use the MQSC command **ALTER PSID** to change the expansion method for a page set.

z/OS MOVE QLOCAL (move messages between local queues) on z/OS

Use the MQSC command MOVE QLOCAL to move all the messages from one local queue to another.

Using MQSC commands

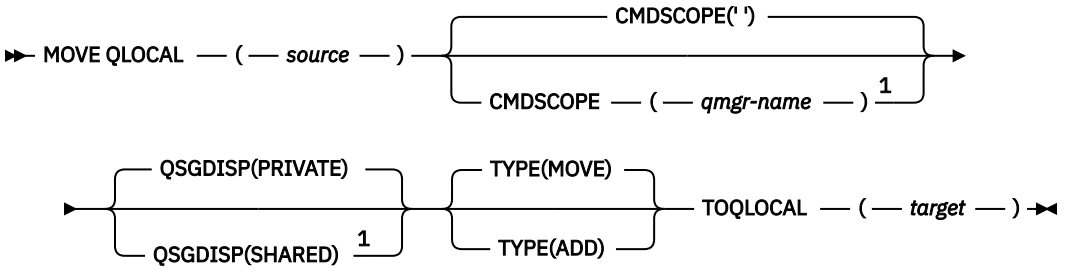
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- “Usage notes for MOVE QLOCAL” on page 852
- “Parameter descriptions for MOVE QLOCAL” on page 853

Synonym: MOVE QL

MOVE QLOCAL



Notes:

[1] Valid only when the queue manager is a member of a queue sharing group.

Usage notes for MOVE QLOCAL

1. A typical use of the MOVE QLOCAL command is to move messages from a private queue to a shared queue when you are setting up a queue sharing group environment.
2. The MOVE QLOCAL command ***moves*** messages; it does not copy them.
3. The MOVE QLOCAL command moves messages in a similar way to an application performing successive MQGET and MQPUT calls. However, the MOVE QLOCAL command does not physically delete logically-expired messages and, therefore, no expiration reports are generated.
4. The priority, context, and persistence of each message are not changed.
5. The command performs no data conversion and calls no exits.
6. Confirm-on-delivery (COD) report messages are not generated but confirm-on-arrival (COA) report messages are. This means that more than one COA report message can be generated for a message.
7. The MOVE QLOCAL command transfers the messages in batches. At COMMIT time, if the trigger conditions are met, trigger messages are produced. This might be at the end of the move operation.

   Note: Before the transfer of messages begins, this command verifies that the number of messages on the source queue, when added to the number of messages on the target queue, does not exceed MAXDEPTH on the target queue.

   If the MAXDEPTH of the target queue were to be exceeded, no messages are moved.
8. The MOVE QLOCAL command can change the sequence in which messages can be retrieved. The sequence remains unchanged only if:
   - You specify TYPE(MOVE) and
   - The MSGDLVSQ parameter of the source and target queues is the same.
9. Messages are moved within one or more syncpoints. The number of messages in each syncpoint is determined by the queue manager.
10. If anything prevents the moving of one or more messages, the command stops processing. This can mean that some messages have already been moved, while others remain on the source queue. Some of the reasons that prevent a message being moved are:
    - The target queue is full.
    - The message is too long for the target queue.
    - The message is persistent, but the target queue cannot store persistent messages.
    - The page set is full.
11. Treatment of message properties depends on the source queue PROPCTL value. Message properties are handled as if an MQGET was performed with MQGMO_PROPERTIES_AS_Q_DEF.

Note: Message properties are always moved when MOVE QLOCAL is used to or from certain SYSTEM queues that hold messages with properties required by IBM MQ.

Parameter descriptions for MOVE QLOCAL

You must specify the names of two local queues: the one you want to move messages from (the source queue) and the one you want to move the messages to (the target queue).

source
The name of the local queue from which messages are moved. The name must be defined to the local queue manager.

The command fails if the queue contains uncommitted messages.

If an application has this queue open, or has open a queue that eventually resolves to this queue, the command fails. For example, the command fails if this queue is a transmission queue, and any queue that is, or resolves to, a remote queue that references this transmission queue, is open.

An application can open this queue while the command is in progress but the application waits until the command has completed.

CMDSCOPE
This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

QSGDISP
Specifies the disposition of the source queue.

PRIVATE
The queue is defined with QSGDISP(QMGR) or QSGDISP(COPY). This is the default value.

SHARED
The queue is defined with QSGDISP(SHARED). This is valid only in a queue sharing group environment.

TYPE
Specifies how the messages are moved.

MOVE
Move the messages from the source queue to the empty target queue.

The command fails if the target queue already contains one or more messages. The messages are deleted from the source queue. This is the default value.

ADD
Move the messages from the source queue and add them to any messages already on the target queue.

The messages are deleted from the source queue.

target
The name of the local queue to which messages are moved. The name must be defined to the local queue manager.

The name of the target queue can be the same as that of the source queue only if the queue exists as both a shared and a private queue. In this case, the command moves messages to the queue that has

the opposite disposition (shared or private) from that specified for the source queue on the QSGDISP parameter.

If an application has this queue open, or has open a queue that eventually resolves to this queue, the command fails. The command also fails if this queue is a transmission queue, and any queue that is, or resolves to, a remote queue that references this transmission queue, is open.

No application can open this queue while the command is in progress.

If you specify TYPE(MOVE), the command fails if the target queue already contains one or more messages.

The DEFTYPE, HARDENBO, and USAGE parameters of the target queue must be the same as those of the source queue.

PING CHANNEL (test channel response)

Use the MQSC command PING CHANNEL to test a channel by sending data as a special message to the remote queue manager, and checking that the data is returned. The data is generated by the local queue manager.

Using MQSC commands

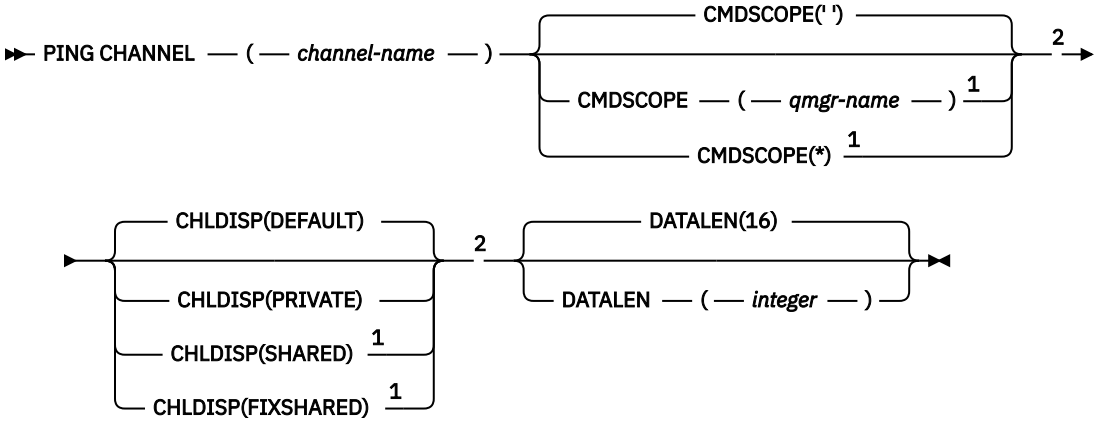
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Usage notes" on page 854
- "Parameter descriptions for PING CHANNEL" on page 855

Synonym: PING CHL

PING CHANNEL



Notes:

[1] Valid only when the queue manager is a member of a queue sharing group.
[2] Valid only on z/OS.

Usage notes

1. z/OS On z/OS, the command server and the channel initiator must be running.

2. Where there is both a locally defined channel and an auto-defined cluster-sender channel of the same name, the command applies to the locally defined channel. If there is no locally defined channel but more than one auto-defined cluster-sender channel, the command applies to the channel that was last added to the local queue manager's repository.
3. This command can be used only for sender (SDR), server (SVR), and cluster-sender (CLUSSDR) channels (including those that have been defined automatically). It is not valid if the channel is running; however, it is valid if the channel is stopped or in retry mode.

Parameter descriptions for PING CHANNEL

(channel-name)
The name of the channel to be tested. This is required.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

If CHLDISP is set to SHARED, CMDSCOPE must be blank or the local queue manager.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

Note: The '*' option is not permitted if CHLDISP is FIXSHARED.

z/OS **CHLDISP**
This parameter applies to z/OS only and can take the values of:

- DEFAULT
- PRIVATE
- SHARED
- FIXSHARED

If this parameter is omitted, then the DEFAULT value applies. This is the value of the default channel disposition attribute, DEFCDISP, of the channel object.

In conjunction with the various values of the CMDSCOPE parameter, this parameter controls two types of channel:

SHARED
A receiving channel is shared if it was started in response to an inbound transmission directed to the queue sharing group.

A sending channel is shared if its transmission queue has a disposition of SHARED.

PRIVATE
A receiving channel is private if it was started in response to an inbound transmission directed to the queue manager.

A sending channel is private if its transmission queue has a disposition other than SHARED.

Note: This disposition is **not** related to the disposition set by the disposition of the queue sharing group of the channel definition.

The combination of the CHLDISP and CMDSCOPE parameters also controls from which queue manager the channel is operated. The possible options are:

- On the local queue manager where the command is issued.
- On another specific named queue manager in the group.
- On the most suitable queue manager in the group, determined automatically by the queue manager itself.

The various combinations of CHLDISP and CMDSCOPE are summarized in the following table.

Table 170. CHLDISP and CMDSCOPE for PING CHANNEL

CHLDISP	CMDSCOPE( ) or CMDSCOPE (local-qmgr)	CMDSCOPE (qmgr-name)	CMDSCOPE(*)
PRIVATE	Ping private channel on the local queue manager	Ping private channel on the named queue manager	Ping private channel on all active queue managers
SHARED	Ping a shared channel on the most suitable queue manager in the group This might automatically generate a command using CMDSCOPE and send it to the appropriate queue manager. If there is no definition for the channel on the queue manager to which the command is sent, or if the definition is unsuitable for the command, the command fails. The definition of a channel on the queue manager where the command is entered might be used to determine the target queue manager where the command is actually run. Therefore, it is important that channel definitions are consistent. Inconsistent channel definitions might result in unexpected command behavior.	Not permitted	Not permitted
FIXSHARED	Ping a shared channel on the local queue manager	Ping a shared channel on the named queue manager	Not permitted

DATALEN(*integer*)
The length of the data, in the range 16 through 32 768. This is optional.

Multi PING QMGR on Multiplatforms (test queue manager response)

Use the MQSC command PING QMGR to test whether the queue manager is responsive to commands.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

- Syntax diagram

- "Usage notes" on page 857

Synonym: PING QMGR

PING QMGR

Usage notes

If commands are issued to the queue manager by sending messages to the command server queue, this command causes a special message to be sent to it, consisting of a command header only, and checking that a positive reply is returned.

Windows Linux AIX PURGE CHANNEL (stop and purge a channel)

Use the MQSC command PURGE CHANNEL to stop and purge a telemetry or AMQP channel. Purging a telemetry or AMQP channel disconnects all the MQTT or AMQP clients connected to it, cleans up the state of the MQTT or AMQP clients, and stops the telemetry or AMQP channel. Cleaning the state of a client deletes all the pending publications, including any last will and testament message required by the client, and removes all the subscriptions from the client.

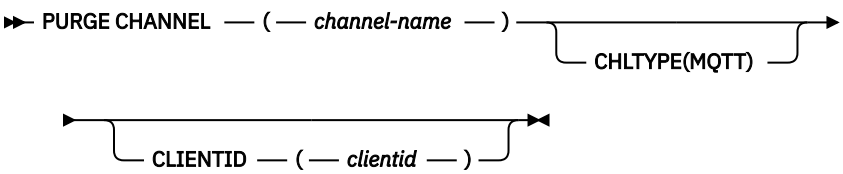
Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

- Syntax diagram
- "Parameter descriptions for PURGE CHANNEL" on page 857

Synonym: None

PURGE CHANNEL



Parameter descriptions for PURGE CHANNEL

(channel name)
The name of the telemetry or AMQP channel to be stopped and purged. This parameter is required.

CHLTYPE ***(string)***
Channel type. This parameter is required. It must follow immediately after the (channel-name) parameter.

The value must be either MQTT or AMQP.

CLIENTID ***(string)***
Client identifier. The client identifier is a 23 byte string that identifies an MQ Telemetry Transport or AMQP client. When the PURGE CHANNEL command specifies a CLIENTID, only the connection for the specified client identifier is purged. If the CLIENTID is not specified, all the connections on the channel are purged.

z/OS RECOVER BSDS (recover bootstrap data set) on z/OS

Use the MQSC command RECOVER BSDS to reestablish a dual bootstrap data set (BSDS), after a data set error one has caused one to stop working.

Using MQSC commands

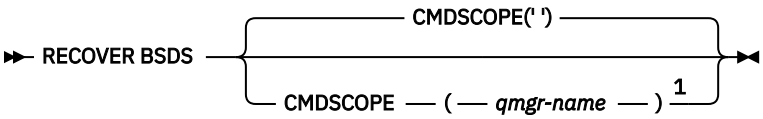
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Usage notes for RECOVER BSDS" on page 858
- "Keyword and parameter descriptions for RECOVER BSDS" on page 858

Synonym: REC BSDS

RECOVER BSDS



Notes:

1 Valid only when the queue manager is a member of a queue-sharing group.

Usage notes for RECOVER BSDS

Note: Command processing consists of allocating a data set with the same name as the one that encountered the error and copying onto the new data set the contents of the BSDS that does not have an error.

Keyword and parameter descriptions for RECOVER BSDS

CMDSCOPE

This parameter specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE cannot be used for commands issued from the first initialization input data set CSQINP1.

' '

The command is run on the queue manager on which it was entered. This is the default value.

qmgr-name

The command is run on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

z/OS RECOVER CFSTRUCT (recover CF application structure) on z/OS

Use the MQSC command RECOVER CFSTRUCT to initiate recovery of CF application structures and associated shared message data sets. This command is valid only when the queue manager is a member of a queue sharing group.

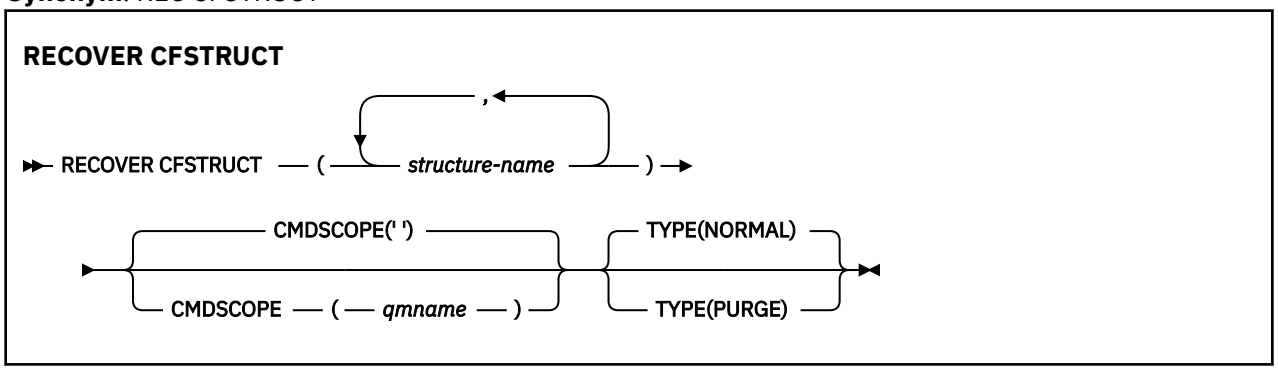
Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Usage notes for RECOVER CFSTRUCT" on page 859
- "Keyword and parameter descriptions for RECOVER CFSTRUCT" on page 860

Synonym: REC CFSTRUCT



Usage notes for RECOVER CFSTRUCT

- The command fails if neither the specified application structure nor its associated shared message data sets are flagged as being in a FAILED state.
- If a data set is marked as FAILED but the corresponding structure is not, then the **RECOVER CFSTRUCT** command changes the structure state to FAILED, deleting the contents to perform recovery. This action deletes all nonpersistent messages stored in the structure and makes the structure unavailable until recovery is complete.
- For a structure with associated shared message data sets, the **RECOVER CFSTRUCT** command recovers the structure plus the offloaded message data for any data sets which are either already marked as FAILED or found to be empty or invalid when opened by recovery processing. Any data sets which are marked as ACTIVE and have valid headers are assumed not to require recovery.
- When recovery processing completes normally, all associated shared message data sets for the recovered structures (including data sets which did not need recovery) are marked as RECOVERED, indicating that the space map needs to be rebuilt.
- Following recovery, space map rebuild processing is performed for each affected data set, to map the space occupied by the recovered message data (ignoring any existing messages which were nonpersistent or backed out). When the space map has been rebuilt for each data set, it is marked as ACTIVE again.
- The command fails if any one of the specified structure names is not defined in the CFRM policy data set.
- The recovery process is both I/O and processor intensive, and can only run on a single z/OS image. It should therefore be run on the most powerful or least busy system in the queue sharing group.

- The most likely failure is the loss of a complete CF and hence the simultaneous loss of all the application structures therein. If backup date and times are similar for each failed application structure, it is more efficient to recover them in a single **RECOVER CFSTRUCT** command.
- This command fails if any of the specified CF structures is defined with either a CFLEVEL of less than 3, or with RECOVER set to NO.
- To use TYPE(NORMAL), you must have taken a backup of the CF structures, using the **BACKUP CFSTRUCT** command.
- If backups of the requested CF structures have not been taken recently, using TYPE(NORMAL) may take a considerable amount of time.
- If a backup of the CF structure, or a required archive log, is not available, you can recover to an empty CF structure using TYPE(PURGE).
- The command **RECOVER CFSTRUCT(CSQSYSAPPL) TYPE(PURGE)** is prohibited. This is to prevent the accidental loss of queue manager internal objects.

Keyword and parameter descriptions for RECOVER CFSTRUCT

CFSTRUCT(*structure-names ...*)
Specify list of names of up to 63 structure names for which the coupling facility application structures are to be recovered, along with any associated shared message data sets which also need recovery. If resources for more than one structure need to be recovered, it is more efficient to recover them at the same time.

CMDSCOPE
This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

TYPE
Specifies which variant of the **RECOVER** command is to be issued. Values are:

NORMAL
Perform true recovery by restoring data from a backup taken using the BACKUP CFSTRUCT command and reapplying logged changes since that time. Any nonpersistent messages are discarded.

This is the default.

PURGE
Reset the structure and associated shared message data sets to an empty state. This can be used to restore a working state when no backup is available, but results in the loss of all affected messages.

REFRESH CLUSTER (rebuild a cluster)

Use the MQSC command REFRESH CLUSTER to discard all locally held cluster information and force it to be rebuilt. The command also processes any autodefined channels that are in doubt. After the command completes processing, you can perform a "cold-start" on the cluster.

Using MQSC commands

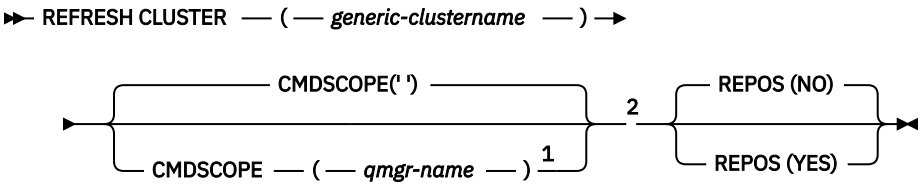
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Usage notes for REFRESH CLUSTER" on page 861
- "Parameter descriptions for REFRESH CLUSTER" on page 863

Synonym: REF CLUSTER

REFRESH CLUSTER



Notes:

1 Valid only when the queue manager is a member of a queue sharing group.
2 Valid only on z/OS.

Usage notes for REFRESH CLUSTER

1. Issuing **REFRESH CLUSTER** is disruptive to the cluster. It might make cluster objects invisible for a short time until the **REFRESH CLUSTER** processing completes. This can affect running applications, as described in Application issues seen when running REFRESH CLUSTER. If an application is publishing or subscribing on a cluster topic, that topic might become temporarily unavailable. See REFRESH CLUSTER considerations for publish/subscribe clusters. The unavailability results in a break in the publication stream until the **REFRESH CLUSTER** command completes. If the command is issued on a full repository queue manager, **REFRESH CLUSTER** might make a large volume of messages flow.
2. For large clusters, use of the **REFRESH CLUSTER** command can be disruptive to the cluster while it is in progress, and again at 27 day intervals thereafter when the cluster objects automatically send status updates to all interested queue managers. See Refreshing in a large cluster can affect performance and availability of the cluster.
3. Quiesce all publish/subscribe applications before issuing the **REFRESH CLUSTER** command, because issuing this command in a publish/subscribe cluster disrupts delivery of publications to and from other queue managers in the cluster, and might result in proxy subscriptions from other queue managers being canceled. If this happens, resynchronize the proxy subscriptions after the cluster has refreshed, and keep all publish/subscribe applications quiesced until after the proxy subscriptions have been resynchronized. See REFRESH CLUSTER considerations for publish/subscribe clusters.
4. When the command returns control to the user, it does not signify the command has completed. Activity on `SYSTEM.CLUSTER.COMMAND.QUEUE` indicates the command is still processing. See also the REFRESH CLUSTER step in Checking that async commands for distributed networks have finished.

5. If cluster-sender channels are running at the time **REFRESH CLUSTER** is issued, the refresh might not complete until the channels stop and restart. To hasten completion, stop all cluster-sender channels for the cluster before you run the **REFRESH CLUSTER** command. During the processing of the **REFRESH CLUSTER** command, if the channel is not in doubt, the channel state might be re-created.
6. If you select REPOS(YES), check that all cluster-sender channels in the relevant cluster are inactive or stopped before you issue the **REFRESH CLUSTER** command.

   If cluster-sender channels are running at the time you run the **REFRESH CLUSTER** REPOS(YES) command, those cluster-sender channels are ended during the operation and left in an INACTIVE state after the operation completes. Alternatively, you can force the channels to stop using the STOP CHANNEL command with MODE(FORCE).

   Stopping the channels ensures that the refresh can remove the channel state, and that the channel runs with the refreshed version after the refresh completes. If the state of a channel cannot be deleted, its state is not renewed after the refresh. If a channel was stopped, it does not automatically restart. The channel state cannot be deleted if the channel is in doubt, or because it is also running as part of another cluster.

   If you choose the option REPOS(YES) on full repository queue manager, you must alter it to be a partial repository. If it is the sole working repository in the cluster, the result is that there is no full repository left in the cluster. After the queue manager is refreshed, and restored to its status of a full repository, you must refresh the other partial repositories to restore a working cluster.

   If it is not the sole remaining repository, you do not need to refresh the partial repositories manually. Another working full repository in the cluster informs the other members of the cluster that the full repository running the **REFRESH CLUSTER** command resumed its role as a full repository.
7. It is not normally necessary to issue a **REFRESH CLUSTER** command except in one of the following circumstances:
   - Messages were removed from either the SYSTEM.CLUSTER.COMMAND.QUEUE, or from another a cluster transmission queue, where the destination queue is SYSTEM.CLUSTER.COMMAND.QUEUE on the queue manager in question.
   - Issuing a **REFRESH CLUSTER** command is recommended by IBM Service.
   - The CLUSRCVR channels were removed from a cluster, or their CONNAME s were altered on two or more full repository queue managers while they could not communicate.
   - The same name was used for a CLUSRCVR channel on more than one queue manager in a cluster. As a result, messages destined for one of the queue managers were delivered to another. In this case, remove the duplicates, and run a **REFRESH CLUSTER** command on the single remaining queue manager with a CLUSRCVR definition.
   - RESET CLUSTER ACTION(FORCEREMOVE) was issued in error.
   - The queue manager was restarted from an earlier point in time than it finished last time it was used; for example, by restoring backed up data.
8. Issuing **REFRESH CLUSTER** does not correct mistakes in cluster definitions, nor is it necessary to issue the command after such mistakes are corrected.
9. During **REFRESH CLUSTER** processing, the queue manager generates the message AMQ9875 followed by the message AMQ9442 or AMQ9404. The queue manager might also generate the message AMQ9420. If the cluster functionality is not affected, the message AMQ9420 can be ignored.
10. z/OS On z/OS, the command fails if the channel initiator is not started.
11. z/OS On z/OS, any errors are reported to the console on the system where the channel initiator is running. They are not reported to the system that issued the command.

Parameter descriptions for REFRESH CLUSTER

(*generic-clustername*)

The name of the cluster to be refreshed. Alternatively *generic-clustername* can be specified as "*". If "*" is specified, the queue manager is refreshed in all the clusters that it is a member of. If used with REPOS(YES), this forces the queue manager to restart its search for full repositories from the information in the local CLUSSDR definitions. It restarts its search, even if the CLUSSDR definitions connect the queue manager to several clusters.

The *generic-clustername* parameter is required.

z/OS **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

' '

The command runs on the queue manager on which it was entered. ' ' is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered. If you do so, you must be using a queue sharing group environment and the command server must be enabled.

REPOS

Specifies whether objects representing full repository cluster queue managers are also refreshed.

NO

The queue manager retains knowledge of all cluster queue manager and cluster queues marked as locally defined. It also retains knowledge of all cluster queue managers that are marked as full repositories. In addition, if the queue manager is a full repository for the cluster, it retains knowledge of the other cluster queue managers in the cluster. Everything else is removed from the local copy of the repository and rebuilt from the other full repositories in the cluster. Cluster channels are not stopped if REPOS(NO) is used. A full repository uses its CLUSSDR channels to inform the rest of the cluster that it completed its refresh.

NO is the default.

YES

Specifies that in addition to the REPOS(NO) behavior, objects representing full repository cluster queue managers are also refreshed. The REPOS(YES) option must not be used if the queue manager is itself a full repository. If it is a full repository, you must first alter it so that it is not a full repository for the cluster in question. The full repository location is recovered from the manually defined CLUSSDR definitions. After the refresh with REPOS(YES) is issued, the queue manager can be altered so that it is once again a full repository, if required.

z/OS On z/OS, N and Y are accepted synonyms of NO and YES.

REFRESH QMGR (refresh a queue manager)

Use the MQSC command REFRESH QMGR to perform special operations on queue managers.

