The component name of the authorization service as specified in the Queue manager's qm.ini file.

WRKMQMAUTD (Work with MQ Authority Data)
Where allowed to run

All environments (*ALL)

Threadsafe

Yes

The Work with MQ Authority Records (WRKMQMAUTD) displays a list of all the users registered to a particular authority profile name and type. This enables you to grant, revoke, delete and create authority records.

Parameters

Keyword	Description	Choices	Notes
<u>OBJ</u>	Object/Profile name	Character value	Required, Positional 1
<u>OBJTYPE</u>	Object type	*Q, *PRC, *MQM, *NMLIST, *AUTHINFO, *CHL, *CLTCN, *SVC, *LSR, *TOPIC	Required, Positional 2
<u>USER</u>	User name	Name, *PUBLIC, *ALL	Optional, Positional 3
<u>MQMNAME</u>	Message Queue Manager name	Character value, *DFT	Optional, Positional 4
<u>SRVCOMP</u>	Service Component name	Character value, *DFT	Optional, Positional 5

Object name (OBJ)

Specify the object name or authority profile name of the object to select.

object-name

Specify the name of an MQ object; all authority records for which the object name or generic profile name match this object name are selected.

generic profile

Specify the generic profile of an MQ object; only the authority record which exactly matches the generic profile is selected. A generic profile is a character string containing one or more generic characters anywhere in the string. The generic characters are (?), (*) and (**).

You are recommended to specify the name required within quotation marks. Using this format ensures that your selection is precisely what you entered.

Object type (OBJTYPE)

Specifies the object type of the authority profile to select.

***Q**

All queue object types.

***AUTHINFO**

Authentication Information object.

***MQM**

Message Queue Manager.

***NMLIST**

Namelist object.

***PRC**

Process definition.

***CHL**

Channel object.

***CLTCN**

Client Connection Channel object.

***LSR**

Listener object.

***SVC**

Service object.

***TOPIC**

Topic object.

User name (USER)

Specifies the name of the user for whom authorities for the named object are displayed.

The possible values are:

***ALL**

List all relevant users.

***PUBLIC**

The user name implying all users of the system.

user-profile-name

Specify the name of the user.

Message Queue Manager name (MQMNAME)

Specifies the name of the queue manager.

***DFT**

Use the default queue manager.

queue-manager-name

Specify the name of the queue manager.

Service Component name (SRVCOMP)

Specify the name of the installed authorization service in which to search for the authorities to display.

The possible values are:

***DFT**

All installed authorization components are searched for the specified authority profile name and object type.

Authorization-service-component-name

The component name of the authorization service as specified in the Queue manager's qm.ini file.

IBM i WRKMQMAUTI (Work with AuthInfo objects)**Where allowed to run**

All environments (*ALL)

Threadsafe

Yes

The Work with MQ AuthInfo objects (WRKMQMAUTI) command allows you to work with multiple authentication information objects which are defined on the local queue manager.

This enables you to change, copy, create, delete, display, and display and change authority to an MQ authentication information object.

Parameters

Keyword	Description	Choices	Notes
<u>AINAME</u>	AuthInfo name	Character value, *ALL	Optional, Positional 1
<u>MQMNAME</u>	Message Queue Manager name	Character value, *DFT	Optional, Positional 2
<u>WHERE</u>	Filter command	Single values: *NONE Other values: <i>Element list</i>	Optional, Positional 3
	Element 1: Filter keyword	*ALTDATA, *ALTTIME, *AUTHTYPE, *CONNAME, *TEXT, *USERNAME, *OCSPURL	
	Element 2: Filter operator	*GT, *LT, *EQ, *NE, *GE, *LE, *LK, *NL, *CT, *EX, *CTG, *EXG	
	Element 3: Filter value	Character value	

AuthInfo name (AINAME)

The name or names of the authentication information objects.

The possible values are:

***ALL or ***

All authentication information objects are selected.

generic-authinfo-name

The generic name of the authentication information objects. A generic name is a character string followed by an asterisk (*). For example ABC*, it selects all authentication information objects having names that start with the character string.

You are recommended to specify the name required within quotation marks. Using this format ensures that your selection is precisely what you entered.

You cannot select all the uppercase and lowercase versions of a generic name on a single panel, without requesting all the names.

authentication-information-name

Specify the name of a single authentication information object.

Message Queue Manager name (MQMNAME)

The name of the queue manager.

The possible values are:

***DFT**

Use the default queue manager.

queue-manager-name

The name of an existing message queue manager. The maximum string length is 48 characters.

Filter command (WHERE)

This parameter can be used to selectively display those AuthInfo objects with particular AuthInfo attributes only.

The parameter takes three arguments, a keyword, an operator, and a value.

Generic strings are allowed for values which are names.

The operator can take one of the following values:

***GT**

Greater than.

Applicable to integer and non-generic string values.

***LT**

Less than.

Applicable to integer and non-generic string values

***EQ**

Equal to.

Applicable to integer and non-generic string values.

***NE**

Not equal to.

Applicable to integer and non-generic string values.

***GE**

Greater than or equal to.

Applicable to integer and non-generic string values.

***LE**

Less than or equal to.

Applicable to integer and non-generic string values.

***LK**

Like.

Applicable to generic string values.

***NL**

Not like.

Applicable to generic string values.

***CT**

Contains.

Applicable to non-generic list values.

***EX**

Excludes.

Applicable to non-generic list values.

***CTG**

Contains generic.

Applicable to generic list values.

***EXG**

Excludes generic.

Applicable to generic list values.

The keyword can take one of the following values:

***ALTDATE**

The date on which the definition or information was last altered.

The filter value is the date in the form yyyy-mm-dd.

***ALTTIME**

The time at which the definition or information was last altered.

The filter value is the time in the form hh:mm:ss.

***AUTHTYPE**

The type of the authentication information object.

The filter value is one of the following:

***CRLLDAP**

The type of the authentication information object is CRLLDAP.

***OCSP**

The type of the authentication information object is OCSP.

***IDPWOS**

Connection authentication user ID and password checking is done using the operating system.

***IDPWLDAP**

Connection authentication user ID and password checking is done using an LDAP server.

***CONNAME**

The address of the host on which the LDAP server is running.

The filter value is the address name.

***TEXT**

Descriptive comment.

The filter value is the text description of the queue.

***USERNAME**

The distinguished name of the user.

The filter value is the distinguished name.

***OCSPURL**

The OCSP Responder URL.

The filter value is the URL name.

 **WRKMQMCHL (Work with MQ Channels)**

Where allowed to run

All environments (*ALL)

Threadsafe

Yes

The Work with IBM MQ Channels (WRKMQMCHL) command allows you to work with one or more channel definitions. This enables you to create, start, end, change, copy, delete, ping, display and reset channels, and resolve in-doubt units of work.

Parameters

<i>Table 324. Command parameters</i>			
Keyword	Description	Choices	Notes
<u>CHLNAME</u>	Channel name	<i>Character value, *ALL</i>	Optional, Positional 1
<u>CHLTYPE</u>	Channel type	*RCVR, *SDR, *SVR, *RQSTR, *SVRCN, *CLUSSDR, *CLUSRCVR, *CLTCN, *ALL	Optional, Positional 2
<u>MQMNAME</u>	Message Queue Manager name	<i>Character value, *DFT</i>	Optional, Positional 3
<u>STATUS</u>	Channel status	*ALL, *INACTIVE, *STOPPED, *BINDING, *RETRYING, *RUNNING, *SWITCHING	Optional, Positional 4

Table 324. Command parameters (continued)

Keyword	Description	Choices	Notes
<u>WHERE</u>	Filter command	Single values: *NONE Other values: <i>Element list</i>	Optional, Positional 5
	Element 1: Filter keyword	*AFFINITY, *ALTDAT, *ALTTIME, *BATCHHB, *BATCHINT, *BATCHLIM, *BATCHSIZE, *CLNTWGHT, *CLUSNL, *CLUSTER, *CLWLPRTY, *CLWL RANK, *CLWLWGHT, *COMPHDR, *COMPMSG, *CONNAME, *CVTMSG, *DSCITV, *HRTBTINTVL, *KAINT, *LOCLADDR, *LONGRTY, *LONGTMR, *MAXINST, *MAXINSTC, *MAXMSGLEN, *MCANAME, *MCATYPE, *MCAUSRID, *MODENAME, *MONCHL, *MSGEXIT, *MSGRTYDATA, *MSGRTYEXIT, *MSGRTYITV, *MSGRTYNBR, *MSGUSRDATA, *NETPRTY, *NPMSPEED, *PROPCTL, *PUTAUT, *RCVEXIT, *RCVUSRDATA, *SCYEXIT, *SCYUSRDATA, *SEQNUMWRAP, *SHARECNV, *SHORTRTY, *SHORTTMR, *SNDEXIT, *SNDUSRDATA, *SSLCAUTH, *SSLCIPH, *SSLPEER, *STATCHL, *TEXT, *TGTMQNAME, *TMQNAME, *TPNAME, *TRPTYPE, *USERID	
	Element 2: Filter operator	*GT, *LT, *EQ, *NE, *GE, *LE, *LK, *NL, *CT, *EX, *CTG, *EXG	
	Element 3: Filter value	Character value	

Channel name (CHLNAME)

Specifies the name or names of the IBM MQ channel definitions to be selected.

The possible values are:

***ALL**

All channel definitions are selected.

generic-channel-name

Specify the generic name of the channel definitions to be selected. A generic name is a character string followed by an asterisk (*). For example ABC*, it selects all channel definitions having names that start with the character string.

You are recommended to specify the name required within quotation marks. Using this format ensures that your selection is precisely what you entered.

You cannot select all the uppercase and lowercase versions of a generic name on a single panel, without requesting all the names.

channel-name

Specify the name of the channel definition.

Channel type (CHLTYPE)

Specifies the type of channel definitions that are to be displayed.

The possible values are:

***ALL**

All the channel types are selected.

***SDR**

Sender channel

***SVR**

Server channel

***RCVR**

Receiver channel

***RQSTR**

Requester channel

***SVRCN**

Server-connection channel

***CLUSSDR**

Cluster-sender channel

***CLUSRCVR**

Cluster-receiver channel

***CLTCN**

Client-connection channel

Message Queue Manager name (MQMNAME)

Specifies the name of the message queue manager.

The possible values are:

***DFT**

The default queue manager is used. If you do not have a default queue manager defined on the system, the command fails.

message-queue-manager-name

The name of a message queue manager.

Channel status (STATUS)

Specifies the status type of the IBM MQ channel definitions to be selected.

The possible values are:

***ALL**

Channels with any status are selected.

***BINDING**

Only channels with a binding status are selected.

***INACTIVE**

Only channels with an inactive status are selected.

***RETRYING**

Only channels with a retrying status are selected.

***RUNNING**

Only channels with a running status are selected.

***STOPPED**

Only channels with a stopped status are selected.

***SWITCHING**

Only channels with a switching status are selected.

Filter command (WHERE)

This parameter can be used to selectively display those channels with particular channel attributes only.

The parameter takes three arguments, a keyword, an operator and a value.

Generic strings are allowed for values which are names.

The operator can take one of the following values:

***GT**

Greater than.

Applicable to integer and non-generic string values.

***LT**

Less than.

Applicable to integer and non-generic string values

***EQ**

Equal to.

Applicable to integer and non-generic string values.

***NE**

Not equal to.

Applicable to integer and non-generic string values.

***GE**

Greater than or equal to.

Applicable to integer and non-generic string values.

***LE**

Less than or equal to.

Applicable to integer and non-generic string values.

***LK**

Like.

Applicable to generic string values.

***NL**

Not like.

Applicable to generic string values.

***CT**

Contains.

Applicable to non-generic list values.

***EX**

Excludes.

Applicable to non-generic list values.

***CTG**

Contains generic.

Applicable to generic list values.

***EXG**

Excludes generic.

Applicable to generic list values.

The keyword can take one of the following values:

***AFFINITY**

Connection Affinity.

The filter value is one of the following:

***PREFERRED**

Preferred connection affinity.

***NONE**

No connection affinity.

***ALTDATE**

The date on which the definition or information was last altered.

The filter value is the data in the form yyyy-mm-dd.

***ALTTIME**

The time at which the definition or information was last altered.

The filter value is the time in the form hh:mm:ss.

***BATCHHB**

Batch heartbeat interval in milliseconds.

The filter value is the integer interval time.

***BATCHINT**

Batch interval in milliseconds.

The filter value is the integer interval time.

***BATCHLIM**

Batch data limit in kilobytes.

The limit of the amount of data that can be sent through a channel.

***BATCHSIZE**

Batch size.

The filter value is the integer batch size.

***CLNTWGHT**

Client channel weight.

The filter value is the integer client channel weight.

***CLUSNL**

Cluster namelist.

The filter value is the list of cluster names.

***CLUSTER**

The cluster to which the channel belongs.

The filter value is the name of the cluster.

***CLWL RANK**

Cluster workload rank.

The filter value is the integer rank.

***CLWL PRTY**

Cluster workload priority.

The filter value is the integer priority.

***CLWL WGHT**

Cluster workload weight.

The filter value is the integer weight.

***COMP HDR**

Header compression.

The filter value is one of the following:

***NONE**

No header data compression is performed.

***SYSTEM**

Header data compression is performed.

***COMP MSG**

Message compression.

The filter value is one of the following:

***NONE**

No message data compression is performed.

***RLE**

Message data compression is performed using RLE.

***ZLIB HIGH**

Message data compression is performed using ZLIB compression. A high level of compression is preferred.

***ZLIB FAST**

Message data compression is performed using ZLIB compression. A fast compression time is preferred.

V 9.4.0 *LZ4 FAST

Message data compression is performed using the LZ4 compression technique. A fast compression time is preferred.

V 9.4.0 *LZ4 HIGH

Message data compression is performed using the LZ4 compression technique. A high level of compression is preferred.

***ANY**

Any compression technique supported by the queue manager can be used.

***CON NAME**

Remote connection name.

The filter value is the connection name string.

***CVT MSG**

Whether the message is converted before transmission.

The filter value is one of the following:

***YES**

The application data in the message is converted before sending.

***NO**

The application data in the message is not converted before sending.

***DSCITV**

Disconnect interval in seconds.

The filter value is the integer interval time.

***HRTBTINTVL**

Heartbeat interval in seconds.

The filter value is the integer interval time.

***KAINT**

Keep alive interval in seconds.

The filter value is the integer interval time.

***LOCLADDR**

Local connection name.

The filter value is the connection name string.

***LONGRTY**

Long retry count.

The filter value is the integer count.

***LONGTMR**

Long retry interval in seconds.

The filter value is the integer interval time.

***MAXINST**

Maximum instances of an individual server-connection channel.

The filter value is the integer number of instances.

***MAXINSTC**

Maximum instances of an individual server-connection channel from a single client.

The filter value is the integer number of instances.

***MAXMSGLEN**

Maximum message length.

The filter value is the integer length.

***MCANAME**

Message channel agent name.

The filter value is the agent name.

***MCATYPE**

Whether the message channel agent program should run as a thread or process.

The filter value is one of the following:

***PROCESS**

The message channel agent runs as a separate process.

***THREAD**

The message channel agent runs as a separate thread.

***MCAUSRID**

Message channel agent user identifier.

The filter value is the user identifier string.

***MODENAME**

SNA mode name.

The filter value is the mode name string.

***MONCHL**

Channel Monitoring.

The filter value is one of the following:

***QMGR**

The collection of Online Monitoring Data is inherited from the setting of the queue manager attribute MONCHL.

***OFF**

Online Monitoring Data collection for this channel is disabled.

***LOW**

Monitoring data collection is turned on with a low ratio of data collection.

***MEDIUM**

Monitoring data collection is turned on with a moderate ratio of data collection.

***HIGH**

Monitoring data collection is turned on with a high ratio of data collection.

***MSGEXIT**

Message exit name.

The filter value is the exit name.

***MSGRTYDATA**

Message retry exit user data.

The filter value is the user data string.

***MSGRTYEXIT**

Message retry exit name.

The filter value is the exit name.

***MSGRTYITV**

Message retry interval interval in seconds.

The filter value is the integer interval time.

***MSGRTYNBR**

Number of message retries.

The filter value is the integer number of retries.

***MSGUSRDATA**

Message exit user data.

The filter value is the user data string.

***NETPRTY**

Network connection priority ranging from 0 through 9.

The filter value is the integer priority value.

***NPMSPEED**

Whether the channel supports fast nonpersistent messages.

The filter value is one of the following:

***FAST**

The channel supports fast nonpersistent messages.

***NORMAL**

The channel does not support fast nonpersistent messages.

***PROPCTL**

Message Property Control.

The filter value is one of the following:

***COMPAT**

Compatibility mode

***NONE**

No properties sent to remote queue manager.

***ALL**

All properties sent to remote queue manager.

***PUTAUT**

Whether the user identifier in the context information is used.

The filter value is one of the following:

***DFT**

No authority check is made before the message is put on the destination queue.

***CTX**

The user identifier in the message context information is used to establish authority to put the message.

***RCVEXIT**

Receive exit name.

The filter value is the exit name.

***RCVUSRDATA**

Receive exit user data.

The filter value is the user data string.

***SCYEXIT**

Security exit name.

The filter value is the exit name.

***SCYUSRDATA**

Security exit user data.

The filter value is the user data string.

***SEQNUMWRAP**

Maximum message sequence number.

The filter value is the integer sequence number.

***SHARECNV**

The number of shared conversations over a TCP/IP socket.

The filter value is the integer number of shared conversations.

***SHORTRTY**

Short retry count.

The filter value is the integer count.

***SHORTTMR**

Short retry interval in seconds.

The filter value is the integer interval time.

***SNDEXIT**

Send exit name.

The filter value is the exit name.

***SNDUSRDATA**

Send exit user data.

The filter value is the user data string.

***SSLCAUTH**

Whether the channel should carry out client authentication over TLS.

The filter value is one of the following:

***REQUIRED**

Client authentication is required.

***OPTIONAL**

Client authentication is optional.

***SSLCIPH**

The CipherSpec using in TLS channel negotiation.

The filter value is the name of the CipherSpec.

***SSLPEER**

The X500 peer name used in TLS channel negotiation.

The filter value is the peer name.

***STATCHL**

Channel Statistics.

The filter value is one of the following:

***QMGR**

The collection of statistics data is inherited from the setting of the queue manager attribute STATCHL.

***OFF**

Statistics data collection for this channel is disabled.

***LOW**

Statistics data collection is turned on with a low ratio of data collection.

***MEDIUM**

Statistics data collection is turned on with a moderate ratio of data collection.

***HIGH**

Statistics data collection is turned on with a high ratio of data collection.

***TEXT**

Descriptive comment.

The filter value is the text description of the channel.

***TGTQMNAME**

Target queue manager name.

The filter value is the target queue manager of the channel.

***TMQNAME**

Transmission queue name.

The filter value is the name of the queue.

***TPNAME**

The SNA transaction program name.

The filter value is the program name string.

***TRPTYPE**

Transport type.

The filter value is one of the following:

***TCP**

Transmission Control Protocol / Internet Protocol (TCP/IP).

***LU62**

SNA LU 6.2.

***USERID**

Task user identifier.

The filter value is the user identifier string.

WRKMQMCHST (Work with MQ Channel Status)
Where allowed to run

All environments (*ALL)

Threadsafe

Yes

The Work with MQ Channel Status (WRKMQMCHST) command allows you to work with the status of one or more channel definitions.

Parameters

Table 325. Command parameters

Keyword	Description	Choices	Notes
<u>CHLNAME</u>	Channel name	Character value, *ALL	Optional, Positional 1
<u>CONNNAME</u>	Connection name	Character value, *ALL	Optional, Positional 2
<u>TMQNAME</u>	Transmission queue name	Character value, *ALL	Optional, Positional 3
<u>MQMNAME</u>	Message Queue Manager name	Character value, *DFT	Optional, Positional 4
<u>CHLSTS</u>	Channel status	*ALL , *SAVED, *CURRENT	Optional, Positional 5
<u>WHERE</u>	Filter command	Single values: *NONE Other values: <i>Element list</i>	Optional, Positional 6
	Element 1: Filter keyword	*CHLSTS, *CHLTYPE, *COMPHDR, *COMPMSG, *CONNNAME, *INDOUBT, *INDMSGGS, *INDSEQNO, *LSTSEQNO, *MONCHL, *RMTMQMNAME, *RMTVERSION, *SHARECNV, *STATUS, *SUBSTATE, *TMQNAME, *XQMSGSA, *LSTMSGDATE, *LSTMSGTIME, *MSGGS	
	Element 2: Filter operator	*GT, *LT, *EQ, *NE, *GE, *LE, *LK, *NL, *CT, *EX, *CTG, *EXG	
	Element 3: Filter value	Character value	

Channel name (CHLNAME)

Specifies the name of the channel definition.

The possible values are:

***ALL**

All channel definitions are selected.

generic-channel-name

Specify the generic name of the channel definitions to be selected. A generic name is a character string followed by an asterisk (*). For example ABC*, it selects all channel definitions having names that start with the character string.

You are recommended to specify the name required within quotation marks. Using this format ensures that your selection is precisely what you entered.

You cannot select all the uppercase and lowercase versions of a generic name on a single panel, without requesting all the names.

channel-name

Specify the name of the channel definition.

Connection name (CONNNAME)

Specifies the name of the machine to connect.

The possible values are:

***ALL**

All the channels are selected.

generic-connection-name

Specify the generic connection name of the required channels.

connection-name

Specify the connection name of the required channels.

Transmission queue name (TMQNAME)

Specifies the name of the transmission queue.

The possible values are:

***ALL**

All the transmission queues are selected.

generic-transmission-queue-name

Specify the generic name of the transmission queues.

transmission-queue-name

Specify the name of the transmission queue. A transmission queue name is required if the channel definition type (CHLTYPE) is *SDR or *SVR.

Message Queue Manager name (MQMNAME)

Specifies the name of the message queue manager.

The possible values are:

***DFT**

The default queue manager is used. If you do not have a default queue manager defined on the system, the command fails.

message-queue-manager-name

The name of a message queue manager.

Channel status (CHLSTS)

Specifies the type of channel status to display.

The possible values are:

***SAVED**

Saved channel status only is displayed. Status is not saved until a persistent message is transmitted across a channel, or a nonpersistent message is transmitted with a NPMSPEED of NORMAL. Because

status is saved at the end of each batch, a channel has no saved status until at least one batch has been transmitted.

***CURRENT**

Current channel status only is displayed. This applies to channels that have been started, or on which a client has connected, and that have not finished or disconnected normally. The current status data is updated as messages are sent or received.

***ALL**

Both saved and current channel status is displayed.

Filter command (WHERE)

This parameter can be used to selectively display the status of only those channels with particular channel status attributes.

The parameter takes three arguments, a keyword, an operator, and a value.

Generic strings are allowed for values which are names.

The operator can take one of the following values:

***GT**

Greater than.

Applicable to integer and non-generic string values.

***LT**

Less than.

Applicable to integer and non-generic string values

***EQ**

Equal to.

Applicable to integer and non-generic string values.

***NE**

Not equal to.

Applicable to integer and non-generic string values.

***GE**

Greater than or equal to.

Applicable to integer and non-generic string values.

***LE**

Less than or equal to.

Applicable to integer and non-generic string values.

***LK**

Like.

Applicable to generic string values.

***NL**

Not like.

Applicable to generic string values.

***CT**

Contains.

Applicable to non-generic list values.

***EX**

Excludes.

Applicable to non-generic list values.

***CTG**

Contains generic.

Applicable to generic list values.

***EXG**

Excludes generic.

Applicable to generic list values.

The keyword can take one of the following values:

***CHLSTS**

The type of channel status.

The filter value is one of the following:

***CURRENT**

Current status for an active channel.

***SAVED**

Saved status for an active or inactive channel.

***CHLTYPE**

The type of channel.

The filter value is one of the following:

***SDR**

Sender channel.

***SVR**

Server channel.

***RCVR**

Receiver channel.

***RQSTR**

Requester channel.

***CLUSSDR**

Cluster-sender channel.

***CLUSRCVR**

Cluster-receiver channel.

***SVRCN**

Server-connection channel.

***COMPHDR**

Whether the channel performs header data compression.

The filter value is one of the following:

***NONE**

No header data compression is performed.

***SYSTEM**

Header data compression is performed.

***COMPMSG**

Whether the channel performs message data compression.

The filter value is one of the following:

***NONE**

No message data compression is performed.

***RLE**

Message data compression is performed using RLE.

***ZLIBHIGH**

Message data compression is performed using ZLIB compression. A high level of compression is preferred.

***ZLIBFAST**

Message data compression is performed using ZLIB compression. A fast compression time is preferred.

***CONNAME**

The connection name of the channel.

The filter value is the connection name string.

***INDOUBT**

Whether there are any in-doubt messages in the network.

The filter value is either *NO or *YES.

***INDMSGS**

The number of in-doubt messages.

The filter value is the integer number of messages.

***INDSEQNO**

The sequence number of the message that is in-doubt.

The filter value is the integer sequence number.

***LSTMSGTIME**

The time the last message was sent on the channel.

The filter value is the time in the form hh:mm:ss.

***LSTMSGDATE**

The date that the last message was sent on the channel.

The filter value is the data in the form yyyy-mm-dd

***LSTSEQNO**

The last message sequence number.

The filter value is the integer sequence number.

***MONCHL**

The current level of monitoring data collection for the channel.

The filter value is one of the following:

***NONE**

No monitoring data is collected.

***LOW**

A low ratio of monitoring data is collected.

***MEDIUM**

A medium ratio of monitoring data is collected.

***HIGH**

A high ratio of monitoring data is collected.

***MSGS**

The number of messages that have been sent on the channel.

The filter value is the integer number of messages.

***RMTMQMNAME**

The remote message queue manager.

The filter value is the message queue manager name.

***RMTVERSION**

The remote partner version.

The filter value is the integer format of the remote partner version.

***SHARECNV**

The number of shared conversations over a TCP/IP socket.

The filter value is the integer number of shared conversations.

***STATUS**

The status of the channel.

The filter value is one of the following:

***BINDING**

The channel is establishing a session.

***INACTIVE**

The channel has ended processing normally or the channel has never started.

***INITIALIZING**

The channel initiator is attempting to start the channel.

***PAUSED**

The channel is waiting for the message retry interval.

***REQUESTING**

The channel has been requested to start.

***RETRYING**

A previous attempt to establish a connection has failed. The channel will retry the connection after the specified interval.

***RUNNING**

The channel is transferring or is ready to transfer data.

***STARTING**

The channel is ready to begin negotiation with the target MCA.

***STOPPED**

The channel has been stopped.

***STOPPING**

The channel has been requested to stop.

***SWITCHING**

The channel is switching transmission queues.

***SUBSTATE**

The channel substate.

The filter value is one of the following:

***ENDBATCH**

End of batch processing.

***SEND**

Sending data.

***RECEIVE**

Receiving data.

***SERIALIZE**

Serializing with the partner channel.

***RESYNCH**

Resynchronizing with the partner channel.

***HEARTBEAT**

Heartbeat processing.

***SCYEXIT**

Processing a security exit.

***RCVEXIT**

Processing a receive exit.

***SENDEXIT**

Processing a send exit.

***MSGEXIT**

Processing a message exit.

***MREXIT**

Processing a message-retry exit.

***CHADEXIT**

Processing a channel auto-definition exit.

***NETCONNECT**

Connecting to remote machine.

***SSLHANDSHK**

Establishing a TLS connection.

***NAMESERVER**

Requesting information from a name server.

***MQPUT**

MQPUT processing.

***MQGET**

MQGET processing.

***MQICALL**

Processing an MQI call.

***COMPRESS**

Compressing or extracting data.

***TMQNAME**

The transmission queue of the channel.

The filter value is the queue name.

***XQMSGSA**

The number of messages queued on the transmission queue available for MQGET. This field is valid for cluster-sender channels.

The filter value is the integer number of messages.

WRKMQMCL (Work with MQ Clusters)

Where allowed to run

All environments (*ALL)

Threadsafe

Yes

The Work with MQ Clusters command, **WRKMQMCL**, allows you to work with multiple cluster queue manager definitions that are defined on the local queue manager.

Parameters

<i>Table 326. Command parameters</i>			
Keyword	Description	Choices	Notes
<u>CLUSQMGR</u>	Cluster Queue Manager name	<i>Character value, *ALL</i>	Optional, Positional 1

Table 326. Command parameters (continued)

Keyword	Description	Choices	Notes
<u>MQMNAME</u>	Message Queue Manager name	Character value, *DFT	Optional, Positional 2
<u>WHERE</u>	Filter command	Single values: *NONE Other values: <i>Element list</i>	Optional, Positional 3
	Element 1: Filter keyword	*ALTDATE, *ALTTIME, *BATCHHB, *BATCHINT, *BATCHLIM, *BATCHSIZE, *CHLNAME, *CLUSDATE, *CLUSQMGR, *CLUSTER, *CLUSTIME, *CLWLPRTY, *CLWLRRANK, *CLWLWGHT, *COMPHDR, *COMPMSG, *CONNAME, *CVTMSG, *DFNTYPE, *DSCITV, *HRTBTINTVL, *KAINT, *LOCLADDR, *LONGRTY, *LONGTMR, *MAXMSGLEN, *MCANAME, *MCATYPE, *MCAUSRID, *MONCHL, *MSGEXIT, *MSGRTYDATA, *MSGRTYEXIT, *MSGRTYITV, *MSGRTYNBR, *MSGUSRDATA, *NETPRTY, *NPMSPEED, *PUTAUT, *QMID, *QMTYPE, *RCVEXIT, *RCVUSRDATA, *SCYEXIT, *SCYUSRDATA, *SEQNUMWRAP, *SHORTRTY, *SHORTTMR, *SNDEXIT, *SNDUSRDATA, *SSLCAUTH, *SSLCIPH, *SSLPEER, *STATCHL, *STATUS, *SUSPEND, *TEXT, *TRPTYPE, *USERID, *XMITQ	
	Element 2: Filter operator	*GT, *LT, *EQ, *NE, *GE, *LE, *LK, *NL, *CT, *EX, *CTG, *EXG	
	Element 3: Filter value	Character value	

Cluster Queue Manager name (CLUSQMGR)

Specifies the name or names of the cluster queue manager definitions.

***ALL**

All cluster queue manager definitions are selected.

generic-cluster-queue-manager-name

Specify the generic name of the MQ cluster queue manager definitions. A generic name is a character string followed by an asterisk (*)> For example ABC*, it selects all cluster queue manager definitions having names that start with the character string. You are recommended to specify the name required within quotation marks. Using this format ensures that your selection is precisely what you entered. You cannot select all the uppercase and lowercase versions of a generic name on a single panel, without requesting all the names.

cluster-queue-manager-name

Specify the name of the MQ cluster queue manager definition.

Message Queue Manager name (MQMNAME)

Specifies the name of the queue manager.

***DFT**

Use the default queue manager.

queue-manager-name

Specify the name of the queue manager.

Filter command (WHERE)

This parameter can be used to selectively display only those cluster queue managers with particular attributes.

The parameter takes three arguments, a keyword, an operator and a value.

Generic strings are allowed for values which are names.

The operator can take one of the following values:

***GT**

Greater than.

Applicable to integer and non-generic string values.

***LT**

Less than.

Applicable to integer and non-generic string values

***EQ**

Equal to.

Applicable to integer and non-generic string values.

***NE**

Not equal to.

Applicable to integer and non-generic string values.

***GE**

Greater than or equal to.

Applicable to integer and non-generic string values.

***LE**

Less than or equal to.

Applicable to integer and non-generic string values.

***LK**

Like.

Applicable to generic string values.

***NL**

Not like.

Applicable to generic string values.

***CT**

Contains.

Applicable to non-generic list values.

***EX**

Excludes.

Applicable to non-generic list values.

***CTG**

Contains generic.

Applicable to generic list values.

***EXG**

Excludes generic.

Applicable to generic list values.

The keyword can take one of the following values:

***ALTDATE**

The date on which the definition or information was last altered.

The filter value is the data in the form yyyy-mm-dd.

***ALTIME**

The time at which the definition or information was last altered.

The filter value is the time in the form hh:mm:ss.

***BATCHHB**

Batch heartbeat interval in milliseconds.

The filter value is the integer interval time.

***BATCHINT**

Batch interval in milliseconds.

The filter value is the integer interval time.

***BATHLIM**

Batch data limit in kilobytes.

The limit of the amount of data that can be sent through a channel.

***BATCHSIZE**

Batch size.

The filter value is the integer batch size.

***CHANNEL**

The channel name of the cluster queue manager.

The filter value is the name of the channel.

***CLUSDATE**

The date on which the definition became available to the local queue manager.

The filter value is the data in the form yyyy-mm-dd.

***CLUSQMGR**

The cluster queue manager name.

The filter value is the name of the cluster queue manager.

***CLUSTER**

The cluster to which the cluster queue manager belongs.

The filter value is the name of the cluster.

***CLUSTIME**

The time at which the definition became available to the local queue manager.

The filter value is the time in the form hh:mm:ss.

***CLWL RANK**

Cluster workload rank.

The filter value is the integer rank.

***CLWL PRTY**

Cluster workload priority.

The filter value is the integer priority.

***CLWL WGT**

Cluster workload weight.

The filter value is the integer weight.

***COMP HDR**

Header compression.

The filter value is one of the following:

***NONE**

No header data compression is performed.

***SYSTEM**

Header data compression is performed.

***COMP MSG**

Message compression.

The filter value is one of the following:

***NONE**

No message data compression is performed.

***RLE**

Message data compression is performed using RLE.

***ZLIB HIGH**

Message data compression is performed using ZLIB compression. A high level of compression is preferred.

***ZLIB FAST**

Message data compression is performed using ZLIB compression. A fast compression time is preferred.

 ***LZ4 FAST**

Message data compression is performed using the LZ4 compression technique. A fast compression time is preferred.

 ***LZ4 HIGH**

Message data compression is performed using the LZ4 compression technique. A high level of compression is preferred.

***ANY**

Any compression technique supported by the queue manager can be used.

***CON NAME**

Remote connection name.

The filter value is the connection name string.

***CVTMSG**

Whether the message should be converted before transmission.

The filter value is one of the following:

***YES**

The application data in the message is converted before sending.

***NO**

The application data in the message is not converted before sending.

***DFNTYPE**

How the cluster channel was defined.

The filter value is one of the following:

***CLUSSDR**

As a cluster-sender channel from an explicit definition.

***CLUSSDRA**

As a cluster-sender channel by auto-definition alone.

***CLUSSDRB**

As a cluster-sender channel by auto-definition and an explicit definition.

***CLUSRCVR**

As a cluster-receiver channel from an explicit definition.

***DSCITV**

Disconnect interval in seconds.

The filter value is the integer interval time.

***HRTBTINTVL**

Heartbeat interval in seconds.

The filter value is the integer interval time.

***KAINT**

Keep alive interval in seconds.

The filter value is the integer interval time.

***LOCLADDR**

Local connection name.

The filter value is the connection name string.

***LONGRTY**

Long retry count.

The filter value is the integer count.

***LONGTMR**

Long retry interval in seconds.

The filter value is the integer interval time.

***MAXMSGLEN**

Maximum message length.

The filter value is the integer length.

***MCANAME**

Message channel agent name.

The filter value is the agent name.

***MCATYPE**

Whether the message channel agent program should run as a thread or process.

The filter value is one of the following:

***PROCESS**

The message channel agent runs as a separate process.

***THREAD**

The message channel agent runs as a separate thread.

***MCAUSRID**

Message channel agent user identifier.

The filter value is the user identifier string.

***MONCHL**

Channel Monitoring.

The filter value is one of the following:

***QMGR**

The collection of Online Monitoring Data is inherited from the setting of the queue manager attribute MONCHL.

***OFF**

Online Monitoring Data collection for this channel is disabled.

***LOW**

Monitoring data collection is turned on with a low ratio of data collection.

***MEDIUM**

Monitoring data collection is turned on with a moderate ratio of data collection.

***HIGH**

Monitoring data collection is turned on with a high ratio of data collection.

***MSGEXIT**

Message exit name.

The filter value is the exit name.

***MSGRTYDATA**

Message retry exit user data.

The filter value is the user data string.

***MSGRTYEXIT**

Message retry exit name.

The filter value is the exit name.

***MSGRTYITV**

Message retry interval interval in seconds.

The filter value is the integer interval time.

***MSGRTYNBR**

Number of message retries.

The filter value is the integer number of retries.

***MSGUSRDATA**

Message exit user data.

The filter value is the user data string.

***NETPRTY**

Network connection priority in the range 0 through 9.

The filter value is the integer priority value.

***NPMSPEED**

Whether the channel supports fast non persistent messages.

The filter value is one of the following:

***FAST**

The channel supports fast non persistent messages.

***NORMAL**

The channel does not support fast non persistent messages.

***PUTAUT**

Whether the user identifier in the context information should be used.

The filter value is one of the following:

***DFT**

No authority check is made before the message is put on the destination queue.

***CTX**

The user identifier in the message context information is used to establish authority to put the message.

***QMID**

The internally generated unique name of the cluster queue manager.

The filter value is the unique name.

***QMTYPE**

The function of the cluster queue manager in the cluster.

The filter value is one of the following:

***REPOS**

Provides a full repository service.

***NORMAL**

Does not provide a full repository service.

***RCVEXIT**

Receive exit name.

The filter value is the exit name.

***RCVUSRDATA**

Receive exit user data.

The filter value is the user data string.

***SCYEXIT**

Security exit name.

The filter value is the exit name.

***SCYUSRDATA**

Security exit user data.

The filter value is the user data string.

***SEQNUMWRAP**

Maximum message sequence number.

The filter value is the integer sequence number.

***SHORTRTY**

Short retry count.

The filter value is the integer count.

***SHORTTMR**

short retry interval in seconds.

The filter value is the integer interval time.

***SNDEXIT**

Send exit name.

The filter value is the exit name.

***SNDUSRDATA**

Send exit user data.

The filter value is the user data string.

***SSLCAUTH**

Whether the channel should carry out client authentication over TLS.

The filter value is one of the following:

***REQUIRED**

Client authentication is required.

***OPTIONAL**

Client authentication is optional.

***SSLCIPH**

The CipherSpec using in TLS channel negotiation.

The filter value is the name of the CipherSpec.

***SSLPEER**

The X500 peer name used in TLS channel negotiation.

The filter value is the peer name.

***STATCHL**

Channel Statistics.

The filter value is one of the following:

***QMGR**

The collection of statistics data is inherited from the setting of the queue manager attribute STATCHL.

***OFF**

Statistics data collection for this channel is disabled.

***LOW**

Statistics data collection is turned on with a low ratio of data collection.

***MEDIUM**

Statistics data collection is turned on with a moderate ratio of data collection.

***HIGH**

Statistics data collection is turned on with a high ratio of data collection.

***STATUS**

The current status of the channel for this cluster queue manager.

The filter value is one of the following:

***STARTING**

The channel is waiting to become active.

***BINDING**

The channel is performing channel negotiation.

***INACTIVE**

The channel is not active.

***INITIALIZING**

The channel initiator is attempting to start a channel.

***RUNNING**

The channel is either transferring messages, or is waiting for messages to arrive on the transmission queue.

***STOPPING**

The channel is stopping, or a close request has been received.

***RETRYING**

A previous attempt to establish a connection has failed. The MCA will reattempt connection after the specified time interval.

***PAUSED**

The channel is waiting for the message-retry interval to complete before retrying an MQPUT operation.

***STOPPED**

The channel has either been manually stopped, or the retry limit has been reached.

***REQUESTING**

A local requester channel is requesting services from a remote MCA.

***SUSPEND**

Whether this cluster queue manager is suspended from the cluster or not.

The filter value is either *NO or *YES.

***TEXT**

Descriptive comment.

The filter value is the text description of the channel.

***TMQNAME**

Transmission queue name.

The filter value is the name of the queue.

***USERID**

Task user identifier.

The filter value is the user identifier string.

***XMITQ**

Name of cluster transmission queue.

The filter value is the transmission queue name string.

 **WRKMQMCLQ (Work with MQ Cluster Queues)**
Where allowed to run

All environments (*ALL)

Threadsafe

Yes

The Work with MQ Cluster Queues (WRKMQMCLQ) command allows you to work with cluster queues that are defined on the local queue manager.

Parameters

<i>Table 327. Command parameters</i>			
Keyword	Description	Choices	Notes
<u>QNAME</u>	Queue name	<i>Character value, *ALL</i>	Optional, Positional 1
<u>MQMNAME</u>	Message Queue Manager name	<i>Character value, *DFT</i>	Optional, Positional 2
<u>CLUSTER</u>	Cluster name	<i>Character value, *ALL</i>	Optional, Positional 3

Table 327. Command parameters (continued)

Keyword	Description	Choices	Notes
<u>WHERE</u>	Filter command	Single values: *NONE Other values: <i>Element list</i>	Optional, Positional 4
	Element 1: Filter keyword	*ALTDATA, *ALTTIME, *CLUSDATE, *CLUSQMGR, *CLUSQTYPE, *CLUSTER, *CLUSTIME, *DEFBIND, *DFTMSGPST, *DFTPTY, *PUTENBL, *QMID, *TEXT	
	Element 2: Filter operator	*GT, *LT, *EQ, *NE, *GE, *LE, *LK, *NL, *CT, *EX, *CTG, *EXG	
	Element 3: Filter value	Character value	

Queue name (QNAME)

Specifies the name or names of the cluster queue definitions.

***ALL**

All cluster queue definitions are selected.

generic-queue-name

Specify the generic name of the MQ cluster queue definitions. A generic name is a character string followed by an asterisk (*). For example ABC*, it selects all cluster queue definitions having names that start with the character string. You are recommended to specify the name required within quotation marks. Using this format ensures that your selection is precisely what you entered. You cannot select all the uppercase and lowercase versions of a generic name on a single panel, without requesting all the names.

queue-name

Specify the name of the MQ cluster queue definition.

Message Queue Manager name (MQMNAME)

Specifies the name of the queue manager.

***DFT**

Use the default queue manager.

queue-manager-name

Specify the name of the queue manager.

Cluster name (CLUSTER)

Specifies the name of the cluster.

***ALL**

All cluster definitions are selected.

generic-cluster-name

Specify the generic name of the MQ cluster definitions. A generic name is a character string followed by an asterisk (*). For example ABC*, it selects all cluster definitions having names that start with the character string. You are recommended to specify the name required within quotation marks. Using this format ensures that your selection is precisely what you entered. You cannot select all the uppercase and lowercase versions of a generic name on a single panel, without requesting all the names.

cluster-name

Specify the name of the MQ cluster definition.

Filter command (WHERE)

This parameter can be used to selectively display only those cluster queues with particular cluster queue attributes.

The parameter takes three arguments, a keyword, an operator and a value.

Generic strings are allowed for values which are names.

The operator can take one of the following values:

***GT**

Greater than.

Applicable to integer and non-generic string values.

***LT**

Less than.

Applicable to integer and non-generic string values

***EQ**

Equal to.

Applicable to integer and non-generic string values.

***NE**

Not equal to.

Applicable to integer and non-generic string values.

***GE**

Greater than or equal to.

Applicable to integer and non-generic string values.

***LE**

Less than or equal to.

Applicable to integer and non-generic string values.

***LK**

Like.

Applicable to generic string values.

***NL**

Not like.

Applicable to generic string values.

***CT**

Contains.

Applicable to non-generic list values.

***EX**

Excludes.

Applicable to non-generic list values.

***CTG**

Contains generic.

Applicable to generic list values.

***EXG**

Excludes generic.

Applicable to generic list values.

The keyword can take one of the following values:

***ALTDATE**

The date on which the definition or information was last altered.

The filter value is the data in the form yyyy-mm-dd.

***ALTTIME**

The time at which the definition or information was last altered.

The filter value is the time in the form hh:mm:ss.

***CLUSDATE**

The date on which the definition became available to the local queue manager.

The filter value is the date in the form yyyy-mm-dd.

***CLUSQMGR**

The name of the queue manager that hosts the queue.

The filter value is the name of the queue manager.

***CLUSQTYPE**

Cluster queue type.

The filter value is one of the following:

***LCL**

The cluster queue represents a local queue.

***ALS**

The cluster queue represents an alias queue.

***RMT**

The cluster queue represents a remote queue.

***MQMALS**

The cluster queue represents a queue manager alias.

***CLUSTER**

The name of the cluster that the queue is in.

The filter value is the name of the cluster.

***CLUSTIME**

The time at which the definition became available to the local queue manager.

The filter value is the time in the form hh:mm:ss.

***DEFBIND**

Default message binding.

The filter value is one of the following:

***OPEN**

The queue handle is bound to a specific instance of the cluster queue when the queue is opened.

***NOTFIXED**

The queue handle is not bound to any particular instance of the cluster queue.

***GROUP**

When the queue is opened, the queue handle is bound to a specific instance of the cluster queue for as long as there are messages in a message group. All messages in a message group are allocated to the same destination instance.

***DFTMSGPST**

Default persistence of the messages put on this queue.

The filter value is one of the following:

***NO**

Messages on this queue are lost across a restart of the queue manager.

***YES**

Messages on this queue survive a restart of the queue manager.

***DFTPTY**

Default priority of the messages put on the queue.

The filter value is the integer priority value.

***PUTENBL**

Whether applications are permitted to put messages to the queue.

The filter value is one of the following:

***NO**

Messages cannot be added to the queue.

***YES**

Messages can be added to the queue by authorized applications.

***QMID**

Internally generated unique name of the queue manager that hosts the queue.

The filter value is the name of the queue manager.

***TEXT**

Descriptive comment.

The filter value is the text description of the queue.

WRKMQMCONN (Work with MQ Connections)

Where allowed to run

All environments (*ALL)

Threadsafe

Yes

The Work with MQ Connections (WRKMQMCONN) command allows you to work with connection information for applications that are connected to the queue manager.

This enables you to display connection handles and end connections to the queue manager.

Parameters

Keyword	Description	Choices	Notes
<u>CONN</u>	Connection Identifier	Character value, *ALL	Optional, Positional 1
<u>MQMNAME</u>	Message Queue Manager name	Character value, *DFT	Optional, Positional 2

Table 328. Command parameters (continued)

Keyword	Description	Choices	Notes
<u>WHERE</u>	Filter command	Single values: *NONE Other values: <i>Element list</i>	Optional, Positional 3
	Element 1: Filter keyword	*APPLDESC, *APPLTAG, *APPTYPE, *CHLNAME, *CONNAME, *PID, *TID, *UOWLOGDA, *UOWLOGTI, *UOWSTDA, *UOWSTTI, *URTYPE, *USERID	
	Element 2: Filter operator	*GT, *LT, *EQ, *NE, *GE, *LE, *LK, *NL, *CT, *EX, *CTG, *EXG	
	Element 3: Filter value	Character value	

Connection Identifier (CONN)

The connection identifiers to work with.

The possible values are:

***ALL**

All connection identifiers are selected.

connection-id

Specify the name of a specific connection identifier. The connection identifier is a 16 character hex string.

Message Queue Manager name (MQMNAME)

Specifies the name of the queue manager.

The possible values are:

***DFT**

Use the default queue manager.

queue-manager-name

The name of a message queue manager.

Filter command (WHERE)

This parameter can be used to selectively display only those queue manager connections with particular connection attributes.

The parameter takes three arguments, a keyword, an operator and a value.

Generic strings are allowed for values which are names.

The operator can take one of the following values:

***GT**

Greater than.

Applicable to integer and non-generic string values.

***LT**

Less than.

Applicable to integer and non-generic string values

***EQ**

Equal to.

Applicable to integer and non-generic string values.

***NE**

Not equal to.

Applicable to integer and non-generic string values.

***GE**

Greater than or equal to.

Applicable to integer and non-generic string values.

***LE**

Less than or equal to.

Applicable to integer and non-generic string values.

***LK**

Like.

Applicable to generic string values.

***NL**

Not like.

Applicable to generic string values.

***CT**

Contains.

Applicable to non-generic list values.

***EX**

Excludes.

Applicable to non-generic list values.

***CTG**

Contains generic.

Applicable to generic list values.

***EXG**

Excludes generic.

Applicable to generic list values.

The keyword can take one of the following values:

***APPLDESC**

The description of the application connected to the queue manager.

The filter value is the application description string.

***APPLTAG**

The tag of the application connected to the queue manager.

The filter value is the application tag string.

***APPTYPE**

The type of application connected to the queue manager.

The possible values are:

***DEF**

The attribute is unchanged.

***CICS**

Represents a CICS/400 application.

***UNIX**

Represents a UNIX or Linux application.

***OS400**

Represents an IBM i application.

***WINDOWS**

Represents a Windows application.

***WINDOWS_NT**

Represents a Windows NT application.

integer

User-defined application type in the range 65536 through 999999999.

***CHLNAME**

The name of the channel that owns the connection.

The filter value is the channel name.

***CONNAME**

The connection name associated with the channel that owns the connection.

The filter value is the connection name.

***PID**

The process identifier of the application that is connected to the queue manager.

The filter value is the process identifier integer.

***TID**

The thread identifier of the application that is connected to the queue manager.

The filter value is the thread identifier integer.

***UOWLOGDA**

The date that the transaction associated with the connection first wrote to the log.

The filter value is the date in the form yyyy-mm-dd.

***UOWLOGTI**

The time that the transaction associated with the connection first wrote to the log.

The filter value is the time in the form hh:mm:ss.

***UOWSTDA**

The date that the transaction associated with the connection was started.

The filter value is the date in the form yyyy-mm-dd.

***UOWSTTI**

The time that the transaction associated with the connection was started.

The filter value is the time in the form hh:mm:ss.

***URTYPE**

The type of unit of recovery identifier as seen by the queue manager.

The filter value is one of the following:

***QMGR**

A queue manager transaction.

***XA**

An externally coordinated transaction. This includes units of work which have been established using IBM i Start Commitment Control (STRCMTCTL).

***USERID**

The user identifier associated with the connection.

The filter value is user identifier name.

IBM i WRKMQMJRN (Work Queue Manager Journals)

Where allowed to run

All environments (*ALL)

Threadsafe

Yes

The Work With Queue Manager Journals command (WRKMQMJRN) displays a list of all the journals which are associated with a specific queue manager. This command can be used, for example, to configure remote journaling for a multi-instance queue manager.

Parameters

Keyword	Description	Choices	Notes
<u>MQMNAME</u>	Message Queue Manager name	<i>Character value, *DFT</i>	Optional, Positional 1

Message Queue Manager name (MQMNAME)

Specifies the name of the message queue manager to work with journals.

queue-manager-name

Specify the name of the queue manager. The name can contain up to 48 characters. The maximum number of characters is reduced if the system is using a double byte character set (DBCS).

IBM i WRKMQMLSR (Work with MQ Listeners)

Where allowed to run

All environments (*ALL)

Threadsafe

Yes

The Work with MQ Listener objects (WRKMQMLSR) command allows you to work with listener objects which are defined on the local queue manager.

This enables you to change, copy, create, delete, start, stop & display listener objects display and change authority to an MQ listener object.

This command also enables you to view the current status of all running listeners on the current system.

Parameters

Keyword	Description	Choices	Notes
<u>OPTION</u>	Option	*STATUS, *OBJECT	Optional, Positional 1
<u>LSRNAME</u>	Listener name	<i>Character value, *ALL</i>	Optional, Positional 2
<u>MQMNAME</u>	Message Queue Manager name	<i>Character value, *DFT</i>	Optional, Positional 3

Table 330. Command parameters (continued)

Keyword	Description	Choices	Notes
<u>WHERE</u>	Filter command	Single values: *NONE Other values: <i>Element list</i>	Optional, Positional 4
	Element 1: Filter keyword	*ALTDATA, *ALTTIME, *BACKLOG, *CONTROL, *IPADDR, *PORT, *TEXT	
	Element 2: Filter operator	*GT, *LT, *EQ, *NE, *GE, *LE, *LK, *NL, *CT, *EX, *CTG, *EXG	
	Element 3: Filter value	Character value	

Option (OPTION)

This option enables you to select whether you want to information on listener status or listener object definitions.

The possible values are:

*STATUS

Listener status information is displayed.

The parameters LSRNAME and WHERE are ignored. If MQMNAME is specified only the status of listeners running on the specified queue manager are displayed.

*OBJECT

Listener object information is displayed.

Listener name (LSRNAME)

The name or names of the listener objects.

The possible values are:

*ALL or *

All listener objects are selected.

generic-listener-name

The generic name of the listener objects. A generic name is a character string followed by an asterisk (*), for example ABC*, and it selects all listener objects having names that start with the character string.

You are recommended to specify the name required within quotation marks. Using this format ensures that your selection is precisely what you entered.

You cannot select all the uppercase and lowercase versions of a generic name on a single panel, without requesting all the names.

listener-name

Specify the name of a single listener object.

Message Queue Manager name (MQMNAME)

Specifies the name of the queue manager.

The possible values are:

*DFT

Use the default queue manager.

queue-manager-name

The name of a message queue manager.

Filter command (WHERE)

This parameter can be used to selectively display only those listener objects with particular listener attributes.

The parameter takes three arguments, a keyword, an operator and a value.

Generic strings are allowed for values which are names.

The operator can take one of the following values:

***GT**

Greater than.

Applicable to integer and non-generic string values.

***LT**

Less than.

Applicable to integer and non-generic string values

***EQ**

Equal to.

Applicable to integer and non-generic string values.

***NE**

Not equal to.

Applicable to integer and non-generic string values.

***GE**

Greater than or equal to.

Applicable to integer and non-generic string values.

***LE**

Less than or equal to.

Applicable to integer and non-generic string values.

***LK**

Like.

Applicable to generic string values.

***NL**

Not like.

Applicable to generic string values.

***CT**

Contains.

Applicable to non-generic list values.

***EX**

Excludes.

Applicable to non-generic list values.

***CTG**

Contains generic.

Applicable to generic list values.

***EXG**

Excludes generic.

Applicable to generic list values.

The keyword can take one of the following values:

***ALTDATE**

The date on which the definition or information was last altered.

The filter value is the date in the form yyyy-mm-dd.

***ALLTIME**

The time at which the definition or information was last altered.

The filter value is the time in the form hh:mm:ss.

***BACKLOG**

The number of concurrent connection requests supported.

The filter value is the integer backlog value.

***CONTROL**

Whether the listener is started and stopped with the queue manager.

The filter value is one of the following:

***MANUAL**

The listener is not automatically started or stopped.

***QMGR**

The listener is started and stopped as the queue manager is started and stopped.

***STARTONLY**

The listener is started as the queue manager is started, but is not requested to stop when the queue manager is stopped.

***IPADDR**

The local IP Address to be used by the listener.

The filter value is the IP Address.

***PORT**

The port number to be used by the listener.

The filter value is the integer port value.

***TEXT**

Descriptive comment.

The filter value is the text description of the listener.

 **WRKMQMSG (Work with MQ Messages)**

Where allowed to run

All environments (*ALL)

Threadsafe

Yes

The Work with MQ Messages (WRKMQMSG) command lists the messages on a specified local queue and allows you to work with those messages. From the list of messages, you can display the contents of a message and its associated message descriptor (MQMD).

Parameters

Keyword	Description	Choices	Notes
<u>QNAME</u>	Queue name	Character value	Required, Positional 1

Table 331. Command parameters (continued)

Keyword	Description	Choices	Notes
<u>MQMNAME</u>	Message Queue Manager name	Character value, *DFT	Optional, Positional 2
<u>FIRST</u>	First Message	1-30000, 1	Optional, Positional 3
<u>MAXMSG</u>	Maximum number of messages	1-30000, 48	Optional, Positional 4
<u>MAXMSGLEN</u>	Maximum message size	128-999999, 1024	Optional, Positional 5

Queue name (QNAME)

Specifies the name of the local queue.

The possible values are:

queue-name

Specify the name of the local queue.

Message Queue Manager name (MQMNAME)

Specifies the name of the message queue manager.

The possible values are:

*DFT

Use the default queue manager.

queue-manager-name

Specify the name of the queue manager.

First Message (FIRST)

Specifies the number of the first message to display.

The possible values are:

1

The number of the first message to display is 1.

message-number

Specify the number of the first message to display ranging from 1 through 30 000.

Maximum number of messages (MAXMSG)

Specifies the maximum number of messages to display.

The possible values are:

48

Display a maximum of 48 messages.

count-value

Specify a value for the maximum number of messages to display ranging from 1 through 30 000.

Maximum message size (MAXMSGLEN)

Specifies the maximum size of message data to display.

The size of a message, greater than the value specified, is suffixed by a plus (+) character to indicate that the message data is truncated.

The possible values are:

1024

The size of the message data is 1024 bytes.

length-value

Specify a value ranging from 128 through 999999.

IBM i WRKMQMNL (Work with MQ Namelist)

Where allowed to run

All environments (*ALL)

Threadsafe

Yes

The Work with MQ Namelists (WRKMQMNL) command allows you to work with multiple namelist definitions that are defined on the local queue manager. This enables you to copy, change, display, delete, display authority and edit authority of an MQ namelist object.

Parameters

Table 332. Command parameters

Keyword	Description	Choices	Notes
<u>NAMELIST</u>	Namelist	Character value, *ALL	Optional, Positional 1
<u>MQMNAME</u>	Message Queue Manager name	Character value, *DFT	Optional, Positional 2
<u>WHERE</u>	Filter command	Single values: *NONE Other values: <i>Element list</i>	Optional, Positional 3
	Element 1: Filter keyword	*ALTDATA, *ALTTIME, *NAMECNT, *NAMES, *TEXT	
	Element 2: Filter operator	*GT, *LT, *EQ, *NE, *GE, *LE, *LK, *NL, *CT, *EX, *CTG, *EXG	
	Element 3: Filter value	Character value	

Namelist (NAMELIST)

Specifies the name or names of the namelists.

The possible values are:

***ALL**

All namelist definitions are selected.

generic-namelist-name

Specify the generic name of the MQ namelists. A generic name is a character string followed by an asterisk (*). For example ABC*, it selects all namelists having names that start with the character string.

You are recommended to specify the name required within quotation marks. Using this format ensures that your selection is precisely what you entered.

You cannot select all the uppercase and lowercase versions of a generic name on a single panel, without requesting all the names.

namelist-name

Specify the name of the MQ namelist.

Message Queue Manager name (MQMNAME)

Specifies the name of the message queue manager.

The possible values are:

***DFT**

The default queue manager is used.

message-queue-manager-name

Specify the name of the queue manager.

Filter command (WHERE)

This parameter can be used to selectively display only those namelists with particular namelist attributes.

The parameter takes three arguments, a keyword, an operator and a value.

Generic strings are allowed for values which are names.

The operator can take one of the following values:

***GT**

Greater than.

Applicable to integer and non-generic string values.

***LT**

Less than.

Applicable to integer and non-generic string values

***EQ**

Equal to.

Applicable to integer and non-generic string values.

***NE**

Not equal to.

Applicable to integer and non-generic string values.

***GE**

Greater than or equal to.

Applicable to integer and non-generic string values.

***LE**

Less than or equal to.

Applicable to integer and non-generic string values.

***LK**

Like.

Applicable to generic string values.

***NL**

Not like.

Applicable to generic string values.

***CT**

Contains.

Applicable to non-generic list values.

***EX**

Excludes.

Applicable to non-generic list values.

***CTG**

Contains generic.

Applicable to generic list values.

***EXG**

Excludes generic.

Applicable to generic list values.

The keyword can take one of the following values:

***ALTDATE**

The date on which the definition or information was last altered.

The filter value is the date in the form yyyy-mm-dd.

***ALTTIME**

The time at which the definition or information was last altered.

The filter value is the time in the form hh:mm:ss.

***NAMECNT**

The number of names in the namelist.

The filter value is the integer number of names.

***NAMES**

The names in the namelist.

The filter value is the string name.

***TEXT**

Descriptive comment.

The filter value is the text description of the queue.

WRKMQMPRC (Work with MQ Processes)

Where allowed to run

All environments (*ALL)

Threadsafe

Yes

The Work with MQ Processes (WRKMQMPRC) command allows you to work with multiple process definitions that are defined on the local queue manager. This enables you to copy, change, display, delete, display authority, and edit authority of an MQ process object.

Parameters

<i>Table 333. Command parameters</i>			
Keyword	Description	Choices	Notes
<u>PRCNAME</u>	Process name	<i>Character value, *ALL</i>	Optional, Positional 1
<u>MQMNAME</u>	Message Queue Manager name	<i>Character value, *DFT</i>	Optional, Positional 2

Table 333. Command parameters (continued)

Keyword	Description	Choices	Notes
<u>WHERE</u>	Filter command	Single values: *NONE Other values: <i>Element list</i>	Optional, Positional 3
	Element 1: Filter keyword	*ALTDATA, *ALTTIME, *APPID, *APPTYPE, *ENVDATA, *TEXT, *USRDATA	
	Element 2: Filter operator	*GT, *LT, *EQ, *NE, *GE, *LE, *LK, *NL, *CT, *EX, *CTG, *EXG	
	Element 3: Filter value	Character value	

Process name (PRCNAME)

Specifies the name or names of the process definitions.

The possible values are:

***ALL**

All process definitions are selected.

generic-process-name

Specify the generic name of the MQ process definitions. A generic name is a character string followed by an asterisk (*). For example ABC*, it selects all process definitions having names that start with the character string.

You are recommended to specify the name required within quotation marks. Using this format ensures that your selection is precisely what you entered.

You cannot select all the uppercase and lowercase versions of a generic name on a single panel, without requesting all the names.

process-name

Specify the name of the MQ process definition.

Message Queue Manager name (MQMNAME)

Specifies the name of the queue manager.

The possible values are:

***DFT**

Use the default queue manager.

queue-manager-name

The name of a message queue manager.

Filter command (WHERE)

This parameter can be used to selectively display only those processes with particular process attributes.

The parameter takes three arguments, a keyword, an operator and a value.

Generic strings are allowed for values which are names.

The operator can take one of the following values:

***GT**

Greater than.

Applicable to integer and non-generic string values.

***LT**

Less than.

Applicable to integer and non-generic string values

***EQ**

Equal to.

Applicable to integer and non-generic string values.

***NE**

Not equal to.

Applicable to integer and non-generic string values.

***GE**

Greater than or equal to.

Applicable to integer and non-generic string values.

***LE**

Less than or equal to.

Applicable to integer and non-generic string values.

***LK**

Like.

Applicable to generic string values.

***NL**

Not like.

Applicable to generic string values.

***CT**

Contains.

Applicable to non-generic list values.

***EX**

Excludes.

Applicable to non-generic list values.

***CTG**

Contains generic.

Applicable to generic list values.

***EXG**

Excludes generic.

Applicable to generic list values.

The keyword can take one of the following values:

***ALTDATE**

The date on which the definition or information was last altered.

The filter value is the date in the form yyyy-mm-dd.

***ALLTIME**

The time at which the definition or information was last altered.

The filter value is the time in the form hh:mm:ss.

***APPID**

The name of the application to start.

The filter value is the name of the application.

***APPTYPE**

The type of the application to start.

The possible values are:

***DEF**

The attribute is unchanged.

***CICS**

Represents a CICS/400 application.

***UNIX**

Represents a UNIX or Linux application.

***OS400**

Represents an IBM i application.

***WINDOWS**

Represents a Windows application.

***WINDOWS_NT**

Represents a Windows NT application.

integer

User-defined application type in the range 65536 through 999999999.

***ENVDATA**

Environment data pertaining to the application.

The filter value is the environment data.

***TEXT**

Descriptive comment.

The filter value is the text description of the queue.

***USRDATA**

User data pertaining to the application.

The filter value is the user data.

 **WRKMQMQ (Work with MQ Queues)**

Where allowed to run

All environments (*ALL)

Threadsafe

Yes

The Work with MQ Queues (WRKMQMQ) command provides the function to work with multiple queues that are defined on the local queue manager. Using this command you can copy, change, display, delete, display authority and edit authority of an MQ Queue object.

Parameters

Table 334. Command parameters

Keyword	Description	Choices	Notes
<u>QNAME</u>	Queue name	Character value, *ALL	Optional, Positional 1
<u>QTYPE</u>	Queue type	*ALL , *ALS, *LCL, *MDL, *RMT	Optional, Positional 2
<u>MQMNAME</u>	Message Queue Manager name	Character value, *DFT	Optional, Positional 3

Table 334. Command parameters (continued)

Keyword	Description	Choices	Notes
<u>CLUSTER</u>	Cluster name	Character value, *ALL	Optional, Positional 4
<u>CLUSNL</u>	Cluster namelist name	Character value, *ALL	Optional, Positional 5
<u>WHERE</u>	Filter command	Single values: *NONE Other values: <i>Element list</i>	Optional, Positional 6
	Element 1: Filter keyword	*ACCTQ, *ALTDATE, *ALTTIME, *BKTTHLD, *BKTQNAME, *CLUSDATE, *CLUSNL, *CLUSQMGR, *CLUSQTYPE, *CLUSTER, *CLUSTIME, *CLWLPRTY, *CLWLRANK, *CLWLUSEQ, *CRDATE, *CRTIME, *CURDEPTH, *DEFBIND, *DFTPUTRESP, *DFNTYPE, *DFTMSGPST, *DFTPTY, *DFTSHARE, *DISTLIST, *FULLEVT, *GETDATE, *GETENBL, *GETTIME, *HDNBKTCNT, *HIGHEVT, *HIGHTHLD, *INITQNAME, *IPPROCS, *JOBS, *LOWEVT, *LOWTHLD, *MAXDEPTH, *MAXMSGLEN, *MEDIAREC, *MONQ, *MSGAGE, *MSGDLYSEQ, *MSGREADAHD, *NPMCLASS, *OPPROCS, *PRCNAME, *PROPCTL, *PUTDATE, *PUTENBL, *PUTTIME, *QMID, *QTYPE, *RMTMQMNAME, *RMTQNAME, *RTNITV, *SHARE, *SRVEVT, *SRVITV, *STATQ, *TARGTYPE, *TEXT, *TGTQNAME, *TMQNAME, *TRGDATA, *TRGDEPTH, *TRGENBL, *TRGMSGPTY, *TRGTYPE, *UNCOM, *USAGE	
	Element 2: Filter operator	*GT, *LT, *EQ, *NE, *GE, *LE, *LK, *NL, *CT, *EX, *CTG, *EXG	
	Element 3: Filter value	Character value	

Queue name (QNAME)

The name or names of the queues to be selected. The queues selected by this parameter can be further limited to a particular type, if the QTYPE keyword is specified.

The possible values are:

***ALL**

All queues are selected.

generic-queue-name

Specify the generic name of the queues to be selected. A generic name is a character string, followed by an asterisk (*). For example ABC*, it selects all queues having names that start with the character string.

Specify the name required within quotation marks. Using this format ensures that your selection is precisely what you entered.

You cannot select all the uppercase and lowercase versions of a generic name on a single panel, without requesting all the names.

queue-name

Specify the name of the queue.

Queue type (QTYPE)

This parameter can be specified to limit the queues that are displayed to a particular type.

The possible values are:

***ALL**

All queue types.

***ALS**

Alias queues.

***LCL**

Local queues.

***MDL**

Model queues.

***RMT**

Remote queues.

Message Queue Manager name (MQMNAME)

Specifies the name of the message queue manager.

The possible values are:

***DFT**

Use the default queue manager.

queue-manager-name

Specify the name of the queue manager.

Cluster name (CLUSTER)

This parameter can be specified to limit the queues that are displayed to be members of a particular cluster.

The possible values are:

***ALL**

All clusters.

generic-cluster-name

The generic name of a cluster.

cluster-name

The name of a cluster.

Cluster namelist name (CLUSNL)

This parameter can be specified to limit the queues that are displayed to be members of clusters within a cluster namelist.

The possible values are:

***ALL**

All cluster namelists.

generic-cluster-namelist-name

The generic name of a cluster namelist.

cluster-namelist-name

The name of a cluster namelist.

Filter command (WHERE)

This parameter can be used to selectively display only those queues with particular queue attributes.

The parameter takes three arguments, a keyword, an operator, and a value.

Generic strings are allowed for values which are names.

The operator can take one of the following values:

***GT**

Greater than.

Applicable to integer and non-generic string values.

***LT**

Less than.

Applicable to integer and non-generic string values

***EQ**

Equal to.

Applicable to integer and non-generic string values.

***NE**

Not equal to.

Applicable to integer and non-generic string values.

***GE**

Greater than or equal to.

Applicable to integer and non-generic string values.

***LE**

Less than or equal to.

Applicable to integer and non-generic string values.

***LK**

Like.

Applicable to generic string values.

***NL**

Not like.

Applicable to generic string values.

***CT**

Contains.

Applicable to non-generic list values.

***EX**

Excludes.

Applicable to non-generic list values.

***CTG**

Contains generic.

Applicable to generic list values.

***EXG**

Excludes generic.

Applicable to generic list values.

The keyword can take one of the following values:

***ACCTQ**

Queue Accounting.

The filter value is one of the following values:

***QMGR**

Accounting data collection is based upon the setting of the queue manager attribute ACCTQ.

***OFF**

Accounting data collection for this queue is disabled.

***ON**

Accounting data collection is enabled for this queue.

***ALTDATE**

The date on which the definition or information was last altered.

The filter value is the data in the form yyyy-mm-dd.

***ALTIME**

The time at which the definition or information was last altered.

The filter value is the time in the form hh:mm:ss.

***BKTTHLD**

Backout threshold.

The filter value is the integer threshold value.

***BKTQNAME**

Backout requeue name.

The filter value is the name of the queue.

***CLUSDATE**

The date on which the definition became available to the local queue manager.

The filter value is the date in the form yyyy-mm-dd.

***CLUSNL**

The namelist that defines the clusters that the queue is in.

The filter value is the name of the namelist.

***CLUSQMGR**

The name of the queue manager that hosts the queue.

The filter value is the name of the queue manager.

***CLUSQTYPE**

Cluster queue type.

The filter value is one of the following values:

***LCL**

The cluster queue represents a local queue.

***ALS**

The cluster queue represents an alias queue.

***RMT**

The cluster queue represents a remote queue.

***MQMALS**

The cluster queue represents a queue manager alias.

***CLUSTER**

The name of the cluster that the queue is in.

The filter value is the name of the cluster.

***CLUSTIME**

The time at which the definition became available to the local queue manager.

The filter value is the time in the form hh:mm:ss.

***CLWLPRTY**

Cluster workload priority.

The filter value is the integer priority.

***CLWLANK**

Cluster workload rank.

The filter value is the integer rank.

***CLWLUSEQ**

Cluster workload queue use.

The filter value is one of the following values:

***QMGR**

The value is inherited from the Queue Manager CLWLUSEQ attribute.

***LOCAL**

The local queue is the sole target of the MQPUT.

***ANY**

The queue manager treats such a local queue as another instance of the cluster queue for the purposes of workload distribution.

***CRDATE**

The date on which the queue was created.

The filter value is the date in the form yyyy-mm-dd.

***CRTIME**

The time at which the queue was created.

The filter value is the time in the form hh:mm:ss.

***CURDEPTH**

Current depth of queue.

The filter value is the integer depth value.

***DEFBIND**

Default message binding.

The filter value is one of the following values:

***OPEN**

The queue handle is bound to a specific instance of the cluster queue when the queue is opened.

***NOTFIXED**

The queue handle is not bound to any instance of the cluster queue.

***GROUP**

When the queue is opened, the queue handle is bound to a specific instance of the cluster queue for as long as there are messages in a message group. All messages in a message group are allocated to the same destination instance.

***DFTPRES**

Default Put Response.

The filter value is one of the following values:

***SYNC**

The put operation is issued synchronously.

***ASYNC**

The put operation is issued asynchronously.

***DFNTYPE**

Queue definition type.

The filter value is one of the following values:

***PREDEF**

Predefined queue.

***PERMDYN**

Permanent dynamic queue.

***TEMPDYN**

Temporary dynamic queue.

***DFTMSGPST**

Default persistence of the messages put on this queue.

The filter value is one of the following values:

***NO**

Messages on this queue are lost across a restart of the queue manager.

***YES**

Messages on this queue survive a restart of the queue manager.

***DFTPTY**

Default priority of the messages put on the queue.

The filter value is the integer priority value.

***DFTSHARE**

Default share option on a queue opened for input.

The filter value is one of the following values:

***NO**

The open request is for exclusive input from the queue.

***YES**

The open request is for shared input from the queue.

***DISTLIST**

Whether distribution lists are supported by the partner queue manager.

The filter value is one of the following values:

***NO**

Distribution lists are not supported by the partner queue manager.

***YES**

Distribution lists are supported by the partner queue manager.

***FULLEVT**

Whether Queue Depth Full events are generated.

The filter value is one of the following values:

***NO**

Queue Depth Full events are not generated.

***YES**

Queue Depth Full events are generated.

***GETDATE**

The date on which the last message was got from the queue since queue manager start. This field is only present when Queue Monitoring is not set to *OFF.

The filter value is the data in the form yyyy-mm-dd.

***GETENBL**

Whether applications are permitted to get messages from the queue.

The filter value is one of the following values:

***NO**

Applications cannot retrieve messages from the queue.

***YES**

Authorized applications can retrieve messages from the queue.

***GETTIME**

The time at which the last message was got from the queue since queue manager start. This field is only present when Queue Monitoring is not set to *OFF.

The filter value is the time in the form hh:mm:ss.

***HDNBKTCNT**

Whether the backout count is hardened.

The filter value is one of the following values:

***NO**

The backout count is not hardened.

***YES**

The backout count is hardened.

***HIGHEVT**

Whether Queue Depth High events are generated.

The filter value is one of the following values:

***NO**

Queue Depth High events are not generated.

***YES**

Queue Depth High events are generated.

***HIGHTHLD**

Queue Depth High event generation threshold.

The filter value is the integer threshold value.

***INITQNAME**

Initiation queue.

The filter value is the name of the queue.

***IPPROCS**

Number of handles indicating that the queue is open for input.

The filter value is the integer number of handles.

***JOBS**

The current number of jobs that have the queue open.

The filter value is the integer number of jobs.

***LOWEVT**

Whether Queue Depth Low events are generated.

The filter value is one of the following values:

***NO**

Queue Depth Low events are not generated.

***YES**

Queue Depth Low events are generated.

***LOWTHLD**

Queue Depth Low event generation threshold.

The filter value is the integer threshold value.

***MAXDEPTH**

Maximum depth of queue.

The filter value is the integer number of messages.

***MAXMSGLEN**

Maximum message length.

The filter value is the integer message length.

***MEDIAREC**

The journal receiver containing the last media recovery image. This field is only present for local queues.

The filter value is the journal receiver string.

***MONQ**

Online Monitoring Data.

The filter value is one of the following values:

***QMGR**

The collection of Online Monitoring Data is inherited from the setting of the queue manager attribute MONQ.

***OFF**

Online Monitoring Data collection for this queue is disabled.

***LOW**

Monitoring data collection is turned on with a low ratio of data collection.

***MEDIUM**

Monitoring data collection is turned on with a moderate ratio of data collection.

***HIGH**

Monitoring data collection is turned on with a high ratio of data collection.

***MSGAGE**

The age in seconds of the oldest message on the Queue. This field is only present when Queue Monitoring is not set to *OFF.

The filter value is the integer message age.

***MSGDLYSEQ**

Message delivery sequence.

The filter value is one of the following values:

***PTY**

Messages are delivered in FIFO order within priority.

***FIFO**

Messages are delivered in FIFO order regardless of priority.

***NPMCLASS**

Non-persistent message class.

The filter value is one of the following values:

***NORMAL**

Non-persistent message class is normal.

***HIGH**

Non-persistent message class is high.

***MSGREADAHD**

Message read ahead.

The filter value is one of the following values:

***DISABLED**

Read ahead is disabled.

***NO**

Non-persistent messages are not sent to the client ahead of an application requesting them.

***YES**

Non-persistent messages are sent to the client ahead of an application requesting them.

***OPPROCS**

Number of handles indicating that the queue is open for output.

The filter value is the integer number of handles.

***PRCNAME**

Process name.

The filter value is the name of the process.

***PROPCTL**

Message Property Control.

The filter value is one of the following values:

***COMPAT**

Compatibility mode

***NONE**

No properties are returned to the application.

***ALL**

All properties are returned to the application.

***FORCE**

Properties are returned to the application in one or more MQRFH2 headers.

***V6COMPAT**

An MQRFH2 header is returned formatted as it was sent. Its code page and encoding might be altered. If the message is a publication it might have a psc folder inserted into its contents.

***PUTDATE**

The date on which the last message was put to the queue since queue manager start. This field is only present when Queue Monitoring is not set to *OFF.

The filter value is the data in the form yyyy-mm-dd.

***PUTENBL**

Whether applications are permitted to put messages to the queue.

The filter value is one of the following values:

***NO**

Messages cannot be added to the queue.

***YES**

Messages can be added to the queue by authorized applications.

***PUTTIME**

The time at which the last message was put to the queue since queue manager start. This field is only present when Queue Monitoring is not set to *OFF.

The filter value is the time in the form hh:mm:ss.

***QMID**

Internally generated unique name of the queue manager that hosts the queue.

The filter value is the name of the queue manager.

***QTYPE**

Queue type.

The filter value is one of the following values:

***LCL**

Local queue.

***ALS**

Alias queue.

***RMT**

Remote queue.

***MDL**

Model queue.

***RMTMQMNAME**

Remote queue manager name.

The filter value is the name of the queue manager.

***RMTQNAME**

Name of the local queue, as known by the remote queue manager.

The filter value is the name of the queue.

***RTNITV**

Retention interval.

The filter value is the integer interval value.

***SHARE**

Whether the queue can be shared.

The filter value is one of the following values:

***NO**

Only a single application instance can open the queue for input.

***YES**

More than one application instance can open the queue for input.

***SRVEVT**

Whether service interval events are generated.

The filter value is one of the following values:

***HIGH**

Service Interval High events are generated.

***OK**

Service Interval OK events are generated.

***NONE**

No service interval events are generated.

***SRVITV**

Service interval event generation threshold.

The filter value is the integer threshold value.

***STATQ**

Statistics data.

The filter value is one of the following values:

***QMGR**

Statistics data collection is based upon the setting of the queue manager attribute STATQ.

***OFF**

Statistics data collection for this queue is disabled.

***ON**

Statistics data collection is enabled for this queue.

***TARGTYPE**

Target Type.

The filter value is one of the following values:

***QUEUE**

Queue object.

***TOPIC**

Topic object.

***TEXT**

Descriptive comment.

The filter value is the text description of the queue.

***TGTQNAME**

Target queue for which this queue is an alias.

The filter value is the name of the queue.

***TMQNAME**

Transmission queue name.

The filter value is the name of the queue.

***TRGDATA**

Trigger data.

The filter value is the text of the trigger message.

***TRGDEPTH**

Trigger depth.

The filter value is the integer number of messages.

***TRGENBL**

Whether triggering is enabled.

The filter value is one of the following values:

***NO**

Triggering is not enabled.

***YES**

Triggering is enabled.

***TRGMSGPTY**

Threshold message priority for triggers.

The filter value is the integer priority value.

***TRGTYPE**

Trigger type.

The filter value is one of the following values:

***FIRST**

When the number of messages on the queue goes from 0 to 1.

***ALL**

Every time a message arrives on the queue.

***DEPTH**

When the number of messages on the queue equals the value of the TRGDEPTH attribute.

***NONE**

No trigger messages are written.

***UNCOM**

The number of uncommitted changes pending for the queue.

The filter value is one of the following values:

***NO**

There are no uncommitted changes pending.

***YES**

There are uncommitted changes pending.

***USAGE**

Whether the queue is a transmission queue.

The filter value is one of the following values:

***NORMAL**

The queue is not a transmission queue.

***TMQ**

The queue is a transmission queue.

WRKMQMSPL (Work with MQM Security Policies)

Where allowed to run

All environments (*ALL)

Threadsafe

Yes

The Work with MQM Security Policies (WRKMQMSPL) command lists all security policies for a queue manager.

Security Policies are used by Advanced Message Security to control how messages should be protected when being put, browsed, or destructively removed from queues.

Additionally, [DSPMQM](#) displays whether security policies are enabled for the queue manager. Note that the Advanced Message Security license must be installed when the queue manager was started for this to occur.

Parameters

Keyword	Description	Choices	Notes
OUTPUT	Output	* , *PRINT	Optional, Positional 1
MQMNAME	Message Queue Manager name	<i>Character value</i> , *DFT	Optional, Positional 2

Output (OUTPUT)

Specifies whether the output from the command is shown at the requesting workstation, or printed with the job's spooled output.

The possible values are:

Output requested by an interactive job is shown on the display. Output requested by a batch job is printed with the job's spooled output.

***PRINT**

A detailed list of the users and their authorities registered with the selected authority profile record is printed with the job's spooled output.

Message Queue Manager name (MQMNAME)

Specifies the name of the queue manager.

***DFT**

Use the default queue manager.

queue-manager-name

Specify the name of the queue manager.

IBM i WRKMQMSTS (Work with Queue Status)

Where allowed to run

All environments (*ALL)

Threadsafe

Yes

The Work with Queue Status (WRKMQMSTS) command lists the jobs which have an IBM MQ queue currently open. The command allows you to determine what options a queue was opened with and also allows you to check to see which channels and connections have a queue open.

Parameters

Keyword	Description	Choices	Notes
<u>MQMNAME</u>	Message Queue Manager name	Character value, *DFT	Optional, Positional 1
<u>QNAME</u>	Queue name	Character value	Optional, Positional 2
<u>WHERE</u>	Filter command	Single values: *NONE Other values: <i>Element list</i>	Optional, Positional 3
	Element 1: Filter keyword	*APPLDESC, *APPLTAG, *BROWSE, *CHLNAME, *CONNAME, *INPUT, *INQUIRE, *JOB, *OUTPUT, *SET, *URTYPE	
	Element 2: Filter operator	*GT, *LT, *EQ, *NE, *GE, *LE, *LK, *NL, *CT, *EX, *CTG, *EXG	
	Element 3: Filter value	Character value	

Message Queue Manager name (MQMNAME)

Specifies the name of the message queue manager.

The possible values are:

***DFT**

Use the default queue manager.

queue-manager-name

Specify the name of the queue manager.

Queue name (QNAME)

Specifies the name of the local queue.

The possible values are:

queue-name

Specify the name of the local queue.

Filter command (WHERE)

This parameter can be used to selectively display only the jobs with particular attributes that have the queue open.

The parameter takes three arguments, a keyword, an operator and a value.

Generic strings are allowed for values which are names.

The operator can take one of the following values:

***GT**

Greater than.

Applicable to integer and non-generic string values.

***LT**

Less than.

Applicable to integer and non-generic string values

***EQ**

Equal to.

Applicable to integer and non-generic string values.

***NE**

Not equal to.

Applicable to integer and non-generic string values.

***GE**

Greater than or equal to.

Applicable to integer and non-generic string values.

***LE**

Less than or equal to.

Applicable to integer and non-generic string values.

***LK**

Like.

Applicable to generic string values.

***NL**

Not like.

Applicable to generic string values.

***CT**

Contains.

Applicable to non-generic list values.

***EX**

Excludes.

Applicable to non-generic list values.

***CTG**

Contains generic.

Applicable to generic list values.

***EXG**

Excludes generic.

Applicable to generic list values.

The keyword can take one of the following values:

***APPLDESC**

The description of the application which has the queue open.

The filter value is the application description string.

***APPLTAG**

The tag of the application which has the queue open.

The filter value is the application tag string.

***BROWSE**

Whether the job has the queue open for browsing.

The filter value is either *NO or *YES.

***CHLNAME**

The name of the channel which has the queue open.

The filter value is the channel name.

***CONNNAME**

The connection name of the channel which has the queue open.

The filter value is the connection name.

***INPUT**

Whether the job has the queue open for input.

The filter value is one of the following:

***NO**

The job does not have the queue open for input.

***SHARED**

The job has the queue open for shared input.

***EXCL**

The job has the queue open for exclusive input.

***INQUIRE**

Whether the job has the queue open for inquiry.

The filter value is either *NO or *YES.

***JOB**

The name of the job which has the queue open.

The filter value is the job name.

***OUTPUT**

Whether the job has the queue open for output.

The filter value is either *NO or *YES.

***SET**

Whether the job has the queue open for set.

The filter value is either *NO or *YES.

***URTYPE**

The type of unit of work recovery identifier.

The filter value is one of the following:

***QMGR**

Queue manager unit of work recovery identifier.

***XA**

XA unit of work recovery identifier.

WRKMQMSUB (Work with MQ Subscriptions)

Where allowed to run

All environments (*ALL)

Threadsafe

Yes

The Work with MQ Subscriptions (WRKMQMSUB) command allows you to work with multiple subscriptions that are defined on the local queue manager. This enables you to copy, change, display and delete IBM MQ subscriptions.

Parameters

<i>Table 337. Command parameters</i>			
Keyword	Description	Choices	Notes
<u>SUBNAME</u>	Subscription name	<i>Character value</i> , *ALL	Optional, Positional 1
<u>MQMNAME</u>	Message Queue Manager name	<i>Character value</i> , *DFT	Optional, Positional 2
<u>WHERE</u>	Filter command	Single values: *NONE Other values: <i>Element list</i>	Optional, Positional 3
	Element 1: Filter keyword	*DEST, *DESTCLASS, *DESTCRLID, *DESTMQM, *EXPIRY, *PSPROP, *PUBACCT, *PUBAPPID, *PUBPTY, *REQONLY, *SELECTOR, *SELTYPE, *SUBSCOPE, *SUBID, *TOPICOBJ, *TOPICSTR, *USERDATA, *VARUSER, *WSHEMA	
	Element 2: Filter operator	*GT, *LT, *EQ, *NE, *GE, *LE, *LK, *NL, *CT, *EX, *CTG, *EXG	
	Element 3: Filter value	Character value	

Subscription name (SUBNAME)

Specifies the name or names of the subscriptions.

The possible values are:

***ALL**

All subscriptions are selected.

generic-subscription-name

Specify the generic name of the MQ subscriptions. A generic name is a character string followed by an asterisk (*). For example ABC*, it selects all subscriptions having names that start with the character string.

You are recommended to specify the name required within quotation marks. Using this format ensures that your selection is precisely what you entered.

You cannot select all the uppercase and lowercase versions of a generic name on a single panel, without requesting all the names.

subscription-name

Specify the name of the MQ subscription.

Message Queue Manager name (MQMNAME)

Specifies the name of the Queue Manager.

The possible values are:

***DFT**

Use the default Queue Manager.

queue-manager-name

The name of a Queue Manager.

Filter command (WHERE)

This parameter can be used to selectively display only those subscriptions with particular subscription attributes.

The parameter takes three arguments, a keyword, an operator and a value.

Generic strings are allowed for values which are names.

The operator can take one of the following values:

***GT**

Greater than.

Applicable to integer and non-generic string values.

***LT**

Less than.

Applicable to integer and non-generic string values

***EQ**

Equal to.

Applicable to integer and non-generic string values.

***NE**

Not equal to.

Applicable to integer and non-generic string values.

***GE**

Greater than or equal to.

Applicable to integer and non-generic string values.

***LE**

Less than or equal to.

Applicable to integer and non-generic string values.

***LK**

Like.

Applicable to generic string values.

***NL**

Not like.

Applicable to generic string values.

***CT**

Contains.

Applicable to non-generic list values.

***EX**

Excludes.

Applicable to non-generic list values.

***CTG**

Contains generic.

Applicable to generic list values.

***EXG**

Excludes generic.

Applicable to generic list values.

The keyword can take one of the following values:

***DEST**

The destination queue for messages published to this subscription.

The filter value is the name of the queue.

***DESTCLASS**

Specifies whether this is a managed subscription.

The filter value is one of the following:

***MANAGED**

The destination is managed.

***PROVIDED**

The destination is a queue.

***DESTCRLID**

The correlation identifier for messages published to this subscription.

The filter value is the 48 character hexadecimal string representing the 24 byte correlation identifier.

***DESTMQM**

The destination queue manager for messages published to this subscription.

The filter value is the name of the queue manager.

***EXPIRY**

The expiry time of the subscription.

The filter value is the integer expiry time.

***PSPROP**

The manner in which publish / subscribe related message properties are added to messages sent to this subscription.

The filter value is one of the following:

***NONE**

Publish / subscribe properties are not added to the message.

***COMPAT**

Publish / subscribe properties are added to the message to maintain compatibility with V6 Publish / Subscribe.

***RFH2**

Publish / subscribe properties are added to the message within an RFH 2 header.

***PUBACCT**

The accounting token for messages published to this subscription.

The filter value is the 64 character hexadecimal string representing the 32 byte publish accounting token.

***PUBAPPID**

The publish application identity for messages published to this subscription.

The filter value is the publish application identifier.

***PUBPTY**

The priority of the message sent to this subscription.

The filter value is the integer priority.

***REQONLY**

Whether the subscriber will poll for updates via MQSUBRQ API, or whether all publications are delivered to this subscription.

The filter value is one of the following:

***YES**

Publications are only delivered to this subscription in response to an MQSUBRQ API.

***NO**

All publications on the topic are delivered to this subscription.

***SELECTOR**

The SQL 92 selector string to be applied to messages published on the named topic to select whether they are eligible for this subscription.

The filter value is the selector string.

***SELTYPE**

The type of SQL 92 selector string that has been specified.

The filter value is one of the following:

***NONE**

No selector has been specified.

***STANDARD**

A selector string has been specified that only references properties of the message and uses the standard selector syntax.

***EXTENDED**

A selector string has been specified that uses extended selectors syntax, typically by referencing the content of the message. Selector strings of this type cannot be handled internally by the queue manager; the use of extended message selectors can only be handled by another program, such as IBM Integration Bus.

***SUBSCOPE**

Determines whether this subscription is forwarded to other queue managers, so that the subscriber receives messages published at those other queue managers.

The filter value is one of the following:

***ALL**

The subscription is forwarded to all queue managers directly connected through a publish/subscribe collective or hierarchy.

***QMGR**

The subscription forwards messages published on the topic only within this queue manager.

Note: Individual subscribers can only restrict **SUBSCOPE**. If the parameter is set to ALL at topic level, then an individual subscriber can restrict it to QMGR for this subscription. However, if the parameter is set to QMGR at topic level, then setting an individual subscriber to ALL has no effect.

***SUBID**

The subscription identifier associated with the subscription.

The filter value is the 48 character hexadecimal string representing the 24 byte subscription identifier.

***TOPICOBJ**

The topic object associated with the subscription.

The filter value is the name of the topic object.

***TOPICSTR**

The topic string associated with the subscription.

The filter value is the topic string.

***USERDATA**

The user data associated with the subscription.

The filter value is the user data.

***VARUSER**

Whether user profiles other than the creator of the subscription can connect to it.

The filter value is one of the following:

***ANY**

Any user profiles can connect to the subscription.

***FIXED**

Only the user profile that created the subscription can connect to it.

***WSHEMA**

The schema to be used when interpreting wildcard characters in the topic string.

The filter value is one of the following:

***TOPIC**

Wildcard characters represent portions of the topic hierarchy.

***CHAR**

Wildcard characters represent portions of strings.

WRKMQMSVC (Work with MQ Service object)

Where allowed to run

All environments (*ALL)

Threadsafe

Yes

The Work with MQ Service objects (WRKMQMSVC) command allows you to work with multiple service objects that are defined on the local queue manager.

This enables you to start, stop, change, copy, create, delete, display, and display and change authority to an MQ service object.

Parameters

Table 338. Command parameters			
Keyword	Description	Choices	Notes
<u>SVCNAME</u>	Service name	Character value, *ALL	Optional, Positional 1
<u>MQMNAME</u>	Message Queue Manager name	Character value, *DFT	Optional, Positional 2
<u>WHERE</u>	Filter command	Single values: *NONE Other values: <i>Element list</i>	Optional, Positional 3
	Element 1: Filter keyword	*ALTDATA, *ALTTIME, *CONTROL, *ENDARG, *ENDCMD, *STDERR, *STDOUT, *STRARG, *STRCMD, *TEXT, *TYPE	
	Element 2: Filter operator	*GT, *LT, *EQ, *NE, *GE, *LE, *LK, *NL, *CT, *EX, *CTG, *EXG	
	Element 3: Filter value	Character value	

Service name (SVCNAME)

The name or names of the service objects.

The possible values are:

***ALL or ***

All service objects are selected.

generic-service-name

The generic name of the service objects. A generic name is a character string followed by an asterisk (*). For example ABC*, it selects all service objects having names that start with the character string.

You are recommended to specify the name required within quotation marks. Using this format ensures that your selection is precisely what you entered.

You cannot select all the uppercase and lowercase versions of a generic name on a single panel, without requesting all the names.

service-name

Specify the name of a single service object.

Message Queue Manager name (MQMNAME)

Specifies the name of the queue manager.

The possible values are:

***DFT**

Use the default queue manager.

queue-manager-name

The name of a message queue manager.

Filter command (WHERE)

This parameter can be used to selectively display only those service objects with particular service attributes.

The parameter takes three arguments, a keyword, an operator and a value.

Generic strings are allowed for values which are names.

The operator can take one of the following values:

***GT**

Greater than.

Applicable to integer and non-generic string values.

***LT**

Less than.

Applicable to integer and non-generic string values

***EQ**

Equal to.

Applicable to integer and non-generic string values.

***NE**

Not equal to.

Applicable to integer and non-generic string values.

***GE**

Greater than or equal to.

Applicable to integer and non-generic string values.

***LE**

Less than or equal to.

Applicable to integer and non-generic string values.

***LK**

Like.

Applicable to generic string values.

***NL**

Not like.

Applicable to generic string values.

***CT**

Contains.

Applicable to non-generic list values.

***EX**

Excludes.

Applicable to non-generic list values.

***CTG**

Contains generic.

Applicable to generic list values.

***EXG**

Excludes generic.

Applicable to generic list values.

The keyword can take one of the following values:

***ALTDATE**

The date on which the definition or information was last altered.

The filter value is the date in the form yyyy-mm-dd.

***ALTTIME**

The time at which the definition or information was last altered.

The filter value is the time in the form hh:mm:ss.

***CONTROL**

Whether the service is started and stopped with the queue manager.

The filter value is one of the following:

***MANUAL**

The service is not automatically started or stopped.

***QMGR**

The service is started and stopped as the queue manager is started and stopped.

***STARTONLY**

The service is started as the queue manager is started, is not be requested to stop when the queue manager is stopped.

***ENDARG**

The arguments passed to the end program when the service is requested to stop.

The filter value is the arguments string.

***ENDCMD**

The name of the executable to run when the service is requested to stop.

The filter value is the program name string.

***STDERR**

The standard error path.

The filter value is the path name.

***STDOUT**

The standard output path.

The filter value is the path name.

***STRARG**

The arguments passed to the program at startup.

The filter value is the arguments string.

***STRCMD**

The name of the program to run.

The filter value is the program name string.

***TEXT**

Descriptive comment.

The filter value is the text description of the service.

***TYPE**

Mode in which to run service.

The filter value is one of the following:

***CMD**

When started the command is executed but no status is collected or displayed.

***SVR**

The status of the executable started is monitored and displayed.

 **WRKMQM TOP (Work with MQ Topics)****Where allowed to run**

All environments (*ALL)

Threadsafe

Yes

The Work with MQ Topics (WRKMQMTOP) command allows you to work with multiple topic objects that are defined on the local queue manager. This enables you to copy, change, display, delete, display authority, edit authority, record and recover an MQ topic object.

Parameters

Table 339. Command parameters

Keyword	Description	Choices	Notes
<u>TOPNAME</u>	Topic name	Character value, *ALL	Optional, Positional 1
<u>MQMNAME</u>	Message Queue Manager name	Character value, *DFT	Optional, Positional 2
<u>WHERE</u>	Filter command	Single values: *NONE Other values: <i>Element list</i>	Optional, Positional 3
	Element 1: Filter keyword	*ALTDAT, *ALTTIME, *DFTMSGPST, *DFTPTY, *DFTPUTRESP, *DURSUB, *MGDDURMDL, *MGDNDURMDL, *NPMSGDLV, *PMSGDLV, *PUBENBL, *SUBENBL, *TEXT, *TOPNAME, *TOPICSTR, *WILDCARD	
	Element 2: Filter operator	*GT, *LT, *EQ, *NE, *GE, *LE, *LK, *NL, *CT, *EX, *CTG, *EXG	
	Element 3: Filter value	Character value	

Topic name (TOPNAME)

Specifies the name or names of the topic objects.

The possible values are:

***ALL**

All topic objects are selected.

generic-topic-name

Specify the generic name of the MQ topic objects. A generic name is a character string followed by an asterisk (*). For example ABC*, it selects all topic objects having names that start with the character string.

You are recommended to specify the name required within quotation marks. Using this format ensures that your selection is precisely what you entered.

You cannot select all the uppercase and lowercase versions of a generic name on a single panel, without requesting all the names.

topic-name

Specify the name of the MQ topic object.

Message Queue Manager name (MQMNAME)

Specifies the name of the Queue Manager.

The possible values are:

***DFT**

Use the default Queue Manager.

queue-manager-name

The name of a Queue Manager.

Filter command (WHERE)

This parameter can be used to selectively display only those topics with particular topic attributes.

The parameter takes three arguments, a keyword, an operator and a value.

Generic strings are allowed for values which are names.

The operator can take one of the following values:

***GT**

Greater than.

Applicable to integer and non-generic string values.

***LT**

Less than.

Applicable to integer and non-generic string values

***EQ**

Equal to.

Applicable to integer and non-generic string values.

***NE**

Not equal to.

Applicable to integer and non-generic string values.

***GE**

Greater than or equal to.

Applicable to integer and non-generic string values.

***LE**

Less than or equal to.

Applicable to integer and non-generic string values.

***LK**

Like.

Applicable to generic string values.

***NL**

Not like.

Applicable to generic string values.

***CT**

Contains.

Applicable to non-generic list values.

***EX**

Excludes.

Applicable to non-generic list values.

***CTG**

Contains generic.

Applicable to generic list values.

***EXG**

Excludes generic.

Applicable to generic list values.

The keyword can take one of the following values:

***ALTDATE**

The date on which the object or information was last altered.

The filter value is the date in the form yyyy-mm-dd.

***ALLTIME**

The time at which the object or information was last altered.

The filter value is the time in the form hh:mm:ss.

***DFTMSGPST**

The default persistence for messages associated with this topic.

The filter value is one of the following:

***ASPARENT**

Default persistence for messages is inherited from the parent topic.

***NO**

Messages associated with this topic are lost across a restart of the queue manager.

***YES**

Messages associated with this topic survive a restart of the queue manager.

***DFTPUTRESP**

Default Put Response.

The filter value is one of the following:

***ASPARENT**

The default response type is based on the setting of the first parent administrative node found in the topic tree relating to this topic.

***SYNC**

Put operations to the queue that specify MQPMO_RESPONSE_AS_Q_DEF are issued as if MQPMO_SYNC_RESPONSE had been specified instead.

***ASYNC**

Put operations to the queue that specify MQPMO_RESPONSE_AS_Q_DEF are always issued as if MQPMO_ASYNC_RESPONSE had been specified instead.

***DFTPTY**

Default priority for messages associated with this topic.

The filter value is the integer priority value.

***DURSUB**

Specifies whether the topic permits durable subscriptions.

The filter value is one of the following:

***ASPARENT**

This topic behaves in the same way as the parent topic.

***NO**

This topic does not permit durable subscriptions.

***YES**

This topic does permit durable subscriptions.

***MGDDURMDL**

The name of the model queue for managed durable subscriptions.

The filter value is the name of the queue.

***MGDNDURMDL**

The name of the model queue for managed non-durable subscriptions.

The filter value is the name of the queue.

***NPMSGDLV**

Specifies the delivery mechanism for non-persistent messages published to this topic.

The filter value is one of the following:

***ALL**

All non-persistent messages are published to this topic.

***ALLDUR**

All durable non-persistent messages are published to this topic.

***ALLAVAIL**

All available non-persistent messages are published to this topic.

***ASPARENT**

This topic behaves in the same way as the parent topic.

***PMSGDLV**

Specifies the delivery mechanism for persistent messages published to this topic.

The filter value is one of the following:

***ALL**

All persistent messages are published to this topic.

***ALLDUR**

All durable persistent messages are published to this topic.

***ALLAVAIL**

All available persistent messages are published to this topic.

***ASPARENT**

This topic behaves in the same way as the parent topic.

***PUBENBL**

Specifies whether the topic allows publications.

The filter value is one of the following:

***ASPARENT**

This topic behaves in the same way as the parent topic.

***NO**

This topic does not have publication enabled.

***YES**

This topic does have publication enabled.

***SUBENBL**

Specifies whether the topic allows subscriptions.

The filter value is one of the following:

***ASPARENT**

This topic behaves in the same way as the parent topic.

***NO**

This topic does not allow subscriptions.

***YES**

This topic allows subscriptions.

***TEXT**

Descriptive comment.

The filter value is the text description of the topic.

***TOPNAME**

The name of the topic.

The filter value is the name of the topic.

***TOPICSTR**

The topic string, used to identify the topic node.

The filter value is a character string.

***WILDCARD**

Specifies the behavior of wildcard subscriptions with respect to this topic.

The filter value is one of the following:

***PASSTHRU**

Subscriptions made to a wildcarded topic less specific than the topic string at this topic object will receive publications made to this topic and to topic strings more specific than this topic.

***BLOCK**

Subscriptions made to a wildcarded topic less specific than the topic string at this topic object will not receive publications made to this topic or to topic strings more specific than this topic.

WRKMQMTRN (Work with MQ Transactions)
Where allowed to run

All environments (*ALL)

Threadsafe

Yes

The work with MQ transactions (WRKMQMTRN) command lists details of internally or externally coordinated in-doubt transactions.

Parameters

<i>Table 340. Command parameters</i>			
Keyword	Description	Choices	Notes
<u>TYPE</u>	Transaction type	*ALL , *EXT, *INT, *MQI, *XA, *OS400	Optional, Positional 1
<u>MQMNAME</u>	Message Queue Manager name	<i>Character value</i> , *DFT	Optional, Positional 2

Transaction type (TYPE)

Specifies the type of transactions.