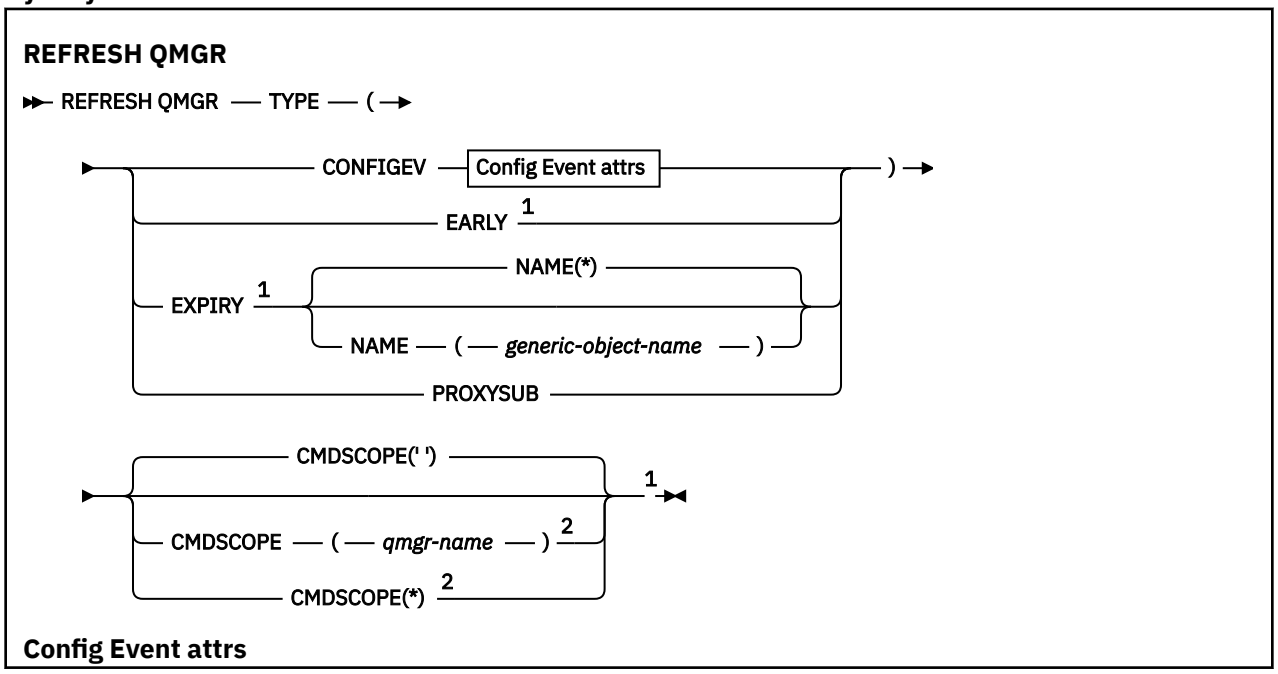
Using MQSC commands

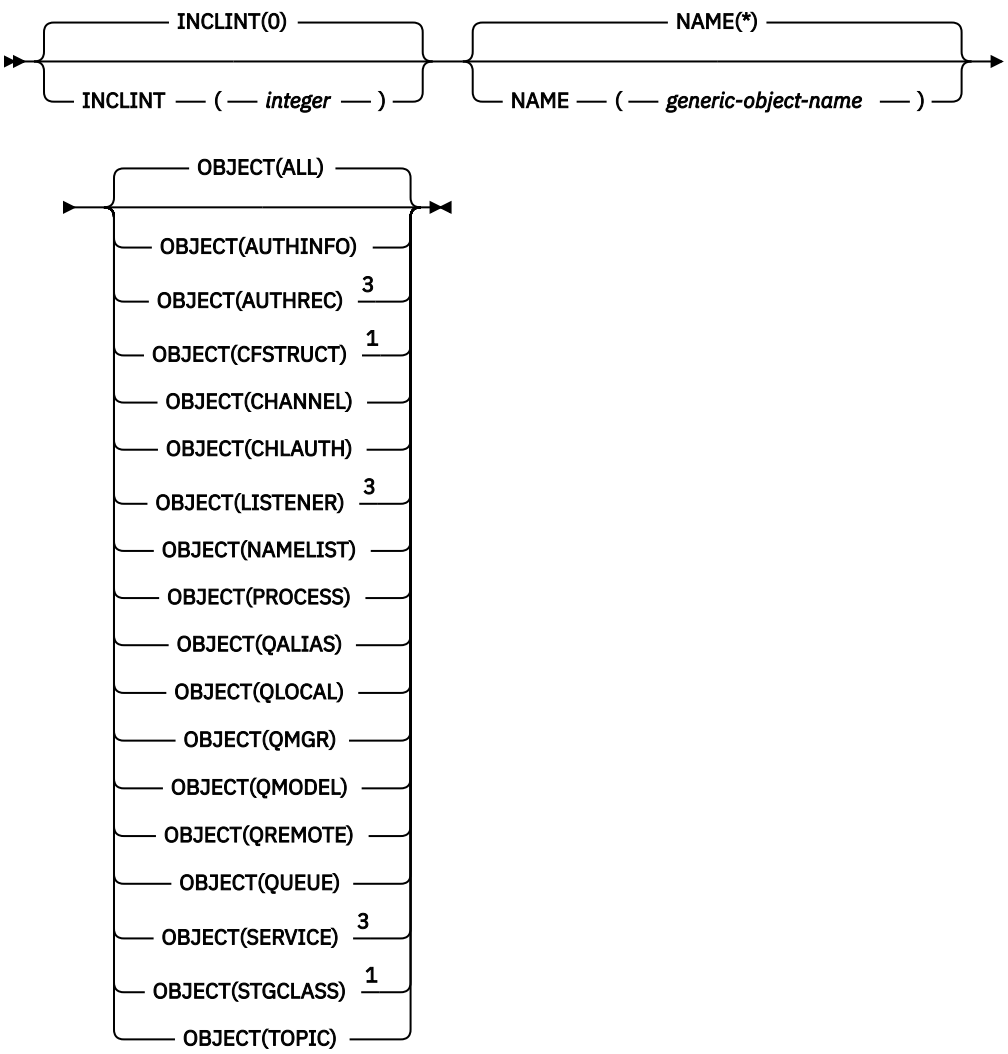
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

- Syntax diagram
- z/OS See "Using REFRESH QMGR on z/OS" on page 865
- "Usage Notes for REFRESH QMGR" on page 866
- "Parameter descriptions for REFRESH QMGR" on page 866

Syntax diagram

Synonym: None





Notes:

[1] Valid only on z/OS.
[2] Valid only when the queue manager is a member of a queue sharing group.
[3] Not valid on z/OS.

Using REFRESH QMGR on z/OS

z/OS

REFRESH QMGR can be used on z/OS. Depending on the parameters used on the command, it may be issued from various sources. For an explanation of the symbols in this table, see Sources from which you can issue MQSC commands on z/OS.

Table 171. REFRESH QMGR command and command sources

Command	Command Sources	Notes
REFRESH QMGR TYPE(CONFIGEV)	2CR	
REFRESH QMGR TYPE(EARLY)	C	Queue manager must not be active.
REFRESH QMGR TYPE(EXPIRY)	2CR	

Table 171. REFRESH QMGR command and command sources (continued)		
Command	**Command Sources**	**Notes**
REFRESH QMGR TYPE(PROXYSUB)	2CR	CHINIT must be active to complete the command.

Usage Notes for REFRESH QMGR

1. Issue this command with TYPE(CONFIGEV) after setting the CONFIGEV queue manager attribute to ENABLED, to bring the queue manager configuration up to date. To ensure that complete configuration information is generated, include all objects; if you have many objects, it might be preferable to use several commands, each with a different selection of objects, but such that all are included.
2. You can also use the command with TYPE(CONFIGEV) to recover from problems such as errors on the event queue. In such cases, use appropriate selection criteria, to avoid excessive processing time and event messages generation.
3. Issue the command with TYPE(EXPIRY) at any time when you believe that a queue could contain numbers of expired messages.
4. z/OS If TYPE(EARLY) is specified, no other keywords are allowed and the command can be issued only from the z/OS console and only if the queue manager is not active.
5. You are unlikely to use **REFRESH QMGR TYPE(PROXYSUB)** other than in exceptional circumstances. See Resynchronization of proxy subscriptions.
6. Successful completion of the **REFRESH QMGR TYPE(PROXYSUB)** command does not mean that the action completed. To check for true completion, see the REFRESH QMGR TYPE(PROXYSUB) step in Checking that async commands for distributed networks have finished.
7. z/OS If a **REFRESH QMGR TYPE(PROXYSUB)** command is issued on z/OS when the CHINIT is not running, the command is queued up and will be processed when the CHINIT starts.
8. Running the command REFRESH QMGR TYPE(CONFIGEV) OBJECT(ALL) includes authority records.

   You cannot specify the **INCLINT** and **NAME** parameters if you explicitly specify AUTHREC events. If you specify **OBJECT**(*ALL*) the **INCLINT** and **NAME** parameters are ignored.

Parameter descriptions for REFRESH QMGR

z/OS **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

' '

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

This parameter is not valid with TYPE(EARLY).

INCLINT ***(integer)***
Specifies a value in minutes defining a period immediately before the current time, and requests that only objects that have been created or changed within that period (as defined by the ALTDATE and ALTTIME attributes) are included. The value must be in the range zero through 999 999. A value of zero means there is no time limit (this is the default).

This parameter is valid only with TYPE(CONFIGEV).

NAME ***(generic-object-name)***
Requests that only objects with names that match the one specified are included. A trailing asterisk (*) matches all object names with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all objects (this is the default). NAME is ignored if OBJECT(QMGR) is specified.

This parameter is not valid with TYPE(EARLY).

OBJECT ***(objtype)***
Requests that only objects of the specified type are included. (Synonyms for object types, such as QL, can also be specified.) The default is ALL, to include objects of every type.

This parameter is valid only with TYPE(CONFIGEV).

TYPE
This is required. Values are:

CONFIGEV
Requests that the queue manager generates a configuration event message for every object that matches the selection criteria specified by the OBJECT, NAME and INCLINT parameters. Matching objects defined with QSGDISP(QMGR) or QSGDISP(COPY) are always included. Matching objects defined with QSGDISP(GROUP) or QSGDISP(SHARED) are included only if the command is being executed on the queue manager where it is entered.

EARLY
Requests that the subsystem function routines (generally known as early code) for the queue manager replace themselves with the corresponding routines in the linkpack area (LPA).

You need to use this command only after you install new subsystem function routines (provided as corrective maintenance or with a new version or release of IBM MQ). This command instructs the queue manager to use the new routines.

z/OS See Update the z/OS link list and LPA for more information about IBM MQ early code routines.

EXPIRY
Requests that the queue manager performs a scan to discard expired messages for every queue that matches the selection criteria specified by the NAME parameter. (The scan is performed regardless of the setting of the EXPRYINT queue manager attribute.)

PROXYSUB
Requests that the queue manager resynchronizes the proxy subscriptions that are held with, and on behalf of, queue managers that are connected in a hierarchy or publish/subscribe cluster.

You should only resynchronize the proxy subscriptions in exceptional circumstances. See Resynchronization of proxy subscriptions.

REFRESH SECURITY (refresh security settings)

Use the MQSC command REFRESH SECURITY to perform a security refresh.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

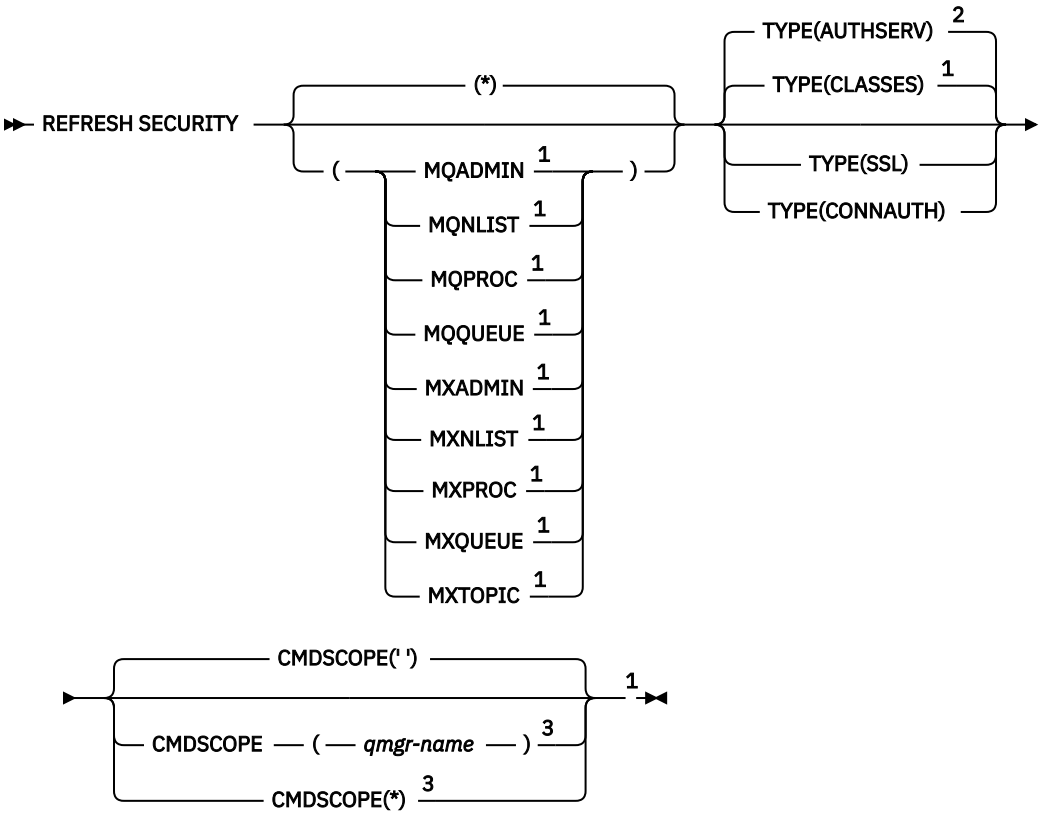
- Syntax diagram

- z/OS See "Using REFRESH SECURITY on z/OS" on page 868
- "Usage notes for REFRESH SECURITY" on page 869
- "Parameter descriptions for REFRESH SECURITY" on page 870

Synonym: REF SEC

z/OS REBUILD SECURITY is another synonym for REFRESH SECURITY on z/OS.

REFRESH SECURITY



Notes:

1 Valid only on z/OS.
2 Not valid on z/OS.
3 Valid only on z/OS when the queue manager is a member of a queue sharing group.

Using REFRESH SECURITY on z/OS

z/OS

REFRESH SECURITY can be used on z/OS. Depending on the parameters used on the command, it may be issued from various sources. For an explanation of the symbols in this table, see Sources from which you can issue MQSC commands on z/OS.

Table 172. REFRESH SECURITY command and command sources

Command	Command Sources	Notes
REFRESH SECURITY TYPE(CLASSES)	CR	

Table 172. REFRESH SECURITY command and command sources (continued)		
Command	**Command Sources**	**Notes**
REFRESH SECURITY TYPE(SSL)	CR	Not allowed from CSQINPT or CSQINP2. Channel initiator must be running.

Usage notes for REFRESH SECURITY

When you issue the REFRESH SECURITY TYPE(SSL) MQSC command, all running TLS channels are stopped and restarted. Sometimes TLS channels can take a long time to shut down and this means that the refresh operation takes some time to complete. There is a time limit of 10 minutes for a TLS refresh to complete z/OS (or 1 minute on z/OS), so it can potentially take 10 minutes for the command to finish. This can give the appearance that the refresh operation has "frozen". The refresh operation will fail with an MQSC error message of AMQ9710 or PCF error MQRCCF_COMMAND_FAILED if the timeout is exceeded before all channels have stopped. This is likely to happen if the following conditions are true:

- The queue manager has many TLS channels running simultaneously when the refresh command is invoked
- The channels are handling large numbers of messages

If a refresh fails under these conditions, retry the command later when the queue manager is less busy. In the case where many channels are running, you can choose to stop some of the channels manually before invoking the REFRESH command.

When using TYPE(SSL):

1. z/OS On z/OS, the command server and channel initiator must be running.
2. z/OS On z/OS, IBM MQ determines whether a refresh is needed due to one, or more, of the following reasons:
   - The contents of the key repository have changed
   - The location of the LDAP server to be used for Certification Revocation Lists has changed
   - The location of the key repository has changed

   If no refresh is needed, the command completes successfully and the channels are unaffected.
3. Multi On Multiplatforms, the command updates all TLS channels regardless of whether a security refresh is needed.
4. If a refresh is to be performed, the command updates all TLS channels currently running, as follows:
   - Sender, server and cluster-sender channels using TLS are allowed to complete the current batch. In general they then run the TLS handshake again with the refreshed view of the TLS key repository. However, you must manually restart a requester-server channel on which the server definition has no CONNAME parameter.
   - AMQP channels using TLS are restarted, with any currently connected clients being forcibly disconnected. The client receives an `amqp:connection:forced` AMQP error message.
   - All other channel types using TLS are stopped with a STOP CHANNEL MODE(FORCE) STATUS(INACTIVE) command. If the partner end of the stopped message channel has retry values defined, the channel retries and the new TLS handshake uses the refreshed view of the contents of the TLS key repository, the location of the LDAP server to be used for Certification Revocation Lists, and the location of the key repository. In the case of a server-connection channel, the client application loses its connection to the queue manager and has to reconnect in order to continue.

z/OS When using TYPE(CLASSES):

- Classes MQADMIN, MQNLIST, MQPROC, and MQQUEUE can only hold profiles defined in uppercase.
- Classes MXADMIN, MXNLIST, MXPROC, and MQXUEUE can hold profiles defined in mixed case.

- Class MXTOPIC can be refreshed whether using uppercase or mixed case classes. Although it is a mixed case class, it is the only mixed case class that can be active with either group of classes.
- The MQCMD and MQCONN classes cannot be specified, and are not included by REFRESH SECURITY CLASS(*).

  Security information from the MQCMD and MQCONN classes is not cached in the queue manager. See Refreshing queue manager security on z/OS for further information.

Notes:

1. Performing a REFRESH SECURITY(*) TYPE(CLASSES) operation is the only way to change the classes being used by your system from uppercase-only support to mixed case support.

   Do this by checking the queue manager attribute SCYCASE to see if it is set to UPPER or MIXED
2. It is your responsibility to ensure that you have copied, or defined, all the profiles you need in the appropriate classes before you carry out a REFRESH SECURITY(*) TYPE(CLASSES) operation.
3. A refresh of an individual class is allowed only if the classes currently being used are of the same type. For example, if MQPROC is in use, you can issue a refresh for MQPROC but not MXPROC.

Parameter descriptions for REFRESH SECURITY

The command qualifier allows you to indicate more precise behavior for a specific TYPE value. Select from:

*****

A full refresh of the type specified is performed. z/OS This is the default value on z/OS systems.

z/OS **MQADMIN**
Valid only if TYPE is CLASSES. Specifies that Administration type resources are to be refreshed. Valid on z/OS only.

Note: If, when refreshing this class, it is determined that a security switch relating to one of the other classes has been changed, a refresh for that class also takes place.

z/OS **MQNLIST**
Valid only if TYPE is CLASSES. Specifies that Namelist resources are to be refreshed. Valid on z/OS only.

z/OS **MQPROC**
Valid only if TYPE is CLASSES. Specifies that Process resources are to be refreshed. Valid on z/OS only.

z/OS **MQQUEUE**
Valid only if TYPE is CLASSES. Specifies that Queue resources are to be refreshed. Valid on z/OS only.

z/OS **MXADMIN**
Valid only if TYPE is CLASSES. Specifies that administration type resources are to be refreshed. Valid on z/OS only.

Note: If, when refreshing this class, it is determined that a security switch relating to one of the other classes has been changed, a refresh for that class also takes place.

z/OS **MXNLIST**
Valid only if TYPE is CLASSES. Specifies that namelist resources are to be refreshed. Valid on z/OS only.

z/OS **MXPROC**
Valid only if TYPE is CLASSES. Specifies that process resources are to be refreshed. Valid on z/OS only.

z/OS **MXQUEUE**
Valid only if TYPE is CLASSES. Specifies that queue resources are to be refreshed. Valid on z/OS only.

z/OS **MXTOPIC**
Valid only if TYPE is CLASSES. Specifies that topic resources are to be refreshed. Valid on z/OS only.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

' '
The command runs on the queue manager on which it was entered. This is the default value z/OS for non-z/OS systems.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

TYPE
Specifies the type of refresh that is to be performed.

Multi **AUTHSERV**
The list of authorizations held internally by the authorization services component is refreshed.

This is the default value.

z/OS **CLASSES**

IBM MQ in-storage ESM (external security manager, for example RACF) profiles are refreshed. The in-storage profiles for the resources being requested are deleted. New entries are created when security checks for them are performed, and are validated when the user next requests access.

You can select specific resource classes for which to perform the security refresh.

This is valid only on z/OS where it is the default.

CONNAUTH

Refreshes the cached view of the configuration for connection authentication.

You must refresh the configuration before the queue manager recognizes the changes.

Multi On Multiplatforms, this is a synonym for AUTHSERV.

See Connection authentication for more information.

SSL
Refreshes the cached view of the Secure Sockets Layer, or Transport Layer Security, key repository and allows updates to become effective on successful completion of the command. Also refreshed are the locations of:

- the LDAP servers to be used for Certified Revocation Lists
- the key repository

as well as any cryptographic hardware parameters specified through IBM MQ.

Any changes made to CHLAUTH rules are immediately available so no refresh is needed.

Related tasks

z/OS Refreshing queue manager security on z/OS

z/OS RESET CFSTRUCT (reset a CF application structure) on z/OS

Use the MQSC command RESET CFSTRUCT to modify the status of a specific application structure.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Notes:" on page 872
- "Parameter descriptions for RESET CFSTRUCT" on page 872

Synonym: None.

RESET CFSTRUCT

Notes:

1. Valid only when the queue manager is a member of a queue sharing group.
2. RESET CFSTRUCT requires the structure to be defined with CFLEVEL(5).

Parameter descriptions for RESET CFSTRUCT

CFSTRUCT(*structure-name*)
Specify the name of the coupling facility application structure that you want to reset.

ACTION(FAIL)
Specify this keyword to simulate a structure failure and set the status of the application structure to FAILED.

Note: Failing a structure deletes all nonpersistent messages stored in the structure, and makes the structure unavailable until recovery is complete. Structure recovery can take a long time to complete. Therefore, this action should be used only in a situation where you can resolve a problem with the structure by forcing the structure to be reallocated and recovered.

RESET CHANNEL (reset message sequence number for a channel)

Use the MQSC command **RESET CHANNEL** to reset the message sequence number for an IBM MQ channel with, optionally, a specified sequence number to be used the next time that the channel is started. This command is normally used when message AMQ9526E is received, where a channel is unable to start because of a sequence number error.

Using MQSC commands

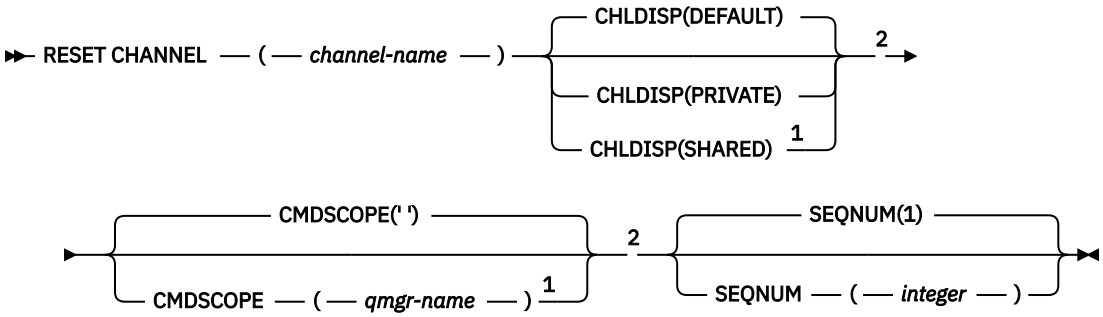
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- “Usage notes” on page 873
- “Parameter descriptions for RESET CHANNEL” on page 873

Synonym: RESET CHL

RESET CHANNEL



Notes:

[1] Valid only when the queue manager is a member of a queue sharing group.
[2] Valid only on z/OS.

Usage notes

1. z/OS On z/OS, the command server and channel initiator must be running.
2. This command can be issued to a channel of any type except SVRCONN and CLNTCONN channels, (including those that have been defined automatically). However, if it is issued to a sender or server channel, then in addition to resetting the value at the end at which the command is issued, the value at the other (receiver or requester) end is also reset to the same value the next time this channel is initiated (and resynchronized if necessary). Issuing this command on a cluster-sender channel might reset the message sequence number at either end of the channel. However, this is not significant because the sequence numbers are not checked on clustering channels.
3. If the command is issued to a receiver, requester, or cluster-receiver channel, the value at the other end is not reset as well; this must be done separately if necessary.
4. Where there is both a locally defined channel and an auto-defined cluster-sender channel of the same name, the command applies to the locally defined channel. If there is no locally defined channel but more than one auto-defined cluster-sender channel, the command applies to the channel that was last added to the local queue manager's repository.
5. If the message is non-persistent, and the RESET CHANNEL command is issued to the sender channel, reset data is sent and flows every time the channel starts.

Parameter descriptions for RESET CHANNEL

(channel-name)
The name of the channel to be reset. This is required.

z/OS **CHLDISP**
This parameter applies to z/OS only and can take the values of:

- DEFAULT
- PRIVATE
- SHARED

If this parameter is omitted, then the DEFAULT value applies. This is taken from the default channel disposition attribute, DEFCDISP, of the channel object.

In conjunction with the various values of the CMDSCOPE parameter, this parameter controls two types of channel:

SHARED
A receiving channel is shared if it was started in response to an inbound transmission directed to the queue sharing group.

A sending channel is shared if its transmission queue has a disposition of SHARED.

PRIVATE
A receiving channel is private if it was started in response to an inbound transmission directed to the queue manager.

A sending channel is private if its transmission queue has a disposition other than SHARED.

Note: This disposition is **not** related to the disposition set by the disposition of the queue sharing group of the channel definition.

The combination of the CHLDISP and CMDSCOPE parameters also controls from which queue manager the channel is operated. The possible options are:

- On the local queue manager where the command is issued.
- On another specific named queue manager in the group.

The various combinations of CHLDISP and CMDSCOPE are summarized in the following table:

Table 173. CHLDISP and CMDSCOPE for RESET CHANNEL

CHLDISP	CMDSCOPE( ) or CMDSCOPE (local-qmgr)	CMDSCOPE (qmgr-name)
PRIVATE	Reset private channel on the local queue manager	Reset private channel on the named queue manager
SHARED	Reset a shared channel on all active queue managers. This might automatically generate a command using CMDSCOPE and send it to the appropriate queue managers. If there is no definition for the channel on the queue managers to which the command is sent, or if the definition is unsuitable for the command, the action fails there. The definition of a channel on the queue manager where the command is entered might be used to determine the target queue manager where the command is actually run. Therefore, it is important that channel definitions are consistent. Inconsistent channel definitions might result in unexpected command behavior.	Not permitted

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

If CHLDISP is set to SHARED, CMDSCOPE must be blank or the local queue manager.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name only if you are using a queue sharing group environment and if the command server is enabled.

SEQNUM(*integer*)
The new message sequence number, which must be in the range 1 through 999 999 999. This is optional.

RESET CLUSTER (reset a cluster)

Use the MQSC command **RESET CLUSTER** to perform special operations on clusters.

Using MQSC commands

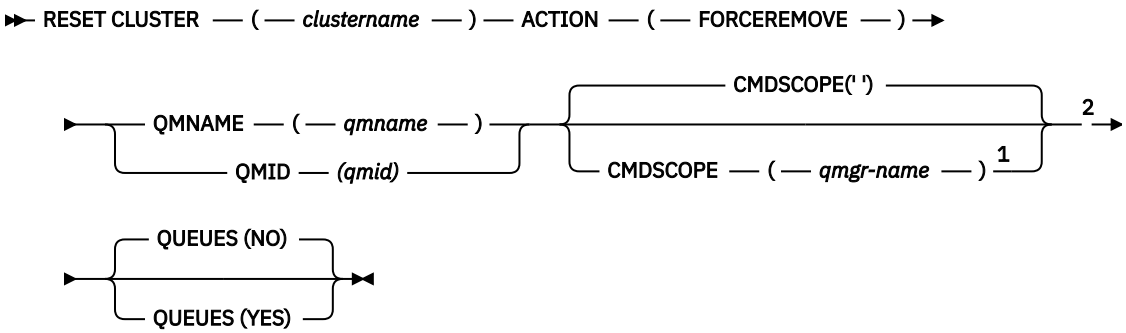
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Usage notes for RESET CLUSTER" on page 875
- "Parameter descriptions for RESET CLUSTER" on page 876

Synonym: None

RESET CLUSTER



Notes:

1 Valid only on z/OS when the queue manager is a member of a queue sharing group.
2 Valid only on z/OS.

Usage notes for RESET CLUSTER

- z/OS On z/OS, the command fails if the channel initiator has not been started.
- z/OS On z/OS, any errors are reported to the console on the system where the channel initiator is running; they are not reported to the system that issued the command.
- To avoid any ambiguity, it is preferable to use QMID rather than QMNAME. The queue manager identifier can be found by commands such as DISPLAY QMGR and DISPLAY CLUSQMGR.

  If QMNAME is used, and there is more than one queue manager in the cluster with that name, the command is not actioned.
- If you use characters other than those listed in Rules for naming IBM MQ objects in your object or variable names, for example in QMID, you must enclose the name in quotation marks.
- If you remove a queue manager from a cluster using this command, you can rejoin it to the cluster by issuing a **REFRESH CLUSTER** command. Wait at least 10 seconds before issuing a **REFRESH**

CLUSTER command, because the repository ignores any attempt to rejoin the cluster within 10 seconds of a **RESET CLUSTER** command. If the queue manager is in a publish/subscribe cluster, you then need to reinstate any required proxy subscriptions. See REFRESH CLUSTER considerations for publish/subscribe clusters.

Note: For large clusters, use of the **REFRESH CLUSTER** command can be disruptive to the cluster while it is in progress, and again at 27 day intervals thereafter when the cluster objects automatically send status updates to all interested queue managers. See Refreshing in a large cluster can affect performance and availability of the cluster.

- Successful completion of the command does not mean that the action completed. To check for true completion, see the RESET CLUSTER step in Checking that async commands for distributed networks have finished.

Parameter descriptions for RESET CLUSTER

(clustername)
The name of the cluster to be reset. This is required.

ACTION(FORCEREMOVE)

Requests that the queue manager is forcibly removed from the cluster. This might be needed to ensure correct cleanup after a queue manager has been deleted.

This action can be requested only by a full repository queue manager.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

QMID(*qmid*)
The identifier of the queue manager to be forcibly removed.

QMNAME(*qmname*)
The name of the queue manager to be forcibly removed.

QUEUES
Specifies whether cluster queues owned by the queue manager being force removed are removed from the cluster.

NO
Cluster queues owned by the queue manager being force removed are not removed from the cluster. This is the default.

YES
Cluster queues owned by the queue manager being force removed are removed from the cluster in addition to the cluster queue manager itself. The cluster queues are removed even if the cluster queue manager is not visible in the cluster, perhaps because it was previously force removed without the QUEUES option.

z/OS On z/OS, **N** and **Y** are accepted synonyms of **NO** and **YES**.

RESET CLUSTER: Forcibly removing a queue manager from a cluster

RESET QMGR (reset a queue manager)

Use the MQSC command RESET QMGR as part of your backup and recovery procedures.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

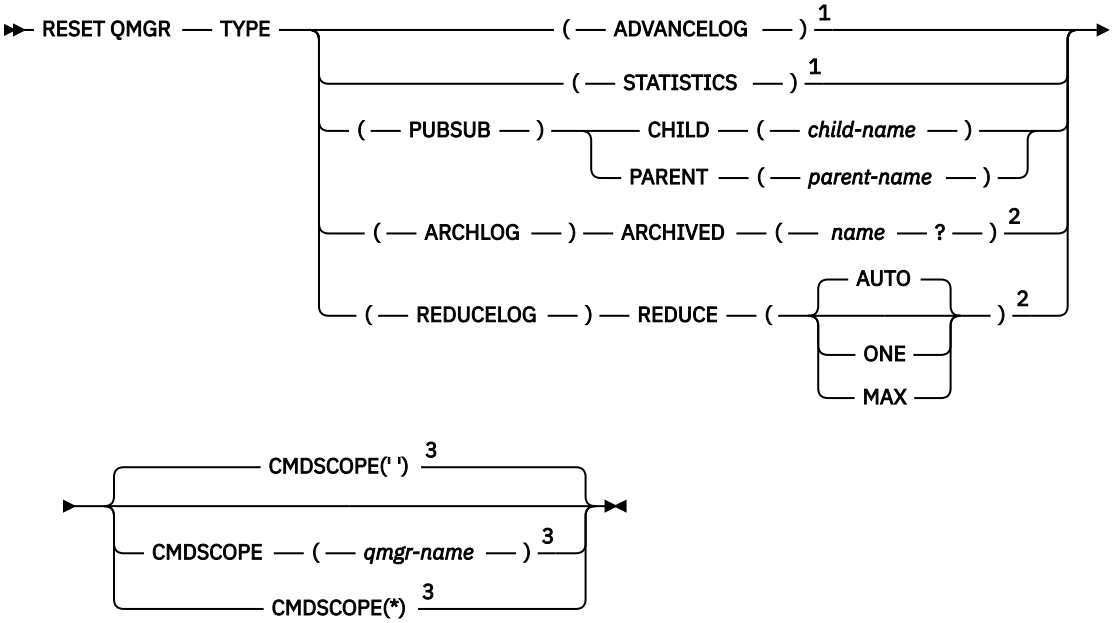
z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

Multi Use the **TYPE(ARCHLOG)** option to notify the queue manager that all log extents, up to the specified one, have been archived. If the log management type is not ARCHIVE, the command fails. Use the **TYPE(REDUCELOG)** option to request that the queue manager reduces the number of log extents, provided they are no longer required.

- Syntax diagram
- "Usage notes for RESET QMGR" on page 877
- "Parameter descriptions for RESET QMGR" on page 879

Synonym: None

RESET QMGR



Notes:

1 Not valid on z/OS.
2 Not valid on IBM i or z/OS.
3 Valid only on z/OS when the queue manager is a member of a queue sharing group

Usage notes for RESET QMGR

- You can use this command to request that the queue manager starts writing to a new log extent, making the previous log extent available for backup. See Updating a backup queue manager. Alternatively, you can use this command to request that the queue manager ends the current statistics collection period and writes the collected statistics. You can also use this command to forcibly remove a publish/

subscribe hierarchical connection for which this queue manager is nominated as either the parent or the child in the hierarchical connection.

- The queue manager might refuse a request to advance the recovery log, if advancing the recovery log would cause the queue manager to become short of space in the active log.
- You are unlikely to use **RESET QMGR** TYPE(PUBSUB) other than in exceptional circumstances. Typically the child queue manager uses **ALTER QMGR** PARENT(' ') to remove the hierarchical connection.
- When you need to disconnect from a child or parent queue manager with which the queue manager has become unable to communicate, you must issue the **RESET QMGR** TYPE (PUBSUB) command from a queue manager. When using this command, the remote queue manager is not informed of the canceled connection. It might, therefore, be necessary to issue the **ALTER QMGR** PARENT(' ') command at the remote queue manager. If the child queue manager is not manually disconnected, it is forcibly disconnected and the parent status is set to REFUSED.
- If you are resetting the parent relationship, issue the **ALTER QMGR** PARENT(' ') command, otherwise the queue manager attempts to re-establish the connection when the publish/subscribe capability of the queue manager is later enabled.
- Successful completion of the **RESET QMGR** TYPE(PUBSUB) command does not mean that the action completed. To check for true completion, see the RESET QMGR TYPE(PUBSUB) step in Checking that async commands for distributed networks have finished.
- You must specify one only of **ADVANCELOG**, **STATISTICS**, **PUBSUB**, **ARCHLOG** or **REDUCELOG**.

Usage notes for TYPE(ARCHLOG)

This option requires change authority on the queue manager object.

The command fails if the log extent is not recognized, or is the current log.

If, for some reason, the programmatic way that your enterprise notifies your log extents are archived is not working, and the disk is filling up with log extents, your administrator can use this command.

You need to determine yourself, the name to pass in from your archiving process, as to what has already been archived.

Usage notes for TYPE(REDUCELOG)

This option requires change authority on the queue manager object.

You should not need this command in normal circumstances. In general, when using automatic management of log files, you should leave it up to the queue manager to reduce the number of log extents as necessary.

For circular logging, you can use this option to remove inactive secondary log extents. A growth in secondary log extents is usually noticed by an increase in disk usage, often due to some specific issue in the past.

Note: For circular logging the command might not be able reduce the log extents by the required number immediately. In that case, the command returns, and the reduction takes place asynchronously at some later point.

For linear logging this can remove log extents that are not required for recovery (and have been archived if you are using archive log management) as noticed by a high value for REUSESZ on the DISPLAY QMSTATUS command.

You should run this command only after some specific event that has caused the number of log extents to be extraordinarily large.

The command blocks until the chosen number of extents have been deleted. Note that the command does not return the number of extents that have been removed, but a queue manager error log message is written, indicating what has taken place.

Parameter descriptions for RESET QMGR

TYPE

ADVANCELOG
Requests that the queue manager starts writing to a new log extent, making the previous log extent available for backup. See Updating a backup queue manager. This command is accepted only if the queue manager is configured to use linear logging.

Multi **ARCHLOG**

ARCHIVED (*name*)
Notifies the queue manager that this extent, and all logically earlier ones, have been archived.

The extent name is, for example, S0000001.LOG or AMQA000001 on IBM i.

PUBSUB
Requests that the queue manager cancels the indicated publish/subscribe hierarchical connection. This value requires that one of the CHILD or PARENT attributes is specified:

CHILD
The name of the child queue manager for which the hierarchical connection is to be forcibly canceled. This attribute is used only with TYPE(PUBSUB). It cannot be used together with PARENT.

PARENT
The name of a parent queue manager for which the hierarchical connection is to be forcibly canceled. This attribute is used only with TYPE(PUBSUB). It cannot be used together with CHILD.

Multi **REDUCELOG**

REDUCE
Requests the queue manager to reduce the number of inactive or superfluous log extents and the way in which the log extents are reduced.

The value can be one of the following:

AUTO
Reduce the log extents by an amount chosen by the queue manager.

ONE
Reduce the log extents by one extent, if possible.

MAX
Reduce the log extents by the maximum number possible.

STATISTICS
Requests that the queue manager ends the current statistics collection period and writes the collected statistics.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' '
The command runs on the queue manager on which it was entered. This value is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of setting this value is the same as entering the command on every queue manager in the queue sharing group.

z/OS RESET QSTATS (report and reset queue performance data) on z/OS

Use the MQSC command RESET QSTATS to report performance data for a queue and then to reset that data.

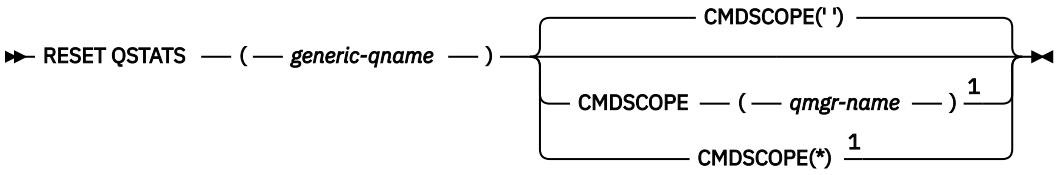
Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Usage notes for RESET QSTATS" on page 880
- "Parameter descriptions for RESET QSTATS" on page 881

Synonym: None



Notes:

[1] Valid only when the queue manager is a member of a queue sharing group.

Usage notes for RESET QSTATS

1. If there is more than one queue with a name that satisfies the *generic q-name*, all those queues are reset.
2. Issue this command from an application, and not the z/OS console or its equivalent, to ensure that the statistical information is recorded.
3. The following information is kept for all queues, both private and shared. For shared queues each queue manager keeps an independent copy of the information:

   MSGIN
   Incremented each time a message is put to the shared queue

   MSGOUT
   Incremented each time a message is removed from the shared queue

   HIQDEPTH
   Calculated by comparing the current value for HIQDEPTH held by this queue manager with the new queue depth obtained from the coupling facility during every put operation. The depth of the queue is affected by all queue managers putting messages to the queue or getting messages from it.

To retrieve the information and obtain full statistics for a shared queue, specify **CMDSCOPE(*)** to broadcast the command to all queue managers in the queue sharing group.

The peak queue depth approximates to the maximum of all the returned HIQDEPTH values, the total MQPUT count approximates to the sum of all the returned MSGIN values, and the total MQGET count approximates to the sum of all the returned MSGOUT values.

4. If the PERFMEV attribute of the queue manager is DISABLED, the command fails.

Parameter descriptions for RESET QSTATS

generic-qname
The name of the local queue with a disposition of QMGR, COPY, or SHARED, but not GROUP, with performance data that is to be reset.

A trailing asterisk (*) matches all queues with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all queues.

The performance data is returned in the same format as parameters returned by DISPLAY commands. The data is:

QSTATS
The name of the queue

z/OS **QSGDISP**
The disposition of the queue, that is, QMGR, COPY, or SHARED.

RESETINT
The number of seconds since the statistics were last reset.

HIQDEPTH
The peak queue depth since the statistics were last reset.

MSGSIN
The number of messages that have been added to the queue by MQPUT and MQPUT1 calls since the statistics were last reset.

The count includes messages added to the queue in units of work that have not yet been committed, but the count is not decremented if the units of work are later backed out. The maximum displayable value is 999 999 999; if the number exceeds this value, 999 999 999 is displayed.

MSGSOUT
The number of messages removed from the queue by destructive (non-browse) MQGET calls since the statistics were last reset.

The count includes messages removed from the queue in units of work that have not yet been committed, but the count is not decremented if the units of work are subsequently backed out. The maximum displayable value is 999 999 999; if the number exceeds this value, 999 999 999 is displayed.

CMDSCOPE
This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

Example output

The following example, shows the output from the command on z/OS.

```
12.44.16 STC16696  CSQM201I !MQ13 CSQMDRTC  RESET QSTATS DETAILS  902
   902             QSTATS(CICS01.INITQ)
   902             QSGDISP(QMGR)
   902             RESETINT(43)
   902             HIQDEPTH(0)
   902             MSGSIN(0)
   902             MSGSOUT(0)
   902              END QSTATS DETAILS
12.44.16 STC16696  CSQM201I !MQ13 CSQMDRTC  RESET QSTATS DETAILS  903
   903             QSTATS(MQ13.DEAD.QUEUE)
   903             QSGDISP(QMGR)
   903             RESETINT(43)
   903             HIQDEPTH(0)
   903             MSGSIN(0)
   903             MSGSOUT(0)
   903              END QSTATS DETAILS
12.44.16 STC16696  CSQM201I !MQ13 CSQMDRTC  RESET QSTATS DETAILS  904
   904             QSTATS(SYSTEM.ADMIN.ACTIVITY.QUEUE)
   904             QSGDISP(QMGR)
   904             RESETINT(43)
   904             HIQDEPTH(0)
   904             MSGSIN(0)
   904             MSGSOUT(0)
```

z/OS RESET SMDS (reset shared message data sets) on z/OS

Use the MQSC command RESET SMDS to modify availability or status information relating to one or more shared message data sets associated with a specific application structure.

Using MQSC commands

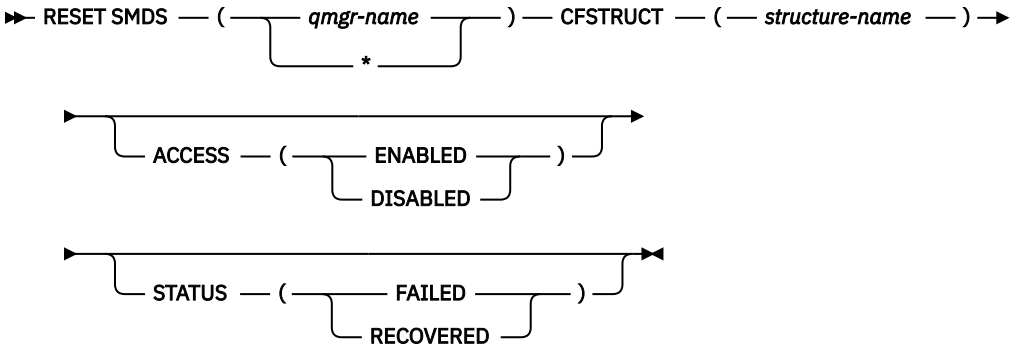
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- “Parameter descriptions for RESET SMDS” on page 883

Synonym:

RESET SMDS



Parameter descriptions for RESET SMDS

This command is only supported when the CFSTRUCT definition is currently using the option OFFLOAD(SMDS).

SMDS(*qmgr-name*|*)
Specify the queue manager for which the shared message data set availability or status information is to be modified, or an asterisk to modify the information for all data sets associated with the specified CFSTRUCT.

CFSTRUCT(*structure-name*)
Specify the coupling facility application structure for which the availability or status information for one or more shared message data sets is to be modified.

ACCESS(ENABLED|DISABLED)
This keyword is used to enable and disable access to a shared message data set, making it available or unavailable to the queue managers in the group.

This keyword is useful when a shared message data set is required to be temporarily unavailable, for example while moving it to a different volume. In this instance, the keyword would be used to mark the data set as ACCESS(DISABLED) causing all of the queue managers to close it normally and deallocate it. When the data set is ready to be used, it can be marked as ACCESS(ENABLED) allowing the queue managers to access it again.

ENABLED
Use the ENABLED parameter to enable access to the shared message data set after previously disabling access, or to retry access after an error has caused the availability state to be set to ACCESS(SUSPENDED).

DISABLED
Use the DISABLED parameter to indicate that the shared message data set cannot be used until the access has been changed back to ENABLED. Any queue managers currently connected to the shared message data set are disconnected from it.

STATUS(FAILED | RECOVERED)
This keyword is used to specify that a shared message data set requires recovery/repair, or to reset the STATUS of the data set from FAILED.

If you have detected that a data set is in need of repair, this keyword can be used to manually mark the data set as STATUS(FAILED). If the queue manager detects that the data set requires repair, it automatically marks it as STATUS(FAILED). Then if RECOVER CFSTRUCT is used to successfully complete a repair to the data set, the queue manager automatically marks it as STATUS(RECOVERED). If another method is used to successfully repair the data set, this keyword can be used to manually mark the data set as STATUS(RECOVERED). It is not necessary to manually alter the ACCESS, as it is automatically changed to SUSPENDED while the STATUS is FAILED and then back to ENABLED when the STATUS is set to RECOVERED.

FAILED
Use the FAILED parameter to indicate that the shared message data set needs to be recovered or repaired, and should not be used until this has been completed. This is only allowed if the current state is STATUS(ACTIVE) or STATUS(RECOVERED). If the current availability state is ACCESS(ENABLED) and is not changed on the same command, this sets ACCESS(SUSPENDED) to prevent further attempts to use the shared message data set until it has been repaired. Any queue managers currently connected to the shared message data set are forced to disconnect from it, by closing and deallocating the data set. This status may be set automatically if a permanent I/O error occurs when accessing a shared message data set or if a queue manager determines that header information in the data set is invalid or is inconsistent with the current state of the structure.

RECOVERED
Use the RECOVERED parameter to reset the state from STATUS(FAILED) if the shared message data set does not actually need to be recovered, for example if it was merely temporarily unavailable. If the current availability state (after any change specified on the same command) is ACCESS(SUSPENDED), this sets ACCESS(ENABLED) to allow the owning queue manager to open

the shared message data set and perform restart processing, after which the status is changed to STATUS(ACTIVE) and other queue managers can use it again.

z/OS RESET TPIPE (reset sequence numbers for an IMS Tpipe) on z/OS

Use the MQSC command RESET TPIPE to reset the recoverable sequence numbers for an IMS Tpipe used by the IBM MQ - IMS bridge.

Using MQSC commands

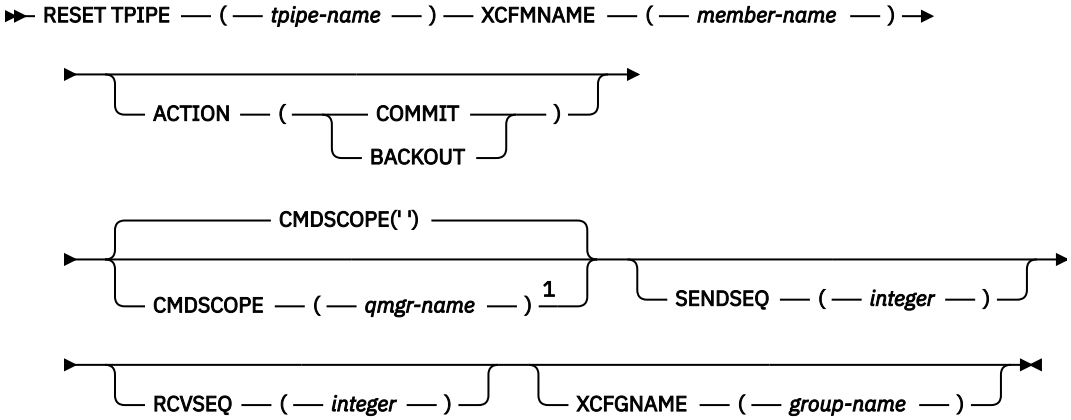
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- “Usage notes” on page 884
- “Parameter descriptions for RESET TPIPE” on page 884

Synonym: There is no synonym for this command.

RESET TPIPE



Notes:

[1] Valid only when the queue manager is a member of a queue sharing group.

Usage notes

1. This command is used in response to the resynchronization error reported in message CSQ2020E, and initiates resynchronization of the Tpipe with IMS.
2. The command fails if the queue manager is not connected to the specified XCF member.
3. The command fails if the queue manager is connected to the specified XCF member, but the Tpipe is open.

Parameter descriptions for RESET TPIPE

(*tpipe-name*)
The name of the Tpipe to be reset. This is required.

CMDSCOPE
This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

ACTION
Specifies whether to commit or back out any unit of recovery associated with this Tpipe. This is required if there is such a unit of recovery reported in message CSQ2020E; otherwise it is ignored.

COMMIT
The messages from IBM MQ are confirmed as having already transferred to IMS ; that is, they are deleted from the IBM MQ - IMS bridge queue.

BACKOUT
The messages from IBM MQ are backed out; that is, they are returned to the IBM MQ - IMS bridge queue.

SENDSEQ(*integer*)
The new recoverable sequence number to be set in the Tpipe for messages sent by IBM MQ and to be set as the partner's receive sequence number. It must be hexadecimal and can be up to 8 digits long, and can optionally be enclosed by X' '. It is optional; if omitted, the sequence number is not changed but the partner's receive sequence is set to the IBM MQ send sequence number.

RCVSEQ(*integer*)
The new recoverable sequence number to be set in the Tpipe for messages received by IBM MQ and to be set as the partner's send sequence number. It must be hexadecimal and can be up to 8 digits long, and can optionally be enclosed by X' '. It is optional; if omitted, the sequence number is not changed but the partner's send sequence is set to the IBM MQ receive sequence number.

XCFGNAME(*group-name*)
The name of the XCF group to which the Tpipe belongs. This is 1 through 8 characters long. It is optional; if omitted, the group name used is that specified in the OTMACON system parameter.

XCFMNAME(*member-name*)
The name of the XCF member within the group specified by XCFGNAME to which the Tpipe belongs. This is 1 through 16 characters long, and is required.

RESOLVE CHANNEL (ask a channel to resolve in-doubt messages)

Use the MQSC command RESOLVE CHANNEL to request a channel to commit or back out in-doubt messages.

Using MQSC commands

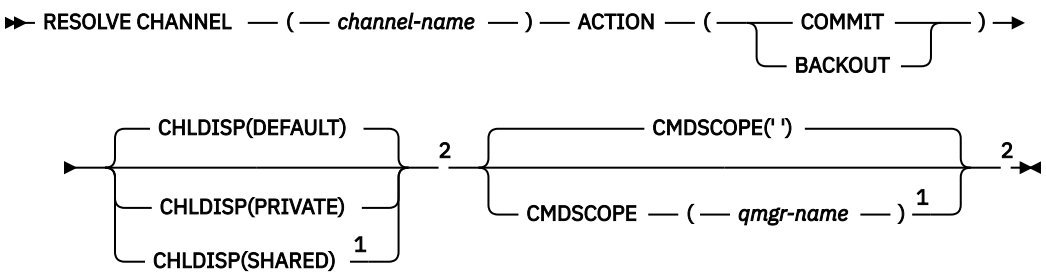
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- “Usage notes for RESOLVE CHANNEL” on page 886
- “Parameter descriptions for RESOLVE CHANNEL” on page 886

Synonym: RESOLVE CHL (RES CHL on z/OS)

RESOLVE CHANNEL



Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[2] Valid only on z/OS.

Usage notes for RESOLVE CHANNEL

1. This command is used when the other end of a link fails during the confirmation period, and for some reason it is not possible to reestablish the connection.
2. In this situation the sending end remains in doubt as to whether the messages were received. Any outstanding units of work must be resolved by being backed out or committed.
3. If the resolution specified is not the same as the resolution at the receiving end, messages can be lost or duplicated.
4. z/OS On z/OS, the command server and the channel initiator must be running.
5. This command can be used only for sender (SDR), server (SVR), and cluster-sender (CLUSSDR) channels (including those that have been defined automatically).
6. Where there is both a locally defined channel and an auto-defined cluster-sender channel of the same name, the command applies to the locally defined channel. If there is no locally defined channel but more than one auto-defined cluster-sender channel, the command applies to the channel that was last added to the local queue manager's repository.

Parameter descriptions for RESOLVE CHANNEL

(channel-name)
The name of the channel for which in-doubt messages are to be resolved. This is required.

ACTION
Specifies whether to commit or back out the in-doubt messages (this is required):

COMMIT
The messages are committed, that is, they are deleted from the transmission queue

BACKOUT
The messages are backed out, that is, they are restored to the transmission queue

z/OS **CHLDISP**
This parameter applies to z/OS only and can take the values of:

- DEFAULT
- PRIVATE
- SHARED

If this parameter is omitted, then the DEFAULT value applies. This is taken from the default channel disposition attribute, DEFCDISP, of the channel object.

In conjunction with the various values of the CMDSCOPE parameter, this parameter controls two types of channel:

SHARED
A receiving channel is shared if it was started in response to an inbound transmission directed to the queue sharing group.

A sending channel is shared if its transmission queue has a disposition of SHARED.

PRIVATE
A receiving channel is private if it was started in response to an inbound transmission directed to the queue manager.

A sending channel is private if its transmission queue has a disposition other than SHARED.

Note: This disposition is **not** related to the disposition set by the disposition of the queue sharing group of the channel definition.

The combination of the CHLDISP and CMDSCOPE parameters also controls from which queue manager the channel is operated. The possible options are:

- On the local queue manager where the command is issued.
- On another specific named queue manager in the group.

The various combinations of CHLDISP and CMDSCOPE are summarized in the following table:

Table 174. CHLDISP and CMDSCOPE for RESOLVE CHANNEL

CHLDISP	CMDSCOPE( ) or CMDSCOPE (local-qmgr)	CMDSCOPE (qmgr-name)
PRIVATE	Resolve private channel on the local queue manager	Resolve private channel on the named queue manager
SHARED	Resolve a shared channel on all active queue managers. This might automatically generate a command using CMDSCOPE and send it to the appropriate queue manager. If there is no definition for the channel on the queue manager to which the command is sent, or if the definition is unsuitable for the command, the command fails. The definition of a channel on the queue manager where the command is entered might be used to determine the target queue manager where the command is actually run. Therefore, it is important that channel definitions are consistent. Inconsistent channel definitions might result in unexpected command behavior.	Not permitted

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

If CHLDISP is set to SHARED, CMDSCOPE must be blank or the local queue manager.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name only if you are using a queue sharing group environment and if the command server is enabled.

z/OS RESOLVE INDOUBT (resolve threads left in doubt) on z/OS

Use the MQSC command RESOLVE INDOUBT to resolve threads left in doubt because IBM MQ or a transaction manager could not resolve them automatically.

Using MQSC commands

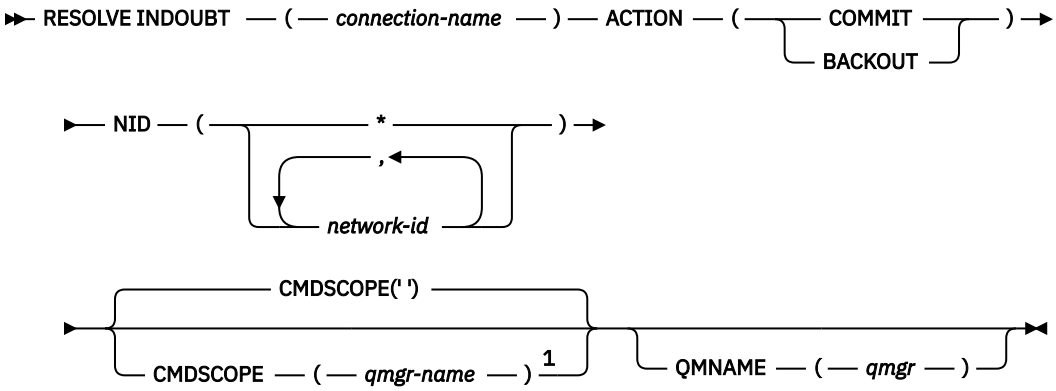
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- “Usage notes” on page 888
- “Parameter descriptions for RESOLVE INDOUBT” on page 888

Synonym: RES IND

RESOLVE INDOUBT



Notes:

1 Valid only when the queue manager is a member of a queue sharing group.

Usage notes

This command does not apply to units of recovery associated with batch or TSO applications, unless you are using the RRS adapter.

Parameter descriptions for RESOLVE INDOUBT

(connection-name)

1 through 8 character connection name.

- For a CICS connection it is the CICS applid.
- For an IMS adapter connection, it is the IMS control region job name.
- For an IMS bridge connection, it is the IBM MQ queue manager name.
- For an RRS connection, it is RRSBATCH.
- For a CHIN connection, it is the IBM MQ channel initiator name.

ACTION

Specifies whether to commit or back out the in-doubt threads:

COMMIT
Commits the threads

BACKOUT
Backs out the threads

CMDSCOPE
This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

NID
Origin identifier. Specifies the thread or threads to be resolved.

(*origin-id*)
This is as returned by the DISPLAY CONN command, and is of the form *origin-node*.*origin-urid*, where:

- *origin-node* identifies the originator of the thread, except RRSBATCH where it is omitted.
- *origin-urid* is the hexadecimal number assigned to the unit of recovery by the originating system for the specific thread to be resolved.

When *origin-node* is present there must be a period (.) between it and *origin-urid*.

You can specify multiple identifiers separated by a commas to resolve more than one thread.

(*)
Resolves all threads associated with the connection.

QMNAME
Specifies that if the designated queue manager is INACTIVE, IBM MQ should search information held in the coupling facility about units of work, performed by the indicated queue manager, that match the connection name and origin identifier.

Matching units of work are either committed or backed out according to the ACTION specified.

Only the shared portion of the unit of work are resolved by this command.

As the queue manager is necessarily inactive, local messages are unaffected and remain locked until the queue manager restarts, or after restarting, connects with the transaction manager.

Examples:

```
RESOLVE INDOUBT(CICSA) ACTION(COMMIT) NID(CICSA.ABCDEF0123456789)
RESOLVE INDOUBT(CICSA) ACTION(BACKOUT) NID(*)
```

RESUME QMGR (resume a cluster queue manager)

Use the MQSC command RESUME QMGR to inform other queue managers in a cluster that the local queue manager is available again for processing and can be sent messages. It reverses the action of the SUSPEND QMGR command.

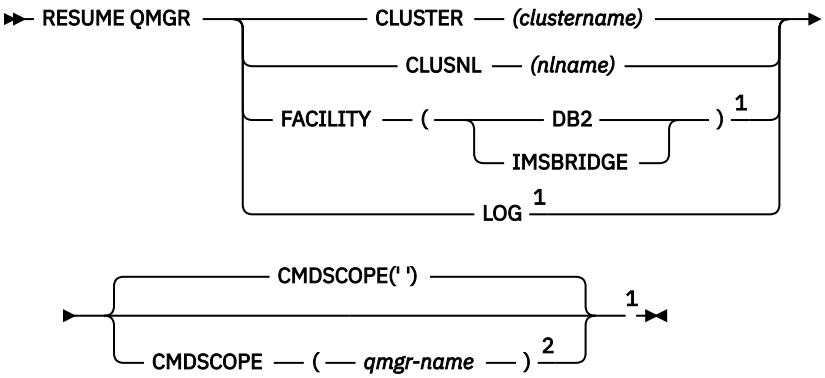
Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

- Syntax diagram
- z/OS See "Using RESUME QMGR on z/OS" on page 890
- "Usage notes" on page 890
- "Parameter descriptions for RESUME QMGR" on page 891

Synonym: None

RESUME QMGR



Notes:

1 Valid only on z/OS.
2 Valid only on z/OS when the queue manager is a member of a queue sharing group.

Using RESUME QMGR on z/OS

z/OS

RESUME QMGR can be used on z/OS. Depending on the parameters used on the command, it may be issued from various sources. For an explanation of the symbols in this table, see Sources from which you can issue MQSC commands on z/OS.