***ALL**

Requests details of all the in-doubt transactions.

***EXT**

Requests details of externally coordinated, in-doubt transactions. Such transactions are those for which IBM MQ has been asked to prepare to commit, but has not yet been informed of the transaction outcome.

***INT**

Requests details of internally coordinated, in-doubt transactions. Such transactions are those for which each resource manager has been asked to prepare to commit, but IBM MQ has yet to inform the resource managers of the transaction outcome.

Message Queue Manager name (MQMNAME)

Specifies the name of the message queue manager.

The possible values are:

***DFT**

Use the default queue manager.

message-queue-manager-name

Specify the name of the queue manager.

MFT commands reference

All Managed File Transfer (MFT) commands are listed with links to their detailed descriptions.

Command name	Purpose
Commands for migration:	
Commands for configuration:	
fteChangeDefaultConfigurationOptions	Change the default configuration options that you want Managed File Transfer to use
fteCreateAgent	Create a Managed File Transfer Agent
fteCreateBridgeAgent	Create a Managed File Transfer protocol bridge agent
fteCreateCDAgent	Create a Managed File Transfer Connect:Direct bridge agent
fteCreateEnvironment	Set the environment variable for the configuration and transfer of files for the Redistributable Managed File Transfer Agent.
fteCreateLogger	Create a Managed File Transfer logger
fteDefine	Generate the configuration scripts necessary to define the specified objects.
fteDelete	Generate the configuration scripts necessary to remove the specified objects.
fteDeleteAgent	Delete a particular Managed File Transfer Agent
fteDeleteLogger	Delete a Managed File Transfer logger
fteModifyAgent	Windows only. Modify an agent, Connect:Direct bridge agent, or protocol bridge agent to run as a Windows service.
fteModifyLogger	Windows only. Modify the logger to run as a Windows service.
fteSetupCommands	Specify the details of the queue manager that connects to the IBM MQ network when you issue commands
fteSetupCoordination	Configure a Managed File Transfer coordination queue manager
Commands for administration:	
fteCancelTransfer	Cancel a file transfer
fteCleanAgent	Clean up the queues used by an agent
fteClearMonitorHistory	Clear the history of a resource monitor
fteCreateMonitor	Create and start a new resource monitor
fteCreateTemplate	Create a transfer template for future use
fteCreateTransfer	Create and start a new file transfer
fteDeleteMonitor	Stop and remove an existing resource monitor
fteDeleteScheduledTransfer	Delete a particular file transfer that you have previously scheduled
fteDeleteTemplates	Delete existing file transfer templates

<i>Table 341. Managed File Transfer commands and their purpose (continued)</i>	
Command name	Purpose
fteListAgents	List all of the agents registered against a particular coordination queue manager
fteListMonitors	List all of the resource monitors registered against a particular coordination queue manager
fteListScheduledTransfers	List all of the Managed File Transfer transfers that you previously created using the command line or the IBM MQ Explorer.
fteListTemplates	List all the file transfer templates for a coordination queue manager
ftePingAgent	Pings an agent to determine whether the agent is active and able to process transfers.
 fteSetProductID	Set z/OS SCRT recording product id
fteShowAgentDetails	Display the details of a particular agent
fteShowLoggerDetails	Display the details of a particular logger
fteStartAgent	Start a particular agent before using it to transfer files
fteStartLogger	Start logger
fteStartMonitor	Start a resource monitor without needing to stop or restart an agent
fteStopAgent	Stop a particular agent
fteStopLogger	Stop logger
fteStopMonitor	Stop a resource monitor without needing to stop or restart an agent
Command for security:	
fteObfuscate	Encrypt sensitive data in credentials files.
Commands for troubleshooting:	
fteDisplayVersion	Display the product version
fteSetAgentLogLevel	Enable or disable diagnostic information logging for file transfers between a Managed File Transfer protocol bridge agent and FTP/SFTP/FTPS file servers.
fteSetAgentTraceLevel	Set the level of agent trace to run
fteSetLoggerTraceLevel	Set the level of logger trace to run
fteRAS	Run the RAS gathering tool

See [Installed MFT command sets](#) for a table showing which commands are installed with which Managed File Transfer offering.

The syntax for each command and its parameters is presented in the form of a syntax diagram. For an explanation of how to use these diagrams, see [How to read syntax diagrams](#).

Related reference

[“Which MFT commands and processes connect to which queue manager” on page 2010](#)

A Managed File Transfer topology consists of a number of different components.

[“\[z/OS\]fteBatch, fteCommon and ftePlatform helper scripts” on page 2020](#)

fteBatch, fteCommon and ftePlatform are scripts that are provided by Managed File Transfer in the `MQ_INSTALLATION_PATH/bin` directory as helper scripts.  The fteBatch script is present on z/OS only.

Which MFT commands and processes connect to which queue manager

A Managed File Transfer topology consists of a number of different components.

These components are:

- One or more agents, with their associated agent queue manager
- A coordination queue manager
- A command queue manager
- A number of commands that are used to administer the topology, and submit managed transfers
- An optional logger, which collects information about the managed transfers that are performed by the agents in the topology
- The IBM MQ Explorer Managed File Transfer plugin, which can be used to perform some administrative tasks and view information about managed transfers.

Agents, loggers, commands, and the IBM MQ Explorer Managed File Transfer plugin connect to one or more queue managers when they run.

The following tables summarizes which queue manager agents, loggers, commands, and IBM MQ Explorer Managed File Transfer plugin connect to, when they run.

If there are no X characters for a command or process in the table, the command does not connect to any queue manager or process when it runs.

Note: Some commands can only be run on specific machines. For more information, see [“Where you can run MFT commands from”](#) on page 2016.

Command name	Agent queue manager	Command queue manager	Coordination queue manager	Logger queue manager
fteAnt				
fteCancelTransfer		X		
fteChangeDefaultConfigurationOptions				
fteCleanAgent “1” on page 2011	X			
fteClearMonitorHistory		X

Note:

1. The agent must be stopped before you run this command

Table 343. Summary of which Managed File Transfer processes connect to which queue manager

Processes	Agent queue manager	Command queue manager	Coordination queue manager	Logger queue manager
Managed File Transfer agents	X			
Managed File Transfer plug-in for IBM MQ Explorer		X	X	
Managed File Transfer logger			X	X

The file that contains the credentials information that is required to connect to each type of queue manager, that is, agent, command, and coordination queue managers, can be specified in the associated properties file. For example, the coordination queue manager has a `coordination.properties` file. In

this file, you can set the **coordinationQMgrAuthenticationCredentialsFile** property to point to the credentials file.

The commands that connect to the coordination queue manager use the credentials information that is specified in that file. If security is enabled on a queue manager and this property is incorrectly set, MFT commands do not successfully complete. For more information, see [MFT and IBM MQ connection authentication](#).

Details of which MFT commands connect to which queue manager

Further information on which Managed File Transfer commands connect to which queue manager.

This topic expands on the information in [“Which MFT commands and processes connect to which queue manager”](#) on page 2010, together with some illustrations.

Agent queue managers

Every agent has its own agent queue manager. The agent uses system queues hosted on this queue manager to maintain state information and receive requests for work.

A single queue manager can act as the agent queue manager for multiple agents. Agent queue managers are connected to the coordination queue manager, the command queue manager, and other agent queue managers using sender and receiver channels.

The **fteCreateAgent**, **fteCreateBridgeAgent**, and **fteCreateCDAgent** commands take the agent queue manager name as an argument.

When these commands are run, they connect to the specified queue manager and send a message to the coordination queue manager indicating that the agent has been added to the Managed File Transfer topology.

Similarly, when **fteDeleteAgent** is run, it connects to the agent queue manager and sends a message to the coordination queue manager, informing it that the agent has now been removed from the Managed File Transfer topology.

Figure 1. The various **fteCreate** commands, along with the **fteDeleteAgent** command, connect to the agent queue manager and send a message to the coordination queue manager to either register or deregister an agent from the topology.

Attention: `fteCleanAgent` connects to the agent queue manager, and removes any state information for that agent from its system queues.

Running this command could have an impact on the whole topology. As such, you should only run this command under guidance from IBM.

Figure 2. The **`fteCleanAgent`** command connects directly to the agent queue manager, and removes state information from the system queues of the agent

The following commands connect to the agent queue manager:

- [`fteCleanAgent`](#)
- [`fteCreateAgent`](#)
- [`fteCreateBridgeAgent`](#)
- [`fteCreateCDAgent`](#)
- [`fteDeleteAgent`](#)

Coordination queue managers

The coordination queue manager for a Managed File Transfer topology is a central hub that has knowledge of the entire topology. The coordination queue manager is connected to all of the agent queue managers in a topology through sender and receiver channels. Agents regularly publish status information to the coordination queue manager, and store their transfer templates there.

Figure 3. Agents publish status information or store transfer templates on the coordination queue manager

When any of the preceding commands that connect to the coordination queue manager are run, they connect directly to the coordination queue manager and either:

- Create or delete a transfer template.
- Query state information about agents, monitors, or scheduled transfers, and display that information to the user.

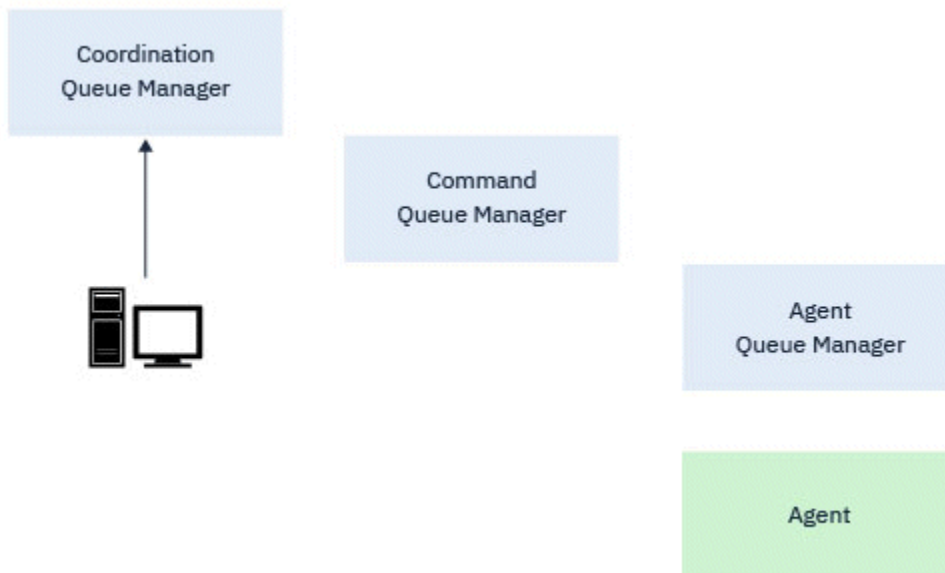

Figure 4. Commands then connect directly to the coordination queue manager to either obtain the appropriate status information or work with transfer templates.

The following commands connect to the coordination queue manager:

- [fteCreateTemplate](#)
- [fteDeleteAgent](#)
- [fteDeleteTemplates](#)

- [fteListAgents](#)
- [fteListMonitors](#)
- [fteListScheduledTransfers](#)
- [fteListTemplates](#)
- [fteShowAgentDetails](#)

Command queue managers

The command queue manager acts as a gateway into an MFT topology. It is connected to the agent queue managers through sender and receiver channels. When one of the commands listed is run, they connect directly to the command queue manager, and send a message to the specified agent. This message is routed through the IBM MQ network to the agent queue manager, where it is picked up by the agent and processed.

When any of the commands that connect to the queue manager are run, they:

- Connect to the command queue manager.
- Create a temporary reply queue.
- Send a message containing the command details to the appropriate agent.

The message is routed through the IBM MQ network to the agent queue manager, where it is picked up by the agent and processed.

After the agent has processed the command, the agent sends a reply back to the command queue manager, where the reply is picked up by the command.

Figure 5. The commands connect to the command queue manager. The message containing the command is then routed through the IBM MQ network to the correct agent queue manager, where it is picked up by the agent.

The following commands connect to the command queue manager:

- [fteCancelTransfer](#)
- [fteCreateMonitor](#)
- [fteCreateTransfer](#)
- [fteDeleteMonitor](#)
- [fteDeleteScheduledTransfer](#)

- [ftePingAgent](#)
- [fteStartMonitor](#)
- [fteStopAgent](#)
- [fteStopMonitor](#)

Where you can run MFT commands from

The following table summarize whether Managed File Transfer commands can be run locally or remotely.

Where the command is shown as:

- Local only - the commands can only run on the local installation.
- Local to agent - the commands can only run on the local agent installation relevant to that command.

For example, the **fteCreateBridgeAgent** command can connect to the local bridge agent, shown as *X (Bridge)* and the **fteCreateCDAgent** command can connect to the local CD agent, shown as *X (CD)*.

- Local to logger agent- the commands can only run on the local logger installation.
- Local and remote - you can run the command from any system that can connect to the command or coordination queue manager.

If there are no X characters for a command in the table, the command cannot be run in that situation.

Command name	Local	Local to agent	Local to logger agent	Local and remote
fteCancelTransfer				X
fteCleanAgent				X
fteCreateAgent		X		
fteCreateBridgeAgent		X (Bridge)		
fteCreateCDAgent		X (CD)		
fteCreateEnvironment		X

Authority to use MFT commands

Your user ID must be a member of the mqm group if you want to issue Managed File Transfer commands, unless you have already configured IBM MQ to allow users who are not in the mqm group to issue commands.

 For more information about defining an alternative group to mqm on z/OS, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

For more information about authorization, see [Authority to administer IBM MQ](#).  If you are using IBM i, start with the following topic: [IBM MQ authorities](#).

A subset of the Managed File Transfer commands can be issued using the IBM MQ Explorer.

Issuing commands from AIX, Linux, and Windows systems

Note the following environment-specific information for issuing commands:

Managed File Transfer for Windows

All commands can be issued from a command line. Command names are not case-sensitive: You can enter them in uppercase, lowercase, or a combination of uppercase and lowercase. However, arguments to control commands (such as queue names) and parameters (such as **-m** for queue manager name) are case-sensitive.

In the syntax descriptions, the hyphen (-) is used as a flag indicator.

Managed File Transfer for AIX and Linux systems

All Managed File Transfer commands can be issued from a shell. All commands are case-sensitive.

Issuing commands from z/OS systems

From IBM MQ for z/OS 9.2, Managed File Transfer is installed in to the `mqft` directory of the z/OS UNIX System Services (z/OS UNIX) Components; for example: `/mqm/V9R2M0/mqft`.

The Managed File Transfer commands are in the `bin` directory underneath the `mqft` directory; for example: `/mqm/V9R2M0/mqft/bin`.

Important: This is different from earlier releases, where the `bin` and `mqft` directories were peers of each other.

The commands can be run from either of the following options:

- Directly from the z/OS UNIX environment by specifying the path to the command or including the `bin` subdirectory in the user command path.
- From a PDSE data set of commands configured from the PDSE command template library, for a particular agent or logger. For more information, see [Creating an MFT Agent or Logger command data set](#).

Issuing commands from the IBM i platform

Note the following environment-specific information for issuing commands on IBM i:

- You can start Managed File Transfer commands using the Qshell interpreter. To start the Qshell interpreter, issue the **STRQSH** command from an IBM i system command line.
- When you run commands in the Qshell environment, command names are not case-sensitive: You can enter them in uppercase, lowercase, or a combination of uppercase and lowercase. However, arguments to control commands (such as queue names) and parameters (such as `-m` for queue manager name) are case-sensitive.

[Return codes for MFT](#)

Tracing MFT commands

You can trace any of the Managed File Transfer commands to help with problem determination from the command line.

Purpose

Use the **-trace** parameter for any MFT command to enable trace at a specified level. The trace files produced are located in your current working directory unless the **-tracePath** parameter is included to identify a different directory.

Because running trace can affect your performance significantly and can produce a large amount of trace data, run trace with care and only when necessary. Typically, enable trace only when asked to do so by your IBM service representative.

You can set further trace properties, for example trace file size and the number of trace files to keep, in the `agent.properties` file. These properties are described in [Advanced agent properties: Tracing and logging](#).

Syntax

Parameters

-trace classes=level

Required. Level to set the trace and which classes to apply the trace to. Specify the following format:

```
classes=level
```

For example:

```
com.ibm.wmqfte=all
```

which traces all Managed File Transfer classes.

Specify a colon-separated list of class specifications that you want the level of trace to apply to. If you do not specify this parameter, the trace level is applied to all agent classes.

If *classes* start with a plus sign (+), the list of trace classes following the plus sign are added to any existing trace classes currently being traced.

The valid trace level options are as follows and are listed in ascending order of trace file size and detail:

off

Switches the agent trace off but continues to write information to the log files. This is the default option.

flow

Captures data for trace points associated with processing flow in the agent.

moderate

Captures a moderate amount of diagnostic information in the trace.

verbose

Captures a verbose amount of diagnostic information in the trace.

all

Sets agent trace to run on all agent classes.

-tracePath directory path

Optional. Specify the directory that you want the trace to be written to. For example, c:\temp.

 If you do not specify this parameter, the value is the directory that the command was issued from. For example, on z/OS:

```
 /u/smith/fte/wmqmft/mqft/logs/MQPV/loggers/BFGLG1/logs/
```

This parameter is valid only when the **-trace** parameter is specified.

Example

In this example the trace level is set to all, meaning that all of the classes belonging to AGENT.NAME are traced for the **fteStartAgent** command:

Note: When the agent is started, the trace goes to *mft_config/logscoordination_qmgr/agents/agent*

```
fteStartAgent -trace com.ibm.wmqfte=all -tracePath /u/mft/trace AGENT.NAME
```

In this example the trace level is set to moderate for the com.ibm.wmqfte.common classes for the agent AGENT.NAME. A moderate amount of trace is captured for the **ftePingAgent** command:

```
ftePingAgent -trace com.ibm.wmqfte.common=moderate AGENT.NAME
```

In this example the trace level is set to moderate for the `com.ibm.wmqfte.common` classes for the agent `AGENT.NAME`, and the trace is written to the `c:\$user` directory. A moderate amount of trace is captured for the **ftePingAgent** command:

```
ftePingAgent -trace com.ibm.wmqfte.common=moderate -tracePath c:\$user AGENT.NAME
```

fteBatch, fteCommon and ftePlatform helper scripts

`fteBatch`, `fteCommon` and `ftePlatform` are scripts that are provided by Managed File Transfer in the `MQ_INSTALLATION_PATH/bin` directory as helper scripts.  The `fteBatch` script is present on z/OS only.

fteBatch script (z/OS only)

`fteBatch` is a helper script for running Managed File Transfer from the JZOS Batch Launcher. `fteBatch` is installed on z/OS only. Typically Managed File Transfer is started using the supplied command shell scripts, which perform some environment configuration before starting the Java class appropriate to that function. When Managed File Transfer is started using the JZOS Batch Launcher, the Java class is started directly from the Launcher. `fteBatch` can be called as part of the launcher setup to place the required class name into an environment variable and performs the setup work that the normal command shell scripts perform before starting Java. This provides a level of isolation between your jobs and the internal class names used by Managed File Transfer.

 The `fteBatch` command is deprecated for Managed File Transfer in IBM MQ 8.0, as you can run Managed File Transfer through the new PDSE data set of commands. For more information, see [Creating an MFT Agent or Logger command data set](#).

fteCommon

`fteCommon` is a helper script started by the other Managed File Transfer command scripts to perform common setup processing before starting Java.

ftePlatform

`ftePlatform` is a helper script started by the `fteCommon` script to perform platform-specific setup processing.

fteCancelTransfer (cancel an MFT transfer)

Use the **fteCancelTransfer** command to cancel a Managed File Transfer transfer. You can issue this command against either the source or destination agent for the transfer.

Purpose

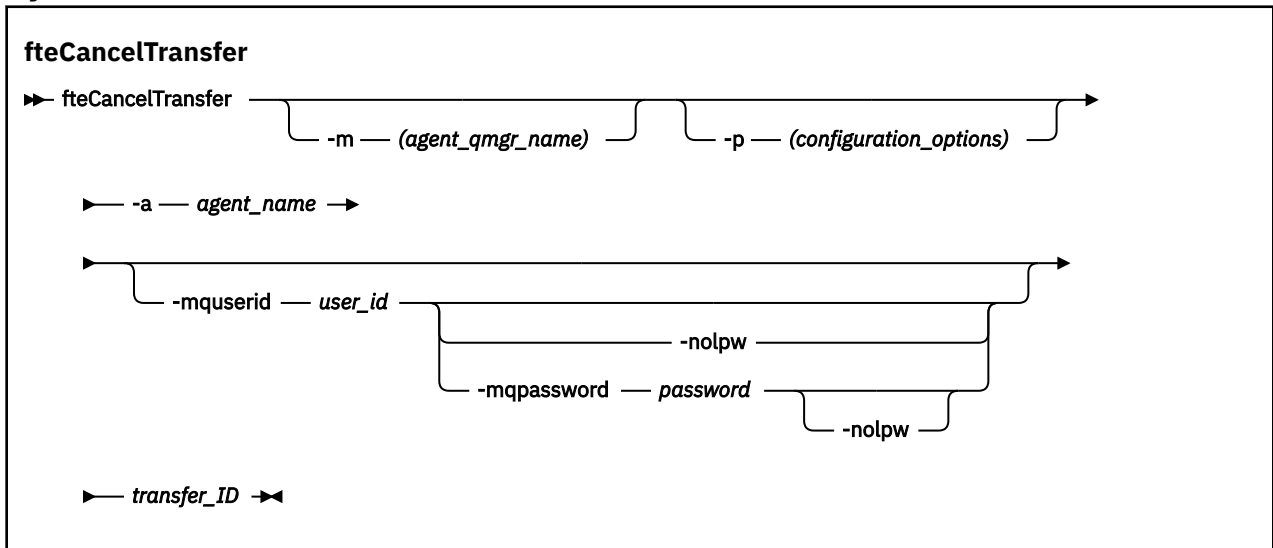

If you issue the **fteCancelTransfer** command while that transfer is currently in progress, any files already transferred as part of that transfer remain on the destination system and are not deleted. Any files partially transferred as part of that transfer are deleted from the destination system. The destination side of the transfer logs that transfer as "cancelled".

If a transfer to a Connect:Direct node is canceled, any files partially transferred as part of the canceled transfer remain on the destination system and are not deleted.

You can run the **fteCancelTransfer** command from any system that can connect to the IBM MQ network and then route to the agent queue manager. Specifically for the command to run, you must have installed Managed File Transfer on this system and you must have configured Managed File Transfer on this system to communicate with the IBM MQ network. If no connectivity details are available, the agent queue manager details are used for connection instead, provided these details are available.

Specify the optional **-p** parameter for this command only if you want to use a set of configuration options different from your default set. See [Configuration options](#) for more information.

Syntax

Parameters

-m agent_qmgr_name

Optional. The name of the agent queue manager. This agent must be either the source or destination agent for the transfer you want to cancel. If you do not specify this parameter, the cancel request is sent to the queue manager identified by the set of configuration options you are using.

-p configuration_options

Optional. This parameter determines the set of configuration options to use to cancel the transfer. By convention use the name of a non-default coordination queue manager as the input for this parameter. The command then uses the set of properties files associated with this non-default coordination queue manager.

If you do not specify this parameter, the set of configuration options based on the default coordination queue manager is used.

-a agent_name

Required. The name of either the source or destination agent of the transfer that you want to cancel.

-mquserid user_id

Optional. Specifies the user ID to authenticate with the command queue manager.

-mqpassword password

Optional. Specifies the password to authenticate with the coordination queue manager.

When the **-mqpassword** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

From IBM MQ 9.3, the command defaults to using [MQCSP](#) authentication, and sends the user ID and password to be authenticated to the queue manager in an MQCSP structure.

-nolpw

Optional. Specify this parameter if the command connects to a queue manager that does not support passwords longer than 12 characters.

When the **-nolpw** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid** and **-nolpw**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

Note: If you specify the **-no1pw** option, and the password is longer than 12 characters the command fails with error message BFGCL0829E.

transfer_ID

Required. The ID of the transfer you want to cancel. The transfer ID (also known as the request ID) is displayed at the command line after you issue the **fteCreateTransfer** command. Transfer IDs are also included in file transfer log messages or are displayed in the IBM MQ Explorer Transfer Log panel.

-? or -h

Optional. Displays command syntax.

Example

In this example AGENT1 is the source agent for the transfer to be canceled.

```
fteCancelTransfer -a AGENT1 414d5120514d5f4c4d343336303920201159c54820027102
```

Return codes

0

Either the command completed successfully or the specified transfer ID is unknown to the agent. If the transfer ID is unknown to the agent, the most likely reason is that the transfer has already completed or has been canceled.

1

Command ended unsuccessfully.

Related reference

[“fteCreateTransfer \(start a new file transfer\)” on page 2079](#)

The **fteCreateTransfer** command creates and starts a new file transfer from the command line. This command can start a file transfer immediately, schedule a file transfer for a future time and date, repeat a scheduled transfer one or more times, and trigger a file transfer based on certain conditions.

fteChangeDefaultConfigurationOptions (change default configuration options for MFT)

Use the **fteChangeDefaultConfigurationOptions** command to change the default configuration options that you want Managed File Transfer to use. The value of the configuration options defines the group of properties files that Managed File Transfer uses.

Important:  On IBM MQ for AIX, Linux, and Windows, only users who are IBM MQ administrators (and members of the mqm group) can run this command. If you try to run this command as a user who is not an IBM MQ administrator, you will receive the error message BFGCL0502E: You are not authorized to perform the requested operation. and the command will not run.

 On z/OS systems, the user must satisfy (at least) one of these conditions in order to run the command:

- Be a member of the mqm group (if the mqm group is defined on the system).
- Be a member of the group named in the BFG_GROUP_NAME environment variable (if one is named).
- Have no value set in the BFG_GROUP_NAME environment variable when the command is run.

Purpose

Your default Managed File Transfer configuration options are established the first time you use the [fteSetupCoordination](#) command to configure a queue manager as the coordination queue manager. During the installation of the MFT product, the mqft directory is created under <MQ_DATA_PATH> if it does not already exist. Additionally, configuration, installations, and logs directories are created under the mqft directory, if they do not already exist.

By using the **fteChangeDefaultConfigurationOptions** command you can change the default coordination queue manager that is defined in the `installation.properties` file. If you change this coordination queue manager, Managed File Transfer uses the configuration options given by the structured set of directories and property files contained in the directory you used as input for `configuration_options` by default. This directory name is the same as the coordination queue manager used by agents under this configuration.

See [Configuration options](#) for more information about the `installation.properties` file.

Syntax

fteChangeDefaultConfigurationOptions

```
►► fteChangeDefaultConfigurationOptions — configuration_options ◄◄
```

Parameters

configuration_options

Required. This parameter specifies the default configuration options that you want to change to. Use the name of a non-default coordination queue manager as the input for this parameter.

-? or -h

Optional. Displays command syntax.

Example

In this example, the default configuration options are changed to QM_COORD2:

```
fteChangeDefaultConfigurationOptions QM_COORD2
```

Return codes

0

Command completed successfully.

1

Command ended unsuccessfully.

Related concepts

[Configuration options](#)

fteCleanAgent (clean up an MFT Agent)

Use the **fteCleanAgent** command to clean up the queues that a Managed File Transfer Agent uses, by deleting messages from the persistent and non-persistent queues used by the agent. Use the **fteCleanAgent** command if you are having problems starting an agent, which might be caused by information remaining on the queues used by the agent.

Purpose

Use the **fteCleanAgent** command to delete messages from the persistent and non-persistent queues used by the agent. Specifically, this command can carry out the following actions:

- Remove any transfers that were in progress to this agent or from this agent before the transfer was stopped. These transfers are not resumed when the agent restarts
- Remove any commands that have already been submitted to the agent, but have not yet been carried out
- Delete all resource monitors stored on the agent

- Delete all scheduled transfers stored on the agent
- Delete all invalid messages stored on the agent

If the agent is a Connect:Direct bridge agent, the **-ms**, **-ss**, and **-ims** parameters are not valid. For Connect:Direct bridge agents the command also carries out the following actions:

- Deletes all files from the directory where the Connect:Direct bridge agent temporarily stores files while they are being transferred. The location of this directory is defined by the **cdTmpDir** parameter
- Displays information about the Connect:Direct processes that are associated with any ongoing transfers

You must, by default, specify which Managed File Transfer state to clear by passing the appropriate parameters to the **fteCleanAgent** command, as well as providing an agent name. This means that, by default, **fteCleanAgent** does not clear all in-progress and pending transfers, resource monitor definitions and scheduled transfer definitions for the agent specified. You can enable or disable this behavior by setting the **failCleanAgentWithNoArguments** property in the `command.properties` file to the appropriate value:

- By default, the value of **failCleanAgentWithNoArguments** is `true`, which means that the **fteCleanAgent** command fails to run if only the **agent_name** parameter is specified.
- If **failCleanAgentWithNoArguments** is set to `false` and only the **agent_name** parameter is specified, **fteCleanAgent** behaves in the same way as it does when you specify the **-all** parameter.

You must run the **fteCleanAgent** command on an agent that has been stopped. If you try to run the command on an agent that is currently running, you receive an error. This command does not start the agent. The **fteCleanAgent** command cleans up an agent on the system where you issue the command. You cannot clean up an agent on a remote system. To run the **fteCleanAgent** command you must have write access to the agent lock file, which is located at `MQ_DATA_PATH\mqft\logs\coordination_QMgr_name\agents\agent_name\agent.lock`

The FTEAGENT group must have GET and BROWSE authority on the following queues to run **fteCleanAgent** successfully:

- `SYSTEM.FTE.COMMAND.agent_name`
- `SYSTEM.FTE.EVENT.agent_name`
- `SYSTEM.FTE.STATE.agent_name`

See [Restricting group authorities for MFT-specific resources](#) for further information about the FTEAGENT group and restricting group authorities.

If you are running the **fteCleanAgent** command on an agent that is connected to its queue manager in bindings mode, and the agent has recently stopped running, the **fteCleanAgent** command might report messaging problem: MQRC 2042. This MQRC occurs because a queue handle for the agent still exists in the queue manager. After a short delay the queue manager removes this handle, and you can reissue **fteCleanAgent**.

Specify the optional **-p** parameter for this command only if you want to use a set of configuration options different from your default set. See [Configuration options](#) for more information.

Note: When cleaning a Connect:Direct bridge agent, the user ID used to run the **fteCleanAgent** command must have read and write access to the Connect:Direct bridge agent temporary directory.

Syntax

Parameters

You can use the **fteCleanAgent** command to delete specific artifacts. For example, you can specify the **-trs** command to delete pending transfers but not change any resource monitors and scheduled transfers.

-trs or -transfers

Optional. Specifies that in-progress and pending transfers are to be deleted from the agent. You cannot specify this parameter with **-all** or **-ims** parameters.

-ms or -monitors

Optional. Specifies that all resource monitor definitions are to be deleted from the agent. You cannot specify this parameter with **-all** or **-ims** parameters.

-ss or -schedules

Optional. Specifies that all scheduled transfer definitions are to be deleted from the agent. You cannot specify this parameter with the **-all** or **-ims** parameters.

-all or -allAgentConfiguration

Optional. Specifies that all transfers, resource monitor definitions, and scheduled transfer definitions are to be deleted from the agent. You cannot specify this parameter with the **-trs**, **-ss**, **-ms**, or **-ims** parameters.

Attention: You should use the **all** parameter only if no other options are available. The action of deleting transfers, resource monitor definitions, and scheduled transfer definitions can have a significant impact on your enterprise.

-ims or -invalidMessages

Optional. Specifies that all invalid messages are to be deleted from the agent. You cannot specify this parameter with the **-trs**, **-ss**, **-ms**, or **-all** parameters.

-cdu user_name

Optional. Only valid if the agent being cleaned is a Connect:Direct bridge agent. If this parameter is specified, the command uses the user name provided to make a connection to the Connect:Direct bridge node and retrieve additional information about existing Connect:Direct processes. If you do not specify this parameter, the agent is cleaned but information about Connect:Direct processes is not displayed.

-cdp password

Optional. Valid only if the agent being cleaned is a Connect:Direct bridge agent and you have specified the **-cdu** parameter. If you specify the **-cdp** parameter, the command uses the password provided to make a connection to the Connect:Direct bridge node and retrieve additional information about existing Connect:Direct processes. If you do not specify this parameter, and the **-cdu** parameter has been specified, you are asked to provide the password interactively.

-mquserid user_id

Optional. Specifies the user ID to authenticate with the agent queue manager.

-mqpassword password

Optional. Specifies the password to authenticate with the coordination queue manager.

When the **-mqpassword** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

From IBM MQ 9.3, the command defaults to using [MQCSP](#) authentication, and sends the user ID and password to be authenticated to the queue manager in an MQCSP structure.

-nolpw

Optional. Specify this parameter if the command connects to a queue manager that does not support passwords longer than 12 characters.

When the **-nolpw** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid** and **-nolpw**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

Note: If you specify the **-nolpw** option, and the password is longer than 12 characters the command fails with error message BFGCL0829E.

-p configuration_options

Optional. This parameter determines the set of configuration options that is used to clean up an agent. By convention use the name of a non-default coordination queue manager as the input for this parameter. The command then uses the set of properties files associated with this non-default coordination queue manager.

If you do not specify this parameter, the set of configuration options based on the default coordination queue manager is used.

agent_name

Required. The name of the Managed File Transfer agent that you want to clean up.

-? or -h

Optional. Displays command syntax.

Examples

In this basic example, all the queues used by AGENT2 are cleaned up:

```
C:\Documents and Settings\Administrator>fteCleanAgent -all AGENT2
5724-H72 Copyright IBM Corp. 2008, 2024. ALL RIGHTS RESERVED

All messages will be deleted from all queues

State Queue Entries:

Transfer Identifier:          414d5120716d31202020202020202020202020202786de4d20485b03
Source Agent Name:          AGENT2
Destination Agent Name:    AGENT3
```

```
Transfer Identifier:      414d5120716d31202020202020202020202020202786de4d20487203
Source Agent Name:      AGENT2
Destination Agent Name: AGENT3
```

Command Queue New Transfer Entries:

Scheduler Queue Schedule Entries:

Directory Monitor Configuration for "MONITOR1" has been cleared from the Agent.

```
Schedule Identifier:      1
Source Agent Name:        AGENT2
Destination Agent Name:   AGENT3
```

BFGCL0149I: The agent 'AGENT2' has been cleaned.

In this example, the invalid messages queue used by AGENT2 are cleaned up:

```
C:\Documents and Settings\Administrator>fteCleanAgent -ims AGENT2
5724-H72 Copyright IBM Corp. 2008, 2024. ALL RIGHTS RESERVED
```

Invalid messages will be deleted from all queues

State Queue Entries:

Warning - Invalid message found on the queue

Command Queue New Transfer Entries:

Warning - Invalid message found on the queue

Scheduler Queue Schedule Entries:

Warning - Invalid message found on the queue

BFGCL0149I: The agent 'AGENT2' has been cleaned.

In this example, the transfers queue used by the Connect:Direct bridge agent, AGENT_CD_BRIDGE, is cleaned up:

```
C:\Documents and Settings\Administrator>fteCleanAgent -trs -cdu USER1 AGENT_CD_BRIDGE
5724-H72 Copyright IBM Corp. 2008, 2024. ALL RIGHTS RESERVED
Enter Connect:Direct password:
```

All messages will be deleted from the state and command queues

State Queue Entries:

```
Transfer Identifier:      414d5120716d31202020202020202020202020202786de4d2048a703
Source Agent Name:        AGENT2
Destination Agent Name:   AGENT_CD_BRIDGE
Connect:Direct PNODE Name: CDNODE1
Connect:Direct SNODE Name: CDNODE2
Connect:Direct Current Processes: Name=FA34F8, Number=139
```

Command Queue New Transfer Entries:

BFGCL0149I: The agent 'AGENT_CD_BRIDGE' has been cleaned.

Return codes

- 0** Command completed successfully.
- 1** Command ended unsuccessfully.

Related reference

[“fteStopAgent \(stop an MFT agent\)” on page 2175](#)

Use the **fteStopAgent** command to either stop a Managed File Transfer agent in a controlled way or to stop an agent immediately if necessary using the **-i** parameter.

[“fteDeleteAgent \(delete an MFT agent and its configuration\)” on page 2104](#)

The **fteDeleteAgent** command deletes a Managed File Transfer Agent and its configuration. If the agent is a protocol bridge agent, the user credentials file is left on the file system.

[The MFT command.properties file](#)

fteClearMonitorHistory (clear resource monitor history)

Use the **fteClearMonitorHistory** command to clear the history of a resource monitor.

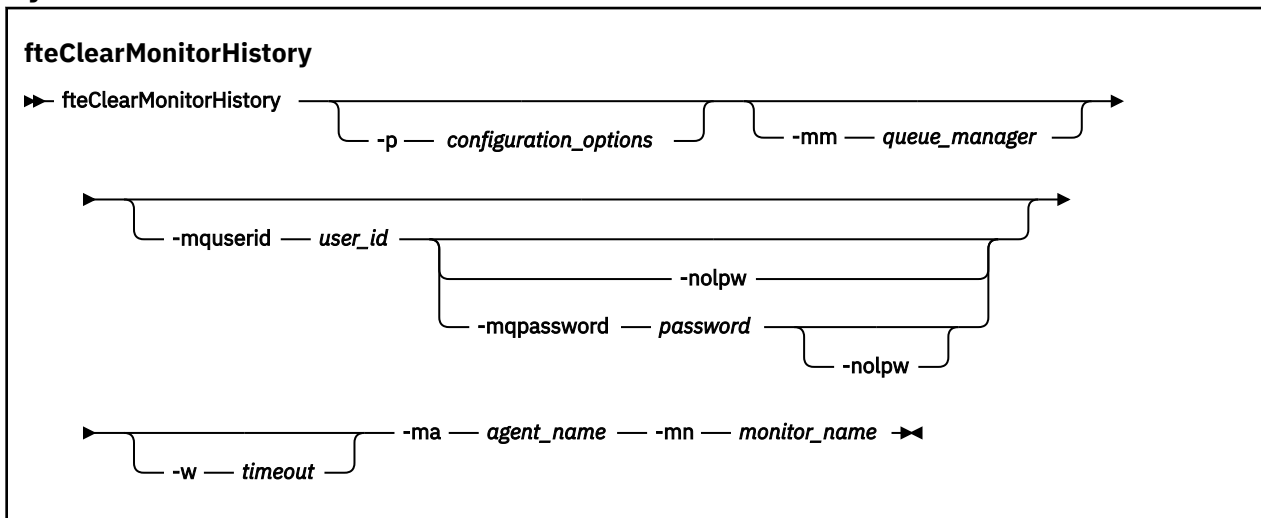

Purpose

The **fteClearMonitorHistory** command can be run from any system where the MFT commands component is installed. This allows you to clear the history from anywhere, rather than being restricted to the system where the agent that owns the resource monitor is running.

Running the **fteClearMonitorHistory** command puts a Clear Monitor History request XML message on the agent's command queue and wait for a reply on a temporary reply queue. The agent completes the following actions:

- Processes the request message.
- Stops the specified resource monitor
- Clears the history of the specified resource monitor.
- Starts the specified resource monitor.

Syntax

Parameters

-ma agent_name

Required. The name of the agent running the monitor operation.

-mm queue_manager

Optional. The name of the queue manager the agent is connected to.

-mn monitor_name

Required. The name of the monitor whose history is to be cleared. The characters '*', '%', and '?' are not allowed in monitor names.

-p configuration_options

Optional. Determines the set of configuration options that is used to clear the history of the monitor. Use the name of a set of configuration options as the value for the **-p** parameter.

By convention, this is the name of a coordination queue manager. If you do not specify this parameter, the default set of configuration options is used.

-w timeout

Optional. Specifies to wait for up to *timeout* seconds for the monitor to respond. If you do not specify a timeout, or specify a timeout value of minus one, then the command waits forever for the monitor to respond. If you do not specify this option then the default is to wait up to five seconds for the monitor to respond.

-mquserid user_id

Optional. Specifies the user ID to authenticate with the command queue manager.

-mqpassword password

Optional. Specifies the password to authenticate with the coordination queue manager.

When the **-mqpassword** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

From IBM MQ 9.3, the command defaults to using MQCSP authentication, and sends the user ID and password to be authenticated to the queue manager in an MQCSP structure.

-nolpw

Optional. Specify this parameter if the command connects to a queue manager that does not support passwords longer than 12 characters.

When the **-nolpw** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid** and **-nolpw**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

Note: If you specify the **-nolpw** option, and the password is longer than 12 characters the command fails with error message BFGCL0829E.

Example

The following example clears the history of the resource monitor JBSWIFT running in the agent JBAGENT:

```
fteClearMonitorHistory -ma JBAGENT -mn JBSWIFT
```

If the history is cleared successfully, the **fteClearMonitorHistory** command outputs the following messages:

```
BFGCL0780I: A request to clear history of resource monitor 'JBSWIFT' of agent 'JBAGENT' has been issued.  
BFGCL0251I: The request has successfully completed.
```

If there is no response from the monitor within the specified timeout period, the **fteClearMonitorHistory** command outputs the following messages:

```
BFGCL0780I: A request to clear history of resource monitor 'JBSWIFT' of agent 'JBAGENT' has been issued.  
BFGCL0253W: No acknowledgement to command from agent within timeout.
```

If authority checking is enabled but the user running the **fteClearMonitorHistory** command does not have authority to clear the history (see [Clearing resource monitor history](#)), the command outputs the following messages:

```
BFGCL0780I: A request to clear history of resource monitor 'JBSWIFT' of agent 'JBAGENT' has been issued.  
BFGCL0267E: This user is not authorized to perform the operation.
```

Resource monitor log

The outcome of running the **fteClearMonitorHistory** command is logged in the resource monitor log `resmoneventN.log`, where *N* stands for a number. Here are example log entries:

```
[07/01/2019 16:08:31:144 IST]00000026 F2FM2 Monitor Stopped Resource Monitor Stopped
[07/01/2019 16:08:31:176 IST]00000026 F2FM2 History Cleared Monitor History has been
cleared
[07/01/2019 16:08:31:176 IST]00000026 F2FM2 Monitor Started Resource Monitor Started
```

Agent event log

The outcome of running the **fteClearMonitorHistory** command is also logged in the agent's `output0.log`, as shown in the following examples.

The **fteClearMonitorHistory** command successfully cleared the resource monitor history:

```
BFGDM0123I: History of resource of monitor 'JBSWIFT' has been
cleared as requested by user 'tjwatson' on host 'hostname'.
```

The resource monitor history is empty when the **fteClearMonitorHistory** command is run:

```
BFGDM0126I: Resource monitor 'JBSWIFT' does not have any items in
its history. The request to clear history was submitted by user 'jbusr'
on host 'hostname'.
```

The **fteClearMonitorHistory** command is issued by the same user who created the monitor but this user does not have the required authority to clear the history (see [Clearing resource monitor history](#)):

```
BFGDM0124E: User 'jbusr' has requested to clear the history of
resource monitor 'JBSWIFT' but does not have either 'Monitor Operations'
or 'MONITOR' authorities required to perform this operation.
```

The **fteClearMonitorHistory** command is issued by a different user from the one who created the resource monitor but this user does not have the Monitor Operations authority to clear the history (see [Clearing resource monitor history](#)).

```
BFGDM0125E: User 'loggerusr' has requested to clear the history of
resource monitor 'JBSWIFT' that belongs to user 'jbusr' but does not
have the required authority 'Monitor Operations' to perform this
operation.
```

fteCreateAgent (create an MFT agent)

The **fteCreateAgent** command creates a Managed File Transfer Agent and its associated configuration.

You can control access to the agent. See [Restricting user authorities on MFT agent actions](#) for further information. You need to use the **-ac** parameter, and give permissions to access some queues.

Important:  On IBM MQ for AIX, Linux, and Windows, only users who are IBM MQ administrators (and members of the `mqm` group) can run this command. If you try to run this command as a user who is not an IBM MQ administrator, you will receive the error message `BFGCL0502E: You are not authorized to perform the requested operation.` and the command will not run.

 On z/OS systems, the user must satisfy (at least) one of these conditions in order to run the command:

- Be a member of the `mqm` group (if the `mqm` group is defined on the system).
- Be a member of the group named in the `BFG_GROUP_NAME` environment variable (if one is named).
- Have no value set in the `BFG_GROUP_NAME` environment variable when the command is run.

Purpose

Use the **fteCreateAgent** command to create an agent. This command provides you with the MQSC commands that you must run against your agent queue manager to create the following agent queues:

- `SYSTEM.FTE.AUTHADM1.agent_name`
- `SYSTEM.FTE.AUTHAGT1.agent_name`

- SYSTEM.FTE.AUTHMON1.agent_name
- SYSTEM.FTE.AUTHOPS1.agent_name
- SYSTEM.FTE.AUTHSCH1.agent_name
- SYSTEM.FTE.AUTHTRN1.agent_name
- SYSTEM.FTE.COMMAND.agent_name
- SYSTEM.FTE.DATA.agent_name
- SYSTEM.FTE.EVENT.agent_name
- SYSTEM.FTE.REPLY.agent_name
- SYSTEM.FTE.STATE.agent_name
- SYSTEM.FTE.HA.agent_name

These queues are internal system queues that you must not modify, delete, or read messages from unless you are deleting the agent. The MQSC commands to run are also supplied in a file in the following location:

`MQ_DATA_PATH\mqft\config\coordination_qmgr_name\agents\agent_name\agent_name_create.mqsc.`

If you later want to delete the agent, this command also provides you with the MQSC commands you must run to clear then delete the queues used by the agent. The MQSC commands are in a file in the following location:

`MQ_DATA_PATH\mqft\config\coordination_qmgr_name\agents\agent_name\agent_name_delete.mqsc.`

Managed File Transfer provides advanced agent properties that help you configure agents. These properties are described in [The agent.properties file](#).

You might need to create a `MQMFTCcredentials.xml` credentials file in order to work with your agent. A sample of this file is located in `MQ_INSTALLATION_PATH/mqft/samples/credentials/`. For more information and examples, see [“MFT credentials file format” on page 2730](#).

Important:

On AIX and Linux Managed File Transfer commands use socket files to communicate with the agent process running on the same host machine.

These socket files are created in the log directory of the agent and are deleted when an agent stops. In the IBM MQ Managed File Transfer installation, this socket file is created with a file path of: `<MQ_DATA_PATH>/mqft/logs/<COORDINATION_QM_NAME>/agents/<AGENT_NAME>/logs/<AGENT_NAME>@<AGENT_QM_NAME>` where `MQ_DATA_PATH` is `/var/mqm` by default.

For a re-distributable agent, this socket file is created under the directory: `<RE_DISTRIBUTABLE_DIRECTORY>/mqft/logs/<COORDINATION_QM_NAME>/agents/<AGENT_NAME>/logs/<AGENT_NAME>@<AGENT_QM_NAME>`.

For example, if the agent name is `SRCAGENT`, the agent queue manager name is `SRCAGENTQM`, the coordination queue manager name is `COORDQM`, and the redistributable agent is running from the directory `/home/myuser/mqmft-redis`, the full path of this socket file is: `/home/myuser/mqmft-redis/mqft/logs/COORDQM/agents/SRCAGENT/logs/SRCAGENT@SRCAGENTQM`

which is a total file path length of 85 characters.

The maximum path length allowed by these operating systems for a socket file is 107 characters. Therefore, when creating an agent, take care to ensure that the socket file path does not exceed 107 characters. This is particularly important with a redistributable agent where the log directory of the agent can be located in an arbitrary directory location. See the [ftecCreateEnvironment](#) command for details on setting up the configuration directory.

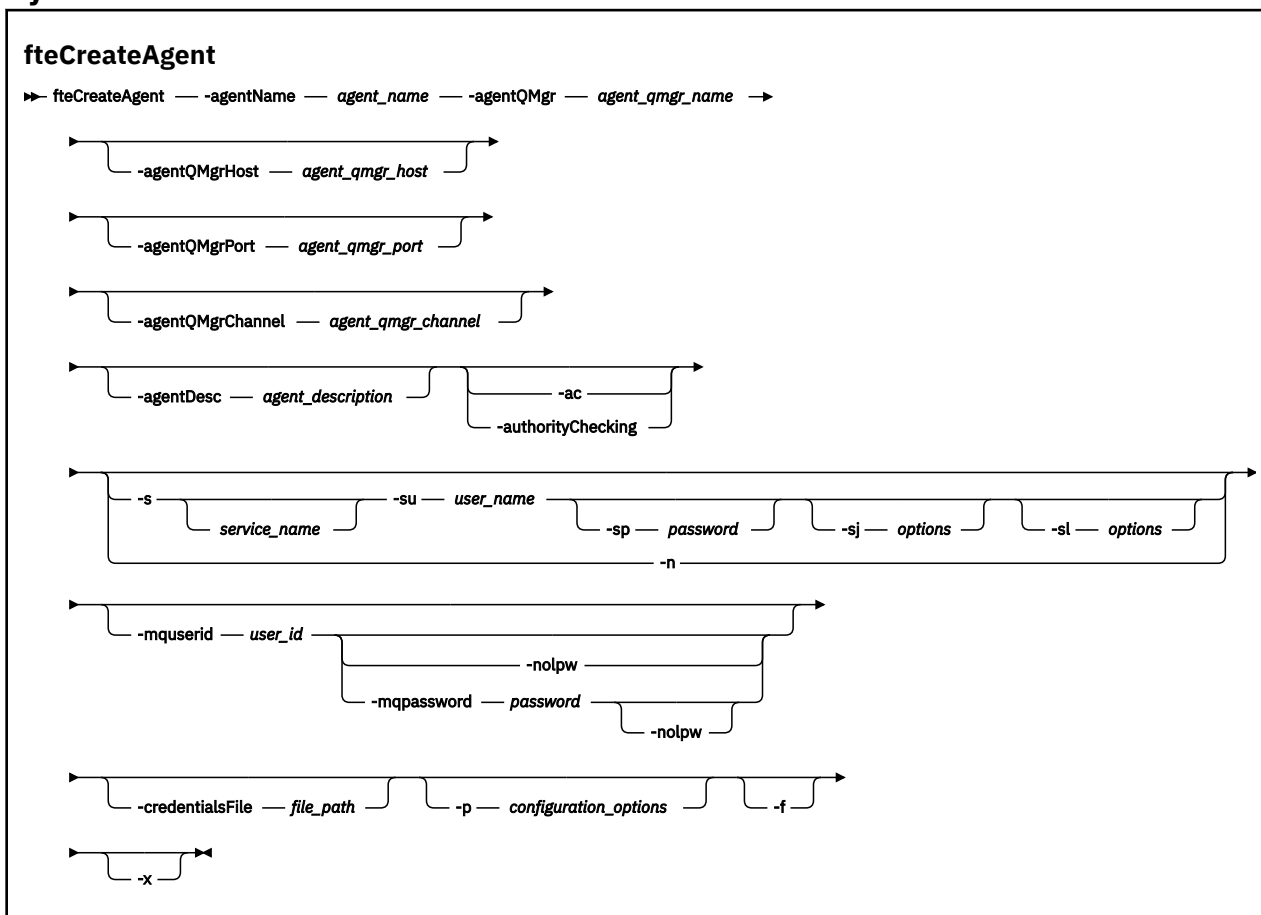

If you start an agent, or other commands that connect to the agent are run, and your path length exceeds 107 characters you receive the following message:

```
BFGNV0159E: Failed trying to bind to socket file with FFDC
```

Special characters

Take care when you use parameter values that contain special characters so that you avoid the command shell interpreting the characters in a way you do not expect. For example, fully qualified file paths and names that contains such characters as space, quotation mark (single or double), backslash or forward slash characters, might be interpreted by the command shell rather than being passed through directly to the command itself. To avoid characters being interpreted by the command shell, enclose the entire parameter in double or single quotation marks or escape the special characters by using the escape sequence of the command shell. When you specify file paths on Windows, ensure the separator character backslash (\) is entered as double backslashes (\\), that is, escaped backslash (\\). Alternatively, you can use a single forward slash (/) character as a separator."

Syntax

Parameters

-agentName *agent_name*

Required. The name of the agent you want to create. The agent name must be unique to its coordination queue manager.

For more information about naming agents, see [Object naming conventions](#).

-agentQMgr *agent_qmgr_name*

Required. The name of the agent queue manager.

-agentQMgrHost *agent_qmgr_host*

Optional. The host name or IP address of the agent queue manager.

-agentQMgrPort *agent_qmgr_port*

Optional. The port number used for client connections to the agent queue manager.

-agentQMGrChannel *agent_qmgr_channel*

Optional. The channel name used to connect to the agent queue manager.

-agentDesc *agent_description*

Optional. A description of the agent, which is displayed in IBM MQ Explorer.

-ac or -authorityChecking

Optional. This parameter enables authority checking. If you specify this parameter, the agent checks that users who are submitting requests are authorized to perform the requested action. For more information, see [Restricting user authorities on MFT agent actions](#).

Windows -s *service_name*

Optional (Windows only). Indicates that the agent is to run as a Windows service, the command must be run from a Windows administrator user ID. If you do not specify *service_name*, the service is named `mqmftAgentAGENTQMGR`, where *AGENT* is the agent name and *QMGR* is your agent queue manager name.

The display name for the service, which is shown in the Windows **Services** window in the **Name** column, is always **Managed File Transfer Agent AGENT@QMGR**.

Note: If the redistributable agent is going to run as a Windows service, then the **BFG_DATA** environment variable needs to be set in the system environment for the service to work.

Windows -su *user_name*

Optional (Windows only). When the agent is to run as a Windows service, this parameter specifies the name of the account under which the service runs. To run the agent using a Windows domain user account specify the value in the form `DomainName\UserName`. To run the service using an account from the local built-in domain specify the value in the form `UserName`.

The Windows user account that you specify using the **-su** parameter must have the **Log on as a service** right. For information about how to grant this right, see [Troubleshooting an MFT agent or logger running as a Windows service](#).

Required when **-s** specified.

Windows -sp *password*

Optional (Windows only).

This parameter is only valid when **-s** is specified. If you do not specify this parameter when you specify the **-s** parameter, a warning message is produced. This message warns you that you must set the password using the Windows Services tool before the service starts successfully.

Windows -sj *options*

Optional (Windows only). When the agent is started as a Windows service, defines a list of options in the form of **-D** or **-X** that are passed to the JVM. The options are separated using a number sign (#) or semicolon (;) character. If you must embed any # or semicolon (;) characters, put them inside single quotation marks.

This parameter is only valid when **-s** is specified.

Windows -sl *options*

Optional (Windows only). Sets the Windows service log level. Valid options are: error, info, warn, debug. The default is info. This option can be useful if you are having problems with the Windows service. Setting it to debug gives more detailed information in the service log file.

This parameter is only valid when **-s** is specified.

Windows -n

Optional (Windows only). Indicates that the agent is to be run as a normal process. This is mutually exclusive with the **-s** option. If neither one of the **-s** parameter and the **-n** parameter is specified, then the agent is configured as a normal Windows process.

-p *configuration_options*

Optional. This parameter determines the set of configuration options that is used to create an agent. By convention use the name of a non-default coordination queue manager as the input for this

parameter. The **fteCreateAgent** command then uses the set of properties files associated with this non-default coordination queue manager.

Specify the optional **-p** parameter only if you want to use configuration options different from your defaults. If you do not specify this parameter, the set of configuration options based on the default coordination queue manager is used.

-mquserid *user_id*

Optional. Specifies the user ID to authenticate with the coordination queue manager.

-mqpassword *password*

Optional. Specifies the password to authenticate with the coordination queue manager.

When the **-mqpassword** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

From IBM MQ 9.3, the command defaults to using MQCSP authentication, and sends the user ID and password to be authenticated to the queue manager in an MQCSP structure.

-nolpw

Optional. Specify this parameter if the command connects to a queue manager that does not support passwords longer than 12 characters.

When the **-nolpw** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid** and **-nolpw**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

Note: If you specify the **-nolpw** option, and the password is longer than 12 characters the command fails with error message BFGCL0829E.

-credentialsFile *file_path*

Optional. The full file path of an existing or new credentials file, to which the IBM MQ authentication details are added.

This command supports the addition of a set of IBM MQ authentication details, to a named Managed File Transfer credentials file. Use this command when IBM MQ connection authentication has been enabled. If you update the existing details, you must use the **-f** force parameter.

-credentialPath *credentials_path*.

This command defines the location to migrate the credential information to. This parameter can be

a directory path to an existing credential file, or a directory path to a new credential file.  On z/OS platforms the credential file can be a pre-existing partitioned data set extended (PDSE). The PDSE can include existing members, or a new member for the credential file. Existing members of the PDSE must be updated to include the credential file. The format of the PDSE must be variable blocked.

-f

Optional. Forces the command to overwrite non-matching existing parameters. Specifying this parameter does not force the replacement of an existing Windows service agent.

-? or -h

Optional. Displays command syntax.

-x

Optional. Creates an agent configuration to run in a high availability mode.

Specifying this parameter adds a new option `highlyAvailable` to the `agent.properties` file.

Example

In this example, AGENT3 is created with an agent queue manager QM_NEPTUNE and uses the default coordination queue manager:

```
fteCreateAgent -agentName AGENT3 -agentQMGr QM_NEPTUNE  
-agentQMGrHost myhost.ibm.com -agentQMGrPort 1415 -agentQMGrChannel CHANNEL1
```

In this example, AGHA is created in high availability mode with an agent queue manager QMHA.

```
fteCreateAgent -agentName AGHA -agentQMgr QMHA -x
```

Return codes

0

Command completed successfully.

1

Command ended unsuccessfully.

Related concepts

Related tasks

[Starting an MFT agent as a Windows service](#)

Related reference

[“fteStartAgent \(start an MFT agent\)” on page 2169](#)

The **fteStartAgent** command starts a Managed File Transfer agent from the command line.

[“fteDeleteAgent \(delete an MFT agent and its configuration\)” on page 2104](#)

The **fteDeleteAgent** command deletes a Managed File Transfer Agent and its configuration. If the agent is a protocol bridge agent, the user credentials file is left on the file system.

fteCreateBridgeAgent (create and configure an MFT protocol bridge agent)

The **fteCreateBridgeAgent** command creates a Managed File Transfer protocol bridge agent and its associated configuration. Create a protocol bridge agent for each file server that you want to send files to and receive files from.

Important:  On IBM MQ for AIX, Linux, and Windows, only users who are IBM MQ administrators (and members of the mqm group) can run this command. If you try to run this command as a user who is not an IBM MQ administrator, you will receive the error message BFGCL0502E: You are not authorized to perform the requested operation. and the command will not run.

 On z/OS systems, the user must satisfy (at least) one of these conditions in order to run the command:

- Be a member of the mqm group (if the mqm group is defined on the system).
- Be a member of the group named in the BFG_GROUP_NAME environment variable (if one is named).
- Have no value set in the BFG_GROUP_NAME environment variable when the command is run.

Purpose

Use the **fteCreateBridgeAgent** command to create a protocol bridge agent. For an overview of how to use the protocol bridge, see [The protocol bridge](#). This **fteCreateBridgeAgent** command provides you with the MQSC commands that you must run against your agent queue manager to create the following agent queues:

- SYSTEM.FTE.AUTHADM1.*agent_name*
- SYSTEM.FTE.AUTHAGT1.*agent_name*
- SYSTEM.FTE.AUTHMON1.*agent_name*
- SYSTEM.FTE.AUTHOPS1.*agent_name*
- SYSTEM.FTE.AUTHSCH1.*agent_name*
- SYSTEM.FTE.AUTHTRN1.*agent_name*
- SYSTEM.FTE.COMMAND.*agent_name*
- SYSTEM.FTE.DATA.*agent_name*

- SYSTEM.FTE.EVENT.*agent_name*
- SYSTEM.FTE.REPLY.*agent_name*
- SYSTEM.FTE.STATE.*agent_name*
- SYSTEM.FTE.HA.*agent_name*

These queues are internal system queues that you must not modify, delete, or read messages from unless you are deleting the agent. The MQSC commands to run are also supplied in a file in the following location:

MQ_DATA_PATH\mqft\config\coordination_qmgr_name\agents\agent_name\agent_name_create.mqsc

If you later want to delete the agent, this command also provides you with the MQSC commands you must run to clear then delete the queues use by the agent. The MQSC commands are in a file in the following location:

MQ_DATA_PATH\mqft\config\coordination_qmgr_name\agents\agent_name\agent_name_delete.mqsc.

The **fteCreateBridgeAgent** command creates a ProtocolBridgeProperties.xml XML file in the following directory:

MQ_DATA_PATH\mqft\config\coordination_qmgr_name\agents\agent_name.

Users are responsible for manually creating the ProtocolBridgeCredentials.xml file, it is no longer created by the **fteCreateBridgeAgent** command.

The ProtocolBridgeCredentials.xml file allows you to define user names and credential information that the protocol bridge agent uses to authorize itself with the protocol server and the ProtocolBridgeProperties.xml file allows you to define multiple protocol file servers so you can transfer to multiple endpoints.

There is a sample ProtocolBridgeCredentials.xml in the *MQ_INSTALLATION_PATH*/mqft/samples/credentials/ directory. For more information, see [“Protocol bridge credentials file format” on page 2733](#) and [“Protocol bridge properties file format” on page 2737](#).

If you run the **fteCreateBridgeAgent** command and specify a default protocol file server (parameter -bt), this default server is contained in the ProtocolBridgeProperties.xml file and its host name is used for the server name. With the -bt parameter, you need to specify the following parameters:

- -bh
- -btz
- -bm
- -bsl
- -bfe
- -bts

If you do not specify a default server, there are no entries in the ProtocolBridgeProperties.xml file; you must add at least one server manually before transfers can take place.

Managed File Transfer provides advanced agent properties that help you configure protocol bridge agents. The properties that relate to the protocol bridge start with protocol. These properties are described in [Advanced agent properties: Protocol bridge](#) and [Advanced agent properties: Protocol bridge agent logging](#). If you see unexpected behavior in the protocol bridge, review these protocol properties and ensure that you have set these properties correctly for your system.

If you see the following output from the **fteCreateBridgeAgent** command:

```
BFGMQ1007I: The coordination queue manager cannot be contacted or has refused a connection attempt.
The WebSphere MQ reason code was 2058. The agent's presence will not be published.
```

it indicates that the coordination queue manager can not be contacted and provides the IBM MQ reason code for why. This information message can indicate that the coordination queue manager is currently unavailable or that you have defined the configuration incorrectly.

Important:

On AIX and Linux Managed File Transfer commands use socket files to communicate with the agent process running on the same host machine.

These socket files are created in the log directory of the agent and are deleted when an agent stops. In the IBM MQ Managed File Transfer installation, this socket file is created with a file path of: <MQ_DATA_PATH>/mqft/logs/<COORDINATION_QM_NAME>/agents/<AGENT_NAME>/logs/<AGENT_NAME>@<AGENT_QM_NAME> where MQ_DATA_PATH is /var/mqm by default.

For a re-distributable agent, this socket file is created under the directory: <RE_DISTRIBUTABLE_DIRECTORY>/mqft/logs/<COORDINATION_QM_NAME>/agents/<AGENT_NAME>/logs/<AGENT_NAME>@<AGENT_QM_NAME>.

For example, if the agent name is SRCAGENT, the agent queue manager name is SRCAGENTQM, the coordination queue manager name is COORDQM, and the redistributable agent is running from the directory /home/myuser/mqmft-redis, the full path of this socket file is: /home/myuser/mqmft-redis/mqft/logs/COORDQM/agents/SRCAGENT/logs/SRCAGENT@SRCAGENTQM

which is a total file path length of 85 characters.

The maximum path length allowed by these operating systems for a socket file is 107 characters. Therefore, when creating an agent, take care to ensure that the socket file path does not exceed 107 characters. This is particularly important with a redistributable agent where the log directory of the agent can be located in an arbitrary directory location. See the **fteCreateEnvironment** command for details on setting up the configuration directory.

If you start an agent, or other commands that connect to the agent are run, and your path length exceeds 107 characters you receive the following message:

```
BFGNV0159E: Failed trying to bind to socket file with FFDC
```

Special characters

Take care when you use parameter values that contain special characters so that you avoid the command shell interpreting the characters in a way you do not expect. For example, fully qualified file paths and names that contains such characters as space, quotation mark (single or double), backslash or forward slash characters, might be interpreted by the command shell rather than being passed through directly to the command itself. To avoid characters being interpreted by the command shell, enclose the entire parameter in double or single quotation marks or escape the special characters by using the escape sequence of the command shell. When you specify file paths on Windows, ensure the separator character backslash (\) is entered as double backslashes (\\), that is, escaped backslash (\\). Alternatively, you can use a single forward slash (/) character as a separator."

Syntax

fteCreateBridgeAgent

► fteCreateBridgeAgent — -agentName *agent_name* -agentQMgr *agent_qmgr_name* →

Parameters

-agentName *agent_name*

Required. The name of the agent you want to create. The agent name must be unique in its administrative domain.

For more information about naming agents, see [Object naming conventions](#).

-agentQMgr *agent_qmgr_name*

Required. The name of the agent queue manager.

-bt *protocol_file_server_type*

Optional. Specifies that you want to define a default protocol file server. Specify one of the following options:

FTP

Standard FTP server

SFTP

SSH FTP server

FTPS

FTP server secured using SSL or TLS

If you do not specify this parameter, no default protocol server is defined.

-bh *server_host_name*

Required only if you also specify a default protocol file server using the **-bt** parameter. The IP host name or IP address of the protocol file server.

-btz *server_time_zone*

Required only if you also specify the **-bt** parameter (FTP and FTPS servers only). The time zone of the protocol file server. Specify the time zone in the following format: Area/Location. For example: Europe/London.

You can use the **-htz** parameter to list the possible values for **-btz**. For example:
`fteCreateBridgeAgent -htz`

-bm *server_platform*

Required only if you also specify a default protocol file server using the **-bt** parameter. The platform type of the protocol file server. Specify one of the following options:

UNIX

Generic UNIX and Linux platform

WINDOWS

Generic Windows platform

OS400

IBM i platform

Note: You must set the both the **bm** parameter to *OS400* and the **blf** parameter to *OS400IFS* if the bridge agent is to communicate with an FTP server running IBM i.

-bsl *server_locale*

Required only if you also specify the **-bt** parameter (FTP and FTPS servers only). The locale of the protocol file server. Specify the locale in the following format: *xx_XX*. For example: en_GB.

- *xx* is the ISO Language Code. For a list of valid values, see [Codes for the Representation of Names of Languages](#)
- *XX* is the ISO Country Code. For a list of valid values, see [Country names and code elements](#)

-bfe *server_file_encoding*

Required only if you also specify a default protocol file server using the **-bt** parameter. The character encoding format of the files stored on the protocol file server. For example: UTF-8.

You can use the **-hcs** parameter to list the possible values for **-bfe**. For example:
`fteCreateBridgeAgent -hcs`

-bts *truststore_file*

Required when you specify the **-bt** parameter (FTPS servers only). Specifies the path to a truststore that is used to validate the certificate presented by the FTPS server.

You can specify the **-bts** parameter only if you have also specified the FTPS option on the **-bt** parameter.

-bp *server_port*

Optional. The IP port that the protocol file server is connected to. Specify this parameter only if your protocol file server does not use the default port for that protocol. If you do not specify this parameter, Managed File Transfer uses the default port for the protocol type of file server.

-blw

Optional. Defines the protocol file server as having limited write abilities. By default, a protocol bridge agent expects the protocol file server to permit file deletion, file renaming, and file opening for append

writing. Specify this parameter to indicate that the protocol file server does not permit these file actions. Instead the file server permits read from and write to file only. If you specify this parameter, any transfers might not be recoverable if they are interrupted and might result in a failure for the file currently being transferred.

-blf server_listing_format

Optional and for FTP and FTPS servers only. Defines the server listing format of the listed file information returned from the default protocol file server. The options are as follows:

UNIX

Generic UNIX and Linux platform

WINDOWS

Generic Windows platform

OS400IFS

Root file system on IBM i platform

Notes:

1. You must set the both the **bm** parameter to *OS400* and the **blf** parameter to *OS400IFS* if the bridge agent is to communicate with an FTP server running IBM i.
2. You can use Managed File Transfer to send and receive files on the root (/) file system only. Other file systems do not work.

To identify which format to select, use a FTP client program and perform a listing of a directory and select which format is the best fit. For example,

UNIX UNIX displays the following type of listing:

```
-rwxr-xr-x 2 userid groupId 4096 2009-07-23 09:36 filename
```

Windows Windows displays the following type of listing:

```
437,909 filename
```

IBM i IBM i displays the following type of listing:

```
OS400IFS -rwxrwsrwx 3 USERID 0 8192 Mar 7 08:33 filename
```

The default is UNIX, which is the format used by most servers.

-agentQMGrHost agent_qmgr_host

Optional. The host name or IP address of the agent queue manager.

-agentQMGrPort agent_qmgr_port

Optional. The port number used for client connections to the agent queue manager.

-agentQMGrChannel agent_qmgr_channel

Optional. The channel name used to connect to the agent queue manager.

-agentDesc agent_description

Optional. A description of the agent, which is displayed in the IBM MQ Explorer.

-ac or -authorityChecking

Optional. This parameter enables authority checking. If you specify this parameter, the agent checks that users who are submitting requests are authorized to perform the requested action. For more information, see [Restricting user authorities on MFT agent actions](#).

Windows -s service_name

Optional (Windows only). Indicates that the agent is to run as a Windows service. If you do not specify *service_name*, the service is named `mqmftAgentAGENTQMGR`, where *AGENT* is the agent name and *QMGR* is your agent queue manager name.

The display name for the service, which is shown in the Windows **Services** window in the **Name** column, is always **Managed File Transfer Agent AGENT@QMGR**.

Windows -su user_name

Optional (Windows only). When the agent is to run as a Windows service, this parameter specifies the name of the account under which the service runs. To run the agent using a Windows domain user account specify the value in the form `DomainName\UserName`. To run the service using an account from the local built-in domain specify the value in the form `UserName`.

The Windows user account that you specify using the **-su** parameter must have the **Log on as a service** right. For information about how to grant this right, see [Troubleshooting an MFT agent or logger running as a Windows service](#).

Required when **-s** specified.

Windows -sp password

Optional (Windows only). Password for the user account set by the **-su** parameter.

This parameter is only valid when **-s** is specified. If you do not specify this parameter when you specify the **-s** parameter, a warning message is produced. This message warns you that you must set the password using the Windows Services tool before the service starts successfully.

Windows -sj options

Optional (Windows only). When the agent is started as a Windows service, defines a list of options in the form of **-D** or **-X** that are passed to the JVM. The options are separated using a number sign (**#**) or semicolon (**;**) character. If you must embed any **#** or semicolon (**;**) characters, put them inside single quotation marks.

This parameter is only valid when **-s** is specified. .

Windows -sl options

Optional (Windows only). Sets the Windows service log level. Valid options are: error, info, warn, debug. The default is info. This option can be useful if you are having problems with the Windows service. Setting it to debug gives more detailed information in the service log file.

This parameter is only valid when **-s** is specified.

Windows -n

Optional (Windows only). Indicates that the agent is to be run as a normal process. This is mutually exclusive with the **-s** option. If neither one of the **-s** parameter and the **-n** parameter is specified, then the agent is configured as a normal Windows process.

-p configuration_options

Optional. This parameter determines the set of configuration options that is used to create an agent. By convention use the name of a non-default coordination queue manager as the input for this parameter. The **fteCreateBridgeAgent** command then uses the set of properties files associated with this non-default coordination queue manager.

Specify the optional **-p** parameter only if you want to use configuration options different from your defaults. If you do not specify **-p**, the configuration options defined in the `installation.properties` file are used. See [Configuration options](#) for more information.

-f

Optional. Forces the command to overwrite the existing configuration.

-htz

Optional. Displays a list of supported time zones that you can use as input for the **-btz** parameter.

-hcs

Optional. Displays a list of supported character sets that you can use as input for the **-bfe** parameter.

Run the **fteCreateBridgeAgent -hcs** command to list the known code pages for the JVM. This information is not available from an external source because the known code pages vary between JVMs.

-mquserid user_id

Optional. Specifies the user ID to authenticate with the command queue manager.

-mqpassword password

Optional. Specifies the password to authenticate with the coordination queue manager.

When the **-mqpassword** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

From IBM MQ 9.3, the command defaults to using [MQCSP](#) authentication, and sends the user ID and password to be authenticated to the queue manager in an MQCSP structure.

-nolpw

Optional. Specify this parameter if the command connects to a queue manager that does not support passwords longer than 12 characters.

When the **-nolpw** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid** and **-nolpw**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

Note: If you specify the **-nolpw** option, and the password is longer than 12 characters the command fails with error message BFGCL0829E.

-credentialsFile file_path

Optional. The full file path of an existing or new credentials file, to which the IBM MQ authentication details are added.

This command supports the addition of a set of IBM MQ authentication details, to a named Managed File Transfer credentials file. Use this command when IBM MQ connection authentication has been enabled. If you update the existing details, you must use the **-f** force parameter.

-userid username

Optional. The user ID used to associate the credential details. If you do not specify a user ID, the credential details will apply to all users. You must also specify the **-credentialsFile** parameter.

-? or -h

Optional. Displays command syntax.

-x

Optional. Creates an agent configuration to run in a high availability mode.

Specifying this parameter adds a new option `highlyAvailable` to the [agent.properties](#) file.

Examples

In this example, a new protocol bridge agent ACCOUNTS1 is created with an agent queue manager QM_ACCOUNTS and uses the default coordination queue manager. ACCOUNTS1 connects to the FTP server accountshost.ibm.com. This FTP server runs on Windows using a time zone of Europe/Berlin, a locale of de_DE, and a file encoding of UTF-8. The number of reconnect retries is 4:

```
fteCreateBridgeAgent -agentName ACCOUNTS1 -agentQMgr QM_ACCOUNTS -bt FTP
-bh accountshost.ibm.com -bm WINDOWS -btz Europe/Berlin -bsl de_DE -bfe UTF8
-agentQMgrHost myhost.ibm.com -agentQMgrPort 1415 -agentQMgrChannel CHANNEL1
```

In this example, a new protocol bridge agent ACCOUNTS2 is created with an agent queue manager QM_ACCOUNTS and uses the default coordination manager. ACCOUNTS2 is created without a default protocol file server.

```
fteCreateBridgeAgent -agentName ACCOUNTS2 -agentQMgr QM_ACCOUNTS
```

Note: The above does not apply to Managed File Transfer Agent redistributable.

The scenario here is that the Managed File Transfer Agent is running on a Linux or Windows box but configured to communicate with an FTP server running IBM i. If you require the destination file to be in

the native code page of IB, you must use the **-dce** code page parameter while submitting the transfer request. For example:

```
fteCreateTransfer -rt -1 -sa SRC -sm MFTQM -da OS400FTP -dm MFTQM -dce 37 -sce 1252
-t text -de overwrite -df "<your-domain>:/home/mft/text/uploadwcp.log"
"C:\temp\os400\Text\uploadwcp.log"
```

and, if you require the receiving file in the native code page from IBM i:

```
fteCreateTransfer -rt -1 -da SRC -dm MFTQM -sa OS400FTP -sm MFTQM -sce 37 -dce 1252
-t text -de overwrite -df "C:\temp\os400\Text\downloadwcp.log"
"<your-domain>:/home/mft/text/uploadwcp.log"
```

Additional customizing

If you used the **-bt** parameter (and the additional parameters that are required) there will be a default server name in the `ProtocolBridgeProperties.xml` file.

If you want to add additional ftp servers, or change the location of the credentials file, see [Defining properties for protocol file servers using the ProtocolBridgeProperties.xml file](#).

Return codes

0

Command completed successfully.

1

Command ended unsuccessfully.

Use the **fteStartAgent** command to start your protocol bridge agent. For more information, see [“fteStartAgent \(start an MFT agent\)” on page 2169](#).  See also [Starting an MFT agent on z/OS](#).

The `ProtocolBridgeProperties.xml` file in the agent configuration directory defines properties for protocol file servers.

fteCreateCDAgent (create a Connect:Direct bridge agent)

The `fteCreateCDAgent` command creates a Managed File Transfer Agent and its associated configuration for use with the Connect:Direct bridge.

Important:  On IBM MQ for AIX, Linux, and Windows, only users who are IBM MQ administrators (and members of the mqm group) can run this command. If you try to run this command as a user who is not an IBM MQ administrator, you will receive the error message BFGCL0502E: You are not authorized to perform the requested operation. and the command will not run.

 On z/OS systems, the user must satisfy (at least) one of these conditions in order to run the command:

- Be a member of the mqm group (if the mqm group is defined on the system).
- Be a member of the group named in the BFG_GROUP_NAME environment variable (if one is named).
- Have no value set in the BFG_GROUP_NAME environment variable when the command is run.

Purpose

Use the **fteCreateCDAgent** command to create a Connect:Direct bridge agent. This type of agent is dedicated to transferring files to and from Connect:Direct nodes. For more information, see [The Connect:Direct bridge](#). For details of the supported operating system versions for the Connect:Direct bridge, see the web page [System Requirements for IBM MQ](#).

This command provides you with the MQSC commands that you must run against your agent queue manager to create the following agent queues:

- SYSTEM.FTE.AUTHADM1.*agent_name*
- SYSTEM.FTE.AUTHAGT1.*agent_name*
- SYSTEM.FTE.AUTHMON1.*agent_name*
- SYSTEM.FTE.AUTHOPS1.*agent_name*
- SYSTEM.FTE.AUTHSCH1.*agent_name*
- SYSTEM.FTE.AUTHTRN1.*agent_name*
- SYSTEM.FTE.COMMAND.*agent_name*
- SYSTEM.FTE.DATA.*agent_name*
- SYSTEM.FTE.EVENT.*agent_name*
- SYSTEM.FTE.REPLY.*agent_name*
- SYSTEM.FTE.STATE.*agent_name*

These queues are internal system queues that you must not modify, delete, or read messages from unless you are deleting the agent. The MQSC commands to run are also supplied in a file in the following location:

```
MQ_DATA_PATH\mqft\config\coordination_qmgr_name\agents\agent_name\agent_name_create.mqsc.
```

If you later want to delete the agent, this command also provides you with the MQSC commands you must run to clear then delete the queues belonging to the agent. The MQSC commands are in a file in the following location:

```
MQ_DATA_PATH\mqft\config\coordination_qmgr_name\agents\agent_name\agent_name_delete.mqsc.
```

Managed File Transfer provides advanced agent properties that help you configure agents. These properties are described in [The MFT agent.properties file](#).

The **fteCreateCDAgent** command creates two XML files in the agent properties directory. `ConnectDirectNodeProperties.xml`, which is used to define information about the remote nodes in a transfer, and `ConnectDirectProcessDefinitions.xml`, which is used to specify which user-defined Connect:Direct processes are started by transfers.

To define user names and passwords that the Connect:Direct bridge agent uses to connect to Connect:Direct nodes, you must manually create a `ConnectDirectCredentials.xml` file. Sample XML files are located in `MQ_INSTALLATION_PATH/mqft/samples/credentials/`. For more information and examples, see [“Connect:Direct credentials file format” on page 2750](#).

Important:

On AIX and Linux Managed File Transfer commands use socket files to communicate with the agent process running on the same host machine.

These socket files are created in the log directory of the agent and are deleted when an agent stops. In the IBM MQ Managed File Transfer installation, this socket file is created with a file path of: `<MQ_DATA_PATH>/mqft/logs/<COORDINATION_QM_NAME>/agents/<AGENT_NAME>/logs/<AGENT_NAME>@<AGENT_QM_NAME>` where `MQ_DATA_PATH` is `/var/mqm` by default.

For a re-distributable agent, this socket file is created under the directory: `<RE_DISTRIBUTABLE_DIRECTORY>/mqft/logs/<COORDINATION_QM_NAME>/agents/<AGENT_NAME>/logs/<AGENT_NAME>@<AGENT_QM_NAME>`.

For example, if the agent name is SRCAGENT, the agent queue manager name is SRCAGENTQM, the coordination queue manager name is COORDQM, and the redistributable agent is running from the directory /home/myuser/mqmf-t-redist, the full path of this socket file is: /home/myuser/mqmf-t-redist/mqft/logs/COORDQM/agents/SRCAGENT/logs/SRCAGENT@SRCAGENTQM

which is a total file path length of 85 characters.

The maximum path length allowed by these operating systems for a socket file is 107 characters. Therefore, when creating an agent, take care to ensure that the socket file path does not exceed 107 characters. This is particularly important with a redistributable agent where the log directory of the agent can be located in an arbitrary directory location. See the **fteCreateEnvironment** command for details on setting up the configuration directory.

If you start an agent, or other commands that connect to the agent are run, and your path length exceeds 107 characters you receive the following message:

```
BFGNV0159E: Failed trying to bind to socket file with FFDC
```

Special characters

Take care when you use parameter values that contain special characters so that you avoid the command shell interpreting the characters in a way you do not expect. For example, fully qualified file paths and names that contains such characters as space, quotation mark (single or double), backslash or forward slash characters, might be interpreted by the command shell rather than being passed through directly to the command itself. To avoid characters being interpreted by the command shell, enclose the entire parameter in double or single quotation marks or escape the special characters by using the escape sequence of the command shell. When you specify file paths on Windows, ensure the separator character backslash (\) is entered as double backslashes (\\), that is, escaped backslash (\\). Alternatively, you can use a single forward slash (/) character as a separator."

Parameters

-agentName *agent_name*

Required. The name of the agent you want to create. The agent name must be unique to its coordination queue manager.

For more information about naming agents, see [Object naming conventions](#).

-agentQMGr *agent_qmgr_name*

Required. The name of the agent queue manager.

-cdNode *cd_node_name*

Required. The name of the Connect:Direct node to use to transfer messages from this agent to destination Connect:Direct nodes. The value of this parameter is used for logging and not to specify to the Connect:Direct bridge agent which node to connect to. The values of the **-cdNodeHost** and **-cdNodePort** specify the Connect:Direct node that is part of the Connect:Direct bridge.

-agentQMGrHost *agent_qmgr_host*

Optional. The host name or IP address of the agent queue manager.

-agentQMGrPort *agent_qmgr_port*

Optional. The port number used for client connections to the agent queue manager.

-agentQMGrChannel *agent_qmgr_channel*

Optional. The channel name used to connect to the agent queue manager.

-agentDesc *agent_description*

Optional. A description of the agent, which is displayed in IBM MQ Explorer.

-ac or -authorityChecking

Optional. This parameter enables authority checking. If you specify this parameter, the agent checks that users who are submitting requests are authorized to perform the requested action. For more information, see [Restricting user authorities on MFT agent actions](#).

-p configuration_options

Optional. This parameter determines the set of configuration options that is used to create an agent. By convention use the name of a non-default coordination queue manager as the input for this parameter. The **fteCreateCDAgent** command then uses the set of properties files associated with this non-default coordination queue manager.

Specify the optional **-p** parameter only if you want to use configuration options different from your defaults. If you do not specify this parameter, the set of configuration options based on the default coordination queue manager is used.

-f

Optional. Forces the command to overwrite non-matching existing parameters. Specifying this parameter does not force the replacement of an existing Windows service agent.

-cdNodeHost cd_node_host_name

Optional. The host name or IP address of the system where the Connect:Direct node, specified by the **-cdNode** parameter, is located. If you do not specify the **-cdNodeHost** parameter, a default of the host name or IP address of the local system is used.

In most cases, the Connect:Direct node is on the same system as the Connect:Direct bridge agent. In these cases, the default value of this property, which is the IP address of the local system, is correct. If your system has multiple IP addresses, or your Connect:Direct node is on a different system to your Connect:Direct bridge agent and their systems share a file system, use this property to specify the correct host name for the Connect:Direct node.

-cdNodePort cd_node_port_name

Optional. The port number of the Connect:Direct node that client applications use to communicate with the node that is specified by the **-cdNode** parameter. In Connect:Direct product documentation, this port is referred to as the API port. If you do not specify the **-cdNodePort** parameter, a default port number of 1363 is assumed.

-cdTmpDir cd_tmp_directory

Optional. The directory to be used by this agent to store files temporarily before they are transferred to the destination Connect:Direct node. This parameter specifies the full path of the directory where files are temporarily stored. For example, if **cdTmpDir** is set to `/tmp` then the files are temporarily placed in the `/tmp` directory. If you do not specify the **-cdTmpDir** parameter, the files are stored temporarily in a directory named `cdbridge-agent_name`. This default directory is created in the location that is defined by the value of the `java.io.tmpdir` property.

The Connect:Direct bridge agent and the Connect:Direct bridge node must be able to access the directory specified by this parameter using the same path name. Consider this when planning the installation of your Connect:Direct bridge. If possible, create the agent on the system where the Connect:Direct node that is part of the Connect:Direct bridge is located. If your agent and node are on separate systems, the directory must be on a shared file system and be accessible from both systems using the same path name. For more information about the supported configurations, see [The Connect:Direct bridge](#).

Note: If you run the **fteCleanAgent** command, all files in this directory are deleted.

Windows -s service_name

Optional (Windows only). Indicates that the agent is to run as a Windows service, the command must be run from a Windows administrator user ID. If you do not specify `service_name`, the service is named `mqmftAgentAGENTQMGR`, where `AGENT` is the agent name and `QMGR` is your agent queue manager name.

Windows -su user_name

Optional (Windows only). When the agent is to run as a Windows service, this parameter specifies the name of the account under which the service runs. To run the agent using a Windows domain user

account specify the value in the form `DomainName\UserName`. To run the service using an account from the local built-in domain specify the value in the form `UserName`.

Windows -sp password

Optional (Windows only).

Windows -sj options

Optional (Windows only). When the agent is started as a Windows service, defines a list of options in the form of `-D` or `-X` that are passed to the JVM. The options are separated using a number sign (`#`) or semicolon (`;`) character. If you must embed any `#` or semicolon (`;`) characters, put them inside single quotation marks.

Windows -sl options

Optional (Windows only). Sets the Windows service log level. Valid options are: `error`, `info`, `warn`, `debug`. The default is `info`. This option can be useful if you are having problems with the Windows service. Setting it to `debug` gives more detailed information in the service log file.

Windows -n

Optional (Windows only). Indicates that the agent is to be run as a normal process. This is mutually exclusive with the `-s` option. If neither one of the `-s` parameter and the `-n` parameter is specified, then the agent is configured as a normal Windows process.

-mquserid user_id

Optional. Specifies the user ID to authenticate with the command queue manager.

-mqpassword password

Optional. Specifies the password to authenticate with the coordination queue manager.

When the `-mqpassword` parameter is specified, you must also specify the `-mquserid` parameter. If you specify `-mquserid`, but do not specify `-mqpassword`, you are prompted to supply the associated password, which will not be displayed.

From IBM MQ 9.3, the command defaults to using MQCSP authentication, and sends the user ID and password to be authenticated to the queue manager in an MQCSP structure.

-nolpw

Optional. Specify this parameter if the command connects to a queue manager that does not support passwords longer than 12 characters.

When the `-nolpw` parameter is specified, you must also specify the `-mquserid` parameter. If you specify `-mquserid` and `-nolpw`, but do not specify `-mqpassword`, you are prompted to supply the associated password, which will not be displayed.

Note: If you specify the `-nolpw` option, and the password is longer than 12 characters the command fails with error message BFGCL0829E.

-credentialsFile file_path

Optional. The full file path of an existing or new credentials file, to which the IBM MQ authentication details are added.

This command supports the addition of a set of IBM MQ authentication details, to a named Managed File Transfer credentials file. Use this command when IBM MQ connection authentication has been enabled. If you update the existing details, you must use the `-f` force parameter.

-userid username

Optional. The user ID used to associate the credential details. If you do not specify a user ID, the credential details will apply to all users. You must also specify the `-credentialsFile` parameter.

Example

In this example, a new Connect:Direct bridge agent `CD_BRIDGE` is created with an agent queue manager `QM_NEPTUNE`. The agent uses the Connect:Direct node `BRIDGE_NODE` to transfer files to other Connect:Direct nodes. The `BRIDGE_NODE` node is located on the same system as the agent and uses the

default port for client connections. Files that are transferred to or from Connect:Direct are temporarily stored in the directory /tmp/cd-bridge.

```
fteCreateCDAgent -agentName CD_BRIDGE -agentQMgr QM_NEPTUNE  
                -cdNode BRIDGE_NODE -cdTmpDir /tmp/cd-bridge
```

Return codes

0

Command completed successfully.

1

Command ended unsuccessfully.

[The Connect:Direct bridge](#)

fteCreateEnvironment (set up environment for Redistributable Managed File Transfer Agent)

The **fteCreateEnvironment** command sets the environment for the configuration and transfer of files for the Redistributable Managed File Transfer Agent.

Purpose

You use the **fteCreateEnvironment** command to set up the environment for using the Redistributable Managed File Transfer Agent.

From IBM MQ 9.3.0, this environment is shared with the Redistributable Managed File Transfer Logger.

You can run this command with the **-d** parameter to specify the location for the MFT Agent data files. If you do not specify the **-d** parameter, the command creates the data files in the Redistributable Managed File Transfer Agent download location and sets the data path.

The **-n** parameter gives you the option of specifying an IBM MQ installation name. The value you specify for this option is used for the rest of the MFT commands run from the same console session.

Syntax

Parameters

-d data_location

Optional. This parameter is used for specifying the location of the data files at the time when the environment is set up.

If you do not specify this parameter, the data directory (if it does not already exist) is created in the location where the Redistributable Managed File Transfer Agent is extracted and the environment variable (BFG_DATA) is set for this location.

-? or -h

Optional. Displays command syntax.

-n *installation_name*

Optional. This parameter is used for specifying the name of an IBM MQ installation, or a unique name. The unique name must adhere to the same naming standards as the IBM MQ installation name. For more information about the naming standards, see [Installation name on AIX, Linux, and Windows](#).

Examples of situations in which you might want to use this parameter are:

- If you want to quickly test a new function or feature using the redistributable package with the existing configuration where agents have been configured to connect to queue manager in clients mode only. (Note that this parameter does not apply to any agent that is configured connect to a queue manager in bindings mode.)
- If you are migrating from a standard Managed File Transfer installation to a Redistributable Managed File Transfer Agent package, and you want to use the same configuration as the one that was created by the standard installation. This is the case where standard Managed File Transfer has been installed but is connecting to an agent queue manager running on another machine.

The default installation name variable is **BFG_INSTALLATION_NAME**.

Examples

Windows In this example, on Windows, the -d parameter specifies the location where the data folders are created:

```
fteCreateEnvironment -d C:\mftRedistributable\mftData
```

Linux On Linux, as a prerequisite, the command has to be run on a bash shell. In a bash shell, the command can be run in various ways, and the command file needs to be sourced:

```
source Path_of_MFTZipBin/fteCreateEnvironment
```

An alternative method is:

```
. Path_of_MFTZipBin/fteCreateEnvironment
```

or, if running from the directory where the command file is present:

```
./fteCreateEnvironment
```

Attention: Note the space following the first period character (.)

This example creates an environment where you specify both the MFT configuration data path, and installation name environment variables:

```
fteCreateEnvironment -d C:/ProgramData/IBM/mq/mqft -n MFTPROD
```

The output from this command is:

```
5724-H72 Copyright IBM Corp. 2008, 2024. ALL RIGHTS RESERVED
BFG_DATA is C:\ProgramData\IBM\MQ
BFG_INSTALLATION_NAME is MFTPROD
```

Both the **BFG_INSTALLATION_NAME** and **BFG_DATA** environment variables get updated to new values.

This example creates a new environment variable for the installation name only. The data path remains unchanged at C:\ProgramData\IBM\MQ.

```
fteCreateEnvironment -n MFTPROD
```

The output from the command is:

```
5724-H72 Copyright IBM Corp. 2008, 2024. ALL RIGHTS RESERVED  
BFG_DATA is C:\ProgramData\IBM\MQ  
BFG_INSTALLATION_NAME is MFTPROD
```

The **BFG_INSTALLATION_NAME** environment variable is updated to the new value *MFTPROD*.

This example creates a new environment variable for the path of the MFT configuration data only. The installation name remains unchanged at *MFTPROD*:

```
fteCreateEnvironment -d C:/ProgramData/IBM/MQ2
```

The output from the command is:

```
5724-H72 Copyright IBM Corp. 2008, 2024. ALL RIGHTS RESERVED  
BFG_DATA is C:\ProgramData\IBM\MQ2  
BFG_INSTALLATION_NAME is MFTPROD
```

fteCreateLogger (create an MFT file or database logger)

Use the **fteCreateLogger** command to create a Managed File Transfer file or database logger.

Important:  On IBM MQ for AIX, Linux, and Windows, only users who are IBM MQ administrators (and members of the mqm group) can run this command. If you try to run this command as a user who is not an IBM MQ administrator, you will receive the error message BFGCL0502E: You are not authorized to perform the requested operation. and the command will not run.

 On z/OS systems, the user must satisfy (at least) one of these conditions in order to run the command:

- Be a member of the mqm group (if the mqm group is defined on the system).
- Be a member of the group named in the BFG_GROUP_NAME environment variable (if one is named).
- Have no value set in the BFG_GROUP_NAME environment variable when the command is run.

Loggers on IBM i

Managed File Transfer loggers are not supported on the IBM i platform.

Purpose

The **fteCreateLogger** command provides you with the MQSC commands that you must run against your logger command queue manager to create the following logger queues:

- SYSTEM.FTE.LOG.CMD.*logger_name*
- SYSTEM.FTE.LOG.RJCT.*logger_name*

These queues are internal system queues that you must not modify, delete, or read messages from unless you are deleting the logger. The MQSC commands to run are also supplied in a file in the following location:

MQ_DATA_PATH\mqft\config\coordination_qmgr\loggers*logger_name**logger_name_create.mqsc*

If you later want to delete the logger, use the **fteDeleteLogger** command.

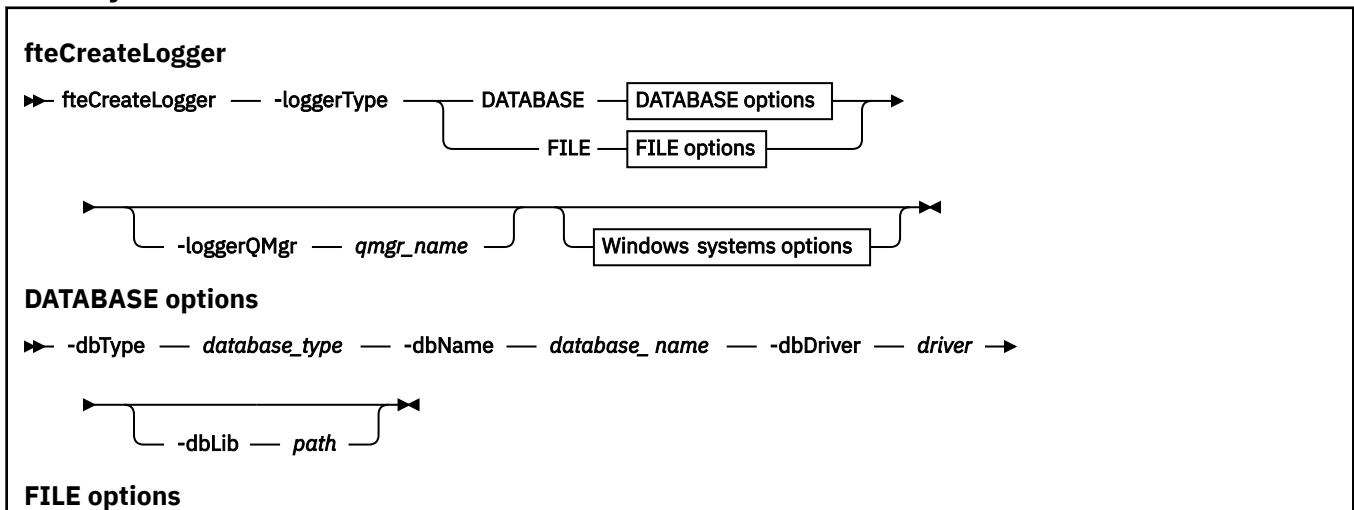

Managed File Transfer provides advanced logger properties that help you configure loggers. See, [MFT logger configuration properties](#)

Note: If the logger you are creating is a database logger and it is not connecting to a local Db2 database, you will need to manually create a *MQMFTCredentials.xml* file. The file contains the user name and password for connecting to the database. You should use the property file, *wmqfte.database.credentials*, in the *logger.properties* file to specify the path to the *MQMFTCredentials.xml* file. A sample of this credentials file is located in *MQ_INSTALLATION_PATH/mqft/samples/credentials/*.

Special characters

Take care when you use parameter values that contain special characters so that you avoid the command shell interpreting the characters in a way you do not expect. For example, fully qualified file paths and names that contains such characters as space, quotation mark (single or double), backslash or forward slash characters, might be interpreted by the command shell rather than being passed through directly to the command itself. To avoid characters being interpreted by the command shell, enclose the entire parameter in double or single quotation marks or escape the special characters by using the escape sequence of the command shell. When you specify file paths on Windows, ensure the separator character backslash (\) is entered as double backslashes (\\), that is, escaped backslash (\). Alternatively, you can use a single forward slash (/) character as a separator."

Syntax

Parameters

-loggerType *type*

Required. Specifies where managed file transfer information will be logged. The options for type are either DATABASE, if transfer information will be logged to a database, or FILE, if the information will be logged to a file.

-loggerQMgr *qmgr_name*

Optional. Determines the queue manager to connect to in order to receive messages containing information about managed file transfers. The queue manager must be on the same system as the logger. If you do not specify the **-loggerQMgr** parameter then the coordination queue manager that is associated with the configuration options set for this logger is used as the default.

If the coordination queue manager connects using a clients mode connection, the logger uses clients mode.

Attention: The **loggerQMgrHost**, **loggerQMgrPort**, and **loggerQMgrChannel** parameters are valid on a File logger only. If you attempt to use any one, or more, of these parameters on a Database logger, you receive the following message:

```
BFGCL0456E: The parameter '-loggerQMgrHost' is not valid for the fteCreateLogger command.
```

-dbType *database_type*

Required when **-loggerType** is DATABASE. Specifies the type of database management system in use for storing managed file transfer information. The options are db2 or oracle

Note: You need to create tables by using SQL files. The .sql files are available from `MQ_INSTALLATION_PATH_/mqft/sql`:

- For Db2 databases: `ftelog_tables_db2.sql`
- For Oracle databases: `ftelog_tables_oracle.sql`

-dbName *database_name*

Required when `-loggerType` is DATABASE. The name of the database where managed file transfer information is stored. The database must be configured with the Managed File Transfer log tables.

-dbDriver *driver*

Required when `-loggerType` is DATABASE. The location of the JDBC driver classes for the database. This is typically the path and file name of a JAR file.

-dbLib *path*

Optional when `-loggerType` is DATABASE. The location of any native libraries needed by your chosen database driver.

-fileLoggerMode *mode*

Required when `-loggerType` is FILE. Specifies the type of file system in use for storing managed file transfer information. The options are LINEAR or CIRCULAR.

Option LINEAR means the file logger will write information to a file until that file reaches its maximum size as defined by `-fileSize`. When the maximum size is reached the file logger will start a new file. Previously written files will not be deleted which allows them to be kept as a historical record of log messages. Files are not deleted when running in this mode, so the `-fileCount` will be ignored as there is no upper limit to the number of files that can be created. As there is no upper limit when running in this mode it will be necessary to track the amount of disk space used by the log files in order to avoid running low on disk space.

Option CIRCULAR means the file logger will write information to a file until that file reaches its maximum size as defined by `-fileSize`. When the maximum size is reached the file logger will start a new file. The maximum number of files written in this mode is controlled by the value defined using the `-fileCount`. When this maximum number of files is reached the file logger will delete the first file and re-create it for use as the currently active file. If the value defined in the `-fileSize` is a fixed size byte unit, the upper limit on the disk space used in this mode will equal `fileSize x fileCount`. If the values defined in `-fileSize` are a time unit, the maximum size will depend on the throughput of log message in your system over these time periods.

For more information, see [MFT logger configuration properties](#)

-fileSize *size*

Required when `-loggerType` is FILE. The maximum size that a log file is allowed to grow to. The value is a positive integer, greater than zero, followed by one of the following units: KB, MB, GB, m (minutes), h (hours), d (days), w (weeks). For example: `-fileSize 5MB` (specifies a maximum size of 5MB), `-fileSize 2d` (specifies a maximum of 2 days worth of data).

-fileCount *number*

Required when `-loggerType` is FILE and `-fileLoggerMode` is CIRCULAR. The maximum number of log files to create. When the amount of data exceeds the maximum amount that can be stored in this number of files, the oldest file is deleted so that the number of log files never exceeds the value specified in this parameter.

-loggerQMgrHost

Host name, or IP address, of the machine where the logger queue manager is running.

The default value is None.

If you do not specify the **-loggerQMgrHost** parameter, the logger is created in bindings mode.

-loggerQMgrPort

Port number where the logger queue manager is listening.

The default value is 1414.

-loggerQMgrChannel

Name of the channel used for connecting to the logger queue manager.

The default value is SYSTEM.DEF.SVRCONN.

Windows**-s *service_name***

Optional (Windows systems only). Indicates that the logger is to run as a Windows service. If you do not specify *service_name*, the service is named `mqmftLogge\LOGGERQMGR`, where `LOGGER` is the logger name and `QMGR` is your logger queue manager name.

The display name for the service, which is shown in the Windows **Services** window in the **Name** column, is always **Managed File Transfer Logger *LOGGER@QMGR***.

Windows **-su user_name**

Optional (Windows only). When the logger is to run as a Windows service, this parameter specifies the name of the account under which the service runs. To run the logger using a Windows domain user account specify the value in the form `DomainName\UserName`. To run the service using an account from the local built-in domain specify the value in the form `UserName`.