Table 175. RESUME QMGR command and command sources

Command	Command Sources	Notes
RESUME QMGR CLUSTER/CLUSNL	CR	Ensure the channel initiator is running
RESUME QMGR FACILITY	CR	
RESUME QMGR LOG	C	

Usage notes

1. Linux AIX The command is valid only on AIX and Linux.

2. z/OS On z/OS, if you define CLUSTER or CLUSNL:
   a. The command fails if the channel initiator has not been started.
   b. Any errors are reported to the console on the system where the channel initiator is running; they are not reported to the system that issued the command.
3. z/OS On z/OS, you cannot issue RESUME QMGR CLUSTER *(clustername)* or RESUME QMGR FACILITY commands from CSQINP2.
4. z/OS This command, with the CLUSTER and CLUSNL parameters, is **not** available on the reduced function form of IBM MQ for z/OS supplied with WebSphere Application Server.
5. z/OS On z/OS, the SUSPEND QMGR and RESUME QMGR commands are supported through the console only. However, all the other SUSPEND and RESUME commands are supported through the console and command server.

Parameter descriptions for RESUME QMGR

CLUSTER *(clustername)*
The name of the cluster for which availability is to be resumed.

CLUSNL *(nlname)*
The name of the namelist specifying a list of clusters for which availability is to be resumed.

FACILITY
Specifies the facility to which connection is to be re-established.

Db2
Re-establishes connection to Db2.

IMSBRIDGE
Resumes normal IMS bridge activity.

This parameter is only valid on z/OS.

LOG
Resumes logging and update activity for the queue manager that was suspended by a previous SUSPEND QMGR command. Valid on z/OS only. If LOG is specified, the command can be issued only from the z/OS console.

CMDSCOPE
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

z/OS RVERIFY SECURITY (set a user reverification flag) on z/OS

Use the MQSC command RVERIFY SECURITY to set a reverification flag for all specified users. The user is reverified the next time that security is checked for that user.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

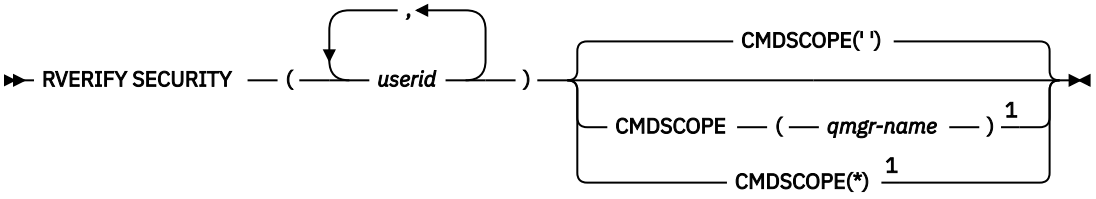
You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- “Parameter descriptions for RVERIFY SECURITY” on page 892

Synonym: REV SEC

REVERIFY SECURITY is another synonym for RVERIFY SECURITY

RVERIFY SECURITY



Notes:

[1] Valid only when the queue manager is a member of a queue sharing group.

Parameter descriptions for RVERIFY SECURITY

(userids...)
You must specify one or more user IDs. Each user ID specified is signed off and signed back on again the next time that a request is issued on behalf of that user that requires security checking.

CMDSCOPE
This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE cannot be used for commands issued from the first initialization input data set CSQINP1.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

z/OS SET ARCHIVE (change archive system settings) on z/OS

Use the MQSC command SET ARCHIVE to dynamically change certain archive system parameter values initially set by your system parameter module at queue manager startup.

Using MQSC commands

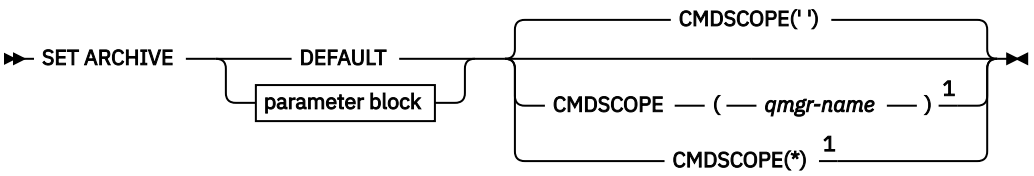
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 12CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

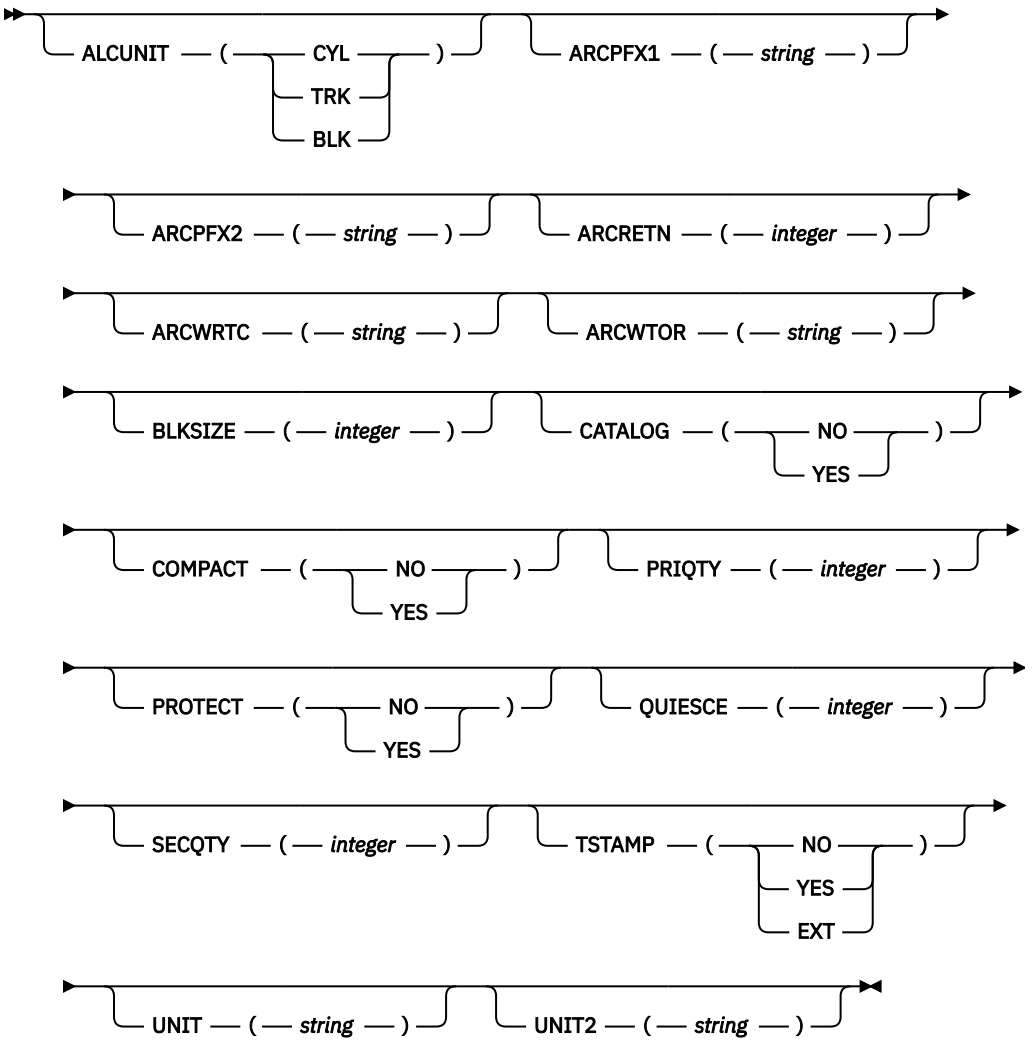
- Syntax diagram
- “Usage notes for SET ARCHIVE” on page 893
- “Parameter descriptions for SET ARCHIVE” on page 894
- “Parameter block” on page 894

Synonym: SET ARC

SET ARCHIVE



Parameter Block



Notes:

[1] Valid only when the queue manager is a member of a queue sharing group.

Usage notes for SET ARCHIVE

1. The new values will be used at the next archive log offload.

2. The queue manager picks up the values in ZPARM, so the **SET ARCHIVE** values you used in the previous cycle are lost.

   To permanently change the values, either change the CSQ6SYSP parameters and regenerate the parameter module, or put the **SET ARCHIVE** commands into a data set in the CSQINP2 concatenation.

Parameter descriptions for SET ARCHIVE

CMDSCOPE
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE cannot be used for commands issued from the first initialization input data set CSQINP1.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which it was entered, only if you are using a queue sharing group environment and if the command server is enabled.

You cannot use CMDSCOPE(*qmgr-name)* for commands issued from the first initialization input data set, CSQINP1.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

You cannot use CMDSCOPE(*) for commands issued from CSQINP1.

DEFAULT
Resets all the archive system parameters to the values set at queue manager startup.

Parameter block

z/OS For a full description of these parameters, see Using CSQ6ARVP.

Parameter block is any one or more of the following parameters that you want to change:

ALCUNIT
Specifies the unit in which primary and secondary space allocations are made.

Specify one of:

CYL
Cylinders

TRK
Tracks

BLK
Blocks

ARCPFX1
Specifies the prefix for the first archive log data set name.

See the TSTAMP parameter for a description of how the data sets are named and for restrictions on the length of ARCPFX1.

ARCPFX2
Specifies the prefix for the second archive log data set name.

See the TSTAMP parameter for a description of how the data sets are named and for restrictions on the length of ARCPFX2.

ARCRETN
Specifies the retention period, in days, to be used when the archive log data set is created.

The parameter must be in the range zero - 9999.

z/OS For more information about discarding archive log data sets, see Discarding archive log data sets.

ARCWRTC
Specifies the list of z/OS routing codes for messages about the archive log data sets to the operator.

Specify up to 14 routing codes, each with a value in the range 1 through 16. You must specify at least one code. Separate codes in the list by commas, not by blanks.

For more information about z/OS routing codes, see *Routing codes* in *Message description* in one of the volumes of the *z/OS MVS System Messages* manuals.

ARCWTOR
Specifies whether a message is to be sent to the operator and a reply received before attempting to mount an archive log data set.

Other IBM MQ users might be forced to wait until the data set is mounted, but they are not affected while IBM MQ is waiting for the reply to the message.

Specify either:

YES
The device needs a long time to mount archive log data sets. For example, a tape drive. (The synonym is **Y**.)

NO
The device does not have long delays. For example, DASD. (The synonym is **N**.)

BLKSIZE
Specifies the block size of the archive log data set. The block size you specify must be compatible with the device type you specify in the UNIT parameter.

The parameter must be in the range 4 097 through 28 672. The value you specify is rounded up to a multiple of 4 096.

This parameter is ignored for data sets that are managed by the storage management subsystem (SMS).

CATALOG
Specifies whether archive log data sets are cataloged in the primary integrated catalog facility (ICF) catalog.

Specify either:

NO
Archive log data sets are not cataloged. (The synonym is **N**.)

YES
Archive log data sets are cataloged. (The synonym is **Y**.)

COMPACT
Specifies whether data written to archive logs is to be compacted. This option applies only to a 3480 or 3490 device that has the improved data recording capability (IDRC) feature. When this feature is turned on, hardware in the tape control unit writes data at a much higher density than normal, allowing for more data on each volume. Specify NO if you do not use a 3480 device with the IDRC feature or a 3490 base model, with the exception of the 3490E. Specify YES if you want the data to be compacted.

Specify either:

NO
Do not compact the data sets. (The synonym is **N**.)

YES
Compact the data sets. (The synonym is **Y**.)

PRIQTY
Specifies the primary space allocation for DASD data sets in ALCUNITs.

The value must be greater than zero.

This value must be sufficient for a copy of either the log data set or its corresponding BSDS, whichever is the larger.

PROTECT
Specifies whether archive log data sets are to be protected by discrete ESM (external security manager) profiles when the data sets are created.

Specify either:

NO
Profiles are not created. (The synonym is **N**.)

YES
Discrete data set profiles are created when logs are offloaded. (The synonym is **Y**.) If you specify YES:

- ESM protection must be active for IBM MQ.
- The user ID associated with the IBM MQ address space must have authority to create these profiles.
- The TAPEVOL class must be active if you are archiving to tape.

Otherwise, offloads will fail.

QUIESCE
Specifies the maximum time in seconds allowed for the quiesce when an ARCHIVE LOG command is issued with MODE QUIESCE specified.

The parameter must be in the range 1 through 999.

SECQTY
Specifies the secondary space allocation for DASD data sets in ALCUNITs.

The parameter must be greater than zero.

TSTAMP
Specifies whether the archive log data set name has a time stamp in it.

Specify either:

NO
Names do not include a time stamp. (The synonym is **N**.) The archive log data sets are named:

```
arcpfxi.A nnnnnnn
```

Where *arcpfxi* is the data set name prefix specified by ARCPFX1 or ARCPFX2. *arcpfxi* can have up to 35 characters.

YES
Names include a time stamp. (The synonym is **Y**.) The archive log data sets are named:

```
arcpfxi.cyyddd.T hhmmsst.A nnnnnnn
```

where *c* is 'D' for the years up to and including 1999 or 'E' for the year 2000 and later, and *arcpfxi* is the data set name prefix specified by ARCPFX1 or ARCPFX2. *arcpfxi* can have up to 19 characters.

EXT
Names include a time stamp. The archive log data sets are named:

```
arcpfxi.D yyyyddd.T hhmmsst.A nnnnnnn
```

Where *arcpfxi* is the data set name prefix specified by ARCPFX1 or ARCPFX2. *arcpfxi* can have up to 17 characters.

UNIT
Specifies the device type or unit name of the device that is used to store the first copy of the archive log data set.

Specify a device type or unit name of 1 through 8 characters.

If you archive to DASD, you can specify a generic device type with a limited volume range.

UNIT2
Specifies the device type or unit name of the device that is used to store the second copy of the archive log data sets.

Specify a device type or unit name of 1 through 8 characters.

If this parameter is blank, the value set for the UNIT parameter is used.

Multi SET AUTHREC (set authority records) on Multiplatforms

Use the MQSC command SET AUTHREC to set authority records associated with a profile name.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

- Syntax diagram
- “Parameter descriptions” on page 899
- Usage notes for SET AUTHREC

See “setmqaut (grant or revoke authority)” on page 178 for more information on the options that you can select.

Parameter descriptions

PROFILE(*profile-name*)
The name of the object or generic profile for which to display the authority records. This parameter is required unless the **OBJTYPE** parameter is QMGR, in which case it can be omitted.

See Using OAM generic profiles on AIX, Linux, and Windows for more information on generic profiles and wildcard characters.

OBJTYPE
The type of object referred to by the profile. Specify one of the following values:

AUTHINFO
Authentication information record

CHANNEL
Channel

CLNTCONN
Client connection channel

COMMINFO
Communication information object

LISTENER
Listener

NAMELIST
Namelist

PROCESS
Process

QUEUE
Queue

QMGR
Queue manager

RQMNAME
Remote queue manager

SERVICE
Service

TOPIC
Topic

PRINCIPAL(*principal-name*)
A principal name. This is the name of a user for whom to set authority records for the specified profile. On IBM MQ for Windows, the name of the principal can optionally include a domain name, specified in this format: `user@domain`.

You must specify either PRINCIPAL or GROUP.

GROUP(*group-name*)
A group name. This is the name of the user group for which to set authority records for the specified profile. You can specify one name only and it must be the name of an existing user group.

Windows For IBM MQ for Windows only, the group name can optionally include a domain name, specified in the following format:

```
GroupName@domain
```

You must specify either PRINCIPAL or GROUP.

AUTHADD
A list of authorizations to add in the authority records. Specify any combination of the following values:

NONE
No authorization

ALTUSR
Specify an alternative user ID on an MQI call

BROWSE
Retrieve a message from a queue by issuing an **MQGET** call with the BROWSE option

CHG
Change the attributes of the specified object, using the appropriate command set

CLR
Clear a queue or a topic

CONNECT
Connect an application to a queue manager by issuing an **MQCONN** call

CRT
Create objects of the specified type using the appropriate command set

DLT
Delete the specified object using the appropriate command set

DSP
Display the attributes of the specified object using the appropriate command set

GET
Retrieve a message from a queue by issuing an **MQGET** call

INQ
Make an inquiry on a specific queue by issuing an **MQINQ** call

PUT
Put a message on a specific queue by issuing an **MQPUT** call

PASSALL
Pass all context

PASSID
Pass the identity context

SET
Set attributes on a queue by issuing an **MQSET** call

SETALL
Set all context on a queue

SETID
Set the identity context on a queue

SUB
Create, alter, or resume a subscription to a topic using the **MQSUB** call

RESUME
Resume a subscription using the MQSUB call

PUB
Publish a message on a topic using the **MQPUT** call

SYSTEM
Give authority to principals or groups, who are authorized to carry out privileged operations on the queue manager, for internal system operations.

CTRL
Start and stop the specified channel, listener, or service, and ping the specified channel

CTRLX
Reset or resolve the specified channel

ALL
Use all operations relevant to the object

`all` authority is equivalent to the union of the authorities `alladm`, `allmqi`, and `system` appropriate to the object type.

ALLADM
Perform all administration operations relevant to the object

ALLMQI
Use all MQI calls relevant to the object

AUTHRMV
A list of authorizations to remove from the authority records. Specify any combination of the following values:

NONE
No authorization

ALTUSR
Specify an alternative user ID on an MQI call

BROWSE
Retrieve a message from a queue by issuing an **MQGET** call with the BROWSE option

CHG
Change the attributes of the specified object, using the appropriate command set

CLR
Clear a queue or a topic

CONNECT
Connect an application to a queue manager by issuing an **MQCONN** call

CRT
Create objects of the specified type using the appropriate command set

DLT
Delete the specified object using the appropriate command set

DSP
Display the attributes of the specified object using the appropriate command set

GET
Retrieve a message from a queue by issuing an **MQGET** call

INQ
Make an inquiry on a specific queue by issuing an **MQINQ** call

PUT
Put a message on a specific queue by issuing an **MQPUT** call

PASSALL
Pass all context

PASSID
Pass the identity context

SET
Set attributes on a queue by issuing an **MQSET** call

SETALL
Set all context on a queue

SETID
Set the identity context on a queue

SUB
Create, alter, or resume a subscription to a topic using the **MQSUB** call

RESUME
Resume a subscription using the MQSUB call

PUB
Publish a message on a topic using the **MQPUT** call

SYSTEM
Use queue manager for internal system operations

CTRL
Start and stop the specified channel, listener, or service, and ping the specified channel

CTRLX
Reset or resolve the specified channel

ALL
Use all operations relevant to the object

`all` authority is equivalent to the union of the authorities `alladm`, `allmqi`, and `system` appropriate to the object type.

ALLADM
Perform all administration operations relevant to the object

ALLMQI
Use all MQI calls relevant to the object

Note: To use SETID or SETALL authority, authorizations must be granted on both the appropriate queue object and also on the queue manager object.

SERVCOMP(*service-component*)
The name of the authorization service for which information is to be set.

If you specify this parameter, it specifies the name of the authorization service to which the authorizations apply. If you omit this parameter, the authority record is set using the registered authorization services in turn in accordance with the rules for chaining authorization services.

Usage notes for SET AUTHREC

The list of authorizations to add and the list of authorizations to remove must not overlap. For example, you cannot add display authority and remove display authority with the same command. This rule applies even if the authorities are expressed using different options. For example, the following command fails because DSP authority overlaps with ALLADM authority:

```
SET AUTHREC PROFILE(*) OBJTYPE(QUEUE) PRINCIPAL(PRINC01) AUTHADD(DSP) AUTHRMV(ALLADM)
```

The exception to this overlap behavior is with the ALL authority. The following command first adds ALL authorities then removes the SETID authority:

```
SET AUTHREC PROFILE(*) OBJTYPE(QUEUE) PRINCIPAL(PRINC01) AUTHADD(ALL) AUTHRMV(SETID)
```

The following command first removes ALL authorities then adds the DSP authority:

```
SET AUTHREC PROFILE(*) OBJTYPE(QUEUE) PRINCIPAL(PRINC01) AUTHADD(DSP) AUTHRMV(ALL)
```

Regardless of the order in which they are provided on the command, the ALL are processed first.

Related concepts
OAM user-based permissions on AIX and Linux

Related reference
“dmpmqaut (dump MQ authorizations)” on page 45
Dump a list of current authorizations for a range of IBM MQ object types and profiles.

“setmqaut (grant or revoke authority)” on page 178
Change the authorizations to a profile, object, or class of objects. Authorizations can be granted to, or revoked from, any number of principals or groups.

“DISPLAY AUTHREC (display authority records) on Multiplatforms” on page 628

Use the MQSC command DISPLAY AUTHREC to display the authority records associated with a profile name.

SET CHLAUTH (create or modify a channel authentication record)

Use the MQSC command SET CHLAUTH to create or modify a channel authentication record.

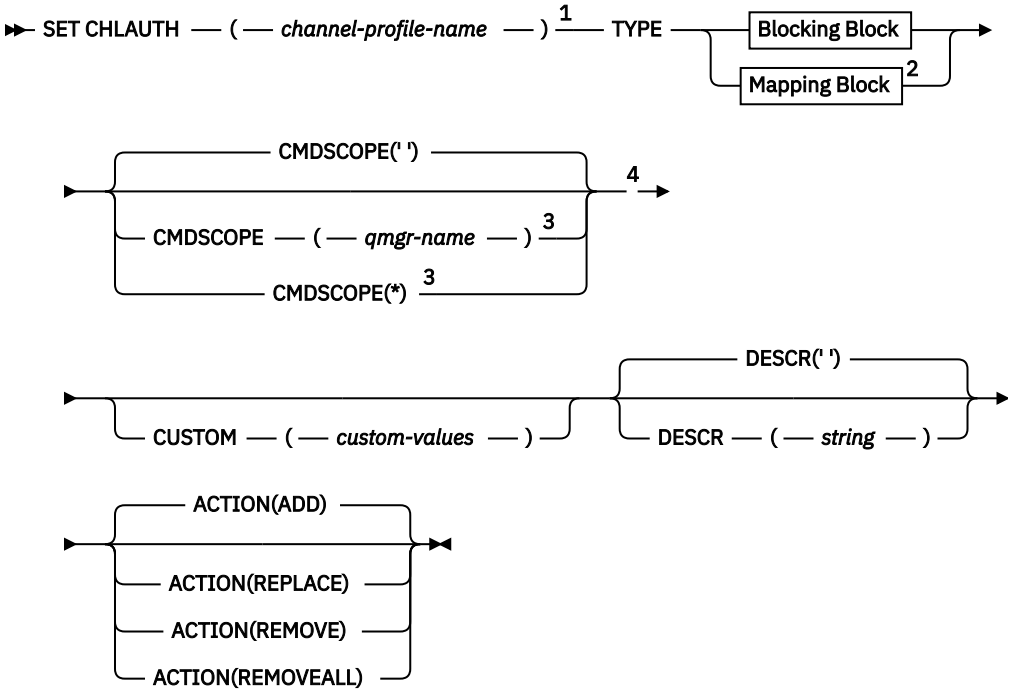
Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

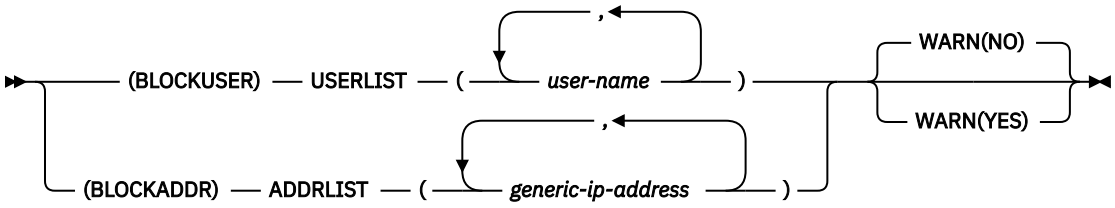
z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- Usage notes
- Parameters

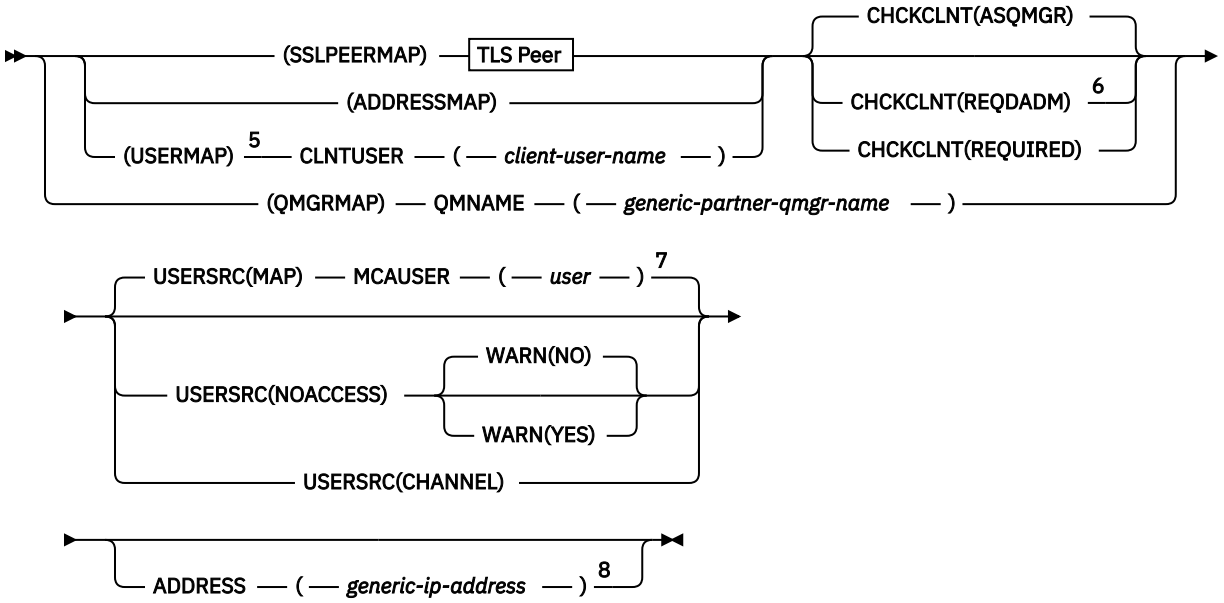
SET CHLAUTH



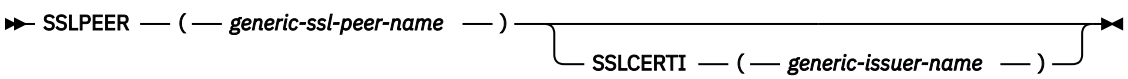
Blocking Block



Mapping Block



TLS Peer



Notes:

[1] The channel profile name must be '*' when TYPE is BLOCKADDR.
[2] Select the appropriate value for TYPE, depending upon the option that you select from the two types of block.
[3] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[4] Valid only on z/OS.
[5] USERMAP rules apply only to server connection channels.
[6] Not valid on z/OS.
[7] If you allow USERSRC to default to MAP, you must set a value for the parameter MCAUSER.
[8] Mandatory when TYPE is ADDRESSMAP.

Usage notes

The following table shows which parameters are valid for each value of **ACTION**:

	Action		
Parameter	**ADD or REPLACE**	**REMOVE**	**REMOVEALL**
CHLAUTH	✓	✓	✓
TYPE	✓	✓	✓
z/OS z/OS CMDSCOPE	✓	✓	✓
ACTION	✓	✓	✓
ADDRESS	✓	✓	
ADDRLIST	✓	✓	

	Action		
Parameter	**ADD or REPLACE**	**REMOVE**	**REMOVEALL**
CHCKCLNT	✓		
CLNTUSER	✓	✓	
MCAUSER	✓		
QMNAME	✓	✓	
SSLCERTI	✓	✓	
SSLPEER	✓	✓	
USERLIST	✓	✓	
USERSRC	✓		
WARN	✓		
DESCR	✓		

Note the following:

- CHLAUTH rules can be used for any channels
- USERMAP rules are valid, only for server connection channels.
- Changes, such as mapping the MCAUSER of the channel, take effect only when starting a channel.

  Therefore, if a channel is already running, that channel must be stopped, and restarted, for the CHLAUTH rule changes to take effect.

Parameters

channel-profile-name
The name of the channel or set of channels for which you are setting channel authentication configuration. You can use one or more asterisks (*), in any position, as wildcards to specify a set of channels. If you set **TYPE** to BLOCKADDR, you must set the generic channel name to a single asterisk, which matches all channel names. On z/OS the generic-channel-name must be in quotes if it contains an asterisk.

TYPE
The **TYPE** parameter must follow the **`channel-profile-name`** parameter.

The type of channel authentication record for which to set allowed partner details or mappings to MCAUSER. This parameter is required. The following values can be used:

BLOCKUSER
This channel authentication record prevents a specified user or users from connecting. The BLOCKUSER parameter must be accompanied by a USERLIST.

BLOCKADDR
This channel authentication record prevents connections from a specified IP address or addresses. The BLOCKADDR parameter must be accompanied by an ADDRLIST. BLOCKADDR operates at the listener before the channel name is known.