The Windows user account that you specify using the **-su** parameter must have the **Log on as a service** right. For information about how to grant this right, see [Troubleshooting an MFT agent or logger running as a Windows service](#).

This parameter is required when **-s** is specified.

Windows **-sp password**

Optional (Windows only). Password for the user account set by the **-su** parameter.

This parameter is only valid when **-s** is specified. If you do not specify this parameter when you specify the **-s** parameter, a warning message is produced. This message warns you that you must set the password using the Windows Services tool before the service starts successfully.

Windows **-sj options**

Optional (Windows only). When the logger is started as a Windows service, defines a list of options in the form of **-D** or **-X** that are passed to the JVM. The options are separated using a number sign (#) or semicolon (;) character. If you must embed any (#) or semicolon (;) characters, put them inside single quotation marks.

This parameter is only valid when **-s** is specified.

Windows **-sl options**

Optional (Windows only). Sets the Windows service log level. Valid options are: error, info, warn, debug. The default is info. This option can be useful if you are having problems with the Windows service. Setting it to debug gives more detailed information in the service log file.

This parameter is only valid when **-s** is specified.

-p configuration_options

Optional. Specifies the set of configuration options that is used to create the logger. By convention, this value is the name of a coordination queue manager. If you do not specify this parameter, the default set of configuration options is used.

-f

Optional. Forces the command to overwrite the existing configuration.

logger_name

Required. Name of the logger to create. This is incorporated into Managed File Transfer queue names, and so must contain only letters, numbers, and the periods (.) and underscore characters (_). It is also limited to a maximum length of 28 characters.

-credentialsFile file_path

Optional. The full file path of an existing or new credentials file, to which the IBM MQ authentication details are added.

This command supports the addition of a set of IBM MQ authentication details, to a named Managed File Transfer credentials file. Use this command when IBM MQ connection authentication has been enabled. If you update the existing details, you must use the **-f** force parameter.

-userid username

Optional. The user ID used to associate the credential details. If you do not specify a user ID, the credential details will apply to all users. You must also specify the **-credentialsFile** parameter.

-? or -h

Optional. Displays command syntax.

Examples

In this example, a circular file logger is created called filelogger1. The file logger will create a maximum of 10 files, each file being 10MB in size, using a maximum of 100MB of disk space in total:

```
fteCreateLogger -loggerType FILE -fileLoggerMode CIRCULAR -fileSize 10MB -fileCount 10
filelogger1
```

In this example, a database logger is created called dblogger1. The database logger connects to a Db2 database called FTEDB:

```
fteCreateLogger -loggerType DATABASE -dbName FTEDB -dbType DB2
-dbDriver "C:\Program Files (x86)\IBM\SQLLIB\java\db2jcc4.jar" dblogger1
```

In this example, a database logger is created called dblogger1. The database logger connects to an Oracle database called FTEDB:

```
fteCreateLogger -loggerType DATABASE -dbName FTEDB -dbType oracle
-dbDriver "C:\app\oracle\product\12.1.0\dbhome_2\jdbc\lib\ojdbc7.jar" dblogger1
```

In this example, a client mode file logger is created, using the host name and default port and channel:

```
fteCreateLogger -loggerType FILE -loggerQMgr CORDQM -loggerQMgrHost cordqm.ibm.com
-fileLoggerMode CIRCULAR -fileSize 10MB -fileCount 10 FL1
```

In this example, a client mode file logger is created, using the host name, port, and channel:

```
fteCreateLogger -loggerType FILE -loggerQMgr CORDQM -loggerQMgrHost cordqm.ibm.com
-loggerQMgrPort 4444 -loggerQMgrChannel LOGGER_CHANNEL -fileLoggerMode CIRCULAR -fileSize 10MB
-fileCount 10 FL1
```

Return codes

0

Command completed successfully.

1

Command ended unsuccessfully.

[“fteModifyLogger \(run an MFT logger as a Windows service\)” on page 2130](#)

Use the **fteModifyLogger** command to modify a Managed File Transfer logger so that it can be run as a Windows service. You can use this command only on Windows platforms, must be run by a user who is an IBM MQ administrator and a member of the mqm group, and you must first stop the logger by using the **fteStopLogger** command.

[“fteStartLogger \(start an MFT logger\)” on page 2171](#)

The **fteStartLogger** command starts a Managed File Transfer logging application.

[“fteStopLogger \(stop an MFT logger\)” on page 2177](#)

The **fteStopLogger** command stops a Managed File Transfer logger.

[“fteDeleteLogger \(delete an MFT logger and its configuration\)” on page 2107](#)

Use the **fteDeleteLogger** command to delete a Managed File Transfer logger and its configuration. Existing log files associated with the logger can either be retained or deleted.

[MFT logger error handling and rejection](#)

[MFT logger configuration properties](#)

fteCreateMonitor (create an MFT resource monitor)

The **fteCreateMonitor** command creates and starts a new resource monitor from the command line. You can monitor a resource (for example, the contents of a directory) by using Managed File Transfer so that when a trigger condition is satisfied, a specified task, such as a file transfer, is started.

Purpose

Use the **fteCreateMonitor** command to create and then start a new resource monitor by using a Managed File Transfer agent. For example, you can use a resource monitor in the following way: An external application puts one or more files in a known directory and when processing is complete, the external application places a trigger file in a monitored directory. The trigger file is then detected and a defined file transfer starts and copies the files from the known directory to a destination agent.

You can use the **-ox** and **-ix** parameters to export and import a resource monitor configuration to an XML file. Importing this file with the **fteCreateMonitor** command creates a new resource monitor with the same parameters as the resource monitor given in the **fteCreateMonitor** command to export to the XML file. Additionally, you can use the **-f** and **-c** parameters to overwrite a monitor configuration dynamically.

Notes:

- There is no restriction on the number of resource monitors that can be created on an agent, and all run with the same priority. Consider the implications of overlapping monitored resources, conflicting trigger conditions and how frequently the resources are polled. For more information, see [MFT resource monitoring concepts](#).
- You cannot create a resource monitor with a task definition that contains scheduled transfers. If you try to create a resource monitor with a transfer definition that points to a transfer that is scheduled to run, and repeat, at a specific time, the following message is displayed: Task definition file contains a scheduled transfer. A scheduled transfer can not be used with a resource monitor.
- The **fteCreateMonitor** command is not supported on protocol bridge agents.

Tip: You can also use the **fteListMonitors** command to export resource monitor configurations to an XML file:

- Using the **fteListMonitors** command with the **-ox** exports the definition for a single resource monitor.
- Using the **fteListMonitors** command with the **-od** exports multiple resource monitor definitions to a specified directory. You can also use the **-od** option to export a single resource monitor definition to a specified directory.

For more information about the **fteListMonitors** command, see [“fteListMonitors \(list MFT resource monitors\)” on page 2119](#).

Special characters

Take care when you use parameter values that contain special characters so that you avoid the command shell interpreting the characters in a way you do not expect. For example, fully qualified file paths and names that contains such characters as space, quotation mark (single or double), backslash or forward slash characters, might be interpreted by the command shell rather than being passed through directly to the command itself. To avoid characters being interpreted by the command shell, enclose the entire parameter in double or single quotation marks or escape the special characters by using the escape sequence of the command shell. When you specify file paths on Windows, ensure the separator character backslash (\) is entered as double backslashes (\\), that is, escaped backslash (\\). Alternatively, you can use a single forward slash (/) character as a separator."

Syntax

fteCreateMonitor

► fteCreateMonitor ►

Parameters

-ix *xml_filename*

Optional. Imports the resource monitor configuration from an XML file.

-ox *xml_filename*

Optional. This parameter must be specified with the **-ma** and **-mn** parameters and can be used with the **-f** parameter. Exports the resource monitor configuration to an XML file.

-mn *monitor_name*

Required. The name that you assign to this monitor. The monitor name must be unique to the monitoring agent. However, you can delete a monitor and then create a monitor with the same name.

The maximum length for a resource monitor name is 256 characters. Resource monitor names are not case-sensitive. Resource monitor names that are entered in lowercase or mixed case are converted to uppercase. Resource monitor names must not contain asterisk (*), percent (%), or question mark (?) characters.

-ma *monitoring_agent_name*

Required. The name of the agent to perform the resource monitoring. This monitoring agent must be the source agent for the monitor task that you want to trigger.

-mm *monitoring_agent_qmgr_name*

The name of the queue manager that the monitoring agent is connected to. Because the monitoring agent and the source agent must be same, this queue manager is also your source agent queue manager.

Note: The **fteCreateMonitor** command connects to the command queue manager for a Managed File Transfer topology. If the command queue manager is also the agent queue manager for the monitoring agent, then this parameter is optional. Otherwise, the parameter is required.

-f

Optional. Use this parameter to overwrite a resource monitor configuration. For example, when the resource monitor name you choose already exists on the resource monitoring agent and you want to update it rather than delete and re-create a monitor with the same name. Using this parameter causes the agent to restart the monitor process.

-c

Optional. This parameter clears the history of an updated resource monitor, which causes the resource monitor to check the trigger conditions again. You can use this parameter with the **-f** parameter only.

-md *directory_path*

Optional. The absolute name of the directory path that you want to monitor. Unless you are using the **-ix** or **-ox** parameters you must specify one of the **-md** or **-mq** parameters.

-mq *queue_name*

Optional. The name of the queue that you want to monitor. This queue must be on the monitoring agent queue manager. Unless you are using the **-ix** or **-ox** parameters you must specify one of the **-md** or **-mq** parameters.

-mt *task_definition_file_name*

Required. The name of the XML document that contains the task definition that you want to carry out when the trigger condition is satisfied. For more information, see [Using transfer definition files](#). The path to the transfer definition XML document must be on the local file system that you run the **fteCreateMonitor** command from. If you do not specify a path to the file, the command looks for it in the current working directory. Unless you are using the **-ix** or **-ox** parameters, **-mt** is a required parameter.

You can use the **-gt** parameter on the [fteCreateTransfer](#) command to generate a template XML document that contains your file transfer request. The monitor uses the transfer template as its task definition.

You can also use the transfer recovery timeout, **-rt** parameter, along with the **-gt** parameter, when you run the **fteCreateMonitor** command. You can set the amount of time in seconds during which the source agent keeps retrying to recover a transfer that is stalled. The recovery timeout parameter is then included in the XML document with the transfer definition that the monitor uses. For more information on how to set this parameter, see [fteCreateTransfer](#) command.

z/OS On z/OS, you must store the task definition document in a UNIX file on z/OS UNIX System Services. You cannot store task definition documents in z/OS sequential files or PDS members.

IBM i On IBM i, you must store the task definition document in the integrated file system.

-rl *number_of_recursion_levels*

Optional. The level of monitoring recursion of the root monitoring directory that is how many levels of subdirectory to go down into. For example, in a directory structure like the following example with C:/wmqfte/monitor set as the root monitoring directory

```
C:/wmqfte/monitor
C:/wmqfte/monitor/reports
C:/wmqfte/monitor/reports/2009
C:/wmqfte/monitor/reports/2009/April
```

If you specify -rl 2, Managed File Transfer searches only as far down as the C:/wmqfte/monitor/reports/2009 directory and its sibling directories. The C:/wmqfte/monitor/reports/2009/April directory is ignored. By default, recursion is set to none.

-pi *interval_period*

Optional. The interval period between each monitor of a directory. The poll interval must be a positive integer value. The default value for -pi is 1.

-pu *units*

Optional. The time units for the monitor poll interval. If you specify the -pu parameter, you must also specify the -pi parameter. The default value for -pu is minutes. Specify one of the following options:

seconds

minutes

hours

days

-tr

Optional. Specifies the trigger condition that must be satisfied for the defined task to take place. If the condition is not satisfied, according to the source agent, the monitor task (for example the file transfer) is not started. A trigger condition consists of two optional parts, condition and pattern, separated by a comma. Specify one of the following formats:

- *condition,pattern*

where *condition* is one of the following values:

match

For each trigger that is satisfied, the defined task is performed. match is the default value.

For example, if the match is *.go and the files LONDON.go and MANCHESTER.go are present, the task is performed for LONDON.go and another task is performed for MANCHESTER.go.

If the same trigger file is present from a previous poll (that is, the file has not been modified), this file has a not satisfied trigger condition. That is, the match trigger file must be new and must have been modified since last the poll before the defined task is performed.

noMatch

No files in the monitored directory match the pattern. That is, if *any* of the files in the monitored directory do not exist, the condition is satisfied. If no files match the trigger condition at the time the monitor is created, the monitor starts instantly, but does not start again until a file match is found, and then removed.

noSizeChange=*n*

A minimum of one of the files in the directory matches the pattern and has a file size that does not change for *n* polling intervals. The value of *n* is a positive integer.

fileSize>=size

A minimum of one of the files in the directory matches the pattern and has a minimum file size greater or equal to *size*. The value *size* is a combination of an integer with an optional size unit of B, KB, MB, or GB. For example, `fileSize">"=10KB`. If you do not specify a size unit, the default size that is used is bytes. On all operating systems, you must enclose the greater than symbol (>) in double quotation marks when you specify the `fileSize` option on the command line, as shown in this example.

The pattern is a file pattern match sequence in wildcard or Java regular expression format. The default value for the pattern is `*`, or match any file, and the default format is wildcard format. Use the **-pt** to specify the format of the pattern.

For example, the following trigger condition is satisfied when a file exists in the monitored directory with the suffix `.go`.

```
-tr match,*.go
```

The following trigger condition is satisfied when there are no files in the monitored directory that have the suffix `.stop`.

```
-tr noMatch,*.stop
```

You can specify *condition,pattern* only if you also specify the **-md** parameter.

- *condition*

where *condition* is one of the following values:

queueNotEmpty

The monitored queue is not empty. That is, if there are *any* IBM MQ messages on the monitored queue, the condition is satisfied. A single task is run for all of the messages on the queue.

completeGroups

There is a complete group on the monitored queue. That is, if *any* of the IBM MQ message groups on the monitored queue are complete, the condition is satisfied. An individual task is run for each complete group on the queue.

If a single message that is not in a group is put on the queue, it is treated as if it is a complete group and a task is run for the single message.

You can specify *condition* only if you also specify the **-mq** parameter.

For each monitor that you create, you can specify the **-tr** parameter once only.

-tc

Optional. Indicates that the triggered file contains one or more file paths to generate a transfer request. The default format of the trigger file's contents is one file entry on each line. Specify the file paths either as *source file path* or *source file path,destination file path*. This parameter is available only for directory monitor triggers match and noSizeChange.

-tcr pattern

Optional. Specifies a replacement regular expression for parsing trigger files. If you specify the **-tcr** parameter, you must also specify the **-tc** parameter.

Design the pattern to parse each line entry completely with one or two capture groups. Group one defines the source file path and the optional group two defines the destination file path. This is the default behavior, which you can change using the **-tcc** parameter.

For more information and examples, see [Using a trigger file](#).

-tcc

Optional. Defines the regular expression capture group order.

srcDest

The default value where group one is the source file path and group two is the destination file path.

destSrc

The reverse of `srcDest`. Group one is the destination file path and group two is the source file path. Ensure that the regular expression for `destSrc` has two capture groups.

If you specify the **-tcc** parameter, you must also specify the **-tcx** parameter.

-x exclude_pattern

Optional. Specifies files that are excluded from the trigger pattern match. The trigger pattern is specified by the **-tr** parameter.

The pattern is a file pattern match sequence in wildcard or Java regular expression format. The default format is wildcard format. Use the **-pt** parameter to specify the format of the pattern.

-mmd monitor_metadata

Optional. Specifies the user-defined metadata that is passed to the monitor's exit points. The parameter can take one or more name pairs that are separated by commas. Each name pair consists of a *name=value*. You can use the **-mmd** parameter more than once in a command.

-pt pattern_type

Optional. The type of pattern that is used by the **-tr** and **-x** parameters. Valid values are:

wildcard

The patterns are evaluated as wildcard patterns. An asterisk (*) matches zero or more characters and a question mark (?) matches exactly one character. This is the default.

regex

The patterns are evaluated as Java regular expressions. For more information, see [“Regular expressions used by MFT” on page 2556](#).

-bs matches_per_task

Optional. The maximum number of trigger matches to include in a single task. For example, if a value of 5 is specified for *matches_per_task* and nine trigger matches occur in a single poll interval, two tasks are performed. The first task corresponds to triggers 1-5 inclusive, and the second task corresponds to triggers 6-9. The default value of *matches_per_task* is 1.

The **-bs** parameter is supported only when the task definition XML that you supply to the **-mt** parameter is a managedTransfer. A managedCall is not supported with the **-bs** parameter.

-mquserid user_id

Optional. Specifies the user ID to authenticate with the command queue manager.

-mqpassword password

Optional. Specifies the password to authenticate with the coordination queue manager.

When the **-mqpassword** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

From IBM MQ 9.3, the command defaults to using MQCSP authentication, and sends the user ID and password to be authenticated to the queue manager in an MQCSP structure.

-nolpw

Optional. Specify this parameter if the command connects to a queue manager that does not support passwords longer than 12 characters.

When the **-nolpw** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid** and **-nolpw**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

Note: If you specify the **-nolpw** option, and the password is longer than 12 characters the command fails with error message BFGCL0829E.

-dv default_variables

Optional. A comma-separated list of default variables that can be used in variable substitution when monitoring a queue. The values are in the format of a key-value pair. For example:

```
-dv size=medium,color=blue
```

For more information about variable substitution, see [Customizing MFT tasks with variable substitution](#). You can only specify the **-dv** parameter if you have also specified the **-mq** parameter.

-? or -h

Optional. Displays command syntax.

-p configuration_options

Optional. This parameter determines the set of configuration options to use to cancel the transfer. By convention use the name of a nondefault coordination queue manager as the input for this parameter. The command then uses the set of properties files that are associated with this nondefault coordination queue manager.

If you do not specify this parameter, the set of configuration options based on the default coordination queue manager is used.

Examples

In this example, a new resource monitor is created called MYMONITOR using the monitoring agent MYAGENT. Provided the trigger condition that a file larger than 5 MB is present in the directory C:/wmqfte/monitors, the file transfer that is defined in the file C:/templates/transfer_reports.xml is started. MYAGENT is also the source agent for the file transfer that is defined in C:/templates/transfer_reports.xml:

```
fteCreateMonitor -ma MYAGENT -md C:/wmqfte/monitors -mn MYMONITOR -mt C:/templates/transfer_reports.xml -tr fileSize">"=5MB,*.*go
```

In this example, a resource monitor called MONITOR1 using the agent AGENT1 is created to transfer files greater than 5 MB and is exported to the XML file monitor.xml.

```
fteCreateMonitor -ox monitor.xml -ma AGENT1 -mn MONITOR1 -mt task.xml -tr "fileSize>=5MB,*.*zip"
```

Then the XML file is imported and changed to exclude any files greater than 10MB.

```
fteCreateMonitor -ix monitor.xml -x "fileSize>=10MB,*.*zip" -f
```

In this example, a new resource monitor is created called MYMONITOR using the agent MYAGENT.

```
fteCreateMonitor -ma MYAGENT -md c:/wmqfte -mn MYMONITOR -mt c:/templates/transfer_reports.xml -tr "fileSize>=5MB,*.*go"
```

However the trigger is initially incorrectly set to monitor c:/wmqfte rather than c:/wmqfte/monitors. The **fteCreateMonitor** request is immediately reissued with the monitor directory corrected and the **-f** (overwrite) and **-c** (clear history) parameters used to update the monitor.

```
fteCreateMonitor -ma MYAGENT -md c:/wmqfte/monitors -mn MYMONITOR -mt c:/templates/transfer_reports.xml -tr "fileSize>=5MB,*.*go" -f -c
```

Return codes

<i>Table 345. Return code names and descriptions</i>	
Return code	Description
0	Command completed successfully.
1	Command ended unsuccessfully.

Related reference

[“fteDeleteMonitor \(delete an MFT resource monitor\)” on page 2109](#)

Use the **fteDeleteMonitor** command to stop and delete an existing Managed File Transfer resource monitor using the command line. Issue this command against the resource monitoring agent.

fteCreateTemplate (create new file transfer template)

The **fteCreateTemplate** command creates a file transfer template that you can keep for future use. The only required parameter is the **-tn** *template_name* parameter. All other parameters are optional, although if you specify a source file specification, you must also provide a destination file. Similarly, if you specify a destination file, you must also specify a source file specification.

Purpose

Use the **fteCreateTemplate** command to create a file transfer template that stores your transfer details until you want to use them at a later date. Use transfer templates to store common file transfer settings for repeated or complex transfers. After you have created a transfer template, submit the template using the IBM MQ Explorer. You cannot submit a transfer template from the command line.

The transfer template that you create using the **fteCreateTemplate** command is not the same as the XML message that you create using the **-gt** parameter on the **fteCreateTransfer** command. You cannot use the two different types of template interchangeably.

You can run the **fteCreateTemplate** command from any system that can connect to the IBM MQ network and then route to the coordination queue manager. Specifically for the command to run, you must have installed Managed File Transfer on this system and you must have configured the Managed File Transfer component on this system to communicate with the IBM MQ network.

From IBM MQ 9.3.0, this command uses the `coordination.properties` file to connect to the coordination queue manager for the Managed File Transfer topology. If the `coordination.properties` file contains the `coordinationQMgrHost` property, then the command connects to the coordination queue manager using the CLIENT transport. Otherwise, the command connects to the coordination queue manager using the BINDINGS transport. For more information, see [The MFT coordination.properties file](#).

You can specify multiple source files for a file transfer but only one destination agent; transferring one file to multiple destination agents is not supported. However, you can transfer multiple source files to multiple destination files on a single destination agent.

For guidance about how to transfer files, see [“Guidelines for transferring files” on page 2523](#).

Special characters

Take care when you use parameters that contain special characters so that you avoid the command shell interpreting the characters in a way you do not expect.  For example, fully qualified data set names that contain single quotation marks and source specifications that contain asterisk characters might be interpreted by the command shell rather than being passed through in the transfer request. To avoid characters being interpreted by the command shell, enclose the entire parameter in double quotation marks as shown in the final two examples [“Examples” on page 2078](#), or escape the special characters using the escape sequence of the command shell.

Relative paths

The **fteCreateTemplate** command supports the use of relative file paths. On distributed systems  and z/OS UNIX System Services by default paths are considered to be relative

to the home directory of the user that the agent is running as. To change the directory that path names are evaluated relative to, set the `transferRoot` property in the `agent.properties` file. This file is located in the `MQ_DATA_PATH/mqft/config/coordination_qmgr/agents/agent_name` directory. Add the following line to the file:

```
transferRoot=directory_name
```

You must escape Windows paths or write them in UNIX format. For example, specify `C:\TransferRoot` as `C:\\TransferRoot` or `C:/TransferRoot`.

z/OS On z/OS, by default the user name that the agent is currently running under is added as a high-level qualifier prefix to data set specifications that have not been fully qualified. For example: `//ABC.DEF`. To change the value that is added as a prefix to the data set name, set the `transferRootHLQ` property in the `agent.properties` file. This file is located in the `MQ_DATA_PATH/mqft/config/coordination_qmgr/agents/agent_name` directory. Add the following line to the file:

```
transferRootHLQ=prepend_value
```

z/OS However, for transfers that involve a Connect:Direct node on a z/OS system, the data set specification is interpreted as a fully qualified name. No high-level qualifier is added to the data set name.

Syntax

fteCreateTemplate

File splitting options

Parameters

-sa *source_agent_name*

Optional. The name of the agent that the source file is transferred from. If you do not specify this agent name when you create the template, you must specify the source agent name when you use the template.

-sm *source_agent_qmgr_name*

Optional. The name of the queue manager that the source agent is connected to.

If you do not specify the **-sm** parameter, the queue manager used is determined by the set of configuration options in use, based on the source agent name. If the queue manager name cannot be determined using these options, the transfer template creation fails. For example, the template creation fails if the `agent.properties` file for the source agent cannot be found.

-da *destination_agent_name*

Optional. The name of the agent that the file is transferred to. If you do not specify the destination agent name when you create the template, you must specify the destination agent name when you use the template.

-dm *destination_agent_qmgr_name*

Optional. The name of the queue manager that the destination agent is connected to.

If you do not specify the **-dm** parameter, the queue manager used is determined by the set of configuration options in use, based on the destination agent name. If the queue manager name cannot be determined using these options, the transfer template creation fails. For example, the template creation fails if the `agent.properties` file for the destination agent cannot be found.

-td *transfer_definition_file*

Optional. The name of the XML document that defines one or more source and destination file specifications for the transfer.

One of the **-td**, **-df**, **-dd**, **-ds**, **-dq**, **-du**, and **-dp** parameters is required. If you specify the **-td** parameter, you cannot specify source files, or specify the **-df**, **-dd**, **-ds**, **-dp**, **-dq**, **-du**, **-sd**, **-r**, **-de**, **-t**, or **-cs** parameters.

The **ftcCreateTemplate** command locates the transfer definition file in relation to your current directory. If you cannot use relative path notation to specify the location of the transfer definition file, use the fully qualified path and file name of the transfer definition file instead.

Alternatively, this parameter can be the name of the XML document that contains a managed transfer request. An XML task definition is created with the **-gt** parameter of the `fteCreateTransfer` command.

z/OS On z/OS, you must store the transfer definition file in a UNIX file on z/OS UNIX System Services. You cannot store transfer definition files in z/OS sequential files or PDS members.

IBM i On IBM i, you must store the transfer definition file in the integrated file system.

For more information, see [Using transfer definition files](#).

-df destination_file

Optional. The name of the destination file. Specify a file name that is valid on the system where the destination agent is running.

If the destination agent is a Connect:Direct bridge agent, the destination file is specified in the format `connect_direct_node_name:file_path`. The Connect:Direct bridge agent accepts only file paths that are specified in this format. **z/OS** If the destination agent is a Connect:Direct bridge agent and the destination is a PDS member, you must also specify the **-de** parameter with a value of overwrite.

One of the **-td**, **-df**, **-dd**, **-ds**, **-dq**, **-du**, and **-dp** parameters is required. If you specify the **-df** parameter, you cannot specify the **-td**, **-dd**, **-dp**, **-dq**, **-du**, or **-ds** parameters because these parameters are mutually exclusive.

-dd destination_directory

Optional. The name of the directory the file is transferred to. Specify a directory name that is valid on the system where the destination agent is running.

If the destination agent is a Connect:Direct bridge agent, the destination directory is specified in the format `connect_direct_node_name:directory_path`. If the destination agent is a Connect:Direct bridge agent and the destination is a PDS, you must also specify the **-de** parameter with a value of overwrite.

One of the **-td**, **-df**, **-dd**, **-ds**, **-dq**, **-du**, and **-dp** parameters is required. If you specify the **-dd** parameter, you cannot specify the **-td**, **-df**, **-dp**, **-dq**, **-du**, or **-ds** parameters because these parameters are mutually exclusive.

z/OS -ds destination_sequential_data_set

z/OS only. Optional. The name of the sequential data set or PDS member that files are transferred into. Specify a sequential data set name or a partitioned data set member.

One of the **-td**, **-df**, **-dd**, **-ds**, **-dq**, **-du**, and **-dp** parameters is required. If you specify the **-ds** parameter, you cannot specify the **-td**, **-dd**, **-df**, **-dq**, **-du**, or **-dp** parameters because these parameters are mutually exclusive.

The syntax for the data set name is as follows:

```
//data_set_name{;attribute;..;attribute}
```

or

```
//pds_data_set_name(member_name){;attribute;..;attribute}
```

That is, a data set name specifier prefixed with `//` and optionally followed by a number of attributes separated by semicolons.

If the data set is located at a Connect:Direct node, you must prefix the data set name with the node name. For example:

```
CD_NODE1://'OBJECT.LIB';RECFM(F,B);BLKSIZE(800);LRECL(80)
```

If the destination agent is a Connect:Direct bridge agent and the destination is a PDS member, you must also specify the **-de** parameter with a value of overwrite. For more information about data set

transfers to or from Connect:Direct nodes, see [“Transferring data sets to and from Connect:Direct nodes” on page 2532](#).

For transfers that only involve Managed File Transfer agents, if the data set name part is enclosed by single quotation mark characters, it specifies a fully qualified data set name. If the data set name is not enclosed by single quotation mark characters, the system adds the default high-level qualifier for the destination agent (either the value for the `transferRootHLQ` agent property or the user ID that the agent runs under, if you have not set `transferRootHLQ`).

Note:   However, for transfers that involve a Connect:Direct node on a z/OS system, the data set specification is interpreted as a fully qualified name. No high-level qualifier is added to the data set name. This is the case even if the data set name is enclosed by single quotation mark characters.

The data set attributes are used either to create a data set or to ensure that an existing data set is compatible. The specification of data set attributes is in a form suitable for BPXWDYN (see [Requesting dynamic allocation](#) for more information). When the agent is to create a destination data set, the following BPXWDYN attributes are automatically specified: `DSN(data_set_name) NEW CATALOG MSG(numeric_file_descriptor)`, where *numeric_file_descriptor* is a file descriptor generated by Managed File Transfer. For a data set to data set transfer, the attributes of RECFM, LRECL, and BLKSIZE from the source are selected for a new destination data set. Note the SPACE setting for a new destination data set is not set by Managed File Transfer and system defaults are used. Therefore, you are recommended to specify the SPACE attribute when a new data set is to be created. You can use the **`bpxwdynAllocAdditionalProperties`** property in the agent `.properties` file to set BPXWDYN options that apply to all transfers. For more information, see [The MFT agent.properties file](#).

Some BPXWDYN options must not be specified when using the **`fteCreateTemplate`** command, the **`fteCreateTransfer`** command or the **`bpxwdynAllocAdditionalOptions`** property in the agent `.properties` file. For a list of these properties, see [BPXWDYN properties you must not use with MFT](#).

When you transfer a file or data set to tape, any existing data set that is already on the tape is replaced. The attributes for the new data set are set from attributes passed in the transfer definition. If no attributes are specified, attributes are set to the same as the source data set or to the default values when the source is a file. The attributes of an existing tape data set are ignored.

The **`-ds`** parameter is not supported when the destination agent is a protocol bridge agent.

 **`-dp destination_partitioned_data_set`**

z/OS only. Optional. The name of the destination PDS that files are transferred into. Specify a partitioned data set name. If a PDS is created as a result of the transfer, this PDS is created as a PDSE by default. You can override the default by specifying `DSNTYPE=PDS`.

One of the **`-td`**, **`-df`**, **`-dd`**, **`-ds`**, **`-dq`**, **`-du`**, and **`-dp`** parameters is required. If you specify the **`-dp`** parameter, you cannot specify the **`-td`**, **`-dd`**, **`-df`**, **`-dq`**, **`-du`**, or **`-ds`** parameters because these parameters are mutually exclusive.

The syntax for the PDS data set name is as follows:

```
//pds_data_set_name{;attribute;..;attribute}
```

The syntax for the data set name is the same as described for the **`-ds destination_sequential_data_set`** parameter. All the syntax details for specifying data sets that are located on Connect:Direct nodes also apply to the **`-dp`** parameter. If the destination agent is a Connect:Direct bridge agent, you must also specify the **`-de`** parameter with a value of `overwrite`.

The **`-dp`** parameter is not supported when the destination agent is a protocol bridge agent.

`-du destination_user`

Optional. The name of the user whose destination file space the files are transferred into.

One of the **-td**, **-df**, **-dd**, **-ds**, **-dp**, **-du**, and **-dq** parameters is required. If you specify the **-du** parameter, you cannot specify the **-td**, **-dd**, **-df**, **-dp**, **-dq**, or **-ds** parameters because these parameters are mutually exclusive.

The **-du** parameter is not supported when the destination agent is a protocol bridge agent or a Connect:Direct bridge agent.

-dq destination_queue

Optional. The name of a destination queue that files are transferred onto. You can optionally include a queue manager name in this specification, using the format QUEUE@QUEUEMANAGER. If you do not specify a queue manager name, the destination agent queue manager name is used if you have not set the enableClusterQueueInputOutput agent property to true. If you have set the enableClusterQueueInputOutput agent property to true, the destination agent uses standard IBM MQ resolution procedures to determine where the queue is located. You must specify a valid queue name that exists on the queue manager.

One of the **-td**, **-df**, **-dd**, **-ds**, **-dp**, **-du**, and **-dq** parameters is required. If you specify the **-dq** parameter, you cannot specify the **-td**, **-dd**, **-df**, **-dp**, **-du**, or **-ds** parameters because these parameters are mutually exclusive.

The **-dq** parameter is not supported when the destination agent is a protocol bridge agent or a Connect:Direct bridge agent, or when the source specification is a queue.

-dqp persistent

Optional. Specifies whether messages written to the destination queue are persistent. The valid options are as follows:

true

Writes persistent messages to the destination queue. This is the default value.

false

Writes non-persistent messages to the destination queue.

qdef

The persistence value is taken from the DefPersistence attribute of the destination queue.

You can only specify the **-dqp** parameter if you have also specified the **-dq** parameter.

-qmp boolean

Optional. Specifies whether the first message written to the destination queue by the transfer has IBM MQ message properties set. The valid options are as follows:

true

Sets message properties on the first message created by the transfer.

false

Does not set message properties on the first message created by the transfer. This is the default value.

You can only specify the **-qmp** parameter if you have also specified the **-dq** parameter. For more information, see [“MQ message properties set by MFT on messages written to destination queues” on page 2581](#)

-qs message_size

Optional. Specifies whether to split the file into multiple fixed-length messages. All the messages have the same IBM MQ group ID; the last message in the group has the IBM MQ LAST_MSG_IN_GROUP flag set. The size of the messages is specified by the value of *message_size*. The format of *message_size* is *lengthunits*, where *length* is a positive integer value and *units* is one of the following values:

B

Bytes. The minimum value allowed is two times the maximum bytes-per-character value of the code page of the destination messages.

K

This is equivalent to 1024 bytes.

M

This is equivalent to 1048576 bytes.

If you specify the value `text` for the **-t** parameter and the file is in a double byte character set or multibyte character set, the file is split into messages on the closest character boundary to the specified message size.

You can only specify the **-qs** parameter if you have also specified the **-dq** parameter. You can only specify one of the **-qs**, **-dqdb**, and **-dqdt** parameters.

-dqdb hexadecimal_delimiter

Optional. Specifies the hexadecimal delimiter to use when splitting a binary file into multiple messages. All the messages have the same IBM MQ group ID; the last message in the group has the IBM MQ `LAST_MSG_IN_GROUP` flag set. The format for specifying a hexadecimal byte as a delimiter is `xNN`, where `N` is a character in the range `0-9` or `a-f`. You can specify a sequence of hexadecimal bytes as a delimiter by specifying a comma-separated list of hexadecimal bytes, for example: `x3e,x20,x20,xbf`.

You can only specify the **-dqdb** parameter if you have also specified the **-dq** parameter and the transfer is in binary mode. You can only specify one of the **-qs**, **-dqdb**, and **-dqdt** parameters.

-dqdt pattern

Optional. Specifies the regular expression to use when splitting a text file into multiple messages. All the messages have the same IBM MQ group ID; the last message in the group has the IBM MQ `LAST_MSG_IN_GROUP` flag set. The format for specifying a regular expression as a delimiter is a regular expression enclosed in parentheses, (*regular_expression*). The value of this parameter is evaluated as a Java regular expression. For more information, see [“Regular expressions used by MFT” on page 2556](#).

By default, the length of the string that the regular expression can match is limited by the destination agent to five characters. You can change this behavior using the `maxDelimiterMatchLength` agent property. For more information, see [Advanced agent properties](#).

You can only specify the **-dqdt** parameter if you have also specified the **-dq** parameter and the value `text` for the **-t** parameter. You can specify only one of the **-qs**, **-dqdb**, and **-dqdt** parameters.

-dqdp

Optional. Specifies the expected position of destination text and binary delimiters when splitting files. You can only specify the **-dqdp** parameter if you have also specified one of the **-dqdt** and **-dqdb** parameters.

Specify one of the following options:

prefix

The delimiters are expected at the beginning of each line.

postfix

The delimiters are expected at the end of each line. This is the default option.

-qi

Optional. Specifies whether to include the delimiter that is used to split the file into multiple messages in the messages. If **-qi** is specified, the delimiter is included at the end of the message that contains the file data preceding the delimiter. By default the delimiter is not included in the messages.

You can only specify the **-qi** parameter if you have also specified one of the **-dqdt** and **-dqdb** parameters.

-de destination_file_behavior

Optional. Specifies the action that is taken if a destination file exists on the destination system. The valid options are as follows:

error

Reports an error and the file is not transferred. This is the default value.

overwrite

Overwrites the existing destination file.

If you specify the **-de** parameter, you cannot specify the **-td** parameter because these parameters are mutually exclusive.

-sd source_file_disposition

Optional. Specifies the action that is taken on a source file when that source file has successfully been transferred to its destination. The valid options are as follows:

leave

The source files are left unchanged. This is the default value.

delete

The source file is deleted from the source system after the source file is successfully transferred.

 On z/OS, if the source is a tape data set and you specify the delete option, the tape is remounted to delete the data set. This behavior is because of the behavior of the system environment.

If the source is a queue and you specify the leave option, the command returns an error and a transfer is not requested.

If the source agent is a Connect:Direct bridge agent and you specify the delete option, the behavior is different to the usual source disposition behavior. One of the following cases occurs:

- If Connect:Direct uses a process that is generated by Managed File Transfer to move the file or data set from the source, specifying the delete option causes the transfer to fail. To specify that the source file is deleted, you must submit a user-defined Connect:Direct process. For more information, see [Submitting a user-defined Connect:Direct process from a file transfer request](#).
- If Connect:Direct uses a user-defined process to move the file or data set from the source, this parameter is passed to the process through the **%FTEFDISP** intrinsic symbolic variable. The user-defined process determines whether the source is deleted. The result that the transfer returns depends on the result that is returned by the user-defined process.

If you specify the **-sd** parameter, you cannot specify the **-td** parameter because these parameters are mutually exclusive. However, you can specify source disposition behavior in the transfer definition file.

-pr transfer_priority

Optional. Specifies the priority level of the transfer. Priority is a value in the range 0-9, where 0 is the lowest priority. The default priority level is 0 and by default the transfer uses the priority level of the source agent.

This value matches the message priority value used by IBM MQ, see [Getting messages from a queue: priority](#) for more information. Message traffic for file transfer data defaults to a priority level of 0, which allows your IBM MQ message traffic to take priority.

-rt transfer_recovery_timeout

Optional. Sets the amount of time, in seconds, during which a source agent keeps trying to recover a stalled file transfer. Specify one of the following options:

-1

The agent continues to attempt to recover the stalled transfer until the transfer is complete. Using this option is the equivalent of the default behavior of the agent when the property is not set.

0

The agent stops the file transfer as soon as it enters recovery.

>0

The agent continues to attempt to recover the stalled transfer for the amount of time in seconds as set by the positive integer value specified. For example,

```
-rt 21600
```

indicates that the agent keeps trying to recover the transfer for 6 hours from when it enters recovery. The maximum value for this parameter is 999999999.

Specifying the transfer recovery timeout value in this way sets it on a per transfer basis. To set a global value for all transfers in a Managed File Transfer network, you can add a [transferRecoveryTimeout](#) property to the `agent.properties` file.

-p configuration_options

Optional. This parameter determines the set of configuration options that is used to create the transfer template. Use the name of a non-default coordination queue manager as the input for this parameter. The command then uses the set of properties files associated with this non-default coordination queue manager.

If you do not specify this parameter, the set of configuration options based on the default coordination queue manager is used.

-r

Optional. Recursively transfer files in subdirectories when *source_specification* contains wildcard characters. When Managed File Transfer is presented with a wildcard character as a *source_specification*, any directories that match the wildcard character are transferred only if you have specified the **-r** parameter. When *source_specification* matches a subdirectory, all files in that directory and its subdirectories (including hidden files) are always transferred.

For more information about how Managed File Transfer handles wildcard characters, see [“Using wildcard characters with MFT”](#) on page 2551

If you specify the **-r** parameter, you cannot specify the **-td** parameter because these parameters are mutually exclusive. However, you can specify recursive behavior in the transfer definition file.

-t

Optional. Specifies the type of file transfer: binary mode or text mode.

binary

The data in the file is transferred without any conversion. This is the default value.

text

The code page and end-of-line characters of the file are converted. The exact conversions performed depend on the operating systems of the source agent and destination agent.

z/OS For example, a file transferred from Windows to z/OS has its code page converted from ASCII to EBCDIC. When a file is converted from ASCII to EBCDIC, the end-of-line characters are converted from ASCII carriage return (CR) and line feed (LF) character pairs to an EBCDIC new line (NL) character.

z/OS For more information about how z/OS data sets are transferred, see [“Transferring files and data sets between z/OS and distributed systems”](#) on page 2524 and [“Transferring between data sets on z/OS”](#) on page 2526.

If you specify the **-t** parameter, you cannot specify the **-td** parameter because these parameters are mutually exclusive. However, you can specify transfer mode behavior in the transfer definition file.

-cs

Optional. Specifies whether a checksum algorithm is run on the file transfer data to check the integrity of the transferred files. Specify one of the following options:

MD5

Computes an MD5 checksum for the data. The resulting checksum for the source and destination files is written to the transfer log for validation purposes. By default, Managed File Transfer computes MD5 checksums for all file transfers.

none

No MD5 checksum is computed for the file transfer data. The transfer log records that checksum was set to none and the value for the checksum is blank. For example:

```
<checksum method="none"></checksum>
```

If you use the none option, you might improve file transfer performance, depending on your environment. However, selecting this option means that there is no validation of the source or destination files.

If you specify the **-cs** parameter, you cannot specify the **-td** parameter because these parameters are mutually exclusive. However, you can specify checksum behavior in the transfer definition file.

-tr

Optional. Specifies a condition that must be true for this file transfer to take place. If the condition is not true, according to the source agent, the file transfer is discarded and no transfer takes place. Specify the following format:

```
condition, namelist
```

where *condition* is one of the following values:

file=exist

A minimum of one of the files in the namelist exists. That is, if *any* of the files in the namelist exists, the condition is true.

file!=exist

A minimum of one of the files in the namelist does not exist. That is, if *any* of the files in the namelist do not exist, the condition is true.

filesize>=size

A minimum of one of the files in the namelist exists and has a minimum size as specified by *size*. The value of *size* is an integer with an optional size unit of KB, MB, or GB. For example, `filesize">="=10KB`. If you do not specify a size unit, the size is assumed to be bytes. On all operating systems, you must enclose the greater than symbol (>) in double quotation marks when you specify the `filesize` option on the command line, as shown in this example.

And where *namelist* is a comma-separated list of file names located on the source system. Depending on your operating system, if you want to use path names or file names in a namelist that contain spaces, you might have to enclose the path names and file names in double quotation marks. You can specify more than one trigger condition by using the **-tr** parameter more than once. However in that case, every separate trigger condition must be true for the file transfer to take place.

Note: To continually monitor a resource for a trigger condition to be true, you are recommended to use [resource monitoring](#). You can create a resource monitor using the `fteCreateMonitor` command.

In the following example, the file `file1.doc` is transferred from AGENT1 to AGENT2, on condition that either file `A.txt`, or file `B.txt`, or both files exist on AGENT1 *and* that either file `A.txt`, or file `B.txt`, or both files are equal to or larger than 1 GB:

```
fteCreateTemplate -tn JUPITER_AGENT_TRIGGER_TEST_TEMPLATE -sa AGENT1 -sm QM_JUPITER -da AGENT2 -dm QM_NEPTUNE
-tr file=exist,C:\export\A.txt,C:\export\B.txt
-tr filesize">="=1GB,C:\export\A.txt,C:\export\B.txt
-df C:\import\file1.doc C:\export\file1.doc
```

You can combine triggering parameters with scheduling parameters. If you do specify both types of parameters, the trigger conditions are applied to the file transfer created by the scheduling parameters.

-tl

Optional. Specifies whether trigger failures are logged. Specify one of the following options:

yes

Log entries are created for failed triggered transfers. This is the default behavior even if you do not specify the **-tl** parameter.

no

No log entries are created for failed triggered transfers.

-md

Optional. Specifies the user-defined metadata that is passed to the exit points of the agent. The **-md** parameter can take one or more name-value pairs separated by commas. Each name pair consists of *name=value*. You can use the **-md** parameter more than once in a command.

z/OS On z/OS, spaces represent delimiters so you must use underscores to separate values. For example, use `kw=text1_text2_text3` rather than `kw="text1 text2 text3"`

-tb

Optional. Specifies the time base you want to use for the scheduled file transfer. That is, whether you want to use a system time or Coordinated Universal Time (UTC). You must use this parameter with the **-ss** parameter only. Specify one of the following options:

admin

The start and end times used for the scheduled transfer are based on the time and date of the system used by the administrator. This is the default value.

source

The start and end times used for the scheduled transfer are based on the time and date of the system where the source agent is located.

UTC

The start and end times used for the scheduled transfer are based on Coordinated Universal Time (UTC).

-jn *job_name*

Optional. A user-defined job name identifier that is added to the log message when the transfer has started.

-ss *schedule_start_time*

Optional. Specifies the time and date that you want the scheduled transfer to take place. Use one of the following formats to specify the time and date. Specify the time using the 24-hour clock:

```
yyyy-MM-ddThh:mm  
hh:mm
```

Scheduled file transfers start within a minute of the schedule start time, if there are no problems that might affect the transfer. For example, there might be issues with your network or agent that prevent the scheduled transfer starting.

-oi

Optional. Specifies the interval that the scheduled transfer occurs at. You must use this parameter with the **-ss** parameter only. Specify one of the following options:

minutes

hours

days

weeks

months

years

-of *occurrence_frequency*

Optional. Specifies the frequency that the scheduled transfer occurs at. For example, every **5** weeks or every **2** months. You must specify this parameter with the **-oi** and **-ss** parameters only. If you do not specify this parameter, a default value of 1 is used.

-oc *occurrence_count*

Optional. Specifies how many times you want this scheduled transfer to occur. After the occurrence count has been met, the scheduled transfer is deleted.

Specify this parameter with the **-oi** and **-ss** parameters only.

If you specify the **-oc** parameter, you cannot specify the **-es** parameter because these parameters are mutually exclusive.

You can omit both the **-oc** and **-es** parameters to create a transfer that repeats indefinitely.

-es *schedule_end_time*

Optional. The time and date that a repeating scheduled transfer ends.

You must specify this parameter with the **-oi** and **-ss** parameters only.

If you specify the **-es** parameter, you cannot specify the **-oc** parameter because these parameters are mutually exclusive.

You can omit both the **-es** and **-oc** parameters to create a transfer that repeats indefinitely.

Use one of the following formats to specify the end time and date. Specify the time using the 24-hour clock:

```
yyyy-MM-ddThh:mm
```

```
hh:mm
```

-tn *template_name*

Required. The name of the template that you want to create. Use a descriptive string that allows you to select the correct template for transfers at a later date. There is no specific limit to the length of this string, but be aware that excessively long names might not be displayed properly in some user interfaces.

Do not create multiple templates with the same name.

-sqgi

Optional. Specifies that the messages are grouped by IBM MQ group ID. The first complete group is written to the destination file. If this parameter is not specified, all messages on the source queue are written to the destination file.

You can only specify the **-sqgi** parameter if you have also specified the **-sq** parameter.

-sqdt *text_delimiter*

Optional. Specifies a sequence of text to insert as the delimiter when appending multiple messages to a text file. You can include Java escape sequences for String literals in the delimiter. For example, `-sqdt \u007d\n`.

You can only specify the **-sqdt** parameter if you have also specified the **-sq** parameter and the value `text` for the **-t** parameter.

-sqdb *hexadecimal_delimiter*

Optional. Specifies one or more byte values to insert as the delimiter when appending multiple messages to a binary file. Each value must be specified as two hexadecimal digits in the range 00-FF, prefixed by x. Multiple bytes must be comma-separated. For example, `-sqdb x08,xA4`.

You can only specify the **-sqdb** parameter if you have also specified the **-sq** parameter. You cannot specify the **-sqdb** parameter if you have also specified the value `text` for the **-t** parameter.

-sqdp

Optional. Specifies the position of insertion of source text and binary delimiters. You can only specify the **-sqdp** parameter if you have also specified one of the **-sqdt** and **-sqdb** parameters.

Specify one of the following options:

prefix

The delimiters are inserted at the start of each message

postfix

The delimiters are inserted at the end of each message. This is the default option.

-sqwt *wait_time*

Optional. Specifies the time, in seconds, to wait for one of the following conditions to be met:

- For a new message to be put on the queue
- If the **-sqgi** parameter was specified, for a complete group to be put on the queue

If neither of these conditions are met within the time specified by *wait_time*, the source agent stops reading from the queue and completes the transfer. If the **-sqwt** parameter is not specified, the source agent stops reading from the source queue immediately if the source queue is empty or, in the case where the **-sqgi** parameter is specified, if there is no complete group on the queue.

You can only specify the **-sqwt** parameter if you have also specified the **-sq** parameter.

-sq

Optional. Specifies that the source of a transfer is a queue.

-mquserid *user_id*

Optional. Specifies the user ID to authenticate with the coordination queue manager.

-mqpassword *password*

Optional. Specifies the password to authenticate with the coordination queue manager.

When the **-mqpassword** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

From IBM MQ 9.3, the command defaults to using [MQCSP](#) authentication, and sends the user ID and password to be authenticated to the queue manager in an MQCSP structure.

-nolpw

Optional. Specify this parameter if the command connects to a queue manager that does not support passwords longer than 12 characters.

When the **-nolpw** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid** and **-nolpw**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

Note: If you specify the **-nolpw** option, and the password is longer than 12 characters the command fails with error message BFGCL0829E.

source_specification

Required if you have specified one of the **-df**, **-dd**, **-dp**, **-dp**, or **-ds** parameters. If you specify the **-td** parameter, do not specify *source_specification*.

- If you have not specified the **-sq** parameter, *source_specification* is one or more file specifications that determine the source, or sources, for the file transfer. File specifications are space delimited. File specifications can take one of five forms and can include wildcard characters. For more information about wildcard characters in WMQFTE, see [“Using wildcard characters with MFT” on page 2551](#). You can escape asterisks that are part of the file specification by using two asterisk characters (**) in the file specification.

To transfer files containing spaces in their file names, place double quotation marks around the file names that contain spaces. For example to transfer file a b.txt to file c d.txt specify the following text as part of the **fteCreateTemplate** command:

```
-df "c d.txt" "a b.txt"
```

Each file specification must be in one of the following formats:

File names

The name of a file, expressed using the appropriate notation for the system where the source agent is running. When a file name is specified as a source file specification, the contents of the file are copied.

Directories

The name of a directory, expressed using the appropriate notation for the system where the source agent is running. When a directory is specified as a source file specification, the contents of the directory are copied. More precisely, all files in the directory and in all its subdirectories, including hidden files, are copied.

For example, to copy the contents of DIR1 to DIR2 only, specify DIR1/* DIR2

 **Sequential data set**

(z/OS only). The name of a sequential data set or partitioned data set member. Denote data sets by preceding the data set name with two forward slash characters (//).

Partitioned data set

(z/OS only). The name of a partitioned data set. Denote data set names by preceding the data set name with two forward slash characters (/).

File name or directory at a Connect:Direct node

(Connect:Direct bridge agent only). The name of a Connect:Direct node, a colon character (:), and a file or directory path on the system that is hosting the Connect:Direct node. For example, `connect_direct_node_name:file_path`.

If the source agent is a Connect:Direct bridge agent, it will only accept source specifications in this form.

Note: Wildcard characters are not supported in file paths when the source agent is a Connect:Direct bridge agent.

- If you have specified the **-sq** parameter, *source_specification* is the name of a local queue on the source agent queue manager. You can specify only one source queue. The source queue is specified in the format:

```
QUEUE_NAME
```

The queue manager name is not included in the source queue specification, because the queue manager must be the same as the source agent queue manager.

-? or -h

Optional. Displays command syntax.

Examples

In this example, a transfer template called `payroll accounts monthly report template` is created. When submitted, this template transfers any file with the extension `.xls` from the agent `PAYROLL1` to the agent `ACCOUNTS` in the directories specified:

```
fteCreateTemplate -tn "payroll accounts monthly report template" -sa PAYROLL -sm QM_PAYROLL1 -da  
ACCOUNTS  
-dm QM_ACCOUNTS -df C:\payroll_reports\*.xls C:\out\*.xls
```

In this example, a transfer template called `jupiter_neptune_sched_template` is created. When submitted, the template transfers the file `originalfile.txt` from the system where `QM_JUPITER` is located to the system where `QM_NEPTUNE` is located. The file transfer is scheduled to take place at 09:00 based on the system time of the system where the source agent is located and occurs every two hours four times:

```
fteCreateTemplate -tn jupiter_neptune_sched_template -sa AGENT1 -sm QM_JUPITER -da AGENT2 -dm QM_NEPTUNE  
-tb source -ss 09:00 -oi hours -of 2 -oc 4  
-df C:\import\transferredfile.txt C:\export\originalfile.txt
```

In this example, a transfer template called `jupiter neptune trigger template` is created. When the template is submitted, the file `originalfile.txt` is transferred from `AGENT1` to `AGENT2`, on condition that the file `A.txt` exists on `AGENT1`:

```
fteCreateTemplate -tn "jupiter neptune trigger template" -sa AGENT1 -sm QM_JUPITER -da AGENT2 -dm  
QM_NEPTUNE  
-tr file=exist,C:\export\A.txt -df C:\import\transferredfile.txt C:\export\originalfile.txt
```

 In this example, a template called `ascii_ebcdic_template` is created. When the template is submitted, the file `originalfile.txt` is transferred from the system where `AGENT1` is

located to a data set //'USERID.TRANS.FILE.TXT' on the system where AGENT2 is located. Text mode has been selected to convert data from ASCII to EBCDIC.

```
fteCreateTemplate -tn ascii_ebcidic_template -t text -sa AGENT1 -da AGENT2
-ds '//TRANS.FILE.TXT;RECFM(V,B);BLKSIZE(6144);LRECL(1028);
SPACE(5,1)" C:\export\originalfile.txt
```

 In this example, a template called `ebcidic_ascii_template` is created. When the template is submitted, a member of a fully qualified data set on the system where AGENT1 is located is transferred to a file on the system where AGENT2 is located. Text mode has been selected to convert the file from EBCDIC to ASCII.

```
fteCreateTemplate -tn ebcidic_ascii_template -t text -sa AGENT1 -da AGENT2 -df /tmp/IEEUJV.txt
"//'SYS1.SAMPLIB(IEEUJV)'"
```

Return codes

Return code	Description
0	Command completed successfully.
1	Command ended unsuccessfully.

Related reference

[“fteCreateTransfer \(start a new file transfer\)” on page 2079](#)

The **fteCreateTransfer** command creates and starts a new file transfer from the command line. This command can start a file transfer immediately, schedule a file transfer for a future time and date, repeat a scheduled transfer one or more times, and trigger a file transfer based on certain conditions.

[“fteListTemplates \(list available MFT transfer templates\)” on page 2125](#)

Use the **fteListTemplates** command to list the available Managed File Transfer transfer templates on a coordination queue manager.

[“fteDeleteTemplates \(delete an MFT template\)” on page 2112](#)

Use the **fteDeleteTemplates** command to delete an existing Managed File Transfer template from a coordination queue manager.

fteCreateTransfer (start a new file transfer)

The **fteCreateTransfer** command creates and starts a new file transfer from the command line. This command can start a file transfer immediately, schedule a file transfer for a future time and date, repeat a scheduled transfer one or more times, and trigger a file transfer based on certain conditions.

Purpose

Use the **fteCreateTransfer** command to create and then start a new file transfer from a Managed File Transfer agent.

Note: File transfers can only take place between agents within the same Managed File Transfer topology.

For guidance about how to transfer files, see [“Guidelines for transferring files” on page 2523](#). For the z/OS platform, you can transfer text files, data sets, and generation data groups (GDGs).

You can run the **fteCreateTransfer** command from any system that can connect to the IBM MQ network and then route to the source agent queue manager. Specifically, for the command to run, you must install a Managed File Transfer component (either Service or Agent) on this system and configure the Managed File Transfer component on this system to communicate with the IBM MQ network.

This command uses a properties file called `command.properties` to connect to the IBM MQ network. If the `command.properties` file does not contain property information, a bindings mode connection is made to the default queue manager on the local system. If the `command.properties` file does not exist, an error is generated. For more information, see [The MFT command.properties file](#).

You can specify multiple source files for a file transfer but they must originate from a single source agent and terminate at a single destination agent. Transferring a single source file to multiple destination files on the same agent or multiple different agents is not supported within a single transfer. Ant scripting can be used to send the same source file to multiple destinations at one or more agents. For more information, see [Using Apache Ant with MFT](#).

Special characters

Take care when you use parameters that contain special characters so that you avoid the command shell interpreting the characters in a way you do not expect. For example, fully qualified data set names that contain single quotation marks, and source specifications that contain asterisk characters, might be interpreted by the command shell rather than being passed through in the transfer request. To avoid characters being interpreted by the command shell, enclose the entire parameter in double quotation marks or escape the special characters by using the escape sequence of the command shell.

Relative paths

The **fteCreateTransfer** command supports the use of relative file paths. For the following platforms, by default, paths are considered to be relative to the home directory of the user that the agent is running as:

- **Multi** Multiplatforms
- **z/OS** z/OS UNIX System Services

To change the directory that path names are evaluated relative to, set the `transferRoot` property in the `agent.properties` file. This file is located in the `MQ_DATA_PATH/mqft/config/coordination_qmgr/agents/agent_name` directory. Add the following line to the file:

```
transferRoot=directory_name
```

Windows For example, specify `C:\TransferRoot` as `C:\\TransferRoot` or `C:/TransferRoot`.

z/OS On z/OS, by default the user name that the agent is running under is added as a high-level qualifier prefix to data set specifications that have not been fully qualified. For example: `//ABC.DEF`. To change the value that is added as a prefix to the data set name, set the `transferRootHLQ` property in the `agent.properties` file. This file is located in the `MQ_DATA_PATH/mqft/config/coordination_qmgr/agents/agent_name` directory. Add the following line to the file:

```
transferRootHLQ=prepend_value
```

z/OS However, for transfers that involve a Connect:Direct node on a z/OS system, the data set specification is interpreted as a fully qualified name. No high-level qualifier is added to the data set name.

Syntax

fteCreateTransfer

File splitting options

Parameters for MQ security

► source_specification ◄

Parameters for agent specification

-sa source_agent_name

Required. The name of the agent that the source files are transferred from.

z/OS If you specify a protocol bridge agent as your source agent, you cannot then specify a data set as the source file specification.

If you specify the **-td** parameter and the transfer definition file contains the source agent that you want to use for the transfer, do not specify the **-sa** parameter.

-sm source_agent_qmgr_name

Optional. The name of the queue manager that the source agent is connected to.

If you do not specify the **-sm** parameter, the queue manager that is used is determined by the set of configuration options in use, which is based on the source agent name. If the `agent.properties` file for the source agent cannot be found, the file transfer fails.

-da destination_agent_name

Required. The name of the agent that the files are transferred to.

If you specify the **-td** parameter and the transfer definition file contains the destination agent that you want to use for the transfer, do not specify the **-da** parameter.

-dm destination_agent_qmgr_name

Optional. The name of the queue manager that the destination agent is connected to.

If you do not specify the **-dm** parameter, the queue manager that is used is determined by the set of configuration options in use, which is based on the destination agent name. If the `agent.properties` file for the destination agent cannot be found, the file transfer fails.

Parameters for generating transfer templates

-gt transfer_template_file_path

Optional. Generates a transfer template XML message and writes this message to a file. If you specify this parameter, no transfer request is sent to Managed File Transfer. Instead, the contents of the transfer request message are written to the named XML document. You can then use this XML document to define the task for resource monitoring. See [fteCreateMonitor command](#) for information

about how to create a resource monitor. If you do not specify this parameter, the default behavior takes place and an actual transfer request is carried out.

You must provide the full path and name of an XML output file as input for this parameter, for example `C:\templates\transfer_reports.xml`

z/OS On z/OS, you must store the transfer template document in a UNIX file on z/OS UNIX System Services. You cannot store transfer template documents in z/OS sequential files or PDS members.

IBM i On IBM i, you must store the transfer template document in the integrated file system.

The transfer template XML message that you create by using the **-gt** parameter is not the same as the transfer you create by using the **fteCreateTemplate** command, which means you cannot use the two different types of template interchangeably.

Note: If you want to generate a transfer template XML document by running the **fteCreateTransfer** command with the **-gt** parameter, and then provide that transfer template XML document as input to the **fteCreateTransfer** command using the **-td** parameter, you must ensure that the transfer template XML document was generated specifying those parameters that are mutually exclusive with the **-td** option.

The parameters mutually exclusive to the **-td** option are:

- **-dd** *destination_directory*
- *Source path*
- **-df** *destination_file*
- **-cs** *checksum*
- **-de** *destination_file_behavior*
- **-dq** *destination_queue*
- **-t** *transfer_type*
- **-sd** *source_file_disposition*

For example, it is not possible to specify both the **-td** and **-t** parameters (indicating whether the transfer is a binary or text transfer) on the **fteCreateTransfer** command. This means that if you want to pass in a transfer template XML document to the command and specify that the transfer should be a text transfer, you should create the XML document by specifying the **-gt** and **-t** text parameters.

This parameter is not supported in the REST API.

Parameters for scheduling transfers

-ss *schedule_start_time*

Optional. Specifies the time and date that you want the scheduled transfer to take place. Use one of the following formats to specify the time and date. Specify the time by using the 24-hour clock:

```
yyyy-MM-ddThh:mm  
hh:mm
```

Scheduled file transfers start within a minute of the schedule start time, if there are no problems that might affect the transfer. For example, there might be issues with your network or agent that prevent the scheduled transfer starting.

-tb

Optional. Specifies the time base you want to use for the scheduled file transfer. That is, whether you want to use a system time or Coordinated Universal Time (UTC). You must use this parameter with the **-ss** parameter only. Specify one of the following options:

admin

The start and end times used for the scheduled transfer are based on the time and date of the system used by the local administrator. This is the default value.

source

The start and end times used for the scheduled transfer are based on the time and date of the system where the source agent is located.

UTC

The start and end times used for the scheduled transfer are based on Coordinated Universal Time (UTC).

-oi

Optional. Specifies the interval that the scheduled transfer occurs at. You must use this parameter with the **-ss** parameter only. Specify one of the following options:

minutes

hours

days

weeks

months

years

-of occurrence_frequency

Optional. Specifies the frequency that the scheduled transfer occurs at. For example, every **5** weeks or every **2** months. You must specify this parameter with the **-oi** and **-ss** parameters only. If you do not specify this parameter, a default value of 1 is used.

-oc occurrence_count

Optional. Specifies how many times you want this scheduled transfer to occur. After the occurrence count is met, the scheduled transfer is deleted.

Specify this parameter with the **-oi** and **-ss** parameters only.

If you specify the **-oc** parameter, you cannot specify the **-es** parameter because these parameters are mutually exclusive.

You can omit both the **-oc** and **-es** parameters to create a transfer that repeats indefinitely.

-es schedule_end_time

Optional. The time and date that a repeating scheduled transfer ends.

You must specify this parameter with the **-oi** and **-ss** parameters only.

If you specify the **-es** parameter, you cannot specify the **-oc** parameter because these parameters are mutually exclusive.

You can omit both the **-es** and **-oc** parameters to create a transfer that repeats indefinitely.

Use one of the following formats to specify the end time and date. Specify the time by using the 24-hour clock:

```
yyyy-MM-ddThh:mm
```

```
hh:mm
```

Parameters for triggering transfers

-tr

Optional. Specifies a condition that must be true for this file transfer to take place. If the condition is not true, according to the source agent, the file transfer is discarded and no transfer takes place. Specify the following format:

condition,namelist

where *condition* is one of the following values:

file=exist

A minimum of one of the files in the namelist exists. That is, if *any* of the files in the namelist exists, the condition is true.

file!=exist

A minimum of one of the files in the namelist does not exist. That is, if *any* of the files in the namelist do not exist, the condition is true.

filesize>=size

A minimum of one of the files in the namelist exists and has a minimum size as specified by *size*. *size* is an integer with an optional size unit of KB, MB, or GB. For example, `filesize">"=10KB`. If you do not specify a size unit, the size is assumed to be bytes. On all operating systems, you must enclose the greater than symbol (>) in double quotation marks when you specify the `filesize` option on the command line, as shown in this example.

And where *namelist* is a comma-separated list of file names located on the same system as the source agent. Depending on your operating system, if you want to use path names or file names in a namelist that contain spaces, you might have to enclose the path names and file names in double quotation marks.

You can specify more than one trigger condition by using the **-tr** parameter more than once. However in that case, every separate trigger condition must be true for the file transfer to take place.

Note: To continually monitor a resource for a trigger condition to be true, you are strongly recommended to use [resource monitoring](#). You can create a resource monitor by using the `fteCreateMonitor` command.

In the following example, the file `file1.doc` is transferred from AGENT1 to AGENT2, on condition that either file `A.txt`, or file `B.txt`, or both files exist on AGENT1 *and* that either file `A.txt`, or file `B.txt`, or both files are equal to or larger than 1 GB:

```
fteCreateTransfer -sa AGENT1 -sm QM_JUPITER -da AGENT2 -dm QM_NEPTUNE
-tr file=exist,C:/export/A.txt,C:/export/B.txt
-tr filesize">"=1GB,C:/export/A.txt,C:/export/B.txt
-df C:/import/file1.doc C:/export/file1.doc
```

You can combine triggering parameters with scheduling parameters. If you do specify both types of parameters, the trigger conditions are applied to the file transfer created by the scheduling parameters.

The **-tr** parameter is not supported on protocol bridge agents, or in the CreateTransfer REST API.

-tl

Optional. Specifies whether trigger failures are written to the transfer log. Specify one of the following options:

yes

Transfer log entries are created for failed triggered transfers. This is the default behavior even if you do not specify the **-tl** parameter.

no

No transfer log entries are created for failed triggered transfers.

Parameters for specifying transfer options

-jn *job_name*

Optional. A user-defined job name identifier that is added to the transfer log message when the transfer starts.

-md

Optional. Specifies the user-defined metadata that is passed to the exit points run by the agent. The **-md** parameter can take one or more name-value pairs that are separated by commas. Each name pair consists of *name=value*. You can use the **-md** parameter more than once in a command.

When the agent property **enableUserMetadataOptions** is set to a value of *true*, certain user-defined metadata keys provide more options to the transfer. For more information about the user-defined metadata keys that are currently supported, see [enableUserMetadataOptions: Supported MFT user-defined metadata keys](#). When the **enableUserMetadataOptions** property is set to *true*, key names starting with `com.ibm.wmqfte.` are not supported for user-defined use.

Any user metadata provided on the **fteCreateTransfer** command is made available as an environment variable to a process called through the **presrc**, **postsrc**, **predst**, and **postdst** parameters.

For example, the following transfer results in an environment variable called **procname** being set to *compress* (**procname=compress**) and is available to the `proc.sh` script:

```
fteCreateTransfer -sa ESBPA1 -sm ESBP10 -da INFOPA1
-dm INFOP1 -md procname=compress -df /home/mqm/hosts.out /etc/hosts -de overwrite
-postdst /home/mqm/proc.sh
```

-cs checksum

Optional. Specifies whether a checksum algorithm is run on the file transfer data to check the integrity of the transferred files. Specify one of the following options:

MD5

Computes an MD5 checksum for the data. The resulting checksum for the source and destination files is written to the transfer log for validation purposes. By default, Managed File Transfer computes MD5 checksums for all file transfers.

none

No MD5 checksum is computed for the file transfer data. The transfer log records that checksum was set to *none* and the value for the checksum is blank. For example:

```
<checksum method="none"></checksum>
```

If you use the *none* option, you might improve file transfer performance, depending on your environment. However, selecting this option means that there is no validation of the source or destination files.

If you specify the **-cs** parameter, you cannot specify the **-td** parameter because these parameters are mutually exclusive. However, you can specify checksum behavior in the transfer definition file.

-pr transfer_priority

Optional. Specifies the priority level of the transfer. Priority is a value in the range 0-9, where 0 is the lowest priority. The default priority level is the priority level of the source agent.

This value matches the message priority value of IBM MQ, see [Getting messages from a queue: priority](#) for more information. Message traffic for file transfer data defaults to a priority level of 0, which allows your IBM MQ message traffic to take priority.

-qmp boolean

Optional. Specifies whether the first message written to the destination queue by the transfer has IBM MQ message properties set. The valid options are as follows:

true

Sets message properties on the first message that is created by the transfer.

false

Does not set message properties on the first message that is created by the transfer. This is the default value.

You can specify the **-qmp** parameter only if you also specify the **-dq** parameter. For more information, see “MQ message properties set by MFT on messages written to destination queues” on page 2581

-qs message_size

Optional. Specifies whether to split the file into multiple fixed-length messages. All the messages have the same IBM MQ group ID; the last message in the group has the IBM MQ `LAST_MSG_IN_GROUP` flag set. The size of the messages is specified by the value of `message_size`. The format of `message_size` is *lengthunits*, where *length* is a positive integer value and *units* is one of the following values:

B

Bytes. The minimum value that is allowed is two times the maximum bytes-per-character value of the code page of the destination messages.

K

This is equivalent to 1024 bytes.

M

This is equivalent to 1048576 bytes.

If the file is transferred in text mode, and is in a double-byte character set or multibyte character set, the file is split into messages on the closest character boundary to the specified message size.

You can specify the **-qs** parameter only if you also specify the **-dq** parameter. You can specify only one of the **-qs**, **-dqdb**, and **-dqdt** parameters.

-qi

Optional. Using this option includes the delimiter that is used to split the file into multiple messages in the messages. The delimiter is included at the beginning or at the end of the message, depending on the **-dqdp** parameter (which specifies prefix or postfix). By default the delimiter is not included in the messages.

You can specify the **-qi** parameter only if you also specify one of the **-dqdt** and **-dqdb** parameters.

-p configuration_options

Optional. This parameter determines the set of configuration options that is used to create the file transfer. Use the name of a non-default coordination queue manager as the input for this parameter. The command then uses the set of properties files that are associated with this non-default coordination queue manager.

If you do not specify this parameter, the set of configuration options that are based on the default coordination queue manager is used.

This parameter is not supported in the REST API interface.

-w timeout

Optional. Specifying the **-w** parameter causes the **fteCreateTransfer** command to wait for a response from the agent before returning. If you do not specify this parameter, the **fteCreateTransfer** command waits a maximum of five seconds to receive an acknowledgment from the source agent for the transfer that the agent has received the transfer request. If no acknowledgment is received during the five-second wait, the **fteCreateTransfer** command returns the following warning message:

```
BFGCL0253W: No acknowledgment to command from agent within timeout.
```

The return code will be 0, unless you used the **-w** option on the command line.

The `timeout` argument is optional. If you specify `timeout`, the **fteCreateTransfer** command waits for up to `timeout` seconds for the agent to respond. If the agent does not respond before the time limit is reached, the command produces a warning and ends with a return code of 2 or 3. If you do not specify a `timeout` value, or you specify a `timeout` value of -1, then the command waits until the agent responds.

The REST service does not provide an equivalent option for this parameter, as ideal wait time is not recommended in a REST service implementation.

-rt *recovery_timeout*

Optional. Sets the amount of time, in seconds, during which a source agent keeps trying to recover a stalled file transfer. Specify one of the following options:

-1

The agent continues to attempt to recover the stalled transfer until the transfer is complete. Using this option is the equivalent of the default behavior of the agent when the property is not set.

0

The agent stops the file transfer as soon as it enters recovery.

>0

The agent continues to attempt to recover the stalled transfer for the amount of time in seconds as set by the positive integer value specified. For example,

```
-rt 21600
```

indicates that the agent keeps trying to recover the transfer for 6 hours from when it enters recovery. The maximum value for this parameter is 999999999.

Specifying the transfer recovery timeout value in this way sets it on a per transfer basis. To set a global value for all transfers in a Managed File Transfer network, you can add a property to the [The agent.properties file](#).

Parameters for invoking programs

For more information about how you can start a program from Managed File Transfer, see [Specifying programs to run with MFT](#). For examples of specifying a program to invoke using the parameters that are described here, see [Examples of using fteCreateTransfer to start programs](#).

-presrc *pre_source_call*

Optional. Specifies a program to invoke at the source agent before the transfer starts. Use the following format for *pre_source_call*:

```
[type:]commandspec [, [retrycount] [, [retrywait] [, [successsrc]]]
```

In this syntax, the variables are:

type

Optional. Valid values are **executable**, **antscript**, and **jcl**. The default value is **executable**.

 The **jcl** value is only applicable when targeted at an agent in a z/OS environment. In this case, the command refers to either a ZFS file, or a QSAM-readable dataset, or a member of a PDS. The contents should be JCL that can be submitted.

commandspec

Required. The command specification. Use one of the following formats:

- Type **executable**: *command* [(*arg1*, *arg2*, ...)]

If arguments contain variable substitutions, like `${FilePath}` or `${FileName}`, which are valid only if the substitution is initiated by a resource monitor, the variables are substituted with the first item in the transfer request.

For example, if a transfer request consists of files "reports01.csv, reports02.csv, reports03.csv", and the destination directory is "/output", the following transfer request:

```
fteCreateTransfer -sa 1 -da 2 -presrc "executable:archive(${FileName})"  
-dd TargetDir "${FilePath}" -gt task.xml
```

is replaced with

```
fteCreateTransfer -sa 1 -da 2 -presrc "executable:archive(reports01.csv)"
-dd TargetDir "/ouptut" -gt task.xml
```

- Type **antscript**: *command* [(*name1=var1|target1,name2=var2|target2,...*)]
- Type **jcl**: *command*

where:

command

Required. The name of the program to call.

The **jcl** value is only applicable when targeted at an agent in a z/OS environment.

Arguments in brackets ([]) are optional and syntax depends on command type. Parentheses, commas (,) and backslashes (\) are special characters in MFT commands, and must be escaped with a backslash (\) character. **Windows** File paths on Windows can be specified either using double backslashes (\\) as a separator, or using single forward slashes (/).

retrycount

Optional. The number of times to retry calling the program if the program does not return a successful return code. Default value is 0.

retrywait

Optional. The time to wait, in seconds, before trying the program invocation again. Default value is 0 (no wait between retries).

successrc

Optional. Expression that is used to determine when the program invocation successfully runs. This expression can be composed of one or more expressions. Combine these expressions with a vertical bar character (|) to represent Boolean OR, or an ampersand (&) character to represent Boolean AND. Each expression is of the following form:

```
[>|<|!]value
```

where

- > Optional. A greater than test of the *value*.
- < Optional. A less than test of the *value*.
- ! Optional. A not equal test of the *value*.

value

Required. A valid integer.

If you do not specify this parameter, a default value of 0 is used.

-predst *pre_destination_call*

Optional. Specifies a program to invoke at the destination agent before the transfer starts. *pre_destination_call* has the same format as *pre_source_call*.

-postsrc *post_source_call*

Optional. Specifies a program to invoke at the source agent after the transfer has completed. *post_source_call* has the same format as *pre_source_call*.

-postdst *post_destination_call*

Optional. Specifies a program to invoke at the destination agent after the transfer has completed. *post_destination_call* has the same format as *pre_source_call*.

Parameters for specifying the destination

One of the **-td**, **-df**, **-dd**, **-ds**, **-dq**, and **-dp** parameters is required. You cannot specify more than one of these parameters in a transfer request; they are mutually exclusive.

-td *transfer_definition_file*

Optional. The name of the XML document that defines one or more source and destination file specifications for the transfer. Alternatively, the name of the XML document that contains a managed transfer request (which might have been generated by the **-gt** parameter). If you specify the **-td** parameter and also specify any other parameters on the command line, these other parameters override the corresponding value from the transfer definition file.

The **ftCreateTransfer** command locates the transfer definition file in relation to your current directory. If you cannot use relative path notation to specify the location of the transfer definition file, use the fully qualified path and file name of the transfer definition file instead.

z/OS On z/OS, you must store the transfer definition file in a UNIX file on z/OS UNIX System Services. You cannot store transfer definition files in z/OS sequential files or PDS members.

IBM i On IBM i, you must store the transfer definition file in the integrated file system.

For more information, see [Using transfer definition files](#).

-df *destination_file*

Optional. The name of the destination file.

If the destination agent is a Connect:Direct bridge agent, the destination file is specified in the format *connect_direct_node_name:file_path*. The Connect:Direct bridge agent accepts only file paths that are specified in this format. **z/OS** If the destination agent is a Connect:Direct bridge agent and the destination is a PDS member, you must also specify the **-de** parameter with a value of `overwrite`.

Note the following information:

- If the destination agent is a protocol bridge agent and you want to specify an endpoint for a file, use the following format:

```
protocol_server:file_path
```

where *protocol_server* is the name of the protocol server (which is optional) and where *file_path* is the path to the file on the protocol server system. If you do not specify a protocol server, the default protocol server is used.

- If you want to invoke any of the Managed File Transfer transfer I/O user exits that you have defined against the destination agent, you can use the **-df** parameter in a transfer.
- **z/OS** When the destination agent is on z/OS, if the file specified starts with `//`, it is assumed to be a partitioned z/OS data set.

-dd *destination_directory*

Optional. The name of the directory the file is transferred to. Specify a valid directory name on the system where the destination agent is running.

If the destination agent is a Connect:Direct bridge agent, the destination directory is specified in the format *connect_direct_node_name:directory_path*. If the destination agent is a Connect:Direct bridge agent and the destination is a PDS, you must also specify the **-de** parameter with a value of `overwrite`.

Note the following information:

- If the destination agent is a protocol bridge agent and you want to specify a directory at a particular endpoint, use the following format:

```
protocol_server:directory_path
```

where *protocol_server* is the name of the protocol server (which is optional) and where *directory_path* is the path to the directory on the protocol server system. If you do not specify a protocol server, the default protocol server is used.

- If you want to invoke any of the Managed File Transfer transfer I/O user exits that you have defined against the destination agent, you can use the **-dd** parameter in a transfer.
- **z/OS** When the destination agent is on z/OS, if the file specified starts with //, it is assumed to be a z/OS partitioned data set.

z/OS -ds destination_sequential_data_set

z/OS only. Optional. The name of the sequential data set or PDS member that files are transferred into. Specify a sequential data set name or a partitioned data set member. For information about transferring data sets, see [“Guidelines for transferring files” on page 2523](#).

The syntax for the data set name is as follows:

```
//data_set_name{;attribute(value);...;attribute(value)}
```

or

```
//pds_data_set_name(member_name){;attribute(value);...;attribute(value)}
```

That is, a data set name specifier prefixed with // and optionally followed by a number of attributes that are separated by semicolons.

For example:

```
//'TEST.FILE.NAME';DSNTYPE(PDS);RECFM(F,B);BLKSIZE(800);LRECL(80);CYL;SPACE(2,2)
```

If the data set is located at a Connect:Direct node, you must prefix the data set name with the node name. For example:

```
CD_NODE1://'OBJECT.LIB';RECFM(F,B);BLKSIZE(800);LRECL(80)
```

If the destination agent is a Connect:Direct bridge agent and the destination is a PDS member, you must also specify the **-de** parameter with a value of overwrite. For more information about data set transfers to or from Connect:Direct nodes, see [“Transferring data sets to and from Connect:Direct nodes” on page 2532](#).

For transfers that only involve Managed File Transfer agents, if the data set name part is enclosed by single quotation mark characters, it specifies a fully qualified data set name. If the data set name is not enclosed by single quotation mark characters, the system adds the default high-level qualifier for the destination agent (either the value for the transferRootHLQ agent property or the user ID that the agent runs under, if you have not set transferRootHLQ).

Note: **z/OS** **z/OS** However, for transfers that involve a Connect:Direct node on a z/OS system, the data set specification is interpreted as a fully qualified name. No high-level qualifier is added to the data set name. This is the case even if the data set name is enclosed by single quotation mark characters.

When you transfer a file or data set to tape, any existing data set that is already on the tape is replaced. The attributes for the new data set are set from attributes that are passed in the transfer definition. If no attributes are specified, attributes are set to the same as the source data set or to the default values when the source is a file. The attributes of an existing tape data set are ignored.

The data set attributes are used either to create a data set or to ensure that an existing data set is compatible. The specification of data set attributes is in a form suitable for BPXWDYN (see

Requesting [dynamic allocation](#) for more information). When the agent is to create a destination data set, the following BPXWDYN attributes are automatically specified: DSN(*data_set_name*) NEW CATALOG MSG(*numeric_file_descriptor*). The value of *numeric_file_descriptor* is generated by Managed File Transfer. For a data set to data set transfer, the attributes of RECFM, LRECL, and BLKSIZE from the source are selected for a new destination data set. The SPACE setting for a new destination data set is not set by Managed File Transfer and system defaults are used. Therefore, you are recommended to specify the SPACE attribute when a new data set is to be created. You can use the **bpxwdynAllocAdditionalProperties** property in the agent .properties file to set BPXWDYN options that apply to all transfers. For more information, see [The MFT agent .properties file](#).

z/OS Some BPXWDYN options must not be specified when using the **fteCreateTemplate** command, the **fteCreateTransfer** command or the **bpxwdynAllocAdditionalProperties** property in the agent .properties file. For a list of these properties, see [“BPXWDYN properties you must not use with MFT” on page 2539](#).

The **-ds** parameter is not supported when the destination agent is a protocol bridge agent.

If you want to invoke any of the Managed File Transfer transfer I/O user exits that you have defined against an agent, do not specify the **-ds** parameter in a transfer. Using the **-ds** parameter prevents the transfer I/O user exits from being invoked for the destination and means that the standard Managed File Transfer I/O is used instead.

z/OS **-dp destination_partitioned_data_set**

z/OS only. Optional. The name of the destination PDS that files are transferred into. Specify a partitioned data set name. If a PDS is created as a result of the transfer, this PDS is created as a PDSE by default. You can override the default by specifying DSNTYPE=PDS.

The syntax for the PDS data set name is as follows:

```
//pds_data_set_name{;attribute;...;attribute}
```

The syntax for the data set name is the same as described for the **-ds destination_sequential_data_set** parameter. All the syntax details for specifying data sets that are located on Connect:Direct nodes also apply to the **-dp** parameter. If the destination agent is a Connect:Direct bridge agent, you must also specify the **-de** parameter with a value of overwrite.

The **-dp** parameter is not supported when the destination agent is a protocol bridge agent.

If you want to invoke any of the Managed File Transfer transfer I/O user exits that you have defined against an agent, do not specify the **-dp** parameter in a transfer. Using the **-dp** parameter prevents the transfer I/O user exits from being invoked for the destination and means that the standard Managed File Transfer I/O is used instead.

-dq destination_queue

Optional. The name of a destination queue that files are transferred onto. You can optionally include a queue manager name in this specification, by using the format QUEUE@QUEUEMANAGER. If you do not specify a queue manager name the destination agent queue manager name is used. You must specify a valid queue name that exists on the queue manager.

The **-dq** parameter is not supported when the destination agent is a protocol bridge agent or a Connect:Direct bridge agent, or when the source specification is a queue.

If you want to invoke any of the Managed File Transfer transfer I/O user exits that you have defined against an agent, do not specify the **-dq** parameter in a transfer. Using the **-dq** parameter prevents the transfer I/O user exits from being invoked for the destination and means that the standard Managed File Transfer I/O is used instead.

-dqp persistent

Optional. Specifies whether messages written to the destination queue are persistent. The valid options are as follows:

true

Writes persistent messages to the destination queue. This is the default value.

false

Writes non-persistent messages to the destination queue.

qdef

The persistence value is taken from the DefPersistence attribute of the destination queue.

You can specify the **-dqpb** parameter only if you also specify the **-dq** parameter.

-dqdb hexadecimal_delimiter

Optional. Specifies the hexadecimal delimiter to use when splitting a binary file into multiple messages. All the messages have the same IBM MQ group ID; the last message in the group has the IBM MQ LAST_MSG_IN_GROUP flag set. The format for specifying a hexadecimal byte as a delimiter is xNN, where N is a character in the range 0-9 or a-f. You can specify a sequence of hexadecimal bytes as a delimiter by specifying a comma-separated list of hexadecimal bytes, for example: x3e, x20, x20, xbf.

You can specify the **-dqdb** parameter only if you also specify the **-dq** parameter and the transfer is in binary mode. You can specify only one of the **-qs**, **-dqdb**, and **-dqdt** parameters.

-dqdt pattern

Optional. Specifies the Java regular expression to use when splitting a text file into multiple messages. All the messages have the same IBM MQ group ID; the last message in the group has the IBM MQ LAST_MSG_IN_GROUP flag set. The format for specifying a regular expression as a delimiter is a regular expression that is enclosed in parentheses, (*regular_expression*), or enclosed in double quotation marks, "*regular_expression*". For more information, see [“Regular expressions used by MFT” on page 2556](#).

By default, the length of the string that the regular expression can match is limited by the destination agent to five characters. You can change this behavior by editing the **maxDelimiterMatchLength** agent property. For more information, see [Advanced agent properties](#).

You can specify the **-dqdt** parameter only if you also specify the **-dq** parameter and the value text for the **-t** parameter. You can specify only one of the **-qs**, **-dqdb**, and **-dqdt** parameters.

-dqdp position

Optional. Specifies the expected position of destination text and binary delimiters when splitting files. You can specify the **-dqdp** parameter only if you also specify one of the **-dqdt** and **-dqdb** parameters.

Specify one of the following options:

prefix

The delimiters are expected at the beginning of each line.

postfix

The delimiters are expected at the end of each line. This is the default option.

-de destination_file_behavior

Optional. Specifies the action that is taken if a destination file exists on the destination system. The valid options are as follows:

error

Reports an error and the file is not transferred. This is the default value.

overwrite

Overwrites the existing destination file.

If you specify the **-de** parameter, you cannot specify the **-td** parameter because these parameters are mutually exclusive. However, you can specify destination file exists behavior in the transfer definition file.

-t transfer type

Optional. Specifies the type of file transfer: binary mode or text mode.

binary

The data in the file is transferred without any conversion. This is the default value.

text

The code page and end-of-line characters of the file are converted. You can specify which code page and line ending to use for the conversion with the **-sce**, **-dce** or **-dle** parameters. If you do not specify the **-sce**, **-dce** or **-dle** parameters, the exact conversions performed depend on the operating system of the source agent and destination agent.

z/OS For example, a file that is transferred from Windows to z/OS has its code page converted from ASCII to EBCDIC. When a file is converted from ASCII to EBCDIC, the end-of-line characters are converted from ASCII carriage return (CR) and line feed (LF) character pairs to an EBCDIC new line (NL) character.

z/OS For more information about how z/OS data sets are transferred, see [“Transferring files and data sets between z/OS and distributed systems” on page 2524](#) and [“Transferring between data sets on z/OS” on page 2526](#).

If you specify the **-t** parameter, you cannot specify the **-td** parameter because these parameters are mutually exclusive. However, you can specify transfer mode behavior in the transfer definition file.

-dce destination_character_encoding

Optional. Specifies which character encoding to use to write the file at the destination. This option is only applicable to text files and so **-t text** must also be specified. The code pages available for conversion depend on the platform of the destination agent. For a list of available code pages, see [Available code pages for MFT](#).

noswaplfnl

By default Managed File Transfer uses swaplfnl with supported EBCDIC character sets. Using swaplfnl changes the behavior of the character set mapping from and to the EBCDIC LF 0x25 character. However, this can sometimes result in a mapping that is not what you want. Use noswaplfnl to override this behavior.

-dle destination_line_ending

Optional. Specifies the end-of-line characters that are used when the file is written at the destination. This option is applicable to text files only and so you must also specify the **-t text** parameter. The valid options are:

LF

Line feed. This is the default for the following platforms:

- **Linux** **AIX** AIX and Linux platforms
- **z/OS** z/OS UNIX System Services files

When you use the standard EBCDIC code pages that are supplied with Managed File Transfer for EBCDIC files, the end-of-line characters are mapped to a NL character (0x15) and not to a LF character (0x25).

CRLF

Carriage return followed by line feed. **Windows** This is the default for Windows.

z/OS If the destination of the transfer is a z/OS data set, this option is ignored.

z/OS -dtr

Optional. Specifies that destination records longer than the LRECL data set attribute are truncated. If this parameter is not specified, the records are wrapped. This parameter is valid only for text mode transfers where the destination is a data set.

-dfa attributes

Optional. When transferring to an IBM MQ 8.0 Managed File Transfer agent running on 4690, this parameter is used to specify a semicolon separated list of file attributes that are associated with the destination files in the transfer. The **-dfa** parameter can be specified with or without a value. For example, without a value:

```
-dfa ATTRIBUTE1;ATTRIBUTE2
```

For example, with a value:

```
-dfa ATTRIBUTE1(VALUE);ATTRIBUTE2(VALUE)
```

For example, one attribute with a value and one without:

```
-dfa ATTRIBUTE1;ATTRIBUTE2(VALUE)
```

You can use the **-dfa** parameter more than once in a command.

For more information about file attributes on 4690, see [File distribution attributes](#) in the IBM MQ 8.0 documentation.

Parameters for security

-mquserid *user_id*

Optional. Specifies the user ID to authenticate with the command queue manager.

-mqpassword *password*

Optional. Specifies the password to authenticate with the coordination queue manager.

When the **-mqpassword** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

From IBM MQ 9.3, the command defaults to using [MQCSP](#) authentication, and sends the user ID and password to be authenticated to the queue manager in an MQCSP structure.

-nolpw

Optional. Specify this parameter if the command connects to a queue manager that does not support passwords longer than 12 characters.

When the **-nolpw** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid** and **-nolpw**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

Note: If you specify the **-nolpw** option, and the password is longer than 12 characters the command fails with error message BFGCL0829E.

Parameters for specifying the source

-sd *source_file_disposition*

Optional. Specifies the action that is taken on a source file in file-to-file or file-to-message transfers when that source file is successfully transferred to its destination. The valid options are as follows:

leave

The source files are left unchanged. This is the default value.

delete

The source files are deleted from the source system after the source files are successfully transferred.

Note: For message-to-file transfers, the messages on the source queue are always deleted once they have been successfully transferred. This means that if the **-sd** parameter is set to `leave` for a message-to-file transfer, the value is ignored.

z/OS On z/OS, if the source is a tape data set and you specify the `delete` option, the tape is remounted to delete the data set. This behavior is because of the behavior of the system environment.

If the source is a queue and you specify the `leave` option, the command returns an error and a transfer is not requested.

If the source agent is a Connect:Direct bridge agent and you specify the `delete` option, the behavior is different to the usual source disposition behavior. One of the following cases occurs:

- If Connect:Direct uses a process that is generated by Managed File Transfer to move the file or data set from the source, specifying the `delete` option causes the transfer to fail. To specify that the source file is deleted, you must submit a user-defined Connect:Direct process. For more information, see [Submitting a user-defined Connect:Direct process from a file transfer request](#).
- If Connect:Direct uses a user-defined process to move the file or data set from the source, this parameter is passed to the process through the `%FTEFDISP` intrinsic symbolic variable. The user-defined process determines whether the source is deleted. The result that the transfer returns depends on the result that is returned by the user-defined process.

If you specify the `-sd` parameter, you cannot specify the `-td` parameter because these parameters are mutually exclusive. However, you can specify source disposition behavior in the transfer definition file.

-r

Optional. Recursively transfer files in subdirectories when *source_specification* contains wildcard characters. When Managed File Transfer is presented with a wildcard character as a *source_specification*, any subdirectories that match the wildcard character are transferred only if you specify the `-r` parameter. When *source_specification* matches a subdirectory, all files in that directory and its subdirectories (including hidden files) are always transferred.

For more information about how Managed File Transfer handles wildcard characters, see [“Using wildcard characters with MFT” on page 2551](#)

If you specify the `-r` parameter, you cannot specify the `-td` parameter because these parameters are mutually exclusive. However, you can specify recursive behavior in the transfer definition file.

-sce source_character_encoding

Optional. Specifies which character encoding to use to read the source file when performing character conversion. This option is only applicable to text files and so `-t text` must also be specified. The code pages available for conversion depend on the platform of the destination agent, because the conversion is performed on the destination system. For a list of available code pages, see [“Available code pages for MFT” on page 2587](#).

noswaplfnl

By default Managed File Transfer uses `swaplfnl` with supported EBCDIC character sets. Using `swaplfnl` changes the behavior of the character set mapping from and to the EBCDIC LF 0x25 character. However, this can sometimes result in a mapping that is not what you want. Use `noswaplfnl` to override this behavior.

z/OS -skeep

Optional. Specifies that trailing spaces are kept on source records that are read from a fixed-length-format record-oriented file (for example, a z/OS data set) as part of a text mode transfer. If you do not specify this parameter, trailing spaces are stripped from source records.

z/OS -srdb delimiter

Optional. For source files that are record oriented (for example, z/OS data sets), specifies one or more byte values to insert as the delimiter when appending records into a binary file. You must specify each value as two hexadecimal digits in the range 00-FF, prefixed by `x`. Separate multiple bytes with commas. For example:

```
-srdb x0A
```

or

```
-srdb x0D,x0A
```

You must configure the transfer in binary mode.

-srdp position

Optional. Specifies the position to insert source record delimiters. You can specify the **-srdp** parameter only if you also specify the **-srdb** parameter.

Specify one of the following options:

prefix

The delimiters are inserted at the start of each record.

postfix

The delimiters are inserted at the end of each record. This is the default option.

-sq

Optional. Specifies that the source of a transfer is a queue.

If you want to invoke any of the Managed File Transfer transfer I/O user exits that you have defined against an agent, do not specify the **-sq** parameter in a transfer. Using the **-sq** parameter prevents the transfer I/O user exits from being invoked for the source and means that the standard Managed File Transfer I/O is used instead.

-sqgi

Optional. Specifies that the messages are grouped by IBM MQ group ID. The first complete group is written to the destination file. If this parameter is not specified, all messages on the source queue are written to the destination file.

You can specify the **-sqgi** parameter only if you also specify the **-sq** parameter.

-sqdt text_delimiter

Optional. Specifies a sequence of text to insert as the delimiter when appending multiple messages to a text file. You can include Java escape sequences for String literals in the delimiter. For example, `-sqdt \u007d\n`.

The text delimiter is encoded to binary format by using the source encoding of the transfer. Each message is read in binary format. The encoded delimiter is prepended or appended in binary format to the message (as specified by the **-sqdp** parameter) and the result is transferred in binary format to the destination agent. If the source agent code page includes shift-in and shift-out states, the agent assumes that each message is in the shift-out state at the end of the message. At the destination agent the binary data is converted in the same way as a file to file text transfer.

You can specify the **-sqdt** parameter only if you also specify the **-sq** parameter and the value `text` for the **-t** parameter.

-sqdb hexadecimal_delimiter

Optional. Specifies one or more byte values to insert as the delimiter when appending multiple messages to a binary file. Each value must be specified as two hexadecimal digits in the range 00-FF, prefixed by x. Multiple bytes must be comma-separated. For example, `-sqdb x08,xA4`.

You can specify the **-sqdb** parameter only if you also specify the **-sq** parameter. You cannot specify the **-sqdb** parameter if you also specify the value `text` for the **-t** parameter.

-sqdp position

Optional. Specifies the position of insertion of source text and binary delimiters. You can specify the **-sqdp** parameter only if you have also specified one of the **-sqdt** and **-sqdb** parameters.

Specify one of the following options:

prefix

The delimiters are inserted at the start of each message

postfix

The delimiters are inserted at the end of each message. This is the default option.

-sqwt wait_time

Optional. Specifies the time, in seconds, to wait for one of the following conditions to be met:

- For a new message to appear on the queue
- If the **-sqgi** parameter was specified, for a complete group to appear on the queue

If neither of these conditions is met within the time that is specified by *wait_time*, the source agent stops reading from the queue and completes the transfer. If the **-sqwt** parameter is not specified, the source agent stops reading from the source queue immediately if the source queue is empty or, in the case where the **-sqgi** parameter is specified, if there is no complete group on the queue.

For information about using the **-sqwt** parameter, see [“Guidance for specifying a wait time on a message-to-file transfer”](#) on page 2586.

You can specify the **-sqwt** parameter only if you also specify the **-sq** parameter.

source_specification

One or more file specifications that determine the source, or sources, for the file transfer.

Required if you specify one of the **-df**, **-dd**, **-dp**, **-dq**, or **-ds** parameters. If you specify the **-td** parameter, do not specify *source_specification*.

- If you have not specified the **-sq** parameter, *source_specification* is one or more file specifications that determine the source, or sources, for the file transfer. File specifications can take one of five forms and can include wildcard characters. For more information about wildcard characters, see [“Using wildcard characters with MFT”](#) on page 2551. You can escape asterisks that are part of the file specification by using two asterisk characters (**) in the file specification.

You can specify multiple source file specifications separated by the space character. However, if you specify multiple source specifications for the **-df** or **-ds** parameters and also specify **-de overwrite**, the destination will contain only the data for the source file that you specified last. If you do not specify **-de overwrite** the transfer can only be partially successful. If the destination file did not previously exist, it will contain the data for the source file that you specified first.

To transfer files that contain spaces in their file names, for example a b.txt to file c d.txt, place double quotation marks around the file names that contain spaces. Specify the following text as part of the **fteCreateTransfer** command:

```
-df "c d.txt" "a b.txt"
```

Each file specification must be in one of the following categories:

File names

The name of a file, expressed in the appropriate notation for the system where the source agent is running. When a file name is specified as a source file specification, the contents of the file are copied.

Directories

The name of a directory, expressed in the appropriate notation for the system where the source agent is running. When a directory is specified as a source file specification, the contents of the directory are copied. More precisely, all files in the directory and in all its subdirectories, including hidden files, are copied.

For example, to copy the contents of DIR1 to DIR2 only, specify `fteCreateTransfer . . . -dd DIR2 DIR1/*`

 **Sequential data set**

The name of a sequential data set or partitioned data set member. Denote data sets by preceding the data set name with two forward slash characters (//).

If you specify a protocol bridge agent as your source agent, you cannot then specify a data set as the source file specification.

Partitioned data set

The name of a partitioned data set. Denote data set names by preceding the data set name with two forward slash characters (//).

If you specify a protocol bridge agent as your source agent, you cannot then specify a data set as the source file specification.

File name or directory at a Connect:Direct node

(Connect:Direct bridge agent only). The name of a Connect:Direct node, a colon character (:), and a file or directory path on the system that is hosting the Connect:Direct node. For example, *connect_direct_node_name:file_path*.

If the source agent is a Connect:Direct bridge agent, it will only accept source specifications in this form.

Note: Wildcard characters are not supported in file paths when the source agent is a Connect:Direct bridge agent.

File name or directory on a protocol file server

The name of a protocol file server, a colon character (:), and a file or directory path on the protocol server system. For example, *protocol_server:file_path*.

If you do not specify a protocol server, the default protocol server is used.

- If you specify the **-sq** parameter, *source_specification* is the name of a local queue on the source agent queue manager. You can specify only one source queue. The source queue is specified in the format:

```
QUEUE_NAME
```

The queue manager name is not included in the source queue specification, because the queue manager must be the same as the source agent queue manager.

-  If the source agent is on z/OS, source files that start with // are assumed to be z/OS partitioned data sets.

Other parameters

-? or -h

Optional. Displays command syntax.

Examples

In this basic example, the file `originalfile.txt` is transferred from AGENT1 to AGENT2 on the same system and renamed to `transferredfile.txt`

```
fteCreateTransfer -sa AGENT1 -da AGENT2 -df C:/import/transferredfile.txt C:/export/originalfile.txt
```

In this example, the files `originalfile.txt` and `originalfile2.txt` are transferred from AGENT1 to AGENT2 on the same system, to the directory `C:/import`

```
fteCreateTransfer -sa AGENT1 -da AGENT2 -dd C:/import C:/export/originalfile.txt C:/export/originalfile2.txt
```

In this example, the file `originalfile.txt` is transferred from AGENT1's system to AGENT2's system. The file transfer is scheduled to take place at 09:00 based on the system time of the source agent's system and occurs every two hours four times:

```
fteCreateTransfer -sa AGENT1 -sm QM_JUPITER -da AGENT2 -dm QM_NEPTUNE
-tb source -ss 09:00 -oi hours -of 2 -oc 4
-df C:/import/transferredfile.txt C:/export/originalfile.txt
```

In this example, the file `originalfile.txt` is transferred from AGENT1 to AGENT2, on condition that the file `A.txt` exists on AGENT1:

```
fteCreateTransfer -sa AGENT1 -sm QM_JUPITER -da AGENT2 -dm QM_NEPTUNE
-tr file=exist,C:/export/A.txt -df C:/import/transferredfile.txt C:/export/originalfile.txt
```

z/OS In this example, the file `originalfile.txt` is transferred from AGENT1's system to a data set `//'USERID.TRANS.FILE.TXT'` on AGENT2's system. Text mode is selected to convert data from ASCII to EBCDIC.

```
fteCreateTransfer -t text -sa AGENT1 -da AGENT2
-ds "//TRANS.FILE.TXT;RECFM(V,B);BLKSIZE(6144);LRECL(1028);
SPACE(5,1)" C:/export/originalfile.txt
```

z/OS In this example, a member of a fully qualified data set on AGENT1's system is transferred to a file on AGENT2's system. Text mode is selected to convert the file from EBCDIC to the default code page of AGENT2's system.

```
fteCreateTransfer -t text -sa AGENT1 -da AGENT2 -df /tmp/IEEUJV.txt "'SYS1.SAMPLIB(IEEUJV)'"
```

In this example, a file that is called `file.bin` on agent AGENT1 is transferred to a destination file called `file.bin` on the protocol file server `accountshost.ibm.com` by using the destination agent BRIDGE1.

```
fteCreateTransfer -sa AGENT1 -da BRIDGE1 -df accountshost.ibm.com:/tmp/file.bin /tmp/file.bin
```

In this example, a wildcard is used without quotation marks. All files in AGENT1's current working directory that end in `.txt` are transferred to directory `C:/import` on AGENT2. The file names remain unchanged.

```
fteCreateTransfer -sa AGENT1 -da AGENT2 -dd C:/import *.txt
```

In this example, a wildcard is used with double quotation marks. All files in AGENT1's transfer root directory that end in `.txt` are transferred to directory `C:/import` on AGENT2. The file names remain unchanged.

```
fteCreateTransfer -sa AGENT1 -da AGENT2 -dd C:/import "*.txt"
```

Return codes

<i>Table 347. Return code names and descriptions</i>	
Return code	Description
0	Command completed successfully.
1	Command ended unsuccessfully.
2	Command ended with a timeout. The command sent a message to the agent, but the agent did not respond within the time specified.