SSLPEERMAP
This channel authentication record maps TLS Distinguished Names (DNs) to MCAUSER values. The SSLPEERMAP parameter must be accompanied by an SSLPEER.

ADDRESSMAP
This channel authentication record maps IP addresses to MCAUSER values. The ADDRESSMAP parameter must be accompanied by an ADDRESS. ADDRESSMAP operates at the channel.

USERMAP
This channel authentication record maps asserted user IDs to MCAUSER values. The USERMAP parameter must be accompanied by a CLNTUSER.

QMGRMAP
This channel authentication record maps remote queue manager names to MCAUSER values. The QMGRMAP parameter must be accompanied by a QMNAME.

ACTION
The action to perform on the channel authentication record. The following values are valid:

ADD
Add the specified configuration to a channel authentication record. This is the default value.

For types SSLPEERMAP, ADDRESSMAP, USERMAP and QMGRMAP, if the specified configuration exists, the command fails.

For types BLOCKUSER and BLOCKADDR, the configuration is added to the list.

REPLACE
Replace the current configuration of a channel authentication record.

For types SSLPEERMAP, ADDRESSMAP, USERMAP and QMGRMAP, if the specified configuration exists, it is replaced with the new configuration. If it does not exist it is added.

For types BLOCKUSER and BLOCKADDR, the configuration specified replaces the current list, even if the current list is empty. If you replace the current list with an empty list, this acts like REMOVEALL.

REMOVE
Remove the specified configuration from the channel authentication records. Note, that if the configuration does not exist the command still works. If you remove the last entry from a list, this acts like REMOVEALL.

REMOVEALL
Remove all members of the list and thus the whole record (for BLOCKADDR and BLOCKUSER) or all previously defined mappings (for ADDRESSMAP, SSLPEERMAP, QMGRMAP and USERMAP) from the channel authentication records. This option cannot be combined with specific values supplied in **ADDRLIST**, **USERLIST**, **ADDRESS**, **SSLPEER**, **QMNAME** or **CLNTUSER**. If the specified type has no current configuration the command still succeeds.

ADDRESS
The filter to be used to compare with the IP address or host name of the partner queue manager or client at the other end of the channel. Channel authentication records containing hostnames are only checked if the queue manager is configured to look them up with REVDNS(ENABLED). Details of the values that are allowed as host names are defined in the IETF documents RFC 952 and RFC 1123. Hostname matching is not case sensitive.

This parameter is mandatory with **TYPE(ADDRESSMAP)**

This parameter is also valid when **TYPE** is SSLPEERMAP, USERMAP, or QMGRMAP and **ACTION** is ADD, REPLACE, or REMOVE. You can define more than one channel authentication object with the same main identity, for example the same TLS peer name, with different addresses. However, you cannot define channel authentication records with overlapping address ranges for the same main identity. See “Generic IP addresses for channel authentication records” on page 910 for more information about filtering IP addresses.

If the address is generic then it must be in quotes.

ADDRLIST
A list of up to 256 generic IP addresses which are banned from accessing this queue manager on any channel. This parameter is only valid with TYPE(BLOCKADDR). See “Generic IP addresses for channel authentication records” on page 910 for more information about filtering IP addresses.

If the address is generic then it must be in quotes.

CHCKCLNT
Specifies whether the connection that matches this rule and is being allowed in with **USERSRC(CHANNEL)** or **USERSRC(MAP)**, must also specify a valid user ID and password. The password cannot contain single quotation marks (').

REQDADM
A valid user ID and password are required for the connection to be allowed if you are using a privileged user ID.

Any connections using a non-privileged user ID are not required to provide a user ID and password. The user ID and password are checked against the user repository details provided in an authentication information object and supplied on **ALTER QMGR** in the **CONNAUTH** field. If no user repository details are provided, so that user ID and password checking are not enabled on the queue manager, the connection is not successful.

A privileged user is one that has full administrative authorities for IBM MQ. See Privileged users for more information.

z/OS This option is not valid on z/OS platforms.

REQUIRED
A valid user ID and password are required for the connection to be allowed. The password cannot contain single quotation marks (').

The user ID and password are checked against the user repository details provided in an authentication information object and supplied on **ALTER QMGR** in the **CONNAUTH** field. If no user repository details are provided, so that user ID and password checking are not enabled on the queue manager, the connection is not successful.

ASQMGR
In order for the connection to be allowed, it must meet the connection authentication requirements defined on the queue manager.

If the **CONNAUTH** field provides an authentication information object, and the value of **CHCKCLNT** is REQUIRED, the connection fails unless a valid user ID and password are supplied. If the **CONNAUTH** field does not provide an authentication information object, or the value of **CHCKCLNT** is not REQUIRED, the user ID and password are not required.

Attention: If you select REQUIRED or REQDADM on Multiplatforms and you have not set the CONNAUTH field on the queue manager, or if the value of CHCKCLNT is NONE, the connection fails. On Multiplatforms, you receive message AMQ9793. On z/OS, you receive message CSQX793E.

This parameter is valid only with **TYPE(USERMAP)**, **TYPE(ADDRESSMAP)**, and **TYPE(SSLPEERMAP)** and only when **USERSRC** is not set to NOACCESS. It only applies to inbound connections which are SVRCONN channels.

Example rules that use this attribute:

- Anything in the defined network can use an asserted user ID if a valid password is supplied:

```
SET CHLAUTH('*.SVRCONN') +
    TYPE(ADDRESSMAP) ADDRESS('192.0.2.*') +
    USERSRC(CHANNEL) CHCKCLNT(REQUIRED)
```

- This rule ensures that SSL authentication must succeed before processing client authentication according to the policy set at the queue manager:

```
SET CHLAUTH('SSL.APP1.SVRCONN') +
    TYPE(SSLPEERMAP) SSLPEER('CN="Steve Smith", L="BankA"') +
    MCAUSER(SSMITH) CHCKCLNT(ASQMGR)
```

CLNTUSER
The client asserted user ID to be mapped to a new user ID, allowed through unchanged, or blocked.

This can be the user ID flowed from the client indicating the user ID the client side process is running under, or the user ID presented by the client on an MQCONNX call using MQCSP.

The maximum length of the string is MQ_CLIENT_USER_ID_LENGTH.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect is the same as entering the command on every queue manager in the queue sharing group.

CUSTOM
Reserved for future use.

DESCR
Provides descriptive information about the channel authentication record, which is displayed when you issue the DISPLAY CHLAUTH command. It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: Use characters from the coded character set identifier (CCSID) for this queue manager. Other characters might be translated incorrectly if the information is sent to another queue manager.

MCAUSER
The user identifier to be used when the inbound connection matches the TLS DN, IP address, client asserted user ID or remote queue manager name supplied.

This parameter is mandatory with **USERSRC(MAP)** and is valid when **TYPE** is SSLPEERMAP, ADDRESSMAP, USERMAP, or QMGRMAP.

If you use lowercase user IDs you must enclose them in quotation marks: For example:

```
SET CHLAUTH('SYSTEM.DEF.SVRCONN') TYPE(USERMAP) CLNTUSER('johndoe') +
    USERSRC(MAP) MCAUSER(JOHNDOE1) +
    ADDRESS('::FFFF:9.20.4.136') +
    DESCR('Client from z/Linux machine') +
    ACTION(REPLACE)
```

This allows the lowercase user ID to use channel SYSTEM.DEF.SVRCONN on IP address ::FFFF:9.20.4.136. The MCA user for the connection is JOHNDOE1.

If you display the Channel Status (CHS) of the channel, the output is MCAUSER(JOHNDOE1).

This parameter can be used only when **ACTION** is ADD or REPLACE.

QMNAME
The name of the remote partner queue manager, or pattern that matches a set of queue manager names, to be mapped to a user ID or blocked.

This parameter is valid only with **TYPE(QMGRMAP)**.

If the queue manager name is generic then it must be in quotes.

SSLCERTI
This parameter is additional to the **SSLPEER** parameter.

SSLCERTI restricts matches to being within certificates issued by a particular Certificate Authority.

A blank **SSLCERTI** acts like a wildcard, matches any Issuer Distinguished Name.

SSLPEER

The filter to use to compare with the Subject Distinguished Name of the certificate from the peer queue manager or client at the other end of the channel.

The **SSLPEER** filter is specified in the standard form used to specify a Distinguished Name. See IBM MQ rules for SSLPEER values for details.

The maximum length of the parameter is 1024 bytes.

USERLIST
A list of up to 100 user IDs which are banned from use of this channel or set of channels. Use the special value `*MQADMIN` to mean privileged or administrative users. The definition of this value depends on the operating system, as follows:

- Windows On Windows, all members of the mqm group, the Administrators group and SYSTEM.
- Linux AIX On AIX and Linux, all members of the mqm group.
- IBM i On IBM i, the profiles (users) qmqm and qmqmadm and all members of the qmqmadm group, and any user defined with the `*ALLOBJ` special setting.
- z/OS On z/OS, the user ID that the channel initiator, queue manager and advanced message security address spaces are running under.

For more information about privileged users, see Privileged users.

This parameter is only valid with **TYPE(BLOCKUSER)**.

USERSRC
The source of the user ID to be used for MCAUSER at run time. The following values are valid:

MAP
Inbound connections that match this mapping use the user ID specified in the **MCAUSER** attribute. This is the default value.

NOACCESS
Inbound connections that match this mapping have no access to the queue manager and the channel ends immediately.

CHANNEL
Inbound connections that match this mapping use the flowed user ID or any user defined on the channel object in the MCAUSER field.

Note that WARN and USERSRC(CHANNEL), or USERSRC(MAP) are incompatible. This is because channel access is never blocked in these cases, so there is never a reason to generate a warning.

WARN
Indicates whether this record operates in warning mode.

NO
This record does not operate in warning mode. Any inbound connection that matches this record is blocked. This is the default value.

YES

This record operates in warning mode. Any inbound connection that matches this record and would therefore be blocked is allowed access. If channel events are configured, a channel event message is created showing the details of what would have been blocked, see Channel Blocked. The connection is allowed to continue. An attempt is made to find another record that is set to WARN(NO) to set the credentials for the inbound channel.

If you want message AMQ9787 to be generated, you must add **ChlauthIssueWarn**=*y* to the Channels stanza of the qm.ini file.

Channel authentication records

Generic IP addresses for channel authentication records

In the various commands that create and display channel authentication records, you can specify certain parameters as either a single IP address or a pattern to match a set of IP addresses.

When you create a channel authentication record, using the MQSC command **SET CHLAUTH** or the PCF command **Set Channel Authentication Record**, you can specify a generic IP address in various contexts. You can also specify a generic IP address in the filter condition when you display a channel authentication record using the commands **DISPLAY CHLAUTH** or **Inquire Channel Authentication Records**.

You can specify the address in any of the following ways:

- a single IPv4 address, such as 192.0.2.0
- a pattern based on an IPv4 address, including an asterisk (*) as a wildcard. The wildcard represents one or more parts of the address, depending on context. For example, the following values are all valid:
  - 192.0.2.*
  - 192.0.*
  - 192.0.*.2
  - 192.*.2
  - *
- a pattern based on an IPv4 address, including a hyphen (-) to indicate a range, for example 192.0.2.1-8
- a pattern based on an IPv4 address, including both an asterisk and a hyphen, for example 192.0.*.1-8
- a single IPv6 address, such as 2001:DB8:0:0:0:0:0:0
- a pattern based on an IPv6 address including an asterisk (*) as a wildcard. The wildcard represents one or more parts of the address, depending on context. For example, the following values are all valid:
  - 2001:DB8:0:0:0:0:0:*
  - 2001:DB8:0:0:0:*
  - 2001:DB8:0:0:0:*:0:1
  - 2001:*:1
  - *
- a pattern based on an IPv6 address, including a hyphen (-) to indicate a range, for example 2001:DB8:0:0:0:0:0:0-8
- a pattern based on an IPv6 address, including both an asterisk and a hyphen, for example 2001:DB8:0:0:0:*:0:0-8

If your system supports both IPv4 and IPv6, you can use either address format. IBM MQ recognizes IPv4 mapped addresses in IPv6.

Certain patterns are invalid:

- A pattern cannot have fewer than the required number of parts, unless the pattern ends with a single trailing asterisk. For example 192.0.2 is invalid, but 192.0.2.* is valid.
- A trailing asterisk must be separated from the rest of the address by the appropriate part separator (a dot (.) for IPv4, a colon (:) for IPv6). For example, 192.0* is not valid because the asterisk is not in a part of its own.
- A pattern may contain additional asterisks provided that no asterisk is adjacent to the trailing asterisk. For example, 192.*.2.* is valid, but 192.0.*.* is not valid.
- An IPv6 address pattern cannot contain a double colon and a trailing asterisk, because the resulting address would be ambiguous. For example, 2001::* could expand to 2001:0000:*, 2001:0000:0000:* and so on

Mapping an IP address to an MCAUSER user ID

Multi SET LOG (notify completion of log archiving) on Multiplatforms

On Multiplatforms, use the MQSC command SET LOG to notify the queue manager that archiving of a log extent is complete. If the log management type is not ARCHIVE, the command fails.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

- Syntax diagram
- “Parameter descriptions for SET LOG” on page 911
- “Usage notes” on page 911

Synonym: SET LOG

SET LOG

Parameter descriptions for SET LOG

ARCHIVED (*name*)
The extent name, for example, S0000001.LOG.

Usage notes

This command requires change authority on the queue manager object.

The command fails if the log extent is not recognized, or is being written.

The command does not fail if the extent has already been marked as having been archived.

Extents prefixed with the letter R are extents that are waiting to be reused so these extents cannot be passed to **SET LOG ARCHIVED**.

Any extent (prefixed with S) can be archived and passed to **SET LOG ARCHIVED**, except for the current extent. So extents needed for restart or media recovery, or both, can be archived and passed to **SET LOG ARCHIVED** because the queue manager has finished writing to them.

Note that extents can be archived and passed to **SET LOG ARCHIVED** in any order - not necessarily in the order in which they were written.

A message is written to the error log if the queue manager is notified about an extent more than once, either from this command, or the “RESET QMGR (reset a queue manager)” on page 877 command.

This command is not valid on IBM i.

z/OS SET LOG (change log system settings) on z/OS

On z/OS, use the MQSC command SET LOG to dynamically change certain log system parameter values that were initially set by your system parameter module at queue manager startup.

Using MQSC commands

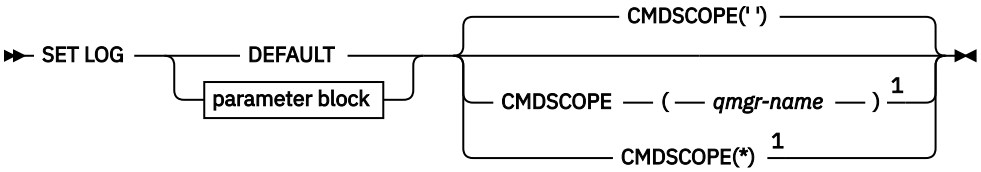
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 12CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

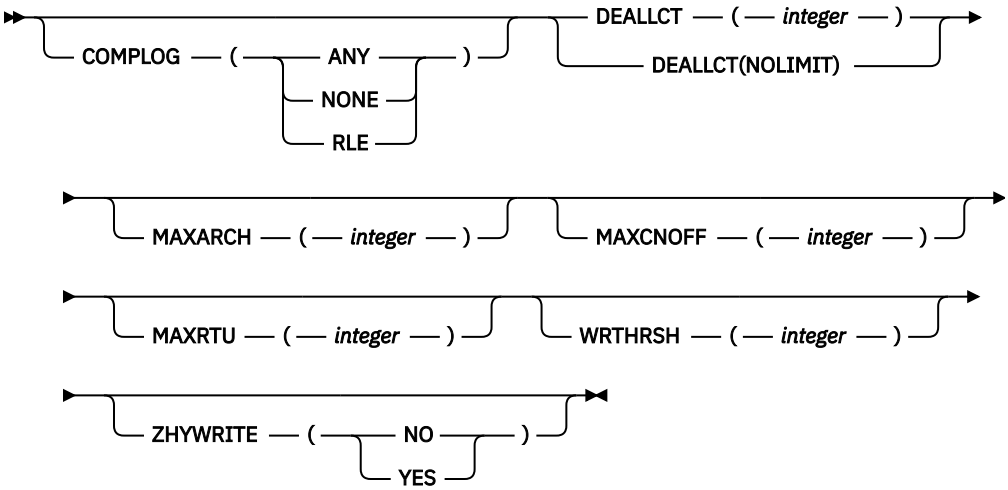
- Syntax diagram
- "Usage notes for SET LOG" on page 912
- "Parameter descriptions for SET LOG" on page 913
- "Parameter block" on page 913

Synonym: SET LOG

SET LOG



Parameter Block



Notes:

[1] Valid only when the queue manager is a member of a queue sharing group.

Usage notes for SET LOG

1. Any changes to WRTHRSH take immediate effect.
2. Any change to MAXARCH takes effect for the next scheduled offload (that is, not for any offload in progress at the time the command is issued).

Parameter descriptions for SET LOG

CMDSCOPE
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

''
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which it was entered, only if you are using a queue sharing group environment and if the command server is enabled.You cannot use CMDSCOPE(*qmgr-name)* for commands issued from the first initialization input data set, CSQINP1.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

You cannot use CMDSCOPE(*) for commands issued from CSQINP1.

DEFAULT
Reset all the log system parameters to the values specified at queue manager startup.

Parameter block

z/OS For a full description of these parameters, see Using CSQ6LOGP.

Parameter block is any one or more of the following parameters that you want to change:

COMPLOG
This parameter specifies whether compression is used by the queue manager when writing log records. Any compressed records are automatically decompressed irrespective of the current COMPLOG setting.

The possible values are:

ANY
Enable the queue manager to select the compression algorithm that gives the greatest degree of log record compression. Using this option currently results in RLE compression.

NONE
No log data compression is used. This is the default value.

RLE
Log data compression is performed using run-length encoding (RLE).

z/OS For more details about log compression, see Log compression.

DEALLCT
Specifies the length of time that an allocated archive read tape unit is allowed to remain unused before it is deallocated. You are recommended to specify the maximum possible values, within system constraints, for both options to achieve the optimum performance for reading archive tapes.

This, together with the MAXRTU parameter, allows IBM MQ to optimize archive log reading from tape devices.

The possible values are:

integer
Specifies the maximum time in minutes, in the range 0 through 1439. Zero means that a tape unit is deallocated immediately.

NOLIMIT or 1440
Indicates that the tape unit is never deallocated.

MAXARCH
Specifies the maximum number of archive log volumes that can be recorded in the BSDS. When this number is exceeded, recording begins again at the start of the BSDS.

Use a decimal number in the range 10 through 1000.

MAXCNOFF
Maximum number of concurrent log offload tasks.

Specify a decimal number between 1 and 31. If no value is specified the default of 31 applies.

Configure a number lower than the default if your archive logs are allocated on a tape device, and there are constraints on the number of such devices that can be concurrently allocated to the queue manager.

MAXRTU(*integer*)
Specifies the maximum number of dedicated tape units that can be allocated to read archive log tape volumes. This overrides the value for MAXRTU set by CSQ6LOGP in the archive system parameters.

This, together with the DEALLCT parameter, allows IBM MQ to optimize archive log reading from tape devices.

Note:

1. The integer value can be in the range 1 - 99.
2. If the number specified is greater than the current specification, the maximum number of tape units allowable for reading archive logs increases.
3. If the number specified is less than the current specification, tape units that are not being used are immediately deallocated to adjust to the new value. Active, or premounted, tape units remain allocated.
4. A tape unit is a candidate for deallocation because of a lowered value only if there is no activity for the unit.
5. When you are asked to mount an archive tape and you reply CANCEL, the MAXRTU value is reset to the current number of tape units.

   For example, if the current value is 10, but you reply CANCEL to the request for the seventh tape unit, the value is reset to six.

WRTHRSH
Specifies the number of 4 KB output buffers to be filled before they are written to the active log data sets.

The larger the number of buffers, the less often the write takes place, and this improves the performance of IBM MQ. The buffers might be written before this number is reached if significant events, such as a commit point, occur.

Specify the number of buffers in the range 1 through 256.

V 9.2.0 **ZHYWRITE**
Specifies whether writes to the active logs are made with zHyperWrite being enabled. The active log datasets need to be on zHyperWrite capable volumes for zHyperWrite to be enabled.

For more information on enabling active logs with zHyperWrite, see Using zHyperWrite with IBM MQ active logs.

The value can be:

NO
zHyperWrite is not enabled.

YES
zHyperWrite is enabled.

Multi SET POLICY (set security policy) on Multiplatforms

Use the MQSC command SET POLICY to set a security policy.

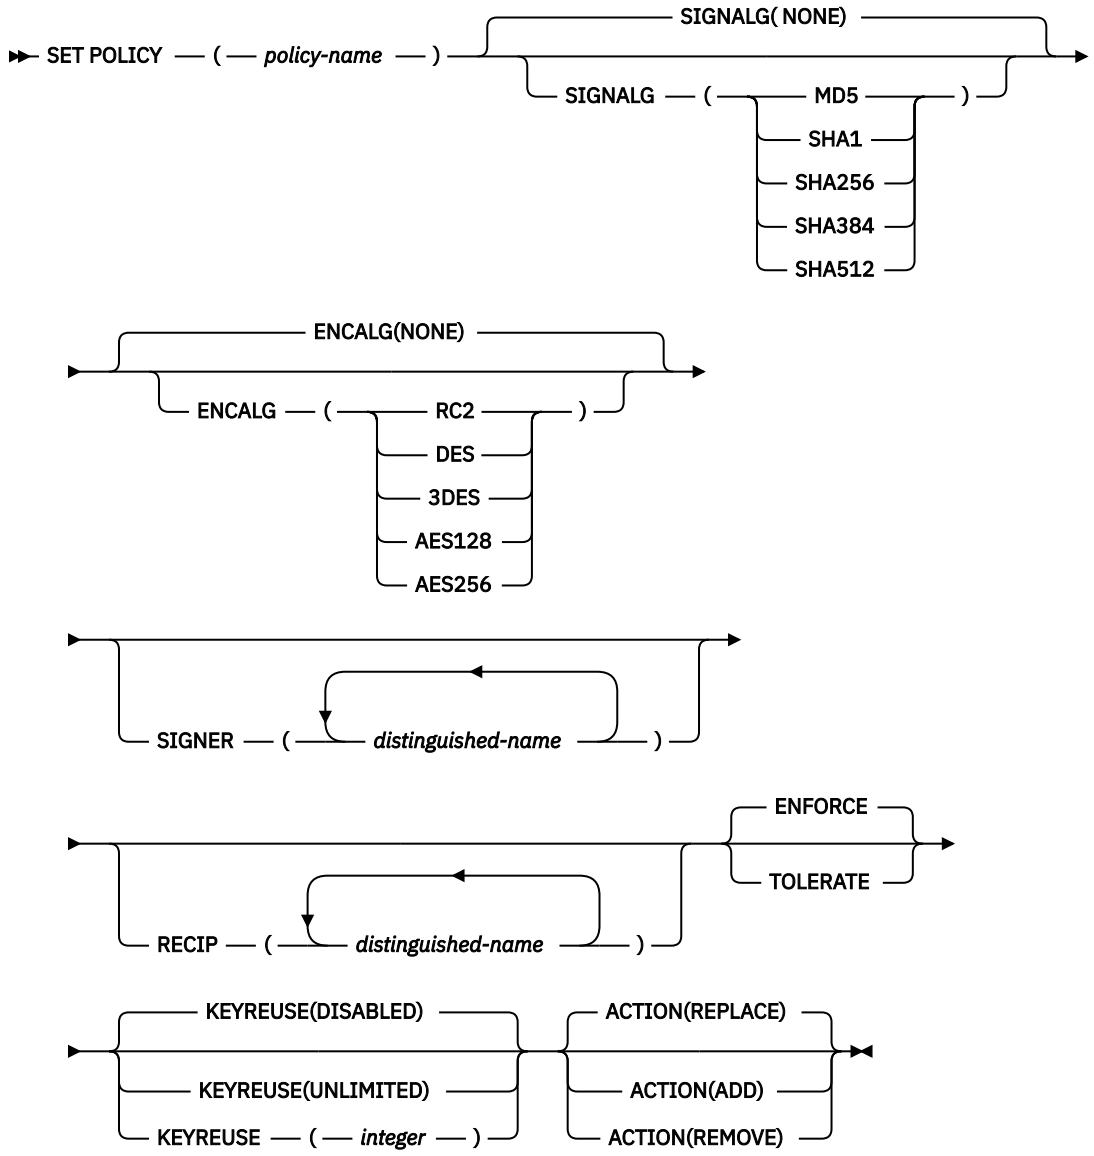
Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

- Syntax diagram
- "Parameter descriptions for SET POLICY" on page 916

Important: You must have an Advanced Message Security (AMS) license installed to issue this command. If you attempt to issue the **SET POLICY** command without an AMS license installed, you receive message AMQ7155 - License file not found or not valid.

SET POLICY



Parameter descriptions for SET POLICY

(policy-name)
Name of the policy, required.

The policy name must match the name of the queue which is to be protected.

SIGNALG
Specifies the digital signature algorithm from one of the following values:

- NONE
- MD5
- SHA1
- SHA256
- SHA384
- SHA512

The default value is NONE.

ENCALG
Specifies the digital encryption algorithm from one of the following values:

- NONE
- RC2
- DES
- 3DES
- AES128
- AES256

The default value is NONE.

RECIP ***(distinguished-name)***
Specifies the message distinguished name (DN) of the recipient, that is, the certificate of a DN provided used to encrypt a given message.

Notes:

1. The attributes names for DNs must be provided in capital letters.
2. Commas must be used as a name separator.
3. You must specify at least one recipient, if you use any encryption algorithm other than NONE.

You can specify multiple **RECIP** parameters on the same policy.

SIGNER ***(distinguished-name)***
Specifies a signature DN that is validated during the message retrieval. Only messages signed by the user, with a DN provided, are accepted during retrieval.

Notes:

1. The attributes name for DNs must be provided in capital letters.
2. Commas must be used as a name separator.
3. You can specify signature DNs, only if you use any signature algorithm other than NONE.

You can specify multiple **SIGNER** parameters on the same policy.

ENFORCE
Specifies that all messages must be protected when retrieved from the queue.

Any unprotected message encountered is moved to the SYSTEM.PROTECTION.ERROR.QUEUE.

ENFORCE is the default value.

TOLERATE
Specifies that the messages that are not protected when retrieved from the queue can ignore the policy.

TOLERATE is optional and exists to facilitate staged implementation, where:

- Policies have been applied to queues, but those queues might already contain unprotected messages, or
- Queues might still receive messages from remote systems that do not yet have the policy set.

KEYREUSE
Specify the number of times that an encryption key can be re-used, in the range 1-9999999, or the special values *DISABLED* or *UNLIMITED*.

Note that this is a maximum number of times a key can be reused, therefore a value of *1* means, at most, two messages can use the same key.

DISABLED
Prevents a symmetric key from being reused

UNLIMITED
Allows a symmetric key to be reused any number of times.

DISABLED is the default value.

Attention: Key reuse is valid only for CONFIDENTIALITY policies, that is, **SIGNALG** set to *NONE* and **ENCALG** set to an algorithm value. For all other policy types, you must omit the parameter, or set the **KEYREUSE** value to *DISABLED*.

ACTION
Specify the action for the parameters supplied, as they apply to any existing policy, using one of the following values:

REPLACE
Has the effect of replacing any existing policy with the parameters supplied.

ADD
Has the effect that signers and recipients parameters have an additive effect. That is, if a signer or recipient is specified, and does not already exist in a preexisting policy, the signer or recipient value is added to the existing policy definition.

REMOVE
Has the opposite effect of *ADD*. That is, if any of the signer or recipient values specified exist in a preexisting policy, those values are removed from the policy definition.

REPLACE is the default value.

Related reference
“DISPLAY POLICY (display a security policy) on Multiplatforms” on page 737
Use the MQSC command DISPLAY POLICY to display a security policy.

“setmqspl (set security policy)” on page 201
Use the **setmqspl** command to define a new security policy, replace an already existing one, or remove an existing policy.

“dspmqspl (display security policy)” on page 88
Use the **dspmqspl** command to display a list of all policies and details of a named policy.

z/OS SET SYSTEM (change system settings) on z/OS

Use the MQSC command SET SYSTEM to dynamically change certain general system parameter values that were initially set from your system parameter module at queue manager startup. To permanently

change these, either change the CSQ6SYSP parameters and regenerate the parameter module, or put the SET SYSTEM commands into a data set in the CSQINP2 concatenation.

Using MQSC commands

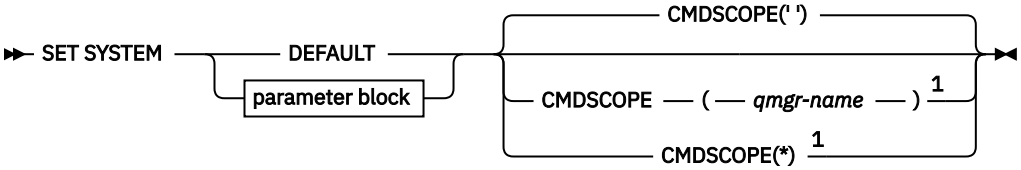
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 12CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

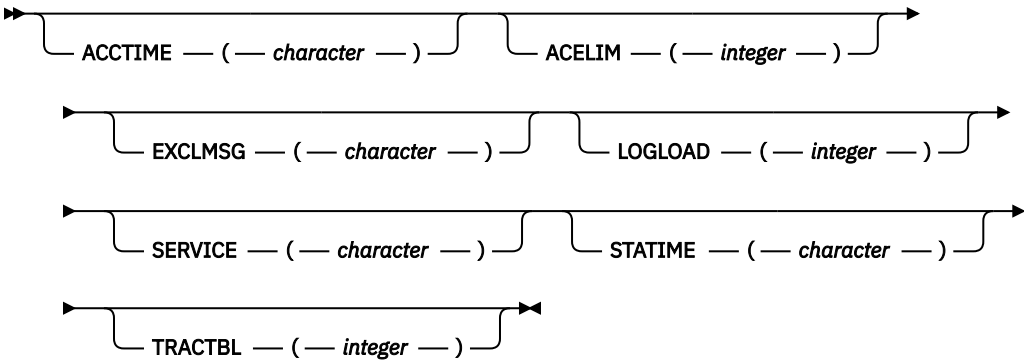
- Syntax diagram
- “Usage notes for SET SYSTEM” on page 918
- “Parameter descriptions for SET SYSTEM” on page 919
- “Parameter block” on page 919

Synonym: None

SET SYSTEM



Parameter Block



Notes:

[1] Valid only when the queue manager is a member of a queue sharing group.

The CTHREAD, IDFORE, and IDBACK parameters are ignored in IBM WebSphere MQ 7.1 or later, but are still allowed for compatibility with earlier versions. Any attempt to change the value of one of these parameters sets it to a default value of 32767.

Usage notes for SET SYSTEM

The new values take immediate effect, with the possible exception of STATIME, V 9.2.4 ACCTIME, and TRACTBL.

Changes to STATIME V 9.2.4 and ACCTIME take effect when the current interval expires, unless the new interval is less than the unexpired portion of the current interval, in which case SMF data is gathered immediately and the new interval then takes effect.

For TRACTBL, if there is any trace currently in effect, the existing trace table continues to be used, and its size is unchanged. A new global trace table is only obtained for a new START TRACE command. If a new

trace table is created with insufficient storage, the old trace table continues to be used, and the message CSQW153E is displayed.

Parameter descriptions for SET SYSTEM

CMDSCOPE

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

' '

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which it was entered, only if you are using a queue sharing group environment and if the command server is enabled. You cannot use CMDSCOPE(*qmgr-name)* for commands issued from the first initialization input data set, CSQINP1.

*****

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

You cannot use CMDSCOPE(*) for commands issued from CSQINP1.

DEFAULT

Resets all the general system parameters to the values set at queue manager startup.

Parameter block

z/OS For a full description of these parameters, see Using CSQ6SYSP.

Parameter block is any one or more of the following parameters that you want to change:

V 9.2.4 **ACCTIME**

Specifies the interval, in minutes and seconds, between consecutive gatherings of accounting data.

Specify a number in the range `0` through 1440 minutes in the format `'mmmm'`, or in the range `0` through 1439 minutes, and `0` - 59 seconds, in the format `'mmmm.ss'`. The default is 30 minutes.

Specify a number, either `-1`, or in the range `0` through 1440 minutes in the format `'mmmm'`, or in the range `0` through 1439 minutes, and `0` - 59 seconds, in the format `'mmmm.ss'`.

Notes:

- When specifying an interval of seconds only, you must prefix the interval with a value of `0`. The smallest possible interval is one second: `'0.01'`.
- If you specify a value of `0`, accounting data is collected at the SMF data collection broadcast. See Using System Management Facility for more information.
- If you specify a value of `-1`, which is the default, accounting data is collected using the STATIME value.

For example:

`'0.30'` sets an interval of 30 seconds.
`'5.30'` sets an interval of 5 minutes and 30 seconds.
`'30'` sets an interval of 30 minutes.

ACELIM

Specifies the maximum size of the ACE storage pool in 1 KB blocks. The number must be in the range 0-999999. The default value of zero means no imposed constraint, beyond what is available in the system.

You should only set a value for ACELIM on queue managers that have been identified as using exorbitant quantities of ECSA storage. Limiting the ACE storage pool has the effect of limiting the number of connections in the system, and so, the amount of ECSA storage used by a queue manager.

Once the queue manager reaches the limit it is not possible for applications to obtain new connections. The lack of new connections causes failures in MQCONN processing, and applications coordinated through RRS are likely to experience failures in any IBM MQ API.

An ACE represents approximately 12.5% of the total ECSA required for the thread-related control blocks for a connection. So, for example, specifying ACELIM=5120 would be expected to cap the total amount of ECSA allocated by the queue manager (for thread-related control blocks) at approximately 40960K; that is 5120 multiplied by 8.

In order to cap the amount total amount of ECSA allocated by the queue manager, for thread-related control blocks at 5120K, an ACELIM value of 640 is required.

You can use SMF 115 subtype 5 records, produced by statistics CLASS(3) trace, to monitor the size of the 'ACE/PEB' storage pool, and hence set an appropriate value for ACELIM.

You can obtain the total amount of ECSA storage used by the queue manager, for control blocks, from SMF 115 subtype 7 records, written by statistics CLASS(2) trace. The total amount of ECSA storage used is the sum of the QSRSPHBGF and QSRSPHBGV fields.

For more information about SMF 115 statistics records, see Interpreting IBM MQ performance statistics.

Note that, you should consider setting ACELIM as a mechanism to protect a z/OS image from a badly behaving queue manager, rather than as a means to control application connections to a queue manager.

EXCLMSG

Specify a list of message identifiers to be excluded from being written to any log. Messages in this list are not sent to the z/OS console and hardcopy log. As a result using the EXCLMSG parameter to exclude messages is more efficient from a CPU perspective than using z/OS mechanisms such as the message processing facility list and should be used instead where possible. This list is dynamic and is updated using the SET SYSTEM command.

The default value is an empty list ( ).

Message identifiers are supplied without the CSQ prefix and without the action code suffix (I-D-E-A). For example, to exclude message CSQX500I, add X500 to this list. This list can contain a maximum of 16 message identifiers.

To be eligible to be included in the list, the message must be issued after normal startup of the MSTR or CHIN address spaces and begin with the one of the following characters E, H, I, J, L, M, N, P, R, T, V, W, X, Y, 2 ,3, 5, 9.

Message identifiers that are issued as a result of processing commands can be added to the list, however are not excluded.

For example:

```
SET SYSTEM EXCLMSG(X511,X512)
```

suppresses the channel started and channel no longer active messages.

LOGLOAD

Specifies the number of log records that IBM MQ writes between the start of one checkpoint and the next. IBM MQ starts a new checkpoint after the number of records that you specify has been written.

Specify a value in the range 200 through 16 000 000.

SERVICE
This parameter is reserved for use by IBM.

STATIME
V 9.2.4 From IBM MQ for z/OS 9.2.4, specifies the time, in minutes and seconds, between consecutive gatherings of statistics data. If ACCTIME is not set, or is `-1`, also specifies the time, between consecutive gatherings of accounting data.

If you specify a value of `0`, data is collected at the SMF data collection broadcast.

Specify a number in the range `0` through 1440 minutes in the format `'mmmm'`, or in the range `0` through 1439 minutes, and `0` - 59 seconds, in the format `'mmmm.ss'`. The default is 30 minutes.

Specify a number, either `-1`, or in the range `0` through 1440 minutes in the format `'mmmm'`, or in the range `0` through 1439 minutes, and `0` - 59 seconds, in the format `'mmmm.ss'`.

Note: When specifying an interval of seconds only, you must prefix the interval with a value of `0`. The smallest possible interval is one second: `'0.01'`.

For example:

`'0.30'` sets an interval of 30 seconds.
`'5.30'` sets an interval of 5 minutes and 30 seconds.
`'30'` sets an interval of 30 minutes.

LTS From IBM MQ for z/OS 9.2.0 to 9.2.3, specifies the interval, in minutes, between consecutive gatherings of statistics.

Specify a number in the range `0` through 1440 minutes.

If you specify a value of `0`, both statistics data and accounting data is collected at the SMF data collection broadcast.

TRACTBL
Specifies the default size, in 4 KB blocks, of trace table where the global trace facility stores IBM MQ trace records.

Specify a value in the range 1 through 999.

Note: Storage for the trace table is allocated in the ECSA. Therefore, you must select this value with care.

START CHANNEL (start a channel)

Use the MQSC command **START CHANNEL** to start a channel.

Using MQSC commands

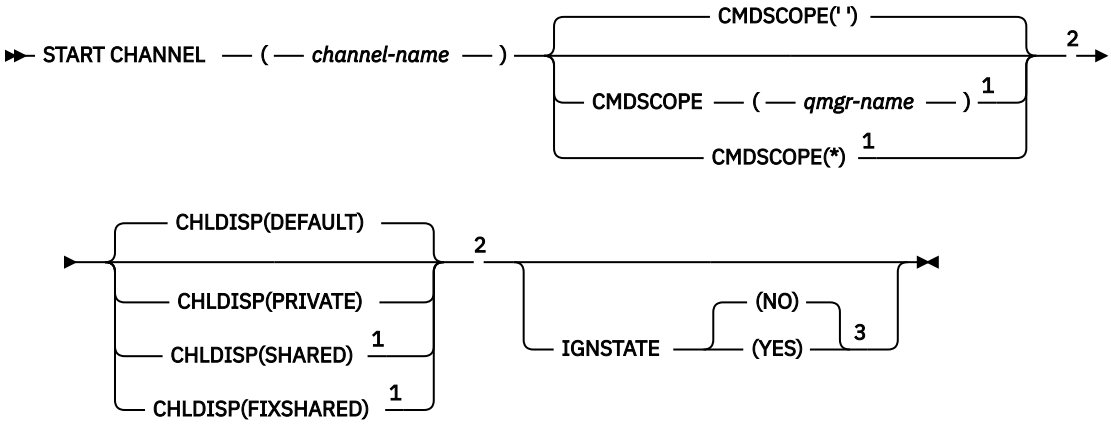
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- “Usage notes” on page 922
- “Parameter descriptions for START CHANNEL” on page 922

Synonym: STA CHL

START CHANNEL



Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[2] Valid only on z/OS.
[3] Not valid on z/OS

Usage notes

1. z/OS On z/OS, the command server and the channel initiator must be running.
2. This command can be issued to a channel of any type except CLNTCONN channels (including those that have been defined automatically). If, however, it is issued to a receiver (RCVR), server-connection (SVRCONN) or cluster-receiver (CLUSRCVR) channel, the only action is to enable the channel, not to start it.
3. Where there is both a locally defined channel and an auto-defined cluster-sender channel of the same name, the command applies to the locally defined channel. If there is no locally defined channel but more than one auto-defined cluster-sender channel, the command applies to the channel that was last added to the local queue manager's repository.

Parameter descriptions for START CHANNEL

(channel-name)
The name of the channel definition to be started. This is required for all channel types. The name must be that of an existing channel.

z/OS **CHLDISP**
This parameter applies to z/OS only and can take the values of:

- DEFAULT
- PRIVATE
- SHARED
- FIXSHARED

If this parameter is omitted, then the DEFAULT value applies. This is taken from the default channel disposition attribute, **DEFCDISP**, of the channel object.

In conjunction with the various values of the **CMDSCOPE** parameter, this parameter controls two types of channel:

SHARED
A receiving channel is shared if it was started in response to an inbound transmission directed to the queue sharing group.

A sending channel is shared if its transmission queue has a disposition of SHARED.

PRIVATE
A receiving channel is private if it was started in response to an inbound transmission directed to the queue manager.

A sending channel is private if its transmission queue has a disposition other than SHARED.

Note: This disposition is not related to the disposition set by the disposition of the queue sharing group of the channel definition.

The combination of the **CHLDISP** and **CMDSCOPE** parameters also controls from which queue manager the channel is operated. The possible options are:

- On the local queue manager where the command is issued.
- On another specific named queue manager in the group.
- On every active queue manager in the group.
- On the most suitable queue manager in the group, determined automatically by the queue manager itself.

The various combinations of **CHLDISP** and **CMDSCOPE** are summarized in the following table:

Table 176. CHLDISP and CMDSCOPE for START CHANNEL

CHLDISP	CMDSCOPE( ) or CMDSCOPE (local-qmgr)	CMDSCOPE (qmgr-name)	CMDSCOPE(*)
PRIVATE	Start as a private channel on the local queue manager	Start as a private channel on the named queue manager	Start as a private channel on all active queue managers
SHARED	For a shared SDR, RQSTR, and SVR channel, start as a shared channel on the most suitable queue manager in the group. For a shared RCVR and SVRCONN channel, start the channel as a shared channel on all active queue managers. For a shared CLUSSDR or CLUSRCVR channel, this option is not permitted. This might automatically generate a command using CMDSCOPE and send it to the appropriate queue managers. If there is no definition for the channel on the queue managers to which the command is sent, or if the definition is unsuitable for the command, the action fails there. The definition of a channel on the queue manager where the command is entered might be used to determine the target queue manager where the command is actually run. Therefore, it is important that channel definitions are consistent. Inconsistent channel definitions might result in unexpected command behavior.	Not permitted	Not permitted

Table 176. CHLDISP and CMDSCOPE for START CHANNEL (continued)			
CHLDISP	**CMDSCOPE( ) or CMDSCOPE (local-qmgr)**	**CMDSCOPE (qmgr-name)**	**CMDSCOPE(*)**
FIXSHARED	For a shared SDR, RQSTR, and SVR channel, with a nonblank CONNAME, start as a shared channel on the local queue manager. For all other types, this option is not permitted.	For a shared SDR, RQSTR, and SVR with a nonblank CONNAME, start as a shared channel on the named queue manager. For all other types, this option is not permitted.	Not permitted

Channels started with **CHLDISP(FIXSHARED)** are tied to the specific queue manager; if the channel initiator on that queue manager stops for any reason, the channels are not recovered by another queue manager in the group. For more information about SHARED and FIXSHARED channels, see Starting a shared channel.

z/OS **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

If **CHLDISP** is set to SHARED, **CMDSCOPE** must be blank or the local queue manager.

' '

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name only if you are using a queue sharing group environment and if the command server is enabled.

*****

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

This option is not permitted if **CHLDISP** is FIXSHARED.

V 9.2.0 Multi **IGNSTATE**

Specifies whether the command fails if the channel is already running. The possible values are:

NO

The command fails if the channel is already running. This is the default value.

YES

The command succeeds regardless of the current state of the channel.

Windows Linux AIX

START CHANNEL (start a channel) MQTT

Use the MQSC command START CHANNEL to start an MQ Telemetry channel.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

The START CHANNEL (MQTT) command is only valid for MQ Telemetry channels. Supported platforms for MQ Telemetry are AIX, Linux, Windows.

Synonym: STA CHL

START CHANNEL

Parameter descriptions for START CHANNEL

(channel-name)
The name of the channel definition to be started. The name must be that of an existing channel.

CHLTYPE
Channel type. The value must be MQTT.

z/OS START CHINIT (start a channel initiator) on z/OS

Use the MQSC command START CHINIT to start a channel initiator.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

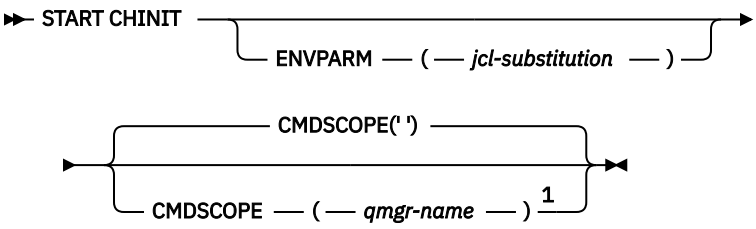
You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Usage notes" on page 925
- "Parameter descriptions for START CHINIT" on page 926

Synonym: STA CHI

Syntax diagram

START CHINIT



Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.

Usage notes

1. The command server must be running.
2. Although START CHINIT is permitted from CSQINP2, its processing is not complete (and the channel initiator is not available) until after CSQINP2 processing has finished. For these commands, consider using CSQINPX instead.

Parameter descriptions for START CHINIT

CMDSCOPE

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

' '

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

ENVPARM(*jcl-substitution*)

The parameters and values to be substituted in the JCL procedure (xxxxCHIN, where xxxx is the queue manager name) that is used to start the channel initiator address space.

jcl-substitution

One or more character strings of the form `keyword=value` enclosed in single quotation marks. If you use more than one character string, separate the strings by commas and enclose the entire list in single quotation marks, for example ENVPARM('HLQ=CSQ,VER=520').

This parameter is valid only on z/OS.

INITQ(*string*)

The name of the initiation queue for the channel initiation process. This is the initiation queue that is specified in the definition of the transmission queue.

The initiation queue on z/OS is always SYSTEM.CHANNEL.INITQ).

Related concepts

Command resource security checking for alias queues and remote queues

z/OS START CMDSERV (start the command server) on z/OS

Use the MQSC command START CMDSERV to initialize the command server.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 12C. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- “Usage notes for START CMDSERV” on page 926

Synonym: STA CS

START CMDSERV

Usage notes for START CMDSERV

1. START CMDSERV starts the command server and allows it to process commands in the system-command input queue (SYSTEM.COMMAND.INPUT), mover commands, and commands using CMDSCOPE.

2. If this command is issued through the initialization files or through the operator console before work is released to the queue manager (that is, before the command server is started automatically), it overrides any earlier STOP CMDSERV command and allows the queue manager to start the command server automatically by putting it into an ENABLED state.
3. If this command is issued through the operator console while the command server is in a STOPPED or DISABLED state, it starts the command server and allows it to process commands on the system-command input queue, mover commands, and commands using CMDSCOPE immediately.
4. If the command server is in a RUNNING or WAITING state (including the case when the command is issued through the command server itself), or if the command server has been stopped automatically because the queue manager is closing down, no action is taken, the command server remains in its current state, and an error message is returned to the command originator.
5. START CMDSERV can be used to restart the command server after it has been stopped, either because of a serious error in handling command messages, or commands using the CMDSCOPE parameter.

START LISTENER (start a channel listener)

Use the MQSC command START LISTENER to start a channel listener.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

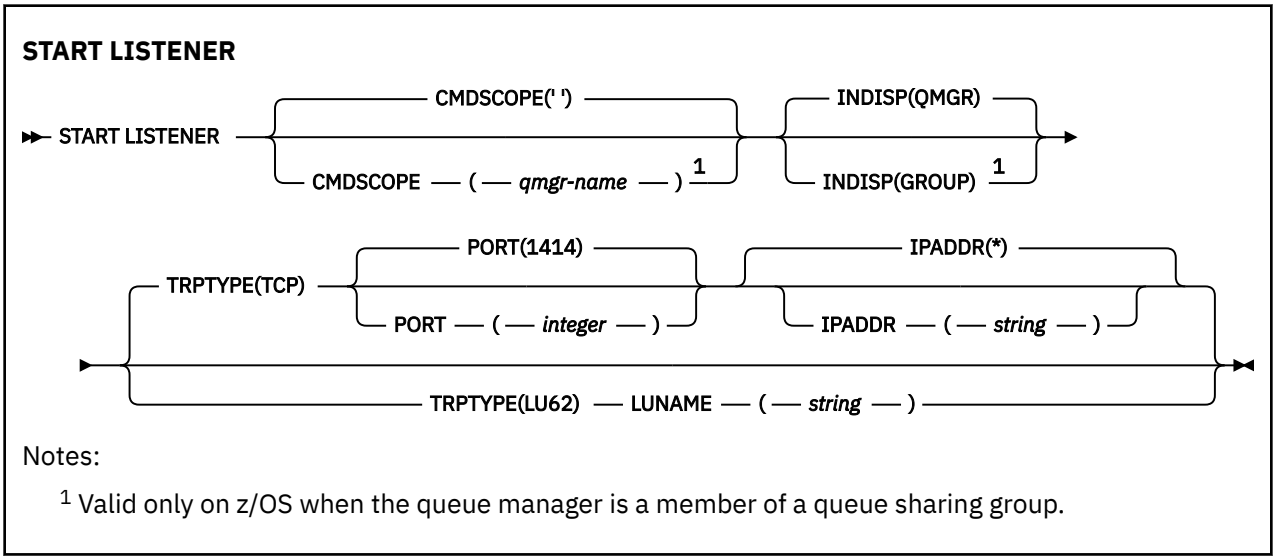
z/OS You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- z/OS Syntax diagram for IBM MQ for z/OS
- Syntax diagram for IBM MQ on other platforms
- “Usage notes” on page 928
- “Parameter descriptions for START LISTENER” on page 928

Synonym: STA LSTR

IBM MQ for z/OS

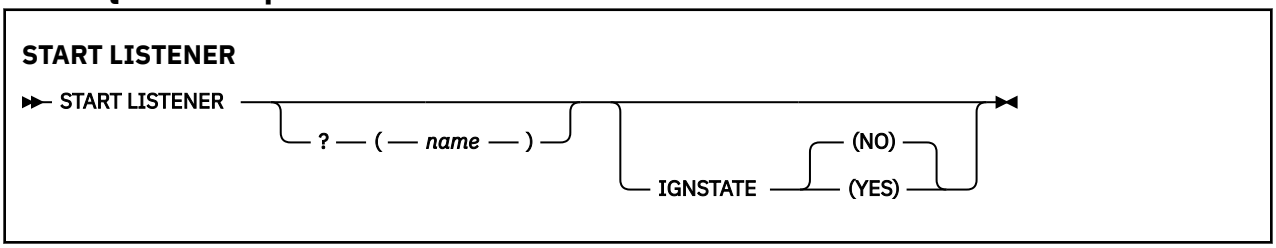
z/OS



Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.

IBM MQ on other platforms



Usage notes

1. z/OS On z/OS:
   a. The command server and the channel initiator must be running.
   b. If IPADDR is not specified, the listener listens on all available IPv4 and IPv6 addresses.
   c. For TCP/IP, it is possible to listen on multiple addresses and port combinations.
   d. For each START LISTENER for TCP/IP request, the address and port combination is added to the list of combinations upon which the listener is currently listening.
   e. A START LISTENER for TCP/IP request fails if it specifies the same, or a subset or superset of an existing, combination of addresses and ports upon which a TCP/IP listener is currently listening.
   f. If you are starting a listener on a specific address to provide a secure interface with a security product, for example a firewall, it is important to ensure there is no linkage to the other non-secure interfaces in the system.

      You should disable IP forwarding and routing from other non-secure interfaces so that packets arriving at the other interface do not get passed to this specific address.

      Consult the appropriate TCP/IP documentation for information on how to do this.
2. On Multiplatforms, this command is valid only for channels for which the transmission protocol (TRPTYPE) is TCP.

Parameter descriptions for START LISTENER

(*name*)
Name of the listener to be started. If you specify this parameter, you cannot specify any other parameters.

If you do not specify a name z/OS (on platforms other than z/OS), the SYSTEM.DEFAULT.LISTENER.TCP is started.

z/OS This parameter is not valid on z/OS.

z/OS **CMDSCOPE**
This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

z/OS **INDISP**

Specifies the disposition of the inbound transmissions that are to be handled. The possible values are:

QMGR
Listen for transmissions directed to the queue manager. This is the default.

GROUP
Listen for transmissions directed to the queue sharing group. This is allowed only if there is a shared queue manager environment.

This parameter is valid only on z/OS.

z/OS **IPADDR**

IP address for TCP/IP specified in IPv4 dotted decimal, IPv6 hexadecimal notation, or alphanumeric form. This is valid only if the transmission protocol (TRPTYPE) is TCP/IP.

This parameter is valid only on z/OS.

z/OS **LUNAME(*string*)**

The symbolic destination name for the logical unit as specified in the APPC side information data set. (This must be the same LU that was specified for the queue manager, using the LUNAME parameter of the ALTER QMGR command.)

This parameter is valid only for channels with a transmission protocol (TRPTYPE) of LU 6.2. A START LISTENER command that specifies TRPTYPE(LU62) must also specify the LUNAME parameter.

This parameter is valid only on z/OS.

z/OS **PORT(*port-number*)**

Port number for TCP. This is valid only if the transmission protocol (TRPTYPE) is TCP.

This parameter is valid only on z/OS.

z/OS **TRPTYPE**

Transport type to be used. This is optional.

TCP
TCP. This is the default if TRPTYPE is not specified.

LU62
SNA LU 6.2.

This parameter is valid only on z/OS.

V 9.2.0 Multi **IGNSTATE**

Specifies whether the command fails if the listener is already running. The possible values are:

NO
The command fails if the listener is already running. This is the default value.

YES
The command succeeds regardless of the current state of the listener.

z/OS START QMGR (start queue manager) on z/OS

Use the MQSC command **START QMGR** to initialize the queue manager. From IBM MQ 9.2.0, you can also use this command to prepare its data for backwards migration using the **BACKMIG** parameter.

Using MQSC commands

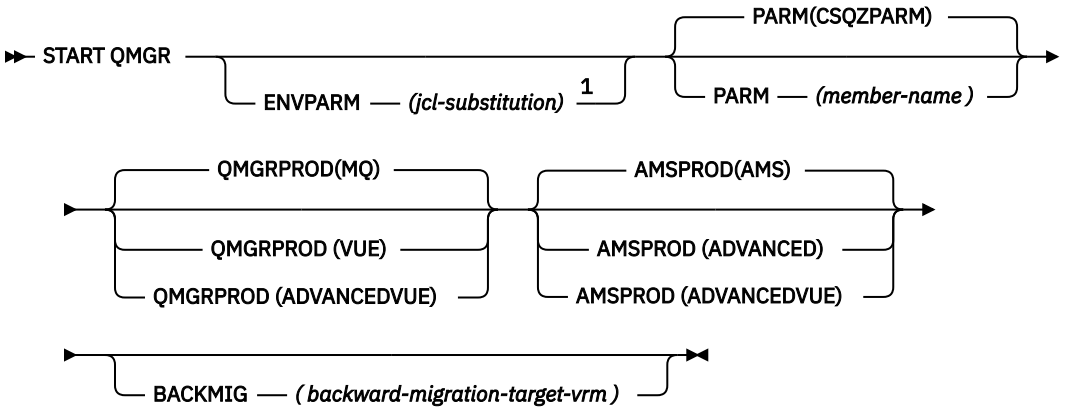
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources C. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Usage notes" on page 930
- "Parameter descriptions for START QMGR" on page 930

Synonym: STA QMGR

START QMGR



Notes:

[1] MSTR is accepted as a synonym for ENVPARM

Usage notes

V 9.2.0 When the command has been completed, the queue manager is active and available to CICS, IMS, batch, and TSO applications, unless you specify the BACKMIG parameter. If you specify the BACKMIG parameter, the queue manager shuts down and is ready for backwards migration, before becoming available to any applications.

V 9.2.0 If you specify the BACKMIG parameter, together with a value for *backward-migration-target-vrm* that is not valid, the queue manager ends abnormally.

The startup parameters **QMGRPROD** and **AMSPROD** indicate against which product that component should have its usage recorded.

You can specify the attribute for the queue manager:

- As a parameter on the START QMGR command
- As a part of the PARM on the EXEC PGM statement in the MSTR JCL procedure
- As part of the compiled queue manager ZPARMS, using the CSQ6USGP macro
- As a default value if not specified elsewhere.

If you specify the attribute by more than one of the above mechanisms, the order of the items in the preceding list defines the order of precedence from highest to lowest. The default value is used if you do not explicitly specify an attribute.

If you specify an attribute that is not valid, an error message is issued and queue manager startup ends.

Parameter descriptions for START QMGR

These are optional.

ENVPARM(*jcl-substitution*)
The parameters and values to be substituted in the JCL procedure (xxxxMSTR, where xxxx is the queue manager name) that is used to start the queue manager address space.

jcl-substitution
One or more character strings of the form:

```
keyword=value
```

enclosed in single quotation marks. If you use more than one character string, separate the strings by commas and enclose the entire list in single quotation marks, for example ENVPARM('HLQ=CSQ,VER=520').

MSTR is accepted as a synonym for ENVPARM

PARM(***member-name*** **)**
The load module that contains the queue manager initialization parameters. *member-name* is the name of a load module provided by the installation.

The default is CSQZPARM, which is provided by IBM MQ.

QMGRPROD
Specifies the product ID against which the queue manager usage is to be recorded. The value can be one of the following:

MQ
The queue manager is a stand-alone IBM MQ for z/OS product, with product ID 5655-MQ9.

LTS Prior to IBM MQ for z/OS 9.1.3, this is the default value if the SCUEAUTH library is not part of the queue manager STEPLIB.

V 9.2.0 From IBM MQ for z/OS 9.1.3 this is the default value.

VUE
The queue manager is a stand-alone VUE product, with product ID 5655-VU9.

LTS Prior to IBM MQ for z/OS 9.1.3, this is the default value if the SCUEAUTH library is part of the queue manager STEPLIB

ADVANCEDVUE
The queue manager is part of an IBM MQ Advanced for z/OS Value Unit Edition product, with product ID 5655-AV1.