Table 347. Return code names and descriptions (continued)

Return code	Description
3	Command ended with a timeout. The command was waiting for an acknowledgment from the agent, but did not receive one within the timeout period.
20	Command completed with partial success and some files were transferred.
21	The queue manager that the fteCreateTransfer command was connected to was stopped before the transfer result was determined.
40	Failed. None of the files specified were transferred.
41	The transfer was canceled.
42	The transfer did not take place because the transfer was conditional and the required condition was not met.
43	The transfer request message was malformed.
44	The source agent did not have sufficient capacity to carry out the transfer.
45	The destination agent did not have sufficient capacity to carry out the transfer.
46	The number of files that are being transferred exceeded the source agent's limit.
47	The number of files transferred exceeds the destination agent's limit.

Note: The return code will always be 0 or 1, unless the **-w** parameter is used on the command line.

fteDefine (generate configuration scripts)

Use the **fteDefine** command to generate the configuration scripts necessary to define the specified Agent Queue Manager objects.

Purpose

You would expect to use the **fteDefine** command when some configuration steps need to be run on a system that is remote to the one containing the configuration data. For example, configuring the queues for an agent on a queue manager to be accessed over a client connection.

Syntax

Parameters

-t type

Required. The type of object to be defined. The options for type are agent.

-d output_dir

Optional. A directory path in which the scripts are written. If not provided, the scripts are written to the standard output stream.

name

Required. One or more names of the objects to be defined. To specify names for more than one object, separate them with a space. For example, *name1 name2 . . .*

-? or -h

Optional. Displays command syntax.

Examples

In this example, the **fteDefine** command is specified with the **-t agent** parameter and a single agent name. The output is written to a file.

```
fteDefine -t agent EXAMPLE.AGENT >EXAMPLE.AGENT_create.mqsc
```

The output that is generated from this command are the MQSC command scripts to be run against the agent queue manager to create the necessary agent queues:

```
$ fteDefine -t agent EXAMPLE.AGENT
5724-H72 Copyright IBM Corp. 2008, 2024. ALL RIGHTS RESERVED
DEFINE QLOCAL(SYSTEM.FTE.COMMAND.EXAMPLE.AGENT) +
  DEFPRTY(0) +

  PUT(ENABLED) +
  RETINTVL(99999999) +
  SHARE +
  NOTRIGGER +
  USAGE(NORMAL) +
  REPLACE
...
etc.
```

In this example, the **fteDefine** command is specified with the **-d outputDir** parameter and several agent names.

```
fteDefine -t agent -d /tmp EXAMPLE.AGENT.1 EXAMPLE.AGENT.2 EXAMPLE.AGENT.3
```

The output that is generated from this command are the absolute file paths to the locations of the MQSC command scripts:

```
$ fteDefine -t agent -d /tmp EXAMPLE.AGENT.1 EXAMPLE.AGENT.2 EXAMPLE.AGENT.3
5724-H72 Copyright IBM Corp. 2008, 2024. ALL RIGHTS RESERVED

“[fteDelete \(generate scripts to remove configuration\)](#)” on page 2103

Use the **fteDelete** command to generate the configuration scripts necessary to remove the specified Agent Queue Manager objects.

fteDelete (generate scripts to remove configuration)

Use the **fteDelete** command to generate the configuration scripts necessary to remove the specified Agent Queue Manager objects.

Purpose

You would expect to use the **fteDelete** command when some configuration steps need to be run on a system that is remote to the one containing the configuration data. For example, removing the queues for a remote client agent on a local queue manager.

Syntax

Parameters

-t type
Required. The type of object to be delete. The options for type are agent.

-d output_dir
Optional. A directory path in which the scripts are written. If not provided, the scripts are written to the standard output stream.

name
Required. One or more names of the objects to be delete. To specify names for more than one object, separate them with a space. For example, *name1 name2 . . .*

-? or -h
Optional. Displays command syntax.

Examples

In this example, the **fteDelete** command is specified with the **-t agent** parameter and a single agent name. The output is written to a file.

```
fteDelete -t agent EXAMPLE.AGENT >EXAMPLE.AGENT_delete.mqsc
```

The output that is generated from this command are the MQSC command scripts to be run against the agent queue manager to delete the agent queues:

```
$ fteDelete -t agent EXAMPLE.AGENT
5724-H72 Copyright IBM Corp. 2008, 2024. ALL RIGHTS RESERVED
CLEAR QLOCAL(SYSTEM.FTE.COMMAND.EXAMPLE.AGENT)
DELETE QLOCAL(SYSTEM.FTE.COMMAND.EXAMPLE.AGENT)
CLEAR QLOCAL(SYSTEM.FTE.DATA.EXAMPLE.AGENT)
DELETE QLOCAL(SYSTEM.FTE.DATA.EXAMPLE.AGENT)
CLEAR QLOCAL(SYSTEM.FTE.REPLY.EXAMPLE.AGENT)
DELETE QLOCAL(SYSTEM.FTE.REPLY.EXAMPLE.AGENT)
CLEAR QLOCAL(SYSTEM.FTE.STATE.EXAMPLE.AGENT)
DELETE QLOCAL(SYSTEM.FTE.STATE.EXAMPLE.AGENT)
CLEAR QLOCAL(SYSTEM.FTE.EVENT.EXAMPLE.AGENT)
DELETE QLOCAL(SYSTEM.FTE.EVENT.EXAMPLE.AGENT)
...
etc.
```

In this example, the **fteDelete** command is specified with the **-d outputDir** parameter and several agent names.

```
fteDelete -t agent -d /tmp EXAMPLE.AGENT.1 EXAMPLE.AGENT.2 EXAMPLE.AGENT.3
```

The output that is generated from this command are the absolute file paths to the locations of the MQSC command scripts:

```
$ fteDelete -t agent -d /tmp EXAMPLE.AGENT.1 EXAMPLE.AGENT.2 EXAMPLE.AGENT.3

```

Return codes

0

Command completed successfully.

1

Command ended unsuccessfully.

Related reference

[“fteDefine \(generate configuration scripts\)” on page 2101](#)

Use the **fteDefine** command to generate the configuration scripts necessary to define the specified Agent Queue Manager objects.

fteDeleteAgent (delete an MFT agent and its configuration)

The **fteDeleteAgent** command deletes a Managed File Transfer Agent and its configuration. If the agent is a protocol bridge agent, the user credentials file is left on the file system.

Purpose

Stop the agent with the [fteStopAgent](#) command before running the **fteDeleteAgent** command.

If you have configured your agent to run as a Windows service, running the **fteDeleteAgent** command deletes the service definition.

Any resource monitor and scheduled transfers are removed when the agent is deleted.

Only users who are IBM MQ administrators (and members of the mqm group) can run this command. If you try to run this command as a user who is not an IBM MQ administrator, you will receive an error message and the command will not run.

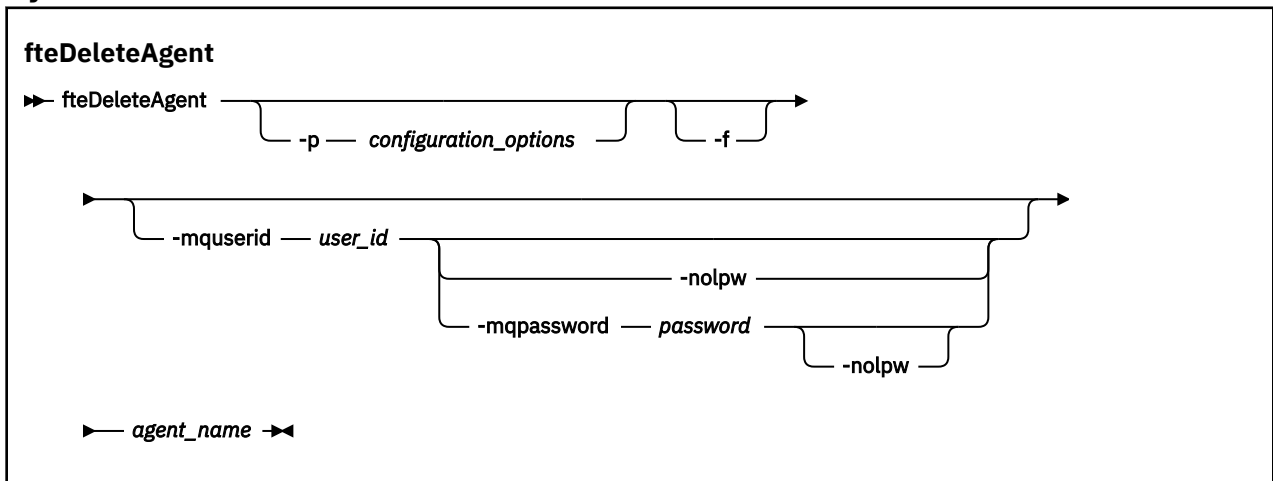

The **fteDeleteAgent** command provides you with the MQSC commands that you must run against your agent's queue manager to clear and delete the agent's system queues. These queues are as follows:

- SYSTEM.FTE.AUTHADM1.*agent_name*
- SYSTEM.FTE.AUTHAGT1.*agent_name*
- SYSTEM.FTE.AUTHMON1.*agent_name*
- SYSTEM.FTE.AUTHOPS1.*agent_name*
- SYSTEM.FTE.AUTHSCH1.*agent_name*
- SYSTEM.FTE.AUTHTRN1.*agent_name*
- SYSTEM.FTE.COMMAND.*agent_name*
- SYSTEM.FTE.DATA.*agent_name*
- SYSTEM.FTE.EVENT.*agent_name*
- SYSTEM.FTE.REPLY.*agent_name*
- SYSTEM.FTE.STATE.*agent_name*

The **fteCreateAgent** command also provides these commands in a file in the following location:

```
MQ_DATA_PATH/mqft/config/coordination_qmgr_name/agents/agent_name/agent_name_delete.mqsc
```

Syntax

Parameters

-p configuration_options

Optional. If you have more than one coordination queue manager, use this parameter to explicitly specify which agent configuration you want to delete. Use the name of a non-default coordination queue manager as the input for this parameter. The command then uses the configuration options associated with this non-default coordination queue manager.

Specify the optional **-p** parameter only if you want to use configuration options different from your defaults. If you do not specify **-p**, the configuration options defined in the `installation.properties` file are used. See [Configuration options](#) for more information.

-f

Optional. Forces the command to deregister the agent from the coordination queue manager even if the agent's configuration files cannot be found. Because information about the agent's queue manager is not available in this situation, the command will connect directly to the coordination queue manager instead of using the agent queue manager as it normally would.

-mquserid *user_id*

Optional. Specifies the user ID to authenticate with the agent queue manager, unless the force **-f** parameter is present. If the **-f** parameter is present, it specifies the user ID to authenticate with the coordination queue manager.

-mqpassword *password*

Optional. Specifies the password to authenticate with the coordination queue manager.

When the **-mqpassword** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

From IBM MQ 9.3, the command defaults to using MQCSP authentication, and sends the user ID and password to be authenticated to the queue manager in an MQCSP structure.

-nolpw

Optional. Specify this parameter if the command connects to a queue manager that does not support passwords longer than 12 characters.

When the **-nolpw** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid** and **-nolpw**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

Note: If you specify the **-nolpw** option, and the password is longer than 12 characters the command fails with error message BFGCL0829E.

agent_name

Required. The name of the agent that you want to delete.

-? or -h

Optional. Displays command syntax.

Example

In this example, AGENT3 and its configuration on coordination queue manager QM_COORD1 are deleted:

```
fteDeleteAgent -p QM_COORD1 AGENT3
```

This example command outputs the following MQSC commands to delete the agent's three queues:

```
CLEAR QLOCAL(SYSTEM.FTE.COMMAND.AGENT3)
DELETE QLOCAL(SYSTEM.FTE.COMMAND.AGENT3)
CLEAR QLOCAL(SYSTEM.FTE.DATA.AGENT3)
DELETE QLOCAL(SYSTEM.FTE.DATA.AGENT3)
CLEAR QLOCAL(SYSTEM.FTE.REPLY.AGENT3)
DELETE QLOCAL(SYSTEM.FTE.REPLY.AGENT3)
CLEAR QLOCAL(SYSTEM.FTE.STATE.AGENT3)
DELETE QLOCAL(SYSTEM.FTE.STATE.AGENT3)
CLEAR QLOCAL(SYSTEM.FTE.EVENT.AGENT3)
DELETE QLOCAL(SYSTEM.FTE.EVENT.AGENT3)
CLEAR QLOCAL(SYSTEM.FTE.AUTHADM1.AGENT3)
DELETE QLOCAL(SYSTEM.FTE.AUTHADM1.AGENT3)
CLEAR QLOCAL(SYSTEM.FTE.AUTHAGT1.AGENT3)
DELETE QLOCAL(SYSTEM.FTE.AUTHAGT1.AGENT3)
CLEAR QLOCAL(SYSTEM.FTE.AUTHTRN1.AGENT3)
DELETE QLOCAL(SYSTEM.FTE.AUTHTRN1.AGENT3)
CLEAR QLOCAL(SYSTEM.FTE.AUTHOPS1.AGENT3)
DELETE QLOCAL(SYSTEM.FTE.AUTHOPS1.AGENT3)
CLEAR QLOCAL(SYSTEM.FTE.AUTHSCH1.AGENT3)
DELETE QLOCAL(SYSTEM.FTE.AUTHSCH1.AGENT3)
CLEAR QLOCAL(SYSTEM.FTE.AUTHMON1.AGENT3)
DELETE QLOCAL(SYSTEM.FTE.AUTHMON1.AGENT3)
```

Return codes

0

Command completed successfully.

1

Command ended unsuccessfully.

Related reference

[“fteStopAgent \(stop an MFT agent\)” on page 2175](#)

Use the **fteStopAgent** command to either stop a Managed File Transfer agent in a controlled way or to stop an agent immediately if necessary using the **-i** parameter.

[“fteCleanAgent \(clean up an MFT Agent\)” on page 2023](#)

Use the **fteCleanAgent** command to clean up the queues that a Managed File Transfer Agent uses, by deleting messages from the persistent and non-persistent queues used by the agent. Use the **fteCleanAgent** command if you are having problems starting an agent, which might be caused by information remaining on the queues used by the agent.

[“fteCreateAgent \(create an MFT agent\)” on page 2030](#)

The **fteCreateAgent** command creates a Managed File Transfer Agent and its associated configuration.

[“fteStartAgent \(start an MFT agent\)” on page 2169](#)

The **fteStartAgent** command starts a Managed File Transfer agent from the command line.

fteDeleteLogger (delete an MFT logger and its configuration)

Use the **fteDeleteLogger** command to delete a Managed File Transfer logger and its configuration. Existing log files associated with the logger can either be retained or deleted.

Important:  On IBM MQ for AIX, Linux, and Windows, only users who are IBM MQ administrators (and members of the mqm group) can run this command. If you try to run this command as a user who is not an IBM MQ administrator, you will receive the error message BFGCL0502E: You are not authorized to perform the requested operation. and the command will not run.

 On z/OS systems, the user must satisfy (at least) one of these conditions in order to run the command:

- Be a member of the mqm group (if the mqm group is defined on the system).
- Be a member of the group named in the BFG_GROUP_NAME environment variable (if one is named).
- Have no value set in the BFG_GROUP_NAME environment variable when the command is run.

Loggers on IBM i

Managed File Transfer loggers are not supported on the IBM i platform.

Purpose

Stop the logger with the **fteStopLogger** command before running the **fteDeleteLogger** command.

If you have configured your logger to run as a Windows service, running the **fteDeleteLogger** command deletes the service definition.

The logger configuration directory contains a MQSC script to delete the queues and the subscription for the logger. These queues are as follows:

- SYSTEM.FTE.LOG.CMD.*logger_name*
- SYSTEM.FTE.LOG.RJCT.*logger_name*

The subscription name is as follows:

- SYSTEM.FTE.AUTO.SUB.*logger_name*

The MQSC script can be found at
`MQ_DATA_PATH\mqft\config\coordination_qmgr\loggers\logger_name\logger_name_delete.mqsc`

Syntax

Parameters

-p configuration_options

Optional. Determines the set of configuration options that is used to start the stand-alone database logger. Use the name of a set of configuration options as the value for the **-p** parameter. By convention this value is the name of a coordination queue manager. If you do not specify this parameter, the default set of configuration options is used.

-f

Optional. Forces the removal of any log files created by this logger. If this parameter is omitted, any log files created by the logger will be retained, and must be manually removed when they are no longer required.

logger_name

Required. The name of the logger that you want to delete.

-? or -h

Optional. Displays command syntax.

Example

In this example, a logger called logger1 is deleted. The **-f** parameter has been specified, which causes the logger's log files to be removed as well as the logger's configuration files.

```
fteDeleteLogger -f logger1
```

Return codes

0

Command completed successfully.

1

Command ended unsuccessfully.

Related reference

[“fteCreateLogger \(create an MFT file or database logger\)” on page 2051](#)

Use the **fteCreateLogger** command to create a Managed File Transfer file or database logger.

[“fteStartLogger \(start an MFT logger\)” on page 2171](#)

The **fteStartLogger** command starts a Managed File Transfer logging application.

[“fteStopLogger \(stop an MFT logger\)” on page 2177](#)

The **fteStopLogger** command stops a Managed File Transfer logger.

[“fteModifyLogger \(run an MFT logger as a Windows service\)” on page 2130](#)

Use the **fteModifyLogger** command to modify a Managed File Transfer logger so that it can be run as a Windows service. You can use this command only on Windows platforms, must be run by a user who is an

IBM MQ administrator and a member of the mqm group, and you must first stop the logger by using the **fteStopLogger** command.

fteDeleteMonitor (delete an MFT resource monitor)

Use the **fteDeleteMonitor** command to stop and delete an existing Managed File Transfer resource monitor using the command line. Issue this command against the resource monitoring agent.

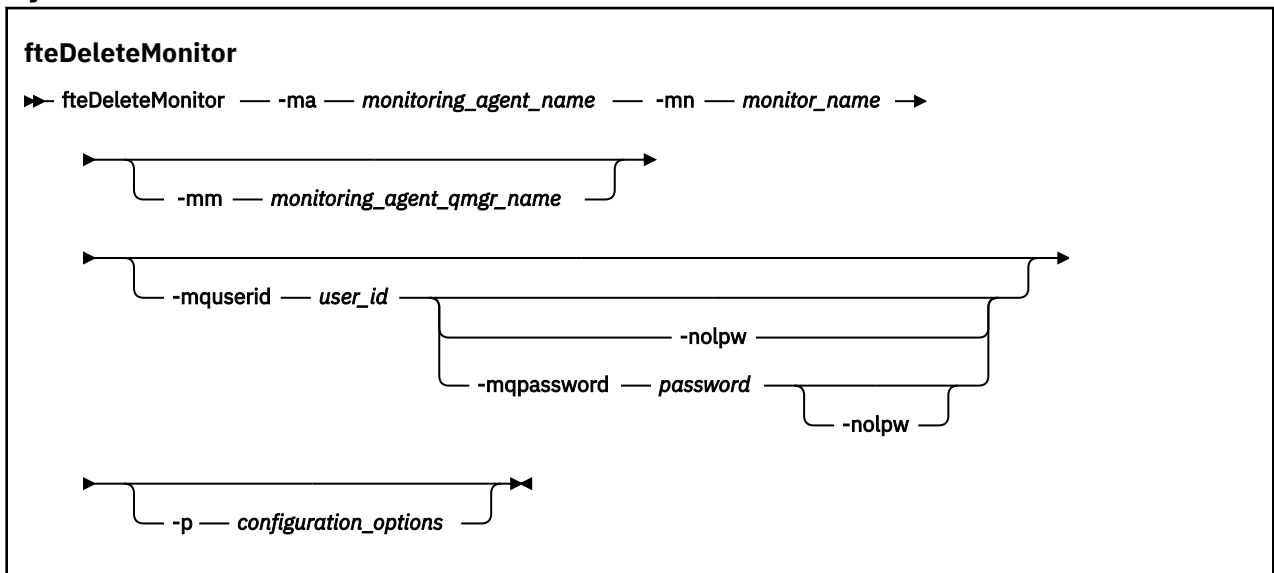

Purpose

Use the **fteDeleteMonitor** command to stop monitoring a resource and remove the monitor's definition from the monitoring agent. When you run this command, no more polls of the resource occur and no further tasks are started.

You can run the **fteDeleteMonitor** command from any system that can connect to the IBM MQ network and subsequently route to the agent's queue manager. Specifically for the command to run, you must have installed a Managed File Transfer component (either Service or Agent) on this system and you must have configured this system's Managed File Transfer to communicate with the IBM MQ network. If no connectivity details are available, the agent queue manager details are used for connection instead, provided these details are available.

Specify the optional **-p** parameter for this command only if you want to use a set of configuration options different from your default set. See [Configuration options](#) for more information.

Syntax

Parameters

-ma monitoring_agent_name

Required. The name of the agent that performs the resource monitoring. This monitoring agent must also have been the source agent for the file transfer that you wanted to trigger.

-mn monitor_name

Required. The name that you assigned to this resource monitor. You can delete a resource monitor and then create a new monitor with the same name.

-mm monitoring_agent_qmgr_name

Optional. The name of the monitoring agent's queue manager. Because the monitoring agent and the source agent of the transfer the monitor triggered must be same, this queue manager is also your source agent's queue manager.

-mquserid user_id

Optional. Specifies the user ID to authenticate with the command queue manager.

-mqpassword password

Optional. Specifies the password to authenticate with the coordination queue manager.

When the **-mqpassword** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

From IBM MQ 9.3, the command defaults to using [MQCSP](#) authentication, and sends the user ID and password to be authenticated to the queue manager in an MQCSP structure.

-nolpw

Optional. Specify this parameter if the command connects to a queue manager that does not support passwords longer than 12 characters.

When the **-nolpw** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid** and **-nolpw**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

Note: If you specify the **-nolpw** option, and the password is longer than 12 characters the command fails with error message BFGCL0829E.

-p configuration_options

Optional. This parameter determines the set of configuration options to use to cancel the transfer. By convention use the name of a non-default coordination queue manager as the input for this parameter. The command then uses the set of properties files associated with this non-default coordination queue manager.

If you do not specify this parameter, the set of configuration options based on the default coordination queue manager is used.

-? or -h

Optional. Displays command syntax.

Example

In this example, the resource monitor MONITOR1 with a monitoring (and file transfer source agent) AGENT1 is deleted:

```
fteDeleteMonitor -ma AGENT1 -mm QM_JUPITER -mn MONITOR1
```

Return codes**0**

Command completed successfully.

1

Command ended unsuccessfully.

Related tasks

[Monitoring MFT resources](#)

Related reference

[“fteCreateMonitor \(create an MFT resource monitor\)” on page 2057](#)

The **fteCreateMonitor** command creates and starts a new resource monitor from the command line. You can monitor a resource (for example, the contents of a directory) by using Managed File Transfer so that when a trigger condition is satisfied, a specified task, such as a file transfer, is started.

[“fteListMonitors \(list MFT resource monitors\)” on page 2119](#)

Use the **fteListMonitors** command to list all of the existing resource monitors in a Managed File Transfer network using the command line.

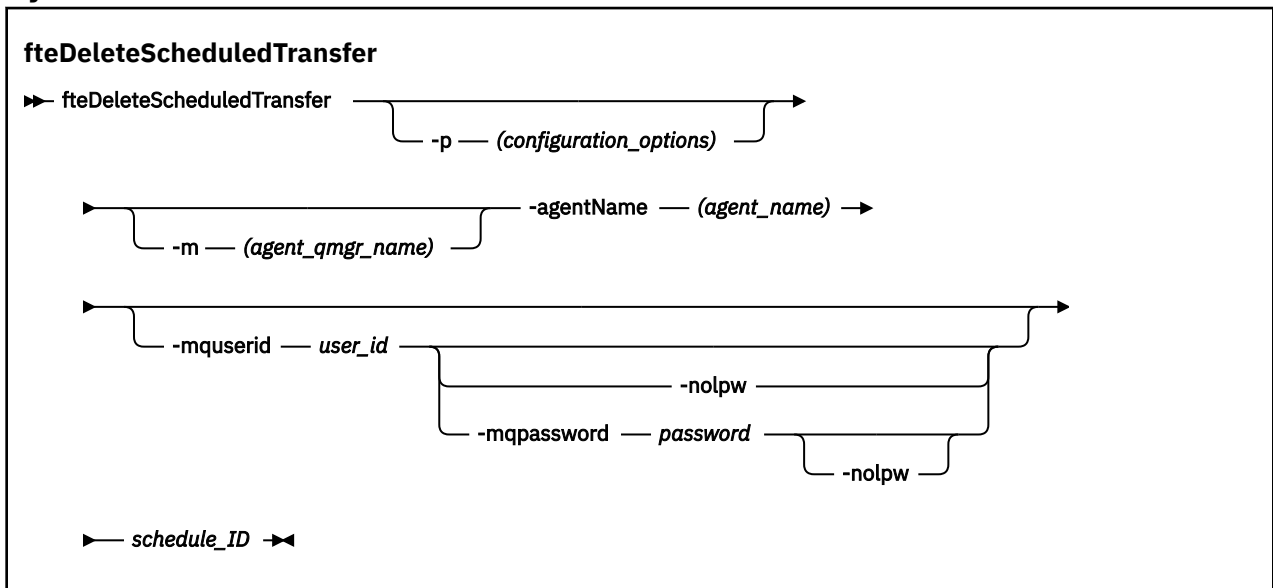

fteDeleteScheduledTransfer (delete a scheduled MFT transfer)

Purpose

Use the **fteDeleteScheduledTransfer** command to delete a Managed File Transfer scheduled transfer that you have previously created either using the command line or the IBM MQ Explorer.

Specify the optional **-p** parameter for this command only if you want to use configuration options different from your defaults. If you do not specify **-p**, the configuration options defined in `installation.properties` are used. See [Configuration options](#) for more information.

Syntax

Parameters

-p configuration_options

Optional. If you have more than one coordination queue manager, use this parameter to explicitly specify which scheduled transfer you want to delete. Use the name of a non-default coordination queue manager as the input for this parameter. The command then uses the configuration options associated with this non-default coordination queue manager.

If you do not specify this parameter, the configuration options based on the default coordination queue manager are used.

-m agent_qmgr_name

Optional. The name of the queue manager that the source agent is connected to. If you do not specify this parameter, the agent's queue manager is determined from the configuration options in use.

-agentName agent_name

Required. The name of the source agent that you want to delete the scheduled transfer from.

-mquserid user_id

Optional. Specifies the user ID to authenticate with the command queue manager.

-mqpassword password

Optional. Specifies the password to authenticate with the coordination queue manager.

When the **-mqpassword** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

From IBM MQ 9.3, the command defaults to using [MQCSP](#) authentication, and sends the user ID and password to be authenticated to the queue manager in an MQCSP structure.

-nolpw

Optional. Specify this parameter if the command connects to a queue manager that does not support passwords longer than 12 characters.

When the **-nolpw** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid** and **-nolpw**, but do not specify **-mqpassword**, you are prompted to supply the associated password which, will not be displayed.

Note: If you specify the **-nolpw** option, and the password is longer than 12 characters the command fails with error message BFGCL0829E.

schedule_ID

Required. The ID of the scheduled transfer that you want to delete.

You can find the schedule ID by running the [fteListScheduledTransfers](#) command against the name of the source agent.

-? or -h

Optional. Displays command syntax.

Example

In this example, a scheduled transfer on source agent AGENT2 with the ID 27 is deleted:

```
fteDeleteScheduledTransfer -agentName AGENT2 27
```

Return codes

0

Command completed successfully.

1

Command ended unsuccessfully.

Related tasks

[Creating a scheduled file transfer](#)

Related reference

[“fteListScheduledTransfers \(list all scheduled transfers\)” on page 2123](#)

Use the **fteListScheduledTransfers** command to list all of the Managed File Transfer transfers that you previously created using the command line or the IBM MQ Explorer.

fteDeleteTemplates (delete an MFT template)

Use the **fteDeleteTemplates** command to delete an existing Managed File Transfer template from a coordination queue manager.

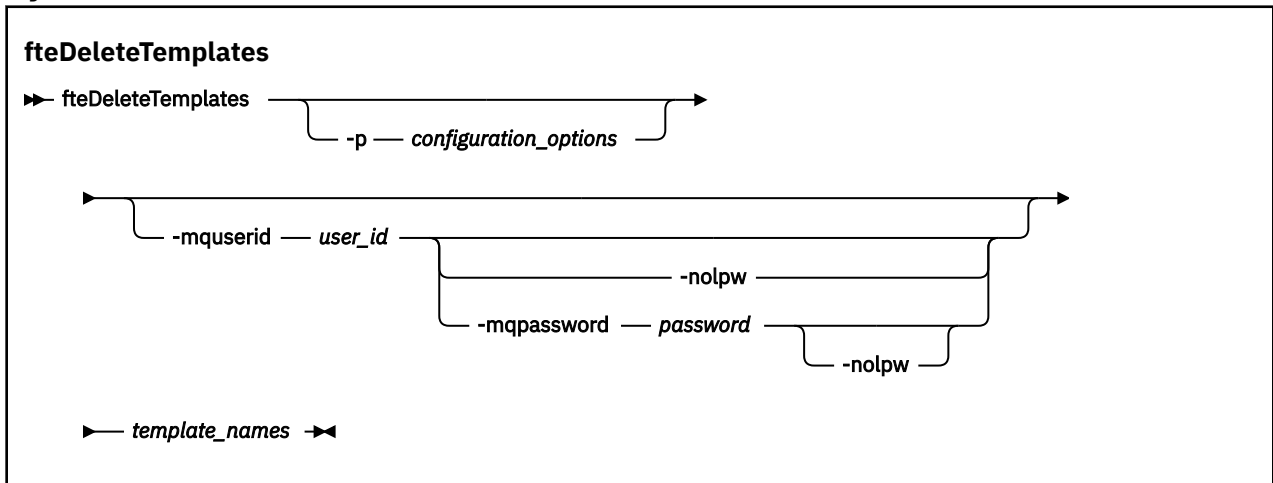

Purpose

The **fteDeleteTemplates** command removes one or more file transfer templates from a coordination queue manager. When you run this command a request is passed to the IBM MQ system to remove the templates from the coordination queue manager so that the templates are no longer available to the IBM MQ Explorer or the command line. The templates you are deleting might continue to be accessed for a brief interval after the command completes until the IBM MQ system actions the request.

You can run the **fteDeleteTemplates** command from any system that can connect to the IBM MQ network and subsequently route to the coordination queue manager. Specifically for the command to run, you must have installed Managed File Transfer on this system and you must have configured this system's Managed File Transfer to communicate with the IBM MQ network. If no connectivity details are available, the agent queue manager details are used for connection instead, provided these details are available.

Specify the optional **-p** parameter for this command only if you want to use a set of configuration options different from your default set. See [Configuration options](#) for more information.

Syntax

Parameters

-p configuration_options

Optional. This parameter determines the set of configuration options to use to delete the template. By convention use the name of a non-default coordination queue manager as the input for this parameter. The command then uses the set of properties files associated with this non-default coordination queue manager.

If you do not specify this parameter, the set of configuration options based on the default coordination queue manager is used.

-mquserid user_id

Optional. Specifies the user ID to authenticate with the coordination queue manager.

-mqpassword password

Optional. Specifies the password to authenticate with the coordination queue manager.

When the **-mqpassword** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

From IBM MQ 9.3, the command defaults to using MQCSP authentication, and sends the user ID and password to be authenticated to the queue manager in an MQCSP structure.

-nolpw

Optional. Specify this parameter if the command connects to a queue manager that does not support passwords longer than 12 characters.

When the **-nolpw** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid** and **-nolpw**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

Note: If you specify the **-nolpw** option, and the password is longer than 12 characters the command fails with error message BFGCL0829E.

template_names

Required. Specify one or more template names that you want to delete. Specify the name as displayed by the **fteListTemplates** command.

-? or -h

Optional. Displays command syntax.

Example

In this example, the template STANDBY is deleted:

```
fteDeleteTemplates STANDBY
```

Return codes

0

Command completed successfully.

1

Command ended unsuccessfully.

Related concepts

[Working with file transfer templates](#)

Related tasks

[Creating a file transfer template using IBM MQ Explorer](#)

Related reference

“[fteCreateTemplate \(create new file transfer template\)](#)” on page 2064

The **fteCreateTemplate** command creates a file transfer template that you can keep for future use. The only required parameter is the **-tn** *template_name* parameter. All other parameters are optional, although if you specify a source file specification, you must also provide a destination file. Similarly, if you specify a destination file, you must also specify a source file specification.

“[fteListTemplates \(list available MFT transfer templates\)](#)” on page 2125

Use the **fteListTemplates** command to list the available Managed File Transfer transfer templates on a coordination queue manager.

fteDisplayVersion (display installed version of MFT)

Use the **fteDisplayVersion** command to display the version of Managed File Transfer (MFT) that you have installed.

Purpose

You might be asked to run the **fteDisplayVersion** command by an IBM Service Representative to help with problem determination.

Syntax

Parameters

-v

Optional. Displays a verbose amount of information about the product version.

The precise details that are displayed when you specify the **-v** parameter might vary between product releases. You are not recommended to rely on specific information being available in the output from the `fteDisplayVersion -v` command.

 On z/OS, **-v** displays the value of the **productId** property, if the product Id has been specified.

-? or -h

Optional. Displays command syntax.

Example with no parameters specified

In this example, the **fteDisplayVersion** command is specified with no parameters.

```
fteDisplayVersion
```

The output from this command is the product version level. For example, this is the output for IBM MQ 9.4.0:

```
fteDisplayVersion -v
5724-H72 Copyright IBM Corp. 2008, 2024. ALL RIGHTS RESERVED
Name:      IBM MQ Managed File Transfer
Version:   9.4.0.0
```

Example with -v parameter specified

In this example, the **fteDisplayVersion** command is specified with the **-v** parameter.

```
fteDisplayVersion -v
```

The output from this command includes more detailed information about the product version. For example:

```
V 9.4.0 IBM MQ 9.4.0
```

```
fteDisplayVersion -v
5724-H72 Copyright IBM Corp. 2008, 2024. ALL RIGHTS RESERVED
Name:      IBM MQ Managed File Transfer
Version:   9.3.1.0
Level:     p931-dfct-USER-L220717.2
Platform:  Windows 10 (10.0)
Architecture: amd64
JVM:      JRE 1.8.0 Windows 10 amd64-64-Bit Compressed References 20220427_27745 (JIT enabled, AOT
enabled)
          OpenJ9   - b15041a
          OMR      - 3671a9f
          IBM      - 1b0232b
Product:   C:\Program Files\IBM\MQ
Configuration: C:\ProgramData\IBM\MQ\mqft
```

IBM MQ Components:

```
Name:      Common Services for Java Platform, Standard Edition
Version:   9.3.1.0
Level:     p931-dfct-USER-L220704.3
```

Note: **V 9.4.0** Before IBM MQ 9.4.0, the output from the **fteDisplayVersion** command included components that MFT does not use. From IBM MQ 9.3.1, these components are no longer included in the output.

Return codes

0

Command completed successfully.

1

Command ended unsuccessfully.

fteListAgents (list the MFT agents for a coordination queue manager)

Use the **fteListAgents** command to list all of the Managed File Transfer agents that are registered with a particular coordination queue manager.

Purpose

You can run the **fteListAgents** command from any system that can connect to the coordination queue manager. The following details for each agent are directed to the standard output device (STDOUT):

- Agent name
- Agent queue manager
- If the agent is a protocol bridge agent, the agent name is appended with (`bridge`)
- If the agent is a Connect:Direct bridge agent, the agent name is appended with (`Connect:Direct bridge`)
- Agent status

This command uses the `coordination.properties` file to connect to the coordination queue manager. For more information, see [The MFT `coordination.properties` file](#).

Specify the optional **-p** parameter for this command only if you want to use a set of configuration options different from your default set. For more information, see [Configuration options](#).

If an agent is not listed by the **fteListAgents** command, use the diagnosis flowchart in the following topic to locate and fix the problem: [What to do if your MFT agent is not listed by the **fteListAgents** command](#).

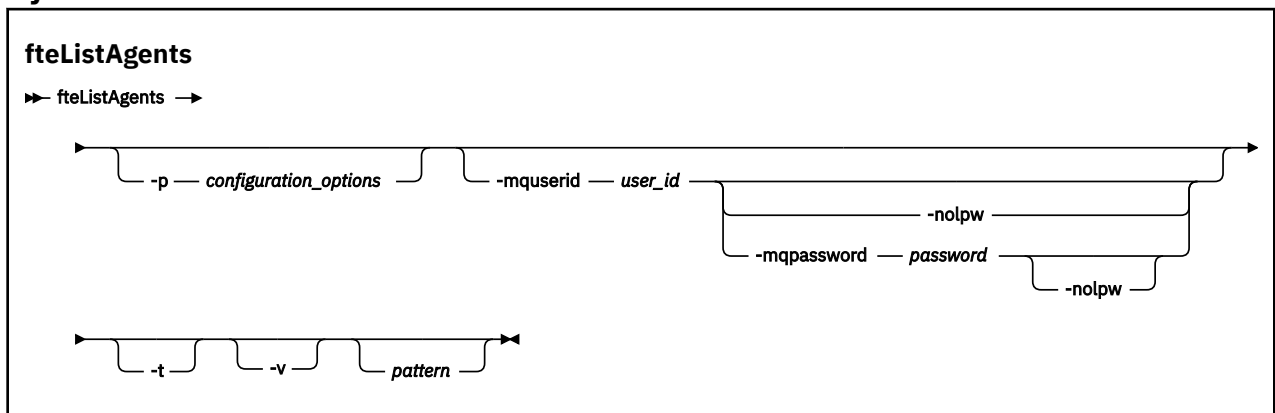

Agent status information

The agent status information produced by this command is generated from the status messages that the agent publishes to the `SYSTEM.FTE` topic. These messages are described in the topic [“MFT agent status message format” on page 2648](#). The status information produced by the **fteListAgents** command gives the agent status at the time when the last status message was published.

The frequency of these status messages depends on the value of the **agentStatusPublishRateLimit** property. For more details about this property, see [The MFT `agent.properties` file](#).

If the **Status Age** is surrounded by parenthesis, this indicates that the value is negative. This situation occurs if the system time of the machine, where the agent is running, is ahead of the system time of the coordination queue manager machine.

Syntax

Parameters

-p *configuration_options*

Optional. This parameter determines the set of configuration options that is used to issue the request to list agents. Use the name of a non-default coordination queue manager as the input for this parameter. The command then uses the set of properties files associated with this non-default coordination queue manager.

If you do not specify this parameter, the set of configuration options based on the default coordination queue manager is used.

-mquserid *user_id*

Optional. Specifies the user ID to authenticate with the coordination queue manager.

-mqpassword *password*

Optional. Specifies the password to authenticate with the coordination queue manager.

When the **-mqpassword** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

From IBM MQ 9.3, the command defaults to using [MQCSP](#) authentication, and sends the user ID and password to be authenticated to the queue manager in an MQCSP structure.

-nolpw

Optional. Specify this parameter if the command connects to a queue manager that does not support passwords longer than 12 characters.

When the **-nolpw** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid** and **-nolpw**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

Note: If you specify the **-nolpw** option, and the password is longer than 12 characters the command fails with error message BFGCL0829E.

-v

Optional. Specifies verbose mode. Verbose mode generates additional output that shows the number of current managed transfers for each agent in the form *Source/Destination*, where:

- *Source* is the current number of source transfers and queued transfers for the agent.
- *Destination* is the current number of destination transfers.

The current transfer information is obtained from the agent status publication, which is described in the “MFT agent status message format” on page 2648 topic. As a result, this transfer information is only accurate to within the setting for the [agentStatusPublishRateLimit](#) agent property value (which defaults to 30 seconds).

-t

Optional. Specifies terse mode. The output includes the **Status Age** column by default. If you do not want to see the **Status Age** information, you can issue the command with the **-t** parameter to hide the column. For more information, see [What to do if an agent is shown as being in an UNKNOWN state](#).

pattern

Optional. The pattern to use to filter the list of Managed File Transfer agents. This pattern is matched against the agent name. Asterisk (*) characters are interpreted as wildcards, that match any value, including zero characters.

  On AIX and Linux systems, you must escape special characters like the asterisk (*) and the number sign (#) with quotation marks (') or double quotation marks (") if you want them to be handled as literals. If you do not escape these characters, they are interpreted according to their meaning on the specific AIX or Linux system.

If you do not specify this parameter, all agents registered with the coordination queue manager are listed.

-? or -h

Optional. Displays command syntax.

Example

In this example, all of the agents registered on the queue manager detailed in the configuration options with names beginning with B are listed:

```
fteListAgents "B*"
```

In this example, agents that are registered with the coordination queue manager QM_EUROPE (the non-default coordination queue manager) are listed in verbose mode:

```
fteListAgents -p QM_EUROPE -v
```

The output from this command is as follows:

Agent Name:	Queue Manager Name:	Transfers: (Source/Destination)	Status:
BERLIN	QM_BERLIN	7/0	RUNNING
LONDON	QM_LONDON	0/0	RUNNING
MADRID	QM_MADRID	0/1	UNREACHABLE

For a list of the possible agent status values and their meanings, see the topic [“MFT agent status values”](#) on page 2518.

In this example, all agents that are registered with the coordination queue manager and that have names beginning with BRIDGE are listed in verbose mode:

```
fteListAgents -v "BRIDGE*"
```

The output from this command is as follows:

```
C:\Program Files\IBM\WMQFTE\bin>fteListAgents -v
5724-H72 Copyright IBM Corp. 2008, 2024. ALL RIGHTS RESERVED
Agent Name:                               Queue Manager Name:   Transfers:   Status:
                                           (Source/Destination)
BRIDGE_FTP ( bridge )                     QM_JUPITER            0/0          STOPPED
BRIDGE_CD1 (Connect:Direct bridge)        QM_JUPITER            0/0          STOPPED
```

The output from the command displays HA by an agent name if that agent is highly available. You must set **highlyAvailable=true** in the [agent.properties](#) file for an agent to be started in highly available mode. Note that HA is displayed, even if there are no standby instances running.

```
5724-H72 Copyright IBM Corp. 2008, 2024. ALL RIGHTS RESERVED
Command executed at 2019-05-15 13:21:08 IDT
Coordination queue manager time 2019-05-15 07:51:08 UTC
Agent Name:                               Queue Manager Name:   Status:       Status Age:
IMQFT02 ( bridge )(HA) MFTQM             STOPPED      8:51:17
SRC (HA)                               MFTQM             READY        0:04:50
DEST                                    MFTQM             READY        0:05:50
```

Return codes

0

Command completed successfully.

1

Command ended unsuccessfully.

Related concepts

[What to do if an agent is shown as being in an UNKNOWN state](#)

Related tasks

[Listing MFT agents](#)

Related reference

[“MFT agent status values” on page 2518](#)

The **fteListAgents** and **fteShowAgentDetails** commands produce agent status information. There are several possible values for this status.

[“fteShowAgentDetails \(display MFT agent details\)” on page 2159](#)

Use the **fteShowAgentDetails** command to display the details of a particular Managed File Transfer Agent. These are the details that are stored by the agent's Managed File Transfer coordination queue manager.

fteListMonitors (list MFT resource monitors)

Use the **fteListMonitors** command to list all of the existing resource monitors in a Managed File Transfer network using the command line.

Purpose

The **fteListMonitors** command lists existing resource monitors. You can filter the command output by specifying an agent name and a resource monitor name.

This command uses the `coordination.properties` file to connect to the coordination queue manager. For more information, see [The MFT coordination.properties file](#).

You can use the **-ox** parameter to export a resource monitor to an XML file. For more information on how to use this XML file, see [“fteCreateMonitor \(create an MFT resource monitor\)” on page 2057](#).

Specify the optional **-p** parameter for this command only if you want to use a set of configuration options different from your default set. For more information, see [Configuration options](#).

Resource monitor names

Resource monitor names can contain characters that might not be valid for file names. If a resource monitor name contains any of the following characters, the **fteListMonitors -od** command converts that character to its ASCII equivalent:

- "\" (Backslash) = %5C
- "/" (Forward slash) = %2F
- ":" (Colon) = %3A
- "<" (Less than) = %3C
- ">" (Greater than) = %3E
- "\"" (Double quotes) = %22
- "|" (Pipe) = %7C

For example, a resource monitor with name:

```
SRC.TEST \ (TESTING-TEST\)
```

is saved to a file called:

```
SRC.TEST %5C (TESTING-TEST%5C)
```

In addition, from IBM MQ 9.1, you no longer have to use an escape character when specifying any special characters while using the **fteListMonitors -ma <agent name> -mn <monitor name>** command.

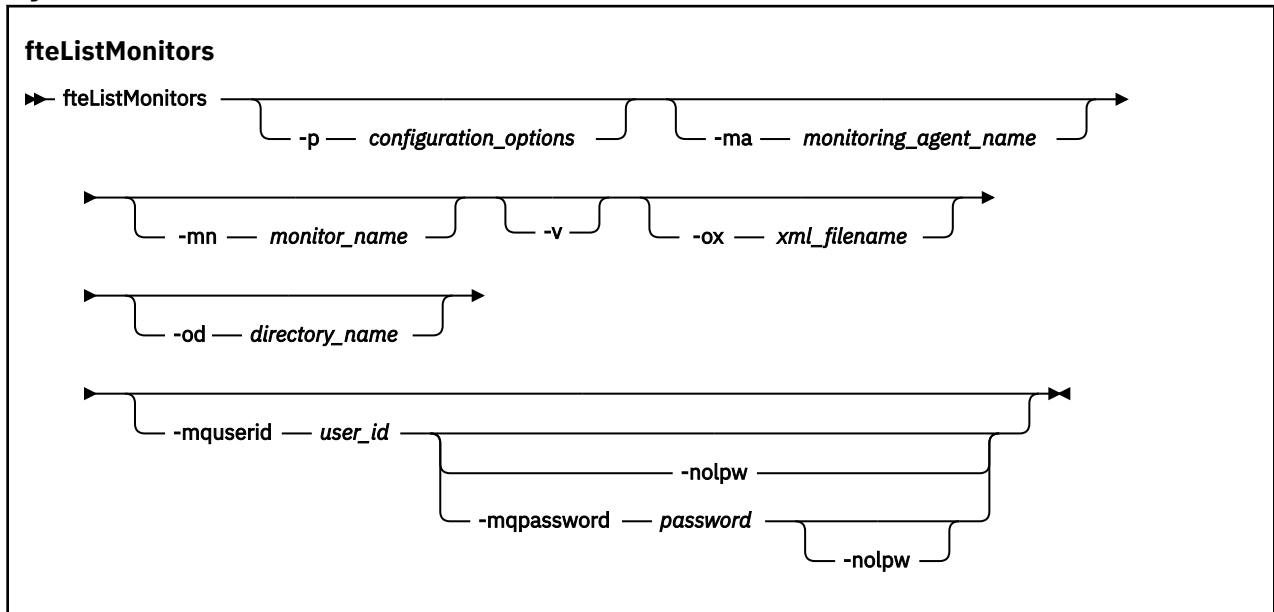

For example, where in earlier releases the command used to be:

```
fteListMonitors -ma SRC -mn "TEST \ (TESTING-TEST\)"
```

from IBM MQ 9.1 you enter:

```
fteListMonitors -ma SRC -mn "TEST (TESTING-TEST)"
```

Syntax

Parameters

-p configuration_options

Optional. This parameter determines the set of configuration options to use to cancel the transfer. By convention use the name of a non-default coordination queue manager as the input for this parameter. The command then uses the set of properties files that are associated with this non-default coordination queue manager.

If you do not specify this parameter, the set of configuration options based on the default coordination queue manager is used.

-ma monitoring_agent_name

Optional. Filters resource monitors by agent name by using the pattern that you provide as input. Asterisk (*) characters are interpreted as wildcards that match zero or more characters. If you do not specify the **-ma** parameter, all resource monitors associated with all agents for the default coordination queue manager are listed by default.

-mn monitor_name

Optional. Filters resource monitors by monitor name by using the pattern that you provide as input. Asterisk (*) characters are interpreted as wildcards that match zero or more characters. If you do not specify the **-mn** parameter, all resource monitors associated with all agents for the default coordination queue manager are listed by default.

-mquserid user_id

Optional. Specifies the user ID to authenticate with the coordination queue manager.

-mqpassword password

Optional. Specifies the password to authenticate with the coordination queue manager.

When the **-mqpassword** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

From IBM MQ 9.3, the command defaults to using MQCSP authentication, and sends the user ID and password to be authenticated to the queue manager in an MQCSP structure.

-nolpw

Optional. Specify this parameter if the command connects to a queue manager that does not support passwords longer than 12 characters.

When the **-nolpw** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid** and **-nolpw**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

Note: If you specify the **-nolpw** option, and the password is longer than 12 characters the command fails with error message BFGCL0829E.

-v

Optional. Generates verbose output that includes additional information about the status of the resource monitor, including whether the resource monitor is started or stopped, the directory resource path that is being monitored and the trigger conditions.

-ox xml_filename

Optional. You must specify this parameter in combination with the **-ma** and **-mn** parameters. Exports the resource monitor to an XML file that can then be used by the **fteCreateMonitor** command and the **-ix** parameter.

The **-ox** parameter must not be combined with the **-od** parameter.

-od directory_name

Optional. Exports multiple resource monitor definitions to the specified directory. Each resource monitor definition is saved to a separate XML file with a name in the format *agent_name.monitor_name.xml*. You must specify a valid target directory for the XML files, otherwise an error message is displayed. This parameter must not be combined with the **-ox** parameter.

-? or -h

Optional. Displays command syntax.

Examples: list resource monitors

In this example, all resource monitors associated with the monitoring agent (and source agent for the file transfers associated with the resource monitor) AGENT1 are listed:

```
fteListMonitors -ma AGENT1
```

The output from this command is as follows:

```
C:/Users/Administrator>fteListMonitors -ma AGENT1
5724-H72 Copyright IBM Corp. 2008, 2024. ALL RIGHTS RESERVED
Agent Name:      Monitor Name:      Resource Type:
AGENT1          MONITOR1          Directory
```

In the following example, the command includes the **-v** parameter, which generates verbose output that includes additional information about the status of the resource monitor:

```
fteListMonitors -ma AGENT1 -v
```

In this case, the output from the command is as follows:

```
C:/Users/Administrator>fteListMonitors -ma AGENT1 -v
5724-H72 Copyright IBM Corp. 2008, 2024. ALL RIGHTS RESERVED
Monitor Information:
Name:              MONITOR1
Agent:             AGENT1
Status:            Stopped
Resource Type:     Directory
Resource:          C:\src
Poll interval:    2 seconds
Batch size:        1
Condition:         Match
Pattern:           * (wildcard)
```

Example: export one resource monitor to an XML file

In this example, a single resource monitor, MONITOR1, on AGENT1 is exported to the XML file filename1.xml by specifying an XML file name with the **-ox** parameter:

```
fteListMonitors -ma AGENT1 -mn MONITOR1 -ox filename1.xml
```

Example: export one resource monitor to a specified directory

In this example, a single resource monitor, MONITOR1, on AGENT1 is exported to the directory that is specified by the **-od** parameter. Except for the difference in the XML file name format, this example is similar to using the **-ox** parameter.

```
fteListMonitors -ma AGENT1 -mn MONITOR1 -od /usr/mft/resmonbackup
```

Examples: export a batch of resource monitors to an XML file in a specified directory

In all of the following examples, the resource monitors are exported to the directory that is specified by the **-od** parameter. Each resource monitor definition is saved to separate XML file with a name in the format *agent name.monitor name.xml*.

In this example, all resource monitors are exported to the specified directory:

```
fteListMonitors -od /usr/mft/resmonbackup
```

In this example, all resource monitors on AGENT1 are exported to the specified directory:

```
fteListMonitors -ma AGENT1 -od /usr/mft/resmonbackup
```

You can use wildcard matching to define which resource monitors to export by using an asterisk character (*) when you specify a pattern to match to agent names, or monitor names, or both.

In this example, all resource monitors on AGENT1 with names that match the pattern MON* are exported to the specified directory:

```
fteListMonitors -ma AGENT1 -mn MON* -od /usr/mft/resmonbackup
```

In this example, all resource monitors on agents with names that match the pattern AGEN* are exported to the specified directory:

```
fteListMonitors -ma AGEN* -od /usr/mft/resmonbackup
```

In this example, all resource monitors with names that match the pattern MON* on agents with names that match the pattern AGEN* are exported to the specified directory:

```
fteListMonitors -ma AGEN* -mn MON* -od /usr/mft/resmonbackup
```

Return codes

0

Command completed successfully.

1

Command ended unsuccessfully.

Related tasks

[Monitoring MFT resources](#)

[Backing up and restoring MFT resource monitors](#)

Related reference

[“fteCreateMonitor \(create an MFT resource monitor\)” on page 2057](#)

The **fteCreateMonitor** command creates and starts a new resource monitor from the command line. You can monitor a resource (for example, the contents of a directory) by using Managed File Transfer so that when a trigger condition is satisfied, a specified task, such as a file transfer, is started.

“[fteDeleteMonitor \(delete an MFT resource monitor\)](#)” on page 2109

Use the **fteDeleteMonitor** command to stop and delete an existing Managed File Transfer resource monitor using the command line. Issue this command against the resource monitoring agent.

fteListScheduledTransfers (list all scheduled transfers)

Use the **fteListScheduledTransfers** command to list all of the Managed File Transfer transfers that you previously created using the command line or the IBM MQ Explorer.

Purpose

You can either list all scheduled transfers based on source agent names or based on the coordination queue manager.

Specify the optional **-p** parameter for this command only if you want to use configuration options different from your defaults. If you do not specify **-p**, the configuration options defined in `installation.properties` are used. See [Configuration options](#) for more information.

When you run the **fteListScheduledTransfers** command, any scheduled transfer that has a transfer definition with a semantically incorrect date and time combination causes error messages to be displayed. From IBM MQ 9.3.0, these messages are BFGCL0810E messages that include the schedule ID of the invalid scheduled transfer. You can then run the **fteDeleteScheduledTransfer** command with the **schedule_ID** parameter to delete the invalid scheduled transfer.

Syntax

Parameters

-p *configuration_options*

Optional. If you have more than one coordination queue manager, use this parameter to explicitly specify which agents you want to list scheduled transfers for. Use the name of a non-default coordination queue manager as the input for this parameter. The command then uses the configuration options associated with this non-default coordination queue manager.

If you do not specify this parameter, the configuration options based on the default coordination queue manager are used.

-mquserid *user_id*

Optional. Specifies the user ID to authenticate with the coordination queue manager.

-mqpassword *password*

Optional. Specifies the password to authenticate with the coordination queue manager.

When the **-mqpassword** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

From IBM MQ 9.3, the command defaults to using [MQCSP](#) authentication, and sends the user ID and password to be authenticated to the queue manager in an MQCSP structure.

-nolpw

Optional. Specify this parameter if the command connects to a queue manager that does not support passwords longer than 12 characters.

When the **-nolpw** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid** and **-nolpw**, but do not specify **-mqpassword**, you are prompted to supply the associated password which will not be displayed.

Note: If you specify the **-nolpw** option, and the password is longer than 12 characters the command fails with error message BFGCL0829E.

pattern

Optional. The pattern to use to filter the list of Managed File Transfer scheduled transfers. This pattern is matched against the source agent name. Asterisk (*) characters are interpreted as wildcards that match zero or more characters.

If you do not specify this parameter, all of the scheduled transfers registered with the coordination queue manager are listed by default.

-? or -h

Optional. Displays command syntax.

Example

In this example, all of the scheduled transfers with source agents that match the pattern *2 are listed:

```
fteListScheduledTransfers "*2"
```

This example command produces the following output. The schedule start time and next transfer time are displayed in Coordinated Universal Time (UTC):

```
Schedule Identifier:      1
Source Agent Name:       AGENT2
Source File Name:        C:/export/Test/workspace/A.exe
Conversion Type:         binary
Destination File Name:   C:/import/Test/workspace/B001.zzx
Destination Agent Name:  AGENT1
Schedule Start Time:     2008-10-23T16:08+0100
Next Transfer:           2008-10-23T16:08+0100
Schedule Time Base:     source
Repeat Interval:         minutes
Repeat Frequency:        1
Repeat Count:           30
```

Return codes

0

Command completed successfully.

1

Command ended unsuccessfully.

fteListTemplates (list available MFT transfer templates)

Use the **fteListTemplates** command to list the available Managed File Transfer transfer templates on a coordination queue manager.

Purpose

This command lists either all template names or a filtered selection of template names. The output format of the list can be any of the following:

- Template names only (default behavior)
- Template names with a summary of the templates (verbose mode)
- Complete XML message describing the templates (**-x** and **-o** parameters)

This command uses the `coordination.properties` file to connect to the coordination queue manager. For more information, see [The MFT coordination.properties file](#).

Specify the optional **-p** parameter for this command only if you want to use a set of configuration options different from your default set. See [Configuration options](#) for more information.

Syntax

Parameters

-p

Optional. This parameter determines the set of configuration options to use to delete the template. By convention use the name of a non-default coordination queue manager as the input for this parameter. The command then uses the set of properties files associated with this non-default coordination queue manager.

If you do not specify this parameter, the set of configuration options based on the default coordination queue manager is used.

-v

Optional. Specifies verbose mode and provides a short summary of each matching template. This parameter is ignored if you have also specified the **-x** parameter.

The **-v** parameter includes a summary of each template. For example:

```
Template Name: STANDBY
```

```

Source Agent Name: AGENT1
Source QMgr: QM_JUPITER
Destination Agent Name: AGENT2
Destination QMgr: QM_NEPTUNE
Transfer Priority: 0
Transfer file specification
File Item Details
  Mode: binary
  Checksum: MD5
  Source File:
    C:\payroll_reports\*.xls
  Recursive: false
  Disposition: leave
  Destination File:
    C:\payroll_backup\*.xls
  Type: file
  Exist: error

```

If you do not specify the **-v** parameter, the default output mode is to list the matching templates names.

-x

Optional. Provides an XML-formatted message for each matching template. This parameter is ignored unless you also specify the **-o** parameter.

Attention: The XML-formatted messages are not compatible with the **fteCreateTemplate** command tools.

-o directory_name

Optional. Sends the XML formatted-message to files in the named directory. One file for each template is created and each file has the same name as the template with an `.xml` suffix. This parameter is ignored unless you also specify the **-x** parameter.

-f

Optional. Forces any existing output file to be overwritten. This parameter is ignored unless you also specify the **-o** parameter. If you do not specify **-f** but you do specify the name of an existing output file, the default behavior is to report an error and continue.

-mquserid user_id

Optional. Specifies the user ID to authenticate with the coordination queue manager.

-mqpassword password

Optional. Specifies the password to authenticate with the coordination queue manager.

When the **-mqpassword** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

From IBM MQ 9.3, the command defaults to using MQCSP authentication, and sends the user ID and password to be authenticated to the queue manager in an MQCSP structure.

-nolpw

Optional. Specify this parameter if the command connects to a queue manager that does not support passwords longer than 12 characters.

When the **-nolpw** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid** and **-nolpw**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

Note: If you specify the **-nolpw** option, and the password is longer than 12 characters the command fails with error message BFGCL0829E.

template_names

Optional. A list of one or more template names to be listed. A template name can include an asterisk as a wildcard that matches zero or more characters. Depending on your operating system, you might need to enclose any template names that include wildcard character in quotation marks (`" "`) or single quotation marks (`' '`) to avoid shell expansion. Shell expansion can cause unexpected behavior.

If you do not specify anything for *template_names*, the default is to list all templates.

-? or -h

Optional. Displays command syntax.

Example

In this example, all the templates with names starting with ST are listed:

```
fteListTemplates "ST*"
```

This example creates the template STANDBY as an XML-formatted message to the file STANDBY.xml in the current directory:

```
fteListTemplates -x -o . STANDBY
```

This command creates the following output in STANDBY.xml:

```
<?xml version="1.0" encoding="UTF-8" ?>
- <transferTemplate id="1864c1dd-ba02-4b34-bda9-dc6862448418" version="3.00">
  <name>STANDBY</name>
  <sourceAgentName>AGENT1</sourceAgentName>
  <sourceAgentQMgr>QM_JUPITER</sourceAgentQMgr>
  <sourceAgentQMgrHost>null</sourceAgentQMgrHost>
  <sourceAgentQMgrPort>-1</sourceAgentQMgrPort>
  <sourceAgentQMgrChannel>null</sourceAgentQMgrChannel>
  <destinationAgentName>AGENT2</destinationAgentName>
  <destinationAgentQMgr>QM_NEPTUNE</destinationAgentQMgr>
- <fileSpecs>
  - <item checksumMethod="MD5" mode="binary">
    - <source disposition="leave" recursive="false">
      <file>C:\payroll_reports\*.xls</file>
    </source>
    - <destination exist="error" type="file">
      <file>C:\payroll_backup\*.xls</file>
    </destination>
  </item>
</fileSpecs>
<priority>0</priority>
</transferTemplate>
```

Return codes

0

Command completed successfully.

1

Command ended unsuccessfully.

Related concepts

[Working with file transfer templates](#)

Related tasks

[Creating a file transfer template using IBM MQ Explorer](#)

[Backing up a file transfer template definition](#)

Related reference

[“fteCreateTemplate \(create new file transfer template\)” on page 2064](#)

The **fteCreateTemplate** command creates a file transfer template that you can keep for future use.

The only required parameter is the **-tn *template_name*** parameter. All other parameters are optional, although if you specify a source file specification, you must also provide a destination file. Similarly, if you specify a destination file, you must also specify a source file specification.

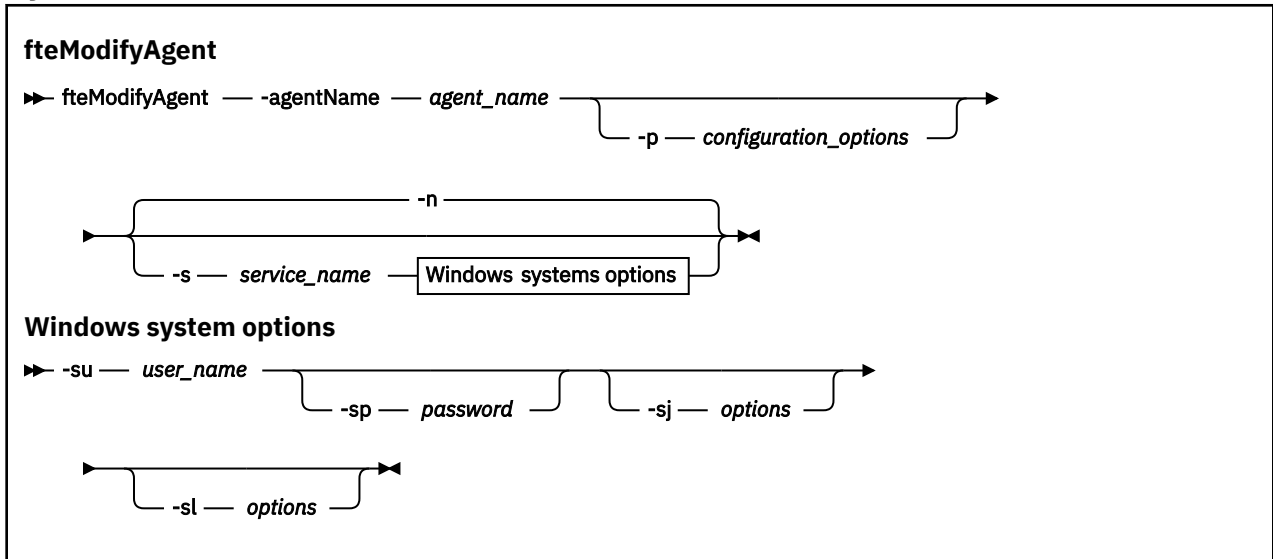

[“fteDeleteTemplates \(delete an MFT template\)” on page 2112](#)

Use the **fteDeleteTemplates** command to delete an existing Managed File Transfer template from a coordination queue manager.

Windows **fteModifyAgent (run an MFT agent as a Windows service)**

The **fteModifyAgent** command modifies an existing agent so that it can be run as a Windows service. This command is only available on Windows, and must be run by a user who is an IBM MQ administrator and a member of the mqm group.

Syntax

Parameters

-agentName agent_name

Required. The name of the agent you want to modify.

-p configuration_options

Optional. This parameter determines the set of configuration options that is used to modify the agent. By convention use the name of a non-default coordination queue manager as the input for this parameter. The **fteModifyAgent** command then uses the set of properties files associated with this non-default coordination queue manager.

Specify the optional **-p** parameter only if you want to use configuration options different from your defaults. If you do not specify this parameter, the set of configuration options based on the default coordination queue manager is used.

-s service_name

Optional. Indicates that the agent is to run as a Windows service. If you do not specify *service_name*, the service is named mqmftAgentAGENTQMGR, where *AGENT* is the agent name and *QMGR* is your agent queue manager name.

The display name for the service, which is shown in the Windows **Services** window in the **Name** column, is always **Managed File Transfer Agent AGENT@QMGR**.

Note: If the redistributable agent is going to run as a Windows service, then the **BFG_DATA** environment variable needs to be set in the system environment for the service to work.

-su user_name

Optional. When the agent is to run as a Windows service, this parameter specifies the name of the account under which the service should run. To run the agent using a Windows domain user account specify the value in the form DomainName\UserName. To run the service using an account from the local built-in domain specify the value in the form UserName.

The Windows user account that you specify using the **-su** parameter must have the **Log on as a service** right. For information about how to grant this right, see [Troubleshooting an MFT agent or logger running as a Windows service](#).

This parameter is required when **-s** is specified.

-sp password

Optional. This parameter is only valid when **-s** is specified.

-sj options

Optional. When the agent is started as a Windows service, this parameter defines a list of options in the form of **-D** or **-X** that will be passed to the Java Virtual Machine (JVM). The options are separated using the number sign (**#**) or semicolon (**;**) character. If you need to embed any **#** or **;** characters, put them inside single quotation marks.

This parameter is only valid when **-s** is specified.

For more information about the way in which the **fteModifyAgent** command handles the validation of updates to the JVM options see [How agent and logger JVM options are processed](#).

-sl options

Optional. Sets the Windows service log level. Valid options are: error, info, warn, debug. The default is info. This option can be useful if you are having problems with the Windows service. Setting it to debug gives more detailed information in the service log file.

This parameter is only valid when **-s** is specified.

-n

Optional. Indicates that the agent is to be run as a normal process. This is mutually exclusive with the **-s** option. If neither the **-s** nor the **-n** option is specified, then the agent is configured as a normal Windows process.

-? or -h

Optional. Displays command syntax.

Example

In this example, AGENT1 is modified to run as a Windows service:

```
fteModifyAgent -agentName AGENT1 -s -su fteuser -sp ftepassword
```

In this example, AGENT1 is modified to remove the Windows service:

```
fteModifyAgent -agentName AGENT1
```

You must stop the agent you want to modify, using the [fteStopAgent](#) command, before you can run the [fteModifyAgent](#) command.

Return codes

0

Command completed successfully.

1

Command ended unsuccessfully.

Related concepts

[Troubleshooting an MFT agent or logger running as a Windows service](#)

Related tasks

[Starting an MFT agent as a Windows service](#)

Related reference

[“fteCreateAgent \(create an MFT agent\)” on page 2030](#)

The **fteCreateAgent** command creates a Managed File Transfer Agent and its associated configuration.

“[fteModifyLogger \(run an MFT logger as a Windows service\)](#)” on page 2130

Use the **fteModifyLogger** command to modify a Managed File Transfer logger so that it can be run as a Windows service. You can use this command only on Windows platforms, must be run by a user who is an IBM MQ administrator and a member of the mqm group, and you must first stop the logger by using the **fteStopLogger** command.

Windows **fteModifyLogger (run an MFT logger as a Windows service)**

Use the **fteModifyLogger** command to modify a Managed File Transfer logger so that it can be run as a Windows service. You can use this command only on Windows platforms, must be run by a user who is an IBM MQ administrator and a member of the mqm group, and you must first stop the logger by using the **fteStopLogger** command.

Purpose

A stand-alone logger, whether for a file or for a database, is shown as "Managed File Transfer logger for property set *logger_name@logger_qm*" in the **Name** column of the **Services** application. The value of *logger_qm* is the name of the command queue manager of the logger.

Syntax

Parameters

-loggerName *logger_name*

Required. The name of the Managed File Transfer logger you want to modify.

-p *configuration_options*

Optional. This parameter determines the set of configuration options that is used to modify the logger. By convention use the name of a non-default coordination queue manager as the input for this parameter. The **fteModifyLogger** command then uses the set of properties files associated with this non-default coordination queue manager.

Specify the optional **-p** parameter only if you want to use configuration options different from your defaults. If you do not specify this parameter, the set of configuration options based on the default coordination queue manager is used.

-s *service_name*

Optional. Indicates that the logger is to run as a Windows service. If you do not specify *service_name*, the service is named `mqmftLogger@LOGGERQMGR`, where *LOGGER* is the logger name and *QMGR* is your logger queue manager name.

The display name for the service, which is shown in the Windows **Services** window in the **Name** column, is always **Managed File Transfer Logger *LOGGER@QMGR***.

-su user_name

Required when **-s** is specified. Specifies the name of the account under which the Windows service should run. To run the agent using a Windows domain user account, specify the value in the form DomainName\UserName. To run the service using an account from the local built-in domain, specify the value in the form UserName.

The Windows user account that you specify using the **-su** parameter must have the permission to log on as a service. For information about how to grant this permission, see [Troubleshooting an MFT agent or logger running as a Windows service](#).

-sp password

Optional. Only valid when **-s** is specified. Password for the user account set by the **-su** parameter.

If you do not specify this parameter when you specify the **-s** parameter, you are warned that you must set the password by using the Windows Services tool before the service can start successfully.

-sj options

Optional. Only valid when **-s** is specified. When the logger is started as a Windows service, this parameter defines a list of options in the form of **-D** or **-X** that will be passed to the JVM. The options are separated using the number sign (#) or semicolon (;) character. If you need to embed any # or ; characters, put them inside single quotation marks (').

For more information about the way in which the **fteModifyLogger** command handles the validation of updates to the JVM options see [How agent and logger JVM options are processed](#).

-sl options

Optional. Only valid when **-s** is specified. Sets the Windows service log level. Valid options are: **error**, **info**, **warn**, **debug**. The default is **info**. This option can be useful if you are having problems with the Windows service. Setting it to **debug** gives more detailed information in the service log file.

-n

Optional. Indicates that the logger is to be run as a normal process. This is mutually exclusive with the **-s** option. If neither the **-s** nor the **-n** option is specified, then the logger is configured as a normal Windows process.

-? or -h

Optional. Displays command syntax.

Example

You must stop the logger by using the [fteStopLogger](#) command, before running the **fteModifyLogger** command.

In this example, a logger named **logger1** has previously been created. This command shows how the logger can be changed to run as a Windows service:

```
fteModifyLogger -loggerName logger1 -s -su fteuser -sp ftepassword
```

Return codes

0

Command completed successfully.

1

Command ended unsuccessfully.

Related concepts

The **fteStopLogger** command stops a Managed File Transfer logger.

fteObfuscate (encrypt sensitive data)

The **fteObfuscate** command encrypts sensitive data in credentials files. This stops the contents of credentials files being read by someone who gains access to the file.

Purpose

User name and password properties in credentials files can be encrypted. These properties are transformed to a new related property, with a Cipher suffix. For example:

```
<!--
MQMFTCredentials properties before
-->
<tns:logger name="logger1" user="user1" password="passw0rd" />
<tns:file path="$HOME/trust.jks" password="passw0rd" />

<!--
MQMFTCredentials properties after
-->
<tns:logger name="logger1" userCipher="e71vKCg2pf" passwordCipher="se71vKCg" />
<tns:file path="$HOME/trust.jks" passwordCipher="e71vKCg2pf" />

<!--
ProtocolBridgeCredentials Properties before
-->
<tns:user name="Fred" serverUserId="fred" serverPassword="passw0rd" />

<!--
ProtocolBridgeCredentials properties after
-->
<tns:user name="Fred" serverUserIdCipher="e51vVCg2pf" serverPasswordCipher="se51vBCg" />

<!--
ConnectDirectCredentials properties before
-->
<tns:user name="fteuser" ignorecase="true" pattern="wildcard"
  cdUserId="cdUser" cdPassword="cdPassword" pNodeUserId="pnodeUser"
  pNodePassword="pnodePassword">
  <tns:snode name="snode1" pattern="wildcard" userId="snodeUser" password="snodePassword"/>
</tns:user>

<!--
ConnectDirectCredentials properties after
-->
<tns:user name="fteuser" ignorecase="true" pattern="wildcard"
  cdUserIdCipher="e71vKCg2pf" cdPasswordCipher="se71vKCg"
  pNodeUserIdCipher="2f1vgCg6df" pNodePasswordCipher="e71vKCg2pf">
  <tns:snode name="snode1" pattern="wildcard" userIdCipher="e51vVCg2pf" passwordCipher="se51vBCg"/>
</tns:user>
```

The preferred formats are:

MFT

```
<tns:qmgr mqPasswordCipher="mqmftcred!1!kvAzYv/1aCMfSQ5igkFVmQ==!f4rX5KL7aFKHJ17Ln0X+0Q=="
mqUserIdCipher="mqmftcred!1!w2PQGhQcyq1NwYzGItz0VA==!Q40i2rRSEMGwrx6gnRFe8g=="
name="MFTQM" user="JOHNDOE"/>
```

ProtocolBridgeCredentials

```
<tns:agent name="agent3">
  <tns:serverHost name="ftpsServer"
    keyStorePasswordCipher="mqmftcred!1!w2PQGhQcyq1NwYzGItz3VA==!
Q40i2rRSEMGwrx6gnRFe8g=="
trustStorePasswordCipher="mqmftcred!1!w2PQGhQcyq1NwYzGktz0VA==!Q40i2rRSEMGwrx6gnRFe8g==">
```

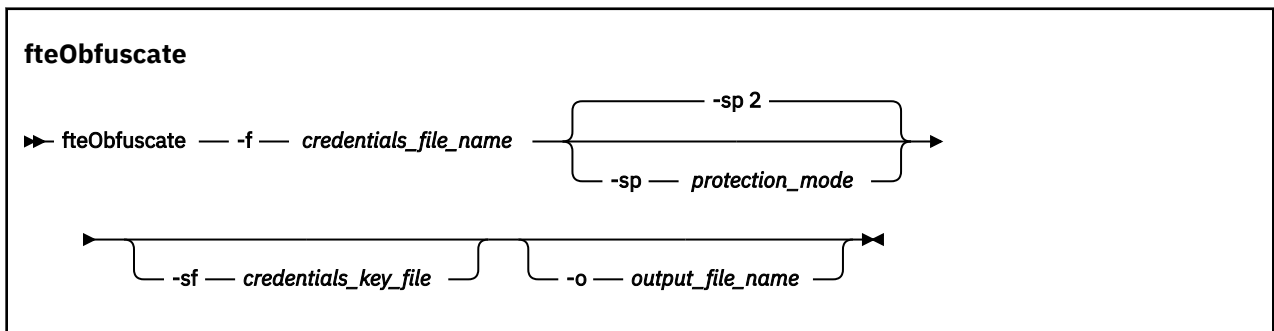

```
</tns:serverHost>
</tns:agent>
```

ConnectDirectCredentials

```
<tns:agent name="CDAGENT01">
  <tns:pnode name="cdnode*" pattern="wildcard">
    <tns:user name="MUSR_.*"
      ignorecase="true"
      pattern="regex"
      cdUserIdCipher="mqmftcred!1!w2PQGhQcyq1NwYzGItz0VA==!Q40i2rRSEMGwrx6gnRFe8g==" />
    cdPasswordCipher=="!mqmftcred!1!w2PQGhQcyq1NwYzGItz0VA==!Q40i2rRSEMGwrx6gnRFe8g==" />
    pnodeUserIdCipher="mqmftcred!1!w2PQGhQcyq1NwYzGItz0VA==!Q40i2rRSEMGwrx6gnRFe8g==" />
    pnodePasswordCipher="mqmftcred!1!w2PQGhQcyq1NwYzGItz0VA==!Q40i2rRSEMGwrx6gnRFe8g==" />
  <tns:snode name="cdnode2" pattern="wildcard" userId="sue" passwordCipher="!mqmftcred!1!
w2PQGhQcyq1NwYzGItz0VA==!Q40i2rRSEMGwrx6gnRFe8g==" />
</tns:user>
</tns:pnode>
</tns:agent>
```

Syntax

The syntax is as follows:

Parameters

-f *credentials_file_name*

Required. Name of the credentials file whose contents will be encrypted.

Note: Deprecated This parameter replaces the **-credentialsFile** parameter that is deprecated from IBM MQ 9.2.0.

-sp *protection_mode*

Optional. The protection mode to be used for encrypting credentials. The value can be:

0

Use the credentials protection method deprecated at IBM MQ 9.2.0.

1

Use the more secure credentials protection method introduced at IBM MQ 9.2.0. For more information, see [Encrypting stored credentials in MFT](#).

This is the default value before IBM MQ 9.3.0.

From IBM MQ 9.3.0, you can use protection mode 1 for compatibility with versions earlier than IBM MQ 9.3.0. However, consider migrating any stored passwords to the enhanced protection provided by setting *protection mode* to 2.

2

Use the enhanced credentials protection mode introduced at IBM MQ 9.3.0. For more information, see [Encrypting stored credentials in MFT](#).

This is the default from IBM MQ 9.3.0.

-sf *credentials_key_file*

Optional. The name of the file containing the credentials key. If this parameter is omitted, the command uses the default credentials key. For more information, see [Protecting passwords in IBM MQ component configuration files](#).

-o *output_file_name*

Optional. Name of the file to output the protected credentials.

-? or -h

Optional. Displays command syntax.

Examples: protection mode 2 (default protection mode)

To encrypt credentials in the `MQMFTCredentials.xml` file using the default protection mode 2 with the latest algorithm and a fixed key, and store them in the enhanced format, issue the following command:

```
fte0bfuscate -f /usr/home/MQMFTCredentials.xml
```

To encrypt credentials in the `MQMFTCredentials.xml` file using the default protection mode 2 with the latest algorithm and a user specified key, and store them in the enhanced format, issue the following command:

```
fte0bfuscate -sf /var/mqmft/credKeyfile.key -f /usr/home/MQMFTCredentials.xml
```

To encrypt credentials in the `MQMFTCredentials.xml` file using the default protection mode 2 with the latest algorithm and a user specified key, and output the encrypted credentials to another file, issue the **fte0bfuscate** command:

```
fte0bfuscate -sf /var/mqmft/credKeyfile.key -sp 2  
-f /usr/home/MQMFTCredentials.xml -o /usr/home/enccred.xml
```

To encrypt credentials in the `ProtocolBridgeCredentials.xml` file using the default protection mode with the latest algorithm and a user specified key, and store them in the enhanced format, issue the following command:

```
fte0bfuscate -sf /var/mqmft/credKeyfile.key  
-f /usr/home/ProtocolBridgeCredentials.xml
```

Examples: protection mode 1

To encrypt credentials in the `MQMFTCredentials.xml` file using protection mode 1 with the latest algorithm and a user specified key, and store them in the more secure format introduced at IBM MQ 9.2.0, issue the following command:

```
fte0bfuscate -sf /var/mqmft/credKeyfile.key -sp 1 -f /usr/home/MQMFTCredentials.xml
```

To encrypt credentials in the `MQMFTCredentials.xml` file using protection mode 1 with the latest algorithm and a user specified key, and output the encrypted credentials to another file, issue the following command:

```
fte0bfuscate -sf /var/mqmft/credKeyfile.key -sp 1  
-f /usr/home/MQMFTCredentials.xml -o /usr/home/enccred.xml
```

Examples: protection mode 0

To encrypt credentials in the `MQMFTCredentials.xml` file using the deprecated algorithm, and store them in the deprecated format, issue the following command:

```
fte0bfuscate -f /usr/home/MQMFTCredentials.xml -sp 0
```

Using data sets on z/OS

Encrypt a data set and output it as an XML file format:

```
fte0bfuscate -f "//test.creds(creds)" -o enc.xml
```

Encrypt a data set with the key specified in the data set:

```
/fte0bfuscate -f "//test.creds(creds)" -sf "//test.creds(key)"
```

Return codes

0

Command completed successfully.

1

Command ended unsuccessfully.

Related reference

[“MFT credentials file format” on page 2730](#)

The `MQMFTCredentials.xml` file contains sensitive user ID and password information. The elements in the `MQMFTCredentials.xml` file must conform to the `MQMFTCredentials.xsd` schema. The security of credentials files is the responsibility of the user.

[MFT and IBM MQ connection authentication](#)

ftePingAgent (check whether an MFT agent is active)

The **ftePingAgent** command pings a Managed File Transfer agent to determine whether the agent is reachable and, if so, whether it is able to respond to a simple query.

Purpose

Use the **ftePingAgent** command to check whether a Managed File Transfer agent is reachable and, if so, whether it is able to respond to a simple query along the lines of `are you there?`. An example output of this command is as follows:

```
C:\> ftePingAgent AGENT86
5724-H72 Copyright IBM Corp. 2008, 2024. ALL RIGHTS RESERVED
BFGPR0127W: No credentials file has been specified to connect to IBM MQ. Therefore, the
assumption is that IBM MQ authentication has been disabled.
BFGCL0212I: Issuing ping request to agent AGENT86
BFGCL0213I: agent AGENT86 responded to ping in 0.094 seconds.
```

Specify the optional **-p** parameter for this command only if you want to use a set of configuration options different from your default set. See [Configuration options](#) for more information.

Syntax

Parameters

-p configuration_options

Optional. This parameter determines the set of configuration options that is used to issue the request to ping an agent. Use the name of a non-default coordination queue manager as the input for this parameter. The command then uses the set of properties files associated with this non-default coordination queue manager. If you do not specify this parameter, the set of configuration options based on the default coordination queue manager is used. See [Configuration options](#) for more information.

-m agent_queue_manager

Optional. The name of the queue manager that the agent you want to ping is connected to. If you do not specify the -m parameter the queue manager used is determined from the set of configuration options in use.

-w timeout

Optional. Specifies that the command should wait for up to *timeout* seconds for the agent to respond. If you do not specify a timeout, or specify a timeout value of -1, then the command waits indefinitely until the agent responds. If you do not specify this option then the default is to wait up to five seconds for the agent to respond.

If *timeout* has been specified, **ftePingAgent** command messages will time out after double the value of *timeout* rather than going to the designated dead letter queue. The command messages will not time out if the command has been set to wait indefinitely.

-mquserid user_id

Optional. Specifies the user ID to authenticate with the command queue manager.

-mqpassword password

Optional. Specifies the password to authenticate with the coordination queue manager.

When the **-mqpassword** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

From IBM MQ 9.3, the command defaults to using [MQCSP](#) authentication, and sends the user ID and password to be authenticated to the queue manager in an MQCSP structure.

-nolpw

Optional. Specify this parameter if the command connects to a queue manager that does not support passwords longer than 12 characters.

When the **-nolpw** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid** and **-nolpw**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

Note: If you specify the **-nolpw** option, and the password is longer than 12 characters the command fails with error message BFGCL0829E.

agent_name

Required. The name of the Managed File Transfer agent that you want to ping.

-? or -h

Optional. Displays command syntax.

Example

In this example, the command pings the agent AGENT1, which is connected to QM_MERCURY. The command waits for up to 40 seconds for AGENT1 to respond before returning.

```
ftePingAgent -m QM_MERCURY -w 40 AGENT1
```

Return codes

0

Command completed successfully. The agent is active and able to process transfers.

1

Command ended unsuccessfully. The command was not able to send a message to the agent.

2

Command ended with a timeout. The command sent a message to the agent, but the agent did not respond within the time.

Related concepts

[What to do if you think that your file transfer is stuck](#)

Related reference

[“fteListAgents \(list the MFT agents for a coordination queue manager\)” on page 2116](#)

Use the **fteListAgents** command to list all of the Managed File Transfer agents that are registered with a particular coordination queue manager.

[“fteShowAgentDetails \(display MFT agent details\)” on page 2159](#)

Use the **fteShowAgentDetails** command to display the details of a particular Managed File Transfer Agent. These are the details that are stored by the agent's Managed File Transfer coordination queue manager.

fteRAS (collect MFT troubleshooting information)

The **fteRAS** command collects troubleshooting information (MustGather data) for Managed File Transfer. The data that **fteRAS** collects is specific to the Managed File Transfer installation on the system where the program is being run.

Purpose

Use the **fteRAS** command to run the Reliability, Availability, and Serviceability information (RAS) gathering tool if you need to collect troubleshooting information to use to help find a solution when a Managed File Transfer agent, database logger or other command is reporting a problem or failing to work properly.

Warning: If there are a large number of Managed File Transfer agents configured on the server, the **fteRAS** command can take a long time to complete. If that happens, you can choose to compress the contents of the Managed File Transfer agent's logs and configuration directories into a zip file.

When you run the **fteRAS** command, the output directory in which the resulting archive (.zip) file is placed can be either the default location, or a directory of your choosing.

Progress information displayed about the fteRAS command while it is running

From IBM MQ 9.3.0, the output of the **fteRAS** command to the console has been enhanced, so that you can see the progress of the command while it is running, by displaying the following information:

- The start time and end time of each step in the format yyyy-MM-dd HH:mm:ss, where the time zone is the local time zone
- The total number of files getting copied to a temporary folder from the configuration, log, installations, and bin directories in the step **FTEConfigLogsCollector**
- The size of the data being compressed
- A counter of the number of bytes compressed
- A counter of the total percentage compressed

From IBM MQ 9.3.0, the output of the **fteRAS** command also includes subscription information. This information shows the number of messages received for agents, resource monitors, and scheduled transfers. It also shows the number of resource monitor definitions saved to the file system.

The following example shows a sample run from the command:

```
C:\Users\Administrator>fteRAS
5724-H72 Copyright IBM Corp. 2008, 2024. ALL RIGHTS RESERVED

C:\ProgramData\IBM\MQ\mqft\logs\fteRAS.zip.\fteRAS.zip.
```

Syntax

Parameters

-p configuration_options

Optional. Determines the set of configuration options that is used to gather the troubleshooting information. Use the name of a set of configuration options as the value for the **-p** parameter. By convention, this name is the name of a coordination queue manager. If you do not specify this parameter, the default set of configuration options is used.

z/OS **-l pds_library_name**

Optional. z/OS only. Specifies the name of a PDS library that contains JCL scripts that invoke MQMFT commands for a particular agent or logger. This option is always set when the command is run from a command PDS library's BFGZRAS JCL script, such that all members of the PDS library are captured in the output directory.

Note: BFGZRAS creates the BFGZRAS member when the BFGCUSTM job is run.

-mquserid user_id

Optional. Specifies the user ID to authenticate with the command queue manager.

-mqpassword password

Optional. Specifies the password to authenticate with the coordination queue manager.

When the **-mqpassword** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

From IBM MQ 9.3, the command defaults to using [MQCSP](#) authentication, and sends the user ID and password to be authenticated to the queue manager in an MQCSP structure.

-nolpw

Optional. Specify this parameter if the command connects to a queue manager that does not support passwords longer than 12 characters.

When the **-nolpw** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid** and **-nolpw**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

Note: If you specify the **-nolpw** option, and the password is longer than 12 characters the command fails with error message BFGCL0829E.

V 9.4.0 **-agents**

Optional. Specifies the names of the agents for which data will be collected.

Agent names must be enclosed in quotes and multiple agent names must be provided as a comma separated list of agent names. For example:

```
fteRAS -agents "AGENT_LIN,AGENT_LIN3"
```

Agent names can include asterisk wildcard characters (*) where * matches zero or more characters. Asterisks are the only type of wildcard character that **fteRAS** supports. For example:

```
fteRAS -agents "AGENT_*
```

```
fteRAS -agents "A*,G*
```

If, during validation, **fteRAS** cannot find an agent on the system with a name that matches the supplied agent name or agent name pattern with a wildcard character, it fails with message [BFGCL0835E](#).

output_directory

Optional. A directory to use when you are gathering the RAS data, and where the output file, for example `fteRAS.zip`, is stored after the data is gathered successfully. If the directory does not exist, it is created. The default location is the `mqt logs` directory.

-? or -h

Optional. Displays command syntax.

Examples

  On AIX and Linux, to store the output file `fteRAS.zip` in the `/var/mqm/errors` directory, run **fteRAS** as shown in the following example:

```
fteRAS /var/mqm/errors
```

The following message confirms that the command has completed successfully:

```
BFGCL0604I: fteRAS command completed successfully. Output is stored in /var/mqm/errors/fteRAS.zip
```

 On Windows, to store the output file `fteRAS.zip` in the default errors directory for a new installation of IBM MQ, run **fteRAS** as shown in the following example:

```
fteRAS "C:\ProgramData\IBM\MQ\errors"
```

The following message confirms that the command has completed successfully:

```
BFGCL0604I: fteRAS command completed successfully. Output is stored in  
C:\ProgramData\IBM\MQ\errors\fteRAS.zip
```

Note: For IBM MQ 8.0 or later, if this is not a new installation of that version of the product, the location of the errors directory might be different on your system. For more information, see [Program and data directory locations on Windows](#).

 On IBM i, to copy the output file to `/QIBM/UserData/mqm/errors`, run the **fteRAS** command from the Qshell as shown in the following example:

```
/QIBM/ProdData/mqm/bin/fteRAS /QIBM/UserData/mqm/errors
```

The following message confirms that the command has completed successfully:

```
BFGCL0604I: fteRAS command completed successfully. Output is stored in /QIBM/UserData/mqm/errors/  
fteRAS.zip
```

fteSetAgentLogLevel (Turn on or turn off logging to file of certain MFT agent operations)

Use the **fteSetAgentLogLevel** command to turn on or turn off logging for the interactions between a protocol bridge agent and file servers, resource monitor activity, and transfer logs.

Purpose

IBM MQ Managed File Transfer provides a logging mechanism that can be used to capture:

- Information about the flows between a protocol bridge agent and file servers
- Details about the polls performed by resource monitors
- Progress of transfers

When you use the **fteSetAgentLogLevel** command to enable logging for a protocol bridge agent, the agent records details of the FTP, SFTP and FTPS commands that are sent to the file server, and the responses that are received. This information is written to a log file called `agenteventN.log`, where *N* stands for a number.

- **Multi** On Multiplatforms, the `agenteventN.log` file is in the `MQ_DATA_PATH/mqft/logs/coordination_qmgr_name/agents/agent_name` directory.
- **z/OS** On z/OS, the `agenteventN.log` file is in the `BFG_DATA/mqft/logs/coordination_qmgr_name/agents/agent_name` directory.

The information in the log file can be useful in diagnosing issues that might occur during a file transfer involving the protocol bridge agent.

When you use the **fteSetAgentLogLevel** command to enable logging for resource monitors, the agent records information about the polls performed by the monitors into a log file called `resmoneventN.log`, where *N* stands for a number.

- **Multi** On Multiplatforms, the `resmoneventN.log` file is in the `MQ_DATA_PATH/mqft/logs/coordination_qmgr_name/agents/agent_name` directory.
- **z/OS** On z/OS, the `resmoneventN.log` file is in the `BFG_DATA/mqft/logs/coordination_qmgr_name/agents/agent_name` directory.

The information in the log file includes:

- The time when the monitor started and finished a poll.
- Details of any managed transfers submitted as a result of a poll.

For more information on resource monitor logging, see [Logging MFT resource monitors](#).

You can turn on, turn off, and set the level of logging that you require, in two ways:

- Use the **fteSetAgentLogLevel** command to enable or disable logging while the agent is running. You do not need to restart the agent for the change to the logging level to take effect.
- Set properties in the `agent.properties` file to enable or disable logging from startup. The properties that need to be set depend on whether logging is being enabled for a protocol bridge agent, or for resource monitors:
 - For protocol bridge agents, logging is controlled using the **agentLog** property.
 - To enable or disable resource monitor logging, use the **resourceMonitorLog** property.

If you use the **fteSetAgentLogLevel** command to enable transfer logging, the agent records information about transfer progress into a log file called `transferlog0.json`.

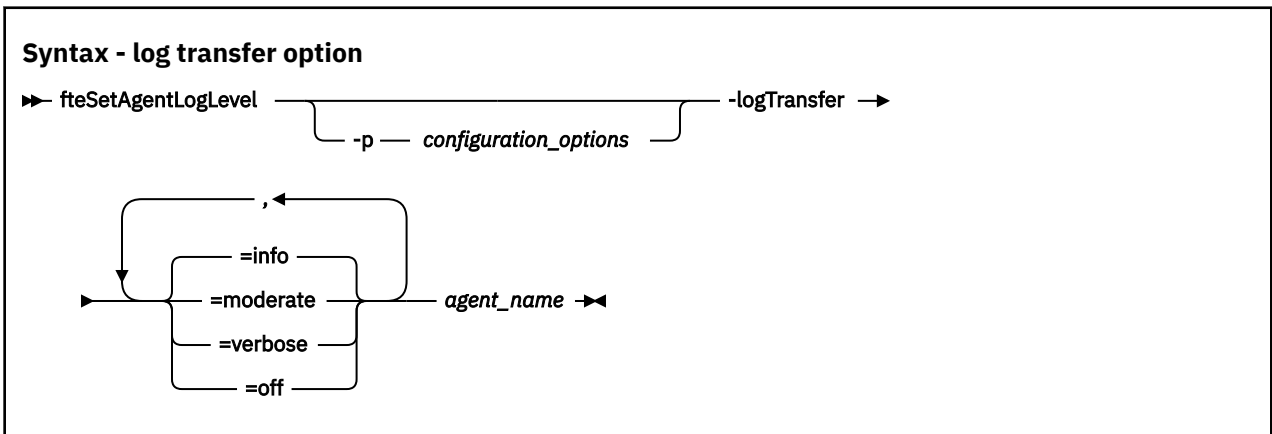

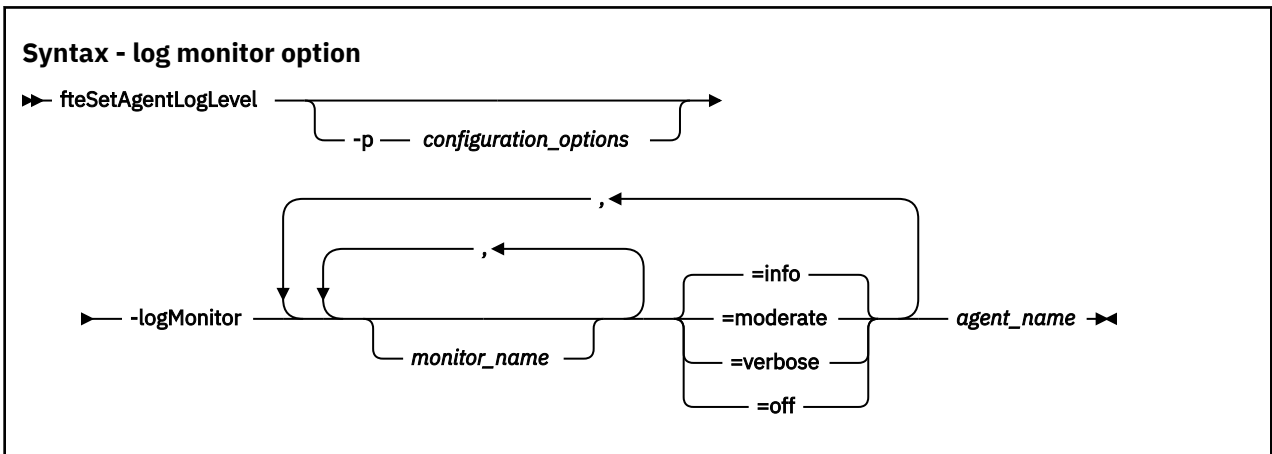

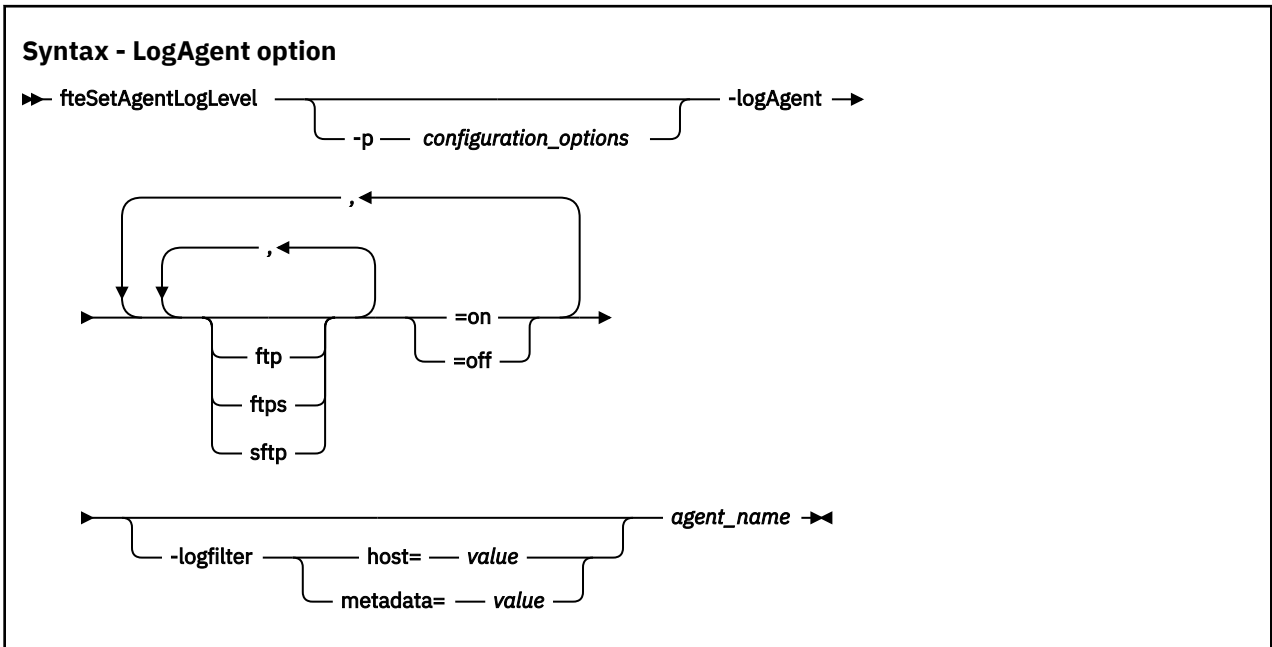

- **Multi** On Multiplatforms, the `transferlog0.json` file is in the `MQ_DATA_PATH/mqft/logs/coordination_qmgr_name/agents/agent_name/logs` directory.

- **z/OS** On z/OS, the transferlog0.json file is in the BFG_DATA/mqft/logs/coordination_qmgr_name/agents/agent_name/logs directory.

For more information, see [The agent.properties file](#).

Attention: When the command is run on the system where a standby instance of a highly available (HA) agent is running, the new log level is applied only to that instance. The log level on the active instance of the agent, and any other standby instances, will not be changed.

Note:

You must select only one of the **logAgent**, **logMonitor** or **logTransfer** options. If you specify more than one option, the command fails with the following error message:

```
BFGCL0756E:Invalid command options. Specify only one of logAgent, logMonitor, or logTransfer options.
```

Parameters

-logMonitor *monitor_name=log_level*

Required.

A comma separated list of resource monitors and logging levels, where:

monitor_name

Optional. The name of the resource monitor, or a comma-separated list of resource monitors, that the logging level is to be applied to. If you do not specify a monitor name, or a comma-separated list of resource monitors, the logging level is applied to all resource monitors running within the agent.

Attention: If you have specified non-existent resource monitor names in the command, no error is displayed on the console.

log_level

Required.

The logging level to use. This can be one of the following values:

info

Turn on information level logging. This is the default value and enables high level logging for the resource monitors of the agent..

To enable **info** level logging for monitor MON1 of agent AGENT1:

```
fteSetAgentLogLevel -logMonitor MON1=info AGENT1
```

moderate

Turn on moderate level logging.

To enable **moderate** level logging for monitors MON1 and MON2 of agent AGENT1:

```
fteSetAgentLogLevel -logMonitor MON1,MON2=moderate AGENT1
```

verbose

Turn on verbose level logging.

Enable **verbose** level logging for all monitors of agent AGENT1:

```
fteSetAgentLogLevel -logMonitor =verbose AGENT1
```

off

Turn off logging.

To turn off logging for monitors MON1 and MON2 of agent AGENT1:

```
fteSetAgentLogLevel -logMonitor MON1,MON2=off AGENT1
```

To turn off logging for monitor MON1 and enable **info** level logging for monitor MON2 of agent AGENT1:

```
fteSetAgentLogLevel -logMonitor MON1=off,MON2=info AGENT1
```

To turn off logging for all monitors of agent AGENT1:

```
fteSetAgentLogLevel -logMonitor=off AGENT1
```

If the same resource monitor name is repeated in a command, then the last occurrence of a component is considered as valid. For example:

```
fteSetAgentLogLevel -logMonitor MON1=info,MONZ=off,MON1=off AGENT1 turns off logging for resource monitor MON1.
```

For more information about the different logging levels, and the resource monitor events that are logged at each level, see [Logging MFT resource monitors](#).

You cannot use the **logMonitor** option with the **logAgent** and **logTransfer** options.

-logAgent component=operation

Required.

Protocol bridge agent logging can be enabled or disabled for the FTP, FTPS, and SFTP protocols. Specify one of the three possible server protocols and add an operation value to turn the logging off or on for the protocol bridge agent.

component

Optional.

The valid components are:

ftp

The logging operation is applied to all communication between a protocol bridge agent and file servers that use the FTP protocol.

ftps

The logging operation is applied to the communication between a protocol bridge agent and file servers that use the FTPS protocol.

sftp

The logging operation is applied to the communication between a protocol bridge agent and file servers that use the SFTP protocol.

If a component starts with a plus sign (+), the list of components following the plus sign are added to any existing log component currently being logged.

operation

The valid log level operation options are as follows:

off

Disable all logging for a protocol bridge agent. This option is the default.

```
fteSetAgentLogLevel -logAgent =off PBA1
```

To disable logging for a specified component that the protocol bridge agent is connecting to, use these commands:

```
fteSetAgentLogLevel -logAgent ftp=off PBA1
```

```
fteSetAgentLogLevel -logAgent ftps=off PBA1
```

```
fteSetAgentLogLevel -logAgent sftp=off PBA1
```

on

To enable logging for all three possible file server components that the protocol bridge agent is connecting to, use this command:

```
fteSetAgentLogLevel -logAgent =on PBA1
```

To enable logging for a specified component that a protocol bridge agent is connecting to, use these commands:

```
fteSetAgentLogLevel -logAgent ftp=on PBA1
```

```
fteSetAgentLogLevel -logAgent ftps=on PBA1
```

```
fteSetAgentLogLevel -logAgent sftp=on PBA1
```

If any component starts with a plus sign (+), the list of components following the plus sign is added to any existing log component currently being logged.

For further configuration options, see [“Example 1” on page 2146](#) and [“Example 2” on page 2146](#).

You cannot use the **logAgent** option with the **logTransfer** and **logMonitor** options.

-logFilter filter=value

Optional.

Use the **logFilter** parameter to limit protocol bridge agent logging based on the specified filter criteria. You must specify a value for either one or more file server hosts, or a property within the user metadata for a managed transfer.

host

Use **host** to filter by:

- The host name of the system where the file server is located.
- A list of comma separated host names or IP addresses.

To log the FTP commands sent to, and the responses received from, the file server `ftpprod.ibm.com`, use this command:

```
fteSetAgentLogLevel -logAgent ftp=on -logFilter host=ftpprod.ibm.com PBA1
```

To log the SFTP commands sent to, and the responses received from, all file servers that have IP addresses starting with `9.182.*`, use this command:

```
fteSetAgentLogLevel -logAgent sftp=on -logFilter host=9.182.* PBA1
```

metadata

Specify any text, as defined by the user during the transfer creation, in a *key=value* format. For example **metadata="BANK=WORLD BANK"**.

To enable logging for all file servers that connect to the protocol bridge agent PBA1 using the FTP protocol, and filter the output to only include entries for managed transfers that contain the metadata `"BANK=WORLD BANK"`, use this command:

```
fteSetAgentLogLevel -logAgent ftp=on metadata="BANK=WORLD BANK" PBA1
```

Note: In order to filter by metadata, the value you are filtering by, must be specified under the **-md** parameter as a part of a file transfer. For more information, see [“fteCreateTransfer \(start a new file transfer\)” on page 2079](#).

-logTransfer log_level

Required.

Attention: If the **fteSetAgentLogLevel** command is run by a user other than the one that started the agent, error message BFGNV0066E is output on the console:

Turn on or turn off transfer logs. Possible log levels are:

info

Turn on high level logging information of a transfer.

To enable `info` level transfer logging of agent AGENTQM:

```
fteSetAgentLogLevel -p AGENTQM -logTransfer info SRC
```

This is the default value which means high level transfer logs are written for every transfer, and will use file system space, up to a maximum of 100MB.

moderate

Turn on intermediate level log information of a transfer

verbose

Turn on detailed log information of a transfer.

Enable detailed level logging of agent AGENTQM:

```
fteSetAgentLogLevel -p AGENTQM -logTransfer verbose SRC
```

off

Turn off transfer logging.

To turn off transfer logging of agent AGENTQM:

```
fteSetAgentLogLevel -p AGENTQM -logTransfer off SRC
```

You cannot use the **logTransfer** option with the **logAgent** and **logMonitor** options.

See [Output produced by the LogTransfer function](#) for examples of the logging information produced.

-p configuration_options

Optional.

Determines the set of configuration options that is used to set the agent log level. Use the name of a set of configuration options as the value for the **-p** parameter.

By convention, this is the name of a coordination queue manager. If you do not specify this parameter, the default set of configuration options is used.

-? or -h

Optional. Displays the command syntax.

agent_name

Required. Name of the protocol bridge agent for which the logging is enabled or disabled.

Attention: If you have specified non-existent resource monitor names in the command, no error is displayed on the console.

Example 1

In this example, multiple components are specified in one command, by using a command delimited group. Logging is enabled for the FTP and SFTP protocol, and disabled for the FTPS protocol, on the protocol bridge agent PBA1.

```
fteSetAgentLogLevel -logAgent ftp=on,ftps=off,sftp=on PBA1
```

You can also separate the components with a comma to achieve the same result, for example;

```
fteSetAgentLogLevel -logAgent ftp,sftp=on,ftps=off PBA1
```

Example 2

In this example, the same component is repeated in a command. The last instance of a *component=operation* pair is considered as valid. This example disables logging for the FTP protocol on the protocol bridge agent PBA1.

```
fteSetAgentLogLevel -logAgent ftp=on,ftp=off PBA1
```

The previous example has the same effect as this example:

```
fteSetAgentLogLevel -logAgent ftp=off PBA1
```

Example 3

This example enables the default value of `info` level logging for monitor `MON1` of agent `AGENT1`:

```
fteSetAgentLogLevel -logMonitor MON1=info AGENT1
```

Example 4

This example enables `, moderate` level logging for monitors `MON1` and `MON2` of agent `AGENT1`:

```
fteSetAgentLogLevel -logMonitor MON1,MON2=moderate AGENT1
```

Example 5

This example turns off logging for monitor `MON1` and enable `info` level logging for monitor `MON2` of agent `AGENT1`:

```
fteSetAgentLogLevel -logMonitor MON1=off,MON2=info AGENT1
```

Return codes

0

Command completed successfully.

1

Command ended unsuccessfully.

Related reference

[The protocol bridge](#)

[The MFT agent.properties file](#)

“[fteCreateTransfer \(start a new file transfer\)](#)” on page 2079

The **fteCreateTransfer** command creates and starts a new file transfer from the command line. This command can start a file transfer immediately, schedule a file transfer for a future time and date, repeat a scheduled transfer one or more times, and trigger a file transfer based on certain conditions.

fteSetAgentTraceLevel (modify current trace level for an agent)

Use the **fteSetAgentTraceLevel** command to modify the current trace level for an agent dynamically.

Purpose

Use this command to switch agent trace on and off or to change the level of agent trace that is set. When you use the **fteSetAgentTraceLevel** command, you do not have to shut down and restart an agent to modify the trace level. The trace files produced are located in `MQ_DATA_PATH/mqft/logs/coordination_qmgr_name/agents/agent_name/logs/trace%PID%/trace%PID%.txt`, where `%PID%` is the process ID for the agent instance.

Attention:

Multi When using IBM MQ on [Multiplatforms](#), only the user that the agent process is running under can run the **fteSetAgentTraceLevel** command.

z/OS The **fteSetAgentTraceLevel** command can be run by either:

- The same userid that the agent process is running as.
- Members of the group specified by the agent property **adminGroup**.

For more information, see the **adminGroup** property in [The MFT agent .properties file](#).

The **fteSetAgentTraceLevel** command also writes a trace for the agent process controller. The trace files produced are located in `MQ_DATA_PATH/mqft/logs/coordination_qmgr_name/agents/agent_name/logs/pctrace%PID%/pctrace%PID%.txt`, where `%PID%` is the process ID for the agent instance.

You can also use the command to cause the agent process to generate a Javacore. The agent generates a Javacore file in the following directory: `MQ_DATA_PATH/mqft/logs/coordination_qmgr_name/agents/agent_name`.

Because running trace can affect your performance significantly and can produce a large amount of trace data, run trace with care and only when necessary. Typically, enable trace only when asked to do so by your IBM service representative.

Attention:

1. You must run this command on the system where the agent is running.
2. The traces and logging do not persist across an agent restart.

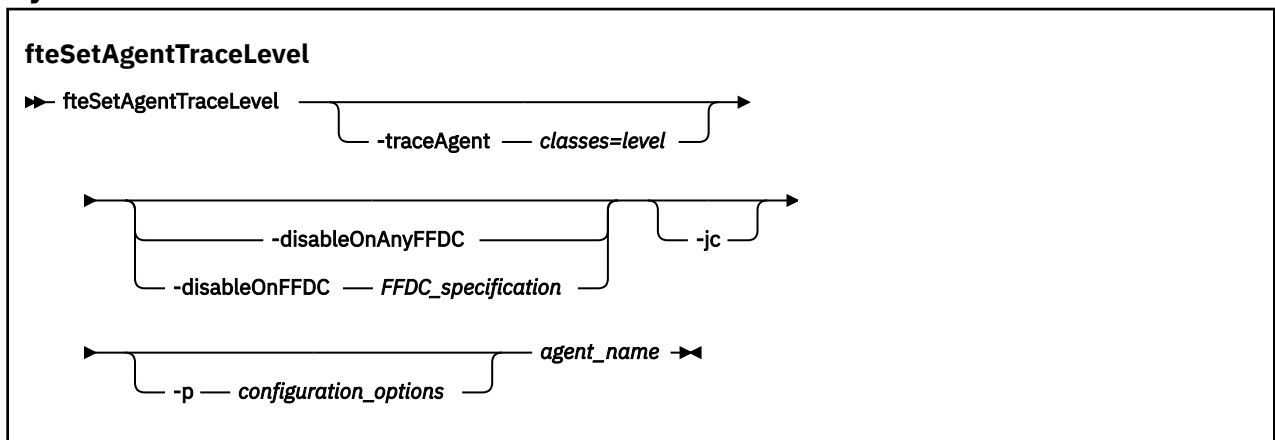

If the agent terminates and is restarted by the Process Controller process, the dynamic traces and logs are not in effect until the `agent .properties` file has been updated to include the required trace and log properties.

3. When the command is run on the system where a standby instance of a highly available (HA) agent is running, the trace level is only applied to that instance. The trace level on the active instance of the agent, and any other standby instances, will not be changed.

You can set further trace properties, for example trace file size and the number of trace files to keep, in the `agent .properties` file. These properties are described in [Advanced agent properties](#).

Specify the optional `-p` parameter for this command only if you want to use a set of configuration options different from your default set. See [The MFT agent .properties file](#) for more information.

Syntax

Parameters

-traceAgent classes=level

Required. Level to set the agent trace and which classes to apply the trace to.

You can specify a colon-separated list of class specifications. This option enables you to set tracing of different classes, and at different levels. For example:

```
fteSetAgentTraceLevel -traceAgent com.ibm.wmqfte.agent=all:com.ibm.wmqfte.cmdhandler=moderate  
AGENT1
```

You can still specify a comma-separated list of class specifications that you want the level of trace to apply to. If you do not specify this parameter, the trace level is applied to all agent classes. Use the following format:

```
classes=level
```

For example:

```
com.ibm.wmqfte=all
```

You can substitute *classes* with a Managed File Transfer package name to trace a specific package only. However, because this option captures just a subset of the agent's behavior, you are generally not recommended to use package filtering.

If *classes* start with a plus sign (+), the list of trace classes following the plus sign are added to any existing trace classes currently being traced.

The valid trace level options are as follows and are listed in ascending order of trace file size and detail:

off

Switches the agent trace off but continues to write information to the log files. This is the default option.

flow

Captures data for trace points associated with processing flow in the agent.

moderate

Captures a moderate amount of diagnostic information in the trace.

verbose

Captures a verbose amount of diagnostic information in the trace.

all

Sets agent trace to run on all agent classes.

To start full tracing for the agent, run the following command:

```
fteSetAgentTraceLevel -traceAgent =all agent_name
```

To stop full tracing for the agent, run the following command:

```
fteSetAgentTraceLevel -traceAgent =off agent_name
```

-disableOnAnyFFDC

Optional. If this parameter is specified, trace is disabled on the agent when it generates a First Failure Data Capture (FFDC) file.

You can specify only one of the **-disableOnAnyFFDC** and **-disableOnFFDC** parameters.

-disableOnFFDC *ffdc_specification*

Optional. If this parameter is specified, trace is disabled on the agent when it generates a First Failure Data Capture (FFDC) file that matches the *ffdc_specification*. *ffdc_specification* is a comma-separated list of values. The format of the values can be either:

class_name

The name of the class where the FFDC originated. For example, `com.ibm.wmqfte.classA`.

class_name:probe_id

The name of the class and the probe ID of the location in the class that the FFDC originated from. For example, `com.ibm.wmqfte.classB:1`.

You can specify only one of the **-disableOnAnyFFDC** and **-disableOnFFDC** parameters.

-jc

Optional. Requests that the agent generates a Javacore file. The IBM service team may request that you run the command with this parameter to assist with problem diagnosis. This parameter cannot be used with any other parameter except **-p**.

-p configuration_options

Optional. This parameter determines the set of configuration options that is used to set the agent trace level. Use the name of a non-default coordination queue manager as the input for this parameter. The command then uses the set of properties files associated with this non-default coordination queue manager.

If you do not specify this parameter, the set of configuration options based on the default coordination queue manager is used.

agent_name

Required. The name of the Managed File Transfer Agent that you want to set the trace level for.

-? or -h

Optional. Displays command syntax.

Example

In this example, the trace level is set to `all` for all classes for `AGENT1`:

```
fteSetAgentTraceLevel -traceAgent com.ibm.wmqfte=all AGENT1
```

In this example, the trace level is set to `all` for the classes `com.ibm.wmqfte.agent.Agent` and `com.ibm.wmqfte.cmdhandler` for `AGENT1`:

```
fteSetAgentTraceLevel -traceAgent com.ibm.wmqfte.agent.Agent,com.ibm.wmqfte.cmdhandler=moderate
AGENT1
```

In this example, subclasses are excluded from the trace because the **-traceLevel** parameter is set to `off`. All classes starting with `com.ibm.outer` are traced at verbose level except classes starting with `com.ibm.outer.inner`:

```
fteSetAgentTraceLevel -traceAgent com.ibm.outer=verbose AGENT1
fteSetAgentTraceLevel -traceAgent +com.ibm.outer.inner=off AGENT1
```

Return codes**0**

Command completed successfully.

1

Command ended unsuccessfully.

fteSetLoggerTraceLevel (modify current trace level for a logger)

Use the **fteSetLoggerTraceLevel** command to modify the current trace level for a Managed File Transfer logger dynamically.

Purpose

Use this command to switch logger trace on and off or change the level of logger trace that is set. When you use the **fteSetLoggerTraceLevel** command, you do not have to shut down and restart a logger to modify the trace level. The trace files that are produced are located in `MQ_DATA_PATH/mqft/logs/coordination_qmgr_name/loggers/logger_name/logs/trace%PID%/trace%PID%.txt`, where `%PID%` is the process ID for the logger instance.

The **fteSetLoggerTraceLevel** command also writes a trace for the logger process controller. The trace files that are produced are located in `MQ_DATA_PATH/mqft/logs/coordination_qmgr_name/`

loggers/*logger_name*/logs/pctrace%*PID*%/pctrace%*PID*%.txt, where %*PID*% is the process ID for the logger instance.

The command can also be used to cause the logger process to generate a Javacore. The logger generates a Javacore file in the following directory: *MQ_DATA_PATH*/mqft/logs/*coordination_qmgr_name*/loggers/*logger_name*.

Because running trace can affect your performance significantly and can produce a large amount of trace data, run trace with care and only when necessary. Typically, enable trace only when asked to do so by your IBM service representative.

You can set further trace properties, for example trace file size and the number of trace files to keep, in the `logger.properties` file. These properties are described in [Logger properties](#).

Specify the optional `-p` parameter for this command only if you want to use a set of configuration options different from your default set. For more information, see [Logger properties](#).

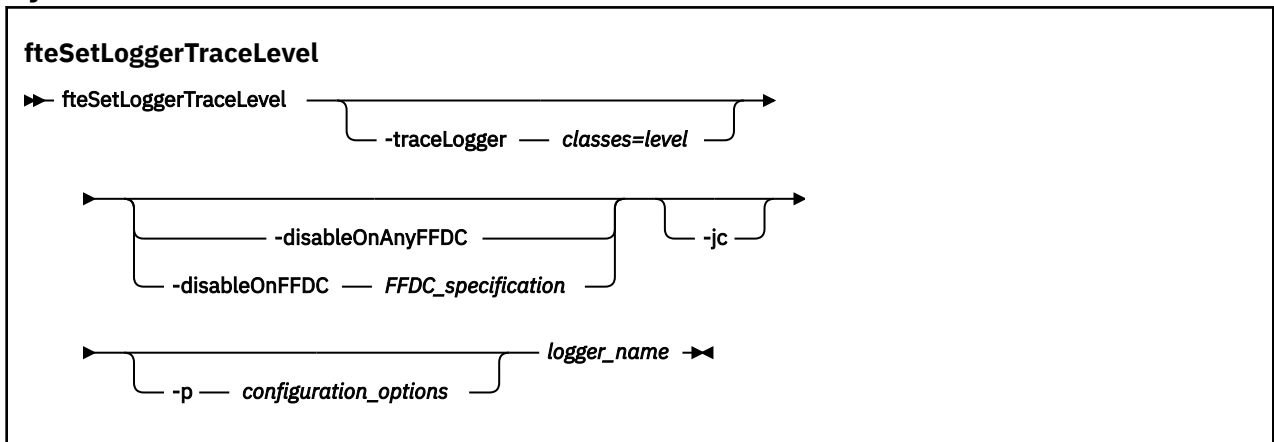

Attention:

1. You must run this command on the system where the logger is running.
2. The traces and logging do not persist across a logger restart.

If the logger terminates and is restarted by the Process Controller process, the dynamic traces and logs are not in effect until the `logger.properties` file has been updated to include the required trace and log properties.

Syntax

Parameters

-traceLogger classes=level

Required. Level to set the logger trace and which classes to apply the trace to.

You can specify a colon-separated list of class specifications. This option enables you to set tracing of different classes, and at different levels. For example:

```
fteSetLoggerTraceLevel -traceLogger com.ibm.wmqfte.logger=all:com.ibm.wmqfte.cmdhandler=moderate  
LOGGER1
```

You can still specify a comma-separated list of class specifications that you want the level of trace to apply to. If you do not specify this parameter, the trace level is applied to all agent classes. Use the following format:

```
classes=level
```

For example:

```
com.ibm.wmqfte=all
```

Specify a comma-separated list of class specifications that you want the level of trace to apply to. If you do not specify this parameter, the trace level is applied to all logger classes.

If (*classes*) start with a plus sign (+), the list of trace classes that follow the plus sign are added to any existing trace classes currently being traced.

The valid trace level options are as follows and are listed in ascending order of trace file size and detail:

off

Switches off the logger trace but continues to write information to the log files. This is the default option.

flow

Captures data for trace points associated with processing flow in the logger.

moderate

Captures a moderate amount of diagnostic information in the trace.

verbose

Captures a verbose amount of diagnostic information in the trace.

all

Sets logger trace to run on all logger classes.

-disableOnAnyFFDC

Optional. If this parameter is specified, trace is disabled on the logger when it generates a First Failure Data Capture (FFDC) file.

You can specify only one of the **-disableOnAnyFFDC** and **-disableOnFFDC** parameters.

-disableOnFFDC *ffdc_specification*

Optional. If this parameter is specified, trace is disabled on the logger when it generates a First Failure Data Capture (FFDC) file that matches the *ffdc_specification*. *ffdc_specification* is a comma-separated list of values. The value can be one of the following formats:

class_name

The name of the class where the FFDC originated. For example, `com.ibm.wmqfte.classA`.

class_name:probe_id

The name of the class and the probe ID of the location in the class that the FFDC originated from. For example, `com.ibm.wmqfte.classB:1`.

You can specify only one of the **-disableOnAnyFFDC** and **-disableOnFFDC** parameters.

-jc

Optional. Requests that the logger generates a Javacore file. The IBM service team might request that you run the command with this parameter to assist with problem diagnosis. You cannot use the **-jc** parameter with any other parameter.

-p *configuration_options*

Optional. This parameter determines the set of configuration options that is used to set the logger trace level. Use the name of a non-default coordination queue manager as the input for this parameter. The command then uses the set of properties files associated with this non-default coordination queue manager.

If you do not specify this parameter, the set of configuration options based on the default coordination queue manager is used.

logger_name

Required. The name of the Managed File Transfer Logger that you want to set the trace level for.

-? or -h

Optional. Displays command syntax.

Example

In this example, the trace level is set to all for all classes for LOGGER1:

```
fteSetLoggerTraceLevel -traceLogger com.ibm.wmqfte=all LOGGER1
```

In this example, the trace level is set to all for the classes `com.ibm.wmqfte.logger.logger` and `com.ibm.wmqfte.cmdhandler` for LOGGER1:

```
fteSetLoggerTraceLevel -traceLogger com.ibm.wmqfte.logger.logger,com.ibm.wmqfte.cmdhandler=moderate LOGGER1
```

In this example, subclasses are excluded from the trace because the **-traceLevel** parameter is set to off. All classes that start with `com.ibm.outer` are traced at verbose level except classes that start with `com.ibm.outer.inner`:

```
fteSetLoggerTraceLevel -traceLogger com.ibm.outer=verbose LOGGER1  
fteSetLoggerTraceLevel -traceLogger +com.ibm.outer.inner=off LOGGER1
```

Return codes

0

Command completed successfully.

1

Command ended unsuccessfully.

fteSetProductId (set z/OS SCRT recording product id)

The **fteSetProductId** is used to set the product type against which Managed File Transfer usage is to be recorded for the installation. This command is valid only on z/OS.

Purpose

This command can be run at any time, after at least one coordination queue manager has been defined, or the `MFT.installation.properties` file for the installation has been created.

See [Reporting product information](#) for more information on product usage recording.

Syntax

Parameters

The product type for usage recording:

Specify one of:

MFT

Usage is recorded as a stand-alone Managed File Transfer product, with product ID 5655-MF9.

ADVANCED

Usage is recorded as part of an IBM MQ Advanced for z/OS product, with product ID 5655-AV9.

ADVANCEDVUE

Usage is recorded as part of an IBM MQ Advanced for z/OS Value Unit Edition product, with product ID 5655-AV1.

Return codes

0

Command completed successfully.

1

Command ended unsuccessfully, or if the product type has not been set to the requested value.

Related tasks

[Configuring the coordination queue manager for MFT](#)

fteSetupCommands (create the MFT command.properties file)

The **fteSetupCommands** command creates the Managed File Transfer `command.properties` file. This properties file specifies the details of the queue manager that connects to the IBM MQ network when you issue commands.

Important:  On IBM MQ for AIX, Linux, and Windows, only users who are IBM MQ administrators (and members of the mqm group) can run this command. If you try to run this command as a user who is not an IBM MQ administrator, you will receive the error message BFGCL0502E: You are not authorized to perform the requested operation. and the command will not run.

 On z/OS systems, the user must satisfy (at least) one of these conditions in order to run the command:

- Be a member of the mqm group (if the mqm group is defined on the system).
- Be a member of the group named in the BFG_GROUP_NAME environment variable (if one is named).
- Have no value set in the BFG_GROUP_NAME environment variable when the command is run.

Purpose

Use the **fteSetupCommands** command to create a `command.properties` file in the coordination queue manager configuration directory. The command uses the `MQ_DATA_PATH` environment variable and the `installation.properties` file to determine where to locate the `command.properties` file. Ensure that you have already created and configured a coordination queue manager before you issue the **fteSetupCommands** command.

For more information about properties files, see [The MFT command.properties file](#).

Syntax

Parameters

-connectionQMgr *connection_qmgr_name*

Required. The name of the queue manager used to connect to the IBM MQ network to issue commands.

-connectionQMgrHost *connection_qmgr_host*

Optional. The host name or IP address of the connection queue manager.

If you do not specify the **-connectionQMgrHost** parameter, a bindings mode connection is assumed. Therefore, this parameter is required if you are using a client mode connection.

If you specify a value for the **-connectionQMgrHost** parameter but do not specify values for the **-connectionQMgrPort** and **-connectionQMgrChannel** properties, a port number of 1414 and a channel of SYSTEM.DEF.SVRCONN are used by default.

-connectionQMgrPort *connection_qmgr_port*

Optional. The port number used to connect to the connection queue manager in client mode. If you specify the **-connectionQMgrPort** parameter, you must also specify the **-connectionQMgrHost** parameter.

-connectionQMgrChannel *connection_qmgr_channel*

Optional. The channel name used to connect to the connection queue manager. If you specify the **-connectionQMgrChannel** parameter, you must also specify the **-connectionQMgrHost** parameter.

-p *configuration_options*

Optional. This parameter determines the set of configuration options that is used to set up a command queue manager. Use the name of a non-default coordination queue manager as the input for this parameter. The **fteSetupCommands** command then uses the set of properties files associated with this non-default coordination queue manager.

If you do not specify this parameter, the set of configuration options based on the default coordination queue manager is used.

-credentialsFile *file_path*

Optional. The full file path of an existing or new credentials file, to which the IBM MQ authentication details are added.

This command supports the addition of a set of IBM MQ authentication details, to a named Managed File Transfer credentials file. Use this command when IBM MQ connection authentication has been enabled. If you update the existing details, you must use the **-f** force parameter.

-userid *user_id*

Optional. The user ID used to associate the credential details. If you do not specify a user ID, the credential details will apply to all users. You must also specify the **-credentialsFile** parameter.

-f

Optional. Forces an overwrite of the existing `command.properties` file with the details specified in this command.

-? or -h

Optional. Displays command syntax.

Example

```
fteSetupCommands -connectionQMGr QM_NEPTUNE -connectionQMGrHost 9.146.157.241  
-connectionQMGrPort 1414 -connectionQMGrChannel SYSTEM.DEF.SVRCONN
```

Return codes

0

Command completed successfully.

1

Command ended unsuccessfully.

Related reference

[The MFT `command.properties` file](#)

[“`fteSetupCoordination` \(set up properties files and directories for coordination queue manager\)” on page 2156](#)

The **`fteSetupCoordination`** command creates properties files and the coordination queue manager directory for Managed File Transfer.

`fteSetupCoordination` (set up properties files and directories for coordination queue manager)

The **`fteSetupCoordination`** command creates properties files and the coordination queue manager directory for Managed File Transfer.

Important:  On IBM MQ for AIX, Linux, and Windows, only users who are IBM MQ administrators (and members of the `mqm` group) can run this command. If you try to run this command as a user who is not an IBM MQ administrator, you will receive the error message `BFGCL0502E: You are not authorized to perform the requested operation.` and the command will not run.

 On z/OS systems, the user must satisfy (at least) one of these conditions in order to run the command:

- Be a member of the `mqm` group (if the `mqm` group is defined on the system).
- Be a member of the group named in the `BFG_GROUP_NAME` environment variable (if one is named).
- Have no value set in the `BFG_GROUP_NAME` environment variable when the command is run.

Purpose

Use the **`fteSetupCoordination`** command to create the following Managed File Transfer objects:

- Coordination queue manager directory
- Data directory `mqft` (if this does not exist)

Parameters

-coordinationQMgr *coordination_qmgr_name*

Required. The name of the coordination queue manager. This queue manager must be an IBM WebSphere MQ 7.0 or later queue manager.

-coordinationQMgrHost *coordination_qmgr_host*

Optional. The host name or IP address of the coordination queue manager.

If you do not specify the **-coordinationQMgrHost** parameter, a bindings mode connection is assumed.

If you specify a value for the **-coordinationQMgrHost** parameter but do not specify values for the **-coordinationQMgrPort** and **-coordinationQMgrChannel** parameters, a port number of 1414 and a channel of SYSTEM.DEF.SVRCONN are used by default.

-coordinationQMgrPort *coordination_qmgr_port*

Optional. The port number used for client connections to the coordination queue manager.

If you specify the **-coordinationQMgrPort** parameter, you must also specify the **-coordinationQMgrHost** parameter.

-coordinationQMgrChannel *coordination_qmgr_channel*

Optional. The channel name used to connect to the coordination queue manager. If you specify the **-coordinationQMgrChannel** parameter, you must also specify the **-coordinationQMgrHost** parameter.

-credentialsFile *file_path*

Optional. The full file path of an existing or new credentials file, to which the IBM MQ authentication details are added.

This command supports the addition of a set of IBM MQ authentication details, to a named Managed File Transfer credentials file. Use this command when IBM MQ connection authentication has been enabled. If you update the existing details, you must use the **-f** force parameter.

-userid *user_id*

Optional. The user ID used to associate the credential details. If you do not specify a user ID, the credential details will apply to all users. You must also specify the **-credentialsFile** parameter.

-f

Optional. Forces an overwrite of the existing coordination queue manager configuration with the details specified in this command.

-default

Optional. Updates the default configuration options to the options associated with the coordination queue manager specified in this command.

-? or -h

Optional. Displays command syntax.

Example

In this example, the required objects are set up for a coordination queue manager called QM_SATURN, which is connected to in client mode:

```
fteSetupCoordination -coordinationQMgr QM_SATURN
-coordinationQMgrHost myhost.ibm.com -coordinationQMgrPort 1415
-coordinationQMgrChannel SYSTEM.DEF.SVRCONN
```

Return codes

0

Command completed successfully.

1

Command ended unsuccessfully.

[The MFT agent.properties file](#)

fteShowAgentDetails (display MFT agent details)

Use the **fteShowAgentDetails** command to display the details of a particular Managed File Transfer Agent. These are the details that are stored by the agent's Managed File Transfer coordination queue manager.

Purpose

You can run the **fteShowAgentDetails** command from any system that can connect to the coordination queue manager. This command uses the `coordination.properties` file to connect to the coordination queue manager.

Specify the optional **-p** parameter for this command only if you want to use a set of configuration options different from your default set. For more information, see [Configuration options](#).

The agent status information that is produced by this command is generated from the status messages that the agent publishes to the `SYSTEM.FTE` topic. These messages are described in “MFT agent status message format” on page 2648. The status information that is produced by the **fteShowAgentDetails** command gives the agent status at the time when the last status message was published. The frequency of these status messages depends on the value of the **agentStatusPublishRateLimit** property. For more information, see [The MFT agent.properties file](#).

Specify the optional **-d** parameter for this command if you want to see diagnostic information about a local agent. This information includes current transfers, scheduled transfers, monitors, and agent queue depths. You can use this information to determine the health and status of a local agent.

 For z/OS, from IBM MQ 9.0.2 and IBM MQ 9.0.0 Fix Pack 1, the **-d** parameter can only be specified if the **fteShowAgentDetails** command is run by:

- The same userid that the agent process is running as.
- Members of the group that is specified by the agent property **adminGroup**.

For more information, see the **adminGroup** property in [The MFT agent.properties file](#).

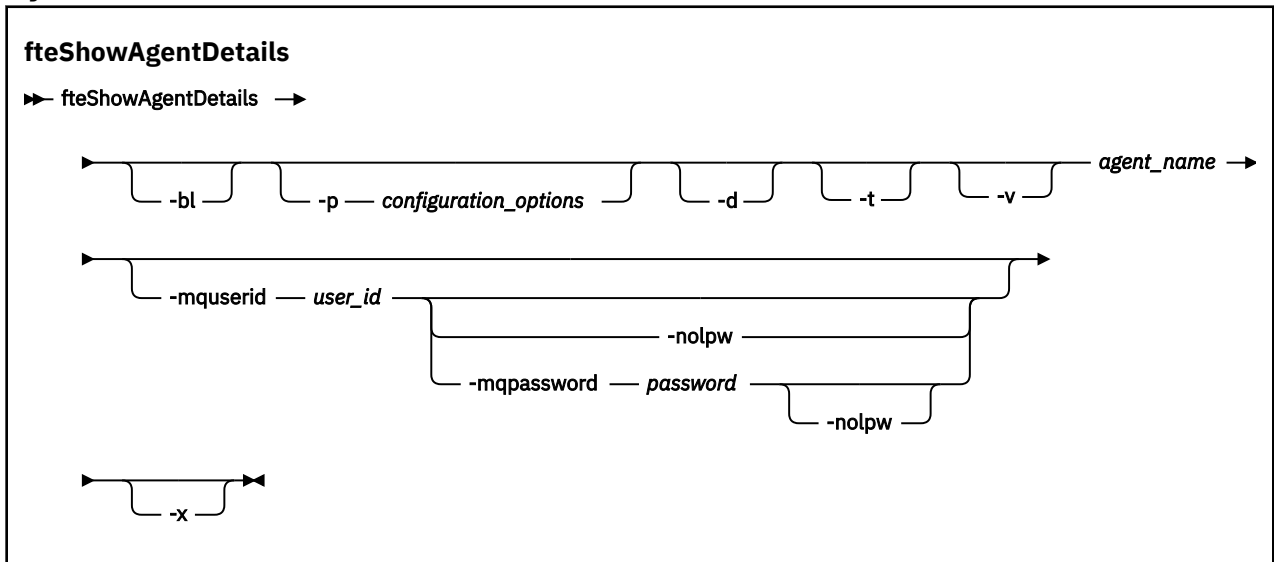

The status of the agent process controller and queue manager is available if you run the command on the same system as the agent. You can use this information to help with problem determination. Also, when you run the command on the same system as the agent, more detailed agent status information is available for the case where the agent ended unexpectedly.

For a list of the possible agent status values and their meanings, see “MFT agent status values” on page 2518.

For a list of the possible status values for the agent process controller and their meanings, see “MFT agent process controller status values” on page 2521.

For a list of agent trace values and FFDC specifications and their meanings, see “[fteSetAgentTraceLevel \(modify current trace level for an agent\)](#)” on page 2147

Syntax

Parameter

-bl

Optional. Additionally outputs the product build level for the agent.

-p *configuration_options*

Optional. This parameter determines the set of configuration options that is used to issue the request to display the details of an agent. Use the name of a non-default coordination queue manager as the input for this parameter. The command then uses the set of properties files associated with this non-default coordination queue manager.

If you do not specify this parameter, the set of configuration options based on the default coordination queue manager is used.

-d

Optional. Specifies that diagnostic information is collected for *agent_name*.

The diagnostic information is output to the console, and written to a file called `diagnostics.<yyyyMMdd>.<HHmmss>.<ssss>.<number>.properties` in the directory `MQ_DATA_PATH\mqft\logs\coordination_qmgr_name\agents\agent_name\logs`. A maximum of five historical files containing diagnostic information about an agent will be created. If five historical files have been created for an agent when the **fteShowAgentDetails** command is run with the **-d** parameter specified, the oldest historical file will be deleted and replaced with a new file containing the latest diagnostic information about the agent.

You can use this parameter only when the agent is running, and on the local system.

-t

Optional. Specifies terse mode. The output includes the **Status Age** information by default. If you do not want to see this information, you can issue the command with the **-t** parameter. For more information, see [What to do if an agent is shown as being in an UNKNOWN state](#).

-v

Optional. Specifies verbose mode, which generates additional output for the agent. These include host name, product version, product build level, trace level, and First Failure Data Capture (FFDC) specification, and a list of transfer states for each of the current source and destination transfers.

The current transfer information is obtained from the agent status publication, which is described in [“MFT agent status message format”](#) on page 2648. Therefore this transfer information is only accurate to within the value of the `agentStatusPublishRateLimit` property. For more details about this property, see [The MFT agent.properties file](#).

agent_name

Required. The name of the Managed File Transfer Agent that you want to display.

-mquserid user_id

Optional. Specifies the user ID to authenticate with the coordination queue manager.

-mqpassword password

Optional. Specifies the password to authenticate with the coordination queue manager.

When the **-mqpassword** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

From IBM MQ 9.3, the command defaults to using [MQCSP](#) authentication, and sends the user ID and password to be authenticated to the queue manager in an MQCSP structure.

-nolpw

Optional. Specify this parameter if the command connects to a queue manager that does not support passwords longer than 12 characters.

When the **-nolpw** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid** and **-nolpw**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

Note: If you specify the **-nolpw** option, and the password is longer than 12 characters the command fails with error message BFGCL0829E.

-? or -h

Optional. Displays command syntax.

-x

Optional. Provides information about all the active and, if they exist, standby instances.

Example

In the following example, running `bindings agent`, issuing the **fteShowAgentDetails** command locally to the agent:

```
fteShowAgentDetails -v AGENT1
```

```
5724-H72 Copyright IBM Corp. 2008, 2024. ALL RIGHTS RESERVED
```

Agent Information:

  Time Zone:                                Greenwich Mean Time

Agent Controller Information:
  Controller type:                           MQMFT Process Controller
  Status:                                    UNKNOWN
  Status Details:                            Information about the agent controller
                                              is not available, either because the

```

```

agent is not running or the agent is
running on a different system.
Agent Restarts within Interval: 0
Total Agent Restart Count: 0

Agent Availability Information:
Status: STOPPED
Status Details: The agent has been stopped. It was shut
down in a controlled manner.

Queue Manager Information:
Name: QM2
Transport: Bindings
Last Status Reported: UNKNOWN
Status Details: Information about the queue manager is
not available, either because the agent
is not running or the agent is running
on a different system.

```

In the following example, bindings agent is waiting to restart with the agent queue manager stopped. The agent has already been restarted once before Total Agent Restart Count: 1, possibly due to a previous agent queue manager restart:

Note: The Last Error MQRC against the Last Status Reported for the queue manager information; this information will remain even when the queue manager becomes available.

```

fteShowAgentDetails AGENT1
5724-H72 Copyright IBM Corp. 2008, 2024. ALL RIGHTS RESERVED
Agent Information:
Name: AGENT1
Type: Standard
Description:
Operating System: Windows Server 2003
Time Zone: Greenwich Mean Time

Agent Controller Information:
Controller type: MQMFT Process Controller
Status: WAITING
Status Details: The agent process controller is waiting
for the queue manager to become
available before starting the agent.

Agent Restarts within Interval: 0
Total Agent Restart Count: 1

Agent Availability Information:
Status: STOPPED
Status Details: The agent has been stopped. It was shut
down in a controlled manner.

Queue Manager Information:
Name: QM1
Transport: Bindings
Last Status Reported: UNAVAILABLE (Last Error MQRC: 2059)
Status Details: The queue manager is unavailable. It
might be that the queue manager has not
been started or an incorrect queue
manager name has been configured. Look
up the MQ reason code reported against
the status to understand the problem.

```

In the following example, the client mode agent has just ended unexpectedly and the agent process controller tries to recover the situation by restarting it after a delay, specified by the maxRestartDelay agent property value. The default maxRestartDelay agent property value is -1, and this causes the agent process controller to terminate; hence in this example the maxRestartDelay property value must have been set to a value greater than 0. The Current Agent Restart Count: 4 implies that there have been 4 restarts within the maxRestartInterval agent property time period. If the maxRestartCount agent property is 4 then after 4 restarts within the maxRestartInterval, the agent process controller will wait for maxRestartDelay seconds before restarting the agent, which is the case here. The Total Agent restart Count: 8 suggests that this has occurred before. This example is not typical and you would only expect to see the agent ending unexpectedly if the agent runs out of

memory, or a custom user exit has caused some sort of runtime error. Full details as to why the agent ended unexpectedly are in the agent's output0.log file:

```

  Operating System: Windows Server 2003
  Time Zone: Greenwich Mean Time

Agent Controller Information:
  Controller type: MQMFT Process Controller
  Status: UNKNOWN
  Status Details: Information about the agent controller
                  is not available, either because the
                  agent is not running or the agent is
                  running on a different system.

  Agent Restarts within Interval: 0
  Total Agent Restart Count: 0

Agent Availability Information:
  Status: STOPPED
  Status Details: The agent has been stopped. It was shut
                  down in a controlled manner.

Queue Manager Information:
  Name: QM_JUPITER
  Transport: Bindings
  Last Status Reported: UNKNOWN
  Status Details: Information about the queue manager is
                  not available, either because the agent
                  is not running or the agent is running
                  on a different system.
```

 In the following example, an agent running on z/OS is registered with the Automatic Restart Manager (ARM):

```
fteShowAgentDetails AGENTZ
5724-H72 Copyright IBM Corp. 2008, 2024. ALL RIGHTS RESERVED
Agent Information:
```

```

Name: AGENTZ
Type: Standard
Description:
Operating System: z/OS
Time Zone: Greenwich Mean Time

Agent Controller Information:
Controller Type: z/OS Automatic Restart Manager (ARM)
Agent registered with ARM: Yes (ELEMENTYPE: SYSBFGAG, ELEMENT: AGENTZ)
Agent Restarted: No

Agent Availability Information:
Status: READY
Status Details: The agent is running and is publishing
its status at regular intervals. The last
update was received within the expected
time period. The agent is ready to
process transfers, but none are currently
in progress.

Queue Manager Information:
Name: ZQM
Transport: Bindings
Last Status Reported: AVAILABLE
Status Details: The queue manager is available.

```

The output from the command displays information of all the available instances when you specify the **-x** parameter. Note that if you do not specify the **-x** parameter the output is unchanged from the current format

```

24-H72 Copyright IBM Corp. 2008, 2024. ALL RIGHTS RESERVED
Host Name:          Type:          Version:
9.122.123.124      Active         9.1.4.0
myhost.ibm.com     Standby       9.1.4.0
10.20.40.123       Standby       9.1.4.0

```

If the agent started in high availability mode has no standby instances running, the output contains information about the active instance only. For example:

```

24-H72 Copyright IBM Corp. 2008, 2024. ALL RIGHTS RESERVED
Host:              Type:          Version:
9.122.123.124     Active         9.1.4.0

```

If you specify the **-x** parameter and the agent has been started as normal, that is, not in high availability mode, you receive the following message:

```

BFGCL0790I: No standby instance information available for agent '<agent name>'.
The agent is either not running or is not publishing status.

```

Return codes

0

Command completed successfully.

1

Command ended unsuccessfully.

[“ftelistagents \(list the MFT agents for a coordination queue manager\)” on page 2116](#)

Use the **ftelistagents** command to list all of the Managed File Transfer agents that are registered with a particular coordination queue manager.

[“MFT agent status values” on page 2518](#)

The **ftelistagents** and **fteshowagentdetails** commands produce agent status information. There are several possible values for this status.

[“MFT agent process controller status values” on page 2521](#)

The **fteShowAgentDetails** command produces agent process controller status information. There are several possible values for this status.

fteShowLoggerDetails (display MFT logger details)

Use the **fteShowLoggerDetails** command to display the details of a particular Managed File Transfer logger.

Purpose

You must run the **fteShowLoggerDetails** command on the same system as the logger. It displays the status of the logger process controller and the logger queue manager, which you can use to help with problem determination. The **fteShowLoggerDetails** command lists the following details for a particular Managed File Transfer logger:

- Logger controller status.
- Logger restarts within interval
- Total logger restart count
- Logger availability status
- Logger queue manager name
- Logger queue manager transport type
- Logger queue manager last status reported (applies to binding transport mode only)

Specify the optional **-p** parameter for this command only if you want to use a set of configuration options different from your default set. See [Configuration options](#) for more information.

For a list of the possible logger status values and their meanings, see [“MFT logger status values”](#) on page 2521.

For a list of the possible status values for the logger process controller and their meanings, see [“MFT logger process controller status values”](#) on page 2522.

The output of the command displays connection information that the logger is using to connect to the queue manager. If the logger is connected in clients mode, the output for:

Last Status Reported

Is shown as UNKNOWN

Status details

Is shown as Information about the queue manager is not available because the logger has a client connection to queue manager.

Syntax

Parameter

-p *configuration_options*

Optional. This parameter determines the set of configuration options that is used to issue the request to display the details of an logger. Use the name of a non-default coordination queue manager as the input for this parameter. The command then uses the set of properties files associated with this non-default coordination queue manager.

If you do not specify this parameter, the set of configuration options based on the default coordination queue manager is used.

logger_name

Required. The name of the Managed File Transfer logger that you want to display.

-? or -h

Optional. Displays command syntax.

Example

In this example, a started logger, issuing the **fteShowLoggerDetails** command locally to the logger:

```
fteShowLoggerDetails LOGGER1
```

```
5724-H72 Copyright IBM Corp. 2008, 2024. ALL RIGHTS RESERVED
Logger Controller Information:
  Status: STARTED
  Status Details: The logger process controller has
                  started the logger process.
  Logger Restarts within Interval: 0
  Total Logger Restart Count: 0

Queue Manager Information:
  Name: QM_gbthink
  Transport: Bindings
  Last Status Reported: AVAILABLE
  Status Details: The queue manager is available.
```

In this example, a logger waiting due to an unavailable queue manager, issuing the **fteShowLoggerDetails** command locally to the logger:

```
fteShowLoggerDetails LOGGER2
```

```
5724-H72 Copyright IBM Corp. 2008, 2024. ALL RIGHTS RESERVED
Logger Controller Information:
  Status: WAITING
  Status Details: The logger process controller is
                  waiting for the queue manager to
                  become available before starting the
                  logger.
  Logger Restarts within Interval: 0
  Total Logger Restart Count: 0

Logger Availability Information:
  Status: STOPPED
  Status Details: The logger has been stopped. It was
                  shut down in a controlled manner.

Queue Manager Information:
  Name: QM_gbthink
  Transport: Bindings
  Last Status Reported: UNAVAILABLE (Last Error MQRC: 2059)
  Status Details: The queue manager is unavailable. It
                  might be that the queue manager has
                  not been started or an incorrect
                  queue manager name has been
                  configured. Look up the MQ reason code
                  reported against the status to
                  understand the problem.
```

In this example on z/OS, a running logger (not registered with ARM):

```
fteShowLoggerDetails loggerv8
```

```
5655-MFT, 5724-H72 Copyright IBM Corp. 2008, 2024. ALL RIGHTS RESERVED
Logger Controller Information:
```

Controller Type:	z/OS Automatic Restart Manager (ARM)
Registered with ARM:	No
Restarted:	n/a
Queue Manager Information:	
Name:	FT8E
Transport:	Bindings
Last Status Reported:	AVAILABLE
Status Details:	The queue manager is available.

z/OS

In this example on z/OS, a logger that is not running, or running on a different system:

```
fteShowLoggerDetails loggerv8
```

```
5655-MFT, 5724-H72 Copyright IBM Corp. 2008, 2024. ALL RIGHTS RESERVED
Logger Controller Information:
  Controller Type:                UNKNOWN

Queue Manager Information:
  Name:                          FT8E
  Transport:                      Bindings
  Last Status Reported:          UNKNOWN
  Status Details:                Information about the queue manager is
                                not available, either because the
                                logger is not running, or the logger
                                is running on a different system.
```

Return codes

- 0** Command completed successfully.
- 1** Command ended unsuccessfully.

Related reference

[“MFT logger status values” on page 2521](#)

The **fteShowLoggerDetails** commands produce logger status information. There are several possible values for this status.

[“MFT logger process controller status values” on page 2522](#)

The **fteShowLoggerDetails** command produces logger process controller status information. There are several possible values for this status.

fteStartAgent (start an MFT agent)

The **fteStartAgent** command starts a Managed File Transfer agent from the command line.

Purpose

Use the **fteStartAgent** command to start a Managed File Transfer agent. You must start an agent before you can use it to perform file transfers. The **fteStartAgent** command starts an agent on the system where you issue the command: you cannot start an agent on a remote system.

For IBM WebSphere MQ 7.5 or later, the agent process controller manages starting the agent. However, the agent process controller may wait for a period of time, for example where there have been a high rate of agent failures, before attempting to start the agent again. As an IBM MQ administrator you can use **fteStartAgent** command to override this wait and initiate a start of the agent. If the agent process controller was waiting for the queue manager to become available this command will also initiate the agent process controller attempting to reconnect to the queue manager.

Windows If you have configured the agent to run as a Windows service by using the [fteCreateAgent](#) or [fteModifyAgent](#) command, running the **fteStartAgent** command starts the Windows service.

This command returns an error if the agent does not start or is already started. The agent communicates with its queue manager based on the values defined in the `agent.properties` file.

Specify the optional **-p** parameter for this command only if you want to use a different set of configuration options than your default set. See [The MFT `agent.properties` file](#) for more information.

Syntax

Parameters

-F

Optional. This parameter runs the agent daemon as a foreground process. The default is for the agent daemon to run in the background.

If you are running on Windows, and you have configured the agent to run as a Windows service by using the **fteCreateAgent** or **fteModifyAgent** commands, the **-F** parameter overrides this configuration.

-p configuration_options

Optional. This parameter determines the set of configuration options that is used to issue the request to start an agent. Use the name of a non-default coordination queue manager as the input for this parameter. The command then uses the set of properties files associated with this non-default coordination queue manager.

If you do not specify this parameter, the set of configuration options based on the default coordination queue manager is used.

agent_name

Required. The name of the Managed File Transfer agent that you want to start.

-? or -h

Optional. Displays command syntax.

Example

In this example, AGENT2 is started and runs in the foreground.

```
fteStartAgent -F AGENT2
```

In the following example (for AIX and Linux systems), AGENT2 is started with a non-default coordination queue manager, QM_SATURN:

```
./fteStartAgent -p QM_SATURN AGENT2
```

You can also run the command by specifying the path to **fteStartAgent** as follows:

```
path/fteStartAgent agentname
```

Return codes

0 (RC_SUCCESS)

Command completed successfully.

1 (RC_FAILURE)

Command ended unsuccessfully.

78 (RC_CONFIG)

A configuration error was encountered.

79 (RC_API_ERROR)

A MFT exception occurred.

80 (RC_IO_ERROR)

A Java IOException occurred.

81 (RC_IPC_ERROR)

An MFT interprocess communication error occurred.

Responses

In some circumstances, you might see error messages after running the **fteStartAgent** command:

- If you run the **fteStartAgent** command and see the following error message, your environment probably has additional library paths that conflict with Managed File Transfer:

```
BFGCL0001E: An internal error has occurred. The exception was: 'CC=2;RC=2495;AMQ8568:  
The native JNI library 'mqjbnf' was not found. [3=mqjbnf]
```

If the LD_LIBRARY_PATH or LIBPATH environment variable is set to reference a 64-bit version of the library before the 32-bit version when the agent is running with a 32-bit version of Java (as is currently the case for most platforms), this error occurs.

To resolve this issue, set the Managed File Transfer agent property javaLibraryPath to reference the correct location for the library. For example, for mqjbnf on AIX, set to: /usr/mqm/java/lib. For mqjbnf on Linux, set to: /opt/mqm/java/lib

Related tasks

 [Starting an MFT agent on z/OS](#)

[Starting an MFT agent as a Windows service](#)

[Listing MFT agents](#)

[Stopping an MFT agent](#)

fteStartLogger (start an MFT logger)

The **fteStartLogger** command starts a Managed File Transfer logging application.

Purpose

Use the **fteStartLogger** command to start a logger.

The logger can be either a file or database application that runs on the same system as the coordination queue manager. For more information, see [Configuring an MFT logger](#).

For IBM WebSphere MQ 7.5, or later, the logger process controller manages starting the logger. However, the logger process controller might wait for a period of time, for example where there has been a high rate of logger failures, before attempting to start the logger again. As an IBM MQ administrator you can use the **fteStartLogger** command to override this wait and initiate a start of the logger. If the logger process controller was waiting for the queue manager to become available, this command will also initiate the logger process controller attempting to reconnect to the queue manager.

 If you have configured a logger to run as a Windows service by using the [fteModifyLogger](#) command, running the **fteStartLogger** command starts the Windows service.

This command returns an error if the logger does not start or is already started.

The logger communicates with its queue manager based on the values defined in the logger.properties file.

Specify the **-p** parameter for this command only if you want to use a set of configuration options different from the default. For more information on logger properties, see [MFT logger configuration properties](#)

Syntax

fteStartLogger

```
► fteStartLogger -p configuration_options -F logger_name ►
```

Parameters

-p configuration_options

Optional. This parameter determines the set of configuration options that is used to issue the request to start a logger. Use the name of a non-default coordination queue manager as the input for this parameter. **fteStartLogger** then uses the set of properties files associated with this non-default coordination queue manager.

If you do not specify this parameter, the set of configuration options based on the default coordination queue manager is used.

-F

Optional. Runs the logger as a foreground process (rather than as the default background process). If you have configured the logger to run as a Windows service by using the **fteModifyLogger** command, the **-F** parameter overrides this configuration.

-? or -h

Optional. Displays command syntax.

logger_name

Required. The name of the Managed File Transfer logger you want to start.

Example

In this example, a logger has previously been created named `logger1`. This command shows how the logger can be started as a foreground process:

```
fteStartLogger -F logger1
```

Return codes

0

Command completed successfully.

1

Command ended unsuccessfully.

Related concepts

[MFT logger error handling and rejection](#)

Related tasks

[Configuring an MFT logger](#)

Related reference

[“fteModifyLogger \(run an MFT logger as a Windows service\)” on page 2130](#)

Use the **fteModifyLogger** command to modify a Managed File Transfer logger so that it can be run as a Windows service. You can use this command only on Windows platforms, must be run by a user who is an IBM MQ administrator and a member of the `mqm` group, and you must first stop the logger by using the **fteStopLogger** command.

[“fteStopLogger \(stop an MFT logger\)” on page 2177](#)

The **fteStopLogger** command stops a Managed File Transfer logger.

fteStartMonitor (start an MFT resource monitor)

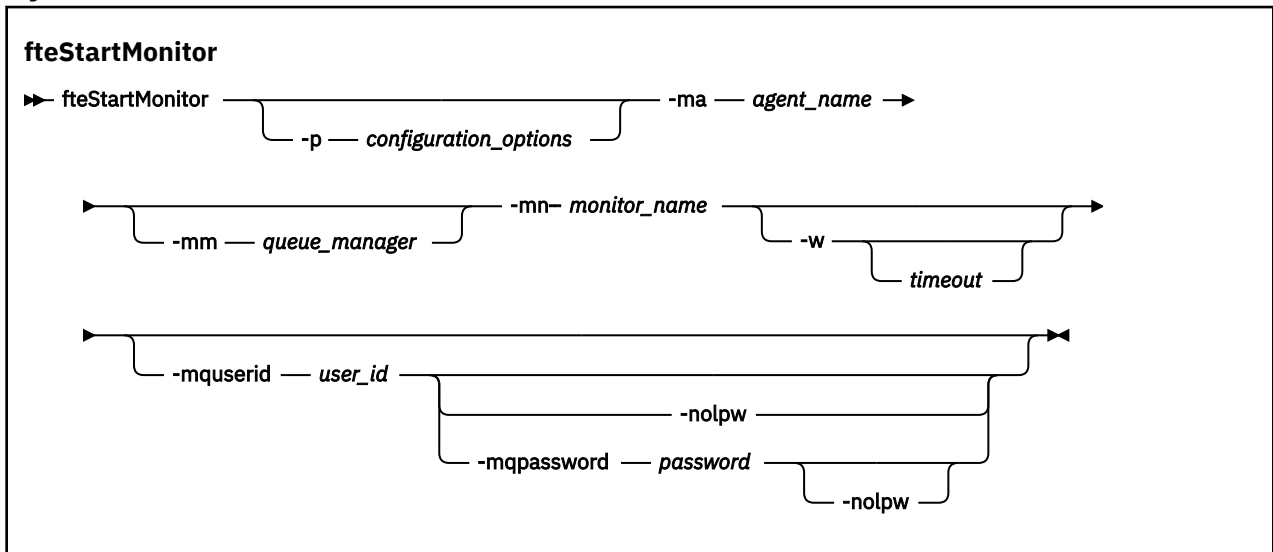

The **fteStartMonitor** command starts a Managed File Transfer resource monitor from the command line.

Purpose

From IBM MQ 9.3.0, you can use the **fteStartMonitor** command to start a resource monitor without needing to stop or restart an agent.

You can run this command from any system where the Managed File Transfer commands component is installed, which means that you can start a resource monitor from anywhere, and are not restricted to the system where the agent that owns the resource monitor is running.

Syntax

Parameters

-p configuration_options

Optional. This parameter determines the set of configuration options that is used to start a resource monitor. Use the name of a set of configuration options as the value for the **-p** parameter. By convention, this is the name of a coordination queue manager. If you do not specify this parameter, the default set of configuration options is used.

-ma agent_name

Required. The name of the agent running the resource monitor operation.

-mm queue_manager

Optional. The name of the queue manager that the agent is connected to.

The **fteStartMonitor** command connects to the command queue manager. If the command queue manager is also the agent queue manager for the monitoring agent, then the **-mm** parameter is optional, otherwise you must specify the agent queue manager with the **-mm** parameter.

-mn monitor_name

Required. The name of the resource monitor that you want to start.

-w timeout

Optional. Specifies to wait for up to timeout seconds for the agent to respond. If you do not specify a timeout, or specify a timeout value of minus one, then the command waits forever for the agent to respond. If you do not specify this option, then the default is to wait up to five seconds for the agent to respond.

-mquserid *user_id*

Optional. Specifies the user ID to authenticate with the command queue manager.

-mqpassword *password*

Optional. Specifies the password to authenticate with the coordination queue manager.

When the **-mqpassword** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

The command defaults to using MQCSP authentication, and sends the user ID and password to be authenticated to the queue manager in an MQCSP structure.

-nolpw

Optional. Specify this parameter if the command connects to a queue manager that does not support passwords longer than 12 characters.

When the **-nolpw** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid** and **-nolpw**, but do not specify **-mqpassword**, you are prompted to supply the associated password which, will not be displayed.

Note: If you specify the **-nolpw** option, and the password is longer than 12 characters the command fails with error message BFGCL0829E.

Example 1

The following command starts a resource monitor in an agent running on the same machine:

```
fteStartMonitor -mn MNTR -ma SOURCE
```

This command outputs the following messages:

```
BFGCL0816I: A request to start resource monitor 'MNTR' of agent 'SOURCE' has been issued.
BFGCL0251I: The request has successfully completed.
```

The following event is logged in the agent's output0.log:

```
BFGDM0032I: Monitor MNTR has been started.
```

External return code = 0

Example 2

The following command starts a resource monitor in an agent running on a different machine:

```
fteStartMonitor -mn MNTR -ma SOURCE -mm SRCQM
```

This command outputs the following messages:

```
BFGCL0816I: A request to start resource monitor 'MNTR' of agent 'SOURCE' has been issued.
BFGCL0251I: The request has successfully completed.
```

The following event is logged in the agent's output0.log:

```
BFGDM0032I: Monitor MNTR has been started.
```

Examples of other messages

If you receive any of the following messages, you can check the state of the agent by using the **fteListMonitors** command with the **-v** parameter. The **-v** parameter generates verbose output that includes additional information about the status of the resource monitor, including whether the resource monitor is started or stopped, the directory resource path that is being monitored and the trigger conditions.

The resource monitor is already in the started state

The command outputs the following messages:

```
BFGCL0816I: A request to start resource monitor 'MNTR' of agent 'SOURCE' has been issued.
BFGCL0814I: Resource monitor 'MNTR' of agent 'SOURCE' is already running.
```

The resource monitor is in an agent that is stopped

The command outputs the following messages:

```
BFGCL0816I: A request to start resource monitor 'MNTR' of agent 'SOURCE' has been issued.  
BFGCL0253W: No acknowledgement to command from agent within timeout.
```

The specified agent is unknown

The command outputs the following message:

```
BFGUB0009E: The following required property file is missing:  
"/root/mftdata/mqft/config/MFTHAQM/agents/UNKNOWNAGENT/agent.properties"
```

The specified resource monitor cannot be found on the specified agent

The command outputs the following messages:

```
BFGCL081608I: A request to start resource monitor 'UNKNOWNMONITOR' of agent 'IJQ' has been issued.  
BFGCL0250E: The monitor could not be found on the given agent.
```

Return codes

0

Command completed successfully.

1

Command ended unsuccessfully.

Related tasks

[Starting an MFT resource monitor](#)

Related reference

[“fteListMonitors \(list MFT resource monitors\)” on page 2119](#)

Use the **fteListMonitors** command to list all of the existing resource monitors in a Managed File Transfer network using the command line.

[“fteStopMonitor \(stop an MFT resource monitor\)” on page 2179](#)

The **fteStopMonitor** command stops a Managed File Transfer resource monitor from the command line.

fteStopAgent (stop an MFT agent)

Use the **fteStopAgent** command to either stop a Managed File Transfer agent in a controlled way or to stop an agent immediately if necessary using the **-i** parameter.

Purpose

When you stop an agent by using the **fteStopAgent** command, you can either allow the agent to complete its current file transfer before stopping, or stop the agent immediately even if the agent is currently transferring a file. When the agent has stopped, you cannot use that agent to transfer files until you restart the agent.

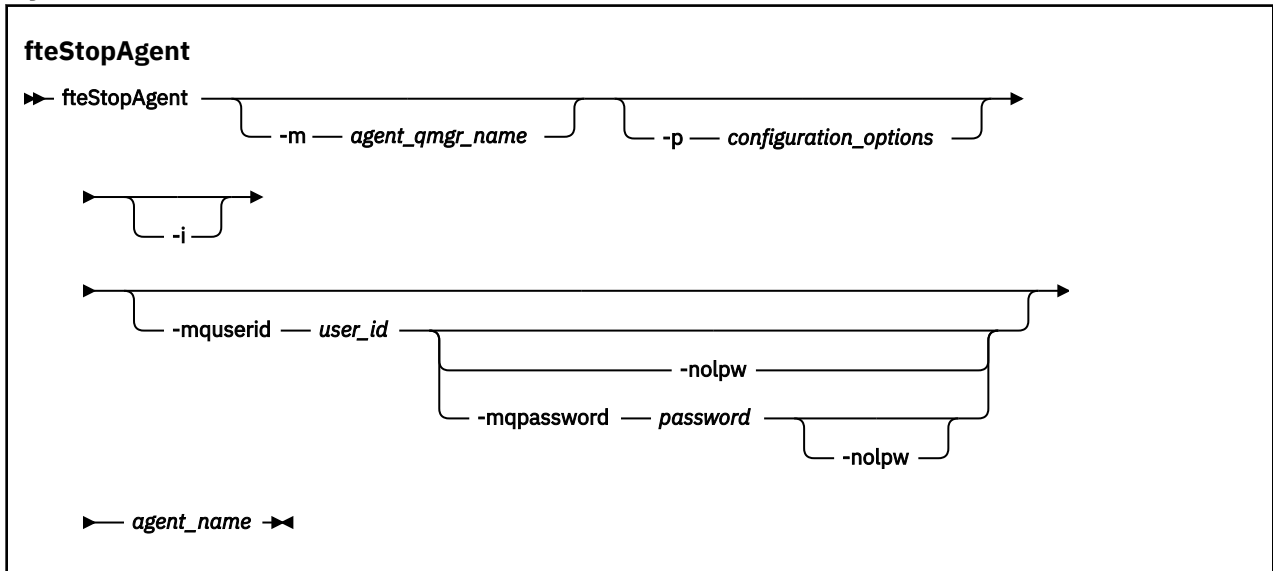

If the agent you want to stop is connected to the IBM MQ network, you can run the **fteStopAgent** command from any system that can connect to the IBM MQ network and route to the agent queue manager. Specifically for the command to run, you must have installed and configured a Managed File Transfer component (either Service or Agent) on this system to communicate with the IBM MQ network. If no connectivity details are available, a bindings mode connection is made to the default queue manager on the local system. If command . properties does not exist then an error is generated.

If the agent you want to stop is not connected to the IBM MQ network, for example if the IBM MQ network is not currently available, you can only run the **fteStopAgent** command from the system that the agent is running on. In order to stop an agent that is not connected to the IBM MQ network you must run the **fteStopAgent** command from the same user the agent is running as. Alternatively, if the agent is running on a Windows system you can run the command as an administrator.

Specify the optional **-p** parameter for this command only if you want to use a set of configuration options different from your default set. See [The MFT agent . properties file](#) for more information.

Windows If your agent is running as a Windows service, running the **fteStopAgent** command stops the Windows service. For more information, see [Starting an MFT agent as a Windows service](#).

Syntax

Parameters

-m agent_qmgr_name

Optional. The name of the queue manager that the agent that you want to stop is connected to.

If the agent is on a remote system, or if the agent is on the local system but you are not the user that started it, you must use the **-m** parameter, and have the appropriate authorities. For more information about authorities, see [Restricting group authorities for MFT-specific resources](#).

-p configuration_options

Optional. This parameter determines the set of configuration options that is used to issue the request to stop an agent. Use the name of a non-default coordination queue manager as the input for this parameter. The command then uses the set of properties files associated with this non-default coordination queue manager.

If you do not specify this parameter, the set of configuration options based on the default coordination queue manager is used.

-i

Optional. Immediately stops the agent. The agent does not complete any transfers that are currently in progress.

If you do not specify the **-i** parameter, the agent completes any transfers currently in progress but the agent does not start any new transfers.

-mquserid user_id

Optional. Specifies the user ID to authenticate with the command queue manager.

-mqpassword password

Optional. Specifies the password to authenticate with the coordination queue manager.

When the **-mqpassword** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

From IBM MQ 9.3, the command defaults to using [MQCSP](#) authentication, and sends the user ID and password to be authenticated to the queue manager in an MQCSP structure.

-nolpw

Optional. Specify this parameter if the command connects to a queue manager that does not support passwords longer than 12 characters.

When the **-nolpw** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid** and **-nolpw**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

Note: If you specify the **-nolpw** option, and the password is longer than 12 characters the command fails with error message BFGCL0829E.

agent_name

Required. The name of the Managed File Transfer agent that you want to stop.

-? or -h

Optional. Displays command syntax.

Example

In this example the agent AGENT2 on queue manager QM_JUPITER is stopped. The **-m** parameter is used because this queue manager that AGENT2 is connected to differs from the queue manager specified by the set of configuration options.

```
fteStopAgent -m QM_JUPITER AGENT2
```

Return codes

0

Command completed successfully.

1

Command ended unsuccessfully.

Related tasks

[Stopping an MFT agent](#)

 [Stopping an MFT agent on z/OS](#)

Related reference

[“fteStartAgent \(start an MFT agent\)” on page 2169](#)

The **fteStartAgent** command starts a Managed File Transfer agent from the command line.

fteStopLogger (stop an MFT logger)

The **fteStopLogger** command stops a Managed File Transfer logger.

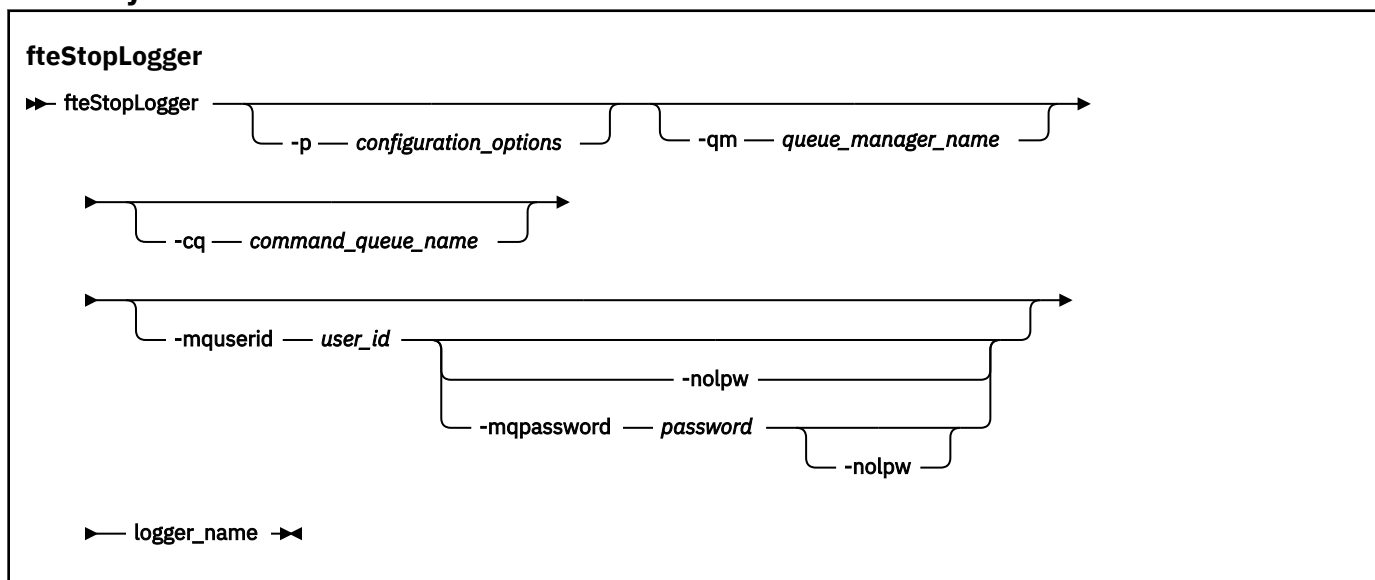

Purpose

Use the **fteStopLogger** command to stop a logger. The logger can be either a file logger, which records a history of managed file transfer activity to a file, or a database logger which records the history to a database.

Additional notes about stopping a stand-alone logger process

If your logger is running as a Windows service, running the **fteStopLogger** command stops the Windows service.

Syntax

Parameters

-p (configuration_options)

Optional. Determines the set of configuration options that is used to stop the logger. Use the name of a set of configuration options as the value for the **-p** parameter. By convention this value is the name of a coordination queue manager. If you do not specify this parameter, the default set of configuration options is used.

-qm (queue_manager_name)

Optional. By default, the logger's command queue is assumed to be on the coordination queue manager specified by the **-p** parameter (or its default). If you want to send logger commands to a command queue located elsewhere, use the **-qm** parameter to specify an alternative destination. In all cases, this command connects to the command queue manager indicated by the **-p** parameter, regardless of the message's ultimate destination.

-cq (command_queue_name)

Optional. Specifies the command queue to send the stop message to. In most cases, loggers use the default queue name meaning this parameter is not necessary.

-mquserid (user_id)

Optional. Specifies the user ID to authenticate with the command queue manager.

-mqpassword password

Optional. Specifies the password to authenticate with the coordination queue manager.

When the **-mqpassword** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

From IBM MQ 9.3, the command defaults to using [MQCSP](#) authentication, and sends the user ID and password to be authenticated to the queue manager in an MQCSP structure.

-nolpw

Optional. Specify this parameter if the command connects to a queue manager that does not support passwords longer than 12 characters.

When the **-nolpw** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid** and **-nolpw**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

Note: If you specify the **-nolpw** option, and the password is longer than 12 characters the command fails with error message BFGCL0829E.

logger_name

Required. The name of the Managed File Transfer logger you want to stop.

-? or -h

Optional. Displays command syntax.

Example

In this example, a logger has previously been created named `logger1` and is currently running. This command shows how the logger can be stopped:

```
fteStopLogger logger1
```

Return codes**0**

Command completed successfully.

1

Command ended unsuccessfully.

Related tasks

[Configuring an MFT logger](#)

Related reference

[“fteModifyLogger \(run an MFT logger as a Windows service\)” on page 2130](#)

Use the **fteModifyLogger** command to modify a Managed File Transfer logger so that it can be run as a Windows service. You can use this command only on Windows platforms, must be run by a user who is an IBM MQ administrator and a member of the `mqm` group, and you must first stop the logger by using the **fteStopLogger** command.

[“fteStartLogger \(start an MFT logger\)” on page 2171](#)

The **fteStartLogger** command starts a Managed File Transfer logging application.

fteStopMonitor (stop an MFT resource monitor)

The **fteStopMonitor** command stops a Managed File Transfer resource monitor from the command line.

Purpose

From IBM MQ 9.3.0, you can use the **fteStopMonitor** command to stop a resource monitor without needing to stop or restart an agent.

You can run this command from any system where the Managed File Transfer commands component is installed, which means that you can stop a resource monitor from anywhere, and are not restricted to the system where the agent that owns the resource monitor is running.

Syntax

Parameters

-p configuration_options

Optional. This parameter determines the set of configuration options that is used to stop a resource monitor. Use the name of a set of configuration options as the value for the **-p** parameter. By convention, this is the name of a coordination queue manager. If you do not specify this parameter, the default set of configuration options is used.

-ma agent_name

Required. The name of the agent running the resource monitor operation.

-mm queue_manager

Optional. The name of the queue manager that the agent is connected to.

The **fteStopMonitor** command connects to the command queue manager. If the command queue manager is also the agent queue manager for the monitoring agent, then the **-mm** parameter is optional, otherwise you must specify the agent queue manager with the **-mm** parameter.

-mn monitor_name

Required. The name of the resource monitor that you want to stop.

-w timeout

Optional. If you do not specify a *timeout* value, the default is to wait up to five seconds for the agent to respond.

The *timeout* value specifies the value in seconds for the agent to respond. If you specify a timeout value of minus one, the command waits forever for the agent to respond.

-mquserid user_id

Optional. Specifies the user ID to authenticate with the command queue manager.

-mqpassword password

Optional. Specifies the password to authenticate with the coordination queue manager.

When the **-mqpassword** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

The command defaults to using MQCSP authentication, and sends the user ID and password to be authenticated to the queue manager in an MQCSP structure.

-nolpw

Optional. Specify this parameter if the command connects to a queue manager that does not support passwords longer than 12 characters.

When the **-nolpw** parameter is specified, you must also specify the **-mquserid** parameter. If you specify **-mquserid** and **-nolpw**, but do not specify **-mqpassword**, you are prompted to supply the associated password, which will not be displayed.

Note: If you specify the **-nolpw** option, and the password is longer than 12 characters the command fails with error message BFGCL0829E.

Example 1: resource monitor and agent on the same machine

The following command stops a resource monitor in an agent running on the same machine:

```
fteStopMonitor -mn MNTR -ma SOURCE
```

This command outputs the following messages:

```
BFGCL0813I: A request to stop resource monitor 'MNTR' of agent 'SOURCE' has been issued.  
BFGCL0251I: The request has successfully completed.
```

The following event is logged in the agent's output0.log.

```
BFGDM0069I: Monitor MNTR has been stopped.
```

Example 2 - resource monitor and agent running on different machines

The following command stops a resource monitor in an agent running on a different machine:

```
fteStopMonitor -mn MNTR -ma SOURCE -mm SRCQM
```

This command outputs the following messages:

```
BFGCL0813I: A request to stop resource monitor 'MNTR' of agent 'SOURCE' has been issued.  
BFGCL0251I: The request has successfully completed.
```

The following event is logged in the agent's output0.log.

```
BFGDM0069I: Monitor MNTR has been stopped.
```

Examples of other messages

If you receive any of the following messages, you can check the state of the agent by using the **fteListMonitors** command with the **-v** parameter. The **-v** parameter generates verbose output that includes additional information about the status of the resource monitor, including whether the resource monitor is started or stopped, the directory resource path that is being monitored and the trigger conditions.

The resource monitor is already in the stopped state

The command outputs the following messages:

```
BFGCL0813I: A request to stop resource monitor 'MNTR' of agent 'SOURCE' has been issued.  
BFGCL0815I: Resource monitor 'MNTR' of agent 'SOURCE' is already stopped.
```

The resource monitor is in an agent that is stopped

The command outputs the following messages:

```
BFGCL0813I: A request to stop resource monitor 'MNTR' of agent 'SOURCE' has been issued.  
BFGCL0253W: No acknowledgement to command from agent within timeout.
```

The specified agent is unknown

The command outputs the following message:

```
BFGUB0009E: The following required property file is missing:  
"/root/mftdata/mqft/config/MFTHAQM/agents/UNKNOWNAGENT/agent.properties"
```

The specified resource monitor cannot be found on the specified agent

The command outputs the following messages:

```
BFGCL0813I: A request to stop resource monitor 'UNKNOWNMONITOR' of agent 'IJQ' has been issued.  
BFGCL0250E: The monitor could not be found on the given agent.
```

Return codes

0

Command completed successfully.

1

Command ended unsuccessfully.

MQIPT commands reference

Reference information about the syntax and usage of the various IBM MQ Internet Pass-Thru (MQIPT) commands.

mqipt (start MQIPT)

Start IBM MQ Internet Pass-Thru (MQIPT).

Purpose

Use the **mqipt** command to start MQIPT. You can optionally specify a name to be given to the MQIPT instance that is being started.

Syntax

```
➤ mqipt — home_directory — -n mqipt_name — -sf encryption_key_file —
```

Required parameters

home_directory

The MQIPT home directory, where the `mqipt.conf` configuration file is located. The MQIPT home directory can be specified as either an absolute path or relative to the current working directory of the command shell.

Optional parameters

-n mqipt_name

The name to be given to the MQIPT instance that is being started. The name of the MQIPT instance is used to administer local instances of MQIPT with the **mqiptAdmin** command without needing to use a command port. If this parameter is not specified, the name of the MQIPT home directory is used as the name of the MQIPT instance.

-sf encryption_key_file

The name of a file that contains the password encryption key. The encryption key is used by MQIPT to access encrypted passwords in the `mqipt.conf` configuration file.

For information about the password encryption key file and other methods to specify the file name when starting MQIPT, see [Specifying the password encryption key](#).

For more information on encrypting stored passwords to be used by MQIPT, see [Encrypting stored passwords](#).

mqiptAdmin (administer MQIPT)

Issue an administrative command to an active instance of IBM MQ Internet Pass-Thru (MQIPT).

Purpose

Use the **mqiptAdmin** command to issue an administrative command to an active instance of MQIPT.

Usage notes

The **mqiptAdmin** command connects to the active instance of MQIPT to administer using one of the following methods:

- by making a network connection to a command port
- by connecting to a local instance of MQIPT without using the command port.

An MQIPT command port might be configured to accept only TLS connections. When connecting to a TLS command port, the **-s** parameter to the **mqiptAdmin** command must be specified.

In order for **mqiptAdmin** to be authorized to connect to a local instance of MQIPT without using the command port, the MQIPT instance must be running on the same system and under the same user ID as **mqiptAdmin**. Alternatively, on AIX and Linux, **mqiptAdmin** can be run as **root**.

Note: The **mqiptAdmin** command is compatible with previous versions of MQIPT, but the command cannot be used to administer versions of MQIPT that are a higher version than the version of the **mqiptAdmin** command. In an environment that includes different versions of MQIPT, use the latest version of the **mqiptAdmin** command.

Syntax

►► mqiptAdmin →

Deprecated syntax

Keywords and parameters

-list

Display the names of all local instances of MQIPT that support local administration without the command port.

On AIX and Linux, if **mqiptAdmin** is running as **root**, all local active instances of MQIPT are displayed. Otherwise, only instances of MQIPT that are running under the same user ID as **mqiptAdmin** are displayed.

-refresh

Refresh an active instance of MQIPT to bring any configuration changes into effect.

-stop

Stops the instance of MQIPT.

MQIPT closes all connections, stops listening for incoming connections, and then exits. The stop command is ignored if the `mqipt.conf` file specifies `RemoteShutDown=false`.

-status

Display information about the connection thread pool usage. The information is displayed in the MQIPT console output. This parameter is intended for use by IBM Support.

-n mqipt_name

The name of a local instance of MQIPT to administer. This parameter must be specified to administer a local instance of MQIPT without using a command port.

-r hostname:port

The host name and command port of an instance of MQIPT to administer using the command port. This parameter is optional. If neither the `-n` nor `-r` parameters are specified, `mqiptAdmin` connects to `localhost`, port 1881.

-s

Secure the connection to MQIPT using TLS. This parameter must be specified to connect to a TLS command port.

-p properties_file

The name of a file containing configuration properties that are necessary to connect to MQIPT using TLS. The name of the properties file can also be specified by setting the `MQS_MQIPTADM_PROP_FILE` environment variable.

For the list of properties that can be specified in the properties file, see [mqiptAdmin properties](#).

Return codes

Table 348. Return code identifiers and descriptions

Return code	Description
0	Command successful.
>0	Command not successful.

mqiptIcons (create MQIPT Start menu icons)

Create and remove IBM MQ Internet Pass-Thru (MQIPT) Start menu icons on Windows platforms.

Purpose

Use the **mqiptIcons** command to create and remove Start menu icons for MQIPT functions on Windows platforms.

You must run the **mqiptIcons** command as a user with administrator privileges.

Syntax

```
➤ mqiptIcons -install installation_name ➤
-remove
```

Parameters**-install**

Create MQIPT icons on the Start menu.

-remove

Remove MQIPT icons from the Start menu.

installation_name

A name that you choose to distinguish this installation of MQIPT from any other. The name is appended to the name of the Start menu folder that is created to contain the MQIPT icons.

Return codes

Table 349. Return code identifiers and descriptions

Return code	Description
0	Command successful.
>0	Command not successful.

mqiptykeytool (manage certificates)

Run the Java **keytool** certificate management utility to manage keystores and certificates that IBM MQ Internet Pass-Thru (MQIPT) uses.

Purpose

Use the **mqiptykeytool** command to manage the trusted certificates in keystores that MQIPT uses.

From IBM MQ 9.4.0, this command replaces the **mqiptykeycmd** command that is used to manage certificates in earlier versions of MQIPT.

Usage notes

The **mqiptykeytool** command calls the **keytool** certificate management utility in the Java runtime environment that is supplied with MQIPT. For more information about the **keytool** command and its usage, see [keytool](#).

Syntax

Keywords and parameters

-certreq

Create a request for a signed certificate to be sent to a certificate authority (CA). You must first create a key pair by using the `-genkeypair` command.

-changealias

Change the label that is associated with an entry in the keystore.

-delete

Delete an entry from the keystore.

-exportcert

Extract the public part of a certificate from the keystore.

-genkeypair

Create a public key and private key pair, and an associated self-signed certificate.

-importcert

Add a certificate to the keystore. Use this command to complete one of the following actions:

- Add a certificate to the keystore as a trusted certificate.
- Receive a certificate that is signed by a certificate authority (CA) into the keystore.

-importkeystore

Import certificates and their associated private keys into the keystore from another keystore.

-keypasswd

Change the password that protects a private key in the keystore.

-list

List the contents of the keystore.

-storepasswd

Change the keystore password.

options

The parameters that are required for the specified command.

All commands and options that are specified are passed unchanged to the Java **keytool** certificate management utility. For more information about the commands and options that can be specified, see [Keytool](#).

Return codes

Table 350. Return code identifiers and descriptions

Return code	Description
0	Command successful.
>0	Command not successful.

mqiptPW (encrypt stored password)

Encrypt a password for use by IBM MQ Internet Pass-Thru (MQIPT).

Purpose

Use the **mqiptPW** command to encrypt a password that is stored for use by MQIPT.

The MQIPT configuration might include passwords to access various resources, as well as the MQIPT access password for administration using the command port.

In versions earlier than IBM MQ 9.1.5, only passwords that are used by MQIPT to access key rings, or cryptographic hardware key stores, can be encrypted. From IBM MQ 9.1.5, all stored passwords for use by MQIPT should be protected by encrypting the password with the **mqiptPW** command.

Syntax

Use this syntax to call the **mqiptPW** command to encrypt any password for use by MQIPT in IBM MQ 9.1.5 or higher. Store the encrypted password in the appropriate property in the `mqipt.conf` configuration file.

The command prompts for the password to be encrypted to be entered.

```
➔ mqiptPW _____
```

 └── -sf ─ encryption_key_file ─┘ └── -sp ─ protection_mode ─┘

Optional parameters

-sf encryption_key_file

The name of a file that contains the password encryption key. If specified, the file must contain at least one character, and only one line.

If this parameter is not specified, the default password encryption key is used.

This parameter can be specified only with password protection mode 1 or higher.

-sp protection_mode

The password protection mode to be used by the command. One of the following values can be specified:

2

Use the latest password protection mode. This is the default value from IBM MQ 9.3.0.

1

Use the IBM MQ 9.1.5 password protection mode for compatibility with versions earlier than IBM MQ 9.3.0. This is the default value in versions earlier than IBM MQ 9.3.0.

0

Deprecated Use the deprecated password protection mode.

Deprecated syntax to encrypt key ring passwords

Use this syntax to call the **mqiptPW** command to encrypt a key ring password. The encrypted password is stored in file which can be read by any version of MQIPT. **Deprecated** This syntax is deprecated from IBM MQ 9.1.5 as it does not offer the most secure encryption method.

```
►► mqiptPW — password — file_name — -replace ►►
```

Parameters for deprecated syntax

Deprecated

password

The clear text password to encrypt. Passwords can include the space character, but the whole password string must be enclosed in quotes for this to be acceptable. There is no limit to the length or format of the password.

file_name

The name of a file to create, to contain the encrypted password.

-replace

Overwrite an existing password file with the same name, if it exists. This parameter is optional.

Return codes

Table 351. Return code identifiers and descriptions

Return code	Description
0	Command successful.
>0	Command not successful.

mqiptService (manage the MQIPT service)

Install or uninstall the IBM MQ Internet Pass-Thru (MQIPT) service.

Purpose

Use the **mqiptService** command to install or uninstall the MQIPT service. The MQIPT service lets you manage and run MQIPT as a Windows service, or as a System V init service on AIX and Linux.

Usage notes

You can only install one MQIPT service on a system, even if there is more than one installation of MQIPT on the system.

Note: Only the installation of MQIPT that installed the service can be used to remove it. For example, if you have two MQIPT installations, one in `/opt/mqipt` and one in `/usr/local/mqipt`, and you run the command `/opt/mqipt/bin/mqiptService -install`, then only the **mqiptService** command from the `/opt/mqipt` installation can subsequently be used to remove the service. Attempting to remove the service using a different installation causes error MQCPE083.

Linux **AIX** On AIX and Linux, you must run the **mqiptService** command as `root` to ensure that you have the authority required to configure services.

Linux On Linux, the MQIPT service is supported only on operating systems which support System V init. On systems which do not support System V init, use another method, such as `systemd`, to manage MQIPT as a service.

Windows On Windows, you must run the `mqiptService` command from an administrator command prompt to ensure that you have the authority required to configure Windows services. The MQIPT service runs under the LocalSystem account. The service cannot be configured to run under a different user ID.

Syntax on AIX and Linux

Syntax on Windows

Keywords and parameters

-install

Install and register theMQIPT service.

Linux **AIX** On AIX and Linux, the `mqipt.conf` file for the service must be located in the top-level MQIPT installation directory of the installation from which you ran `mqiptService`.

Windows On Windows, you must supply the fully-qualified path to the directory containing the `mqipt.conf` configuration file as a parameter. Enclose the path in double quotation marks (") if it contains spaces.

If the MQIPT configuration contains passwords that have been encrypted using an encryption key other than the default, the password encryption key must be present in a file named `mqipt_cred.key` in the same directory as the `mqipt.conf` file. For more information on encrypting passwords in the MQIPT configuration, see [Encrypting stored passwords](#).

Installing the service does not automatically start it. The service starts the next time the system is restarted. Consult your operating system service documentation if you need to start the MQIPT service immediately, without restarting.

-remove

Remove the MQIPT service so that it no longer starts at system boot time.

On Windows, the MQIPT service is stopped if it is currently active, and all routes are subject to immediate shutdown.

Return codes

Table 352. Return code identifiers and descriptions

Return code	Description
0	Command successful.
>0	Command not successful.

mqiptVersion (display MQIPT version information)

Display IBM MQ Internet Pass-Thru (MQIPT) version and build information.

Purpose

Use the **mqiptVersion** command to display MQIPT version and build information.

Syntax

►► mqiptVersion 

Optional parameters

-v

Display verbose output including build information and the version of the Java runtime environment supplied with MQIPT.

Return codes

Table 353. Return code identifiers and descriptions

Return code	Description
0	Command successful.
>0	Command not successful.

Administrative REST API reference

Reference information about the administrative REST API.

For more information about using the administrative REST API, see [Administration using the REST API](#).

For more information about configuring the administrative REST API, see [Configuring the REST API](#).

For more information about securing the administrative REST API, see [Securing the REST API](#).

REST API resources

This collection of topics provides reference information for each of the administrative REST API resources.

For more information about using the administrative REST API, see [Administration using the REST API](#).

For more information about configuring the administrative REST API, see [Configuring the REST API](#).

For more information about securing the administrative REST API, see [Securing the REST API](#).

/admin/action/qmgr/{qmgrName}/mqsc

You can use the HTTP POST method with the `/admin/action/qmgr/{qmgrName}/mqsc` resource to execute an arbitrary MQSC command on a queue manager.

Note: **V9.4.0** You cannot use this resource with the stand-alone IBM MQ Web Server. For more information about the installation options for the IBM MQ component that runs the administrative REST API, see [The IBM MQ Console and REST API](#).

You can use the administrative REST API gateway with this resource URL.

POST - plain text MQSC command

Use the HTTP POST method with this resource to submit administrative commands directly to a queue manager. These administrative commands are submitted in the body of the request, either as a plain text MQSC command, or as a JSON formatted command.

Note: **V9.4.0** You cannot use this resource with the stand-alone IBM MQ Web Server. For more information about the installation options for the IBM MQ component that runs the administrative REST API, see [The IBM MQ Console and REST API](#).

You can use the administrative REST API to submit an MQSC command by using either a plain text MQSC command or with a JSON formatted command:

- With a plain text MQSC command, the body of the request contains an MQSC command specified as you would type it on a command line. For example:

```
{
  "type": "runCommand",
  "parameters": {
    "command": "DEFINE CHANNEL(NEWSVRCONN) CHLTYPE(SVRCONN)"
  }
}
```

The response is returned in a plain text format.

- With a JSON formatted command, the body of the request contains an MQSC command in a JSON format. For example:

```
{
  "type": "runCommandJSON",
  "command": "define",
  "qualifier": "channel",
  "name": "NEWSVRCONN",
  "parameters": {
    "chltype": "svrconn"
  }
}
```

The response is returned in JSON format.

For more information about using the JSON formatted MQSC command, see [“POST - JSON formatted command” on page 2197](#).

You can use this REST API command with HTTP to run any MQSC command in plain text format.

On AIX, Linux, and Windows, this REST API command is similar to the [“MQCMD_ESCAPE \(Escape\) on Multiplatforms” on page 1181](#) PCF command.

On z/OS, this REST API command is similar to submitting commands directly to the command server:

- Messages are put to a request queue. These messages have MsgType set to MQMT_REQUEST, Format set to MQFMT_STRING or MQFMT_NONE, and the payload set to the text of an MQSC command.
- The command server running in the queue manager reads the messages, validates them, and passes the valid commands to the command processor.
- The command processor then executes the commands, and puts replies to the commands as messages on the reply-to queues that are specified in the incoming messages.
- [“Resource URL” on page 2192](#)
- [“Request headers” on page 2192](#)
- [“Request body format” on page 2192](#)
- [“Security requirements” on page 2193](#)
- [“Response status codes” on page 2193](#)
- [“Response headers” on page 2193](#)
- [“Response body format” on page 2194](#)

- [“Examples” on page 2194](#)

Resource URL

`https://host:port/ibmmq/rest/v2/admin/action/qmgr/qmgrName/mqsc`

qmgrName

Specifies the name of the queue manager on which to execute the command.

You can specify a remote queue manager as the **qmgrName**. If you specify a remote queue manager, you must configure a gateway queue manager. For more information, see [Remote administration using the REST API](#).

The queue manager name is case-sensitive.

If the queue manager name includes a forward slash, a period, or a percent sign, these characters must be URL encoded:

- A forward slash (/) must be encoded as %2F.
- A percent sign (%) must be encoded as %25.
- A period (.) must be encoded as %2E.

You can use HTTP instead of HTTPS if you enable HTTP connections. For more information about enabling HTTP, see [Configuring HTTP and HTTPS ports](#).

Request headers

The following headers must be sent with the request:

Content-Type

This header must be sent with a value of `application/json` optionally followed by `; charset=UTF-8`.

ibm-mq-rest-csrf-token

This header must be set, but the value can be anything, including being blank.

Authorization

This header must be sent if you are using basic authentication. For more information, see [Using HTTP basic authentication with the REST API](#).

The following headers can optionally be sent with the request:

ibm-mq-rest-gateway-qmgr

This header specifies the queue manager that is to be used as the gateway queue manager. The gateway queue manager is used to connect to a remote queue manager. For more information, see [Remote administration using the REST API](#).

Request body format

The request body must be in JSON format in UTF-8 encoding. Within the request body attributes are defined, and named JSON objects are created to specify extra attributes.

The following attributes can be included in the request body:

type

Required.

String.

Specifies the type of action to be performed.

runCommand

Specifies that a plain text MQSC command is to be executed

parameters

Required.

Nested JSON Object.

Specifies the parameters for the action.

This nested object contains only one attribute.

command

Required.

A valid plain text MQSC command to be executed.

For more information about the MQSC commands, see [“MQSC commands reference” on page 280](#).

Security requirements

The caller must be authenticated to the mqweb server and must be a member of one or more of the MQWebAdmin, MQWebAdminRO, or MQWebUser roles. For more information about security for the administrative REST API, see [IBM MQ Console and REST API security](#).

If token based security is used, the LTPA token that is used to authenticate the user must be provided with the request as a cookie. For more information about token-based authentication, see [Using token-based authentication with the REST API](#).

The security principal of the caller must be granted the ability to issue MQSC commands against the specified queue manager.

ALW On AIX, Linux, and Windows, you can grant authority to security principals to use IBM MQ resources by using the **setmqaut** command. For more information, see [setmqaut \(grant or revoke authority\)](#).

On z/OS, see [Setting up security on z/OS](#).

Response status codes

200

The specified command was passed successfully to the queue manager for processing.

400

Invalid data provided.

For example, an invalid MQSC command is specified.

401

Not authenticated.

The caller must be authenticated to the mqweb server and must be a member of one or more of the MQWebAdmin, MQWebAdminRO, or MQWebUser roles. The `ibm-mq-rest-csrf-token` header must also be specified.

403

Access prohibited for one of the following reasons:

- Not authorized. The caller is authenticated to the mqweb server and is associated with a valid principal. However, the principal does not have access to the required IBM MQ resources.
- **V9.4.0** Access prohibited in the current server environment. You cannot use the administrative REST API with the stand-alone IBM MQ Web Server.

404

Queue manager does not exist.

500

Server issue or error code from IBM MQ.

503

Queue manager not running.

Response headers

The following headers are returned with the response:

Content-Type

This header is returned with a value of `application/json;charset=utf-8`.

ibm-mq-rest-gateway-qmgr

This header is returned if a remote queue manager is specified in the resource URL. The value of this header is the name of the queue manager that is used as the gateway queue manager.

Response body format

If an error occurs, the response body contains an error message. For more information, see [REST API error handling](#).

The format of the response body is standardized, with a consistent JSON schema. However, the content is platform-dependent, reflecting the underlying mechanism for executing MQSC commands.

The response body has the following JSON structure:

```
{
  "commandResponse" : [
    {
      "completionCode" : number,
      "reasonCode" : number,
      "text" : [
        "string",
        ...
      ]
    },
    ...
  ]
  "overallCompletionCode" : number,
  "overallReasonCode" : number
}
```

The fields in the response have the following meanings:

commandResponse

A JSON array of JSON objects that represent individual responses from the execution of the command.

Each response contains the following data:

completionCode

The completion code that is associated with the operation.

reasonCode

The reason code that is associated with the operation.

text

A JSON array of strings that contain the response text that is associated with the operation for this instance. Note that embedded newlines are stripped from this text.

On AIX, Linux, and Windows, this field contains a single string that contains the response from the command, with any newlines escaped in the usual JSON manner.

On z/OS, this field contains multiple entries. For further information, see [Interpreting the reply messages from the command server](#).

overallCompletionCode

The completion code that is associated with the operation as a whole.

overallReasonCode

The reason code that is associated with the operation as a whole.

Examples

 The following sequence shows how to create a new server-connection channel that is called NEWSVRCONN on AIX, Linux, and Windows queue managers - our example queue manager is called QM_T1.

- First check that the channel does not exist. The following URL is used with the HTTP POST method:

```
https://localhost:9443/ibmmq/rest/v2/admin/action/qmgr/QM_T1/mqsc
```

The following JSON payload is sent:

```
{
  "type": "runCommand",
  "parameters": {
    "command": "DISPLAY CHANNEL(NEWSVRCONN)"
  }
}
```

A response code of 200 is returned, as the REST command succeeded. The response body that is returned contains the following JSON.

```
{
  "commandResponse": [
    {
      "completionCode": 2,
      "reasonCode": 2085,
      "text": [
        "AMQ8147: IBM MQ object NEWSVRCONN not found."
      ]
    }
  ],
  "overallCompletionCode": 2,
  "overallReasonCode": 3008
}
```

The individual response shows a reason code of 2085 (MQRC_UNKNOWN_OBJECT_NAME) and the MQSC command has an overall reason code of 3008 (MQRCCF_COMMAND_FAILED) as it failed to display the requested channel's details.

- Now create the channel. The same URL is used with the HTTP POST method:

```
https://localhost:9443/ibmmq/rest/v2/admin/action/qmgr/QM_T1/mqsc
```

The following JSON payload is sent:

```
{
  "type": "runCommand",
  "parameters": {
    "command": "DEFINE CHANNEL(NEWSVRCONN) CHLTYPE(SVRCONN)"
  }
}
```

A response code of 200 is returned, as the REST command succeeded. The response body that is returned contains the following JSON.

```
{
  "commandResponse": [
    {
      "completionCode": 0,
      "reasonCode": 0,
      "text": [
        "AMQ8014: IBM MQ channel created."
      ]
    }
  ],
  "overallCompletionCode": 0,
  "overallReasonCode": 0
}
```

- Finally, check that the channel does exist. Again the same URL is used with the HTTP POST method:

```
https://localhost:9443/ibmmq/rest/v2/admin/action/qmgr/QM_T1/mqsc
```

The following JSON payload is sent:

```
{
  "type": "runCommand",
  "parameters": {
```

```

    "command": "DISPLAY CHANNEL(NEWSVRCONN) ALL"
  }
}

```

A response code of 200 is returned, as the REST command succeeded. The response body that is returned contains the following JSON. The response body is edited for brevity after the CHLTYPE attribute.

```

{
  "commandResponse": [
    {
      "completionCode": 0,
      "reasonCode": 0,
      "text": [
        "AMQ8414: Display Channel details.    CHANNEL(NEWSVRCONN)
CHLTYPE(SVRCONN)"
      ]
    }
  ],
  "overallCompletionCode": 0,
  "overallReasonCode": 0
}

```

 The following sequence shows how to create a new server-connection channel that is called NEWSVRCONN on a z/OS queue manager - our example queue manager is called QM21.

- First check that the channel does not exist. The following URL is used with the HTTP POST method:

```
https://localhost:9443/ibmmq/rest/v2/admin/action/qmgr/QM21/mqsc
```

The following JSON payload is sent:

```

{
  "type": "runCommand",
  "parameters": {
    "command": "DISPLAY CHANNEL(NEWSVRCONN)"
  }
}

```

A response code of 200 is returned, as the REST command succeeded. The response body that is returned contains the following JSON.

```

{
  "commandResponse": [
    {
      "completionCode": 0,
      "reasonCode": 0,
      "text": [
        "CSQN205I    COUNT=          3, RETURN=00000000, REASON=00000000",
        "CSQM297I ]MQ21 CSQMDRTS NO CHANNEL FOUND MATCHING REQUEST CRITERIA ",
        "CSQ9022I ]MQ21 CSQMDRTS ' DISPLAY CHANNEL ' NORMAL COMPLETION "
      ]
    }
  ],
  "overallCompletionCode": 0,
  "overallReasonCode": 0
}

```

The completion and reason codes here are zero, as on z/OS the command is regarded as succeeding, although no matching channel was found.

- Now create the channel. The same URL is used with the HTTP POST method:

```
https://localhost:9443/ibmmq/rest/v2/admin/action/qmgr/QM21/mqsc
```

The following JSON payload is sent:

```

{
  "type": "runCommand",
  "parameters": {
    "command": "DEFINE CHANNEL(NEWSVRCONN) CHLTYPE(SVRCONN)"
  }
}

```

A response code of 200 is returned, as the REST command succeeded. The response body that is returned contains the following JSON.

```
{
  "commandResponse": [
    {
      "completionCode": 0,
      "reasonCode": 0,
      "text": [
        "CSQN205I  COUNT=          2, RETURN=00000000, REASON=00000000",
        "CSQ9022I ]MQ21 CSQMACHL ' DEFINE CHANNEL' NORMAL COMPLETION"
      ]
    }
  ],
  "overallCompletionCode": 0,
  "overallReasonCode": 0
}
```

- Finally, check that the channel does exist. Again the same URL is used with the HTTP POST method:

```
https://localhost:9443/ibmmq/rest/v2/admin/action/qmgr/QM21/mqsc
```

The following JSON payload is sent:

```
{
  "type": "runCommand",
  "parameters": {
    "command": "DISPLAY CHANNEL(NEWSVRCONN) ALL"
  }
}
```

A response code of 200 is returned, as the REST command succeeded. The response body that is returned contains the following JSON. The response body is edited for brevity after the TRPTYPE attribute.

```
{
  "commandResponse": [
    {
      "completionCode": 0,
      "reasonCode": 0,
      "text": [
        "CSQN205I  COUNT=          3, RETURN=00000000, REASON=00000000",
        "CSQM415I ]MQ21 CHANNEL(NEWSVRCONN          ) CHLTYPE(SVRCONN          ) QSGDISP(QMGR          )",
        "DEFCDISP(PRIVATE          ) TRPTYPE(LU62          )",
        "CSQ9022I ]MQ21 CSQMDRTS ' DISPLAY CHANNEL' NORMAL COMPLETION "
      ]
    }
  ],
  "overallCompletionCode": 0,
  "overallReasonCode": 0
}
```

POST - JSON formatted command

Use the HTTP POST method with this resource to submit administrative commands directly to a queue manager. These administrative commands are submitted in the body of the request, either as a plain text MQSC command, or as a JSON formatted command.