AMSPROD
Specifies the product ID against which the queue manager usage is to be recorded. The value can be one of the following:

AMS
Advanced Message Security (AMS) is a stand-alone Advanced Message Security for z/OS product, with product ID 5655-AM9.

LTS This is the default value, unless the attribute for the queue manager indicates IBM MQ Advanced for z/OS Value Unit Edition.

ADVANCED
AMS is part of an IBM MQ Advanced for z/OS product, with product ID 5655-AV9.

ADVANCEDVUE
AMS is part of an IBM MQ Advanced for z/OS Value Unit Edition product, with product ID 5655-AV1. This is the default value, if the attribute for the queue manager is also **ADVANCEDVUE**.

V 9.2.0 **BACKMIG(** ***backward-migration-target-vrm*** **)**
The queue manager is to start up and perform backward migration actions such that it can be restarted at the *backward-migration-target-vrm*, and then the queue manager is to shut down without ever being available to any applications.

backward-migration-target-vrm
The version, release and modification number for the target version for backward migration, for example 910. Backward migration to this release must be allowed.

The release, if any, to which backward migration is allowed, is indicated in the CSQY039I message at queue manager start up. If the CSQY039I message is not emitted, backward migration is not supported to any release.

Attention: Follow the process documented in Reverting a queue manager to a previous version on z/OS when using the BACKMIG parameter.

Multi START SERVICE (start a service) on Multiplatforms

Use the MQSC command **START SERVICE** to start a service. The identified service definition is started within the queue manager and inherits the environment and security variables of the queue manager.

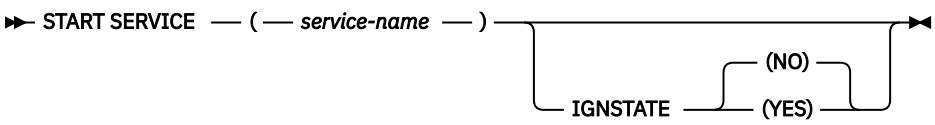
Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

- Syntax diagram
- "Parameter descriptions for START SERVICE" on page 932

Synonym:

STA SERVICE



Parameter descriptions for START SERVICE

(*service-name*)
The name of the service definition to be started. This is required. The name must that of an existing service on this queue manager.

If the service is already running, and the operating system task is active, an error is returned.

V 9.2.0 Multi **IGNSTATE**
Specifies whether the command fails if the service is already running. The possible values are:

NO
The command fails if the service is already running. This is the default value.

YES
The command succeeds regardless of the current state of the service.

z/OS START SMDSCONN (restart a shared message data set connection) on z/OS

Use the MQSC command START SMDSCONN to enable a previously stopped connection from this queue manager to the specified shared message data sets, allowing them to be allocated and opened again.

Using MQSC commands

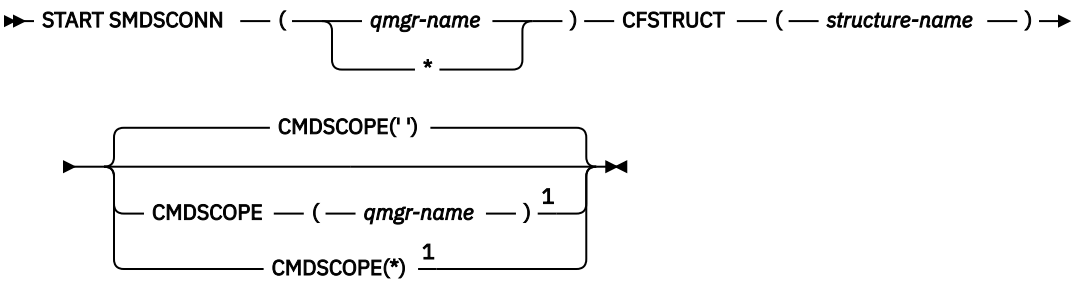
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Parameter descriptions for START SMDSCONN" on page 933

Synonym:

START SMDSCONN



Notes:

1 Valid only when the queue manager is a member of a queue sharing group.

Parameter descriptions for START SMDSCONN

This command is used after connections have been put into the AVAIL(STOPPED) state by a previous STOP SMDSCONN command. It can also be used to signal to the queue manager to retry a connection which is in the AVAIL(ERROR) state after a previous error.

SMDSCONN(*qmgr-name*| *)
Specify the queue manager which owns the shared message data set for which the connection is to be started or an asterisk to start connections to all shared message data sets associated with the specified structure.

CFSTRUCT(*structure-name*)
Specify the structure name for which shared message data set connections are to be started.

CMDSCOPE
This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

z/OS START TRACE (start trace) on z/OS

Use the MQSC command START TRACE to start traces.

Using MQSC commands

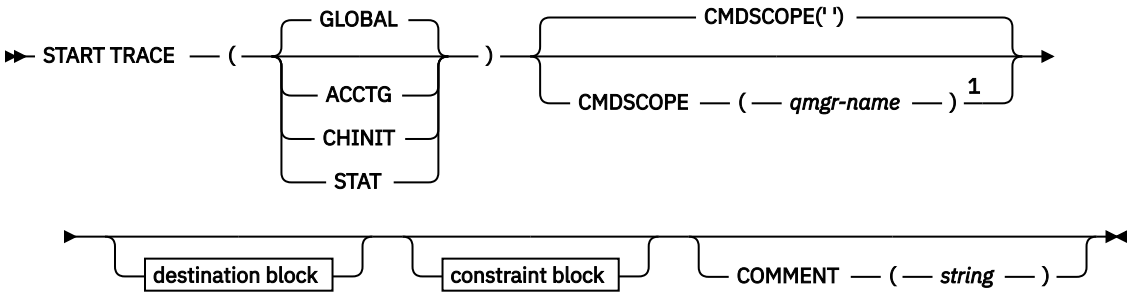
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 12CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

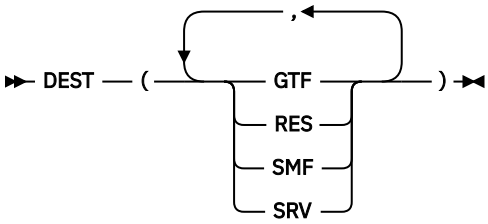
- Syntax diagram
- "Usage notes" on page 935
- "Parameter descriptions for START TRACE" on page 935
- "Destination block" on page 936
- "Constraint block" on page 936

Synonym: STA TRACE

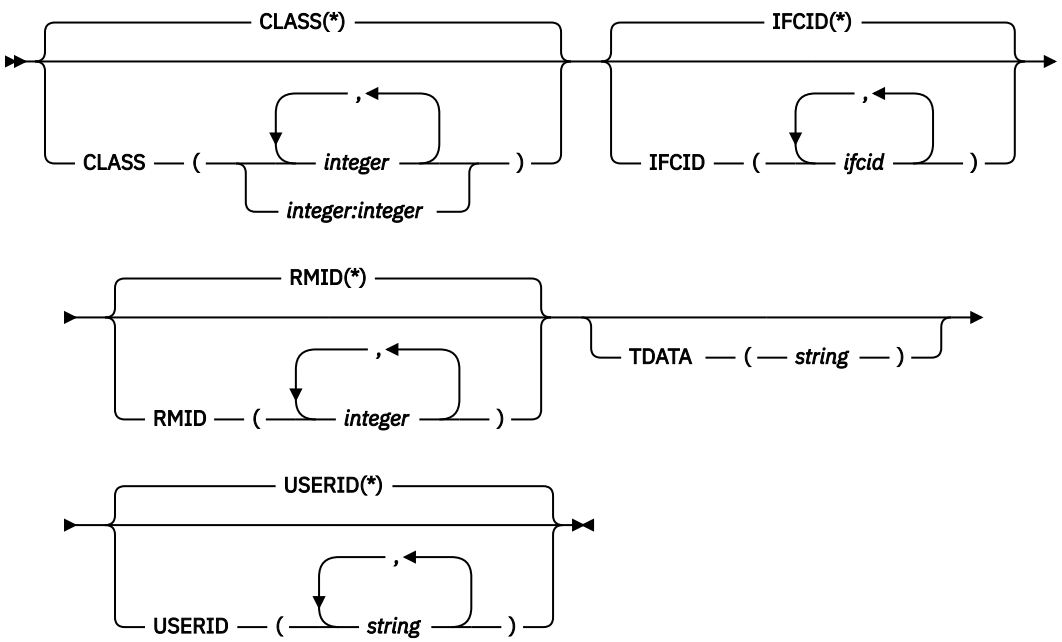
START TRACE



Destination block



Constraint block



Notes:

[1] Valid only when the queue manager is a member of a queue sharing group.

Usage notes

When you issue this command, a trace number is returned in message number CSQW130I. You can use this trace number (TNO) in ALTER TRACE, DISPLAY TRACE, and STOP TRACE commands.

Parameter descriptions for START TRACE

If you do not specify a trace type to be started, the default (GLOBAL) trace is started. The types are:

ACCTG
Enables accounting data which provides information about how applications are interacting with the queue manager in the form of SMF 116 records. The synonym is A.

Note: Accounting data can be lost if the accounting trace is started or stopped while applications are running. For information about the conditions that must be satisfied for successful collection of accounting data, see Using IBM MQ trace.

CHINIT
This includes data from the channel initiator. The synonym is CHI or DQM. If tracing for the channel initiator is started, it stops if the channel initiator stops.

Note that you cannot issue START TRACE(CHINIT) if the command server or the channel initiator is not running.

GLOBAL
This includes data from the entire queue manager except the channel initiator. The synonym is G.

STAT
Enables high level statistics about the state of the queue manager in the form of SMF 115 records. The synonym is S.

CMDSCOPE
This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE cannot be used for commands issued from the first initialization input data set CSQINP1.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

COMMENT(***string*** **)**
Specifies a comment that is reproduced in the trace output record (except in the resident trace tables). It can be used to record why the command was issued.

string is any character string. It must be enclosed in single quotation marks if it includes a blank, comma, or special character.

Destination block

DEST
Specifies where the trace output is to be recorded. More than one value can be specified, but do not use the same value twice.

The meaning of each value is as follows:

GTF
The z/OS Generalized Trace Facility (GTF). If used, the GTF must be started and accepting user (USR) records before the START TRACE command is issued.

RES
A wrap-around table residing in the ECSA, or a data space for CHINIT.

SMF
The System Management Facility (SMF). If used, the SMF must be functioning before the START TRACE command is issued. The SMF record numbers used by IBM MQ are 115 and 116. For SMF record type 115, subtypes 1, 2, and 215 are provided for the performance statistics trace.

SRV
A serviceability routine reserved for IBM use only; not for general use.

Note: If your IBM support center need you to use this destination for your trace data they will supply you with module CSQWVSER. If you try to use destination SRV without CSQWVSER an error message is produced at the z/OS console when you issue the START TRACE command.

Allowed values, and the default value, depend on the type of trace started, as shown in the following table:

Table 177. Destinations allowed for each trace type

Type	GTF	RES	SMF	SRV
GLOBAL	Allowed	Default	No	Allowed
STAT	No	No	Default	Allowed
ACCTG	Allowed	No	Default	Allowed
CHINIT	No	Default	No	Allowed

Constraint block

The constraint block places optional constraints on the kinds of data collected by the trace. The allowed constraints depend on the type of trace started, as shown in the following table:

Table 178. Constraints allowed for each trace type				
Type	**CLASS**	**IFCID**	**RMID**	**USERID**
GLOBAL	Allowed	Allowed	Allowed	Allowed
STAT	Allowed	No	No	No
ACCTG	Allowed	No	No	No
CHINIT	Allowed	Allowed	No	No

CLASS

Introduces a list of classes of data gathered. The classes allowed, and their meaning, depend on the type of trace started:

(*)

For GLOBAL and CHINIT traces, starts traces for all classes of data.

For ACCTG and STAT traces, starts traces for classes 1 to 3. Channel initiator statistics and channel accounting data are not started with CLASS(*), and must be started with CLASS(4).

Attention: You can specify a comma-separated list of classes, for example TRACE(ACCTG) CLASS(01,03,04); there is no CLASS2. To stop these classes you have started, you must specify CLASS(01,03,04) on the STOP command. That is, you must specify the full range of classes that are active on the STOP command before you can restart the classes you require.

(*integer*)

Any number in the class column of the table that follows. You can use more than one of the classes that are allowed for the type of trace started. A range of classes can be specified as *m:n* (for example, CLASS(01:03)). If you do not specify a class, the default is to start class 1, except when you are using the **START TRACE(STAT)** command with no class where the default is to start class 1 and 2.

Table 179. Descriptions of trace events and classes	
Class	**Description**
	Global trace
01	Reserved for IBM service
02	User parameter error detected in a control block
03	User parameter error detected on entry to MQI
	User parameter error detected on exit from MQI
	User parameter error detected in a control block
04	Reserved for IBM service
	Statistics trace
01	Subsystem statistics
	Queue manager statistics
02	Queue manager storage summary statistics. Class 1 statistics must also be enabled to collect this class of data.
03	Queue manager storage detail summary. Class 1 statistics must also be enabled to collect this class of data.

Table 179. Descriptions of trace events and classes (continued)	
Class	**Description**
04	Channel initiator statistics
	Accounting trace
01	The processor time spent processing MQI calls and a count of MQPUT, MQPUT1 and MQGET calls
03	Enhanced accounting and statistical data
04	Channel accounting data
	CHINIT trace
01	Reserved for IBM service
04	Reserved for IBM service

IFCID
Reserved for IBM service.

RMID
Introduces a list of specific resource managers for which trace information is gathered. You cannot use this option for STAT, ACCTG, or CHINIT traces.

(*)
Starts a trace for all resource managers.

This is the default.

(*integer*)
The identifying number of any resource manager in the following table. You can use up to 8 of the allowed resource manager identifiers; do not use the same one twice.

Table 180. Resource Manager identifiers that are allowed	
RMID	**Resource manager**
1	Initialization procedures
2	Agent services management
3	Recovery management
4	Recovery log management
6	Storage management
7	Subsystem support for allied memories
8	Subsystem support for subsystem interface (SSI) functions
12	System parameter management
16	Instrumentation commands, trace, and dump services
23	General command processing
24	Message generator
26	Instrumentation accounting and statistics
148	Connection manager
163	Topic Manager
197	CF manager

Table 180. Resource Manager identifiers that are allowed (continued)	
RMID	**Resource manager**
199	Functional recovery
200	Security management
201	Data management
211	Lock management
212	Message management
213	Command server
215	Buffer management
242	IBM MQ IMS - bridge
245	Db2 manager

TDATA
Reserved for IBM service.

USERID
Introduces a list of specific user IDs for which trace information is gathered. You cannot use this option for STAT, ACCTG, or CHINIT traces.

(*)
Starts a trace for all user IDs. This is the default.

(*userid*)
Names a user ID. You can use up to 8 user IDs; a separate trace is started for each. The user ID is the primary authorization ID of the task, used by IBM MQ inside the queue manager. This is the userid displayed by the MQSC command DISPLAY CONN.

Related tasks
Tracing on z/OS

STOP CHANNEL (stop a channel)

Use the MQSC command **STOP CHANNEL** to stop a channel.

Using MQSC commands

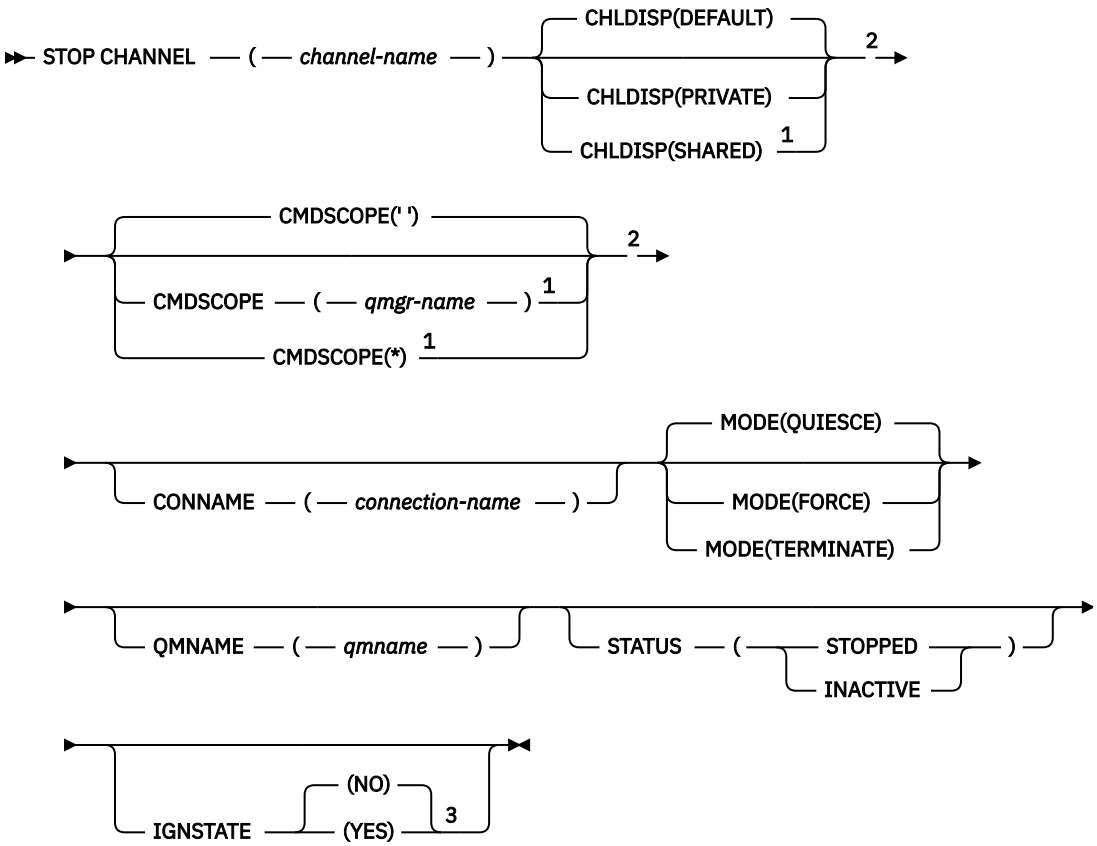
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- “Usage notes for STOP CHANNEL” on page 940
- “Parameter descriptions for STOP CHANNEL” on page 940

Synonym: STOP CHL

STOP CHANNEL



Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.
[2] Valid only on z/OS.
[3] Not valid on z/OS

Usage notes for STOP CHANNEL

1. If you specify either **QMNAME** or **CONNAME**, **STATUS** must either be INACTIVE or not specified. Do not specify a **QMNAME** or **CONNAME** and **STATUS(STOPPED)**. It is not possible to have a channel stopped for one partner but not for others. This sort of function can be provided by a channel security exit. For more information about channel exits, see Channel exit programs.
2. z/OS On z/OS, the command server and the channel initiator must be running.
3. Any channels in STOPPED state need to be started manually; they are not started automatically. See Restarting stopped channels for information about restarting stopped channels.
4. This command can be issued to a channel of any type except CLNTCONN channels (including those that have been defined automatically).
5. Where there is both a locally defined channel and an auto-defined cluster-sender channel of the same name, the command applies to the locally defined channel. If there is no locally defined channel but more than one auto-defined cluster-sender channel, the command applies to the channel that was last added to the local queue manager repository.

Parameter descriptions for STOP CHANNEL

(channel-name)
The name of the channel to be stopped. This parameter is required for all channel types.

z/OS **CHLDISP**

This parameter applies to z/OS only and can take the values of:

- DEFAULT
- PRIVATE
- SHARED

If this parameter is omitted, then the DEFAULT value applies. This is taken from the default channel disposition attribute, **DEFCDISP**, of the channel object.

In conjunction with the various values of the **CMDSCOPE** parameter, this parameter controls two types of channel:

SHARED
A receiving channel is shared if it was started in response to an inbound transmission directed to the queue sharing group.

A sending channel is shared if its transmission queue has a disposition of SHARED.

PRIVATE
A receiving channel is private if it was started in response to an inbound transmission directed to the queue manager.

A sending channel is private if its transmission queue has a disposition other than SHARED.

Note: This disposition is not related to the disposition set by the disposition of the queue sharing group of the channel definition.

The combination of the **CHLDISP** and **CMDSCOPE** parameters also controls from which queue manager the channel is operated. The possible options are:

- On the local queue manager where the command is issued.
- On another specific named queue manager in the group.
- On every active queue manager in the group.
- On the most suitable queue manager in the group, determined automatically by the queue manager itself.

The various combinations of **CHLDISP** and **CMDSCOPE** are summarized in the following table:

Table 181. CHLDISP and CMDSCOPE for STOP CHANNEL

CHLDISP	CMDSCOPE( ) or CMDSCOPE (local-qmgr)	CMDSCOPE (qmgr-name)	CMDSCOPE(*)
PRIVATE	Stop as a private channel on the local queue manager.	Stop as a private channel on the named queue manager	Stop as a private channel on all active queue managers

Table 181. CHLDISP and CMDSCOPE for STOP CHANNEL (continued)

CHLDISP	CMDSCOPE( ) or CMDSCOPE (local-qmgr)	CMDSCOPE (qmgr-name)	CMDSCOPE(*)
SHARED	For RCVR and SVRCONN channels, stop as shared channel on all active queue managers. For SDR, RQSTR, and SVR channels, stop as a shared channel on the queue manager where it is running. If the channel is in an inactive state (not running), or if it is in RETRY state because the channel initiator on which it was running has stopped, a STOP request for the channel is issued on the local queue manager. This might automatically generate a command using **CMDSCOPE** and send it to the appropriate queue manager. If there is no definition for the channel on the queue manager to which the command is sent, or if the definition is unsuitable for the command, the command fails. The definition of a channel on the queue manager where the command is entered might be used to determine the target queue manager where the command is actually run. Therefore, it is important that channel definitions are consistent. Inconsistent channel definitions might result in unexpected command behavior.	Not permitted	Not permitted

z/OS **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

If **CHLDISP** is set to SHARED, **CMDSCOPE** must be blank or the local queue manager.

' '

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name only if you are using a queue sharing group environment and if the command server is enabled.

*****

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

CONNAME ***(connection-name)***

Connection name. Only channels matching the specified connection name are stopped.

When issuing the **STOP CHANNEL** command using a **CONNAME** parameter, ensure that the value specified in the **CONNAME** parameter is exactly as shown in "DISPLAY CHSTATUS (display channel status)" on page 667.

MODE
Specifies whether the current batch is allowed to finish in a controlled manner. This parameter is optional.

QUIESCE
This is the default.

On Multiplatforms, allows the current batch to finish processing.

On z/OS, the channel stops after the current message has finished processing. (The batch is then ended and no more messages are sent, even if there are messages waiting on the transmission queue.)

For a receiving channel, if there is no batch in progress, the channel waits for either of the following to take place before it stops:

- The next batch to start
- The next heartbeat (if heartbeats are being used)

For server-connection channels, allows the current connection to end.

If you issue a `STOP CHANNEL` *`channelname`* `MODE (QUIESCE)` command on a server-connection channel, the IBM MQ client infrastructure becomes aware of the stop request in a timely manner. This time is dependent upon the speed of the network.

If a client application is using the server-connection channel and is performing either of the following operations at the time that the command is issued, then the MQPUT or MQGET operation fails:

- An MQPUT operation with the PMO option MQPMO_FAIL_IF_QUIESCING set.
- An MQGET operation with the GMO option MQGMO_FAIL_IF_QUIESCING set.

The client application receives reason code MQRC_CONNECTION_QUIESCING.

If a client application is using the server-connection channel and is performing either of the following operations, then the client application is allowed to complete the MQPUT or MQGET operation:

- An MQPUT operation without the PMO option MQPMO_FAIL_IF_QUIESCING set.
- An MQGET operation without the GMO option MQGMO_FAIL_IF_QUIESCING set.

Any subsequent FAIL_IF_QUIESCING calls using this connection fail with MQRC_CONNECTION_QUIESCING. Calls which do not specify FAIL_IF_QUIESCING, are usually permitted to complete, although the application should complete such operations in a timely manner, to permit the channel to end.

If the client application is not performing an MQ API call when the server-connection channel is stopped, it becomes aware of the stop request as a result of issuing a subsequent call to IBM MQ and receives return code MQRC_CONNECTION_QUIESCING.

After sending the MQRC_CONNECTION_QUIESCING return code to the client, and allowing any outstanding MQPUT or MQGET operations to complete if necessary, the server ends the client connections for the server-connection channel.

Due to the imprecise timing of network operations, the client application should not attempt further MQ API operations.

FORCE
For server-connection channels, breaks the current connection, returning MQRC_CONNECTION_QUIESCING or MQRC_CONNECTION_BROKEN. For other channel types, terminates transmission of any current batch. This is likely to result in in-doubt situations.

z/OS On IBM MQ for z/OS, specifying **FORCE** interrupts any message reallocation in progress, which might leave BIND_NOT_FIXED messages partially reallocated or out of order.

TERMINATE

z/OS On z/OS, **TERMINATE** is synonymous with **FORCE**.

Multi On other platforms, **TERMINATE** terminates transmission of any current batch.

This allows the command to actually terminate the channel thread or process.

For server-connection channels, **TERMINATE** breaks the current connection, returning MQRC_CONNECTION_QUIESCING or MQRC_CONNECTION_BROKEN. Using **TERMINATE** can cause unpredictable results to occur.

z/OS On z/OS, specifying **TERMINATE** interrupts any message reallocation in progress, which might leave BIND_NOT_FIXED messages partially reallocated or out of order.

QMNAME ***(qmname)***

Queue manager name. Only channels matching the specified remote queue manager are stopped.

STATUS

Specifies the new state of any channels stopped by this command. For more information about channels in STOPPED state, especially SVRCONN channels on z/OS, see Restarting stopped channels.

STOPPED

The channel is stopped. For a sender or server channel the transmission queue is set to **GET(DISABLED)** and NOTRIGGER.

This is the default if **QMNAME** or **CONNAME** are not specified.

INACTIVE

The channel is inactive.

This is the default if **QMNAME** or **CONNAME** are specified.

V 9.2.0 Multi **IGNSTATE**

Specifies whether the command fails if the channel is already stopped. The possible values are:

NO

The command fails if the channel is already stopped. This is the default value.

YES

The command succeeds regardless of the current state of the channel.

Windows Linux AIX STOP CHANNEL (stop a channel) MQTT

Use the MQSC command STOP CHANNEL to stop an MQ Telemetry channel.

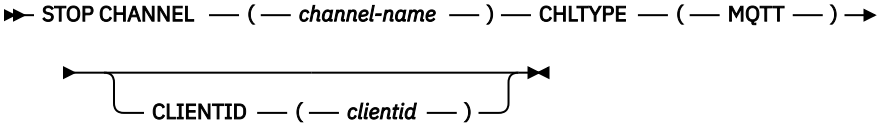
Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

The STOP CHANNEL (MQTT) command is only valid for MQ Telemetry channels.

Synonym: STOP CHL

STOP CHANNEL



Usage notes for STOP CHANNEL

1. Any channels in STOPPED state need to be started manually; they are not started automatically.

Parameter descriptions for STOP CHANNEL

(channel-name)
The name of the channel to be stopped. This parameter is required for all channel types including MQTT channels.

CHLTYPE
Channel type. Tthe value must be MQTT.

CLIENTID *(string)*
Client identifier. The client identifier is a 23-byte string that identifies an MQ Telemetry Transport client. When the STOP CHANNEL command specifies a CLIENTID, only the connection for the specified client identifier is stopped. If the CLIENTID is not specified, all the connections on the channel are stopped.

z/OS STOP CHINIT (stop channel initiator) on z/OS

Use the MQSC command STOP CHINIT to stop a channel initiator. The command server must be running.

Using MQSC commands

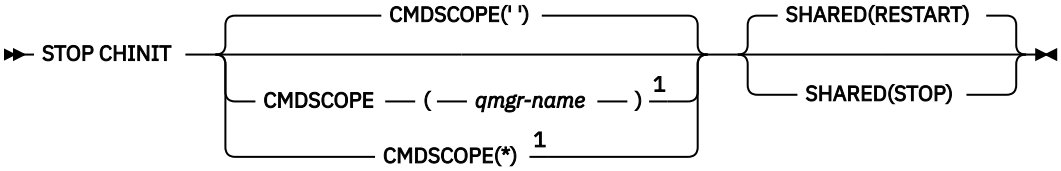
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Usage notes for STOP CHINIT" on page 945
- "Parameter descriptions for STOP CHINIT" on page 946

Synonym: STOP CHI

STOP CHINIT



Notes:

[1] Valid only when the queue manager is a member of a queue sharing group.

Usage notes for STOP CHINIT

1. When you issue the STOP CHINIT command, IBM MQ stops any channels that are running in the following way:
   - Sender and server channels are stopped using STOP CHANNEL MODE(QUIESCE) STATUS(INACTIVE)
   - All other channels are stopped using STOP CHANNEL MODE(FORCE)

   See "STOP CHANNEL (stop a channel)" on page 939 for information about what this involves.
2. You might receive communications-error messages as a result of issuing the STOP CHINIT command.

Parameter descriptions for STOP CHINIT

CMDSCOPE
This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

SHARED
Specifies whether the channel initiator should attempt to restart any active sending channels, started with CHLDISP(SHARED), that it owns on another queue manager. The possible values are:

RESTART
Shared sending channels are to be restarted. This is the default.

STOP
Shared sending channels are not to be restarted, so will become inactive.