Note: **V9.4.0** You cannot use this resource with the stand-alone IBM MQ Web Server. For more information about the installation options for the IBM MQ component that runs the administrative REST API, see [The IBM MQ Console and REST API](#).

You can use the administrative REST API to submit an MQSC command by using the either a plain text MQSC command or with a JSON formatted command:

- With a plain text MQSC command, the body of the request contains an MQSC command specified as you would type it on a command line. For example:

```
{
  "type": "runCommand",
  "parameters": {
```

```
    "command": "DEFINE CHANNEL(NEWSVRCONN) CHLTYPE(SVRCONN)"
  }
}
```

The response is returned in a plain text format.

- With a JSON formatted command, the body of the request contains an MQSC command in a JSON format. For example:

```
{
  "type": "runCommandJSON",
  "command": "define",
  "qualifier": "channel",
  "name": "NEWSVRCONN",
  "parameters": {
    "chltype": "svrconn"
  }
}
```

The response is returned in JSON format.

For more information about using the plain text MQSC command, see [“POST - plain text MQSC command” on page 2191](#).

You can use this REST API command with HTTP to run any MQSC command. However, the following MQSC commands are not supported when you use a JSON formatted command in the request body:

- DISPLAY ARCHIVE
- DISPLAY CHINIT
- DISPLAY GROUP
- DISPLAY LOG
- DISPLAY SECURITY
- DISPLAY SYSTEM
- DISPLAY THREAD
- DISPLAY TRACE
- DISPLAY USAGE

On AIX, Linux, and Windows, this REST API command is similar to the [“MQCMD_ESCAPE \(Escape\) on Multiplatforms” on page 1181](#) PCF command.

On z/OS, this REST API command is similar to submitting commands directly to the command server:

- Messages are put to a request queue. These messages have `MsgType` set to `MQMT_REQUEST`, `Format` set to `MQFMT_STRING` or `MQFMT_NONE`, and the payload set to the text of an MQSC command.
- The command server running in the queue manager reads the messages, validates them, and passes the valid commands to the command processor.
- The command processor then executes the commands, and puts replies to the commands as messages on the reply-to queues that are specified in the incoming messages.
- [“Resource URL” on page 2199](#)
- [“Request headers” on page 2199](#)
- [“Request body format” on page 2199](#)
- [Security requirements](#)
- [Response status codes](#)
- [Response headers](#)
- [“Response body format” on page 2203](#)
- [“Examples” on page 2204](#)

Resource URL

`https://host:port/ibmmq/rest/v2/admin/action/qmgr/qmgrName/mqsc`

qmgrName

Specifies the name of the queue manager on which to execute the command.

You can specify a remote queue manager as the **qmgrName**. If you specify a remote queue manager, you must configure a gateway queue manager. For more information, see [Remote administration using the REST API](#).

The queue manager name is case-sensitive.

If the queue manager name includes a forward slash, a period, or a percent sign, these characters must be URL encoded:

- A forward slash (/) must be encoded as %2F.
- A percent sign (%) must be encoded as %25.
- A period (.) must be encoded as %2E.

You can use HTTP instead of HTTPS if you enable HTTP connections. For more information about enabling HTTP, see [Configuring HTTP and HTTPS ports](#).

Request headers

The following headers must be sent with the request:

Content-Type

This header must be sent with a value of `application/json` optionally followed by `; charset=UTF-8`.

ibm-mq-rest-csrf-token

This header must be set, but the value can be anything, including being blank.

Authorization

This header must be sent if you are using basic authentication. For more information, see [Using HTTP basic authentication with the REST API](#).

The following headers can optionally be sent with the request:

ibm-mq-rest-gateway-qmgr

This header specifies the queue manager that is to be used as the gateway queue manager. The gateway queue manager is used to connect to a remote queue manager. For more information, see [Remote administration using the REST API](#).

Request body format

The request body must be in JSON format in UTF-8 encoding. Within the request body attributes are defined, and named JSON objects are created to specify extra attributes. Any attributes that are not specified use the default value.

The following attributes can be included in the request body:

type

Required.

String.

Specifies the type of action to be performed.

runCommandJSON

Specifies that a JSON formatted MQSC command is to be executed

command

Required.

String.

Specifies the initial keyword of the MQSC command. The value can be any one of the following values:

- alter
- archive
- backup
- clear
- define
- delete
- display
- move
- ping
- purge
- recover
- refresh
- reset
- resolve
- resume
- rverify
- set
- start
- stop
- suspend

qualifier

String.

Specifies the secondary keyword in the MQSC command.

For example, for an **ALTER QLOCAL (qName)** command, the qualifier is **QLOCAL**.

name

Optional.

String.

Specifies the primary argument of the MQSC command.

For example, for an **ALTER QLOCAL (qName)** command, the name attribute is qName.

For some commands, this attribute is not required. For example, a **REFRESH SECURITY** command does not require a primary argument.

responseParameters

Optional.

String array.

Specifies which parameters are returned in the response to a request where the value of the command attribute is **DISPLAY**.

You can specify a value of ["all"] to return all applicable parameters for MQSC commands where the **all** parameter is supported.

parameters

Optional.

Nested JSON Object.

Specifies the parameters for the command in name and value pairs.

You can specify the parameters in any order, and in any case. Any double quotation marks or backslash characters used within a value must be escaped:

- A double quotation mark must be represented as \ "

- A backslash must be represented as \\

The name and value pairs are constructed based on the following mapping from the MQSC command:

name

The name part of the name and value pair is the same as the name of the MQSC parameter.

For example, the **TRIGTYPE** parameter on a **DEFINE QLOCAL** MQSC command maps to **"trigtype"** in the JSON format.

value

The value part of the name and value pair is the value that is used with the MQSC parameter. The JSON that is used to represent the value depends on the type of the value:

- For an MQSC value that is a string or an enumerated type, then the value used in the JSON format is a JSON string. For example:

```
"ch1type" : "SDR",
"descr" : "A String Description."
```

Unlike using plain-text MQSC, if the string is case-sensitive, or if it contains special characters, you do not need to enclose the string in single quotation marks.

- For an MQSC value that is an integer, then the value that is used in the JSON format is an integer. For example:

```
"maxmsgl" : 50000
```

- For an MQSC parameter that has no associated value, you must specify a value of YES if the attribute applies. For example, for **TRIGGER** on a local queue:

```
"trigger" : "yes"
```

You cannot specify `"trigger" : "no"`. Instead, you must use the attribute **NOTRIGGER**:

```
"nottrigger" : "yes"
```

Similarly, for the attribute **REPLACE**, you must specify the following string:

```
"replace" : "yes"
```

You cannot specify `"replace" : "no"`. To indicate that the MQ object should not be replaced, you must use the attribute **NOREPLACE**:

```
"noreplace" : "yes"
```

- For an MQSC value that is a list, then the value that is used in the JSON format is a JSON array. Each element in the array is a member of the list. A list with no members must be specified as an empty array. For example:

```
"msgexit" : ["exit1", "exit2", "exit3"],
"rcvexit" : []
```

The following MQSC attributes are lists:

- addrlist
- arcwrtc
- authadd
- authlist
- authrmv
- comphdr
- compmsg
- comprate

- comptime
- connopts
- exclmsg
- exittime
- logs
- msgdata
- msgexit
- names
- nettime
- nid, except on CONN commands
- openopts
- protocol, only on CHANNEL commands
- rcvdata
- rcvexit
- recip
- security, except on REFRESH commands
- senddata
- sendexit
- signer
- suiteb
- userid, only on TRACE commands
- userlist
- xbatchsz
- xqtime

Single quotation marks that are used in the value are automatically escaped. For example, a `descr` attribute with the value *single 'quotation' marks* is represented in the JSON request body as `"descr" : "single 'quotation' marks"`.

For examples of how to format the JSON request, see [“Examples” on page 2204](#)

For more information about the MQSC commands, see [“MQSC commands reference” on page 280](#).

Security requirements

The caller must be authenticated to the mqweb server and must be a member of one or more of the `MQWebAdmin`, `MQWebAdminRO`, or `MQWebUser` roles. For more information about security for the administrative REST API, see [IBM MQ Console and REST API security](#).

If token based security is used, the LTPA token that is used to authenticate the user must be provided with the request as a cookie. For more information about token-based authentication, see [Using token-based authentication with the REST API](#).

The security principal of the caller must be granted the ability to issue MQSC commands against the specified queue manager.

 On AIX, Linux, and Windows, you can grant authority to security principals to use IBM MQ resources by using the `setmqaut` command. For more information, see [setmqaut \(grant or revoke authority\)](#).

On z/OS, see [Setting up security on z/OS](#).

Response status codes

200

The specified command was passed successfully to the queue manager for processing.

400

Invalid data provided.

For example, an invalid MQSC command is specified.

401

Not authenticated.

The caller must be authenticated to the mqweb server and must be a member of one or more of the MQWebAdmin, MQWebAdminRO, or MQWebUser roles. The `ibm-mq-rest-csrf-token` header must also be specified.

403

Access prohibited for one of the following reasons:

- Not authorized. The caller is authenticated to the mqweb server and is associated with a valid principal. However, the principal does not have access to the required IBM MQ resources.
- **V9.4.0** Access prohibited in the current server environment. You cannot use the administrative REST API with the stand-alone IBM MQ Web Server.

404

Queue manager does not exist.

500

Server issue or error code from IBM MQ.

503

Queue manager not running.

Response headers

The following headers are returned with the response:

Content-Type

This header is returned with a value of `application/json;charset=utf-8`.

ibm-mq-rest-gateway-qmgr

This header is returned if a remote queue manager is specified in the resource URL. The value of this header is the name of the queue manager that is used as the gateway queue manager.

Response body format

If an error occurs, the response body contains an error message. For more information, see [REST API error handling](#).

The format of the response body is standardized, with a consistent JSON schema. However, the content is platform-dependent, reflecting the underlying mechanism for executing MQSC commands.

The response body has the following JSON structure:

```
{
  "commandResponse" : [
    {
      "completionCode" : number,
      "reasonCode" : number,
      "message" : [
        "string",
        ...
      ]
    },
    ...
  ]
  "overallCompletionCode" : number,
```

```
"overAllReasonCode" : number
}
```

The fields in the response have the following meanings:

commandResponse

A JSON array of JSON objects that represent individual responses from the execution of the command.

Each response contains the following data:

completionCode

The completion code that is associated with the operation.

reasonCode

The reason code that is associated with the operation.

message

A JSON array of strings that contain any messages that are returned.

parameters

If an IBM MQ object is returned by the request, this object returns name and value pairs that represent the IBM MQ object. For example, after a **DISPLAY QUEUE** command is sent, a local queue q0 is returned:

```
"parameters": {
  "queue": "q0",
  "type": "QLOCAL",
  "acctq": "QMGR",
  "altdat": "2018-07-16",
  ...
}
```

sourceQmgr

The queue manager from which the response was received.

This object is returned only if the queue manager that the command is issued to is in a queue sharing group and responses are received from other queue managers in the queue sharing group.

overallCompletionCode

The completion code that is associated with the operation as a whole.

overallReasonCode

The reason code that is associated with the operation as a whole.

Examples

- Define a local queue, Q1. The following URL is used with the HTTP POST method:

```
https://localhost:9443/ibmmq/rest/v2/admin/action/qmgr/QM1/mqsc
```

The following JSON payload is sent:

```
{
  "type": "runCommandJSON",
  "command": "define",
  "qualifier": "qlocal",
  "name": "Q1",
  "parameters": {
    "share": "yes",
    "trigdata": "lowercasetrigdata",
    "trigdpth": 7,
    "usage": "normal"
  }
}
```

A response code of 200 is returned, as the REST command succeeded. The response body that is returned contains the following JSON:

ALW

On AIX, Linux, and Windows:

```
{
  "commandResponse": [
    {
      "completionCode": 0,
      "message": ["AMQ8006I: IBM MQ queue created."],
      "reasonCode": 0
    }
  ],
  "overallCompletionCode": 0,
  "overallReasonCode": 0
}
```

z/OS

On z/OS:

```
{
  "commandResponse": [],
  "overallCompletionCode": 0,
  "overallReasonCode": 0
}
```

- Display the queue. The following URL is used with the HTTP POST method:

```
https://localhost:9443/ibmmq/rest/v2/admin/action/qmgr/QM1/mqsc
```

The following JSON payload is sent:

```
{
  "type": "runCommandJSON",
  "command": "display",
  "qualifier": "qlocal",
  "name": "Q1"
}
```

A response code of 200 is returned, as the REST command succeeded. The response body that is returned contains the following JSON:

```
{
  "commandResponse": [
    {
      "completionCode": 0,
      "parameters": {
        "acctq": "QMGR",
        "altdat": "2019-06-06",
        "alttime": "12.01.21",
        "boqname": "",
        "bothresh": 0,
        "clchname": "",
        "clusnl": "",
        "cluster": "xxxx",
        "clwlprty": 0,
        "clwlrank": 0,
        "clwluseq": "QMGR",
        "share": "YES",
        "trigtype": "FIRST",
        "type": "QLOCAL",
        "usage": "NORMAL"
      },
      "reasonCode": 0
    }
  ],
  "overallCompletionCode": 0,
  "overallReasonCode": 0
}
```

- Display all the queues on the queue manager, requesting that the `alttime` and `trigdpth` parameters are returned. The following URL is used with the HTTP POST method:

```
https://localhost:9443/ibmmq/rest/v2/admin/action/qmgr/QM1/mqsc
```

The following JSON payload is sent:

```
{
  "type": "runCommandJSON",
  "command": "display",
  "qualifier": "qlocal",
  "name": "*",
  "responseParameters": ["altime","trigdpth"]
}
```

A response code of 200 is returned, as the REST command succeeded. The response body that is returned contains the following JSON:

```
{
  "commandResponse": [
    {
      "completionCode": 0,
      "parameters": {
        "altime": "13.36.31",
        "queue": "Q0",
        "trigdpth": 1,
        "type": "QLOCAL"
      },
      "reasonCode": 0
    },
    {
      "completionCode": 0,
      "parameters": {
        "altime": "13.37.59",
        "queue": "Q1",
        "trigdpth": 7,
        "type": "QLOCAL"
      },
      "reasonCode": 0
    }
  ],
  "overallCompletionCode": 0,
  "overallReasonCode": 0
}
```

- ▶ **z/OS** On z/OS, display the local queue Q0, which is defined on both QMGR1 and QMGR2 in a queue sharing group. The following URL is used with the HTTP POST method:

```
https://localhost:9443/ibmmq/rest/v2/admin/action/qmgr/QMGR1/mqsc
```

The following JSON payload is sent:

```
{
  "type": "runCommandJSON",
  "command": "display",
  "qualifier": "qlocal",
  "name": "q0",
  "parameters": {
    "cmdscope": "*"
  }
}
```

A response code of 200 is returned, as the REST command succeeded. The response body that is returned contains the following JSON:

```
{
  "commandResponse": [
    {
      "completionCode": 0,
      "parameters": {
        "acctq": "QMGR",
        "altdat": "2019-01-21",
        "altime": "10.23.43",
        "boqname": "",
        "bothresh": 0,
        "cfstruct": "",
        "clchname": "",
        "clusnl": "",
        "cluster": "",
        "clwlprty": 0,

```

```

        "clwlrank": 0,
        "clwluseq": "QMGR",
        ...
        "trigtype": "FIRST",
        "type": "QLOCAL",
        "usage": "NORMAL"
    },
    "reasonCode": 4,
    "sourceQmgr": "QMGR1"
},
{
    "completionCode": 0,
    "parameters": {
        "acctq": "QMGR",
        "altdat": "2019-03-19",
        "alttime": "13.05.02",
        "boqname": "",
        "bothresh": 0,
        "cfstruct": "",
        "clchname": "",
        "clusnl": "",
        "cluster": "",
        "clwlprty": 0,
        "clwlrank": 0,
        ...
        "trigtype": "FIRST",
        "type": "QLOCAL",
        "usage": "NORMAL"
    },
    "reasonCode": 4,
    "sourceQmgr": "QMGR2"
}
],
"overallCompletionCode": 0,
"overallReasonCode": 0
}

```

- Example of using the **where** parameter:

```

{
  "type": "runCommandJSON",
  "command": "DISPLAY",
  "qualifier": "CHSTATUS",
  "name": "*",
  "parameters": {
    "where": "CHLTYPE EQ RCVR"
  }
}

```

The response body that is returned contains the following JSON:

```

{
  "commandResponse": [{
    "completionCode": 0,
    "reasonCode": 0,
    "parameters": {
      "current": "YES",
      "stopreq": "NO",
      "substate": "RECEIVE",
      "rqmname": "MQBB",
      "chldisp": "PRIVATE",
      "chltype": "RCVR",
      "conname": "192.168.0.1",
      "chstatus": "MQAA.TO.MQBB",
      "status": "RUNNING"
    }
  }],
  "overallReasonCode": 0,
  "overallCompletionCode": 0
}

```

/admin/installation

You can use the HTTP GET method with the installation resource to request information about installations.

You cannot use the administrative REST API gateway with this resource URL.

GET

Use the HTTP GET method with the `installation` resource to request information about the installation that the administrative REST API runs in.

The information that is returned is similar to the information that is returned by the [“dspmqver \(display version information\)”](#) on page 104 control command.

- [Resource URL](#)
- [Optional query parameters](#)
- [“Request headers”](#) on page 2209
- [Request body format](#)
- [“Security requirements”](#) on page 2209
- [Response status codes](#)
- [“Response headers”](#) on page 2210
- [Response body format](#)
- [Examples](#)

Resource URL

`https://host:port/ibmmq/rest/v2/admin/installation/{installationName}`

installationName

Optionally specifies the name of the installation to query. This name must be the name of the installation that the REST API is running in.

You can use HTTP instead of HTTPS if you enable HTTP connections. For more information about enabling HTTP, see [Configuring HTTP and HTTPS ports](#).

Optional query parameters

`attributes={extended|*|extended.attributeName,...}`

extended

Specifies that all extended attributes are returned.

*

Specifies all attributes. This parameter is equivalent to **extended**.

extended.attributeName,...

Specifies a comma-separated list of extended attributes to return:

level

String.

IBM MQ build level.

operatingSystem

  This attribute is only available on z/OS, AIX, Linux, and Windows.

String.

Full descriptive text of the operating system.

description

 This attribute is only available on AIX, Linux, and Windows.

String.

Installation description.

installationPath

 This attribute is only available on AIX, Linux, and Windows.

String.

The path to the installation.

dataPath

 This attribute is only available on AIX, Linux, and Windows.

String.

The path to where the data for the installation is stored.

maximumCommandLevel

  This attribute is only available on the IBM MQ Appliance, AIX, Linux, and Windows.

Integer.

Maximum command level that is supported.

primary

 This attribute is only available on AIX, Linux, and Windows.

Boolean.

Primary installation status.

Request headers

The following headers must be sent with the request:

Authorization

This header must be sent if you are using basic authentication. For more information, see [Using HTTP basic authentication with the REST API](#).

Request body format

None.

Security requirements

The caller must be authenticated to the mqweb server and must be a member of one or more of the MQWebAdmin, MQWebAdminRO, or MQWebUser roles. For more information about security for the administrative REST API, see [IBM MQ Console and REST API security](#).

If token based security is used, the LTPA token that is used to authenticate the user must be provided with the request as a cookie. For more information about token-based authentication, see [Using token-based authentication with the REST API](#).

There are no specific authorization requirements for an HTTP GET on the `installation` resource.

Response status codes

200

Installation information retrieved successfully.

400

Invalid data provided.

For example, invalid installation attributes specified.

401

Not authenticated.

The caller must be authenticated to the mqweb server and must be a member of one or more of the MQWebAdmin, MQWebAdminRO, or MQWebUser roles. For more information, see [“Security requirements” on page 2209](#).

404

Installation does not exist.

500

Server issue or error code from IBM MQ.

Response headers

The following headers are returned with the response:

Content-Type

This header is returned with a value of `application/json; charset=utf-8`.

Response body format

The response is in JSON format in UTF-8 encoding. The response contains an outer JSON object that contains a single JSON array called `installation`. Each element in the array is a JSON object that represents information about an installation. Each JSON object contains the following attributes:

name

 This attribute is only available on AIX, Linux, and Windows.

String.

The installation name.

version

String.

The version of IBM MQ for the installation.

platform

String.

One of the following values:

- appliance
- ibm-i
- unix
- windows
- z/os

extended

JSON object.

If requested, contains one or more of the following extra properties:

level

String.

IBM MQ build level.

operatingSystem

  This attribute is only available on z/OS, AIX, Linux, and Windows.

String.

Full descriptive text of the operating system.

description

 This attribute is only available on AIX, Linux, and Windows.

String.

Installation description.

installationPath

 This attribute is only available on AIX, Linux, and Windows.

String.

The path to the installation.

dataPath

 This attribute is only available on AIX, Linux, and Windows.

String.

The path to where the data for the installation is stored.

maximumCommandLevel

  This attribute is only available on the IBM MQ Appliance, AIX, Linux, and Windows.

Integer.

Maximum command level that is supported.

primary

 This attribute is only available on AIX, Linux, and Windows.

Boolean.

Primary installation status.

If an error occurs, the response body contains an error message. For more information, see [REST API error handling](#).

Examples for AIX, Linux, and Windows

- The following example gets basic information about the installation that the REST API is running in. The following URL is used with the HTTP GET method:

```
https://localhost:9443/ibmmq/rest/v2/admin/installation
```

The following JSON response is returned:

```
{
  "installation":
  [
    {
      "name": "Installation1",
      "platform": "windows",
      "version": "9.1.0.0"
    }
  ]
}
```

- The following example gets extended information about the installation Installation1. The following URL is used with the HTTP GET method:

```
https://localhost:9443/ibmmq/rest/v2/admin/installation/Installation1?attributes=*
```

The following JSON response is returned:

```
{
  "installation":
  [
    {
      "extended": {
        "dataPath": "C:\\Program Files (x86)\\IBM\\WebSphere MQ",
        "description": "My MQ installation",
        "installationPath": "C:\\Program Files\\IBM\\WebSphere MQ",
        "level": "p910-L180501",
        "maximumCommandLevel": 910,
        "operatingSystem": "Windows 7 Professional x64 Edition, Build 7601: SP1",
        "primary": true
      },
      "name": "Installation1",
      "platform": "windows",
      "version": "9.1.0.0"
    }
  ]
}
```

- The following example gets the installation path for Installation1. The following URL is used with the HTTP GET method:

```
https://localhost:9443/ibmmq/rest/v2/admin/installation/Installation1?attributes=extended.installationPath
```

The following JSON response is returned:

```
{
  "installation": [{
    "extended": {
      "installationPath": "C:\\Program Files\\IBM\\MQ"
    },
    "name": "Installation1",
    "platform": "windows",
    "version": "9.1.0.0"
  }]
}
```

Examples for z/OS

z/OS

- The following example gets basic information about the installation. The following URL is used with the HTTP GET method:

```
https://REST.example.com:9443/ibmmq/rest/v2/admin/installation
```

The following JSON response is returned:

```
{
  "installation": [{
    "platform": "z/os",
    "version": "9.1.0"
  }]
}
```

- The following example gets extended information about the installation. The following URL is used with the HTTP GET method:

```
https://REST.example.com:9443/ibmmq/rest/v2/admin/installation?attributes=extended
```

The following JSON response is returned:

```
{
  "installation": [{
    "extended": {
      "level": "V910-L180501",
      "operatingSystem": "z/OS 01.00 02"
    },
    "platform": "z/os",
    "version": "9.1.0"
  }]
}
```

/login

You can use the HTTP GET method together with the `login` resource to get information about the user that is logged in to the REST API. You can use the HTTP POST method to log in a user and get an LTPA token. You can use the HTTP DELETE method to log out a user and end the session.

POST

Use the HTTP POST method with the `login` resource to log in a user and start a token-based authentication session for the REST API. An LTPA token is returned for the user to authenticate further REST requests.

For more information about how to use token based authentication, see [Using token based authentication with the REST API](#).

- [Resource URL](#)
- [Optional query parameters](#)
- [“Request headers” on page 2213](#)
- [Request body format](#)
- [Response status codes](#)
- [“Response headers” on page 2214](#)
- [Response body format](#)
- [Examples](#)

Resource URL

`https://host:port/ibmmq/rest/v2/login`

Optional query parameters

None.

Request headers

The following headers must be sent with the request:

Content-Type

This header must be sent with a value of `application/json` optionally followed by `; charset=UTF-8`.

Request body format

The request body must be in JSON format in UTF-8 encoding. Within the request body attributes are defined. The following attributes can be included in the request body:

username

String.

Specifies the user name to authenticate with.

The user name that is specified must be defined within the mqweb server user registry, and must be a member of one or more of the `MQWebAdmin`, `MQWebAdminRO`, or `MQWebUser` roles. This user name is case sensitive.

Note: If the user name specified has the `MQWebUser` role, ensure that the user name has the same case in the user registry as on the IBM MQ system. For example, if the user ID is defined on the IBM MQ system in uppercase, it must be defined in the registry in uppercase. If the user name is specified in different cases, the user might be authenticated by the REST API, but might not be authorized to use IBM MQ resources.

password

String.

Specifies the password of the user that is specified by the **username** attribute.

Response status codes**204**

User logged in successfully.

400

Invalid data provided.

For example, an integer value is specified for the user name.

401

Not authenticated.

An invalid user name or password was provided.

500

Server issue or error code from IBM MQ.

Response headers

None.

Response body format

The response body is empty if the login is successful. If an error occurs, the response body contains an error message. For more information, see [REST API error handling](#).

An LTPA security token is returned in a cookie with a successful login. This token is used to authenticate all further REST requests. By default on z/OS, AIX, Linux, and Windows, the cookie name starts with the prefix `LtpaToken2`, but the name can be changed by setting the **LtpaCookieName** property with the **setmqweb** command. For more information, see [Configuring the LTPA token](#). On the IBM MQ Appliance, the LTPA token cookie name is `LtpaToken2`.

Examples

The following example logs in a user called `mqadmin` with the password `mqadmin`. The following URL is used with the HTTP POST method:

```
https://localhost:9443/ibmmq/rest/v2/login
```

The following JSON payload is sent:

```
{
  "username" : "mqadmin",
  "password" : "mqadmin"
}
```

In cURL, the log in request might look like the following Windows example. The LTPA token is stored in the `cookiejar.txt` file by using the `-c` flag:

```
curl -k "https://localhost:9443/ibmmq/rest/v2/login" -X POST
-H "Content-Type: application/json" --data
"{\"username\": \"mqadmin\", \"password\": \"mqadmin\"}"
-c c:\cookiejar.txt
```

After the user is logged in, the LTPA token and `ibm-mq-rest-csrf-token` HTTP header are used to authenticate further requests. For example, to create a local queue, `Q1`, the following cURL might be used. The LTPA token is retrieved from the `cookiejar.txt` file by using the `-b` flag. The contents of the `ibm-mq-rest-csrf-token` HTTP header can be anything including blank.

```
curl -k "https://localhost:9443/ibmmq/rest/v2/admin/qmgr/QM1/queue" -X POST
-b c:\cookiejar.txt
-H "ibm-mq-rest-csrf-token: value" -H "Content-Type: application/json"
--data '{"name\":"Q1\"}'
```

GET

Use the HTTP GET method with the `login` resource to request information about the user that is authenticated with the REST API.

- [Resource URL](#)
- [Optional query parameters](#)
- [“Request headers” on page 2215](#)
- [Request body format](#)
- [“Security requirements” on page 2215](#)
- [Response status codes](#)
- [“Response headers” on page 2216](#)
- [Response body format](#)
- [Examples](#)

Resource URL

`https://host:port/ibmmq/rest/v2/login`

Optional query parameters

None.

Request headers

The following headers must be sent with the request:

Authorization

This header must be sent if you are using basic authentication. For more information, see [Using HTTP basic authentication with the REST API](#).

Request body format

None.

Security requirements

The request must be authenticated by using one of the following authentication mechanisms:

- For HTTP basic authentication, you must provide the user name and password to authenticate. For more information, see [Using HTTP basic authentication with the REST API](#).
- For token based authentication, you must provide the LTPA token to authenticate. For more information, see [Using token based authentication with the REST API](#).
- For client certificate authentication, you must provide the client certificate to authenticate. For more information, see [Using client certificate authentication with the REST API](#).

Response status codes

200

User queried successfully.

400

Invalid data provided.

401

Not authenticated.
An invalid credential was provided.

404

Resource was not found.

500

Server issue or error code from IBM MQ.

Response headers

The following headers are returned with the response:

Content-Type

This header is returned with a value of `application/json; charset=utf-8`.

Response body format

The response is in JSON format in UTF-8 encoding. The response contains an outer JSON object that contains a single JSON array called `user`. This array contains the following attributes:

name

String.

Specifies the name of the user that is used to check for authorization.

This name might be different from the credentials that are specified using, for example, LDAP user mapping or client certificate user mapping.

role

JSON array.

Specifies which roles the user is granted.

The value is one or more of the following values:

- `MQWebAdmin`
- `MQWebAdminRO`
- `MQWebUser`

Examples

The following example queries the user. The following URL is used with the HTTP GET method:

```
https://localhost:9443/ibmmq/rest/v2/login
```

The following JSON response is returned:

```
{
  "user" :
  [ {
    "name" : "reader",
    "role" : [
      "MQWebAdminRO",
      "MQWebUser"
    ]
  } ]
}
```

In cURL, the log in query might look like the following Windows example that uses token based authentication. The LTPA token is retrieved from the `cookiejar.txt` file by using the `-b` flag:

```
curl -k "https://localhost:9443/ibmmq/rest/v2/login" -X GET
-b c:\cookiejar.txt
```

DELETE

Use the HTTP DELETE method with the `login` resource to log out a user and end a token-based authentication session for the REST API.

For more information about how to use token based authentication, see [Using token based authentication with the REST API](#).

- [Resource URL](#)
- [Optional query parameters](#)
- [“Request headers” on page 2217](#)
- [Request body format](#)
- [“Security requirements” on page 2217](#)
- [Response status codes](#)
- [“Response headers” on page 2218](#)
- [Response body format](#)
- [Examples](#)

Resource URL

`https://host:port/ibmmq/rest/v2/login`

Optional query parameters

None.

Request headers

The following headers must be sent with the request:

ibm-mq-rest-csrf-token

This header must be set, but the value can be anything, including being blank.

Request body format

None.

Security requirements

The LTPA token that is used to authenticate the user must be provided with the request as a cookie. By default, this token starts with the prefix `LtpaToken2`.

With the response to the REST request, an instruction to delete the LTPA token from the local cookie store is included. Ensure that you process this instruction. If the instruction is not processed, and the LTPA token remains in the local cookie store, then the LTPA token can be used to authenticate future REST requests. That is, when the user attempts to authenticate with the LTPA token after the session is ended, a new session is created that uses the existing token.

Response status codes

204

User logged out successfully.

400

Invalid data provided.

401

Not authenticated.

An invalid LTPA token was provided, or the `ibm-mq-rest-csrf-token` header was missing.

404

Resource was not found.

500

Server issue or error code from IBM MQ.

Response headers

None.

Response body format

The response body is empty if the logout is successful. If an error occurs, the response body contains an error message. For more information, see [REST API error handling](#).

Examples

The following cURL example for Windows logs out a user.

The LTPA token is retrieved from the `cookiejar.txt` file by using the `-b` flag. CSRF protection is provided by the presence of the `ibm-mq-rest-csrf-token` HTTP header. The location of the `cookiejar.txt` file is specified by the `-c` flag so that the LTPA token is deleted from the file:

```
curl -k "https://localhost:9443/ibmmq/rest/v2/login" -X DELETE
-H "ibm-mq-rest-csrf-token: value" -b c:\cookiejar.txt
-c c:\cookiejar.txt
```

/admin/qmgr

You can use the HTTP GET method with the `qmgr` resource to request information about queue managers, including status information.

Note: **V9.4.0** You cannot use this resource with the stand-alone IBM MQ Web Server. For more information about the installation options for the IBM MQ component that runs the administrative REST API, see [The IBM MQ Console and REST API](#).

You can use the administrative REST API gateway with this resource URL.

For more information about the PCF equivalents to the queue manager REST API parameters and attributes, see [“REST API and PCF equivalents for queue managers” on page 2410](#).

GET

Use the HTTP GET method with the `qmgr` resource to request basic information and status information about queue managers.

Note: **V9.4.0** You cannot use this resource with the stand-alone IBM MQ Web Server. For more information about the installation options for the IBM MQ component that runs the administrative REST API, see [The IBM MQ Console and REST API](#).

The information that is returned is similar to the information that is returned by the `dspmq (display queue managers)` on page 73 control command, the **DISPLAY QMSTATUS** MQSC command, and the **Inquire Queue Manager Status** PCF command. You can also obtain status for high availability (HA) and disaster recovery (DR) configurations on the IBM MQ Appliance as returned by the `dspmq -o HA` and `dspmq -o DR` commands. For more information, see `dspmq (display queue managers)` in the IBM MQ Appliance documentation.

- [Resource URL](#)
- [Optional query parameters](#)
- [“Request headers” on page 2221](#)
- [Request body format](#)

- [“Security requirements” on page 2221](#)
- [Response status codes](#)
- [“Response headers” on page 2222](#)
- [Response body format](#)
- [Examples](#)

Resource URL

`https://host:port/ibmmq/rest/v2/admin/qmgr/{qmgrName}`

qmgrName

Optionally specifies the name of the queue manager to query.

You can specify a remote queue manager as the **qmgrName**. If you specify a remote queue manager, you must configure a gateway queue manager. For more information, see [Remote administration using the REST API](#).

If you specify a remote queue manager, only the following attributes are returned:

- name
- started
- channelInitiatorState
- ldapConnectionState
- connectionCount
- publishSubscribeState

The queue manager name is case-sensitive.

If the queue manager name includes a forward slash, a period, or a percent sign, these characters must be URL encoded:

- A forward slash (/) must be encoded as %2F.
- A percent sign (%) must be encoded as %25.
- A period (.) must be encoded as %2E.

You can use HTTP instead of HTTPS if you enable HTTP connections. For more information about enabling HTTP, see [Configuring HTTP and HTTPS ports](#).

Optional query parameters

attributes={extended}|*|extended.attributeName,...}

 This parameter is only available on the IBM MQ Appliance, AIX, Linux, and Windows.

This parameter is not valid if you specify a remote queue manager in the resource URL.

extended

Specifies that all extended attributes are retrieved.

*

Specifies all attributes. This parameter is equivalent to **extended**.

extended.attributeName,...

Specifies a comma-separated list of extended attributes to return.

For example, to return the `installationName` attribute, specify `extended.installationName`.

For a full list of extended attributes, see [Extended attributes for queue managers](#).

status={status|*|status.attributeName,...}

status

Specifies that all status attributes are returned.

Specifies all attributes. This parameter is equivalent to **status**.

status.attributeName,...

Specifies a comma-separated list of queue manager status attributes to return.

The queue manager must be running to return the status attributes.

For example, to return the `connectionCount` attribute, specify `status.connectionCount`.

For a full list of status attributes, see [Status attributes for queue managers](#).

state=state

Specifies that only queue managers with the specified state are returned. The following values are valid values:

On all platforms:

- running
- ended

 On AIX, Linux, and Windows:

- endedImmediately
- endedPreemptively
- endedUnexpectedly
- starting
- quiescing
- endingImmediately
- endingPreemptively
- beingDeleted
- stateNotAvailable
- runningAsStandby
- runningElsewhere

You can specify the `state=state` optional query parameter only if you do not specify a queue manager name within the resource URL. That is, you cannot request information about a specific queue manager in a specific state.

 **ha={*|ha|attributeName,...}**

Specifies that HA information is returned for HA queue managers. You can specify that all HA attributes are returned (* or ha), or specify particular attributes (one or more of `ha.type`, `ha.floatingIPAddress`, and `ha.floatingIPInterface`). You can combine DR attributes with any other attributes of the `qmgr` resource.

If you specify this attribute on a platform other than IBM MQ Appliance, the response is bad request 400.

 **dr={*|dr|attributeName,...}**

Specifies that DR information is returned for DR queue managers. You can specify that all DR attributes are returned (* or dr), or specify particular attributes (`dr.replicationPort` or `dr.remoteIPAddress`). You can combine DR attributes with any other attributes of the `qmgr` resource.

If you specify this attribute on a platform other than IBM MQ Appliance, the response is bad request 400.

Request headers

The following headers must be sent with the request:

Authorization

This header must be sent if you are using basic authentication. For more information, see [Using HTTP basic authentication with the REST API](#).

The following headers can optionally be sent with the request:

ibm-mq-rest-gateway-qmgr

This header specifies the queue manager that is to be used as the gateway queue manager. The gateway queue manager is used to connect to a remote queue manager. For more information, see [Remote administration using the REST API](#).

Request body format

None.

Security requirements

The caller must be authenticated to the mqweb server and must be a member of one or more of the MQWebAdmin, MQWebAdminRO, or MQWebUser roles. For more information about security for the administrative REST API, see [IBM MQ Console and REST API security](#).

If token based security is used, the LTPA token that is used to authenticate the user must be provided with the request as a cookie. For more information about token-based authentication, see [Using token-based authentication with the REST API](#).

When the **status** optional query parameter is specified, the ability to issue certain PCF commands is required. If only a subset of the status attributes is to be returned, only the permissions for the corresponding PCF commands are required. The security principal of the caller must be granted the ability to issue the following PCF commands for the specified queue manager:

-   On the IBM MQ Appliance, AIX, Linux, and Windows:
 - To return the started, channelInitiatorState, ldapConnectionState, or connectionCount attributes, authority to issue the **MQCMD_INQUIRE_Q_MGR_STATUS** PCF command must be granted.
 - To return the publishSubscribeState attribute, authority to issue the **MQCMD_INQUIRE_PUBSUB_STATUS** PCF command must be granted.
-  On z/OS:
 - To return the started attribute, authority to issue the **MQCMD_INQUIRE_LOG** PCF command must be granted.
 - To return the channelInitiatorState attribute, authority to issue the **MQCMD_INQUIRE_CHANNEL_INIT** PCF command must be granted.
 - To return the connectionCount attribute, authority to issue the **MQCMD_INQUIRE_CONNECTION** PCF command must be granted.
 - To return the publishSubscribeState attribute, authority to issue the **MQCMD_INQUIRE_PUBSUB_STATUS** PCF command must be granted.

 On AIX, Linux, and Windows, you can grant authority to security principals to use IBM MQ resources by using the **setmqaut** command. For more information, see [setmqaut \(grant or revoke authority\)](#).

On z/OS, see [Setting up security on z/OS](#).

Response status codes

200

Queue manager information retrieved successfully.

400

Invalid data provided.

For example, invalid queue manager specified.

401

Not authenticated.

The caller must be authenticated to the mqweb server and must be a member of one or more of the MQWebAdmin, MQWebAdminRO, or MQWebUser1 roles. For more information, see [“Security requirements” on page 2221](#).

403

Access prohibited for one of the following reasons:

- Not authorized. The caller is authenticated to the mqweb server and is associated with a valid principal. However, the principal does not have access to the required IBM MQ resources. For more information about the access that is required, see [“Security requirements” on page 2221](#).
- **V9.4.0** Access prohibited in the current server environment. You cannot use the administrative REST API with the stand-alone IBM MQ Web Server.

404

Queue manager does not exist.

500

Server issue or error code from IBM MQ.

Response headers

The following headers are returned with the response:

Content-Type

This header is returned with a value of `application/json; charset=utf-8`.

ibm-mq-rest-gateway-qmgr

This header is returned if a remote queue manager is specified in the resource URL. The value of this header is the name of the queue manager that is used as the gateway queue manager.

Response body format

The response is in JSON format in UTF-8 encoding. The response contains an outer JSON object that contains a single JSON array called `qmgr`. Each element in the array is a JSON object that represents information about a queue manager. Each JSON object contains the following attributes:

name

String.

The queue manager name.

state

String.

This attribute is not returned if the queue manager that is specified in the resource URL is a remote queue manager.

One of the following values:

On all platforms:

- running
- ended

ALW

On AIX, Linux, and Windows:

- endedImmediately
- endedPreemptively
- endedUnexpectedly
- starting
- quiescing
- endingImmediately
- endingPreemptively
- beingDeleted
- stateNotAvailable
- runningAsStandby
- runningElsewhere

The following objects can be included in the JSON object that represents information about a queue manager. Which objects and attributes are returned depends on the URL that was specified for the request:

status

Contains attributes that are related to status information for the queue manager.

extended

MQ Appliance

ALW

These attributes are only available on the IBM MQ Appliance, AIX, Linux, and Windows.

These attributes are not returned if the queue manager that is specified in the resource URL is a remote queue manager.

Contains extended attributes.

ha

MQ Appliance

These attributes are only available on the IBM MQ Appliance.

Contains high availability attributes.

dr

MQ Appliance

These attributes are only available on the IBM MQ Appliance.

Contains disaster recovery attributes.

For more information, see [“Response body attributes for queue managers”](#) on page 2226.

If an error occurs, the response body contains an error message. For more information, see [REST API error handling](#).

Examples for AIX, Linux, and Windows

ALW

- The following example gets basic information about all queue managers. The following URL is used with the HTTP GET method:

```
https://localhost:9443/ibmmq/rest/v2/admin/qmgr
```

The following JSON response is returned:

```
{
  "qmgr": [
    {
      "name": "QM_T1",
      "state": "endedImmediately"
    },
    {
      "name": "RESTQM0",
      "state": "endedUnexpectedly"
    }
  ]
}
```

```
}
  {}]
}
```

- The following example gets extended information about the queue manager QM_T1. The following URL is used with the HTTP GET method:

```
https://localhost:9443/ibmmq/rest/v2/admin/qmgr/QM_T1?attributes=extended
```

The following JSON response is returned:

```
{
  "qmgr": [{
    "extended": {
      "installationName": "Installation1",
      "isDefaultQmgr": false,
      "permitStandby": "notApplicable"
    },
    "name": "QM_T1",
    "state": "endedImmediately"
  }]
}
```

- The following example gets specific information about all queue managers. The following URL is used with the HTTP GET method:

```
https://localhost:9443/ibmmq/rest/v2/admin/qmgr?attributes=extended.permitStandby
```

The following JSON response is returned:

```
{
  "qmgr": [{
    "extended": {
      "permitStandby": "notApplicable"
    },
    "name": "QM_T1",
    "state": "endedImmediately"
  }, {
    "extended": {
      "permitStandby": "notApplicable"
    },
    "name": "RESTQM0",
    "state": "endedUnexpectedly"
  }]
}
```

- The following example gets status for the queue manager QM1. The following URL is used with the HTTP GET method:

```
http://localhost:9443/ibmmq/rest/v2/admin/qmgr/QM1?status=*
```

The following JSON response is returned:

```
{
  "qmgr":
  [{
    "name": "QM1",
    "state": "running",
    "status":
    {
      "started": "2016-11-08T11:02:29.000Z",
      "channelInitiatorState": "running",
      "ldapConnectionState": "disconnected",
      "connectionCount": 23,
      "publishSubscribeState": "running"
    }
  }]
}
```

Examples for IBM MQ Appliance

[MQ Appliance](#)

- The following example gets HA information from all queue managers on the appliance. The following URL is used with the HTTP GET method:

```
https://appliance.example.com:5554/ibmmq/rest/v2/admin/qmgr/?ha=*
```

In the example configuration, there is one HA queue manager named HAQM1. The following JSON response is returned:

```
{
  "qmgr": [
    {
      "name": "HAQM1",
      "ha": {
        "floatingIPAddress": "172.20.37.16",
        "floatingIPInterface": "eth22",
        "type": "replicated"
      },
      "state": "endedImmediately"
    }
  ]
}
```

- The following example gets DR information from all queue managers on the appliance. The following URL is used with the HTTP GET method:

```
https://appliance.example.com:5554/ibmmq/rest/v2/admin/qmgr/?dr=*
```

In the example configuration, there is one DR queue manager named DRQM1. The following JSON response is returned:

```
{
  "qmgr": [
    {
      "name": "DRQM1",
      "state": "endedUnexpectedly",
      "dr": {
        "remoteIPAddress": [
          "172.20.39.0"
        ],
        "replicationPort": 1419
      }
    }
  ]
}
```

- The following example gets extended information about the queue manager QM1. The following URL is used with the HTTP GET method:

```
https://appliance.example.com:5554/ibmmq/rest/v2/admin/qmgr/QM1?attributes=extended
```

The following JSON response is returned:

```
{
  "qmgr": [{
    "extended": {
      "installationName": "MQAppliance",
      "isDefaultQmgr": false,
      "encryptedFileSystem": "yes"
    },
    "name": "QM1",
    "state": "endedImmediately"
  }]
}
```

Examples for z/OS

- The following example gets basic information about all queue managers. The following URL is used with the HTTP GET method:

```
https://REST.example.com:9443/ibmmq/rest/v2/admin/qmgr
```

The following JSON response is returned:

```
{
  "qmgr": [{
    "name": "MQ5B",
    "state": "ended"
  }]
}
```

Response body attributes for queue managers

When you use the HTTP GET method with the `qmgr` object to request information about queue managers, the following attributes are returned within named JSON objects.

The following objects are available:

- [“status” on page 2226](#)
- [“extended” on page 2227](#)
- [“ha” on page 2228](#)
- [“dr” on page 2228](#)

For more information about the PCF equivalents to the queue manager REST API parameters and attributes, see [“REST API and PCF equivalents for queue managers” on page 2410](#).

status

The status object contains status information about queue managers:

started

String.

Specifies the date and time at which the queue manager was started.

For more information about the time stamp format that is used to return the date and time, see [REST API time stamps](#).

channelInitiatorState

String.

Specifies the current state of the channel initiator.

On all platforms, the value is one of the following values:

- stopped
- running

  On the IBM MQ Appliance, AIX, Linux, and Windows, the value can also be one of the following values:

- starting
- stopping

 On z/OS, the value can also be one of the following values:

- unknown

This value indicates that the channel initiator did not return a response to the status request. The channel initiator might be running, but busy. Retry the request after a short time to resolve the issue.

ldapConnectionState

  This attribute is only available on the IBM MQ Appliance, AIX, Linux, and Windows.

String.

Specifies the current state of the connection to the LDAP server.

The value is one of the following values:

- connected
- error
- disconnected

connectionCount

Integer.

Specifies the current number of connections to the queue manager.

On z/OS, this attribute includes threads that might be disassociated from a connection, together with connections that are in-doubt and connections where external intervention is required.

publishSubscribeState

String.

Specifies the current state of the publish/subscribe engine of the queue manager.

The value is one of the following values:

stopped

Specifies that the publish/subscribe engine, and the queued publish/subscribe interface is not running.

starting

Specifies that the publish/subscribe engine is initializing.

running

Specifies that the publish/subscribe engine, and the queued publish/subscribe interface are running.

compatibility

Specifies that the publish/subscribe engine is running, but that the publish/subscribe interface is not running. Therefore, it is possible to publish or subscribe by using the application programming interface. However, any message that is put to the queues that are monitored by the queued publish/subscribe interface are not acted upon.

error

The publish/subscribe engine failed.

stopping

The publish/subscribe engine is stopping.

extended

  This object is only available on the IBM MQ Appliance, AIX, Linux, and Windows. This object is not returned if the queue manager that is specified in the resource URL is a remote queue manager. The extended object contains extended information about queue managers:

isDefaultQmgr

Boolean.

Specifies whether the queue manager is the default queue manager.

The value is `true` if the queue manager is the default queue manager.

permitStandby

 This attribute is only available on AIX, Linux, and Windows.

String.

Specifies the permissible standby state.

The value can be one of the following values:

- permitted
- notPermitted
- notApplicable

installationName

String.

Specifies the name of the installation that the queue manager is associated with.

encryptedFileSystem

This attribute is only available on IBM MQ Appliance.

String.

Set to yes if the queue manager file system is encrypted, or no if the file system is not encrypted.

ha

► MQ Appliance

This object is only available on the IBM MQ Appliance. The ha object returns information about the high availability (HA) configuration on the appliance:

type

String.

Specifies whether the queue manager is configured for HA. Is set to "replicated" for an HA queue manager, or is an empty string otherwise.

floatingIPAddress

String.

Specifies the floating IP address if one has been configured for an HA queue manager.

floatingIPInterface

String.

Specifies the local interface that is used to connect to the queue manager on the two appliances in the HA group, if one has been configured for an HA queue manager.

dr

► MQ Appliance

This object is only available on the IBM MQ Appliance. The dr object returns information about the disaster recovery (DR) configuration on the appliance:

replicationPort

Integer.

Specifies the port used by the data replication listener. Contains zero if DR is not configured.

remoteIPAddress

String list.

The list can contain up to two elements, zero if DR is not configured, one if DR if configured to a single remote appliance or to a HA pair with a DR floating IP address, or two if DR if configured to a HA pair without using a DR floating IP address.

/admin/mft/agent

You can use the HTTP GET method with the agent resource, to request information about Managed File Transfer agents.

Note: ► V9.4.0 You cannot use this resource with the stand-alone IBM MQ Web Server. For more information about the installation options for the IBM MQ component that runs the administrative REST API, see [The IBM MQ Console and REST API](#).

Related tasks

[Getting started with the REST API for MFT](#)

Related reference

["/admin/mft/transfer"](#) on page 2284

You can use the HTTP GET method with the transfer resource to request information about Managed File Transfer transfers. You can use the HTTP POST method to put a transfer request message to the command queue manager, which will be routed to the source agent queue manager.

GET

Use the HTTP GET method with the agent resource to request information about Managed File Transfer agents.

Note: V9.4.0 You cannot use this resource with the stand-alone IBM MQ Web Server. For more information about the installation options for the IBM MQ component that runs the administrative REST API, see [The IBM MQ Console and REST API](#).

The information that is returned is similar to the information returned by the “[fteListAgents \(list the MFT agents for a coordination queue manager\)](#)” on page 2116 and “[fteShowAgentDetails \(display MFT agent details\)](#)” on page 2159 commands.

For more information about configuring the MFT REST API, see [Configuring the REST API for MFT](#).

- [Resource URL](#)
- [Optional query parameters](#)
- “[Request headers](#)” on page 2231
- [Request body format](#)
- “[Security requirements](#)” on page 2231
- [Response status codes](#)
- “[Response headers](#)” on page 2232
- [Response body format](#)
- [Examples](#)

Resource URL

```
https://host:port/ibmmq/rest/v2/admin/mft/agent/{agentname}
```

agentName

Optionally specifies the name of the agent to query.

The agent name is not case-sensitive, but agent names that are entered in lowercase or mixed case are converted to uppercase. The agent name value that is received as a response from the REST API is always in uppercase.

The agent name can contain a maximum of 28 characters, and must conform to the IBM MQ rules [for naming objects](#). In addition to the IBM MQ object naming conventions, the percent (%) character cannot be used in agent names.

You can use HTTP instead of HTTPS if you enable HTTP connections. For more information about enabling HTTP, see [Configuring the HTTP and HTTPS ports](#).

Optional query parameters

attributes={object,...[*]*object.attributeName*,...}

object

Specifies a comma-separated list of JSON objects that are added to a JSON object, which is a subsection of the complete details.

For example to return:

- All general details of all agents or a particular agent, specify *general*.
- All queue manager connection details of all agents or a particular agent specify *qmgrConnection*.

- Details of connect direct bridge agent, specify *connectDirectBridge*. (applicable only for agent of type "connect direct bridge")
- Details of protocol agent, specify *protocolBridge*. (applicable only for agents of type "protocol bridge")

For a full list of attributes see [“Response body attributes for agents” on page 2234](#)

Specifies all attributes.

object.attributeName,...

Specifies a comma-separated list of agent attributes to return.

Each attribute must specify the JSON object that contains the attribute, in the form `object.attributeName`. For example, to return the `statusAge` attribute, which is contained in the `general` object, specify `general.statusAge`.

You cannot specify the same attribute more than once. If you request attributes that are not valid for a particular agent, the attributes are not returned for that agent.

name=name

This parameter cannot be used if you specify an agent name in the resource URL. Specifies a wildcard agent name to filter on.

The name specified must include an `*` as a wildcard character. You can specify one of the following combinations:

Specifies that all agents are returned.

prefix*

Specifies that all agents with the specified prefix in the agent name are returned.

suffix*

Specifies that all agents with the specified suffix in the agent name are returned.

prefix*suffix

Specifies that all agents with the specified prefix and specified suffix in the agent name are returned.

type=validAgentType

Specifies the type of agent to return information about. The value can be one of the following values:

all

Specifies that information about all agents is returned. `standard`, `connectDirectBridge`, and `protocolBridge` agent information is returned.

This is the default value.

standard

Specifies that information about agent of type `standard` is returned.

connectDirectBridge

Specifies that information about agents of type `connect direct bridge` is returned.

protocolBridge

Specifies that information about agents of type `protocol bridge` is returned.

state=validAgentState

Specifies the state of the agent to return information about. The value can be one of the following values:

all

Specifies that information about all agents is returned. This information includes all the valid states listed in the following text.

This is the default value.

active

Specifies that information about agents that are in an active state is returned.

ready

Specifies that information about agents that are in a ready state is returned.

starting

Specifies that information about agents that are in a starting state is returned.

unreachable

Specifies that information about agents that are in an unreachable state is returned.

stopped

Specifies that information about agents that are in a stopped state is returned.

stopping

Specifies that information about agents that are in a stopping state is returned.

endedUnexpectedly

Specifies that information about agents that are in an endedUnexpectedly state is returned.

noInformation

Specifies that information about agents that are in a noInformation state is returned.

unknown

Specifies that information about agents that are in an unknown state is returned.

problem

Specifies that information about agents that are in a problem state is returned.

Request headers

The following header must be sent with the request:

Authorization

This header must be sent if you are using basic authentication. For more information, see [Using HTTP basic authentication with the REST API](#).

Request body format

None.

Security requirements

The caller must be authenticated to the mqweb server and must be a member of one or more of the MFTWebAdmin, MFTWebAdminRO or MQWebUser roles. For more information about security for the administrative REST API, see [IBM MQ Console and REST API security](#).

The security principal of the caller must be granted authority to subscribe to the SYSTEM.FTE/Agents topic.

If token based security is used, the LTPA token that is used to authenticate the user must be provided with the request as a cookie. For more information about token-based authentication, see [Using token-based authentication with the REST API](#).

Response status codes

200

Agent information retrieved successfully.

400

Invalid data provided.

For example, invalid agent attributes specified.

401

Not authenticated.

The caller must be authenticated to the mqweb server. For more information, see [“Security requirements” on page 2231](#).

403

Access prohibited for one of the following reasons:

- Not authorized. The caller is authenticated to the mqweb server and is associated with a valid principal. However, the principal is not a member of one or more of the MFTWebAdmin, MFTWebAdminRO, or MQWebUser1 roles. For more information about the access that is required, see [“Security requirements” on page 2231](#).
- **V9.4.0** Access prohibited in the current server environment. You cannot use the administrative REST API with the stand-alone IBM MQ Web Server.

404

Agent does not exist.

500

Server issue or error code from IBM MQ.

503

Queue manager not running.

Response headers

Content-Type

This header is returned with a value of `application/json;charset=utf-8`.

Response body format

The response is in JSON format in UTF-8 encoding. The response contains an outer JSON object that contains a single JSON array called `agent`. Each element in the array is a JSON object that represents information about an agent. Each of these JSON objects contains the following attributes:

name

String.

Specifies the name of the agent.

This attribute is always returned.

type

String.

Specifies the type of agent.

The value is one of the following values:

- `standard`
- `connectDirectBridge`
- `protocolBridge`

state

Specifies the state of the agent. The value can be one of the following values:

- `active`
- `ready`
- `starting`
- `unreachable`
- `stopping`
- `stopped`

general

Contains attributes that are related to general agent properties, such as the agent description, the agent age, and the version and level of the queue manager.

queueManagerConnection

This object provides information about the queue manager connections, such as the queue manager name, and transport type.

connectDirectBridge

This object provides information about to connect direct bridge type agent, such as the node name, host, and port.

protocolBridge

This object provides information about protocol bridge type agent, such as the endpoints and default server.

standbyInstance

This object provides information about the status of the standby instances

For more information, see [“Response body attributes for transfers”](#) on page 2303.

If an error occurs, see [REST API error handling](#).

Examples

The following example returns the basic details of all agents, that is, only the following information is displayed:

- agent name
- agent type
- agent state

The following URL is used with the HTTP GET method:

```
https://localhost:9443/ibmmq/rest/v2/admin/mft/agent/
```

The following JSON response is returned:

```
{
  "agent": [
    {
      "name": "AGENT1",
      "state": "ready",
      "type": "standard"
    },
    {
      "name": "AGENT2",
      "state": "ready",
      "type": "standard"
    },
    {
      "name": "BRIDGE_AGENT3",
      "type": "protocolBridge",
      "state": "ready"
    },
    {
      "name": "CD_AGENT",
      "type": "connectDirectBridge",
      "state": "ready"
    }
  ]
}
```

The following example lists all the agent of type **standard**, along with the **general** object. The following URL is used with the HTTP GET method:

```
https://localhost:9443/ibmmq/rest/v2/admin/mft/agent?attributes=general&type=standard
```

The following JSON response is returned:

```
{
  "agent": [
    {
      "name": "SRC",
      "state": "ready",
      "type": "standard",

```

```

    "general": {
      "description": "Standard connected to the qmgr in client mode",
      "statusAge": "06:31:00",
      "version": "9.1.5.0",
      "level": "p915-L190514",
      "statusPublicationRate": 300,
      "statusPublishTime": "2019-05-14T06:57:07.000Z",
      "maximumQueuedTransfers": 1000,
      "maximumDestinationTransfers": 25,
      "maximumSourceTransfers": 25,
      "operatingSystem": "Windows10"
    },
    "standbyInstance": [
      {
        "host": "MFTHA1",
        "version": "9.1.5.0"
      },
      {
        "host": "9.122.123.124",
        "version": "9.1.5.0"
      }
    ]
  }
}

```

Note that the `standbyInstance` attributes are displayed only if the agent is enabled as highly available.

The following example lists all the agents starting with the name AGENT, in a **ready** state, and of type **standard**, along with the **general** object of `statusAge`. The following URL is used with the HTTP GET method:

```

https://localhost:9443/ibmmq/rest/v2/admin/mft/agent?
name=AGENT*&state=ready&type=standard&attributes=general.statusAge

```

The following JSON response is returned:

```

{
  "agent": [
    {
      "name": "AGENT1",
      "state": "ready",
      "type": "standard",
      "general": {
        "statusAge": "05:00:00"
      }
    },
    {
      "name": "AGENT2",
      "state": "ready",
      "type": "standard",
      "general": {
        "statusAge": "03:00:00"
      }
    },
    {
      "name": "AGENT3",
      "state": "ready",
      "type": "standard",
      "general": {
        "statusAge": "05:00:00"
      }
    }
  ]
}

```

general

description

String.

Specifies the description of the agent.

statusAge

String.

Specifies the age of the agent. The age is calculated as the difference in time between the system time of the machine where the coordination queue manager is running, and the time the last status was published by an agent.

version

String.

Specifies the version of the queue manager.

level

String.

Specifies the build level on which the queue manager is running.

statusPublicationRate

Integer.

Specifies the rate, in seconds, that the agent publishes its status.

The default value for this attribute is 300 seconds.

statusPublishTime

String.

Specifies the time at which the agent published its status, in Universal Time Constant format.

maximumQueuedTransfers

Integer.

Specifies the maximum number of pending transfers that can be queued by an agent until the agent rejects a new transfer request.

The default value for this attribute is 1000.

maximumQueuedTransfers

Integer.

Specifies the maximum number of pending transfers that can be queued by an agent until the agent rejects a new transfer request.

The default value for this attribute is 1000

maximumDestinationTransfers

Integer.

Specifies the maximum number of concurrent transfers that the destination agent processes at any given point in time.

The default value for this attribute is 25.

maximumSourceTransfers

Integer.

Specifies the maximum number of concurrent transfers that the source agent processes at any given point in time.

The default value for this attribute is 25.

operatingSystem

String

Specifies the operating system where the agent queue manager is created.

qmgrConnection

This object provides information about the queue manager connections.

qmgrName

String.

Specifies the name of the agent queue manager.

transportType

String.

Specifies the transport type in which the agent is connecting with the queue manager. The transport type can be client or bindings.

The default value is bindings.

host

String.

Specifies the agent queue manager host name; applicable only if **transportType** is client.

port

Integer.

Specifies the agent queue manager channel communication port; applicable only if **transportType** is client.

channelName

String.

Specifies the agent queue manager channel; applicable only if **transportType** is client.

The default value for this attribute is SYSTEM.DEF.SVRCONN

standbyHost

String.

Specifies the host name used by client connections to connect to the standby instance of a multi-instance agent queue manager.

standbyPort

Integer.

Specifies the port number through which a client can connect to the standby instance of a multi-instance agent queue manager.

The default value for this attribute is -1.

connectDirectBridge

This object provides information about to connect direct bridge type agent. For other type of agents this object is not added.

nodeName

String.

Specifies the name of the Connect:Direct node to use to transfer messages from this agent to the destination Connect:Direct nodes.

host

String.

Specifies the host name or IP address of the system where the Connect:Direct node, specified by the **-cdNode** parameter, is located.

If you do not specify the **-cdNodeHost** parameter, a default of the host name or IP address of the local system is used.

The default value for this attribute are the details of the host where it is configured, for example, localhost.

port

Integer.

Specifies the port number of the Connect:Direct node that client applications use to communicate with the node.

The default value for this attribute is 1363.

protocolBridge

This object provides information about protocol bridge type agent. For other type of agents this object is not added.

endpoint

String.

Specifies the number of endpoints the bridge can support.

The default value for this attribute is *multiple* from version 7.0.1.

defaultServer

String.

Specifies the host name or IP address of the default protocol server if it is set. If the default protocol field is not set, this value is blank.

The value is a complete string containing the protocol type, server, and port, in the following format:

```
<protocolType>://<serverName or IP address>:<port>
```

For example:

```
"ftp://localhost:21"
```

standbyInstance

This object provides information about the status of the standby instance, and is present only if the agent is enabled as highly available.

host

String

Specifies the agent queue manager host name.

version

String.

Specifies the version of the queue manager. The version must be 9.1.4.0 or higher.

[Getting started with the REST API for MFT](#)

Related reference

[“GET” on page 2229](#)

Use the HTTP GET method with the agent resource to request information about Managed File Transfer agents.

/admin/mft/call

You can use the HTTP GET method with the call resource to request information about the status of a Managed File Transfer managed call. You can use the HTTP POST method to create a managed call.

Note: **V 9.4.0** You cannot use this resource with the stand-alone IBM MQ Web Server. For more information about the installation options for the IBM MQ component that runs the administrative REST API, see [The IBM MQ Console and REST API](#).

For more information about managed calls, see [Managed calls](#).

GET - managed call

Use the HTTP GET method with the call resource to request information about the status of a Managed File Transfer managed call. You can query only the managed calls that are initiated after the mqweb server is started.

Note:

- This resource is available only from version 3 of the IBM MQ REST API.
- **V 9.4.0** This resource is not available in a stand-alone IBM MQ Web Server installation. For more information about the installation options for the IBM MQ component that runs the administrative REST API, see [The IBM MQ Console and REST API](#).

For more information about managed calls, see [Managed calls](#).

- [Resource URL](#)
- [Optional query parameters](#)
- [“Request headers” on page 2239](#)
- [Request body format](#)
- [“Security requirements” on page 2239](#)
- [Response status codes](#)
- [“Response headers” on page 2240](#)
- [Response body format](#)
- [Examples](#)

Resource URL

`https://mqweb.ibm.com:9443/ibmmq/rest/v3/admin/mft/call`

returns the attributes of a specified managed call in the response body.

Optional query parameters

attributes

Specifies a comma-separated list of attributes to retrieve.

If you do not specify **attributes**, the default set of attributes is returned. See [“Response body attributes for transfers” on page 2303](#) for a list of the available attributes.

You cannot request the same attribute multiple times.

You can specify an asterisk, *, to specify that all attributes are returned.

You can make a request that specifies attributes that are not valid for some of the managed call. However, if you make a request that specifies a managed call ID and includes attributes that are not valid for that managed call, an error occurs.

limit

Specifies the maximum number of managed calls to retrieve.

This query parameter is valid only when no managed call ID is specified.

For example, if the limit=200, the REST API returns a maximum of 200 managed calls.

after

Specifies a managed call ID. All managed calls that are initiated after the specified managed call are retrieved. If you specify **after**, you cannot also specify **before**.

This query parameter is valid only when no managed call ID is specified.

before

Specifies a managed call ID. All managed calls that are initiated before that particular managed call are retrieved. If you specify **before**, you cannot also specify **after**.

This query parameter is valid only when no managed call ID is specified.

Request headers

The following header must be sent with the request:

Authorization

This header must be sent if you are using basic authentication. For more information, see [Using HTTP basic authentication with the REST API](#).

Request body format

None.

Security requirements

The caller must be authenticated to the mqweb server and must be a member of one or more of the MFTWebAdmin, MFTWebAdminRO, or MQWebUser roles. For more information about security for the administrative REST API, see [IBM MQ Console and REST API security](#).

The security principal of the caller must be granted authority to subscribe to the SYSTEM.FTE topic.

If token based security is used, the LTPA token that is used to authenticate the user must be provided with the request as a cookie. For more information about token-based authentication, see [Using token-based authentication with the REST API](#).

Response status codes**200**

Managed call information retrieved successfully.

400

Invalid data provided.

For example, invalid attributes specified.

401

Not authenticated.

The caller must be authenticated to the mqweb server. For more information, see [“Security requirements” on page 2239](#).

403

Access prohibited for one of the following reasons:

- Not authorized. The caller is authenticated to the mqweb server and is associated with a valid principal. However, the principal is not a member of one or more of the MFTWebAdmin, MFTWebAdminRO, or MQWebUser roles. For more information about the access that is required, see [“Security requirements” on page 2239](#).

- **V9.4.0** Access prohibited in the current server environment. You cannot use the administrative REST API with the stand-alone IBM MQ Web Server.

404

A managed call with the specified ID does not exist.

500

Server issue or error code from IBM MQ.

503

Queue manager not running.

Response headers

Content-Type

This header is returned with a value of `application/json;charset=utf-8`.

ibm-mq-rest-mft-total-managed-calls

This header is returned with a value that is the total number of managed calls that have details available in the mqweb server cache.

Response body format

The response is in JSON format in UTF-8 encoding. The response contains an outer JSON object that contains a single JSON array called `call`. Each element in the array is a JSON object that represents information about a managed call. Each of these JSON objects can contain the following objects and attributes.

Attention: Use the appropriate **name** parameter for the variable that your enterprise uses.

Which objects and attributes are returned depends on the URL that was specified for the request:

job

JSON object.

Name of the group containing the name of the job given to a managed call.

name

String

Specifies a user-defined job name for the managed call.

agent

JSON object.

Name of the group containing details of the agent to which a managed call request is submitted

name

String

Attribute in the **agent** group and refers to the agent name

qmgrName

String

Attribute in the **agent** group and refers to the agent queue manager name

priority

Integer

Priority assigned to the managed call. Same as `MQMD.Priority` with a value of 0 to 9.

userProperties

JSON object

Name of the group that contains attributes where each attribute refers to user-defined meta data. The name and value of each attribute is defined by the user.

command

JSON object

Name of the group containing attributes describing a managed call request.

retryCount

Integer

Specifies the number of attempts to run the command before ceasing.

retryWait

Integer

Specifies the amount of time to wait, in seconds, between retry attempts.

successReturnCode

String

Specifies the condition, based on the return code from the executable, AntScript, or JCL, that must be true in the order for the managed call to be successful.

The condition is specified as an operator, followed by a value. Valid characters for the operator are >, <, !, and =.

It is valid to have a combination of more than one operator. See [“successrc” on page 2089](#) for more information on the operators.

For example, an expression ">2&<7&!5|0|14" indicates that the return codes of 0, 3, 4, 6, and 14 are considered as success.

The default value is zero.

type

String

Identifies the type of managed call. *antScript*, *executable*, and *jcl* are the supported values

executable

JSON object

A JSON object that can contain attributes related to a platform-specific executable program to be invoked. This object can be specified only when the value of the **type** attribute is *executable*.

name

String

Specifies the name of the program to run. This attribute is required if the **executable** JSON object is specified.

arguments

String

Specifies a list of user-defined custom data in space separated key=value pairs.

antScript

JSON object

A JSON object that can contain attributes related to an Apache Ant script to be invoked. This object can only be specified when the value of the **type** attribute is *antScript*.

name

String

Specifies the name of the Ant script to run.

target

String

Specifies the target to invoke in the specified Ant script. If this attribute is not specified, the target named **default** is invoked

arguments

JSON object

Specifies a list of user-defined custom data in key=value pairs.

 **jcl**
JSON object

A JSON object that can contain attributes related to a z/OS JCL job to submit. This object can only be specified when the value of the **type** attribute is *jcl*.

name

String

Specifies the name of the JCL to submit.

results

JSON array

An array of JSON objects that describes the outcome of the processing of the script or program.

The response can contain multiple result object if the specified command has been retried.

Assuming the processing failed first and succeeded in the next attempt, the first result object has details of the failure and the second one has details of the success.

returnCode

Integer

Return code that describes the code returned by the processing of the command.

time

String

Date and time when processing of the command completed.

outcome

String

Outcome of the processing of a command. The possible values are *success* or *failure*.

consoleOutput

JSON array

A JSON array object that describes each line of the console output when the command was processed. This includes output in both `stdout` and `stderr`.

retries

Integer

Describes the number of times the command was retried before completing. The value can also be equal to the maximum retry count specified in the request if the command failed to succeed.

finalOutcome

String

Provides the description of the overall result of the processing of the command.

id

String

Unique identifier of the managed call.

originator

JSON object

A JSON object that identifies the initiator of managed call.

host

String

Identifies the name of the machine from where the managed call was submitted.

userId

String

Identifies the user that submitted the request.

mqmdUserId

String

Identifies the IBM MQ user that submitted the request.

status

JSON object

Contains attributes that are related to the status of the managed call. The **state** attribute in this object is always returned.

state

String

Describes the state of the managed call. Possible values are *successful*, *failed*, or *in-progress*

lastStatusUpdate

String

Describes the time (in UTC) when the state of the managed call was last updated.

statistics

JSON object

Describes the statistics of a managed call. Attributes of this object include the start and end time of the managed call.

Note: The managed call fails to complete if the total length of the console output exceeds 10KB. Message BFGCR0004E is logged by the agent in such a situation.

If an error occurs, see [REST API error handling](#).

Examples

The following is an example of a response body with the default attributes of a managed call:

```
{
  "call": [
    {
      "agent": {
        "name": "SECURITIES.AGENT"
      },
      "id": "414D51204D4654514D202020202020202020202020987C936103A80140",
      "command": {
        "retryWait": 0,
        "successReturnCode": "0",
        "retryCount": 0,
        "type": "antScript",
        "antScript": {
          "name": "/usr/cmds/hubprocess.xml",
          "arguments": "out.file=c:/temp/Catted.xsd",
          "target": "concatenate"
        }
      },
      "originator": {
        "host": "host.johnwatson.com",
        "userId": "john.watson"
      },
      "status": {
        "state": "started"
      }
    }
  ]
}
```

The following is an example of a response body with the status of the call in started state:

```
{
  "call": [
    {
      "agent": {
        "qmgrName": "SECURITIES.QM",
        "name": "SECURITIES.AGENT"
      },
      "priority": 0,
      "userProperties": {
        "com.ibm.wmqfte.SourceAgent": "SECURITIES.AGENT",
        "com.ibm.wmqfte.OriginatingUser": "john.watson",
        "com.ibm.wmqfte.OriginatingHost": "host.johnwatosn.com",
        "com.ibm.wmqfte.TransferId": "414d51204d4654514d202020202020202020202020987c936103a80140",
        "com.ibm.wmqfte.MqmdUser": "john.watson",
        "com.ibm.wmqfte.Priority": "0",
        "com.ibm.wmqfte.DestinationAgent": "SECURITIES.AGENT"
      }
    }
  ]
}
```

```

"command": {
  "retryWait": 0,
  "retryCount": 0,
  "successReturnCode": "0",
  "type": "antScript",
  "antscript": {
    "name": "/usr/sample/hubprocess.xml",
    "target": "concatenate"
    "arguments": "out.file=/usr/out/outfile.txt
      in.file1=/usr/sample/input/infile1.txt
      in.file2=/usr/sample/input/infile2.txt"
  }
},
"id": "414D51204D4654514D20202020202020987C936103A80140",
"originator": {
  "host": "host.johnwatson.com",
  "mqmdUserId": "john.watson",
  "userId": "john.watson"
},
"job": {
  "name": "pushsecurities"
},
"status": {
  "lastStatusUpdate": "2021-11-17T07:12:35.459Z",
  "state": "started"
},
"statistics": {
  "startTime": "2021-11-17T07:12:35.459Z"
}
}
]
}

```

The following is an example of a response body with failed status.

```

{
  "call": [{
    "agent": {
      "qmgrName": "SECURITIES.QM",
      "name": "SECURITIES.AGENT"
    },
    "priority": 0,
    "userProperties": {
      "com.ibm.wmqfte.SourceAgent": "SECURITIES.AGENT",
      "com.ibm.wmqfte.OriginatingUser": "john.watson",
      "com.ibm.wmqfte.OriginatingHost": "host.johnwatson.com",
      "com.ibm.wmqfte.TransferId": "414d51204d4654514d202020202020987c936103a80140",
      "com.ibm.wmqfte.MqmdUser": "john.watson",
      "com.ibm.wmqfte.Priority": "0",
      "com.ibm.wmqfte.DestinationAgent": "SECURITIES.AGENT"
    },
    "results": {
      "result": [{
        "returnCode": 1,
        "completionTime": "2021-11-23T03:40:05.794Z",
        "outcome": "failure"
        "consoleOutput": [
          "BFGCL0207E: Target \"concatenate1\" does not exist in the project \"null\"."
        ]
      }],
      "retries": 0,
      "finalOutcome": "failure"
    },
    "command": {
      "retryWait": 0,
      "retryCount": 0,
      "type": "antScript",
      "antscript": {
        "name": "/usr/sample/hubprocess.xml",
        "target": "concatenate"
        "successReturnCode": "0"
        "arguments": "out.file=/usr/out/outfile.txt
          in.file1=/usr/sample/input/infile1.txt
          in.file2=/usr/sample/input/infile2.txt"
      }
    },
    "id": "414D51204D4654514D20202020202020987C936103A80140",
    "originator": {
      "host": "host.johnwatson.com",
      "mqmdUserId": "john.watson",

```

```

    "userId": "john.watson"
  },
  "job": {
    "name": "pushsecurities"
  },
  "status": {
    "lastStatusUpdate": "2021-11-17T07:12:35.459Z",
    "state": "failed"
  }
  "statistics": {
    "startTime": "2021-11-23T03:40:03.967Z",
    "endTime": "2021-11-23T03:40:05.794Z"
  }
}
]
}

```

[“POST - managed call” on page 2245](#)

Use the HTTP POST method with the `call` resource to create a Managed File Transfer managed call.

POST - managed call

Use the HTTP POST method with the `call` resource to create a Managed File Transfer managed call.

Note:

- This resource is available only from version 3 of the IBM MQ REST API.
- **V9.4.0** You cannot use this resource with the stand-alone IBM MQ Web Server. For more information about the installation options for the IBM MQ component that runs the administrative REST API, see [The IBM MQ Console and REST API](#).

For more information about managed calls, see [Managed calls](#).

- [Resource URL](#)
- [“Request headers” on page 2245](#)
- [Request body format](#)
- [“Security requirements” on page 2248](#)
- [Response status codes](#)
- [“Response headers” on page 2250](#)
- [Response body format](#)
- [Examples](#)

Resource URL

`https://mqweb.ibm.com:9443/ibmmq/rest/v3/admin/mft/call`

You can use HTTP instead of HTTPS if you enable HTTP connections. For more information about enabling HTTP, see [Configuring the HTTP and HTTPS ports](#).

Request headers

The following headers must be sent with the request:

Content-Type

This header must be sent with a value of `application/json` optionally followed by `; charset=UTF-8`.

ibm-mq-rest-csrf-token

This header must be set, but the value can be anything, including being blank.

Authorization

This header must be sent if you are using basic authentication. For more information, see [Using HTTP basic authentication with the REST API](#).

Request body format

The request body must contain attributes for only one managed call. Submitting multiple managed calls in a single request is not allowed.

The body can contain details of an **AntScript** or **executable**, or a **JCL** (for agents running on z/OS).

The following section describes the request body format for each of the types. Note that the attributes of the command section of a managed call are the same as the attributes described in the [“preSourceCall”](#) on page 2297 section of *Request body attributes for transfers with HTTP POST*.

Attention: Use the appropriate **name** parameter for the variable that your enterprise uses.

Which objects and attributes are returned depends on the URL that was specified for the request:

job

JSON object.

Optional

Name of the group containing the name of the job given to a managed call.

name

String

Required if you specified the **job** attributes

Specifies a user-defined job name for the managed call.

agent

JSON object.

Required

Name of the group containing details of the agent to which a managed call request is submitted

name

String

Required

Attribute in the **agent** group and refers to the agent name

qmgrName

String

Required

Attribute in the **agent** group and refers to the agent queue manager name

priority

Integer

Optional

Priority assigned to the managed call. Same as MQMD.**Priority** with a value of 0 to 9.

userProperties

JSON object

Optional

Name of the group that contains attributes where each attribute refers to user-defined meta data. The name and value of each attribute is defined by the user.

command

JSON object

Required

Name of the group containing attributes describing a managed call request.

retryCount

Integer

Optional - zero is assumed if not specified.

Specifies the number of attempts to run the command before ceasing.

retryWait

Integer

Optional - zero is assumed if not specified.

Specifies the amount of time to wait, in seconds, between retry attempts.

successReturnCode

String

Required

Specifies the condition, based on the return code from the executable, AntScript, or JCL, that must be true in the order for the managed call to be successful.

The condition is specified as an operator, followed by a value. Valid characters for the operator are >, <, !, and =.

It is valid to have a combination of more than one operator. See [“successrc” on page 2089](#) for more information on the operators.

For example, an expression ">2&<7&!5|0|14" indicates that the return codes of 0, 3, 4, 6, and 14 are considered as success.

The default value is zero.

type

String

Required

Identifies the type of managed call. *antScript*, *executable*, and *jcl* are the supported values

executable

JSON object

Required if the value of the **type** attribute is *executable*, and can be specified only when the value of the **type** attribute is *executable*

A JSON object that can contain attributes related to a platform-specific executable program to be invoked.

name

String

Required if the value of the **type** attribute is *executable*, and can be specified only when the value of the **type** attribute is *executable*

Specifies the name of the program to run.

arguments

String

Optional

Specifies a list of user-defined custom data in space separated key=value pairs.

antScript

JSON object

Required if the value of the **type** attribute is *antScript*, and can be specified only when the value of the **type** attribute is *antScript*

A JSON object that can contain attributes related to an Apache Ant script to be invoked.

name

String

Required if the value of the **type** attribute is *antScript*, and can be specified only when the value of the **type** attribute is *antScript*

Specifies the name of the Ant script to run.

target

String

Specifies the target to invoke in the specified Ant script. If this attribute is not specified, the target named **default** is invoked

arguments

JSON object

Optional

Specifies a list of user-defined custom data in key=value pairs.

jcl

JSON object

Required if the value of the **type** attribute is *jcl*, and can be specified only when the value of the **type** attribute is *jcl*

 A JSON object that can contain attributes related to a z/OS JCL job to submit.

name

String

Required if the value of the **type** attribute is *jcl*, and can be specified only when the value of the **type** attribute is *jcl*

Specifies the name of the JCL to submit.

Security requirements

The caller must be authenticated to the mqweb server and must be a member of the MFTWebAdmin or MQWebUser roles. For more information about security for the administrative REST API, see [IBM MQ Console and REST API security](#).

If token based security is used, the LTPA token that is used to authenticate the user must be provided with the request as a cookie. For more information about token-based authentication, see [Using token-based authentication with the REST API](#).

If you have set up a [user sandbox](#), grant additional authority to the mqweb server user ID to access the specified file system location. For example, to restrict file system or queue access to only user IDs that contain the characters a, A or b, B:

```
<tns:userSandboxes
  xmlns:tns="http://wmqfte.ibm.com/UserSandboxes"
  xmlns:xsi="https://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://wmqfte.ibm.com/UserSandboxes UserSandboxes.xsd">
  <tns:agent>
    <tns:sandbox user="^[a-bA-B]*$" userPattern="regex">
      <tns:read>
        <tns:include name="/mountpath/**"/>
        <tns:include name="*" type="queue"/>
      </tns:read>
      <tns:write>
        <tns:include name="/mountpath/**"/>
        <tns:include name="*" type="queue"/>
      </tns:write>
    </tns:sandbox>
  </tns:agent>
</tns:userSandboxes>
```

If you have MFT authority checking turned on, grant additional authorities as described in [Restricting user authorities on MFT agent actions](#).

For the MFTWebAdmin role, managed call requests are submitted under the context of the mqweb server user ID. To distinguish between different principals of the MFTWebAdmin role, and for audit purposes, the managed call request submitted contains the name of the authenticated user as the managed call originator. This method ensures that there is a record of who initiated the managed call request.

For example, if the user `mftadminusr`, of the `MFTWebAdmin` role, initiates a managed call, the originator data in the XML that is created to describe the managed call has `mftadminusr` in the `userID` element, as shown in this example:

```
<originator>
  <hostName>example.com</hostName>
  <userID>mftadminusr</userID>
  <mqmdUserId>mqm</mqmdUserId>
</originator>
```

where:

hostName

Is the name of host where the mqweb server is running.

userId

Is the name of the user that is logged in to the mqweb server.

mqmdUserId

Is the name of the user under which the mqweb server is running and connects to the command queue manager.

If the caller is a member of the `MQWebUser` role, the security principal of the caller must be granted one of the following authorities:

1. If the command queue is local, that is, the command queue manager and source agent queue manager are the same, grant put authority to the command queue.
2. If the command queue is remote, that is, the command queue manager and source agent queue manager are different, grant put authority to the transmission queue.

Notes:

- If the user ID of a principal that is a member of the `MQWebUser` role is longer than 12 characters, the request fails. Response status code 403 is returned to the caller.
- If the caller is assigned more than one role, the highest privilege role that is applicable to the operation is used.

If security is disabled on the mqweb server, the transfer request submitted contains the name "UNAUTHENTICATED" as the transfer originator.

Response status codes

202

The managed call request has been accepted by the REST API. It might still get rejected by the MFT agent. You should issue a GET command, using the URL from the `location` response header to ascertain the state of the managed call.

400

Invalid data provided.

For example, invalid attributes specified.

401

Not authenticated.

The user must be authenticated to the mqweb server. For more information, see [“Security requirements” on page 2248](#).

The `ibm-mq-rest-csrf-token` header must also be specified.

403

Access prohibited for one of the following reasons:

- Not authorized. The caller is authenticated to the mqweb server and is associated with a valid principal. However, the principal does not have access to the required IBM MQ or MFT resources.

- **V9.4.0** Access prohibited in the current server environment. You cannot use the administrative REST API with the stand-alone IBM MQ Web Server.

500

Server issue, or error code from IBM MQ or MFT.

503

Queue manager not running.

Response headers

The following header is returned with the response:

location

If the request was successful, this header specifies the URL for the new managed call.

Response body format

The response body is empty if the transfer is created successfully.

If an error occurs, the response body contains an error message; see [REST API error handling](#).

Examples

An example of a request body format for a managed call for running an *antScript*:

```
{
  "job": {
    "name": "pushsecurities"
  },
  "agent": {
    "name": "SECURITIES.AGENT",
    "qmgrName": "SECURITIES.QM"
  },
  "priority": 0,
  "command": {
    "retryCount": 0,
    "retryWait": 0,
    "successReturnCode": "0",
    "type": "antScript",
    "antScript": {
      "name": "publish.xml",
      "target": "publishsecurities",
      "arguments": "filename=abc.csv updateInterval=5"
    }
  }
}
```

An example of a request body format for a managed call for running an *executable*:

```
{
  "job": {
    "name": "compressfiles"
  },
  "agent": {
    "name": "SECURITIES.AGENT",
    "qmgrName": "SECURITIES.QM"
  },
  "priority": 0,
  "command": {
    "retryCount": 0,
    "retryWait": 0,
    "successReturnCode": "0",
    "type": "executable",
    "executable": {
      "name": "compress.sh",
      "arguments": "filename zlib"
    }
  }
}
```

 An example of a request body format for a managed call with JCL to be run by an agent running z/OS:

```
{
  "job": {
    "name": "pushsecurities"
  },
  "agent": {
    "name": "SECURITIES.AGENT"
    "qmgrName": "SECURITIES.QM"
  },
  "priority": 0,
  "command": {
    "retryCount": 0,
    "retryWait": 0,
    "successReturnCode": "0",
    "type": "jcl",
    "jcl": {
      "name": "publish",
    }
  }
}
```

Related reference

[“GET - managed call” on page 2238](#)

Use the HTTP GET method with the `call` resource to request information about the status of a Managed File Transfer managed call. You can query only the managed calls that are initiated after the mqweb server is started.

/admin/mft/monitor

You can use the HTTP GET method with the `monitor` resource to request information about a Managed File Transfer resource monitor. You can use the HTTP POST method to create a resource monitor, and the HTTP DELETE method to delete a resource monitor.

Note:  You cannot use this resource with the stand-alone IBM MQ Web Server. For more information about the installation options for the IBM MQ component that runs the administrative REST API, see [The IBM MQ Console and REST API](#).

Related tasks

[Getting started with the REST API for MFT](#)

Related reference

[“/admin/mft/agent” on page 2228](#)

You can use the HTTP GET method with the `agent` resource, to request information about Managed File Transfer agents.

[“/admin/mft/transfer” on page 2284](#)

You can use the HTTP GET method with the `transfer` resource to request information about Managed File Transfer transfers. You can use the HTTP POST method to put a transfer request message to the command queue manager, which will be routed to the source agent queue manager.

POST

Use the HTTP POST method with the `monitor` resource to create a Managed File Transfer resource monitor.

Note:

- Set the command queue manager in the configuration before issuing any MFT Create Monitor or Transfer REST API command. See [Configuring the REST API for MFT](#) for more information.
-  This resource is not available in a stand-alone IBM MQ Web Server installation. For more information about the installation options for the IBM MQ component that runs the administrative REST API, see [The IBM MQ Console and REST API](#).

- [“Response headers” on page 2254](#)
- [Response body format](#)
- [Examples](#)

Resource URL

`https://host:port/ibmmq/rest/v2/admin/mft/monitor`

You can use HTTP instead of HTTPS if you enable HTTP connections. For more information about enabling HTTP, see [Configuring the HTTP and HTTPS ports](#).

Request headers

The following headers must be sent with the request:

Content-Type

This header must be sent with a value of `application/json` optionally followed by `; charset=UTF-8`.

ibm-mq-rest-csrf-token

This header must be set, but the value can be anything, including being blank.

Authorization

This header must be sent if you are using basic authentication. For more information, see [Using HTTP basic authentication with the REST API](#).

Request body format

The request body must be in JSON format in UTF-8 encoding. Attributes marked *required* are mandatory, and if you do not provide values for the other parameters in the request body, the default values are used.

name

JSON string.

Contains the name of the resource monitor.

The name is not case sensitive - lower case characters are folded to upper case characters, and you cannot use the wildcard character (*).

The name is required.

type

JSON string.

Type of the resource to be monitored.

general

JSON object.

This JSON object contains details of the poll interval, the units of the poll interval, and the matches per task.

resource

JSON object.

This JSON object contains details of the resource, that is the name for both monitoring a queue and a directory, and for a directory resource the recursion level.

The **name** attributes in this object are required.

triggerCondition

JSON object.

This JSON object contains the type attribute and various other attribute depending upon whether the resource type is a directory or a queue. See [“Request body attributes for MFT resource monitors” on page 2256](#) for details of this attribute.

The **type** attributes in this object are required.

userProperties

JSON object.

Specifies the user-defined metadata that is passed to the exit points of the monitor. The parameter can take one or more name pairs that are separated by commas. Each name pair consists of a name=value.

transferDefinition

JSON object.

Contains details about the transfer, for example, source agent and queue manager, destination agent and queue manager, and so on. See [“Request body attributes for MFT resource monitors” on page 2256](#) for details of this attribute.

[“Request body attributes for MFT resource monitors” on page 2256](#) lists all the attributes.

Security requirements

The caller must be authenticated to the mqweb server and must be a member of the MFTWebAdmin or MFTWebUser roles. For more information about security for the administrative REST API, see [IBM MQ Console and REST API security](#).

If token based security is used, the LTPA token that is used to authenticate the user must be provided with the request as a cookie. For more information about token-based authentication, see [Using token-based authentication with the REST API](#).

If you have set up a user sandbox, and MFT authority checking, or MFT authority checking, is turned on, you need to grant an additional authority for the user that started the WebSphere Liberty server to access the specified file system location.

For the MFTWebAdmin role, transfer requests are submitted under the context of the user that started the Liberty server. To distinguish between different principals of the MFTWebAdmin role, and for audit purposes, the transfer request submitted contains the name of the authenticated user as the transfer originator. This method ensures that there is a record of who initiated the transfer request.

For example, if the user mftadminusr, of the MFTWebAdmin role, initiates a transfer, the originator data in the XML has mftadminusr in the userID element, as shown in this example:

```
<originator>
  <hostName>example.com.</hostName>
  <userID>mftadminusr</userID>
</originator>
```

If the caller is a member of the MQWebUser role, the security principal of the caller must be granted one of the following authorities:

1. If the command queue is local, that is, the command queue manager and source agent queue manager are the same, grant put authority to the command queue.
2. If the command queue is remote, that is, the command queue manager and source agent queue manager are different, grant put authority to the transmission queue.

Notes:

- If the user ID of a principal that is a member of the MQWebUser role is longer than 12 characters, the request fails. Response status code 403 is returned to the caller.
- If the caller is assigned more than one role, the highest privilege role that is applicable to the operation is used.

If security is disabled on the mqweb server, the transfer request submitted contains the name "UNAUTHENTICATED" as the transfer originator.

Response status codes

202

The create monitor request has been accepted by the mqweb server. It might still get rejected by the MFT agent.

400

Invalid or unknown data provided to create resource monitor.
For example, invalid attributes specified.

401

Not authenticated.

The user must be authenticated to the mqweb server. For more information, see [“Security requirements”](#) on page 2253.

The `ibm-mq-rest-csrf-token` header must also be specified.

403

Access prohibited for one of the following reasons:

- Not authorized. The caller is authenticated to the mqweb server and is associated with a valid principal. However, the principal does not have access to the required IBM MQ or MFT resources.
- **V9.4.0** Access prohibited in the current server environment. You cannot use the administrative REST API with the stand-alone IBM MQ Web Server.

500

Server issue, or error code from IBM MQ or MFT.

Response headers

The following header is returned with the response:

location

If the request is successfully submitted, the **location** attribute in the response header is updated with the url, through which details about the resource monitor can be further queried.

Response body format

The response body is empty if the transfer is created successfully.

If an error occurs, the response body contains an error message; see [REST API error handling](#).

Examples

The following example creates a resource monitor for monitoring a directory:

```
{
  "name": "DIRMONREGEX",
  "type": "directory",
  "general": {"pollingInterval": 1, "pollingIntervalUnit": "minutes", "matchesPerTask": 5 },
  "userProperties": {"companyName": "IBM", "unit": "ISL" },
  "resource": { "name": "/MFT/TRIGGER", "recursionLevel": 2 },
  "triggerCondition": { "excludePattern": "*.xls", "includePattern":
  "*.txt", "type": "matchAll
  },
  "transferDefinition" {
    "sourceAgent": { "qmgrName": "srcQmgr", "name": "SRC" },
    "destinationAgent": { "qmgrName": "desQmgr", "name": "DES" },
    "transferSet": {
      "item": [
        { "source": { "name": "C:\\src\\test.txt", "type": "file" },
          "destination": { "name": "C:\\dst\\test.txt", "type": "file" } } ],

```

```

    "userProperties": { "ARCHIVE_PATH": "C:\\MFT\\ARCHIVE",
                      "REJECT_PATH": "C:\\MFT\\REJECT" },
    "postSourceCall": { "name": "posttransfersource.exe",
                       "executable": { "arguments": "data1 data2" } },
    "postDestinationCall": { "name": "posttransferdest.exe",
                              "executable": { "arguments": "dataDest1 dataDest2" } },
    "preDestinationCall": { "name": "pretransferdest.exe" },
    "preSourceCall": { "name": "posttransferdest.exe",
                      "executable": { "arguments": "predata1 predata2" } },
    "priority": 0,
    "recoveryTimeout": 21600 } }
}

```

The following example creates a resource monitor for monitoring a queue:

```

{
  "name": "QMON", "type": "queue",
  "general": { "pollingInterval": 1 "pollingIntervalUnit": "minutes", "matchesPerTask": 5 },
  "triggerCondition": { "excludePattern": "*.xls", "includePattern": "*.txt", "type":
"matchAll" },
  "userProperties": { "companyName": "IBM", "unit": "ISL" },
  "resource": { "name": "MSGQ", "matchCondition": "containsMessages" },
  "transferDefinition": {
    "job": { "name": "testJob" },
    "sourceAgent": { "name": "SRC", "qmgrName": "srcQmgr" },
    "destinationAgent": { "name": "DES", "qmgrName": "desQmgr" },
    "transferSet": {
      "item": [ {
        "source": { "name": "C:\\temp\\src\\test.txt", "type": "file",
                  "recursive": false "disposition": "leave" },
        "destination": { "name": "LQ@NYQMGR", "type": "queue",
                       "actionIfExists": "error", "delimiterType": "size",
                       "messagePersistence": "persistent",
                       "queueExtended": { "messageSize": 4, "setMQProperties": "false" } },
        "priority": 1, "recoveryTimeout": -1, "checksum": "md5", "mode": "text" } ] } } }
}

```

The following example creates a resource monitor for monitoring a directory with more attributes:

```

{
  "name": "DIRMONREGEX", "type": "directory", "agentName": "SRC",
  "general": { "pollingInterval": 1, "pollingIntervalUnit": "minutes", "matchesPerTask": 5 },
  "userProperties": { "companyName": "IBM", "unit": "ISL" },
  "resource": { "name": "/MFT/TRIGGER", "recursionLevel": 2 },
  "triggerCondition": { "matchPattern": "[a-zA-Z]{3}", "excludePattern": "[d-fD-F]{3}",
                      "patternType": "regularExpression",
                      "matchCondition": { "matchNoSizeChangeInterval": 5 } },
  "transferDefinition": {
    "sourceAgent": { "name": "SRC", "qmgrName": "srcQmgr" },
    "destinationAgent": { "name": "NY.AGENT", "qmgrName": "NYQMGR" },
  "transferSet": {
    "item": [ { "source": { "name": "C:\\temp\\src\\source.exe", "type": "file" },
              "destination": { "name": "C:\\temp\\dst", "type": "file",
                              "mode": "binary" } } ] } }
}

```

The following example creates a resource monitor, demonstrating variable substitution functionality:

```

{
  "name":
"VARSUB-TEST", "type": "directory", "agentName": "SRC",
  "general": { "pollInterval": 1, "pollIntervalUnit": "minutes" },
  "resource": { "name": "c\\source_dir" },
  "triggerCondition": { "excludePattern": "*.exe", "includePattern": "*.txt",
                      "matchPattern": "wildcard", "type": "matchAll" },
  "transferDefinition": {
    "job": { "name": "varSub" },
    "sourceAgent": { "name": "SRC", "qmgrName": "gandhi" },
    "destinationAgent": { "name": "DES", "qmgrName": "gandhi", "actionIfExists": "overwrite" },
    "transferSet": { "item": [ {
      "destination": { "name": "C:\\dest\\${fileName}", "type": "directory" },
      "source": { "name": "C:\\source_dir\\file.txt", "type": "file" },
      "mode": "text" } ] } }
}

```

The Create Monitor REST API takes the input attributes as JSON objects.

Request body attributes for MFT resource monitors

The Create Monitor REST API takes the input attributes as JSON objects.

The following list shows the attributes that you need to be provide to a REST call:

- [name](#)
- [type](#)
- [“general” on page 2256](#)
- [“resource” on page 2257](#)
- [“transferDefinition” on page 2257](#)
- [“triggerCondition” on page 2264](#)

name

String.

A unique name for the resource monitor or queue.

The name is not case sensitive - lower case characters are folded to upper case characters, and you cannot use the wildcard character (*).

The name attribute is required.

type

String.

Type of the resource monitor

The value is one of the following values:

directory

Type of the resource to create is a file system directory.

queue

Type of the resource to create is an IBM MQ queue.

general

Group element that defines the basic attributes of the monitor.

pollInterval

Integer.

Frequency, in units of time, at which a monitor polls a resource.

The default value is 1.

pollIntervalUnit

String.

Specifies the time interval for the **pollInterval** attribute. Possible values are seconds, minutes, hours, days.

The default value is minutes.

matchesPerTask

Integer.

Maximum of trigger matches to include in a single task.

The default value is 2.

resource

Group element that defines the details about the resource to be monitored.

The **name** attribute in this object is always returned.

name

String.

Specifies the name of the resource to be monitored. It can be absolute path of a file or directory, or the name of a queue.

recursionLevel

Integer.

Specifies the level in the directory structure that needs to be monitored.

The default value is 1.

Note: This attribute is valid only for a directory type of resource monitor.

transferDefinition

This attribute contains details for the transfer, which is initiated when the trigger condition is satisfied.

destinationAgent

Group element containing elements that define a destination agent.

The **name** and the **qmgrName** attributes in this object are always returned.

qmgrName

String.

The name of the queue manager on the destination system.

name

String.

The name of the agent on the destination system.

job

Contains the name of the transfer job:

name

String.

User defined job name for the transfer.

sourceAgent

Group element containing elements that define a source agent.

The **name** and the **qmgrName** attributes in this object are always returned.

qmgrName

String.

The name of the queue manager on the source system.

name

String.

The name of the agent on the source system.

transferSet

Group element that contains the elements specifying a transfer request.

The **item** attribute in this object is always returned.

priority

Number (optional).

Priority assigned to the transfer request with zero being the default, if no value is set.

userProperties

Object (optional).

User defined properties specified in the transfer request.

item

Object.

Array of group elements that describes the source and destination item configuration to transfer.

source

Object.

Group element that contains the attributes of a source item.

The **name** and **type** attributes in this object are always returned.

name

String.

Specifies the absolute path of the file, directory, data set, partitioned data set, or queue at source end.

type

String.

The type of source. The value is one of the following values:

queue

Specifies an IBM MQ queue as the source.

file

Specifies a file as the source.

directory

Specifies a directory as the source.

sequentialDataset

Specifies a z/OS sequential data set as the source.

partitionedDataset

Specifies a z/OS partitioned data set as the source.

recursive

Boolean (optional).

Specifies that files are transferred recursively in subdirectories when the source element is a directory, or contains wildcard characters.

disposition

String (optional).

Specifies the action that is taken on the source element when a source has successfully been transferred to its destination. possible values are:

leave

The source files are left unchanged.

delete

The source files are deleted from the source system after the source file is successfully transferred.

encoding

String (optional)

Specifies which character encoding to use, to read the source file when performing character conversion. This option is only applicable to text files and the possible value is any valid code page number.

datasetExtended

Object (optional).

Group element that defines additional attributes of the source specification, if the source is a z/OS data set in a transfer request.

The **hexDelimiters** and **delimiterPosition** attributes in this object are always returned.

keepTrailingSpaces

Boolean (optional).

Describes the action that is taken if there are trailing spaces in the source records that are read from a fixed-length-format record-oriented file (for example, a z/OS data set) as part of a text mode transfer.

hexDelimiters

String.

For source files that are record oriented (for example, z/OS data sets), specifies one or more byte values to insert as the delimiter when appending records into a binary file. Each value is represented as two hexadecimal digits in the range 00-FF, prefixed by x.

delimiterPosition

String

Specifies the position of insertion for source text and binary delimiters. The value is one of the following values:

prefix

The delimiters are inserted at the start of each record.

postfix

The delimiters are inserted at the end of each record; this is the default option.

queueExtended

Object (optional).

Group element that defines additional attributes of a source specification, if the source is an IBM MQ queue in a transfer request.

The **useMessageGroup** and **groupID** attributes in this object are always returned.

useMessageGroup

Boolean.

Specifies that the messages are grouped by IBM MQ group ID. The first complete group is written to the destination file. If this parameter is not specified, all messages on the source queue are written to the destination file.

groupID

String.

Group ID to be used when getting messages from a queue.

textDelimiters

String (optional).

Specifies a sequence of text to insert as the delimiter, when appending multiple messages to a text file.

hexDelimiters

String (optional).

Comma separated string of hexadecimal bytes to use, when appending multiple messages to a file. For example x12 or x03 , x7F.

delimiterPosition

String (optional).

Defines where the delimiters are positioned in the message being put to the source queue. The value is one of the following values:

prefix

Before the beginning of the message body.

postfix

After the end of the message body; this is the default option.

messageArrivalWaitTime

Integer.

Time in seconds, to wait for arrival of messages in the source queue.

destination

Object.

Group element that contains the attributes of a destination item.

The **name** and **type** attributes in this object are always returned.

name

String.

Specifies the absolute path of the file, directory, data set, partitioned data set, or queue at the destination end.

type

String.

The type of destination. The value is one of the following values:

queue

Specifies an IBM MQ queue as the destination.

file

Specifies a file as the destination.

directory

Specifies a directory as the destination.

sequentialDataset

Specifies a z/OS sequential data set as the destination.

partitionedDataset

Specifies a z/OS partitioned data set as the destination.

actionIfExists

String(optional).

Specifies the action that is taken if a destination file exists on the destination system. The value is one of the following values:

error

Reports an error and the file is not transferred; this is the default value.

overwrite

Overwrites the existing destination file.

encoding

String (optional).

Specifies which character encoding to use, to read the source file when performing character conversion. This option is only applicable to text files and the possible value is any valid code page number.

endOfLine

String (optional).

Specifies the end-of-line characters that are used when the file is written at the destination. This option is applicable to text files only.

userId

String (optional).

The name of the user, whose destination file space the files are transferred into.

datasetExtended

Object (optional).

Group element that defines additional attributes of the destination specification, if the destination is a z/OS data set in a transfer request.

truncateRecords

Boolean.

Specifies that destination records longer than the LRECL data set attribute are truncated. If this parameter is not specified, the records are wrapped. This parameter is valid only for text mode transfers where the destination is a data set.

queueExtended

Object (optional).

Group element that defines additional attributes of a destination specification, if the destination is an IBM MQ queue in a transfer request.

The **messagePersistence** and **delimiterType** attributes in this object are always returned.

messagePersistence

String.

Defines if the message put to the destination queue is persistent or non-persistent. The value is one of the following values:

persistent

Messages are persistent.

nonPersistent

Messages are non-persistent.

asQueueDefault

Message persistency is set, depending on the queue definition.

delimiterType

String.

Defines the type of delimiter to use when splitting incoming data into messages. The value is one of the following values:

size

Split based on given size.

binary

Split based on given delimiters.

hexDelimiters

String (optional).

Comma separated string of hexadecimal bytes to use when splitting messages. For example x12 or x03 , x7F.

textDelimiters

String (optional).

Specifies the Java regular expression to use, when splitting a text file into multiple messages.

includeDelimitersInMessage

Boolean.

Defines whether delimiters are included in a message being put to the destination queue.

delimiterPosition

String

Defines where the delimiters are positioned in the message being put to the destination queue. The value is one of the following values:

prefix

Before the beginning of the message body.

postfix

After the end of the message body; this is the default option.

setMQProperties

Boolean (optional).

Valid only when the destination is a queue. The value is one of the following values:

true

Sets message properties on the first message that is created by the transfer.

false

Does not set message properties on the first message that is created by the transfer.

messageSize

Number.

Defines a size in bytes to split the incoming data into the message.

checksum

String (optional).

Checksum method for verifying data integrity. The value is one of the following values:

md5

MD5 algorithm used for integrity validation.

none

No checksum validation.

mode

String (optional).

Specifies the transfer mode as either binary or text. The value is one of the following values:

text

Data is transferred as text.

binary

Data is transferred in binary.

recoveryTimeout

Number (optional).

Time in seconds to wait for a transfer to recover, with -1 being the default if no value is set.

preSourceCall

Object (optional).

Group elements that contain the elements for program invocation before a transfer begins at the source.

These group elements are not present if a resource monitor is not configured to use any program invocation.

type

String (optional).

Defines the type of the program to be invoked. The value is one of the following values:

executable

This value is the default value.

Defines attributes for a platform specific executable program:

name

String.

Name of the program to process.

arguments

String (optional).

Argument or arguments to be passed to the program being invoked.

antScript

Defines attributes for Ant Script:

name

String.

Name of the Ant script to process.

target

String (optional)

Target to invoke in the specified Ant script. Attribute is not present in the JSON response, if the default target is to be invoked.

arguments

String (optional).

A list of user defined custom data in space separated key=value pair of type **String**. For example:

```
"arguments": "coffeeType=Arabica teaChoice=lemon"
```

jcl

Defines attributes for z/OS JCL to submit.

name

String.

Name of the JCL to submit.

retryCount

Number (optional).

A positive number of attempts to run the command before ceasing.

retryWait

Number (optional).

Amount of time to wait, in seconds, between two retry attempts.

successReturnCode

String (optional).

Reason code that is returned when transfer is complete. This is looked for before running the specified program, script, or JCL. This return code is a combination of an operator and value in the form of "[>|<|!] value". Note that it is valid to have a combination of more than one operator, for example ">= 40".

postSourceCall

Object (optional).

Group elements that contain the elements for program invocation after a transfer completes at source. This object contains the same elements as **preSourceCall**.

preDestinationCall

Object (optional).

Group elements that contain the elements for program invocation before a transfer begins at the destination. This object contains the same elements as **preSourceCall**.

postDestinationCall

Object (optional).

Group elements that contain the elements for program invocation after a transfer completes at the destination. This object contains the same elements as **preSourceCall**.

triggerCondition

Group element that defines details of a trigger condition used by a resource monitor.

type

String.

Indicates the type of matching done, to decide on triggering a transfer. Possible values are:

For resource type **Directory**:

matchAll

Must match the value specified for the **includePattern** and **excludePattern** attributes.

matchNone

None of the files in the monitored directory match the value specified for the **includePattern** and **excludePattern** attributes.

noChangeInSize

Initiate a transfer, if the size of the file being monitored does not change for a specified number of poll intervals.

sizeGreaterOrEqualTo

Initiate a transfer, if the size of the file being monitored is greater than or equal to a specified size.

For resource type **Queue**:

queueNotEmpty

Queue must have at least one message.

completeMessageGroups

Queue must have at least one group of messages.

noFileSizeChangePollCount

Number.

Refers to the number of polling intervals during which the size of the monitored file does not change. Used in conjunction with the **noChangeInSize** attribute

fileSize

Number.

Refers to the size of the trigger file being monitored, whose size is equal to or greater. Used in conjunction with the **sizeGreaterOrEqualTo** attribute.

fileSizeUnit

String

Defines the unit for the **fileSize** attribute. The value is one of the following values:

bytes

File size unit is in bytes

kilobytes

File size unit is in kilobytes

megabytes

File size unit is in megabytes

gigabytes

File size unit is in gigabytes

includePattern

String.

A pattern of the name, or names, of files to be included, while doing match for a trigger condition.

excludePattern

String.

A pattern of the name, or names, of files to be excluded, while doing match for a trigger condition.

matchPattern

String.

Indicates how to interpret the contents of the **includePattern** and **excludePattern** attributes. The value is one of the following values:

wildcard

- Indicates the **includePattern** and **excludePattern** attributes contain wildcard characters, for example, *.

regularExpression

Indicates the **includePattern** and **excludePattern** attributes contain Java regular expressions.

[Getting started with the REST API for MFT](#)

Related reference

[“/admin/mft/monitor” on page 2251](#)

You can use the HTTP GET method with the `monitor` resource to request information about a Managed File Transfer resource monitor. You can use the HTTP POST method to create a resource monitor, and the HTTP DELETE method to delete a resource monitor.

GET

Use the HTTP GET method with the `monitor` resource to list information about the MFT resource monitor status, and other configuration information.

Note:

- You must set a coordination queue manager before you can use the `monitor` resource. For more information, see [Configuring the REST API for MFT](#).
- **V9.4.0** This resource is not available in a stand-alone IBM MQ Web Server installation. For more information about the installation options for the IBM MQ component that runs the administrative REST API, see [The IBM MQ Console and REST API](#).

For more information about configuring the MFT REST service, see [Configuring the REST API for MFT](#).

- [Resource URL](#)
- [Optional query parameters](#)
- [“Request headers” on page 2267](#)
- [Request body format](#)
- [“Security requirements” on page 2267](#)
- [Response status codes](#)
- [“Response headers” on page 2268](#)
- [Response body format](#)
- [Examples](#)

Resource URL

`https://host:port/ibmmq/rest/v2/admin/mft/monitor/{monitorName}`

monitorName

Optionally specifies the name of the monitor to query.

If you do not specify a monitor name, a list of monitors is returned.

If you want to return a list of monitors with a wild carded monitor name, use the **name** optional query parameter to specify the monitor name instead of specifying the monitor name in the base URL.

You can use HTTP instead of HTTPS if you enable HTTP connections. For more information about enabling HTTP, see [Configuring the HTTP and HTTPS ports](#).

Optional query parameters

attributes

Specifies a comma-separated list of attributes to retrieve.

If you do not specify **attributes**, the default set of attributes is returned. See “[Response body attributes for list resource monitor](#)” on page 2271 for a list of the available attributes.

You cannot request the same attribute multiple times.

You can specify an asterisk, *, to specify that all attributes are returned.

You can make a request that specifies attributes that are not valid for some of the resource monitor information. However, if you make a request that specifies resource monitor information and includes attributes that are not valid for that information, an error occurs.

You cannot have more than three levels of nesting. For example, you cannot directly query the `transferDefinition.transferSet.postDestCall.retryWait`, only the `transferDefinition.transferSet.postDestCall`. Therefore, when querying the **transferDefinition**, you can query only the following attributes:

transferDefinition

Returns the complete details of the transfer definition.

transferDefinition.sourceAgent

Returns the complete details of the **sourceAgent** section of the transfer definition.

transferDefinition.destinationAgent

Returns the complete details of the **destinationAgent** section of the transfer definition.

transferDefinition.originator

Returns the complete details of the **originator** section of the transfer definition.

transferDefinition.transferSet

Returns the complete details of the **transferSet** section of the transfer definition.

transferDefinition.transferSet.item

Returns the complete details of all transfer items in the **item** section of the transfer definition.

transferDefinition.transferSet.preSourceCall

Returns the complete details of the **preSourceCall** section of the transfer definition.

transferDefinition.transferSet.postSourceCall

Returns the complete details of the **postSourceCall** section of the transfer definition.

transferDefinition.transferSet.preDestCall

Returns the complete details of the **preDestCall** section of the transfer definition.

transferDefinition.transferSet.postDestCall

Returns the complete details of the **postDestCall** section of the transfer definition.

name

Specifies the name of the resource monitor.

This query parameter is valid only when *monitorName* is not specified in the base resource URL.

By specifying the name of the resource monitor as an optional query parameter instead of in the base URL, you can query a wild carded resource monitor name, and can combine the query with the **state** and **type** query parameters.

The value can be any string value and * can be used as a wildcard character. Note that the ? character is not permitted.

agentName

Name of the agent that owns the resource monitor.

As resource monitors are agent scoped it is possible to have a resource monitor with the same name under more than one agent. In this situation, the REST API returns multiple resource monitor definitions. You can use the **agentName** query parameter to return the resource monitors that are associated with that specific agent.

For example, if a resource monitor with name MONITOR1 exists in more than one agent, the following URL returns more than one resource monitor definition:

```
https://localhost:9443/ibmmq/rest/v1/admin/mft/monitor/MONITOR1
```

Adding the **agentName** query parameter, you can return an agent specific resource monitor:

```
https://localhost:9443/ibmmq/rest/v1/admin/mft/monitor/MONITOR1?agentName=AGENT1
```

The value can be any string value and * can be used as a wildcard character. Note that the ? character is not permitted.

state

The status of the resource monitor.

This query parameter is valid only when *monitorName* is not specified in the base resource URL.

The value can be one of the following values:

started

Only monitors that are in a started state are returned.

stopped

Only monitors that are in a stopped state are returned.

all

All monitors, regardless of state, are returned.

The default value is **all**.

type

The type of the resource monitor.

This query parameter is valid only when *monitorName* is not specified in the base resource URL.

The value can be one of the following values:

directory

Only directory type monitors are returned.

queue

Only queue type monitors are returned.

all

All monitors, regardless of type, are returned.

The default value is **all**.

Request headers

The following header must be sent with the request:

Authorization

This header must be sent if you are using basic authentication. For more information, see [Using HTTP basic authentication with the REST API](#).

Request body format

None.

Security requirements

The caller must be authenticated to the mqweb server and must be a member of one or more of the MFTWebAdmin, MFTWebAdminRO, or MQWebUser roles. For more information about security for the administrative REST API, see [IBM MQ Console and REST API security](#).

The security principal of the caller must be granted authority to subscribe to the SYSTEM.FTE/Monitor topic.

If token based security is used, the LTPA token that is used to authenticate the user must be provided with the request as a cookie. For more information about token-based authentication, see [Using token-based authentication with the REST API](#).

Response status codes

200

Resource monitor information retrieved successfully.

400

Invalid data provided.

For example, invalid attributes specified.

401

Not authenticated.

The caller must be authenticated to the mqweb server. For more information, see [“Security requirements”](#) on page 2267.

403

Access prohibited for one of the following reasons:

- Not authorized. The caller is authenticated to the mqweb server and is associated with a valid principal. However, the principal is not a member of one or more of the MFTWebAdmin, MFTWebAdminRO, or MQWebUser roles. For more information about the access that is required, see [“Security requirements”](#) on page 2267.
- **V9.4.0** Access prohibited in the current server environment. You cannot use the administrative REST API with the stand-alone IBM MQ Web Server.

404

Specified monitor not found.

405

Method not allowed.

Returned for any other request apart from GET.

500

Server issue or error code from IBM MQ.

503

Service unavailable. IBM MQ specific reason code is also returned.

Response headers

Content-Type

This header is returned with a value of `application/json; charset=utf-8`.

Response body format

The response is in JSON format in UTF-8 encoding. The response contains an outer JSON object that contains a single JSON array called `monitor`.

Each element in the array is a JSON object that represents information about a resource monitor. Each of these JSON objects can contain the following objects and attributes. Which objects and attributes are returned depends on the URL that was specified for the request:

name

String.

Specifies the name of the resource monitor.

agentName

String.

Specifies the name of the agent that runs the resource monitor.

type

String.

Specifies the type of resource monitor:

directory

The type of the resource to be monitored is the file system directory.

queue

The type of the resource to be monitored is an IBM MQ queue.

state

String.

Specifies the state of the resource monitor:

started

The monitor is running.

stopped

The monitor has stopped.

resource

JSON Object.

Specifies the monitored resource, either a directory or queue.

userProperties

JSON Object.

Specifies a list of user defined custom data in key-value pair of type **String**. For example:

```
"userProperties": {"key1": "value1"}
```

This maps to a metadata attribute in resource monitor definition. An empty array is included in the response, if there are no user properties in the resource monitor configuration.

defaultVariables

JSON Object.

Specifies list of user defined variables and their values in key-value pair of type **String**. Resource monitor uses the values as a "variable substitution" while submitting the transfer request. For example:

```
"defaultVariables": {"groupId": "4F4F4FDEEDF1"}
```

general

JSON object.

Specifies other high-level attributes of the resource monitor.

triggerCondition

JSON object.

Specifies details of a trigger condition that is used by a resource monitor.

triggerFileContentFormat

JSON object.

Specifies a list of files that are transferred when a trigger condition is satisfied.

transferDefinition

JSON object.

Specifies details of a list of files to be transferred when a resource monitor trigger condition is satisfied.

This object includes the following nested objects:

job

JSON object.

Contains the user-defined job name for the transfer.

sourceAgent

JSON object.

Contains attributes that are related to the agent on the destination system.

destinationAgent

JSON object.

Contains attributes that are related to the agent on the destination system.

originator

JSON object.

Contains attributes that are related to the originator of the request.

transferSet

JSON object.

Contains attributes that are related to the group of file transfers.

For more information, see [“ Response body attributes for list resource monitor” on page 2271.](#)

If an error occurs, see [REST API error handling.](#)

Examples

The following example returns a default set of data for all resource monitors.

The following URL is used with the HTTP GET method:

```
https://localhost:9443/ibmmq/rest/v2/admin/mft/monitor
```

The following JSON response is returned:

```
{
  "monitor": [
    {
      "name": "DIRMONWILDCARD",
      "agentName": "SRCWILDCARD",
      "type": "directory",
      "state": "started",
      "resource": {
        "name": "C:\\MFT"
      }
    },
    {
      "name": "DIRMONREGEX",
      "agentName": "SRCDIRREG",
      "type": "directory",
      "state": "started",
      "resource": {
        "name": "C:\\MFT"
      }
    },
    {
      "name": "DIRMONREGEXFILESIZECHANGE",
      "agentName": "SRCDIR",
      "type": "directory",
      "state": "started",
      "resource": {
        "name": "C:\\MFT"
      }
    }
  ]
}
```

The following example lists the default attributes for a specified resource monitor whose name is DIRMONWILDCARD. The following URL is used with the HTTP GET method:

```
https://localhost:9443/ibmmq/rest/v2/admin/mft/monitor/DIRMONWILDCARD
```

The following JSON response is returned:

```
{
  "monitor": [
    {
      "name": "DIRMONWILDCARD",
      "agentName": "SRCWILDCARD",

```

```

    "type": "directory",
    "state": "started",
    "resource": {
      "name": "C:\\MFT"
    }
  }
}

```

The following example lists the default attributes for all the resource monitors whose names begin with DIR. The following URL is used with the HTTP GET method:

```
https://localhost:9443/ibmmq/rest/v2/admin/mft/monitor?name=DIR*
```

The following JSON response is returned:

```

{"monitor": [
  {
    "name": "DIRMONWILDCARD",
    "agentName": "SRCWILDCARD",
    "type": "directory",
    "state": "started",
    "resource": {
      "name": "C:\\MFT"
    }
  },
  {
    "name": "DIRMONREGEX",
    "agentName": "SRCDIRREG",
    "type": "directory",
    "state": "started",
    "resource": {
      "name": "C:\\MFT"
    }
  },
  {
    "name": "DIRMONREGEXFILESIZECHANGE",
    "agentName": "SRCDIR",
    "type": "directory",
    "state": "started",
    "resource": {
      "name": "C:\\MFT"
    }
  }
]}

```

The following example lists details for all the resource monitors whose type is `directory` and the state is `stopped`. The following URL is used with the HTTP GET method:

```
https://localhost:9443/ibmmq/rest/v2/admin/mft/monitor?type=directory&state=stopped
```

```

{"monitor": [
  {
    "name": "TRIGCONTENTSCSTM",
    "type": "directory",
    "state": "stopped",
    "agentName": "TRIGCONTSCSTM",
    "resource": {
      "name": "C:\\MFT"
    }
  }
]}

```

name

String.

The unique name of the resource monitor

Type

String.

Type of the resource monitor

The value is one of the following values:

directory

The type of the resource to be monitored is file system directory.

queue

The type of the resource to be monitored is an IBM MQ queue.

agentName

String.

Name of the agent that owns the resource monitor.

State

String.

State of the monitor.

The value is one of the following values:

started

The monitor is running.

stopped

The monitor is stopped.

general

Group element that defines the other high level attributes of monitor.

pollInterval

Integer.

Frequency at which a monitor polls a resource. The unit of time that is used for this value is specified in the **pollIntervalUnit** attribute.

pollIntervalUnit

String.

Specifies the time interval for the **pollInterval** attribute. Possible values are seconds, minutes, hours, days.

matchesPerTask

Integer.

Maximum number of trigger matches to include in a single task.

resource

Group element that defines the monitored resource.

The **name** attribute in this object is always returned.

name

String.

Specifies either the absolute path of a file system directory, or a queue name.

This attribute is always returned.

recursionLevel

Integer.

Specifies the number of subdirectories to search to find a matching trigger file. This attribute is valid, only for a directory type of resource monitor.

transferDefinition

A list of items that are transferred when a trigger event fires. There is at least one item in the response.

destinationAgent

Group element that contains elements that define a destination agent.

The **name** and the **qmgrName** attributes in this object are always returned.

qmgrName

String.

The name of the queue manager on the destination system.

name

String.

The name of the agent on the destination system.

job

A group that contains the following attribute, which is always returned:

name

String.

User defined job name for the transfer.

originator

Group element that contains the elements that specify the originator of the transfer request.

The **host** and **userid** attributes in this object are always returned.

host

String.

The host name of the system where the source file is located.

userid

String.

The user ID that originated the file transfer.

sourceAgent

Group element that contains the elements that define a source agent.

The **name** and the **qmgrName** attributes in this object are always returned.

qmgrName

String.

The name of the queue manager on the source system.

name

String.

The name of the agent on the source system.

transferSet

Group element that contains the elements that specify a transfer request.

The **item** attribute in this object is always returned.

priority

Integer (optional).

Priority assigned to the transfer request. If no value is set, the default is zero.

userProperties

Object (optional).

User defined properties specified in the transfer request.

item

Object.

Array of group elements that describe the source and destination item configuration to transfer.

source

Object.

Group element that contains the attributes of a source item.

The **name** and **type** attributes in this object are always returned.

name

String.

Specifies the absolute path of the file, directory, data set, partitioned data set, or queue at source end.

type

String.

The type of source. The value is one of the following values:

queue

Specifies an IBM MQ queue as the source.

file

Specifies a file as the source.

directory

Specifies a directory as the source.

sequentialDataset

Specifies a z/OS sequential data set as the source.

partitionedDataset

Specifies a z/OS partitioned data set as the source.

recursive

Boolean (optional).

Specifies that files are transferred recursively in subdirectories when the source element is a directory, or contains wildcard characters.

disposition

String (optional).

Specifies the action that is taken on the source element when a source has successfully been transferred to its destination. The value of disposition is one of the following values:

leave

The source files are left unchanged.

delete

The source files are deleted from the source system after the source file is successfully transferred.

encoding

String (optional)

Specifies which character encoding to use to read the source file when performing character conversion. This option is only applicable to text files and the possible value is any valid code page number.

datasetExtended

Object (optional).

Group element that defines additional attributes of the source specification, if the source is a z/OS data set in a transfer request.

The **hexDelimiters** and **delimiterPosition** attributes in this object are always returned.

keepTrailingSpaces

Boolean (optional).

Describes the action that is taken if there are trailing spaces in the source records that are read from a fixed-length-format record-oriented file (for example, a z/OS data set) as part of a text mode transfer.

hexDelimiters

String.

For source files that are record oriented (for example, z/OS data sets), specifies one or more byte values to insert as the delimiter when appending records into a binary file. Each value is represented as two hexadecimal digits in the range 00-FF, prefixed by x.

delimiterPosition

String.

Specifies the position of insertion for source text and binary delimiters. The value is one of the following values:

prefix

The delimiters are inserted at the start of each record.

postfix

The delimiters are inserted at the end of each record. This option is the default option.

queueExtended

Object (optional).

Group element that defines additional attributes of a source specification, if the source is an IBM MQ queue in a transfer request.

The **useMessageGroup** and **groupID** attributes in this object are always returned.

useMessageGroup

Boolean.

Specifies that the messages are grouped by IBM MQ group ID. The first complete group is written to the destination file. If this parameter is not specified, all messages on the source queue are written to the destination file.

groupID

String.

Group ID to be used when getting messages from a queue.

textDelimiters

String (optional).

Specifies a sequence of text to insert as the delimiter, when appending multiple messages to a text file.

hexDelimiters

String (optional).

Comma separated string of hexadecimal bytes to use, when appending multiple messages to a file. For example x12 or x03 , x7F.

delimiterPosition

String (optional).

Defines where the delimiters are positioned in the message being put to the source queue. Possible values are:

prefix

Before the beginning of the message body.

postfix

After the end of the message body; this is the default option.

messageArrivalWaitTime

Integer.

Time in seconds, to wait for arrival of messages in the source queue.

destination

Object.

Group element that contains the attributes of a destination item.

The **name** and **type** attributes in this object are always returned.

name

String.

Specifies the absolute path of the file, directory, data set, partitioned data set, or queue at the destination end.

type

String.

The type of destination. The value is one of the following values:

queue

Specifies an IBM MQ queue as the destination.

file

Specifies a file as the destination.

directory

Specifies a directory as the destination.

sequentialDataset

Specifies a z/OS sequential data set as the destination.

partitionedDataset

Specifies a z/OS partitioned data set as the destination.

actionIfExists

String(optional).

Specifies the action that is taken if a destination file exists on the destination system. The value is one of the following values:

error

Reports an error and the file is not transferred; this is the default value.

overwrite

Overwrites the existing destination file.

encoding

String (optional).

Specifies which character encoding to use to read the source file when performing character conversion. This option is only applicable to text files and the possible value is any valid code page number.

endOfLine

String (optional).

Specifies the end-of-line characters that are used when the file is written at the destination. This option is applicable to text files only.

userId

String (optional).

The name of the user whose destination file space the files are transferred into.

datasetExtended

Object (optional).

Group element that defines additional attributes of the destination specification, if the destination is a z/OS data set in a transfer request.

truncateRecords

Boolean.

Specifies that destination records longer than the LRECL data set attribute are truncated. If this parameter is not specified, the records are wrapped. This parameter is valid only for text mode transfers where the destination is a data set.

queueExtended

Object (optional).

Group element that defines additional attributes of a destination specification, if the destination is an IBM MQ queue in a transfer request.

The **messagePersistence** and **delimiterType** attributes in this object are always returned.

messagePersistence

String.

Defines if the message put to the destination queue is persistent or non-persistent. The value is one of the following values:

persistent

Messages are persistent.

nonPersistent

Messages are non-persistent.

asQueueDefault

Message persistency is set, depending on the queue definition.

delimiterType

String.

Defines the type of delimiter to use when splitting incoming data into messages. The value is one of the following values:

size

Split based on given size.

binary

Split based on given delimiters.

hexDelimiters

String (optional).

Comma separated string of hexadecimal bytes to use when splitting messages. For example x12 or x03 , x7F.

textDelimiters

String (optional).

Specifies the Java regular expression to use when splitting a text file into multiple messages.

includeDelimitersInMessage

Boolean.

Defines whether delimiters are included in a message being put to the destination queue.

delimiterPosition

String.

Defines where the delimiters are positioned in the message being put to the destination queue. The value is one of the following values:

prefix

Before the beginning of the message body.

postfix

After the end of the message body; this is the default option.

setMQProperties

Boolean (optional).

Valid only when the destination is a queue. The value is one of the following values:

true

Sets message properties on the first message that is created by the transfer.

false

Does not set message properties on the first message that is created by the transfer.

messageSize

Integer.

Defines a size in bytes to split the incoming data into the message.

checksum

String (optional).

Checksum method for verifying data integrity. The value is one of the following values:

md5

MD5 algorithm used for integrity validation.

none

No checksum validation.

mode

String (optional).

Specifies the transfer mode as either binary or text. The value is one of the following values:

text

Data is transferred as text.

binary

Data is transferred in binary.

recoveryTimeout

Integer (optional).

Time in seconds to wait for a transfer to recover.

-1 is the default value.

preSourceCall

Object (optional).

Group elements that contain the elements for program invocation before a transfer begins at the source.

These group elements are not present if a resource monitor is not configured to use any program invocation.

type

String (optional).

Defines the type of the program to be invoked. The value is one of the following values:

executable

This value is the default value.

Defines attributes for a platform specific executable program:

name

String.

Name of the program to process.

arguments

String (optional).

Argument or arguments to be passed to the program being invoked.

antScript

Defines attributes for Ant Script:

name

String.

Name of the Ant script to process.

target

String (optional)

Target to invoke in the specified Ant script. Attribute is not present in the JSON response, if the default target is to be invoked.

arguments

String (optional).

A list of user defined custom data in space separated key=value pair of type **String**. For example:

```
"arguments": "coffeeType=Arabica teaChoice=lemon"
```

jcl

Defines attributes for z/OS JCL to submit.

name

String.

Name of the JCL to submit.

retryCount

Integer (optional).

A positive number of attempts to run the command before ceasing.

retryWait

Integer (optional).

Amount of time to wait, in seconds, between two retry attempts.

successReturnCode

String (optional).

Reason code that is returned when transfer is complete. This is looked for before running the specified program, script, or JCL. This return code is a combination of an operator and value in the form of "[>|<|!] value". Note that it is valid to have a combination of more than one operator, for example ">= 40".

postSourceCall

Object (optional).

Group elements that contain the elements for program invocation after a transfer completes at source. This object contains the same elements as **preSourceCall**.

preDestinationCall

Object (optional).

Group elements that contain the elements for program invocation before a transfer begins at the destination. This object contains the same elements as **preSourceCall**.

postDestinationCall

Object (optional).

Group elements that contain the elements for program invocation after a transfer completes at the destination. This object contains the same elements as **preSourceCall**.

triggerCondition

Group element that defines details of a trigger condition used by a resource monitor.

type

String.

Indicates the type of matching done, to decide on triggering a transfer. The value is one of the following values:

For resource type **Directory**:

matchAll

Must match the value specified for the **includePattern** and **excludePattern** attributes.

matchNone

None of the files in the monitored directory match the value specified for the **includePattern** and **excludePattern** attributes.

noChangeInSize

Initiate a transfer, if the size of the file being monitored does not change for a specified number of poll intervals.

sizeGreaterOrEqualTo

Initiate a transfer, if the size of the file being monitored is greater than or equal to a specified size.

For resource type **Queue**:

queueNotEmpty

Queue must have at least one message.

completeMessageGroups

Queue must have at least one group of messages.

noFileSizeChangePollCount

Integer.

Refers to the number of polling intervals during which the size of the monitored file does not change. Used in conjunction with the **noChangeInSize** attribute

fileSize

Integer.

Refers to the size of the trigger file being monitored, whose size is equal to or greater. Used in conjunction with the **sizeGreaterOrEqualTo** attribute.

fileSizeUnit

String.

Defines the unit for the **fileSize** attribute. The value is one of the following values:

bytes

File size unit is in bytes

kilobytes

File size unit is in kilobytes

megabytes

File size unit is in megabytes

gigabytes

File size unit is in gigabytes

includePattern

String.

A pattern of the name, or names, of files to be included, while doing match for a trigger condition.

excludePattern

String.

A pattern of the name, or names, of files to be excluded, while doing match for a trigger condition.

matchPattern

String.

Indicates how to interpret the contents of the **includePattern** and **excludePattern** attributes. The value is one of the following values:

wildcard

- Indicates the **includePattern** and **excludePattern** attributes contain wildcard characters, for example, *.

regularExpression

Indicates the **includePattern** and **excludePattern** attributes contain Java regular expressions.

triggerFileContentFormat

A trigger file defines a list of files transferred when a trigger condition is satisfied. The trigger file might define only the source path, or both source and destination paths. Each line in a trigger file points to a file to transferred.

This object is valid only for **triggerCondition.type** of **matchAll** and **noChangeInSize**.

groupOrder

String.

The trigger file contains names of source file names, destination file names, or both. This attribute defines the order of the source file names, destination file names, or both. The value is one of the following values:

sourceDestination

Source file name appears first, followed by destination file name.

destinationSource

Destination file name appears first followed by source file name.

customPattern

String (optional).

A Java regular expression to apply, while parsing trigger file contents for generating a list of files to transfer.

[Getting started with the REST API for MFT](#)

Related reference

["/admin/mft/monitor" on page 2251](#)

You can use the HTTP GET method with the `monitor` resource to request information about a Managed File Transfer resource monitor. You can use the HTTP POST method to create a resource monitor, and the HTTP DELETE method to delete a resource monitor.

DELETE

Use the HTTP DELETE method with the `monitor` resource to delete an existing monitor, or delete the history of an existing monitor.

Note:

- Set the command queue manager in the configuration before issuing any MFT Create Monitor or Transfer REST API command. See [Configuring the REST API for MFT](#) for more information.
- **V9.4.0** You cannot use this resource with the stand-alone IBM MQ Web Server. For more information about the installation options for the IBM MQ component that runs the administrative REST API, see [The IBM MQ Console and REST API](#).
- [Resource URL](#)
- ["Request headers" on page 2282](#)
- [Request body format](#)

- [“Security requirements” on page 2282](#)
- [Response status codes](#)
- [“Response headers” on page 2283](#)
- [Response body format](#)

Resource URL

To delete an existing monitor:

```
https://host:portibmmq/rest/v2/admin/mft/monitor/
{monitor name}?agent=<agentName>&agentQmgr=<QmgrName>
```

To delete the history of an existing monitor:

```
https://host:portibmmq/rest/v2/admin/mft/monitor/
{monitor name}/history?agent=<agentName>&agentQmgr=<QmgrName>
```

You can use HTTP instead of HTTPS if you enable HTTP connections. For more information about enabling HTTP, see [Configuring the HTTP and HTTPS ports](#).

Request headers

The following headers must be sent with the request:

Content-Type

This header must be sent with a value of `application/json` optionally followed by `; charset=UTF-8`.

ibm-mq-rest-csrf-token

This header must be set, but the value can be anything, including being blank.

Authorization

This header must be sent if you are using basic authentication. For more information, see [Using HTTP basic authentication with the REST API](#).

Request body format

None.

Security requirements

The caller must be authenticated to the mqweb server and must be a member of the MFTWebAdmin or MFTWebUser roles. For more information about security for the administrative REST API, see [IBM MQ Console and REST API security](#).

If token based security is used, the LTPA token that is used to authenticate the user must be provided with the request as a cookie. For more information about token-based authentication, see [Using token-based authentication with the REST API](#).

If you have set up a [user sandbox](#), and [MFT authority checking](#), or MFT authority checking, is turned on, you need to grant an additional authority for the user that started the WebSphere Liberty server to access the specified file system location.

For the MFTWebAdmin role, transfer requests are submitted under the context of the user that started the Liberty server. To distinguish between different principals of the MFTWebAdmin role, and for audit purposes, the transfer request submitted contains the name of the authenticated user as the transfer originator. This method ensures that there is a record of who initiated the transfer request.

For example, if the user `mftadminusr`, of the MFTWebAdmin role, initiates a transfer, the originator data in the XML has `mftadminusr` in the `userID` element, as shown in this example:

```
<originator>
```

```
<hostName>example.com.</hostName>
<userID>mftadminusr</userID>
</originator>
```

If the caller is a member of the MQWebUser role, the security principal of the caller must be granted one of the following authorities:

1. If the command queue is local, that is, the command queue manager and source agent queue manager are the same, grant put authority to the command queue.
2. If the command queue is remote, that is, the command queue manager and source agent queue manager are different, grant put authority to the transmission queue.

Notes:

- If the user ID of a principal that is a member of the MQWebUser role is longer than 12 characters, the request fails. Response status code 403 is returned to the caller.
- If the caller is assigned more than one role, the highest privilege role that is applicable to the operation is used.

If security is disabled on the mqweb server, the transfer request submitted contains the name "UNAUTHENTICATED" as the transfer originator.

Response status codes

202

The delete request has been accepted by the REST API. It might still get rejected by the MFT agent.

400

Invalid or unknown data provided to delete resource monitor.

For example, invalid attributes specified.

401

Not authenticated.

The user must be authenticated to the mqweb server. For more information, see [“Security requirements”](#) on page 2282.

The `ibm-mq-rest-csrf-token` header must also be specified.

403

Access prohibited for one of the following reasons:

- Not authorized. The caller is authenticated to the mqweb server and is associated with a valid principal. However, the principal does not have access to the required IBM MQ or MFT resources.
- **V9.4.0** Access prohibited in the current server environment. You cannot use the administrative REST API with the stand-alone IBM MQ Web Server.

500

Server issue, or error code from IBM MQ or MFT.

Response headers

The following header is returned with the response:

location

If the request was successful, this header specifies the URL with the details of the deleted resource monitor. `https://host:port/ibmmq/rest/v1/admin/mft/monitor/{monitorName}` .

Response body format

The response body is empty if the deletion is successful.

If an error occurs, the response body contains an error message; see [REST API error handling](#).

Related tasks

[“Request body attributes for MFT resource monitors” on page 2256](#)

The Create Monitor REST API takes the input attributes as JSON objects.

/admin/mft/transfer

You can use the HTTP GET method with the `transfer` resource to request information about Managed File Transfer transfers. You can use the HTTP POST method to put a transfer request message to the command queue manager, which will be routed to the source agent queue manager.

Note: **V9.4.0** You cannot use this resource with the stand-alone IBM MQ Web Server. For more information about the installation options for the IBM MQ component that runs the administrative REST API, see [The IBM MQ Console and REST API](#).

Overview of the HTTP GET method

As a user you can obtain the transfer details of file transfers that have been initiated.

You can retrieve the transfer details of all the transfers that are initiated using the coordination queue manager defined in the `mqwebuser.xml` and a list of all the transfers initiated by yourself. For example, if you initiated 100 transfers and want to know the status of those transfers, the GET method serves the purpose.

See [“GET” on page 2298](#) for more information.

Overview of the HTTP POST method

As an administrator, you must create a file transfer as necessary for a particular task, or to schedule a new file transfer. This API facilitates in creating the transfer, and also allows you to request a scheduled file transfer.

You can perform a scheduled file transfer once or repeat the transfer multiple times. You can :

- Schedule a file transfer to occur once, or to occur at regular intervals, for example, every minute.
- Specify the occurrences to stop at a defined time and date, or after a defined number of occurrences.
- Specify that the occurrences continue forever.

See [“POST” on page 2284](#) for more information.

Related tasks

[Getting started with the REST API for MFT](#)

Related reference

[“/admin/mft/agent” on page 2228](#)

You can use the HTTP GET method with the `agent` resource, to request information about Managed File Transfer agents.

POST

Use the HTTP POST method with the `transfer` resource to create a Managed File Transfer transfer.

Note:

- You must set a command queue manager before you can create a transfer with the `transfer` resource. For more information, see [Configuring the REST API for MFT](#).
- **V9.4.0** This resource is not available in a stand-alone IBM MQ Web Server installation. For more information about the installation options for the IBM MQ component that runs the administrative REST API, see [The IBM MQ Console and REST API](#).

- [Request body format](#)
- [“Security requirements” on page 2285](#)
- [Response status codes](#)
- [“Response headers” on page 2287](#)
- [Response body format](#)
- [Examples](#)

Resource URL

`https://host:port/ibmmq/rest/v2/admin/mft/transfer/`

You can use HTTP instead of HTTPS if you enable HTTP connections. For more information about enabling HTTP, see [Configuring the HTTP and HTTPS ports](#).

Request headers

The following headers must be sent with the request:

Content-Type

This header must be sent with a value of `application/json` optionally followed by `; charset=UTF-8`.

ibm-mq-rest-csrf-token

This header must be set, but the value can be anything, including being blank.

Authorization

This header must be sent if you are using basic authentication. For more information, see [Using HTTP basic authentication with the REST API](#).

Request body format

The request body must be in JSON format in UTF-8 encoding. Attributes marked *required* are mandatory. If you do not provide values for the other parameters in the request body, the default values are used.

The following objects can be included in the request body:

job

Contains attributes that are related to the transfer job.

sourceAgent

Contains attributes that are related to the source agent. This object is required.

destinationAgent

Contains attributes that are related to the destination agent. This object is required.

scheduleTransfer

Contains attributes that are related to scheduling a transfer.

transferSet

Contains attributes that are related to the transfer.

See [“Request body attributes for transfers with HTTP POST” on page 2290](#) for a list of all the attributes.

Security requirements

The caller must be authenticated to the mqweb server and must be a member of the MFTWebAdmin or MQWebUser roles. For more information about security for the administrative REST API, see [IBM MQ Console and REST API security](#).

If token based security is used, the LTPA token that is used to authenticate the user must be provided with the request as a cookie. For more information about token-based authentication, see [Using token-based authentication with the REST API](#).

If you have MFT authority checking turned on, grant additional authorities as described in [Restricting user authorities on MFT agent actions](#). You need to grant the following additional authorities:

1. If the caller is a member of the MFTWebAdmin role, the user ID which started the mqweb server must be granted authority access to the transfer source location.
2. If the caller is a member of the MQWebUser role, the security principal of the caller must be granted access to the transfer source location.

For the MFTWebAdmin role, transfer requests are submitted under the context of the mqweb server user ID. To distinguish between different principals of the MFTWebAdmin role, and for audit purposes, the transfer request submitted contains the name of the authenticated user as the transfer originator. This method ensures that there is a record of who initiated the transfer request.

For example, if the user mftadminusr, of the MFTWebAdmin role, initiates a transfer, the originator data in the XML that is created to describe the transfer has mftadminusr in the userID element, as shown in this example:

```
<originator>
  <hostName>example.com.</hostName>
  <userID>mftadminusr</userID>
</originator>
```

If the caller is a member of the MQWebUser role, the security principal of the caller must be granted one of the following authorities:

1. If the command queue is local, that is, the command queue manager and source agent queue manager are the same, grant put authority to the command queue.
2. If the command queue is remote, that is, the command queue manager and source agent queue manager are different, grant put authority to the transmission queue.

Notes:

- If the user ID of a principal that is a member of the MQWebUser role is longer than 12 characters, the request fails. Response status code 403 is returned to the caller.
- If the caller is assigned more than one role, the highest privilege role that is applicable to the operation is used.

If security is disabled on the mqweb server, the transfer request submitted contains the name "UNAUTHENTICATED" as the transfer originator.

Response status codes

202

The file transfer request has been accepted by the REST API. It might still get rejected by the MFT agent. You should issue a GET command, using the URL from the location response header to ascertain the state of the transfer.

400

Invalid data provided.

For example, invalid attributes specified.

401

Not authenticated.

The user must be authenticated to the mqweb server. For more information, see [“Security requirements”](#) on page 2285.

The `ibm-mq-rest-csrf-token` header must also be specified.

403

Access prohibited for one of the following reasons:

- Not authorized. The caller is authenticated to the mqweb server and is associated with a valid principal. However, the principal does not have access to the required IBM MQ or MFT resources.

- **V9.4.0** Access prohibited in the current server environment. You cannot use the administrative REST API with the stand-alone IBM MQ Web Server.

500

Server issue, or error code from IBM MQ or MFT.

503

Queue manager not running.

Response headers

The following header is returned with the response:

location

If the request was successful, this header specifies the URL for the new transfer.

Response body format

The response body is empty if the transfer is created successfully.

If an error occurs, the response body contains an error message; see [REST API error handling](#).

Examples

- The following example creates a simple file transfer. The following URL is used with the HTTP POST method:

```
https://localhost:9443/ibmmq/rest/v2/admin/mft/transfer/
```

The following JSON payload is sent:

```
{
  "sourceAgent": {
    "qmgrName": "NYQM",
    "name": "NY.AGENT"
  },
  "destinationAgent": {
    "qmgrName": "WASHQM",
    "name": "WASH.AGENT"
  },
  "transferSet": {
    "item": [
      {
        "source": {
          "name": "C:\\temp\\src\\test.txt",
          "type": "file"
        },
        "destination": {
          "name": "C:\\temp\\dst\\test.txt",
          "type": "file"
        }
      }
    ]
  }
}
```

- The following example creates a transfer from a file to a queue. The following URL is used with the HTTP POST method:

```
https://localhost:9443/ibmmq/rest/v2/admin/mft/transfer/
```

The following JSON payload is sent:

```
{
  "job": {
    "name": "TESTJOB",
  },
  "sourceAgent": {
    "name": "WASH.AGENT",
  }
}
```

```

    "qmgrName": "WASHQM"
  },
  "destinationAgent": {
    "name": "NY.AGENT",
    "qmgrName": "NYQMGR"
  },
  "transferSet": {
    "priority": 1,
    "recoveryTimeout": -1,
    "item": [
      {
        "checksum": "md5",
        "mode": "text",
        "destination": {
          "actionIfExists": "error",
          "name": "LQ@NYQMGR",
          "type": "queue",
          "delimiterType": "size",
          "messagePersistence": "persistent",
          "queueExtended": {
            "messageSize": 4,
            "setMQProperties": false
          }
        },
        "source": {
          "disposition": "leave",
          "name": "C:\\temp\\src\\test.txt",
          "recursive": false,
          "type": "file"
        }
      }
    ]
  }
}

```

- The following example creates a transfer from a directory to a directory. The following URL is used with the HTTP POST method:

```
https://localhost:9443/ibmmq/rest/v2/admin/mft/transfer/
```

The following JSON payload is sent:

```

{
  "job": {
    "name": "TESTJOB",
  },
  "sourceAgent": {
    "name": "WASH.AGENT",
    "qmgrName": "WASHQM"
  },
  "destinationAgent": {
    "name": "NY.AGENT",
    "qmgrName": "NYQMGR"
  },
  "transferSet": {
    "item": [
      {
        "checksum": "md5",
        "destination": {
          "actionIfExists": "error",
          "name": "C:\\temp\\dst",
          "type": "directory"
        },
        "source": {
          "disposition": "leave",
          "name": "C:\\temp\\src",
          "recursive": false,
          "type": "directory"
        }
      }
    ]
  }
}

```

- The following example creates a transfer from a file to a file, using `preSourceCall`, `postSourceCall`, `preDestinationCall`, and `postDestinationCall` to invoke programs during the transfer. The following URL is used with the HTTP POST method:

```
https://localhost:9443/ibmmq/rest/v2/admin/mft/transfer/
```

The following JSON payload is sent:

```
{
  "sourceAgent": {
    "qmgrName": "NYQM",
    "name": "NY.AGENT"
  },
  "destinationAgent": {
    "qmgrName": "WASHQM",
    "name": "WASH.AGENT"
  },
  "transferSet": {
    "item": [
      {
        "source": {
          "name": "C:\\temp\\src\\test.txt",
          "type": "file"
        },
        "destination": {
          "name": "C:\\temp\\dst\\test.txt",
          "type": "file"
        }
      }
    ],
    "userProperties": {
      "ARCHIVE_PATH": "C:\\MFT\\ARCHIVE",
      "REJECT_PATH": "C:\\MFT\\REJECT"
    },
    "postSourceCall": {
      "type": "executable",
      "executable": {
        "name": "posttransfersource.exe",
        "arguments": "postdata1 postdata2"
      }
    },
    "postDestinationCall": {
      "type": "executable",
      "executable": {
        "name": "posttransferdest.exe",
        "arguments": "postdataDest1 postdataDest2"
      }
    },
    "preDestinationCall": {
      "type": "executable",
      "executable": {
        "name": "pretransferdest.exe"
      }
    },
    "preSourceCall": {
      "type": "executable",
      "executable": {
        "name": "posttransferdest.exe",
        "arguments": "predata1 predata2"
      }
    },
    "priority": 0,
    "recoveryTimeout": 21600
  }
}
```

When you create the request body for creating a transfer request with the administrative REST API for MFT, you can specify attributes for the transfer within named JSON objects. A number of objects and attributes are available.

Request body attributes for transfers with HTTP POST

When you create the request body for creating a transfer request with the administrative REST API for MFT, you can specify attributes for the transfer within named JSON objects. A number of objects and attributes are available.

The following objects are available:

- [“job” on page 2290](#)
- [“sourceAgent” on page 2290](#)
- [“destinationAgent” on page 2290](#)
- [“scheduleTransfer” on page 2290](#)
- [“transferSet” on page 2291](#)

job

The `job` object can contain the following attributes that relate to the transfer job:

name

String.

Specifies a user-defined job name for the transfer.

sourceAgent

The `sourceAgent` object can contain the following attributes that relate to the source agent:

name

String.

Specifies the name of the agent on the source system.

This attribute is required.

qmgrName

String.

Specifies the name of the queue manager on the source system.

This attribute is required.

destinationAgent

The `destinationAgent` object can contain the following attributes that relate to the destination agent:

name

String.

Specifies the name of the agent on the destination system.

This attribute is required.

qmgrName

String.

Specifies the name of the queue manager on the destination system.

This attribute is required.

scheduleTransfer

The `scheduleTransfer` object can contain the following attributes that relate to a scheduled transfer:

startTime

String.

Specifies the start time and date for the scheduled transfer in the format yyyy-MM-ddThh:mm or hh:mm. Specify the time by using the 24-hour clock.

timeBase

String.

Specifies the time base for the start and end time of the scheduled file transfer.

The value must be one of the following values:

admin

The start and end time for the scheduled transfer are based on the time and date of the system where the mqweb server is running.

source

The start and end time for the scheduled transfer are based on the time and date of the system where the source agent is located.

utc

The start and end time for the scheduled transfer are based on Coordinated Universal Time.

occurrenceInterval

String.

Specifies the interval that the scheduled transfer occurs at.

Use this attribute in conjunction with the startTime and occurrenceFrequency attributes.

The value must be one of the following values:

- minutes
- hours
- days
- weeks
- months
- years

occurrenceFrequency

Integer.

Specifies the frequency of a repeating scheduled transfer. Use this attribute in conjunction with the startTime and occurrenceInterval attributes.

occurrenceCount

Integer.

Specifies the number of times that the scheduled transfer will occur.

Use this attribute in conjunction with the startTime and occurrenceInterval attributes.

This attribute can not be specified with the endTime attribute.

endTime

String.

Specifies the time and date when a repeating scheduled transfer ends in format yyyy-MM-ddThh:mm or hh:mm. Specify the time by using the 24-hour clock.

Use this attribute in conjunction with the startTime and occurrenceInterval attributes.

This attribute can not be specified with the occurrenceCount attribute.

transferSet

The transferSet object can contain the following attributes that relate to the transfer:

priority

Integer.

Specifies the priority assigned to the transfer request. The default value is zero.

userProperties

JSON object.

Specifies user-defined metadata that is passed to exits run by the agents involved in the transfer.

item

JSON array.

An array of JSON objects that describe the source and destination item configurations to transfer.

source

JSON object.

A JSON object that contains attributes that relate to the source item to transfer.

name

String.

Specifies the absolute path of the file, directory, data set, partitioned data set, or queue at the source end.

This attribute is required.

type

String.

Specifies the type of source.

The value must be one of the following values:

queue

The source is an IBM MQ.

file

The source is a file.

recursive

Boolean.

Specifies whether files are transferred recursively in subdirectories when the source element is a directory, or contains wildcard characters.

disposition

String.

Specifies the action that is taken on the source element when a source has successfully been transferred to its destination.

The value must be one of the following values:

leave

The source files are left unchanged.

delete

The source files are deleted from the source system when they have been successfully transferred.

encoding

String

Specifies which character encoding to use, to read the source file when performing character conversion. This option is only applicable to text files.

The values can be any valid code page number.

 **datasetExtended**

JSON object.

A JSON object that contains additional source attributes, if the source is a z/OS sequential or partitioned data set.

keepTrailingSpaces

Boolean.

Specifies whether trailing spaces are kept in the source records that are read from a fixed-length format record oriented file (for example, a z/OS data set) as part of a text mode transfer.

If you do not specify this parameter, trailing spaces are stripped from source records.

hexDelimiters

String.

For source files that are record oriented (for example, z/OS data sets), specifies one or more byte values to insert as the delimiter when appending records into a binary file.

You must specify each value as two hexadecimal digits in the range 00-FF, prefixed by x. Separate multiple bytes with commas.

delimiterPosition

String

Specifies the position to insert source record delimiters. This attribute is used in conjunction with the hexDelimiters attribute.

The value must be one of the following values:

prefix

The delimiters are inserted at the start of each record.

postfix

The delimiters are inserted at the end of each record; this is the default option.

queueExtended

JSON object.

A JSON object that contains additional source attributes, if the source is an IBM MQ queue.

messageGroup

Boolean.

Specifies whether messages are grouped by IBM MQ group ID. The first complete group is written to the destination file.

If this parameter is not specified, all messages on the source queue are written to the destination file.

groupID

String.

Specifies the group ID to be used when getting messages from a queue.

textDelimiters

String.

Specifies a sequence of text to insert as the delimiter, when appending multiple messages to a text file.

hexDelimiters

String.

Specifies one or more byte values to use, when appending multiple messages to a file.

You must specify each value as two hexadecimal digits in the range 00-FF, prefixed by x. Separate multiple bytes with commas. For example x12 or x03 , x7F.

delimiterPosition

String.

Specifies where the delimiters are positioned in the message being put to the source queue.

The value must be one of the following values:

prefix

The delimiters are inserted at the start of each message.

postfix

The delimiters are inserted at the end of each message; this is the default option.

messageArrivalWaitTime

Integer.

Specifies the time in seconds to wait for the arrival of messages on the source queue.

destination

JSON object.

A JSON object that contains attributes that relate to the destination item.

name

String.

Specifies the absolute path of the file, directory, data set, partitioned data set, or queue at the destination.

This attribute is required.

type

String.

Specifies the type of destination.

This attribute is required.

The value must be one of the following values:

queue

The destination is an IBM MQ queue.

file

The destination is a file.

directory

The destination is a directory.

 **sequentialDataset**

The destination is a z/OS sequential data set.

 **partitionedDataset**

The destination is a z/OS partitioned data set.

actionIfExists

String.

Specifies the action that is taken if a destination file, directory, or data set exists on the destination system.

The value must be one of the following values:

error

An error is reported and the file is not transferred; this is the default value.

overwrite

The existing destination file is overwritten.

encoding

String.

Specifies which character encoding to use to write the file at the destination. This option is only applicable to text files.

The value can be any valid code page number.

endOfLine

String.

Specifies the end-of-line characters that are used when the file is written at the destination. This option is applicable to text files only.

The value must be one of the following values:

LF

Line feed.

CRLF

Carriage return followed by line feed.

z/OS datasetExtended

JSON object.

A JSON object that contains additional destination attributes, if the destination is a z/OS data set.

truncateRecords

Boolean.

Specifies whether destination records longer than the data set LRECL attribute are truncated. If this parameter is not specified, the records are wrapped.

This parameter is valid only for text mode transfers where the destination is a data set.

queueExtended

JSON object.

A JSON object that contains additional destination attributes, if the destination is an IBM MQ queue.

messagePersistence

String.

Specifies the persistence of the message put to the destination queue.

The value must be one of the following values:

persistent

Messages are persistent.

notPersistent

Messages are not persistent.

asQueue

The message persistence is as set in the queue definition. This is the default value.

delimiterType

String.

Specifies the type of delimiter to use when splitting a file into multiple messages.

The value must be one of the following values:

size

Split based on a specified size.

binary

Split based on specified delimiters.

hexDelimiters

String.

Specifies the hexadecimal delimiter to use when splitting a binary file into multiple messages.

You must specify each value as two hexadecimal digits in the range 00-FF, prefixed by x. You can specify a sequence of hexadecimal bytes as a delimiter by specifying a comma-separated list of hexadecimal bytes. For example x12 or x03 , x7F.

textDelimiters

String.

Specifies the Java regular expression to use, when splitting a text file into multiple messages.

includeDelimitersInMessage

Boolean.

Specifies whether delimiters are inserted in the message put to the destination queue.

delimiterPosition

String

Specifies where the delimiters are positioned in the message put to the destination queue.

The value must be one of the following values:

prefix

The delimiters are inserted at the beginning of the message body.

postfix

The delimiters are inserted at the end of the message body.

setMQProperties

Boolean.

Specifies whether message properties are set on the first message that is created by the transfer.

messageSize

Integer.

Specifies whether to split the file into multiple fixed-length messages of this size in bytes.

checksum

String.

Specifies the checksum method for verifying data integrity.

The value must be one of the following values:

md5

The MD5 algorithm is used for integrity validation.

none

No checksum validation.

mode

String.

Specifies the transfer mode.

The value must be one of the following values:

text

Data is transferred as text.

binary

Data is transferred in binary.

This is the default value.

recoveryTimeout

Integer.

Specifies the length of time during which a source agent attempts to recover a stalled file transfer.

The value must be one of the following values:

-1

The agent continues to attempt to recover the stalled transfer until the transfer is complete.

This is the default value.

0

The agent stops the file transfer as soon as it enters recovery.

n

The agent continues to attempt to recover the stalled transfer for the specified amount of time in seconds.

The value must be in the range 1 - 999,999,999.

preSourceCall

JSON object.

A JSON object that contains attributes that are related to the program to invoke at the source agent, before a transfer begins.

type

String.

Specifies the type of the program to be invoked.

The value must be one of the following values:

executable

A platform-specific executable is invoked. This is the default value.

antScript

An Apache Ant script is invoked.

A z/OS JCL job is submitted.

executable

JSON object.

A JSON object that can contain attributes related to a platform-specific executable program to be invoked. This object can only be specified when the value of the `type` attribute is `executable`.

name

String.

Specifies the name of the program to run.

This attribute is required if the `executable` JSON object is specified.

arguments

String.

Specifies arguments to be passed to the program that is invoked.

antScript

JSON object.

A JSON object that can contain attributes related to an Apache Ant script to be invoked. This object can only be specified when the value of the `type` attribute is `antScript`.

name

String.

Specifies the name of the Ant script to run.

This attribute is required if the `antScript` JSON object is specified.

target

Specifies the target to invoke in the specified Ant script.

If this attribute is not specified, the target named `default` is invoked.

arguments

String.

Specifies a list of user-defined custom data in space separated key=value pairs.

jcl

JSON object.

A JSON object that can contain attributes related to a z/OS JCL job to submit. This object can only be specified when the value of the `type` attribute is `jcl`.

name

String.

Specifies the name of the JCL to submit.

retryCount

Integer.

Specifies the number of attempts to run the command before ceasing.

retryWait

Integer.

Specifies the amount of time to wait, in seconds, between retry attempts.

successReturnCode

String.

Specifies the condition, based on the return code from the transfer, that must be true in order for the specified program, script, or JCL to be run.

The condition is specified as an operator, followed by a value. Valid characters for the operator are >, <, ! and =. It is valid to have a combination of more than one operator. For example, ">= 40".

The default value is zero.

postSourceCall

JSON object.

A JSON object that contains attributes that are related to the program to invoke at the source agent, after a transfer completes.

The attributes that can be specified are the same as for the `preSourceCall` object.

preDestinationCall

JSON object.

A JSON object that contains attributes that are related to the program to invoke at the destination agent, before a transfer begins.

The attributes that can be specified are the same as for the `preSourceCall` object.

postDestinationCall

JSON object.

A JSON object that contains attributes that are related to the program to invoke at the destination agent, after a transfer completes.

The attributes that can be specified are the same as for the `preSourceCall` object.

Related tasks

[Getting started with the REST API for MFT](#)

GET

Use the HTTP GET method with the `transfer` resource to request information about transfers and transfer status. You can query only the transfers that are initiated after the mqweb server is started.

Note:

- You must set a coordination queue manager before you can use the `transfer` resource. For more information, see [Configuring the REST API for MFT](#).
- The mqweb server caches information about transfers and returns this information when a request is made. This cache is reset when the mqweb server is restarted. You can see if the server has been restarted by viewing the `console.log` and `messages.log` files, or on z/OS looking at the output from the started task.
- **V9.4.0** This resource is not available in a stand-alone IBM MQ Web Server installation. For more information about the installation options for the IBM MQ component that runs the administrative REST API, see [The IBM MQ Console and REST API](#).

For more information about configuring the MFT REST service, see [Configuring the REST API for MFT](#).

- [Resource URL](#)
- [Optional query parameters](#)
- [“Request headers” on page 2299](#)

- [Request body format](#)
- [“Security requirements” on page 2300](#)
- [Response status codes](#)
- [“Response headers” on page 2300](#)
- [Response body format](#)
- [Examples](#)

Resource URL

`https://host:port/ibmmq/rest/v2/admin/mft/transfer/{transferID}`

transferID

Optionally specifies the ID of the transfer to query.

If you do not specify a transfer ID, a list of transfers is returned.

You can use HTTP instead of HTTPS if you enable HTTP connections. For more information about enabling HTTP, see [Configuring the HTTP and HTTPS ports](#).

Optional query parameters

attributes

Specifies a comma-separated list of attributes to retrieve.

This query parameter is valid only when a transfer ID is specified.

If you do not specify **attributes**, the default set of attributes is returned. See [“Response body attributes for transfers” on page 2303](#) for a list of the available attributes.

You cannot request the same attribute multiple times.

You can specify an asterisk, *, to specify that all attributes are returned.

You can make a request that specifies attributes that are not valid for some of the transfers. However, if you make a request that specifies a transfer ID and includes attributes that are not valid for that transfer, an error occurs.

limit

Specifies the maximum number of transfers to retrieve.

This query parameter is valid only when no transfer ID is specified.

For example, if the limit=200, the REST API returns a maximum of 200 transfers.

after

Specifies a transfer ID. All transfers that are initiated after the specified transfer are retrieved. If you specify **after**, you cannot also specify **before**.

This query parameter is valid only when no transfer ID is specified.

before

Specifies a transfer ID. All transfers that are initiated before that particular transfer are retrieved. If you specify **before**, you cannot also specify **after**.

This query parameter is valid only when no transfer ID is specified.

Request headers

The following header must be sent with the request:

Authorization

This header must be sent if you are using basic authentication. For more information, see [Using HTTP basic authentication with the REST API](#).

Request body format

None.

Security requirements

The caller must be authenticated to the mqweb server and must be a member of one or more of the MFTWebAdmin, MFTWebAdminRO, or MQWebUser roles. For more information about security for the administrative REST API, see [IBM MQ Console and REST API security](#).

The security principal of the caller must be granted authority to subscribe to the SYSTEM.FTE/Transfer topic.

If token based security is used, the LTPA token that is used to authenticate the user must be provided with the request as a cookie. For more information about token-based authentication, see [Using token-based authentication with the REST API](#).

Response status codes

200

Transfer information retrieved successfully.

400

Invalid data provided.

For example, invalid attributes specified.

401

Not authenticated.

The caller must be authenticated to the mqweb server. For more information, see [“Security requirements” on page 2300](#).

403

Access prohibited for one of the following reasons:

- Not authorized. The caller is authenticated to the mqweb server and is associated with a valid principal. However, the principal is not a member of one or more of the MFTWebAdmin, MFTWebAdminRO, or MQWebUser roles. For more information about the access that is required, see [“Security requirements” on page 2300](#).
- **V9.4.0** Access prohibited in the current server environment. You cannot use the administrative REST API with the stand-alone IBM MQ Web Server.

404

A transfer with the specified ID does not exist.

500

Server issue or error code from IBM MQ.

503

Queue manager not running.

Response headers

Content-Type

This header is returned with a value of `application/json; charset=utf-8`.

ibm-mq-rest-mft-total-transfers

This header is returned with a value that is the total number of transfers that have details available in the mqweb server cache.

Response body format

The response is in JSON format in UTF-8 encoding. The response contains an outer JSON object that contains a single JSON array called `transfer`. Each element in the array is a JSON object that represents

information about a transfer. Each of these JSON objects can contain the following objects and attributes. Which objects and attributes are returned depends on the URL that was specified for the request:

id

String.

Specifies the unique transfer or transaction ID. The ID can be a maximum of 48 alphanumeric characters.

This attribute is always returned.

job

JSON object.

Contains the job name for the transfer.

userProperties

JSON object.

Contains additional meta data about the transfer. For example: "userProperties":
{ "key1": "value1" }

sourceAgent

JSON object.

Contains attributes that are related to the agent on the source system.

The **name** attribute in this object is always returned.

destinationAgent

JSON object.

Contains attributes that are related to the agent on the destination system.

The **name** attribute in this object is always returned.

originator

JSON object.

Contains attributes that are related to the originator of the request.

The **host** and **host** attributes in this object are always returned.

transferSet

JSON object.

Contains attributes that are related to the group of file transfers.

status

JSON object.

Contains attributes that are related to the status of the transfer.

The **state** attribute in this object is always returned.

statistics

JSON object.

Contains attributes that are related to the statistics of the transfer.

The **startTime**, **numberOfFileFailures**, **numberOfFileSuccesses**, **numberOfFileWarnings**, **numberOfFiles** and **endTime** attributes in this object are always returned.

For more information, see [“ Response body attributes for transfers” on page 2303.](#)

If an error occurs, see [REST API error handling.](#)

Examples

The following example returns a default set of data in the response.

The following URL is used with the HTTP GET method:

```
https://localhost:9443/ibmmq/ibmmq/rest/v2/admin/mft/transfer/414d512050524d465444454d4f312020f5189c5921f22302
```

The following JSON response is returned:

```
{
  "transfer": [
    {
      "id": "414D512050524D465444454D4F312020F5189C5921F22302",
      "destinationAgent": {
        "name": "AGENT.TRI.BANK"
      },
      "originator": {
        "host": "192.168.99.1",
        "userId": "johndoe"
      },
      "sourceAgent": {
        "name": "TESTAGENT"
      },
      "statistics": {
        "endTime": "2018-01-08T16:22:15.569Z",
        "numberOfFileFailures": 0,
        "numberOfFileSuccesses": 2,
        "numberOfFileWarnings": 0,
        "numberOfFiles": 2,
        "startTime": "2018-01-08T16:22:15.242Z"
      },
      "status": {
        "state": "successful"
      }
    }
  ]
}
```

The following example lists all the attributes for the specified transfer ID, on the coordination queue manager. The following URL is used with the HTTP GET method:

```
https://localhost:9443/ibmmq/rest/v2/admin/mft/transfer/414d512050524d465444454d4f312020c5c6705924cf9e02?attributes=*
```

The following JSON response is returned:

```
{
  "transfer": [
    {
      "id": "414D512050524D465444454D4F312020C5C6705924CF9E02",
      "sourceAgent": {
        "qmgrName": "PRMFTDEM01",
        "name": "AGENT2"
      },
      "destinationAgent": {
        "qmgrName": "PRMFTDEM01",
        "name": "AGENT1"
      },
      "originator": {
        "host": "192.168.56.1",
        "userId": "johndoe",
        "mqmdUserId": "johndoe"
      },
      "transferSet": {
        "item": [
          {
            "source": {
              "file": {
                "lastModified": "2017-07-13T11:25:20.780Z",
                "size": 179367055,
                "path": "D:/ProgramFiles/WASlibertyprofile.zip"
              },
              "checksum": {
                "method": "md5",
                "value": "5F0ED36FBD3C0E1F4083B12B34A318D3"
              },
              "disposition": "leave",
              "type": "file"
            },
            "destination": {
              "file": {
                "lastModified": "2017-07-28T08:00:12.065Z",

```

Specifies the name of the queue manager on the destination system.

originator

host

String.

Specifies the host name of the system where the source file is located.

This attribute is always returned.

mqmdUserId

String.

Specifies the IBM MQ user ID that was supplied in the message descriptor (MQMD).

userID

String.

Specifies the user ID that originated the file transfer.

This attribute is always returned.

sourceAgent

name

String.

Specifies the name of the agent on the source system.

This attribute is always returned.

qmgrName

String.

Specifies the name of the queue manager on the source system.

statistics

endTime

String.

Specifies the time when the transfer completed. This field is updated only when the transfer is complete. If the transfer is in any other state, then **endTime** is an empty string.

This attribute is always returned.

numberOfFileFailures

Integer.

Specifies the number of files that failed to transfer successfully.

This attribute is always returned.

numberOfFileSuccesses

Integer.

Specifies the number of files that successfully transferred.

This attribute is always returned.

numberOfFileWarnings

Integer.

Specifies the number of files that generated warnings, but otherwise transferred successfully.

This attribute is always returned.

numberOfFiles

Integer.

Specifies the total number of files included in the transfer request. This number includes all the files considered for the transfer operation.

This attribute is always returned.

retryCount

Integer.

Specifies the number of times that the transfer went into the recovery state and was retried by the agent.

A transfer can go into a recovery state because the source and destination agents lose communication, either because of an IBM MQ network error, or because the agents are not receiving data or acknowledgment messages for a period. This period is determined by the agent properties:

transferAckTimeout and **transferAckTimeoutRetries**.

startTime

String.

Specifies the time when the transfer was submitted in UTC format.

This attribute is always returned.

status**description**

String.

Specifies detailed information about the status upon completion, such as whether it was partially successful, successful, or failed.

lastStatusUpdate

String.

Specifies the most recent time when the transfer status was captured, in UTC format.

state

String.

Specifies the state of the transfer. The value can be one of the following values:

- started
- inProgress
- successful
- failed
- partiallySuccessful
- cancelled
- malformed
- notAuthorized
- deleted
- inProgressWithFailures
- inProgressWithWarnings

This attribute is always returned.

transferSet**bytesSent**

Integer.

Specifies the total bytes sent.

item

JSON object.

Contains elements that specify the source and destination file names and locations:

destination

JSON object.

actionIfExists

String.

Specifies the action that is taken if a destination file exists on the destination system. The valid options are as follows:

error

Reports an error and the file is not transferred.

overwrite

Overwrites the existing destination file.

checksum

JSON object.

This object does not appear if a checksum was not performed.

Specifies the type of hash algorithm that generated the message digest to create the digital signature. Managed File Transfer supports Message Digest algorithm 5 (md5) only. The checksum provides a way for you to confirm the integrity of transferred files is intact.

The JSON object includes the following elements:

method

String.

Specifies the method that is used for generating the checksum.

value

String.

Specifies the checksum value generated.

dataset

JSON object.

This object is not returned if the `file` or `queue` object is returned.

Specifies a z/OS dataset with the following elements:

attributes

String.

Specifies attributes related to the dataset.

name

String.

Specifies the name of the dataset.

size

Integer.

Specifies the file size.

file

JSON object.

This object is not returned if the `queue` or `dataset` object is returned.

Specifies information about the file that was transferred in the following elements:

encoding

String.

Specifies the encoding for a text file transfer.

endOfLine

Specifies the end of line marker. This value can be either of the following values:

- LF - line feed character only.
- CRLF - carriage return and line feed character sequence.

lastModified

String.

Specifies the last modified date and time for the file, in UTC format.

path

String.

Specifies the path location of the file.

size

Integer.

Specifies the file size.

queue

JSON object.

This object is not returned if the `file` or `dataset` object is returned.

Specifies information about the queue that messages were transferred to, in the following elements:

delimiter

String.

Specifies the delimiter used.

If **delimiterType** is set to *size*, this element specifies the delimiter size. If

delimiterType is set to *binary*, the value is the number of delimiter bytes.

If **delimiter** is an empty string, the field is not set while initiating the transfer.

delimiterPosition

String.

This element is valid only when **delimiterType** is *binary*. The value is one of the following values:

"prefix"

Before each message.

"postfix"

After each message.

If **delimiterPosition** is an empty string, the field is not set while initiating the transfer.

delimiterType

String.

Specifies the type of delimiter that is used to split the messages. The value can be one of the following values:

binary

Split by delimiter bytes.

size

Split by size.

If **delimiterType** is an empty string, the field is not set while initiating the transfer.

includeDelimiterInMessage

Boolean.

This element is valid only when **delimiterType** is *binary*.

Specifies whether the delimiter is included in the message.

messageCount

Integer.

Specifies the number of messages that were written to the queue.

messageLength

Integer.

Specifies the length of the message written to the queue.

messageOrGroupId

String.

If the transfer request did not specify that the file is split into multiple messages, the value of this attribute is the IBM MQ message ID of the message written to the queue.

If the transfer request specified that the file is split into multiple messages, the value of this attribute is the IBM MQ group ID of the messages written to the queue.

name

String.

Specifies the name of the queue and the queue manager, in the following format:

```
queueName@queueManagerName
```

type

String.

Specifies the type of destination. The destination is one of the following destinations:

queue

Specifies an IBM MQ queue as the destination.

file

Specifies a file as the destination.

dataset

Specifies a z/OS dataset as the destination.

mode

String.

Specifies the transfer mode as either binary or text.

source

JSON object.

checksum

JSON object.

This object does not appear if a checksum was not performed.

Specifies the type of hash algorithm that generated the message digest to create the digital signature. Managed File Transfer supports Message Digest algorithm 5 (md5) only. The checksum provides a way for you to confirm the integrity of transferred files is intact.

The JSON object includes the following elements:

method

String.

Specifies the method that is used to generate the checksum.

value

String.

Specifies the checksum value that is generated.

disposition

String.

Specifies the action that is taken on the source element when source has successfully been transferred to its destination. This string is one of the following options:

leave

Specifies that the source files are left unchanged

delete

Specifies that the source files are deleted from the source system after the source file is successfully transferred

dataset

JSON object.

This object is not returned if the `file` or `queue` object is returned.

Specifies a z/OS dataset with the following elements:

attributes

String.

Specifies attributes related to the dataset.

name

String.

Specifies the name of the dataset.

size

Integer.

Specifies the file size.

file

JSON object.

This object is not returned if the `queue` or `dataset` object is returned.

This object contains the following elements:

encoding

String.

Specifies the encoding for a text file transfer.

endOfLine

Specifies the end of line marker. This value can be either of the following values:

- LF - line feed character only.
- CRLF - carriage return and line feed character sequence.

lastModified

String.

Specifies the last modified date and time for the file, in UTC format.

path

String.

Specifies the path location for the file.

size

Integer.

Specifies the size of the file.

queue

JSON object.

This object is not returned if the `file` or `dataset` object is returned.

Specifies information about the queue that transferred messages were retrieved from, in the following elements:

messageCount

Integer.

Specifies the number of messages that were read from the queue.

name

String.

Specifies the name of the queue and the queue manager, in the following format:

```
queueName@queueManagerName
```

setMqProperties

Boolean.

Specifies whether IBM MQ message properties are set on the first message in a file, and any messages written to the queue when an error occurs.

type

String.

Specifies the type of source. The source is one of the following sources:

queue

Specifies an IBM MQ queue as the source.

file

Specifies a file as the source, if the source is a file or directory.

dataset

Specifies a z/OS dataset as the source.

status

JSON object.

Specifies the status of a single item in the transfer set. The status object contains the following elements:

description

String.

Specifies detailed information about the status completion, such as whether it was partially successful, successful, or failed.

state

String.

Specifies the state of the transfer. The value can be one of the following values:

- started
- inProgress
- successful
- failed
- partiallySuccessful
- cancelled
- malformed
- notAuthorized
- deleted
- inProgressWithFailures
- inProgressWithWarnings

Related reference

[“/admin/mft/agent” on page 2228](#)

You can use the HTTP GET method with the agent resource, to request information about Managed File Transfer agents.

/admin/qmgr/{qmgrName}/channel

You can use the HTTP GET method with the channel resource to request information about channels.

Note:

- This resource URL is available only in version 1 of the REST API. To query channels using version 2 of the REST API, use the [“/admin/action/qmgr/{qmgrName}/mqsc” on page 2190](#) resource.

- **V 9.4.0** You cannot use this resource with the stand-alone IBM MQ Web Server. For more information about the installation options for the IBM MQ component that runs the administrative REST API, see [The IBM MQ Console and REST API](#).

You can use the administrative REST API gateway with this resource URL.

For more information about the PCF equivalents to the channel REST API parameters and attributes, see [“REST API and PCF equivalents for channels” on page 2422](#).

GET

Use the HTTP GET method with the `channel` resource to request information about channels.

Note:

- This resource URL is available only in version 1 of the REST API. To query channels using version 2 of the REST API, use the [“/admin/action/qmgr/{qmgrName}/mqsc” on page 2190](#) resource.
- **V 9.4.0** You cannot use this resource with the stand-alone IBM MQ Web Server. For more information about the installation options for the IBM MQ component that runs the administrative REST API, see [The IBM MQ Console and REST API](#).

The information that is returned is similar to the information returned by the [“MQCMD_INQUIRE_CHANNEL \(Inquire Channel\)” on page 1219](#) and [“MQCMD_INQUIRE_CHANNEL_STATUS \(Inquire Channel Status\)” on page 1245](#) PCF commands, and the [“DISPLAY CHANNEL \(display channel definition\)” on page 688](#) and [“DISPLAY CHSTATUS \(display channel status\)” on page 712](#) MQSC commands.

Note: **z/OS** On z/OS, the channel initiator must be running before you use the `channel` resource with the HTTP GET method specifying the `status` parameter.

Note: The REST API supports only the following channels:

- Channels that have a transport type of TCP.
- Sender, receiver, server, requester, cluster-sender, and cluster-receiver channels.

Other channels are not returned.

- [“Response headers” on page 2317](#)
- [Response body format](#)
- [“Examples” on page 2319](#)

Resource URL

`https://host:port/ibmmq/rest/v1/admin/qmgr/{qmgrName}/channel/{channelName}`

qmgrName

Specifies the name of the queue manager on which to query the channels.

You can specify a remote queue manager as the `qmgrName`. If you specify a remote queue manager, you must configure a gateway queue manager. For more information, see [Remote administration using the REST API](#).

The queue manager name is case-sensitive.

If the queue manager name includes a forward slash, a period, or a percent sign, these characters must be URL encoded:

- A forward slash (/) must be encoded as %2F.
- A percent sign (%) must be encoded as %25.
- A period (.) must be encoded as %2E.

channelName

Optionally specifies the name of a channel to query. This channel must exist on the specified queue manager.

The channel name is case-sensitive.

If the channel name includes a forward slash or a percent sign, these characters must be URL encoded:

- A forward slash, /, must be encoded as %2F.
- A percent sign, %, must be encoded as %25.

You can use HTTP instead of HTTPS if you enable HTTP connections. For more information about enabling HTTP, see [Configuring HTTP and HTTPS ports](#).

Optional query parameters

attributes={object,...[*|object.attributeName,...]}

object,...

Specifies a comma-separated list of JSON objects that contain related channel configuration attributes to return.

For example, to return all channel configuration attributes that are related to time stamps, specify `timestamps`. To return all channel configuration attributes that are related to compression and to connection management, specify `compression,connectionManagement`.

The status objects cannot be specified with this query parameter. Use the **status** query parameter to return these attributes.

You cannot specify the same object more than once. If you request objects that are not valid for a particular channel, the attributes are not returned for that channel. However, if you specify a value for the **type** parameter that is not `all`, and request objects that are not valid for that channel type, an error is returned.

For a full list of objects and associated attributes, see [Attributes for channels](#).

Specifies all attributes.

object.attributeName,...

Specifies a comma-separated list of channel configuration attributes to return.

Each attribute must specify the JSON object that contains the attribute, in the form `object.attributeName`. For example, to return the `keepAliveInterval` attribute, which is contained in the `connectionManagement` object, specify `connectionManagement.keepAliveInterval`.

Attributes can be nested inside multiple JSON objects, such as `exits.message.name`, which is an attribute inside a message object inside an exits object.

The keyword `[type]` can be used as a wildcard to include multiple channel-type-specific sections that contain the same attribute. For example, `[type].clusterName` is equivalent to `clusterSender.clusterName,clusterReceiver.clusterName`.

Attributes from the status object cannot be specified with this query parameter. Use the **status** query parameter to return these attributes.

You cannot specify the same attribute more than once. If you request attributes that are not valid for a particular channel, the attributes are not returned for that channel. However, if you specify

the **type** parameter and request attributes that are not valid for that channel type, an error is returned.

For a full list of attributes and associated objects, see [Attributes for channels](#).

status={*|currentStatus|savedStatus|currentStatus.attributeName,savedStatus.attributeName,...}

Specifies that all savedStatus and currentStatus attributes are returned.

currentStatus

Specifies that all currentStatus attributes are returned.

savedStatus

Specifies that all savedStatus attributes are returned.

currentStatus.attributeName,savedStatus.attributeName,...

Specifies a comma-separated list of current status and saved status attributes to return.

For example, to return the state attribute, specify `currentStatus.state`.

For a full list of status attributes, see [Current status attributes for channels](#) and [Saved status attributes for channels](#).

filter=filterValue

Specifies a filter for the channel definitions that are returned.

If you specify a channel name in the resource URL, you can only filter on status attributes.

If you filter on a current status attribute, the only current status objects returned are those that match the filter parameter. All saved status objects for the corresponding channels are returned, if requested.

If you filter on a saved status attribute, the only saved status objects returned are those that match the filter parameter. All current status objects for the corresponding channels are returned, if requested.

You can specify only one filter. If you filter on a status attribute, you must specify the corresponding **status** query parameter.

filterValue has the following format:

```
attribute:operator:value
```

where:

attribute

Specifies one of the applicable attributes. For a full list of attributes, see [Attributes for channels](#). The following attributes cannot be specified:

- name
- type
-  queueSharingGroup.disposition
- [type].connection.port
- connectionManagement.localAddress.port
- connectionManagement.localAddress.portRange
- currentStatus.general.connection.port
- currentStatus.connectionManagement.localAddress.port

The keyword [type] can be used as a wildcard to include multiple channel-type-specific sections that contain the same attribute, such as `sender.connection` and `clusterReceiver.connection`.

To filter on any attributes that are time stamps, the filter can specify any portion of the time stamp, with a trailing asterisk, *. The format of a time stamp is, YYYY-MM-DDThh:mm:ss. For example, you can specify `2001-11-1*` to filter on dates in the range 2001-11-10 to 2001-11-19, or `2001-11-12T14:*` to filter any minute in the specified hour of the specified day.

Valid values for the YYYY section of the date are in the range 1900 - 9999.

The time stamp is a string. Therefore, only the `equalTo` and `notEqualTo` operators can be used with the time stamp.

operator

Specifies one of the following operators:

lessThan

Use this operator only with integer attributes.

greaterThan

Use this operator only with integer attributes.

equalTo

Use this operator with any attribute except string array attributes and integer array attributes.

notEqualTo

Use this operator with any attribute except string array attributes and integer array attributes.

lessThanOrEqualTo

Use this operator only with integer attributes.

greaterThanOrEqualTo

Use this operator only with integer attributes.

contains

Use this operator only with integer array attributes and string array attributes.

doesNotContain

Use this operator only with integer array attributes and string array attributes.

value

Specifies the constant value to test against the attribute.

The value type is determined by the attribute type.

For string and boolean attributes, you can omit the value field after the colon. For string attributes, omit the value to return channels with no value for the specified attribute. For boolean attributes, omit the value to return any channels that have the specified attribute set to false. For example, the following filter returns all channels where the description attribute is not specified:

```
filter=general.description:equalTo:
```

You can use a single asterisk, `*`, at the end of the value as a wildcard. You cannot use only an asterisk.

If the value includes a space, a forward slash, a percent sign, or an asterisk that is not a wildcard, these characters must be URL encoded:

- A space must be encoded as `%20`
- A plus, `+`, must be encoded as `%2B`
- A forward slash, `/`, must be encoded as `%2F`.
- A percent sign, `%`, must be encoded as `%25`.
- An asterisk, `*`, must be encoded as `%2A`.

name=*name*

This query parameter cannot be used if you specify a channel name in the resource URL.

Specifies a wildcard channel name to filter on.

The *name* specified must include an asterisk, `*`, as a wildcard. You can specify one of the following combinations:

Specifies that all channels are returned.

prefix*

Specifies that all channels with the specified prefix in the channel name are returned.

***suffix**

Specified that all channels with the specified suffix in the channel name are returned.

prefix*suffix

Specifies that all channels with the specified prefix and the specified suffix in the channel name are returned.

type=type

Specifies the type of channel to return information about.

The value can be one of the following values:

all

Specifies that information about all channels is returned.

sender

Specifies that information about sender channels is returned.

receiver

Specifies that information about receiver channels is returned.

server

Specifies that information about server channels is returned.

requester

Specifies that information about requester channels is returned.

clusterSender

Specifies that information about cluster sender channels is returned.

clusterReceiver

Specifies that information about cluster receiver channels is returned.

The default value is `all`.

queueSharingGroupDisposition=*disposition*

 This parameter is only available on z/OS.

Specifies the disposition of the channels for which information is to be returned.

The value can be one of the following values:

live

Return channels defined with `qmgr` or `copy` disposition.

all

Return channels defined with `qmgr`, `copy` or `group` disposition.

copy

Return channels defined with `copy` disposition.

group

Return channels defined with `group` disposition.

private

Return channels defined with `copy` or `qmgr` disposition.

qmgr

Return channels defined with `qmgr` disposition.

The default value is `live`.

Request headers

The following headers must be sent with the request:

Authorization

This header must be sent if you are using basic authentication. For more information, see [Using HTTP basic authentication with the REST API](#).

The following headers can optionally be sent with the request:

ibm-mq-rest-gateway-qmgr

This header specifies the queue manager that is to be used as the gateway queue manager. The gateway queue manager is used to connect to a remote queue manager. For more information, see [Remote administration using the REST API](#).

Request body format

None.

Security requirements

The caller must be authenticated to the mqweb server and must be a member of one or more of the MQWebAdmin, MQWebAdminRO, or MQWebUser roles. For more information about security for the administrative REST API, see [IBM MQ Console and REST API security](#).

If token based security is used, the LTPA token that is used to authenticate the user must be provided with the request as a cookie. For more information about token-based authentication, see [Using token-based authentication with the REST API](#).

The security principal of the caller must be granted the ability to issue the following PCF commands for the specified queue manager:

- If the **status** query parameter is not specified:
 - For the channel that is specified by the *{channelName}* portion of the resource URL, or for channels that match the specified query parameters, authority to issue the **MQCMD_INQUIRE_CHANNEL** PCF command must be granted.
- If the **status** query parameter is specified:
 - For the channel that is specified by the *{channelName}* portion of the resource URL, or for channels that match the specified query parameters, authority to issue the **MQCMD_INQUIRE_CHANNEL** PCF command must be granted.
 - For the channel that is specified by the *{channelName}* portion of the resource URL, or for channels that match the specified query parameters, authority to issue the **MQCMD_INQUIRE_CHSTATUS** PCF command must be granted.

A principal has display authority if the principal can issue one or both of the **MQCMD_INQUIRE_CHANNEL** and **MQCMD_INQUIRE_CHSTATUS** PCF commands. If the principal has display authority for only some of the channels that are specified by the resource URL and query parameters, then the array of channels that is returned from the REST request is limited to those channels that the principal has authority to display. No information is returned about channels that cannot be displayed. If the principal does not have display authority for any of the channels that are specified by the resource URL and query parameters, an HTTP status code of 403 is returned.

Multi On Multiplatforms, if the attribute `currentStatus.monitoring.messagesAvailable` is to be returned, authority to issue the **MQCMD_INQUIRE_Q** on the transmission queues used by cluster sender channels is required.

ALW On AIX, Linux, and Windows, you can grant authority to security principals to use IBM MQ resources by using the **setmqaut** command. For more information, see [setmqaut \(grant or revoke authority\)](#).

On z/OS, see [Setting up security on z/OS](#).

Response status codes

200

Channel information retrieved successfully.

400

Invalid data provided.

For example, invalid channel attributes specified.

401

Not authenticated.

The caller must be authenticated to the mqweb server and must be a member of one or more of the MQWebAdmin, MQWebAdminRO, or MQWebUser roles. For more information, see [“Security requirements” on page 2316](#).

403

Access prohibited for one of the following reasons:

- Not authorized. The caller is authenticated to the mqweb server and is associated with a valid principal. However, the principal does not have access to the required IBM MQ resources. For more information about the access that is required, see [“Security requirements” on page 2316](#).
- **V9.4.0** Access prohibited in the current server environment. You cannot use the administrative REST API with the stand-alone IBM MQ Web Server.

404

Channel does not exist.

500

Server issue or error code from IBM MQ.

503

Queue manager not running.

Response headers

The following headers are returned with the response:

Content-Type

This header is returned with a value of `application/json; charset=utf-8`.

ibm-mq-rest-gateway-qmgr

This header is returned if a remote queue manager is specified in the resource URL. The value of this header is the name of the queue manager that is used as the gateway queue manager.

Response body format

The response is in JSON format in UTF-8 encoding. The response contains an outer JSON object that contains a single JSON array called `channel`. Each element in the array is a JSON object that represents information about a channel. Each of these JSON objects contains the following attributes:

name

String.

Specifies the name of the channel.

This attribute is always returned.

type

String.

Specifies the type of channel.

The value is one of the following values:

- `sender`
- `receiver`
- `server`
- `requester`
- `clusterSender`
- `clusterReceiver`

This attribute is always returned.

The following objects can be included in the JSON object that represents information about a channel. Which objects and attributes are returned depends on the URL that was specified for the request:

sender

Contains attributes that are related to sender channels.

server

Contains attributes that are related to server channels.

requester

Contains attributes that are related to requester channels.

clusterSender

Contains attributes that are related to cluster sender channels.

clusterReceiver

Contains attributes that are related to cluster receiver channels.

clusterRouting

Contains attributes that are related to the routing of messages in a cluster.

connectionManagement

Contains attributes that are related to connection management including:

- A JSON array of connection objects that are labeled connectionManagement, which contain host and port information
- longRetry and shortRetry objects, containing count and interval attributes

compression

Contains attributes that are related to compression

dataCollection

Contains attributes that are related to monitoring and statistics

exits

Contains exit objects and arrays of exit objects, each containing:

- Exit name attribute
- User data attribute

extended

Contains attributes that are related to extended channel properties, such as data conversion, and sequence numbers.

failedDelivery

Contains attributes that are related to message delivery failure, such as retry options.

general

Contains attributes that are related to general channel properties, such as the description of the channel.

batch

Contains attributes that are related to message batches.

queueSharingGroup

Contains attributes that are related to queue sharing groups on z/OS.

receiverSecurity

Contains attributes that are related to security for receiving channels.

transmissionSecurity

Contains attributes that are related to transmission security and encryption.

For more information, see [“Response body attributes for channels”](#) on page 2321.

If a damaged object is found, and the REST request did not specify a channel name within the resource URL, an extra JSON array that is called damaged is returned. This JSON array contains a list of the objects that are damaged, specifying the object names. If the REST request specifies a channel name within the resource URL, but the object is damaged, an error is returned.

If an error occurs, the response body contains an error message. For more information, see [REST API error handling](#).

Examples

- The following example lists all channels on the queue manager QM1. The following URL is used with the HTTP GET method:

```
https://localhost:9443/ibmmq/rest/v1/admin/qmgr/QM1/channel
```

The following JSON response is returned:

```
{
  "channel": [
    {
      "name": "RECEIVER.CHL",
      "type": "receiver"
    },
    {
      "name": "SENDER.CHL",
      "type": "sender",
      "sender": {
        "connection": [
          {
            "host": "example.com",
            "port": "1414"
          }
        ],
        "transmissionQueueName": "XMIT.Q"
      }
    },
    {
      "name": "SERVER.CHL",
      "type": "server",
      "server": {
        "transmissionQueueName": "XMIT.Q"
      }
    },
    {
      "name": "REQUESTER.CHL",
      "type": "requester",
      "requester": {
        "connection": [
          {
            "host": "example.com",
            "port": 1414
          }
        ]
      }
    },
    {
      "name": "CLUSSDR.CHL",
      "type": "clusterSender",
      "clusterSender": {
        "connection": [
          {
            "host": "example.com",
            "port": 1414
          }
        ],
        "clusterName": "CUSTER1"
      }
    },
    {
      "name": "CLUSRCVR.CHL",
      "type": "clusterReceiver",
      "clusterReceiver": {
        "connection": [
          {
            "host": "example.com",
            "port": 1414
          }
        ],
        "clusterName": "CUSTER1"
      }
    }
  ]
}
```

- The following example lists all receiver channels on the queue manager QM1, showing their connection retry attempts information. The following URL is used with the HTTP GET method:

```
https://localhost:9443/ibmmq/rest/v1/admin/qmgr/QMGR2/channel?
type=sender&attributes=connectionManagement.shortRetry,connectionManagement.longRetry
```

The following JSON response is returned:

```
{
  "channel":
```

```
[{
  "name": "SENDER.CHL",
  "type": "sender",
  "connectionManagement": {
    "longRetry": {
      "count": 999999999,
      "interval": 1200
    },
    "shortRetry": {
      "count": 10,
      "interval": 60
    }
  },
  "sender": {
    "connection": [{
      "host": "example.com",
      "port": 1414
    }],
    "transmissionQueueName": "XMIT.Q"
  },
  {
    "name": "SYSTEM.DEF.SENDER",
    "type": "sender",
    "connectionManagement": {
      "longRetry": {
        "count": 999999999,
        "interval": 1200
      },
      "shortRetry": {
        "count": 10,
        "interval": 60
      }
    },
    "sender": {
      "connection": [],
      "transmissionQueueName": ""
    }
  }
}]
}
```

- The following example lists some status attributes for the channel CHL1, on channel manager QM1. The following URL is used with the HTTP GET method:

```
https://localhost:9443/ibmmq/rest/v1/admin/qmgr/QM1/channel/CHL1?
status=currentStatus.timestamps,currentStatus.batch.currentMessages,savedStatus.batch.currentM
essages
```

The following JSON response is returned:

```
{
  "channel":
  [{
    "name": "CHL1",
    "type": "sender",
    "currentStatus": [{
      "inDoubt": false,
      "state": "running",
      "batch": {
        "currentMessages": 10
      },
      "timestamps": {
        "lastMessage": "2017-10-02T09:17:42.314Z",
        "started": "1993-12-31T23:59:59.000Z"
      }
    }],
    "savedStatus": [{
      "inDoubt": false,
      "batch": {
        "currentMessages": 5
      }
    }],
    {
      "inDoubt": false,
      "batch": {
        "currentMessages": 7
      }
    }
  ]
}
```

- The following example shows how to get all information, including current status and saved status, for the channel CHL2 on queue manager QM1. The following URL is used with the HTTP GET method:

```
https://localhost:9443/ibmmq/rest/v1/admin/qmgr/QM1/channel/CHL2?attributes=*&status=*
```

- The following example shows how to get all channel configuration and status information for channels that are currently running, for the queue manager QM1. The following URL is used with the HTTP GET method:

```
https://localhost:9443/ibmmq/rest/v1/admin/qmgr/QM1/channel?attributes=*&status=*&filter=currentStatus.state:equalTo:running
```

Response body attributes for channels

When you receive the response body from using the HTTP verb GET with the channel object to request information about channels, attributes for the channels are returned within named JSON objects.

The following objects are available:

- “sender” on page 2321
- “server” on page 2322
- “requester” on page 2322
- “clusterSender” on page 2323
- “clusterReceiver” on page 2323
- “clusterRouting” on page 2324
- “connectionManagement” on page 2324
- “compression” on page 2325
- “dataCollection” on page 2326
- “exits” on page 2327
- “extended” on page 2328
- “failedDelivery” on page 2329
- “general” on page 2330
- “batch” on page 2330
- “queueSharingGroup” on page 2331
- “receiverSecurity” on page 2331
- “transmissionSecurity” on page 2332
- “currentStatus” on page 2332
- “savedStatus” on page 2342

For more information about the PCF equivalents to the queue REST API parameters and attributes, see [“REST API and PCF equivalents for channels”](#) on page 2422.

Note: The REST API supports only channels that have TCP as their transport type, and are of type sender, receiver, server, requester, cluster-sender, or cluster-receiver. Other channels are not returned.

sender

The `sender` object contains information about sender channels and is returned only for sender channels:

connection

An array of JSON objects that can contain the following attributes that define the channel connection:

host

String.

Specifies the host that this channel connects to.

port

Integer.

Specifies the port that this channel uses on this host.

This attribute cannot be used to filter results.

These attributes are always returned if they are available. If no connection information is available, an empty array is returned. If the connection does not conform to the expected syntax, an array containing a single host attribute having the value of the entire connection is returned.

transmissionQueueName

String.

Specifies the name of the transmission queue in use by this channel.

This attribute is always returned.

server

The `server` object contains information about server channels and is returned only for server channels:

connection

An array of JSON objects that can contain the following attributes that define the channel connection:

host

String.

Specifies the host that this channel connects to.

port

Integer.

Specifies the port that this channel uses on this host.

This attribute cannot be used to filter results.

These attributes are always returned if they are available. If no connection information is available, an empty array is returned. If the connection does not conform to the expected syntax, an array containing a single host attribute having the value of the entire connection is returned.

transmissionQueueName

String.

Specifies the name of the transmission queue in use by this channel.

This attribute is always returned.

requester

The `requester` object contains information about requester channels and is returned only for requester channels:

connection

An array of JSON objects that can contain the following attributes that define the channel connection:

host

String.

Specifies the host that this channel connects to.

port

Integer.

Specifies the port that this channel uses on this host.

This attribute cannot be used to filter results.

If no connection information is available, an empty array is returned.

If the connection does not conform to the expected syntax, an array containing a single host attribute having the value of the entire connection is returned.

clusterSender

The `clusterSender` object contains information about cluster sender channels and is returned only for cluster sender channels:

connection

An array of JSON objects that can contain the following attributes that define the channel connections:

host

String.

Specifies the host that this channel connects to.

port

Integer.

Specifies the port that this channel uses on this host.

This attribute cannot be used to filter results.

These attributes are always returned if they are not empty. If no connection information is available, an empty array is returned.

If the connection does not conform to the expected syntax, an array containing a single host attribute having the value of the entire connection is returned.

clusterName

String.

Specifies the name of the cluster to which the channel belongs.

This attribute is always returned if it is not empty.

clusterNameList

String.

Specifies a list of clusters to which the channel belongs.

This attribute is always returned if it is not empty.

clusterReceiver

The `clusterReceiver` object contains information about cluster receiver channels and is returned only for cluster receiver channels:

connection

An array of JSON objects that can contain the following attributes that define the channel connections:

host

String.

Specifies the host that this channel connects to.

port

Integer.

Specifies the port that this channel uses on this host.

This attribute cannot be used to filter results.

These attributes are always returned if they are not empty. If no connection information is available, an empty array is returned.

If the connection does not conform to the expected syntax, an array containing a single host attribute having the value of the entire connection is returned.

clusterName

String.

Specifies the name of the cluster to which the channel belongs.

This attribute is always returned if it is not empty.

clusterNameList

String.

Specifies a list of clusters to which the channel belongs.

This attribute is always returned if it is not empty.

clusterRouting

The `clusterRouting` object contains information about routing within clusters and is returned only for cluster receiver and cluster sender channels:

workloadPriority

Integer.

Specifies the channel priority for cluster workload distribution.

A value of 0 specifies the lowest priority and a value of 9 specifies the highest priority.

workloadRank

Integer.

Specifies the channel rank for cluster workload distribution.

A value of 0 specifies the lowest rank and a value of 9 specifies the highest rank.

workloadWeight

Integer.

Specifies channel weighting for cluster workload distribution.

A value of 1 specifies the lowest weight and a value of 99 specifies the highest weight.

networkPriority

Integer.

Specifies priority for the network connection. If there are multiple paths available, distributed queuing selects the path with the highest priority.

A value of 0 specifies the lowest priority and a value of 9 specifies the highest priority.

connectionManagement

The `connectionManagement` object contains information about connection management:

heartbeatInterval

Integer.

Specifies the time, in seconds, between heartbeat flows that are passed from the sending MCA when there are no messages on the transmission queue. This interval gives the receiving MCA the opportunity to quiesce the channel.

disconnectInterval

Integer.

Specifies the maximum number of seconds that the channel waits for messages to be put on a transmission queue before the channel ends.

A value of zero causes the message channel agent to wait indefinitely.

keepAliveInterval

Integer.

Specifies the value that is passed to the communications stack for KeepAlive timing for the channel.

localAddress

An array of JSON objects that can contain the following attributes that define the local communications address of the channel:

host

String.

Specifies the local IP address or host name.

This value is returned if the local address in the channel definition contains a host name or IP address.

port

Integer.

Specifies the local port number.

This value is returned if the local address in the channel definition contains a port number.

This attribute cannot be used to filter results.

portRange

JSON object that contains a range of local ports:

low

Integer.

Specifies the start of the port range.

high

Integer.

Specifies the end of the port range.

Returned if a port range is specified in the local address in the channel definition.

This attribute cannot be used to filter results.

If no local address information is available, an empty array is returned.

If the local address does not conform to the expected syntax, an array containing a single host attribute having the value of the entire local address is returned.

shortRetry

JSON object.

Specifies the maximum number and interval of attempts that are made to establish a connection to the remote machine before the `longRetry.count` and `longRetry.interval` are used:

count

Integer.

Specifies the maximum number of attempts to connect to the remote machine.

interval

Integer.

Specifies the interval in seconds between attempts to connect to the remote machine.

longRetry

JSON object.

Specifies the maximum number of attempts and interval of attempts that are made to establish a connection to the remote machine after the count by `shortRetry.count` is exhausted:

count

Integer.

Specifies the maximum number of attempts to connect to the remote machine.

interval

Integer.

Specifies the interval in seconds between attempts to connect to the remote machine.

compression

The `compression` object contains attributes that are related to data compression:

header

String array.

Specifies the header data compression techniques that are supported by the channel. The values that are returned are in order of preference.

The value is one of the following values:

none

Specifies that no header data compression is performed.

system

Specifies that header data compression is performed.

message

String array.

Specifies the message data compression techniques that are supported by the channel. The values that are returned are in order of preference.

The value is one of the following values:

none

Specifies that no header data compression is performed.

runLengthEncoding

Specifies that message data compression is performed by using run-length encoding.

zlibFast

Specifies that message data compression is performed by using ZLIB encoding with speed prioritized.

zlibHigh

Specifies that message data compression is performed by using ZLIB encoding with compression prioritized.

V 9.4.0 LZ4Fast

Specifies that message data compression is performed by using LZ4 encoding with speed prioritized.

V 9.4.0 LZ4High

Specifies that message data compression is performed by using LZ4 encoding with compression prioritized.

any

Specifies that any compression technique that is supported by the queue manager can be used.

This value is only valid for channels of type receiver and requester.

dataCollection

The dataCollection object contains attributes that are related to data collection, monitoring, and statistics:

monitoring

String.

Specifies whether online monitoring data is collected, and if so, the rate at which the data is collected.

The value is one of the following values:

off

Specifies that online monitoring data is not collected for the channel.

asQmgr

Specifies that the queue inherits the value from the queue manager MONCHL MQSC parameter.

low

Specifies that online monitoring data is collected for the channel if the MONCHL MQSC parameter on the queue manager is not set to none. The rate of data collection is low.

medium

Specifies that online monitoring data is collected for the channel if the MONCHL MQSC parameter on the queue manager is not set to none. The rate of data collection is moderate.

high

Specifies that online monitoring data is collected for the channel if the MONCHL MQSC parameter on the queue manager is not set to none. The rate of data collection is high.

statistics

String.

Specifies whether statistics data is collected for the channel.

The value is one of the following values:

off

Specifies that statistics data is not collected for the channel.

asQmgr

Specifies that the channel inherits the value from the queue manager STATCHL MQSC parameter.

low

Specifies that statistics data is collected for the channel if the STATCHL MQSC parameter on the channel manager is not set to none. The rate of data collection is low.

medium

Specifies that statistics data is collected for the channel if the STATCHL MQSC parameter on the channel manager is not set to none. The rate of data collection is moderate.

high

Specifies that statistics data is collected for the channel if the STATCHL MQSC parameter on the channel manager is not set to none. The rate of data collection is high.

exits

The `exits` object contains information about channel exits:

message

An array of JSON objects that contain the following attributes that define the channel message exits:

name

String.

Specifies the message exit name.

userData

String.

Specifies the user data that is passed to the message exit.

messageRetry

A JSON object that contains the following attributes that define the channel message retry exit:

name

String.