(Active channels started with CHLDISP(FIXSHARED) are not restarted, and always become inactive.)

z/OS STOP CMDSERV (stop the command server) on z/OS

Use the MQSC command STOP CMDSERV to stop the command server.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 12C. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Usage notes for STOP CMDSERV" on page 946

Synonym: STOP CS

STOP CMDSERV

Usage notes for STOP CMDSERV

1. STOP CMDSERV stops the command server from processing commands in the system-command input queue (SYSTEM.COMMAND.INPUT), mover commands, and commands using CMDSCOPE.
2. If this command is issued through the initialization files or through the operator console before work is released to the queue manager (that is, before the command server is started automatically), it prevents the command server from starting automatically and puts it into a DISABLED state. It overrides an earlier START CMDSERV command.

3. If this command is issued through the operator console or the command server while the command server is in a RUNNING state, it stops the command server when it has finished processing its current command. When this happens, the command server enters the STOPPED state.
4. If this command is issued through the operator console while the command server is in a WAITING state, it stops the command server immediately. When this happens, the command server enters the STOPPED state.
5. If this command is issued while the command server is in a DISABLED or STOPPED state, no action is taken, the command server remains in its current state, and an error message is returned to the command originator.

Multi STOP CONN (stop a connection) on Multiplatforms

Use the MQSC command STOP CONN to break a connection between an application and the queue manager.

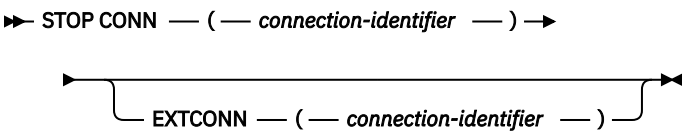
Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

- Syntax diagram
- "Usage notes" on page 947
- "Parameter descriptions for STOP CONN" on page 947

Synonym: STOP CONN

STOP CONN



Usage notes

There might be circumstances in which the queue manager cannot implement this command when the success of this command cannot be guaranteed.

Parameter descriptions for STOP CONN

(*connection-identifier*)
The identifier of the connection definition for the connection to be broken.

When an application connects to IBM MQ, it is given a unique 24-byte connection identifier (ConnectionId). The value of CONN is formed by converting the last eight bytes of the ConnectionId to its 16-character hexadecimal equivalent.

EXTCONN
The value of EXTCONN is based on the first sixteen bytes of the ConnectionId converted to its 32-character hexadecimal equivalent.

Connections are identified by a 24-byte connection identifier. The connection identifier comprises a prefix, which identifies the queue manager, and a suffix which identifies the connection to that queue manager. By default, the prefix is for the queue manager currently being administered, but you can specify a prefix explicitly by using the EXTCONN parameter. Use the CONN parameter to specify the suffix.

When connection identifiers are obtained from other sources, specify the fully qualified connection identifier (both EXTCONN and CONN) to avoid possible problems related to non-unique CONN values.

Related reference

"DISPLAY CONN (display application connection information)" on page 707

Use the MQSC command **DISPLAY CONN** to display connection information about the applications connected to the queue manager. This is a useful command because it enables you to identify applications with long-running units of work.

STOP LISTENER (stop a channel listener)

Use the MQSC command STOP LISTENER to stop a channel listener.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

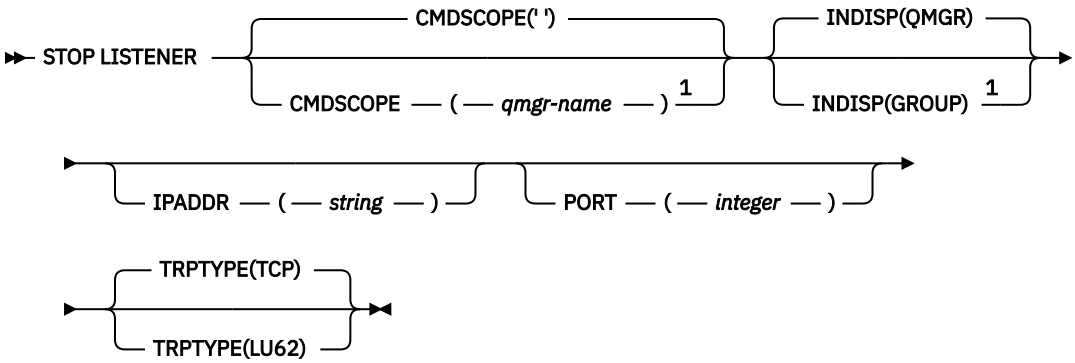
- z/OS Syntax diagram for IBM MQ for z/OS
- Syntax diagram for IBM MQ on other platforms
- z/OS "Usage notes" on page 949
- "Parameter descriptions for STOP LISTENER" on page 949

Synonym: STOP LSTR

z/OS

z/OS

STOP LISTENER

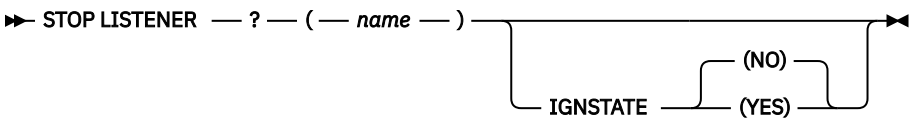


Notes:

1 Valid only on z/OS when the queue manager is a member of a queue sharing group.

Other platforms

STOP LISTENER



Usage notes

The listener stops in quiesce mode (it disregards any further requests).

z/OS On z/OS:

- The command server and the channel initiator must be running.
- If a listener is listening on multiple addresses or ports, only the address and port combinations with the address, or port, specified are stopped.
- If a listener is listening on all addresses for a particular port, a stop request for a specific IPADDR with the same port fails.
- If neither an address nor a port is specified, all addresses and ports are stopped and the listener task ends.

Parameter descriptions for STOP LISTENER

(*name*)
Name of the listener to be stopped. If you specify this parameter, you cannot specify any other parameters.

This parameter is required on all platforms z/OS other than z/OS where it is not a supported parameter.

z/OS **CMDSCOPE**
This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

This parameter is valid only on z/OS.

z/OS **INDISP**
Specifies the disposition of the inbound transmissions that the listener handles. The possible values are:

QMGR
Handling for transmissions directed to the queue manager. This is the default.

GROUP
Handling for transmissions directed to the queue sharing group. This is allowed only if there is a shared queue manager environment.

This parameter is valid only on z/OS.

z/OS **IPADDR**
IP address for TCP/IP specified in IPv4 dotted decimal, IPv6 hexadecimal notation, or alphanumeric form. This is valid only if the transmission protocol (TRPTYPE) is TCP/IP.

This parameter is valid only on z/OS.

z/OS **PORT**
The port number for TCP/IP. This is the port number on which the listener is to stop listening. This is valid only if the transmission protocol is TCP/IP.

This parameter is valid only on z/OS.

z/OS **TRPTYPE**

Transmission protocol used. This is optional.

TCP
TCP. This is the default if TRPTYPE is not specified.

LU62
SNA LU 6.2.

This parameter is valid only on z/OS.

V 9.2.0 Multi **IGNSTATE**

Specifies whether the command fails if the listener is already stopped. The possible values are:

NO
The command fails if the listener is already stopped. This is the default value.

YES
The command succeeds regardless of the current state of the listener.

z/OS STOP QMGR (stop queue manager) on z/OS

Use the MQSC command STOP QMGR to stop the queue manager.

Using MQSC commands

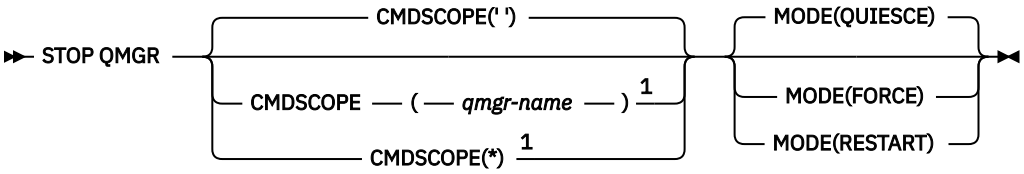
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- Syntax diagram
- "Parameter descriptions for STOP QMGR" on page 950

Synonym: There is no synonym for this command.

STOP QMGR



Notes:

[1] Valid only when the queue manager is a member of a queue sharing group.

Parameter descriptions for STOP QMGR

The parameters are optional.

CMDSCOPE
This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

MODE
Specifies whether programs currently being executed are allowed to finish.

QUIESCE
Allows programs currently being executed to finish processing. No new program is allowed to start. This is the default.

This option means that all connections to other address spaces must terminate before the queue manager stops. The system operator can determine whether any connections remain by using the DISPLAY CONN command, and can cancel remaining connections using z/OS commands.

This option deregisters IBM MQ from the z/OS automatic restart manager (ARM).

FORCE
Terminates programs currently being executed, including utilities. No new program is allowed to start. This option might cause in-doubt situations.

This option might not work if all the active logs are full, and log archiving has not occurred. In this situation you must issue the z/OS command CANCEL to terminate.

This option deregisters IBM MQ from the z/OS automatic restart manager (ARM).

RESTART
Terminates programs currently being executed, including utilities. No new program is allowed to start. This option might cause in-doubt situations.

This option might not work if all the active logs are full, and log archiving has not occurred. In this situation you must issue the z/OS command CANCEL to terminate.

This option does not deregister IBM MQ from ARM, so the queue manager is eligible for immediate automatic restart.

Multi STOP SERVICE (stop a service) on Multiplatforms

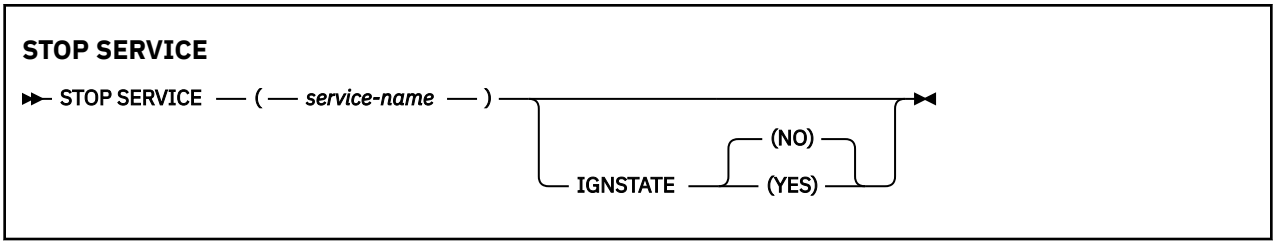
Use the MQSC command **STOP SERVICE** to stop a service.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

- Syntax diagram
- “Usage notes” on page 952
- “Parameter descriptions for STOP SERVICE” on page 952

Synonym:



Usage notes

If the service is running, it is requested to stop. This command is processed asynchronously so might return before the service has stopped.

If the service that is requested to stop has no STOP command defined, an error is returned.

Parameter descriptions for STOP SERVICE

(*service-name*)
The name of the service definition to be stopped. This is required. The name must that of an existing service on this queue manager.

V 9.2.0 **IGNSTATE**
Specifies whether the command fails if the service is already stopped. The possible values are:

NO
The command fails if the service is already stopped. This is the default value.

YES
The command succeeds regardless of the current state of the service.

Related concepts
Working with services
Related tasks
Managing services
Related reference
"ALTER SERVICE (alter a service definition) on Multiplatforms" on page 398
Use the MQSC command **ALTER SERVICE** to alter the parameters of an existing IBM MQ service definition.

"START SERVICE (start a service) on Multiplatforms" on page 932
Use the MQSC command **START SERVICE** to start a service. The identified service definition is started within the queue manager and inherits the environment and security variables of the queue manager.

Examples of using service objects

z/OS STOP SMDSCONN (stop shared message data sets connection) on z/OS

Use the MQSC command STOP SMDSCONN to terminate the connection from this queue manager to one or more specified shared message data sets (causing them to be closed and deallocated) and to mark the connection as STOPPED.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

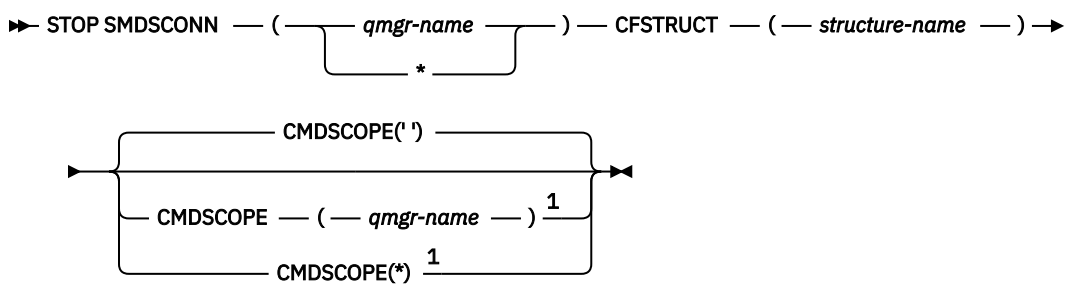
You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

- "Syntax diagram for STOP SMDSCONN" on page 953

- “Parameter descriptions for STOP SMDSCONN” on page 953

Syntax diagram for STOP SMDSCONN

Synonym:



Notes:

[1] Valid only when the queue manager is a member of a queue sharing group.

Parameter descriptions for STOP SMDSCONN

SMDSCONN
Specify the queue manager which owns the shared message data set for which the connection is to be stopped, or an asterisk to stop connections to all shared message data sets associated with the specified structure.

CFSTRUCT
Specify the structure name for which shared message data set connections are to be stopped.

CMDSCOPE
This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*****
The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

z/OS STOP TRACE (stop trace) on z/OS

Use the MQSC command STOP TRACE to stop tracing.

Using MQSC commands

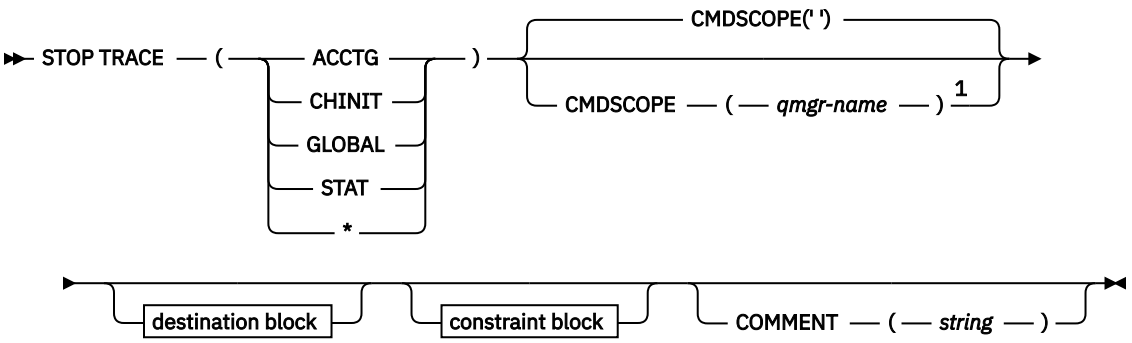
For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

You can issue this command from sources 12CR. For an explanation of the source symbols, see Sources from which you can issue MQSC commands on z/OS.

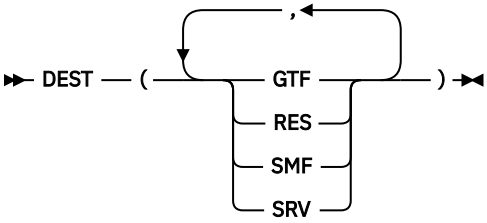
- Syntax diagram
- “Parameter descriptions for STOP TRACE” on page 954
- “Destination block” on page 955
- “Constraint block” on page 956

Synonym: There is no synonym for this command.

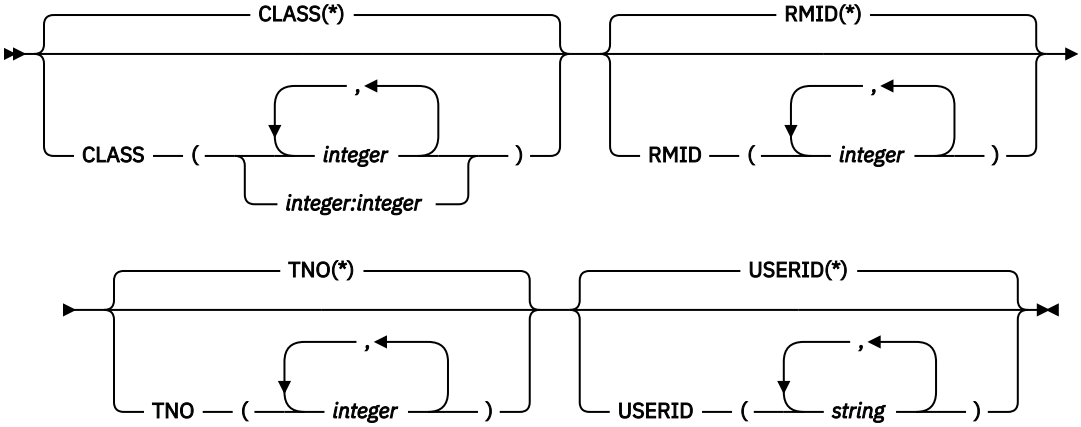
STOP TRACE



Destination block



Constraint block



Notes:

[1] Valid only on z/OS when the queue manager is a member of a queue sharing group.

Parameter descriptions for STOP TRACE

Each option that you use limits the effect of the command to active traces that were started using the same option, either explicitly or by default, with exactly the same parameter values.

You must specify a trace type or an asterisk. STOP TRACE(*) stops all active traces.

The trace types are:

ACCTG
Accounting data (the synonym is A)

Note: Accounting data can be lost if the accounting trace is started or stopped while applications are running. For information about the conditions that must be satisfied for successful collection of accounting data, see Using IBM MQ trace.

CHINIT
Service data from the channel initiator. The synonym is CHI or DQM.

If the only trace running on the CHINIT is the one started automatically when the CHINIT was started, that tracing can be stopped only by explicitly stating the TNO for the default CHINIT trace (0). For example: `STOP TRACE(CHINIT) TNO(0)`

GLOBAL
Service data from the entire queue manager except for the channel initiator. The synonym is G.

STAT
Statistical data (the synonym is S)

*****
All active traces

CMDSCOPE
This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE cannot be used for commands issued from the first initialization input data set CSQINP1.

' '
The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name
The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

COMMENT(*string*)
Specifies a comment that is reproduced in the trace output record (except in the resident trace tables), and can be used to record why the command was issued.

string is any character string. It must be enclosed in single quotation marks if it includes a blank, comma, or special character.

Destination block

DEST
Limits the action to traces started for particular destinations. More than one value can be specified, but do not use the same value twice. If no value is specified, the list is not limited.

Possible values and their meanings are:

GTF
The Generalized Trace Facility

RES
A wrap-around table residing in the ECSA

SMF
The System Management Facility

SRV
A serviceability routine designed for problem diagnosis

Constraint block

CLASS(*integer*)
Limits the command to traces started for particular classes. See the START TRACE command for a list of allowed classes. A range of classes can be specified as *m:n* (for example, CLASS(01:03)). You cannot specify a class if you did not specify a trace type.

The default is CLASS(*), which does not limit the command.

Attention: You can specify a comma-separated list of classes, for example TRACE(ACCTG) CLASS(01,03,04); there is no CLASS2. To stop these classes you have started, you must specify CLASS(01,03,04) on the STOP command. That is, you must specify the full range of classes that are active on the STOP command before you can restart the classes you require.

RMID(*integer*)
Limits the command to traces started for particular resource managers. See the START TRACE command for a list of allowed resource manager identifiers.

Do not use this option with the STAT, ACCTG, or CHINIT trace type.

The default is RMID(*), which does not limit the command.

TNO(*integer*)
Limits the command to particular traces, identified by their trace number (0 to 32). Up to 8 trace numbers can be used. If more than one number is used, only one value for USERID can be used.

0 is the trace that the channel initiator can start automatically. Traces 1 to 32 are those for queue manager or the channel initiator that can be started automatically by the queue manager, or manually, using the START TRACE command.

The default is TNO(*), which applies the command to all active traces with numbers 1 to 32, but **not** to the 0 trace. You can stop trace number 0 only be specifying it explicitly.

USERID(*string*)
Limits the action of the STOP TRACE to traces started for particular user ID. Up to 8 user IDs can be used. If more than one user ID is used, only one value can be used for TNO. Do not use this option with the STAT, ACCTG, or CHINIT trace type.

The default is USERID(*), which does not limit the command.

SUSPEND QMGR (suspend a cluster queue manager)

Use the MQSC command SUSPEND QMGR to advise other queue managers in a cluster to avoid sending messages to the local queue manager if possible.

Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

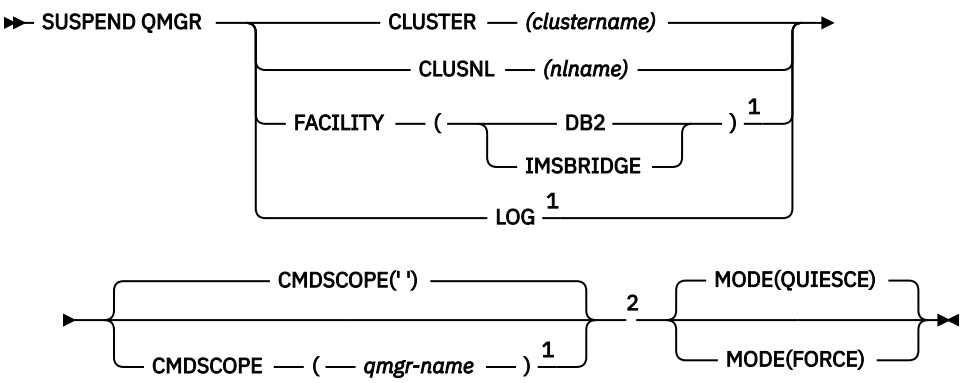
For further details about using the SUSPEND QMGR and RESUME QMGR commands to remove a queue manager from a cluster temporarily, see SUSPEND QMGR, RESUME QMGR and clusters.

z/OS On z/OS this command can also be used to suspend logging and update activity for the queue manager until a subsequent RESUME QMGR command is issued. Its action can be reversed by the RESUME QMGR command. This command does not mean that the queue manager is disabled.

- Syntax diagram
- z/OS See “Using SUSPEND QMGR on z/OS” on page 957
- z/OS “Usage notes” on page 957
- “Parameter descriptions for SUSPEND QMGR” on page 957

Synonym: None

SUSPEND QMGR



Notes:

[1] Valid only on z/OS.
[2] Valid only on IBM MQ for z/OS when the queue manager is a member of a queue sharing group.

Using SUSPEND QMGR on z/OS

z/OS

SUSPEND QMGR can be used on z/OS. Depending on the parameters used on the command, it may be issued from various sources. For an explanation of the symbols in this table, see Sources from which you can issue MQSC commands on z/OS.

Table 182. SUSPEND QMGR command and command sources

Command	Command Sources	Notes
SUSPEND QMGR CLUSTER/CLUSNL	CR	Ensure the channel initiator is running
SUSPEND QMGR FACILITY	CR	
SUSPEND QMGR LOG	C	

Usage notes

z/OS On z/OS:

- If you define CLUSTER or CLUSNL, be aware of the following behavior:
  - The command fails if the channel initiator has not been started.
  - Any errors are reported to the system console where the channel initiator is running; they are not reported to the system that issued the command.
- The SUSPEND QMGR and RESUME QMGR commands are supported through the console only. However, all the other SUSPEND and RESUME commands are supported through the console and command server.

Parameter descriptions for SUSPEND QMGR

The SUSPEND QMGR with the CLUSTER or CLUSNL parameters to specify the cluster or clusters for which availability is suspended, how the suspension takes effect .

z/OS On z/OS, controls logging and update activity and how the command runs when the queue manager is a member of a queue sharing group.

You can use the SUSPEND QMGR FACILITY(Db2) command to terminate the queue manager connection to Db2. This command might be useful if you want to apply service to Db2. Be aware, if you use this option then there is no access to Db2 resources, for example, large messages which might be offloaded to Db2 from a coupling facility.

z/OS You can use the **SUSPEND QMGR FACILITY(IMSBRIDGE)** command to stop sending messages from the IBM MQ IMS bridge to IMS OTMA. z/OS See Controlling the IMS bridge for more information about controlling message delivery to shared and non-shared queues.

CLUSTER ***(clustername)***
The name of the cluster for which availability is to be suspended.

CLUSNL ***(nlname)***
The name of the namelist that specifies a list of clusters for which availability is to be suspended.

z/OS **FACILITY**
Specifies the facility to which connection is to be terminated. The parameter must have one of the following values:

Db2
Causes the existing connection to Db2 to be terminated. The connection is re-established when the **RESUME QMGR** command is issued. When the Db2 connection is SUSPENDED, any API requests which must access Db2 to complete will be suspended until the RESUME QMGR FACILITY(Db2) command is issued. API requests include:

- The first MQOPEN of a shared queue since the queue manager started
- MQPUT, MQPUT1 and MQGET to or from a shared queue where the message payload has been offloaded to Db2

z/OS **IMSBRIDGE**
Stops the sending of messages from IMS bridge queues to OTMA. The IMS connection is not affected. When the tasks that transmit messages to IMS have been terminated, no further messages are sent to IMS until one of the following actions happens:

- OTMA or IMS is stopped and restarted
- IBM MQ is stopped and restarted
- A **RESUME QMGR** command is processed

Return messages from IMS OTMA to the queue manager are unaffected.

To monitor progress of the command, issue the following command and ensure that none of the queues are open:

```
DIS Q(*) CMDSCOPE(qmgr) STGCLASS(bridge_stgclass) IPPROCS
```

If any queue is open, use DISPLAY QSTATUS to verify that the MQ-IMS bridge does not have it open.

This parameter is valid only on z/OS.

z/OS **LOG**
Suspends logging and update activity for the queue manager until a subsequent RESUME request is issued. Any unwritten log buffers are externalized, a system checkpoint is taken (non-data sharing environment only), and the BSDS is updated with the high-written RBA before the update activity is suspended. A highlighted message (CSQJ372I) is issued and remains on the system console until update activity has been resumed. Valid on z/OS only. If LOG is specified, the command can be issued only from the z/OS system console.

This option is not permitted when a system quiesce is active by either the ARCHIVE LOG or STOP QMGR command.

Update activity remains suspended until a RESUME QMGR LOG or STOP QMGR command is issued.

This command must not be used during periods of high activity, or for long periods of time. Suspending update activity can cause timing-related events such as lock timeouts or IBM MQ diagnostic memory dumps when delays are detected.

z/OS **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

' '

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

MODE

Specifies how the suspension of availability is to take effect:

QUIESCE

Other queue managers in the cluster are advised to avoid sending messages to the local queue manager if possible. It does not mean that the queue manager is disabled.

FORCE

All inbound cluster channels from other queue managers in the cluster are stopped forcibly. This occurs only if the queue manager has also been forcibly suspended from all other clusters to which the cluster receiver channel for this cluster belongs.

The MODE keyword is permitted only with CLUSTER or CLUSNL. It is not permitted with the LOG or FACILITY parameter.

Related reference

"RESUME QMGR (resume a cluster queue manager)" on page 890
Use the MQSC command RESUME QMGR to inform other queue managers in a cluster that the local queue manager is available again for processing and can be sent messages. It reverses the action of the SUSPEND QMGR command.

SUSPEND QMGR, RESUME QMGR and clusters

Programmable command formats (PCFs) reference

PCFs define command and reply messages that can be exchanged across a network between a program and any queue manager that supports PCFs. This simplifies queue manager administration and other network administration.

For an introduction to PCFs, see Introduction to Programmable Command Formats.

For the full list of PCFs, see "Definitions of the Programmable Command Formats" on page 960.

PCF commands and responses have a consistent structure including of a header and any number of parameter structures of defined types. For information about these structures, see "Structures for PCF commands and responses" on page 1482.

For an example PCF, see "PCF example" on page 1508.

How the PCF definitions are shown

The definitions of the Programmable Command Formats (PCFs) including their commands, responses, parameters, constants, and error codes are shown in a consistent format.

For each PCF command or response, there is a description of what the command or response does, giving the command identifier in parentheses. See Constants for all values of the command identifier. Each command description starts with a table that identifies the platforms on which the command is valid. For additional, more detailed, usage notes for each command, see the corresponding command description in the "Definitions of the Programmable Command Formats" on page 960.

IBM MQ products, other than IBM MQ for z/OS, can use the IBM MQ Administration Interface (MQAI), which provides a simplified way for applications written in the C and Visual Basic programming language to build and send PCF commands. For information about the MQAI see the second section of this topic.

Commands

The *required parameters* and the *optional parameters* are listed.

Multi On Multiplatforms, the parameters must occur in this order:

1. All required parameters, in the order stated, followed by
2. Optional parameters as required, in any order, unless noted in the PCF definition.

z/OS On z/OS, the parameters can be in any order.

Responses

The response data attribute is *always returned* whether it is requested or not. This parameter is required to identify, uniquely, the object when there is a possibility of multiple reply messages being returned.

The other attributes shown are *returned if requested* as optional parameters on the command. The response data attributes are not returned in a defined order.

Parameters and response data

Each parameter name is followed by its structure name in parentheses (details are given in "Structures for PCF commands and responses" on page 1482). The parameter identifier is given at the beginning of the description.

Constants

For the values of constants used by PCF commands and responses see Constants.