Specifies the message retry exit name.

userData

String.

Specifies the user data that is passed to the message retry exit.

receive

An array of JSON objects that contain the following attributes that define the channel receive exits:

name

String.

Specifies the receive exit name.

userData

String.

Specifies the user data that is passed to the receive exit.

security

A JSON object that contains the following attributes that define the channel security exit:

name

String.

Specifies the security exit name.

userData

String.

Specifies the user data that is passed to the security exit.

send

An array of JSON objects that contain the following attributes that define the channel send exits:

name

String.

Specifies the send exit name.

userData

String.

Specifies the user data that is passed to the send exit.

extended

The extended object contains attributes that are related to extended channel properties, such as data conversion and sequence number settings:

channelAgentType

String.

Specifies the type of the message channel agent program.

The value is one of the following values:

process**thread****messagePropertyControl**

String.

Specifies what happens to message properties when the message is about to be sent to a V6 or earlier queue manager, which does not understand the concept of a property descriptor.

The value is one of the following values:

compatible

If the message contains a property with a prefix of mcd., jms., usr. or mqext., all message properties are delivered to the application in an MQRFH2 header. Otherwise, all properties of the message, except those properties that are contained in the message descriptor (or extension), are discarded and are no longer accessible to the application.

none

All properties of the message, except those properties in the message descriptor (or extension), are removed from the message before the message is sent to the remote queue manager.

all

All properties of the message are included with the message when it is sent to the remote queue manager. The properties, except those properties in the message descriptor (or extension), are placed in one or more MQRFH2 headers in the message data.

senderDataConversion

Boolean.

Specifies whether the sender must convert application data.

sequenceNumberWrap

Integer.

Specifies the maximum message sequence number.

When the maximum is reached, sequence numbers wrap to start again at 1.

resetSequenceNumber

Integer.

Specifies the pending reset sequence number.

A nonzero value indicates that a reset channel request is outstanding. The value is in the range 1 - 999999999.

securityPolicyProtection

String

Specifies what happens to messages across the channel when AMS is active and an applicable policy exists.

This parameter is applicable to Sender, Server, Receiver and Requester channels.

The value is one of the following:

passThrough

Pass through, unchanged, any messages sent or received by the MCA for this channel.

This value is valid for channels with a channel type of sender, server, receiver, or requester, and is the default value.

remove

Remove any AMS protection from messages retrieved from the transmission queue by the MCA, and send the messages to the partner.

When the message channel agent gets a message from the transmission queue, if an AMS policy is defined for the transmission queue, it is applied to remove any AMS protection from the message prior to sending the message across the channel. If an AMS policy is not defined for the transmission queue, the message is sent as is.

This value is valid for channels with a channel type of sender or server only.

asPolicy

Based on the policy defined for the target queue, apply AMS protection to inbound messages prior to putting them on to the target queue.

When the message channel agent receives an inbound message, if an AMS policy is defined for the target queue, AMS protection is applied to the message prior to the message being put to the target queue. If an AMS policy is not defined for the target queue, the message is put to the target queue as is.

This value is valid for channels with a channel type of receiver or requester only.

failedDelivery

The `failedDelivery` object contains attributes that are related to channel behavior when delivery of a message fails:

retry

JSON object.

Specifies the maximum number of attempts and the interval of attempts that are made to establish a connection to the remote machine before the `longRetry.count` and `longRetry.interval` are used:

count

Integer.

Specifies the maximum number of attempts to redeliver the message.

interval

Integer.

Specifies the interval, in milliseconds, between attempts to redeliver the message.

This attribute is only returned for channels of type receiver, requester, and clusterReceiver.

useDeadLetterQueue

Boolean.

Specifies whether the dead-letter queue is used when messages cannot be delivered by channels:

false

Specifies that messages that cannot be delivered by a channel are treated as a failure. The channel either discards the message, or the channel ends, in accordance with the `nonPersistentMessageSpeedFast` setting.

true

Specifies that when the `DEADQ` attribute of a queue manager provides the name of a dead-letter queue, then the dead letter queue is used. Otherwise, the behavior is as for `false`.

general

The `general` object contains attributes that are related to more generic channel properties, such as description:

description

String.

Specifies the description of the channel.

maximumMessageLength

Integer.

Specifies the maximum message length that can be transmitted on the channel. This value is compared with the value for the remote channel, and the actual maximum is the lower of the two values.

batch

The `batch` object contains attributes that are related to batches of messages that are sent through the channel:

preCommitHeartbeat

Integer.

Specifies whether batch heartbeats are used.

The value is the length of the heartbeat in milliseconds.

timeExtend

Integer.

Specifies the approximate time, in milliseconds, that a channel keeps a batch open if fewer than `batch.messageLimit` messages have been transmitted in the current batch.

dataLimit

Integer.

Specifies the limit, in KB, of the amount of data that can be sent through a channel before a sync point is taken.

messageLimit

Integer.

Specifies the maximum number of messages that can be sent through a channel before a sync point is taken.

nonPersistentMessageSpeedFast

Boolean.

Specifies whether fast speed is used to send nonpersistent messages.

Fast speed means that nonpersistent messages on a channel need not wait for a syncpoint before the messages are made available for retrieval.

queueSharingGroup

The `queueSharingGroup` object contains attributes that are related to queue sharing groups on z/OS:

disposition

String.

 This attribute is only available on z/OS.

Specifies the disposition of the channel. That is, where it is defined and how it behaves.

This value is always returned if the queue manager is a member of the queue sharing group.

The value is one of the following values:

qmgr

Specifies that the channel definition exists on the page set of the queue manager that runs the command.

group

Specifies that the channel definition exists in the shared repository.

copy

Specifies that the channel definition exists on the page set of the queue manager that runs the command, copying its definition from the channel of the same name defined in the shared repository.

This attribute cannot be used to filter results.

defaultChannelDisposition

String.

 This attribute is only available on z/OS.

Specifies the intended disposition of a channel when it is activated or started.

The value is one of the following values:

private

Specifies that the intended use of the object is as a private channel.

fixShared

Specifies that the intended use of the object is as a fixshared channel.

shared

Specifies that the intended use of the object is as a shared channel.

receiverSecurity

The `receiverSecurity` object contains attributes that are related to security for receiving channels:

channelAgentUserId

String.

Specifies the user identifier that is to be used by the message channel agent for authorization to access IBM MQ resources, including authorization to put the message to the destination queue for receiver or requester channels.

If the value is blank, the message channel agent uses its default user identifier.

putAuthority

String.

Specifies which user identifiers are used to establish authority to put messages to the destination queue.

The value is one of the following values:

default

Specifies that the default user identifier is used.

context

Specifies that the user ID from the `UserIdentifier` field of the message descriptor is used.

alternateOrChannelAgent

Specifies that the user ID from the `UserIdentifier` field of the message descriptor is used.

This value is only supported on z/OS.

onlyChannelAgent

Specifies that the user ID derived from `MCAUSER` is used.

transmissionSecurity

The `transmissionSecurity` object contains attributes that are related to security for message transmission:

certificateLabel

String.

Specifies which personal certificate in the key repository is sent to the remote peer.

If this attribute is blank, the certificate is determined by the queue manager **CERTLABL** parameter.

cipherSpecification

String.

Specifies the name of the cipher that the channel uses.

requirePartnerCertificate

Boolean.

Specifies whether IBM MQ requires a certificate from the TLS client.

certificatePeerName

String.

Specifies the filter to use to compare with the Distinguished Name of the certificate from the peer queue manager or client at the other end of the channel. A Distinguished Name is the identifier of the TLS certificate.

currentStatus

The `currentStatus` object contains attributes that are related to current status information:

inDoubt

Boolean.

Specifies whether the channel is in doubt.

A sending channel is in doubt only while the sending message channel agent is waiting for an acknowledgment that a batch of sent messages has been successfully received.

state

String.

Specifies the current status of the channel.

The value is one of the following values:

binding

Specifies that the channel is negotiating with the partner.

starting

Specifies that the channel is waiting to become active.

running

Specifies that the channel is transferring or waiting for messages.

paused

Specifies that the channel is paused.

stopping

Specifies that the channel is in process of stopping.

retrying

Specifies that the channel is reattempting to establish connection.

stopped

Specifies that the channel is stopped.

requesting

Specifies that the requester channel is requesting connection.

switching

Specifies that the channel is switching transmission queues.

initializing

Specifies that the channel is initializing.

agent

A JSON object that contains attributes that are related to the message channel agent:

jobName

String.

Specifies the name of the MCA job.

running

Boolean.

Specifies whether the MCA is running or not.

state

String.

Specifies the current action being performed by the MCA.

The value is one of the following values:

runningChannelAutoDefinitionExit

Specifies that the MCA is running a channel auto-definition exit.

compressingData

Specifies that the MCA is compressing or decompressing data.

processingEndOfBatch

Specifies that the MCA is performing end of batch processing.

performingSecurityHandshake

Specifies that the MCA is performing TLS handshaking.

heartbeating

Specifies that the MCA is heartbeating with a partner.

executingMQGET

Specifies that the MCA is performing an MQGET.

executingMQI

Specifies that the MCA is executing an IBM MQ API call, other than an MQPUT or MQGET.

executingMQPUT

Specifies that the MCA is performing an MQPUT.

runningRetryExit

Specifies that the MCA is running a retry exit.

runningMessageExit

Specifies that the MCA is running a message exit.

communicatingWithNameServer

Specifies that the MCA is processing a name server request.

connectingToNetwork

Specifies that the MCA is connecting to the network.

undefined

Specifies that the MCA is in an undefined state.

runningReceiveExit

Specifies that the MCA is running a receive exit.

receivingFromNetwork

Specifies that the MCA is receiving from the network.

resynchingWithPartner

Specifies that the MCA is resynching with a partner.

runningSecurityExit

Specifies that the MCA is running a security exit.

runningSendExit

Specifies that the MCA is running a send exit.

sendingToNetwork

Specifies that the MCA is performing a network send.

serializingAccessToQmgr

Specifies that the MCA is serialized on queue manager access.

userId

Specifies the user ID that is in use by the MCA.

This attribute is only applicable to receiver, requester, and cluster receiver channels.

batch

JSON Object containing attributes that are related to batches of messages:

count

Integer.

Specifies the number of completed batches.

currentMessages

Integer.

Specifies the number of messages that are sent or received in the current batch.

When a sending channel becomes in-doubt, it specifies the number of the messages that are in-doubt.

The number is reset to 0 when the batch is committed.

luwid

JSON object that contains attributes that are related to logical units of work:

current

String.

This identifier is represented as 2 hexadecimal digits for each byte.

Specifies the logical unit of work identifier that is associated with the current batch.

For a sending channel, when the channel is in-doubt it is the LUWID of the in-doubt batch.

last

String.

This identifier is represented as 2 hexadecimal digits for each byte.

Specifies the logical unit of work identifier that is associated with the last committed batch.

nonPersistentMessageSpeedFast

Boolean.

Specifies whether non-persistent messages are to be sent at fast speed.

sequenceNumber

JSON object that contains attributes that are related to sequence numbers:

current

Integer.

Specifies the message sequence number of the last message sent or received.

When a sending channel becomes in-doubt, it is the message sequence number of the last message in the in-doubt batch.

last

Integer.

Specifies the sequence number of last message in last committed batch.

size

Integer.

Specifies the negotiated batch size.

compression

JSON Object that contains attributes that are related to data compression:

header

JSON object that contains attributes that are related to header data compression:

default

String.

Specifies the default header data compression value that is negotiated for this channel.

The value is one of the following values:

none

Specifies that no header data compression is performed.

system

Specifies that header data compression is performed.

lastMessage

String.

Specifies the header data compression value that was used for the last message sent.

The value is one of the following values:

none

Specifies that no header data compression was performed.

system

Specifies that header data compression was performed.

unavailable

Specifies that no message was sent.

message

JSON object that contains attributes that are related to message data compression:

default

String.

Specifies the default message data compression value that was negotiated for this channel.

The value is one of the following values:

none

Specifies that no message data compression is performed.

runLengthEncoding

Specifies that message data compression is performed by using run-length encoding.

zlibFast

Specifies that message data compression is performed by using ZLIB encoding with speed prioritized.

zlibHigh

Specifies that message data compression is performed by using ZLIB encoding with compression prioritized.

> V 9.4.0 LZ4Fast

Specifies that message data compression is performed by using LZ4 encoding with speed prioritized.

> V 9.4.0 LZ4High

Specifies that message data compression is performed by using LZ4 encoding with compression prioritized.

lastMessage

String.

Specifies the message data compression value that was used for the last message sent.

The value is one of the following values:

none

Specifies that no message data compression was performed.

runLengthEncoding

Specifies that message data compression was performed by using run-length encoding.

zlibFast

Specifies that message data compression was performed by using ZLIB encoding with speed prioritized.

zlibHigh

Specifies that message data compression was performed by using ZLIB encoding with compression prioritized.

> V 9.4.0 LZ4Fast

Specifies that message data compression is performed by using LZ4 encoding with speed prioritized.

> V 9.4.0 LZ4High

Specifies that message data compression is performed by using LZ4 encoding with compression prioritized.

unavailable

Specifies that no message was sent.

connectionManagement

JSON Object that contains attributes that are related to connection management:

heartbeatInterval

Integer.

Specifies the heartbeat interval in seconds.

keepAliveInterval

Integer.

Specifies the value that is passed to the communications stack for KeepAlive timing for the channel.

z/OS This parameter is only available on the z/OS

localAddress

An array of JSON objects that can contain the following attributes that define the local communications address of the channel:

host

String.

Specifies the IP address or host name that is used for local communications.

port

Integer.

Specifies the port number that is used for local communications.

This attribute cannot be used to filter results.

If no local address information is available, an empty array is returned.

remainingRetries

JSON object that contains attributes that are related to connection retry attempts:

long

Integer.

Specifies the number of long retry attempts remaining.

last

Integer.

Specifies the number of short retry attempts remaining.

This object is applicable only to sender, server, and cluster-sender channels.

extended

JSON object that contains attributes that are related to extended channel status properties:

buffers

JSON object that contains the following attributes that are related to buffers:

received

Integer.

Specifies the number of buffers received.

sent

Integer.

Specifies the number of buffers sent.

bytes

JSON object that contains the following attributes that are related to data transmission:

received

Integer.

Specifies the number of bytes received.

sent

Integer.

Specifies the number of bytes sent.

messageCount

Integer.

Specifies the total number of messages that are sent or received, or the number of MQI calls handled.

general

JSON Object containing more generic attributes that are related to channels:

heartbeatInterval

Integer.

Specifies the heartbeat interval in seconds.

keepAliveInterval

Integer.

Specifies the value that is passed to the communications stack for KeepAlive timing for the channel.

 This parameter is only available on the z/OS

connection

An array of JSON objects that can contain the following attributes that define the remote communications address of the channel:

host

String.

Specifies the remote IP address or host name.

port

Integer.

Specifies the remote port number.

This attribute cannot be used to filter results.

If no connection information is available, an empty array is returned.

If the connection does not conform to the expected syntax, an array containing a single host attribute having the value of the entire connection is returned.

maximumMessageLength

Integer.

Specifies the maximum length of a message.

statistics

String.

Specifies the rate at which statistics data is collected for the channel.

The value is one of the following values:

off

Specifies that no data is collected.

low

Specifies a low rate of data collection.

medium

Specifies a medium rate of data collection.

high

Specifies a high rate of data collection.

stopRequested

Boolean.

Specifies whether a stop request from the user has been received.

transmissionQueueName

String.

Specifies the name of the transmission queue in use by the channel.

monitoring

JSON object that contains more generic attributes that are related to channel monitoring:

messagesInBatch

JSON object that contains information about the number of messages in a batch:

shortSamplePeriod

Specifies the number of messages in a batch, based on recent activity over a short period.

longSamplePeriod

Specifies the number of messages in a batch, based on activity over a long period.

rate

String.

Specifies the rate at which monitoring data is collected for the channel.

The value is one of the following values:

off

Specifies that no data is collected.

low

Specifies a low rate of data collection.

medium

Specifies a medium rate of data collection.

high

Specifies a high rate of data collection.

compressionRate

JSON object that contains information about data compression rates:

shortSamplePeriod

Specifies the compression rate as a percentage, based on recent activity over a short period.
If no measurement is available, a value of -1 is returned.

longSamplePeriod

Specifies the compression rate as a percentage, based on activity over a long period.
If no measurement is available, a value of -1 is returned.

compressionTime

JSON object that contains information about data compression rates:

shortSamplePeriod

Specifies the compression speed as the time in microseconds spent compressing or decompressing each message, based on recent activity over a short period.
If no measurement is available, a value of -1 is returned.

longSamplePeriod

Specifies the compression speed as the time in microseconds spent compressing or decompressing each message, based on activity over a long period.
If no measurement is available, a value of -1 is returned.

exitTime

JSON object that contains information about exit processing speed:

shortSamplePeriod

Specifies the exit processing speed as the time in microseconds spent processing user exits for each message, based on recent activity over a short period.
If no measurement is available, a value of -1 is returned.

longSamplePeriod

Specifies the exit processing speed as the time in microseconds spent processing user exits for each message, based on activity over a long period.
If no measurement is available, a value of -1 is returned.

messagesAvailable

Integer.

Specifies the number of messages currently queued on the transmission queue and available for MQGETs.

networkTime

JSON object that contains information about network performance:

shortSamplePeriod

Specifies the time, in microseconds, to send a request to the remote end of the channel and receive a response, based on recent activity over a short period.
If no measurement is available, a value of -1 is returned.

longSamplePeriod

Specifies the time, in microseconds, to send a request to the remote end of the channel and receive a response, based on activity over a long period.
If no measurement is available, a value of -1 is returned.

transmissionQueueTime

JSON object that contains information about transmission queue delay:

shortSamplePeriod

Specifies the time, in microseconds, that messages remain on the transmission queue before being retrieved, based on recent activity over a short period.

If no measurement is available, a value of -1 is returned.

longSamplePeriod

Specifies the time, in microseconds, that messages remain on the transmission queue before being retrieved, based on activity over a long period.

If no measurement is available, a value of -1 is returned.

This attribute is only applicable to sender, server, and cluster sender channels.

partner

JSON Object that contains attributes that are related to the remote end queue manager:

productIdentifier

String.

Specifies the product identifier for the IBM MQ version that is running at the remote end of the channel.

The value is one of the following values:

MQMM

Queue Manager (non z/OS Platform)

MQMV

Queue Manager on z/OS

MQCC

IBM MQ C client

MQNM

IBM MQ .NET fully managed client

MQJB

IBM MQ Classes for Java

MQJM

IBM MQ Classes for JMS (normal mode)

MQJN

IBM MQ Classes for JMS (migration mode)

MQJU

Common Java interface to the MQI

MQXC

XMS client C/C++ (normal mode)

MQXD

XMS client C/C++ (migration mode)

MQXN

XMS client .NET (normal mode)

MQXM

XMS client .NET (migration mode)

MQXU

IBM MQ .NET XMS client (unmanaged/XA)

MQNU

IBM MQ .NET unmanaged client

qmgrName

String.

Specifies the name of the remote queue manager or queue sharing group.

version

String.

Specifies the version of IBM MQ running at the remote end of the channel, in the form V.R.M.F.

maximumMessageLength

Integer.

Specifies the maximum length of a message.

queueSharingGroup

JSON Object that contains attributes that are related to the queue sharing group this channel belongs to:

channelDisposition

String.

 This attribute is only available on z/OS.

Specifies the disposition of the channel. That is, where it is defined and how it behaves.

The value is one of the following values:

qmgr

Specifies that the channel definition exists on the page set of the queue manager that runs the command.

group

Specifies that the channel definition exists in the shared repository.

copy

Specifies that the channel definition exists on the page set of the queue manager that runs the command, copying its definition from the channel of the same name defined in the shared repository.

timestamps

JSON object that contains attributes that are related to date and time information:

started

String.

Specifies the date and time at which the channel was started.

For more information about the time stamp format that is used to return the date and time, see [REST API time stamps](#).

lastMessage

String.

Specifies the date and time at which the last message was sent over the channel.

For more information about the time stamp format that is used to return the date and time, see [REST API time stamps](#).

transmissionSecurity

JSON object that contains attributes that are related to transmission security:

certificateIssuerName

String.

Specifies the full Distinguished Name of the issuer of the remote certificate.

certificateUserId

String.

Specifies the local user ID that is associated with the remote certificate.

cipherSpecification

String.

Specifies the name of the cipher that the channel uses.

keyLastReset

String.

Specifies the date and time of the last successful TLS secret key reset.

For more information about the time stamp format that is used to return the date and time, see [REST API time stamps](#).

keyResetCount

String.

Specifies the number of successful TLS secret key resets since the channel started.

protocol

String.

  This parameter is available on AIX, Linux, and Windows platforms and on the IBM MQ Appliance.

 This parameter is also available on z/OS.

Specifies the security protocol currently in use.

The value is one of the following values:

none

Specifies that no security protocol is in use.

sslV30

Specifies that SSL 3.0 is in use.

tlsV10

Specifies that TLS 1.0 is in use.

tlsV12

Specifies that TLS 1.2 is in use.

shortPeerName

String.

Specifies the Distinguished Name of the peer queue manager or client at the other end of the channel.

savedStatus

The savedStatus object contains attributes that are related to saved status information:

inDoubt

Boolean.

Specifies whether the channel was in doubt.

A sending channel is only in doubt while the sending message channel agent is waiting for an acknowledgment that a batch of messages, which it has sent, has been successfully received.

batch

JSON Object that contains attributes that are related to batches of messages:

currentMessages

Integer.

Specifies the number of messages that are sent or received in the current batch or, if the channel was in-doubt, the number of messages that were in-doubt.

In the context of saved status, this number is only meaningful if the channel was in-doubt, but this value is returned regardless.

luwid

JSON object that contains attributes that are related to logical units of work:

current

String. This identifier is represented as 2 hexadecimal digits for each byte.

Specifies the logical unit of work identifier that is associated with the current batch.

For a sending channel, if the channel was in-doubt, it specifies the LUWID of the in-doubt batch.

In the context of saved status, this number is only meaningful if the channel was in-doubt, but this value is returned regardless.

last

Hex string.

Specifies the logical unit of work identifier that is associated with the last committed batch.

sequenceNumber

JSON object that contains attributes that are related to sequence numbers:

current

Integer.

Specifies the message sequence number of the last message that is sent or received.

When a sending channel is in-doubt, it specifies the sequence number of the last message in the in-doubt batch.

last

Integer.

Specifies the sequence number of the last message in the last committed batch.

general

JSON Object that contains more generic attributes that are related to channels:

connection

An array of JSON objects that can contain the following attributes that define the remote communications address of the channel:

host

String.

Specifies the remote IP address or host name.

port

Integer.

Specifies the remote port number.

This attribute cannot be used to filter results.

If no connection information is available, an empty array is returned.

If the connection does not conform to the expected syntax, an array containing a single host attribute having the value of the entire connection is returned.

transmissionQueueName

String.

Specifies the name of the transmission queue in use by the channel.

queueSharingGroup

JSON Object that contains attributes that are related to the queue sharing group this channel belonged to:

channelDisposition

String.

 This attribute is only available on z/OS.

Specifies the disposition of the channel. That is, where it was defined and how it behaved.

The value is one of the following values:

qmgr

Specifies that the channel definition existed on the page set of the queue manager that runs the command.

group

Specifies that the channel definition existed in the shared repository.

copy

Specifies that the channel definition existed on the page set of the queue manager that runs the command, copying its definition from the channel of the same name defined in the shared repository.

/admin/qmgr/{qmgrName}/queue

You can use the HTTP GET method with the queue resource to request information about queues. You can use the HTTP POST method to create queues, the PATCH method to modify queues, and the DELETE method to delete queues.

Note:

- This resource URL is available only in version 1 of the REST API. To create, update, delete, or display queues using version 2 of the REST API, use the [“/admin/action/qmgr/{qmgrName}/mqsc” on page 2190 resource](#).
- **V 9.4.0** You cannot use this resource with the stand-alone IBM MQ Web Server. For more information about the installation options for the IBM MQ component that runs the administrative REST API, see [The IBM MQ Console and REST API](#).

You can use the administrative REST API gateway with this resource URL.

For more information about the PCF equivalents to the queue REST API parameters and attributes, see [REST API and PCF equivalents for queues](#).

POST

Use the HTTP POST method with the queue resource to create a queue on a specified queue manager.

Note:

- This resource URL is available only in version 1 of the REST API. To create queues using version 2 of the REST API, use the [“/admin/action/qmgr/{qmgrName}/mqsc” on page 2190 resource](#).
- **V 9.4.0** You cannot use this resource with the stand-alone IBM MQ Web Server. For more information about the installation options for the IBM MQ component that runs the administrative REST API, see [The IBM MQ Console and REST API](#).

This REST API command is similar to the [“Change, Copy, and Create Queue” on page 1093 PCF command](#), and the [“DEFINE queues” on page 574 MQSC commands](#).

- [Resource URL](#)
- [Optional query parameters](#)
- [“Request headers” on page 2346](#)
- [Request body format](#)
- [“Security requirements” on page 2347](#)
- [Response status codes](#)
- [“Response headers” on page 2348](#)
- [Response body format](#)
- [Examples](#)

Resource URL

`https://host:port/ibmmq/rest/v1/admin/qmgr/{qmgrName}/queue`

qmgrName

Specifies the name of the queue manager on which to create the queue.

You can specify a remote queue manager as the **qmgrName**. If you specify a remote queue manager, you must configure a gateway queue manager. For more information, see [Remote administration using the REST API](#).

If the queue manager name includes a forward slash, a period, or a percent sign, these characters must be URL encoded:

- A forward slash (/) must be encoded as %2F.
- A percent sign (%) must be encoded as %25.
- A period (.) must be encoded as %2E.

You can use HTTP instead of HTTPS if you enable HTTP connections. For more information about enabling HTTP, see [Configuring HTTP and HTTPS ports](#).

Optional query parameters

commandScope=scope

 This parameter is only available on z/OS.

Specifies how the command is run when the queue manager is a member of a queue sharing group. You cannot specify this parameter if the queue manager is not a member of a queue sharing group. *scope* can be one of the following values:

The name of a queue manager

Specifies that the command is run on the queue manager that is named. The queue manager must be active within the same queue sharing group as the queue manager that is specified in the resource URL.

You cannot specify the queue manager name that is the queue manager that is specified in the resource URL.

If the queue manager name includes a percent sign, %, this character must be URL encoded as %25.

*

Specifies that the command is run on the local queue manager and also passed to every active queue manager in the queue sharing group.

If this option is used, an `ibm-mq-qmgrs` response header is returned with a comma-separated list of the queue managers that generated a response. For example, the header might look like the following header:

```
ibm-mq-qmgrs: MQ21, MQ22
```

like=qName

Specifies an existing queue definition to copy.

 On z/OS, the way that a queue is copied depends on the value that is specified for the **disposition** parameter in the request body:

- If copy is specified, the **like** parameter is ignored. The queue to copy is a queue with the name that is specified by the **name** parameter in the request body and with a disposition of `group`.
- If copy is not specified, the queue to copy is a queue with the name that is specified by the **like** parameter and a disposition of `qmgr`, `copy`, or `shared`.

noReplace

Specifies that the queue is not replaced if it exists. If this flag is not specified, the queue is replaced. If a queue is replaced, any messages that are on the existing queue are retained.

The queue is not replaced in the following scenarios:

- The queue is a local queue. **allowedSharedInput** is changed to `false`, and more than one application has the local queue open for input.
- The queue is a local queue. The value of **isTransmissionQueue** is changed, and one or more applications has the local queue open, or if one or more messages are on the queue.

- The queue is a remote queue. The value of **transmissionQueueName** is changed, and an application has a remote queue open that would be affected by this change.
- The queue is a remote queue. The value of **queueName**, **qmgrName**, or **transmissionQueueName** is changed, and one or more applications has a queue open that resolved through this definition as a queue manager alias.

Request headers

The following headers must be sent with the request:

Content-Type

This header must be sent with a value of `application/json` optionally followed by `; charset=UTF-8`.

ibm-mq-rest-csrf-token

This header must be set, but the value can be anything, including being blank.

Authorization

This header must be sent if you are using basic authentication. For more information, see [Using HTTP basic authentication with the REST API](#).

The following headers can optionally be sent with the request:

ibm-mq-rest-gateway-qmgr

This header specifies the queue manager that is to be used as the gateway queue manager. The gateway queue manager is used to connect to a remote queue manager. For more information, see [Remote administration using the REST API](#).

Request body format

The request body must be in JSON format in UTF-8 encoding. Within the request body attributes are defined, and named JSON objects are created to specify extra attributes. Any attributes that are not specified use the default value. These default values are as specified for the `SYSTEM.DEFAULT` queues on the queue manager. For example, a local queue inherits the values that are defined in `SYSTEM.DEFAULT.LOCAL.QUEUE`.

For example, the following JSON contains some attributes, and then the named JSON objects, `events` and `storage`. These named JSON objects define the extra attributes to create a local queue with queue depth high events enabled, and a maximum queue depth of 1000:

```
{
  "name": "queue1",
  "type": "local",
  "events": {
    "depth": {
      "highEnabled" : true,
      "highPercentage" : 75
    }
  },
  "storage": {
    "maximumDepth" : 1000
  }
}
```

For more examples, see [examples](#).

The following attributes can be included in the request body:

name

Required.

String.

Specifies the name of the queue to create.

type

String.

Specifies the type of queue.

The value can be one of the following values:

- local
- alias
- model
- remote

The default value is local.

The following objects can be included in the request body to specify extra attributes:

remote

Contains attributes that are related to remote queues. The attributes in this object are supported only for remote queues.

alias

Contains attributes that are related to alias queues. The attributes in this object are supported only for alias queues.

model

Contains attributes that are related to model queues. The attributes in this object are supported only for model queues.

cluster

Contains attributes that are related to clusters.

trigger

Contains attributes that are related to triggering.

events

Contains two objects, one for queue depth and one for queue service interval events. Each object contains attributes that are related to the event type.

applicationDefaults

Contains attributes that are related to default behavior such as message persistence, message priority, shared input settings, and read ahead settings.

queueSharingGroup

Contains attributes that are related to queue sharing groups on z/OS.

dataCollection

Contains attributes that are related to data collection, monitoring, and statistics.

storage

Contains attributes that are related to message storage, such as the maximum depth of the queue, and the maximum length of messages that are allowed on the queue.

general

Contains attributes that are related to general queue properties, such as whether get or put operations are inhibited, the description of the queue, and transmission queue settings.

extended

Contains attributes that are related to extended queue properties, such as backout queue settings, and shared input settings.

For more information, see [“Request body attributes for queues” on page 2350](#).

Security requirements

The caller must be authenticated to the mqweb server and must be a member of one or more of the MQWebAdmin, MQWebAdminRO, or MQWebUser roles. For more information about security for the administrative REST API, see [IBM MQ Console and REST API security](#).

If token based security is used, the LTPA token that is used to authenticate the user must be provided with the request as a cookie. For more information about token-based authentication, see [Using token-based authentication with the REST API](#).

The security principal of the caller must be granted the ability to issue the following PCF commands for the specified queue manager:

- If the **like** optional query parameter is not specified:
 - For the queue that is specified by the **name** attribute in the request body, authority to issue the **MQCMD_CREATE_Q** PCF command must be granted.
 - For the relevant `SYSTEM.DEFAULT.*.QUEUE`, authority to issue the **MQCMD_INQUIRE_Q** PCF command must be granted.
- If the **like** optional query parameter is specified:
 - For the queue that is specified by the **name** attribute in the request body, authority to issue the **MQCMD_COPY_Q** PCF command must be granted.
 - For the queue that is specified by the **like** optional query parameter, authority to issue the **MQCMD_INQUIRE_Q** PCF command must be granted.

ALW On AIX, Linux, and Windows, you can grant authority to security principals to use IBM MQ resources by using the **setmqaut** command. For more information, see [setmqaut \(grant or revoke authority\)](#).

On z/OS, see [Setting up security on z/OS](#).

Response status codes

201

Queue created successfully.

400

Invalid data provided.

For example, invalid queue data is specified.

401

Not authenticated.

The caller must be authenticated to the mqweb server and must be a member of one or more of the MQWebAdmin, MQWebAdminRO, or MQWebUser roles. The `ibm-mq-rest-csrf-token` header must also be specified. For more information, see [“Security requirements” on page 2347](#).

403

Access prohibited for one of the following reasons:

- Not authorized. The caller is authenticated to the mqweb server and is associated with a valid principal. However, the principal does not have access to the required IBM MQ resources. For more information about the access that is required, see [“Security requirements” on page 2347](#).

- **V9.4.0** Access prohibited in the current server environment. You cannot use the administrative REST API with the stand-alone IBM MQ Web Server.

500

Server issue or error code from IBM MQ.

503

Queue manager not running.

Response headers

The following headers are returned with the response:

location

If the request was successful, this header specifies the URL for the new queue.

If the optional query parameter `commandScope=*` is used, the URL that is returned is the URL for the local copy of the queue. If the optional query parameter `commandScope=qmgrName` is used, the URL that is returned is a partial URL that does not include information about the host and port.

On z/OS, if the optional query parameter `commandScope=*` is used, this header is returned with a comma-separated list of the queue managers that generated a response. For example, the header might look like the following header:

```
ibm-mq-qmgrs: MQ21, MQ22
```

If an error occurs before the command is issued to the queue managers, the response header does not contain the list of queue managers. For example, a request that generates a 200 or 201 status code has the header because the command was successful. A request that generates a 401 (not authenticated) status code does not have the header because the request was rejected. A request that generates a 403 (not authorized) status code has the header because individual queue managers decide whether the command is authorized.

ibm-mq-rest-gateway-qmgr

This header is returned if a remote queue manager is specified in the resource URL. The value of this header is the name of the queue manager that is used as the gateway queue manager.

Response body format

The response body is empty if the queue is created successfully. If an error occurs, the response body contains an error message. For more information, see [REST API error handling](#).

Examples

- The following example creates a local queue called `localQueue`. The following URL is used with the HTTP POST method:

```
https://localhost:9443/ibmmq/rest/v1/admin/qmgr/QM1/queue/
```

The following JSON payload is sent:

```
{
  "name": "localQueue"
}
```

- The following example creates a remote queue called `remoteQueue`. The following URL is used with the HTTP POST method:

```
https://localhost:9443/ibmmq/rest/v1/admin/qmgr/QM1/queue/
```

The following JSON payload is sent:

```
{
  "name": "remoteQueue",
  "type": "remote",
  "remote": {
    "queueName": "localQueue",
    "qmgrName": "QM2"
  }
}
```

- The following example creates an alias queue called `aliasQueue`. The following URL is used with the HTTP POST method:

```
https://localhost:9443/ibmmq/rest/v1/admin/qmgr/QM1/queue/
```

The following JSON payload is sent:

```
{
  "name": "aliasQueue",
  "type": "alias",
  "alias": {
    "targetName": "localQueue"
  }
}
```

```
}  
}
```

- The following example creates a model queue called `modelQueue`. The following URL is used with the HTTP POST method:

```
https://localhost:9443/ibmmq/rest/v1/admin/qmgr/QM1/queue/
```

The following JSON payload is sent:

```
{  
  "name": "modelQueue",  
  "type": "model",  
  "model": {  
    "type": "permanentDynamic"  
  }  
}
```

- The following example creates a clustered remote queue that is called `remoteQueue1`. The following URL is used with the HTTP POST method:

```
https://localhost:9443/ibmmq/rest/v1/admin/qmgr/QM1/queue/
```

The following JSON payload is sent:

```
{  
  "name": "remoteQueue1",  
  "type": "remote",  
  "remote": {  
    "queueName": "aLocalQueue1",  
    "qmgrName": "QM2",  
    "transmissionQueueName": "MY.XMITQ"  
  },  
  "general": {  
    "description": "My clustered remote queue"  
  },  
  "cluster": {  
    "name": "Cluster1",  
    "workloadPriority": 9  
  }  
}
```

- The following example creates a clustered remote queue, `remoteQueue2`, based on another queue, `remoteQueue1`. All the attributes from `remoteQueue1` are used, except for the queue name and the remote queue name. The following URL is used with the HTTP POST method:

```
https://localhost:9443/ibmmq/rest/v1/admin/qmgr/QM1/queue/?like=remoteQueue1
```

The following JSON payload is sent:

```
{  
  "name": "remoteQueue2",  
  "type": "remote",  
  "remote": {  
    "queueName": "aLocalQueue2"  
  }  
}
```

Request body attributes for queues

When you create the request body for creating or modifying a queue with the administrative REST API, you can specify attributes for the queue within named JSON objects. A number of objects and attributes are available.

The following objects are available:

- [“remote” on page 2351](#)
- [“alias” on page 2351](#)
- [“model” on page 2352](#)

- [“cluster” on page 2352](#)
- [“trigger” on page 2353](#)
- [“events” on page 2354](#)
- [“applicationDefaults” on page 2356](#)
- [“queueSharingGroup” on page 2357](#)
- [“dataCollection” on page 2359](#)
- [“storage” on page 2360](#)
- [“general” on page 2361](#)
- [“extended” on page 2362](#)

For more information about the PCF equivalents to the queue REST API parameters and attributes, see [“REST API and PCF equivalents for queues” on page 2411](#).

remote

Note: The `remote` object and the `qmgrName` attribute are required when you create a remote queue by using the HTTP POST method. You cannot use the `remote` object unless you are creating a remote queue, or updating a remote queue.

The `remote` object can contain the following attributes that relate to remote queues:

queueName

String.

Specifies the name of the queue as it is known on the remote queue manager.

If this attribute is omitted, a queue manager alias or reply-to queue alias is created.

qmgrName

String.

Specifies the name of the remote queue manager.

Required when you create a queue by using the HTTP POST method, unless you use the **like** optional query parameter.

If this remote queue is used as a queue manager alias, this attribute is the name of the queue manager. The value can be the name of the queue manager in the resource URL.

If this remote queue is used as a reply-to queue alias, this attribute is the name of the queue manager that is to be the reply-to queue manager.

transmissionQueueName

String.

Specifies the name of the transmission queue that is to be used for messages that are destined for either a remote queue or for a queue manager alias definition.

This attribute is ignored in the following cases:

- The remote queue is used as a queue manager alias and **qmgrName** attribute is the name of the queue manager in the resource URL.
- The remote queue is used as a reply-to queue alias.

If this attribute is omitted, a local queue with the name that is specified by the **qmgrName** attribute must exist. This queue is used as the transmission queue.

alias

Note: The `alias` object and the `targetName` attribute are required when you create an alias queue by using the HTTP POST method. You cannot use the `alias` object unless you are creating an alias queue, or updating an alias queue.

The `alias` object can contain the following attributes that relate to alias queues:

targetName

String.

Specifies the name of the queue or topic that the alias resolves to.

Required when you create a queue by using the HTTP POST method, unless you use the **like** optional query parameter.

targetType

String.

Specifies the type of object that the alias resolves to.

The value must be one of the following values:

queue

Specifies that the object is a queue.

topic

Specifies that the object is a topic.

The default value is queue.

model

Note: The `model` object and the `type` attribute are required when you create a model queue by using the HTTP POST method. You cannot use the `model` object unless you are creating a model queue, or updating a model queue.

The `model` object can contain the following attributes that relate to model queues:

type

String.

Specifies the model queue definition type.

The value must be one of the following values:

permanentDynamic

Specifies that the queue is a dynamically defined permanent queue.

sharedDynamic

 This attribute is only available on z/OS.

Specifies that the queue is a dynamically defined shared queue.

temporaryDynamic

Specifies that the queue is a dynamically defined temporary queue.

The default value is `temporaryDynamic`.

cluster

The `cluster` object can contain the following attributes that relate to clusters:

name

String.

Specifies the name of the cluster that the queue belongs to.

Specify either the **name** or **namelist** cluster attributes. You cannot specify both attributes.

namelist

String.

Specifies the namelist that lists the clusters that the queue belongs to.

Specify either the **name** or **namelist** cluster attributes. You cannot specify both attributes.

transmissionQueueForChannelName

String.

Specifies the generic name of the cluster-sender channels that use the queue as a transmission queue. The attribute specifies which cluster-sender channels send messages to a cluster-receiver channel from the cluster transmission queue.

You can also set this attribute to a cluster-sender channel manually. Messages that are destined for the queue manager that is connected by the cluster-sender channel are stored in the transmission queue that identifies the cluster-sender channel. The messages are not stored in the default cluster transmission queue.

If you set the **transmissionQueueForChannelName** attribute to blanks, the channel switches to the default cluster transmission queue when the channel restarts. The default cluster transmission queue is `SYSTEM.CLUSTER.TRANSMIT.QUEUE` if the queue manager **DefClusterXmitQueueType** attribute is set to `SCTQ`. A specific cluster transmission queue, `SYSTEM.CLUSTER.TRANSMIT.ChannelName`, is used for each cluster-sender channel if the queue manager **DefClusterXmitQueueType** attribute is set to `CHANNEL`.

By specifying asterisks, `*`, in **transmissionQueueForChannelName**, you can associate a transmission queue with a set of cluster-send channels. The asterisks can be at the beginning, end, or any number of places in the middle of the channel name string.

workloadPriority

Integer.

Specifies the priority of the queue in cluster workload management.

The value must be in the range 0 - 9, where 0 is the lowest priority and 9 is the highest.

workloadRank

Integer.

Specifies the rank of the queue in cluster workload management.

The value must be in the range 0 - 9, where 0 is the lowest priority and 9 is the highest.

workloadQueueUse

String.

Specifies whether remote and local instances of the clustered queues are to be used in cluster workload distribution.

The value must be one of the following values:

asQmgr

Use the value that is defined on the queue manager.

any

Use remote and local instances of the queues.

local

Use only local instances of the queues.

trigger

The **trigger** object can contain the following attributes that relate to triggering:

data

String.

Specifies the user data that is included in the trigger message. This data is made available to the monitoring application that processes the initiation queue and to the application that is started by the monitor.

depth

Integer.

Specifies the number of messages that initiates a trigger message to the initiation queue.

The value must be in the range 1 - 999,999,999.

This attribute is required when **type** is set to `depth`.

enabled

Boolean.

Specifies whether trigger messages are written to the initiation queue.

If the value is set to `true`, trigger messages are written to the initiation queue.

initiationQueueName

String.

Specifies the local queue for trigger messages that relate to the queue. The queues must be on the same queue manager.

messagePriority

Integer.

Specifies the minimum priority that a message must have before it can cause, or be counted for, a trigger event.

The value must be in the range 0 - 9.

processName

String.

Specifies the local name of the IBM MQ process that identifies the application to be started when a trigger event occurs.

If the queue is a transmission queue, the process definition contains the name of the channel to be started.

type

String.

Specifies the condition that initiates a trigger event. When the condition is true, a trigger message is sent to the initiation queue.

The value must be one of the following values:

none

Send no trigger messages.

every

Send a trigger message for every message that arrives on the queue.

first

Send a trigger message when the queue depth goes from 0 to 1.

depth

Send a trigger message when the queue depth exceeds the value of the **depth** attribute.

events

The `events` object can contain the following objects and attributes that relate to queue depth and queue service interval events:

depth

JSON object.

A JSON object that can contain the following attributes that related to queue depth events:

fullEnabled

Boolean.

Specifies whether queue full events are generated.

A queue full event indicates that no more messages can be put on a queue because the queue is full. That is, the queue depth reached the maximum queue depth, as specified by the **maximumDepth** attribute in the `storage` object.

If the value is set to `true`, queue full events are enabled.

highEnabled

Boolean.

Specifies whether queue depth high events are generated.

A queue depth high event indicates that the number of messages on the queue is greater than or equal to the queue depth high limit, **highPercentage**.

If the value is set to `true`, queue depth high events are enabled.

highPercentage

Integer.

Specifies the threshold against which the queue depth is compared to generate a queue depth high event.

This value is expressed as a percentage of the maximum queue depth, as specified by the **maximumDepth** attribute in the `storage` object. The value must be a value in the range 0 - 100.

lowEnabled

Boolean.

Specifies whether queue depth low events are generated.

A queue depth low event indicates that the number of messages on the queue is less than or equal to the queue depth low limit, **lowPercentage**.

If the value is set to `true`, queue depth low events are enabled.

lowPercentage

Integer.

Specifies the threshold against which the queue depth is compared to generate a queue depth low event.

This value is expressed as a percentage of the maximum queue depth, as specified by the **maximumDepth** attribute in the `storage` object. The value must be a value in the range 0 - 100.

serviceInterval

JSON object.

A JSON object that can contain the following attributes that are related to queue service interval events:

duration

Integer.

Specifies the service interval duration that is used for comparison to generate queue service interval high and queue service interval OK events.

The value must be a value in the range 0 - 999,999,999 milliseconds.

highEnabled

Boolean.

Specifies whether queue service interval high events are generated.

A queue service interval high event is generated when a check indicates that no messages were put to, or retrieved from, the queue for at least the amount of time specified by the **duration** attribute.

If the value is set to `true`, queue service interval high events are enabled.

If you set the **highEnabled** attribute to `false`, you must also specify a value for the **okEnabled** attribute. You cannot set both the **highEnabled** attribute and the **okEnabled** attribute to `true` at the same time.

okEnabled

Boolean.

Specifies whether queue service interval OK events are generated.

A queue service interval OK event is generated when a check indicates that a message was retrieved from the queue within the amount of time that is specified by the **duration** attribute.

If the value is set to `true`, queue service interval OK events are enabled.

If you set the **okEnabled** attribute to `false`, you must also specify a value for **highEnabled**. You cannot set both the **highEnabled** attribute and the **okEnabled** attribute to `true` at the same time.

applicationDefaults

The `applicationDefaults` object can contain the following attributes that relate to default behavior such as message persistence:

clusterBind

String.

Specifies the binding to be used when `MQOO_BIND_AS_Q_DEF` is specified on the `MQOPEN` call.

The value must be one of the following values:

onOpen

Specifies that the binding is fixed by the `MQOPEN` call.

notFixed

Specifies that the binding is not fixed.

onGroup

Specifies that the application can request that a group of messages is allocated to the same destination instance.

messagePersistence

String.

Specifies the default for message persistence on the queue. Message persistence determines whether messages are preserved across restarts of the queue manager.

The value must be one of the following values:

persistent

Specifies that the messages on the queue are persistent, and are preserved when the queue manager restarts.

nonPersistent

Specifies that the messages on the queue are not persistent, and are lost when the queue manager restarts.

messagePriority

Integer.

Specifies the default priority of messages that are put on the queue.

The value must be in the range 0 - 9, where 0 represents the lowest priority, and 9 represents the highest priority.

messagePropertyControl

String.

Specifies how message properties are handled when messages are retrieved from queues when `MQGMO_PROPERTIES_AS_Q_DEF` is specified on the `MQGET` call.

This attribute is applicable to local, alias, and model queues.

The value must be one of the following values:

all

Specifies that all properties of the message are included when the message is sent to the remote queue manager. The properties, except those properties in the message descriptor or extension, are placed in one or more `MQRFH2` headers in the message data.

compatible

Specifies that if the message contains a property with the prefix `mcd.`, `jms.`, `usr.`, or `mqext.`, all message properties are delivered to the application in an `MQRFH2` header. Otherwise, all properties, except those properties in the message descriptor or extension, are discarded and are no longer accessible.

force

Specifies that properties are always returned in the message data in an MQRFH2 header regardless of whether the application specifies a message handle. A valid message handle that is included in the MsgHandle field of the MQGMO structure on the MQGET call is ignored. Properties of the message are not accessible by using the message handle.

none

Specifies that all properties of the message are removed from the message before the message is sent to the remote queue manager. Properties in the message descriptor, or extension, are not removed.

version6Compatible

Any application MQRFH2 header is received as it was sent. Any properties set by using MQSETMP must be retrieved by using MQINQMP. They are not added to the MQRFH2 created by the application. Properties that were set in the MQRFH2 header by the sending application cannot be retrieved by using MQINQMP.

putResponse

String.

Specifies the type of response that is to be used for put operations to the queue when an application specifies MQPMO_RESPONSE_AS_Q_DEF.

The value must be one of the following values:

synchronous

The put operation is run synchronously, returning a response.

asynchronous

The put operation is run asynchronously, returning a subset of MQMD fields.

readAhead

String.

Specifies the default read-ahead behavior for non-persistent messages that are delivered to the client.

The value must be one of the following values:

no

Specifies that non-persistent messages are not read ahead unless the client application is configured to request read ahead.

yes

Specifies that non-persistent messages are sent ahead to the client before an application requests them. Non-persistent messages can be lost if the client ends abnormally or if the client does not consume all the messages that it is sent.

disabled

Specifies that non-persistent messages are not read ahead, regardless of whether read ahead is requested by the client application.

sharedInput

Boolean.

Specifies the default share option for applications that open this queue for input.

If the value is set to true, queues are enabled to get messages with shared access.

queueSharingGroup

 The queueSharingGroup object can contain the following attributes that relate to queue sharing groups:

disposition

String.

 This attribute is only available on z/OS.

Specifies where the queue is defined and how it behaves. That is, it specifies the disposition of the queue.

The value must be one of the following values:

copy

Specifies that the queue definition exists on the page set of the queue manager that runs the command. The group object of the same name as the **name** attribute is used to create the queue.

For local queues, messages are stored on the page sets of each queue manager and are available only through that queue manager.

group

Specifies that the queue definition exists in the shared repository.

This value is allowed only in a shared queue manager environment.

If the creation is successful, the following MQSC command is generated and sent to all active queue managers in the queue sharing group. The command attempts to make or refresh local copies on page set zero:

```
DEFINE queue(q-name) REPLACE QSGDISP(COPY)
```

The creation of the group object takes effect even if the generated command with QSGDISP(COPY) fails.

qmgr

Specifies that the queue definition exists on the page set of the queue manager that runs the command.

For local queues, messages are stored on the page sets of each queue manager and are available only through that queue manager.

shared

This value is only valid for local queues.

Specifies that the queue exists in the shared repository.

Messages are stored in the coupling facility and are available to any queue manager in the queue sharing group. You can specify shared only if the following things are true:

- The value of **structureName** is not blank.
- The value of **indexType** is not messageToken.
- The queue is not SYSTEM.CHANNEL.INITQ or SYSTEM.COMMAND.INPUT.

The default value is qmgr.

structureName

String.

 This attribute is only available on z/OS.

Specifies the name of the coupling facility structure where you want to store messages when you used shared queues.

The value cannot have more than 12 characters, it must start with an uppercase letter (A - Z), and can include only the characters A - Z and 0 - 9.

The name of the queue sharing group to which the queue manager is connected is prefixed to the name you supply. The name of the queue sharing group is always 4 characters, padded with the at sign, @, if necessary. For example, if you use a queue sharing group that is named NY03 and you supply the name PRODUCT7, the resultant coupling facility structure name is NY03PRODUCT7. Note the administrative structure for the queue sharing group (in this case NY03CSQ_ADMIN) cannot be used for storing messages.

For local and model queues, the following rules apply. The rules apply if you create a queue without specifying the **noReplace** optional query parameter, or if you change the queue:

- On a local queue with a **disposition** value of shared, **structureName** cannot change. If you need to change the **structureName** or the **disposition**, you must delete and redefine the queue. To preserve any of the messages on the queue, you must offload the messages before you delete the queue. Reload the messages after you redefine the queue, or move the messages to another queue.
- On a model queue with a **definitionType** value of sharedDynamic, the **structureName** cannot be blank.

For local and model queues, when you create a queue with the **noReplace** optional query parameter, the following rules apply:

- On a local queue with a **disposition** value of shared, or a model queue with a **definitionType** value of sharedDynamic, the **structureName** cannot be blank.

dataCollection

The dataCollection object can contain the following attributes that relate to the collection of data, monitoring, and statistics:

accounting

String.

Specifies whether accounting data is collected for the queue.

The value must be one of the following values:

asQmgr

Specifies that the queue inherits the value from the queue manager MQSC parameter ACCTQ.

off

Specifies that accounting data is not collected for the queue.

on

Specifies that accounting data is collected for the queue if the ACCTQ MQSC parameter on the queue manager is not set to none.

monitoring

String.

Specifies whether online monitoring data is to be collected, and if so, the rate at which the data is collected.

The value must be one of the following values:

off

Specifies that online monitoring data is not collected for the queue.

asQmgr

Specifies that the queue inherits the value from the queue manager MQSC parameter MONQ.

low

Specifies that online monitoring data is collected for the queue if the MONQ MQSC parameter on the queue manager is not set to none. The rate of data collection is low.

medium

Specifies that online monitoring data is collected for the queue if the MONQ MQSC parameter on the queue manager is not set to none. The rate of data collection is moderate.

high

Specifies that online monitoring data is collected for the queue if the MONQ MQSC parameter on the queue manager is not set to none. The rate of data collection is high.

statistics

This attribute is only available on the IBM MQ Appliance, AIX, Linux, and Windows.

String.

Specifies whether statistics data is to be collected for the queue.

The value must be one of the following values:

asQmgr

Specifies that the queue inherits the value from the queue manager STATQ MQSC parameter.

off

Specifies that statistics data is not collected for the queue.

on

Specifies that statistics data is collected for the queue if the STATQ MQSC parameter on the queue manager is not set to none.

storage

The `storage` object can contain the following attributes that relate to message storage:

indexType

 This attribute is only available on z/OS.

String.

Specifies the type of index that is maintained by the queue manager to expedite MQGET operations on the queue. For shared queues, the type of index determines what type of MQGET calls can be used.

The value must be one of the following values:

none

Specifies that there is no index. Messages are retrieved sequentially.

correlationId

Specifies that the queue is indexed by using correlation identifiers.

groupId

Specifies that the queue is indexed by using group identifiers.

messageId

Specifies that the queue is indexed by using message identifiers.

messageToken

Specifies that the queue is indexed by using message tokens.

The default value is none.

maximumDepth

Integer.

Specifies the maximum number of messages that are allowed on the queue.

The value must be in the range 0 - 999,999,999.

maximumMessageLength

Integer.

Specifies the maximum message length that is allowed for messages on the queue.

Do not set a value that is greater than the **maximumMessageLength** attribute for the queue manager.

The value must be in the range 0 - 104,857,600 bytes.

messageDeliverySequence

String.

Specifies whether messages are delivered in priority order or by sequence.

The value must be one of the following values:

priority

Specifies that messages are returned in priority order.

fifo

Specifies that messages are returned in first in, first out order.

nonPersistentMessageClass

 MQ Appliance

 ALW

This attribute is only available on the IBM MQ Appliance, AIX, Linux, and Windows.

String.

This attribute is valid only on local and model queues.

Specifies the level of reliability to be assigned to non-persistent messages that are put to the queue.

The value must be one of the following values:

normal

Specifies that non-persistent messages persist for the lifetime of the queue manager session. They are discarded if the queue manager restarts.

high

Specifies that the queue manager attempts to retain non-persistent messages for the lifetime of the queue. Non-persistent messages might still be lost if a failure occurs.

storageClass

 z/OS

This attribute is only available on z/OS.

String.

Specifies the name of the storage class.

general

The `general` object can contain the following attributes that relate to general queue properties:

description

String.

Specifies a description for the queue.

The characters in the description field are converted from UTF-8 into the CCSID of the queue manager. Ensure that you use only the characters that can be converted. Certain characters must be escaped:

- Double quotation marks, `"`, must be escaped as `\ "`
- A backslash, `\`, must be escaped as `\\`
- A forward slash, `/`, must be escaped as `\/`

inhibitGet

Boolean.

Specifies whether `get` operations are allowed on the queue.

If the value is set to `true`, `get` operations are not allowed on the queue.

inhibitPut

Boolean.

Specifies whether `put` operations are allowed on the queue.

If the value is set to `true`, `put` operations are not allowed on the queue.

isTransmissionQueue

String.

Specifies whether the queue is for normal usage or for transmitting messages to a remote queue manager.

If the value is set to `true`, the queue is a transmission queue for transmitting messages to a remote queue manager.

The `isTransmissionQueue` attribute must not normally be changed while messages are on the queue. The format of messages changes when they are put on a transmission queue.

extended

The extended object can contain the following attributes that relate to extended queue properties:

allowSharedInput

Boolean.

Specifies whether multiple instances of applications can open the queue for input.

If the value is set to `true`, multiple instances of applications can open the queue for input.

backoutRequeueQueueName

String.

Specifies the name of the queue to which a message is transferred if it is backed out more times than the value of **backoutThreshold**.

The backout queue does not need to exist when the queue is created, but it must exist when the **backoutThreshold** value is exceeded.

backoutThreshold

Integer.

Specifies the number of times that a message can be backed out before it is transferred to the backout queue that is specified by the **backoutRequeueQueueName** attribute.

If the **backoutThreshold** value is later reduced, messages that are already on the queue that were backed out at least as many times as the new value remain on the queue. Those messages are transferred if they are backed out again.

The value must be a value in the range 0 - 999,999,999.

custom

String.

Specifies custom attributes for new features.

This attribute contains the values of attributes, as pairs of attribute name and value, which are separated by at least one space. The attribute name-value pairs have the form `NAME (VALUE)`. Single quotation marks, `'`, must be escaped with another single quotation mark.

enableMediaImageOperations

  This attribute is available only on the IBM MQ Appliance, AIX, Linux, and Windows.

Specifies whether a local or permanent dynamic queue object is recoverable from a media image, if linear logging is being used.

String.

The value must be one of the following values:

yes

Specifies that this queue object is recoverable.

no

The `rcdmqimg` and `rcrmqobj` commands are not permitted for these objects. If automatic media images are enabled, the media images are not written for these objects.

asQmgr

Specifies that the queue inherits the value from the queue manager `ImageRecoverQueue` attribute.

This is the default value for this attribute.

hardenGetBackout

 This attribute is only available on z/OS.

Boolean.

Specifies whether the count of the number of times that a message was backed out is saved, to ensure that it is accurate across restarts of the queue manager.

If the value is set to `true`, the backout count is always accurate across restarts of the queue manager.

supportDistributionLists

MQ Appliance **ALW** This attribute is only available on the IBM MQ Appliance, AIX, Linux, and Windows.

Boolean.

Specifies whether distribution-list messages can be placed on the queue.

If the value is set to `true`, distribution lists can be placed on the queue.

PATCH

Use the HTTP PATCH method with the queue resource to modify a queue on a specified queue manager.

Note:

- This resource URL is available only in version 1 of the REST API. To modify queues using version 2 of the REST API, use the [“/admin/action/qmgr/{qmgrName}/mqsc”](#) on page 2190 resource.
- **V9.4.0** You cannot use this resource with the stand-alone IBM MQ Web Server. For more information about the installation options for the IBM MQ component that runs the administrative REST API, see [The IBM MQ Console and REST API](#).

This REST API command is similar to the “Change, Copy, and Create Queue” on page 1093 PCF command, and the “ALTER queues (alter queue settings)” on page 411 MQSC commands.

- [Resource URL](#)
- [Optional query parameters](#)
- [“Request headers” on page 2365](#)
- [Request body format](#)
- [“Security requirements” on page 2366](#)
- [Response status codes](#)
- [“Response headers” on page 2367](#)
- [Response body format](#)
- [Examples](#)

Resource URL

`https://host:port/ibmmq/rest/v1/admin/qmgr/{qmgrName}/queue/{queueName}`

qmgrName

Specifies the name of the queue manager on which the queue to modify exists.

The queue manager name is case sensitive.

If the queue manager name includes a forward slash, a period, or a percent sign, these characters must be URL encoded:

- A forward slash (/) must be encoded as %2F.
- A period (.) must be encoded as %2E.
- A percent sign (%) must be encoded as %25.

queueName

Specifies the name of the queue to modify.

You can specify a remote queue manager as the **qmgrName**. If you specify a remote queue manager, you must configure a gateway queue manager. For more information, see [Remote administration using the REST API](#).

The queue manager name is case-sensitive.

If the queue manager name includes a forward slash, a period, or a percent sign, these characters must be URL encoded:

- A forward slash (/) must be encoded as %2F.
- A percent sign (%) must be encoded as %25.
- A period (.) must be encoded as %2E.

You can use HTTP instead of HTTPS if you enable HTTP connections. For more information about enabling HTTP, see [Configuring HTTP and HTTPS ports](#).

Optional query parameters

commandScope=scope

 This parameter is only available on z/OS.

Specifies how the command is run when the queue manager is a member of a queue sharing group. You cannot specify this parameter if the queue manager is not a member of a queue sharing group. *scope* can be one of the following values:

The name of a queue manager

Specifies that the command is run on the queue manager that is named. The queue manager must be active within the same queue sharing group as the queue manager that is specified in the resource URL.

You cannot specify the queue manager name that is the queue manager that is specified in the resource URL.

If the queue manager name includes a percent sign, %, this character must be URL encoded as %25.

Specifies that the command is run on the local queue manager and also passed to every active queue manager in the queue sharing group.

If this option is used, an `ibm-mq-qmgrs` response header is returned with a comma-separated list of the queue managers that generated a response. For example, the header might look like the following header:

```
ibm-mq-qmgrs: MQ21, MQ22
```

force

Specifies that the command is forced to complete, regardless of whether completing affects an open queue.

This parameter is not valid for model queues.

An open queue is affected in the following cases:

- The queue is an alias queue. The **targetName** is modified, and an application has the alias queue open.
- The queue is a local queue. The **allowedSharedInput** attribute is modified, and more than one application has the queue open for input.
- The queue is a local queue. The **isTransmissionQueue** attribute is modified, and messages are on the queue, or applications have the queue open.
- The queue is a remote queue. The **transmissionQueueName** attribute is modified, and an application has a remote queue open that would be affected by this change.
- The queue is remote queue. The **queueName**, **qmgrName**, or **transmissionQueueName** attributes are modified, and one or more applications has a queue open that resolved through this definition as a queue manager alias.

Request headers

The following headers must be sent with the request:

Content-Type

This header must be sent with a value of `application/json` optionally followed by `; charset=UTF-8`.

ibm-mq-rest-csrf-token

This header must be set, but the value can be anything, including being blank.

Authorization

This header must be sent if you are using basic authentication. For more information, see [Using HTTP basic authentication with the REST API](#).

The following headers can optionally be sent with the request:

ibm-mq-rest-gateway-qmgr

This header specifies the queue manager that is to be used as the gateway queue manager. The gateway queue manager is used to connect to a remote queue manager. For more information, see [Remote administration using the REST API](#).

Request body format

The request body must be in JSON format in UTF-8 encoding. Within the request body attributes are specified, and named JSON objects are created to specify extra attributes to modify. Any attributes that are not specified are not changed.

For example, the following JSON contains the attribute **type**, and then the named JSON objects, **events** and **storage**. The named JSON objects define the additional attributes to modify the queue to disable queue depth high events, and change the maximum queue depth to 2000:

```
{
  "type": "local",
  "events" : {
    "serviceInterval" : {
      "highEnabled" : false,
      "okEnabled" : false
    }
  },
  "storage" : {
    "maximumDepth" : 2000
  }
}
```

For more examples, see [examples](#).

The following attributes can be included in the request body:

type

String.

Specifies the type of queue.

The value can be one of the following values:

- `local`
- `alias`
- `model`
- `remote`

The default value is `local`.

The following objects can be included in the request body to specify extra attributes:

remote

Contains attributes that are related to remote queues. The attributes in this object are supported only for remote queues.

alias

Contains attributes that are related to alias queues. The attributes in this object are supported only for alias queues.

model

Contains attributes that are related to model queues. The attributes in this object are supported only for model queues.

cluster

Contains attributes that are related to clusters.

trigger

Contains attributes that are related to triggering.

events

Contains two objects, one for queue depth and one for queue service interval events. Each object contains attributes that are related to the event type.

applicationDefaults

Contains attributes that are related to default behavior such as message persistence, message priority, shared input settings, and read ahead settings.

queueSharingGroup

Contains attributes that are related to queue sharing groups on z/OS.

dataCollection

Contains attributes that are related to data collection, monitoring, and statistics.

storage

Contains attributes that are related to message storage, such as the maximum depth of the queue, and the maximum length of messages that are allowed on the queue.

general

Contains attributes that are related to general queue properties, such as whether get or put operations are inhibited, the description of the queue, and transmission queue settings.

extended

Contains attributes that are related to extended queue properties, such as backout queue settings, and shared input settings.

For more information, see [“Request body attributes for queues” on page 2350](#).

Security requirements

The caller must be authenticated to the mqweb server and must be a member of one or more of the MQWebAdmin, MQWebAdminRO, or MQWebUser roles. For more information about security for the administrative REST API, see [IBM MQ Console and REST API security](#).

If token based security is used, the LTPA token that is used to authenticate the user must be provided with the request as a cookie. For more information about token-based authentication, see [Using token-based authentication with the REST API](#).

The security principal of the caller must be granted the ability to issue the following PCF commands for the specified queue manager:

- For the queue that is specified by the *{queueName}* portion of the resource URL, authority to issue the **MQCMD_CHANGE_Q** PCF command must be granted.

 On AIX, Linux, and Windows, you can grant authority to security principals to use IBM MQ resources by using the **setmqaut** command. For more information, see [setmqaut \(grant or revoke authority\)](#).

On z/OS, see [Setting up security on z/OS](#).

Response status codes

204

Queue modified successfully.

400

Invalid data provided.

For example, invalid queue data is specified.

401

Not authenticated.

The caller must be authenticated to the mqweb server and must be a member of one or more of the MQWebAdmin, MQWebAdminRO, or MQWebUser roles. The `ibm-mq-rest-csrf-token` header must also be specified. For more information, see [“Security requirements” on page 2366](#).

403

Access prohibited for one of the following reasons:

- Not authorized. The caller is authenticated to the mqweb server and is associated with a valid principal. However, the principal does not have access to the required IBM MQ resources. For more information about the access that is required, see [“Security requirements” on page 2366](#).
- **V9.4.0** Access prohibited in the current server environment. You cannot use the administrative REST API with the stand-alone IBM MQ Web Server.

404

Queue does not exist.

500

Server issue or error code from IBM MQ.

503

Queue manager not running.

Response headers

The following headers are returned with the response:

ibm-mq-qmgrs

On z/OS, if the optional query parameter `commandScope=*` is used, this header is returned with a comma-separated list of the queue managers that generated a response. For example, the header might look like the following header:

```
ibm-mq-qmgrs: MQ21, MQ22
```

If an error occurs before the command is issued to the queue managers, the response header does not contain the list of queue managers. For example, a request that generates a 200 or 201 status code has the header because the command was successful. A request that generates a 401 (not authenticated) status code does not have the header because the request was rejected. A request that generates a 403 (not authorized) status code has the header because individual queue managers decide whether the command is authorized.

ibm-mq-rest-gateway-qmgr

This header is returned if a remote queue manager is specified in the resource URL. The value of this header is the name of the queue manager that is used as the gateway queue manager.

Response body format

The response body is empty if the queue is modified successfully. If an error occurs, the response body contains an error message. For more information, see [REST API error handling](#).

Examples

- The following example modifies an alias queue called `aliasQueue`. The following URL is used with the HTTP PATCH method:

```
https://localhost:9443/ibmmq/rest/v1/admin/qmgr/QM1/queue/aliasQueue
```

The following JSON payload is sent:

```
{
  "type": "alias",
  "alias": {
    "targetName": "aDifferentLocalQueue"
  }
}
```

GET

Use the HTTP GET method with the queue resource to request information about queues.

Note:

- This resource URL is available only in version 1 of the REST API. To request information about queues using version 2 of the REST API, use the [“/admin/action/qmgr/{qmgrName}/mqsc”](#) on page 2190 resource.
- **V 9.4.0** You cannot use this resource with the stand-alone IBM MQ Web Server. For more information about the installation options for the IBM MQ component that runs the administrative REST API, see [The IBM MQ Console and REST API](#).

The information that is returned is similar to the information returned by the [“MQCMD_INQUIRE_Q \(Inquire Queue\)”](#) on page 1343 and [“MQCMD_INQUIRE_Q_STATUS \(Inquire Queue Status\)”](#) on page 1415 PCF commands, and the [“DISPLAY QUEUE \(display queue attributes\)”](#) on page 828 and [“DISPLAY QSTATUS \(display queue status\)”](#) on page 816 MQSC commands.

Note:  On z/OS, the channel initiator must be running before you use the queue resource with the HTTP GET method in either of the following situations:

- The **type** optional query parameter is not specified.
- The **type** optional query parameter is specified as either `all` or `cluster`.
- [Resource URL](#)
- [Optional query parameters](#)
- [“Request headers”](#) on page 2374
- [Request body format](#)
- [“Security requirements”](#) on page 2374
- [Response status codes](#)
- [“Response headers”](#) on page 2375
- [Response body format](#)
- [Examples](#)

Resource URL

```
https://host:port/ibmmq/rest/v1/admin/qmgr/{qmgrName}/queue/{queueName}
```

qmgrName

Specifies the name of the queue manager on which to query the queues.

You can specify a remote queue manager as the **qmgrName**. If you specify a remote queue manager, you must configure a gateway queue manager. For more information, see [Remote administration using the REST API](#).

The queue manager name is case-sensitive.

If the queue manager name includes a forward slash, a period, or a percent sign, these characters must be URL encoded:

- A forward slash (/) must be encoded as %2F.
- A percent sign (%) must be encoded as %25.
- A period (.) must be encoded as %2E.

queueName

Optionally specifies the name of a queue that exists on the queue manager specified.

The queue name is case-sensitive.

If the queue name includes a forward slash or a percent sign, these characters must be URL encoded:

- A forward slash, /, must be encoded as %2F.
- A percent sign, %, must be encoded as %25.

You can use HTTP instead of HTTPS if you enable HTTP connections. For more information about enabling HTTP, see [Configuring HTTP and HTTPS ports](#).

Optional query parameters

attributes={object,...[*|object.attributeName,...]}

object,...

Specifies a comma-separated list of JSON objects that contain related queue configuration attributes to return.

For example, to return all queue configuration attributes that are related to time stamps, specify `timestamps`. To return all queue configuration attributes that are related to storage and to data collection, specify `storage,dataCollection`.

The `status` and `applicationHandle` objects cannot be specified with this query parameter. Use the **status** and **applicationHandle** query parameters to return these attributes.

You cannot specify the same object more than once. If you request objects that are not valid for a particular queue, the attributes are not returned for that queue. However, if you specify a value for the **type** parameter that is not `all`, and request objects that are not valid for that queue type, an error is returned.

For a full list of objects and associated attributes, see [Attributes for queues](#).

Specifies all attributes.

object.attributeName,...

Specifies a comma-separated list of queue configuration attributes to return.

Each attribute must specify the JSON object that contains the attribute, in the form `object.attributeName`. For example, to return the `maximumDepth` attribute, which is contained in the `storage` object, specify `storage.maximumDepth`.

Attributes from the `status` and `applicationHandle` objects cannot be specified with this query parameter. Use the **status** and **applicationHandle** query parameters to return these attributes.

You cannot specify the same attribute more than once. If you request attributes that are not valid for a particular queue, the attributes are not returned for that queue. However, if you specify the **type** parameter and request attributes that are not valid for that queue type, an error is returned.

For a full list of attributes and associated objects, see [Attributes for queues](#).

status={status|*|status.attributeName,...}

status

Specifies that all status attributes are returned.

Specifies all attributes. This parameter is equivalent to **status**.

status.attributeName,...

Specifies a comma-separated list of status attributes to return.

For example, to return the `currentDepth` attribute, specify `status.currentDepth`.

For a full list of status attributes, see [Status attributes for queues](#).

If you specify the **status** optional query parameter, you can specify the **type** parameter only with the `all` or `local` values. You cannot specify the **queueSharingGroupDisposition** parameter with the `group` value.

applicationHandle={applicationHandle|*|applicationHandle.attributeName,...}

applicationHandle

Specifies that all application handle attributes are returned.

Specifies all attributes. This parameter is equivalent to **applicationHandle**.

applicationHandle.attributeName,...

Specifies a comma-separated list of application handle attributes to return.

For example, to return the `handleState` attribute, specify `applicationHandle.handleState`.

For a full list of application handle attributes, see [Application handle attributes for queues](#).

If you specify the **applicationHandle** optional query parameter, you can specify the **type** parameter only with the `all` or `local` values. You cannot specify the **queueSharingGroupDisposition** parameter with the `group` value.

commandScope=scope

 This parameter is only available on z/OS.

Specifies how the command is run when the queue manager is a member of a queue sharing group.

You cannot specify this parameter if the queue manager is not a member of a queue sharing group.

scope can be one of the following values:

The name of a queue manager

Specifies that the command is run on the queue manager that is named. The queue manager must be active within the same queue sharing group as the queue manager that is specified in the resource URL.

You cannot specify the queue manager name that is the queue manager that is specified in the resource URL.

If the queue manager name includes a percent sign, %, this character must be URL encoded as %25.

Specifies that the command is run on the local queue manager and also passed to every active queue manager in the queue sharing group.

If this option is used, an `ibm-mq-qmgrs` response header is returned with a comma-separated list of the queue managers that generated a response. For example, the header might look like the following header:

```
ibm-mq-qmgrs: MQ21, MQ22
```

filter=filterValue

Specifies a filter for the queue definitions that are returned.

If you specify a queue name in the resource URL, you can only filter on application handle attributes. If you filter on an application handle attribute, the only application handles returned are those that match the filter parameter.

You can specify only one filter. If you filter on an application handle attribute, you must specify the **applicationHandle** query parameter. If you filter on a status attribute, you must specify the **status** query parameter.

filterValue has the following format:

```
attribute:operator:value
```

where:

attribute

Specifies one of the applicable attributes. For a full list of attributes, see [Attributes for queues](#). The following attributes cannot be specified:

- name
- type
-  queueSharingGroup.disposition
- status.onQueueTime
- status.tpipeName
- applicationHandle.qmgrTransactionId
- applicationHandle.unitOfWorkId
- applicationHandle.openOptions

To filter on any attributes that are time stamps, the filter can specify any portion of the time stamp, with a trailing asterisk, *. The format of a time stamp is, YYYY-MM-DDThh:mm:ss. For example, you can specify 2001-11-1* to filter on dates in the range 2001-11-10 to 2001-11-19, or 2001-11-12T14:* to filter any minute in the specified hour of the specified day.

Valid values for the YYYY section of the date are in the range 1900 - 9999.

The time stamp is a string. Therefore, only the equalTo and notEqualTo operators can be used with the time stamp.

Note:  If either the **filter** query parameter, or the **name** query parameter with a wildcard, are used with the **commandScope=*** query parameter, and there are no matching queues on at least one of the active queue managers in the queue sharing group, then an error message is returned.

operator

Specifies one of the following operators:

lessThan

Use this operator only with integer attributes.

greaterThan

Use this operator only with integer attributes.

equalTo

Use this operator with any attribute.

notEqualTo

Use this operator with any attribute.

lessThanOrEqualTo

Use this operator only with integer attributes.

greaterThanOrEqualTo

Use this operator only with integer attributes.

value

Specifies the constant value to test against the attribute.

The value type is determined by the attribute type.

For string and boolean attributes, you can omit the value field after the colon. For string attributes, omit the value to return queues with no value for the specified attribute. For boolean attributes, omit the value to return any queues that have the specified attribute set to false. For example, the following filter returns all queues where the description attribute is not specified:

```
filter=general.description:equalTo:
```

You can use a single asterisk, *, at the end of the value as a wildcard. You cannot use only an asterisk.

If the value includes a space, a forward slash, a percent sign, or an asterisk that is not a wildcard, these characters must be URL encoded:

- A space must be encoded as %20
- A forward slash, /, must be encoded as %2F.
- A percent sign, %, must be encoded as %25.
- An asterisk, *, must be encoded as %2A.

 If the filter query parameter is used with the **commandScope=*** query parameter, and there are no matching values on at least one of the active queue managers in the queue sharing group, an error message is returned.

name=*name*

This query parameter cannot be used if you specify a queue name in the resource URL.

Specifies a wildcard queue name to filter on.

The *name* specified must include an asterisk, *, as a wildcard. You can specify one of the following combinations:

Specifies that all queues are returned.

prefix*

Specifies that all queues with the specified prefix in the queue name are returned.

***suffix**

Specifies that all queues with the specified suffix in the queue name are returned.

prefix*suffix

Specifies that all queues with the specified prefix and the specified suffix in the queue name are returned.

 If the name query parameter is used with a wildcard, the **commandScope=*** query parameter is specified, and there are no matching values on at least one of the active queue managers in the queue sharing group, an error message is returned.

queueSharingGroupDisposition=*disposition*

 This parameter is only available on z/OS.

Specifies where the queue for which information is to be returned is defined and how it behaves. That is, it specifies the disposition of the queue for which information is to be returned.

You cannot specify the **queueSharingGroupDisposition** parameter if you specify **type=cluster** for the **type** parameter.

The value can be one of the following values:

live

Specifies that the queue is defined as qmgr or copy.

In a shared queue manager environment, **live** also displays information for queues that are defined with **shared**.

If the **commandScope** optional query parameter is specified with the **live** option, then any queue definitions with a disposition of shared are returned only by the queue manager that received the REST request. Other queue managers in the group do not return these queue definitions.

If you specify **live** with the **attributes** parameter, and specify the **commandScope** parameter with a queue manager name, queue attributes are not returned for shared queues.

all

Specifies that the queue is defined as qmgr or copy.

In a shared queue manager environment, **all** also displays information for queues that are defined with group or shared.

If the **commandScope** optional query parameter is specified with **all**, then any queue definitions with a disposition of group or shared are returned only by the queue manager that received the REST request. Other queue managers in the group do not return these queue definitions.

If you specify **all** with the **attributes** parameter, and specify the **commandScope** parameter with a queue manager name, queue attributes are not returned for shared queues.

If you specify **all** and specify **type=all**, no cluster queues are returned.

copy

Specifies that the queue is defined as copy.

group

Specifies that the queue is defined as group.

If you specify **group**, you cannot specify the **commandScope** optional query parameter.

private

Specifies that the queue is defined as copy or qmgr.

qmgr

Specifies that the queue is defined as qmgr.

shared

Specifies that the queue is defined as shared.

You cannot specify the **commandScope** optional query parameter with this option, unless the **status** or **applicationHandle** optional query parameter is also specified.

You cannot specify this option with the **attributes** parameter if you also specify the **commandScope** parameter with a queue manager name.

If you specify **shared** and specify **type=all**, all shared queues are returned, including cluster queues with a disposition of shared.

The default value is `live`.

type=type

Specifies the type of queue to return information about.

The value can be one of the following values:

all

Specifies that information about all queues, including cluster queues, is returned.

 On z/OS, ensure that the channel initiator is running when you use this option.

local

Specifies that information about local queues is returned.

alias

Specifies that information about alias queues is returned.

remote

Specifies that information about remote queues is returned.

cluster

Specifies that information about cluster queues is returned.

▶ **z/OS** You cannot specify **type=cluster** if you specify the **queueSharingGroupDisposition** parameter.

▶ **z/OS** On z/OS, ensure that the channel initiator is running when you use this option.

model

Specifies that information about model queues is returned.

The default value is all.

Request headers

The following headers must be sent with the request:

Authorization

This header must be sent if you are using basic authentication. For more information, see [Using HTTP basic authentication with the REST API](#).

The following headers can optionally be sent with the request:

ibm-mq-rest-gateway-qmgr

This header specifies the queue manager that is to be used as the gateway queue manager. The gateway queue manager is used to connect to a remote queue manager. For more information, see [Remote administration using the REST API](#).

Request body format

None.

Security requirements

The caller must be authenticated to the mqweb server and must be a member of one or more of the MQWebAdmin, MQWebAdminRO, or MQWebUser roles. For more information about security for the administrative REST API, see [IBM MQ Console and REST API security](#).

If token based security is used, the LTPA token that is used to authenticate the user must be provided with the request as a cookie. For more information about token-based authentication, see [Using token-based authentication with the REST API](#).

The security principal of the caller must be granted the ability to issue the following PCF commands for the specified queue manager:

- If the **status** or **applicationHandle** query parameters are not specified:
 - For the queue that is specified by the *{queueName}* portion of the resource URL, or for queues that match the specified query parameters, authority to issue the **MQCMD_INQUIRE_Q** PCF command must be granted.
- If the **status** or **applicationHandle** query parameters are specified:
 - For the queue that is specified by the *{queueName}* portion of the resource URL, or for queues that match the specified query parameters, authority to issue the **MQCMD_INQUIRE_Q** PCF command must be granted.
 - For the queue that is specified by the *{queueName}* portion of the resource URL, or for queues that match the specified query parameters, authority to issue the **MQCMD_INQUIRE_QSTATUS** PCF command must be granted.

A principal has display authority if the principal can issue one or both of the **MQCMD_INQUIRE_Q** and **MQCMD_INQUIRE_QSTATUS** PCF commands. If the principal has display authority for only some of the queues that are specified by the resource URL and query parameters, then the array of queues that is returned from the REST request is limited to those queues that the principal has authority to display. No information is returned about queues that cannot be displayed. If the principal does not have display authority for any of the queues that are specified by the resource URL and query parameters, an HTTP status code of 403 is returned.

ALW On AIX, Linux, and Windows, you can grant authority to security principals to use IBM MQ resources by using the **setmqaut** command. For more information, see [setmqaut \(grant or revoke authority\)](#).

On z/OS, see [Setting up security on z/OS](#).

Response status codes

200

Queue information retrieved successfully.

400

Invalid data provided.

For example, invalid queue attributes specified.

401

Not authenticated.

The caller must be authenticated to the mqweb server and must be a member of one or more of the MQWebAdmin, MQWebAdminRO, or MQWebUser roles. For more information, see [“Security requirements” on page 2374](#).

403

Access prohibited for one of the following reasons:

- Not authorized. The caller is authenticated to the mqweb server and is associated with a valid principal. However, the principal does not have access to the required IBM MQ resources. For more information about the access that is required, see [“Security requirements” on page 2374](#).
- **V9.4.0** Access prohibited in the current server environment. You cannot use the administrative REST API with the stand-alone IBM MQ Web Server.

404

Queue does not exist.

500

Server issue or error code from IBM MQ.

503

Queue manager not running.

Response headers

The following headers are returned with the response:

Content-Type

This header is returned with a value of `application/json;charset=utf-8`.

z/OS **ibm-mq-qmgrs**

On z/OS, if the optional query parameter `commandScope=*` is used, this header is returned with a comma-separated list of the queue managers that generated a response. For example, the header might look like the following header:

```
ibm-mq-qmgrs: MQ21, MQ22
```

If an error occurs before the command is issued to the queue managers, the response header does not contain the list of queue managers. For example, a request that generates a 200 or 201 status code has the header because the command was successful. A request that generates a 401 (not authenticated) status code does not have the header because the request was rejected. A request that generates a 403 (not authorized) status code has the header because individual queue managers decide whether the command is authorized.

ibm-mq-rest-gateway-qmgr

This header is returned if a remote queue manager is specified in the resource URL. The value of this header is the name of the queue manager that is used as the gateway queue manager.

Response body format

The response is in JSON format in UTF-8 encoding. The response contains an outer JSON object that contains a single JSON array called `queue`. Each element in the array is a JSON object that represents information about a queue. Each of these JSON objects contains the following attributes:

name

String.

Specifies the name of the queue.

This attribute is always returned.

type

String.

Specifies the type of queue.

The value is one of the following values:

- `local`
- `alias`
- `remote`
- `cluster`
- `model`

This attribute is always returned.

The following objects can be included in the JSON object that represents information about a queue. Which objects and attributes are returned depends on the URL that was specified for the request:

remote

Contains attributes that are related to remote queues.

alias

Contains attributes that are related to alias queues.

dynamic

Contains attributes that are related to dynamic queues.

model

Contains attributes that are related to model queues.

cluster

Contains attributes that are related to clusters.

trigger

Contains attributes that are related to triggering.

events

Contains two objects, one for queue depth and one for queue service interval events. Each object contains attributes that are related to the event type.

applicationDefaults

Contains attributes that are related to default behavior such as message persistence, message priority, shared input settings, and read ahead settings.

queueSharingGroup

Contains attributes that are related to queue sharing groups on z/OS.

dataCollection

Contains attributes that are related to data collection, monitoring, and statistics.

storage

Contains attributes that are related to message storage, such as the maximum depth of the queue, and the maximum length of messages that are allowed on the queue.

general

Contains attributes that are related to general queue properties, such as whether get or put operations are inhibited, the description of the queue, and transmission queue settings.

extended

Contains attributes that are related to extended queue properties, such as backout queue settings, and shared input settings.

timestamps

Contains attributes that are related to date and time information, such as the time stamp of when a queue was created.

status

Contains attributes that are related to queue status information.

applicationHandle

Contains attributes that are related to application handle information.

If a queue has no application handles, but information about application handles is requested, an empty object is returned.

For more information, see [“Response body attributes for queues” on page 2379](#).

If a damaged object is found, and the REST request did not specify a queue, an extra JSON array that is called `damaged` is returned. This JSON array contains a list of the objects that are damaged, specifying the object names. If the REST request specifies a queue name within the resource URL, but the object is damaged, an error is returned.

If an error occurs, the response body contains an error message. For more information, see [REST API error handling](#).

Examples

Note: Information about the `SYSTEM.*` queues is returned. It is expected that all queues are returned. However, for brevity, the results shown in the following examples do not include all the expected results.

- The following example lists all queues on the queue manager `QM1`. The following URL is used with the HTTP GET method:

```
https://localhost:9443/ibmmq/rest/v1/admin/qmgr/QM1/queue
```

The following JSON response is returned:

```
{
  "queue": [
    {
      "name": "localQueue",
      "type": "local"
    },
    {
      "name": "remoteQueue",
      "type": "remote",
      "remote": {
        "queueName": "queueOnQM1",
        "qmgrName": "QM1"
      }
    },
    {
      "name": "aliasQueue",
      "type": "alias",
      "alias": {
        "targetName": "localQueue"
      }
    },
    {
      "name": "modelQueue",
      "type": "model",
      "model": {
        "type": "permanentDynamic"
      }
    },
    {
      "name": "permanentDynamicQueue",
      "type": "local",
      "dynamic": {
        "type": "permanentDynamic"
      }
    },
    {
      "name": "aliasQueue2",
      "type": "cluster",
      "cluster": {

```

```

        "name": "CLUSTER1",
        "qmgrName": "QM2",
        "queueType": "alias"
    }
  }
}

```

- The following example lists all local queues on the queue manager QM1, showing whether they are get or put enabled. The following URL is used with the HTTP GET method:

```

https://localhost:9443/ibmmq/rest/v1/admin/qmgr/QMGR2/queue?
type=local&attributes=general.inhibitPut,general.inhibitGet

```

The following JSON response is returned:

```

{
  "queue":
  [
    {
      "name": "localQueue",
      "type": "local",
      "general": {
        "inhibitPut": true,
        "inhibitGet": false,
      }
    },
    {
      "name": "permanentDynamicQueue",
      "type": "local",
      "dynamic": {
        "type": "permanentDynamic"
      },
      "general": {
        "inhibitPut": false,
        "inhibitGet": false,
      }
    }
  ]
}

```

- The following example lists the status attributes for the queue Q1, on queue manager QM1. The following URL is used with the HTTP GET method:

```

https://localhost:9443/ibmmq/rest/v1/admin/qmgr/QM1/queue/Q1?status=*

```

The following JSON response is returned:

```

{
  "queue":
  [
    {
      "name": "Q1",
      "status": {
        "currentDepth": 0,
        "lastGet": "2016-12-05T15:56:28.000Z",
        "lastPut": "2016-12-05T15:56:28.000Z",
        "mediaRecoveryLogExtent": "",
        "oldestMessageAge": 42,
        "onQueueTime": {
          "longSamplePeriod": 3275,
          "shortSamplePeriod": 3275
        },
        "openInputCount": 1,
        "openOutputCount": 1,
        "uncommittedMessages": 2
      },
      "type": "local"
    }
  ]
}

```

- The following example lists the application handle attributes for a queue Q1, on queue manager QM1. The following URL is used with the HTTP GET method:

```

https://localhost:9443/ibmmq/rest/v1/admin/qmgr/QM1/queue/Q1?applicationHandle=*

```

The following JSON response is returned:

```
{
  "queue":
  [ {
    "applicationHandle":
    [ {
      "asynchronousState": "none",
      "channelName": "",
      "connectionName": "",
      "description": "",
      "state": "inactive",
      "openOptions": [
        "MQOO_INPUT_SHARED",
        "MQOO_BROWSE",
        "MQOO_INQUIRE",
        "MQOO_SAVE_ALL_CONTEXT",
        "MQOO_FAIL_IF_QUIESCING"
      ],
      "processID": 9388,
      "qmgrTransactionID": "AAAAAAhAAAA=",
      "recoveryID": "AAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAA==",
      "tag": "IBM\\Java70\\jre\\bin\\javaw.exe",
      "threadID": 0,
      "transactionType": "qmgr",
      "type": "userApplication",
      "userID": "myID"
    },
    {
      "asynchronousState": "none",
      "channelName": "",
      "connectionName": "",
      "description": "",
      "state": "inactive",
      "openOptions": [
        "MQOO_OUTPUT",
        "MQOO_FAIL_IF_QUIESCING"
      ],
      "processID": 9388,
      "qmgrTransactionID": "AAAAAAhAAAA=",
      "recoveryID": "AAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAA==",
      "tag": "IBM\\Java70\\jre\\bin\\javaw.exe",
      "threadID": 0,
      "transactionType": "qmgr",
      "type": "userApplication",
      "userID": "myID"
    }
  ],
  "name": "Q1",
  "type": "local"
} ]
}
```

- The following example shows how to get all information, including status and application handles, for the queue Q2 on queue manager QM1. The following URL is used with the HTTP GET method:

```
https://localhost:9443/ibmmq/rest/v1/admin/qmgr/QM1/queue/Q2?
attributes=* & status=* & applicationHandle=*
```

- The following example shows how to get all queue configuration and status information for queues with an **openInputCount** greater than three, for the queue manager QM1. The following URL is used with the HTTP GET method:

```
https://localhost:9443/ibmmq/rest/v1/admin/qmgr/QM1/queue?
attributes=* & status=* & filter=status.openInputCount:greaterThan:3
```

Response body attributes for queues

When you use the HTTP GET method with the queue object to request information about queues, the following attributes are returned within named JSON objects.

The following objects are available:

- [“remote”](#) on page 2380
- [“alias”](#) on page 2380

- [“dynamic” on page 2381](#)
- [“model” on page 2381](#)
- [“cluster” on page 2381](#)
- [“trigger” on page 2383](#)
- [“events” on page 2383](#)
- [“applicationDefaults” on page 2384](#)
- [“queueSharingGroup” on page 2386](#)
- [“dataCollection” on page 2387](#)
- [“storage” on page 2388](#)
- [“general” on page 2389](#)
- [“extended” on page 2389](#)
- [“timestamps” on page 2390](#)
- [“status” on page 2391](#)
- [“applicationHandle” on page 2392](#)

For more information about the PCF equivalents to the queue REST API parameters and attributes, see [“REST API and PCF equivalents for queues” on page 2411](#).

remote

The `remote` object contains information about remote queues and is returned only for remote queues:

qmgrName

String.

Specifies the name of the remote queue manager.

If this remote queue is used as a queue manager alias, this attribute is the name of the queue manager.

If this remote queue is used as a reply-to queue alias, this attribute is the name of the queue manager that is to be the reply-to queue manager.

This attribute is always returned.

queueName

String.

Specifies the name of the queue as it is known on the remote queue manager.

This attribute is always returned.

transmissionQueueName

String.

Specifies the name of the transmission queue that is used for messages that are destined for either a remote queue or for a queue manager alias definition.

alias

The `alias` object contains information about alias queues and is returned only for alias queues:

targetName

String.

Specifies the name of the queue or topic that the alias resolves to.

This attribute is always returned.

targetType

String.

Specifies the type of object that the alias resolves to.

The value is one of the following values:

queue

Specifies that the object is a queue.

topic

Specifies that the object is a topic.

dynamic

The `dynamic` object contains information about dynamic queues and is returned only for local queues that are programmatically created from a model queue:

type

String.

Specifies the type of dynamic queue.

This attribute is always returned.

The value is one of the following values:

permanentDynamic

Specifies that the queue is a dynamically defined permanent queue.

sharedDynamic

 This attribute is only available on z/OS.

Specifies that the queue is a dynamically defined shared queue.

temporaryDynamic

Specifies that the queue is a dynamically defined temporary queue.

model

The `model` object contains information about model queues and is returned only for model queues:

type

String.

Specifies the model queue definition type.

This attribute is always returned.

The value is one of the following values:

permanentDynamic

Specifies that the queue is a dynamically defined permanent queue.

sharedDynamic

 This attribute is only available on z/OS.

Specifies that the queue is a dynamically defined shared queue.

temporaryDynamic

Specifies that the queue is a dynamically defined temporary queue.

cluster

The `cluster` object contains information about queues that are part of one or more clusters. The object is returned only for queues when `type=cluster` is specified, or if requested by the attributes `query` parameter:

name

String.

Specifies the name of the cluster that the queue belongs to.

This attribute, or the **nameList** attribute, is always returned.

namelist

String.

Specifies the namelist that lists the clusters that the queue belongs to.

This attribute, or the **name** attribute, is always returned.

qmgrId

String.

Specifies the unique identifier of the queue manager.

This attribute is returned only when `type=cluster` is specified.

qmgrName

String.

Specifies the name of the local queue manager.

This attribute is returned only when `type=cluster` is specified.

queueType

String.

Specifies the type of queue.

This attribute is returned only when `type=cluster` is specified.

The value is one of the following values:

local

Specifies that the cluster queue represents a local queue.

alias

Specifies that the cluster queue represents an alias queue.

remote

Specifies that the cluster queue represents a remote queue.

qmgrAlias

Specifies that the cluster queue represents a queue manager alias.

transmissionQueueForChannelName

String.

Specifies the generic name of the cluster-sender channels that use the queue as a transmission queue. The attribute specifies which cluster-sender channels send messages to a cluster-receiver channel from the cluster transmission queue.

workloadPriority

Integer.

Specifies the priority of the queue in cluster workload management.

A value of 0 specifies the lowest priority and 9 specifies the highest priority.

workloadQueueUse

String.

Specifies whether remote and local instances of the clustered queues are used in cluster workload distribution.

The value is one of the following values:

asQmgr

Use the value that is defined on the queue manager.

any

Use remote and local instances of the queues.

local

Use only local instances of the queues.

workloadRank

Integer.

Specifies the rank of the queue in cluster workload management.

A value of 0 specifies the lowest priority and 9 specifies the highest priority.

trigger

The `trigger` object contains information about triggering:

enabled

Boolean.

Specifies whether trigger messages are written to the initiation queue.

data

String.

Specifies the user data that is included in the trigger message.

depth

Integer.

Specifies the number of messages that initiates a trigger message to the initiation queue.

initiationQueueName

String.

Specifies the local queue for trigger messages that relate to the queue.

messagePriority

Integer.

Specifies the minimum priority that a message must have before it can cause, or be counted for, a trigger event.

processName

String.

Specifies the local name of the IBM MQ process that identifies the application to be started when a trigger event occurs.

If the queue is a transmission queue, the process definition contains the name of the channel to be started.

type

String.

Specifies the condition that initiates a trigger event. When the condition is true, a trigger message is sent to the initiation queue.

The value is one of the following values:

none

Send no trigger messages.

every

Send a trigger message for every message that arrives on the queue.

first

Send a trigger message when the queue depth goes from 0 to 1.

depth

Send a trigger message when the queue depth exceeds the value of the **depth** attribute.

events

The `events` object contains two objects, one for queue depth and one for queue service interval events. Each object contains attributes that are related to the event type:

depth

JSON object.

A JSON object that can contain the following attributes that related to queue depth events:

highEnabled

Boolean.

Specifies whether queue depth high events are generated.

A queue depth high event indicates that the number of messages on the queue is greater than or equal to the queue depth high limit, **highPercentage**.

highPercentage

Integer.

Specifies the threshold against which the queue depth is compared to generate a queue depth high event.

This value is expressed as a percentage of the maximum queue depth.

lowEnabled

Boolean.

Specifies whether queue depth low events are generated.

A queue depth low event indicates that the number of messages on the queue is less than or equal to the queue depth low limit, **lowPercentage**.

lowPercentage

Integer.

Specifies the threshold against which the queue depth is compared to generate a queue depth low event.

This value is expressed as a percentage of the maximum queue depth.

fullEnabled

Boolean.

Specifies whether queue full events are generated.

A queue full event indicates that no more messages can be put on a queue because the queue is full. That is, the queue depth reached the maximum queue depth.

serviceInterval

JSON object.

A JSON object that can contain the following attributes that are related to queue service interval events:

highEnabled

Boolean.

Specifies whether queue service interval high events are generated.

A queue service interval high event is generated when no messages were put to, or retrieved from, the queue for at least the amount of time specified by the **duration** attribute.

okEnabled

Boolean.

Specifies whether queue service interval OK events are generated.

A queue service interval OK event is generated when a message was retrieved from the queue within the amount of time that is specified by the **duration** attribute.

duration

Integer.

Specifies the service interval duration, in milliseconds, that is used to generate queue service interval high and queue service interval OK events.

applicationDefaults

The `applicationDefaults` object contains attributes that are related to default behavior such as message persistence, message priority, shared input settings, and read ahead settings:

clusterBind

String.

Specifies the binding to be used when `MQ00_BIND_AS_Q_DEF` is specified on the `MQOPEN` call.

The value is one of the following values:

onOpen

Specifies that the binding is fixed by the MQOPEN call.

notFixed

Specifies that the binding is not fixed.

onGroup

Specifies that the application can request that a group of messages is allocated to the same destination instance.

messagePropertyControl

String.

Specifies how message properties are handled when messages are retrieved from queues when MQGMO_PROPERTIES_AS_Q_DEF is specified on the MQGET call.

This attribute is applicable to local, alias, and model queues.

The value is one of the following values:

all

Specifies that all properties of the message are included when the message is sent to the remote queue manager. The properties, except those properties in the message descriptor or extension, are placed in one or more MQRFH2 headers in the message data.

compatible

Specifies that if the message contains a property with the prefix `mcd.`, `jms.`, `usr.`, or `mqext.`, all message properties are delivered to the application in an MQRFH2 header. Otherwise, all properties, except those properties in the message descriptor or extension, are discarded and are no longer accessible.

force

Specifies that properties are always returned in the message data in an MQRFH2 header regardless of whether the application specifies a message handle. A valid message handle that is included in the `MsgHandle` field of the MQGMO structure on the MQGET call is ignored. Properties of the message are not accessible by using the message handle.

none

Specifies that all properties of the message are removed from the message before the message is sent to the remote queue manager. Properties in the message descriptor, or extension, are not removed.

version6Compatible

Any application MQRFH2 header is received as it was sent. Any properties set by using MQSETMP must be retrieved by using MQINQMP. They are not added to the MQRFH2 created by the application. Properties that were set in the MQRFH2 header by the sending application cannot be retrieved by using MQINQMP.

messagePersistence

String.

Specifies the default for message persistence on the queue. Message persistence determines whether messages are preserved across restarts of the queue manager.

The value is one of the following values:

persistent

Specifies that the messages on the queue are persistent, and are preserved when the queue manager restarts.

nonPersistent

Specifies that the messages on the queue are not persistent, and are lost when the queue manager restarts.

messagePriority

Integer.

Specifies the default priority of messages that are put on the queue.

putResponse

String.

Specifies the type of response that is used for put operations to the queue when an application specifies MQPMO_RESPONSE_AS_Q_DEF.

The value is one of the following values:

synchronous

The put operation is run synchronously, returning a response.

asynchronous

The put operation is run asynchronously, returning a subset of MQMD fields.

readAhead

String.

Specifies the default read-ahead behavior for non-persistent messages that are delivered to the client.

The value is one of the following values:

no

Specifies that non-persistent messages are not read ahead unless the client application is configured to request read ahead.

yes

Specifies that non-persistent messages are sent ahead to the client before an application requests them. Non-persistent messages can be lost if the client ends abnormally or if the client does not consume all the messages that it is sent.

disabled

Specifies that non-persistent messages are not read ahead, regardless of whether read ahead is requested by the client application.

sharedInput

Boolean.

Specifies the default share option for applications that open this queue for input.

If the value is set to true, queues are enabled to get messages with shared access.

queueSharingGroup

The queueSharingGroup object contains attributes that are related to queue sharing groups on z/OS:

disposition

String.

 This attribute is only available on z/OS.

Specifies where the queue is defined and how it behaves. That is, it specifies the disposition of the queue.

This value is always returned if the queue manager is a member of the queue sharing group.

The value is one of the following values:

copy

Specifies that the queue definition exists on the page set of the queue manager that runs the command. For local queues, messages are stored on the page sets of each queue manager and are available only through that queue manager.

group

Specifies that the queue definition exists in the shared repository.

qmgr

Specifies that the queue definition exists on the page set of the queue manager that runs the command. For local queues, messages are stored on the page sets of each queue manager and are available only through that queue manager.

shared

This value is only valid for local queues.

Specifies that the queue exists in the shared repository. Messages are stored in the coupling facility and are available to any queue manager in the queue sharing group.

qmgrName

String.

 This attribute is only available on z/OS.

Specifies the name of the queue manager that generates the response to the REST request.

This attribute is only returned if the queue manager to which the REST request is made is part of a queue sharing group, and the **commandScope** optional query parameter is specified.

structureName

String.

 This attribute is only available on z/OS.

Specifies the name of the coupling facility structure where messages are stored when you used shared queues.

dataCollection

The `dataCollection` object contains attributes that are related to data collection, monitoring, and statistics:

accounting

String.

Specifies whether accounting data is collected for the queue.

The value is one of the following values:

asQmgr

Specifies that the queue inherits the value from the queue manager MQSC parameter ACCTQ.

off

Specifies that accounting data is not collected for the queue.

on

Specifies that accounting data is collected for the queue if the ACCTQ MQSC parameter on the queue manager is not set to none.

monitoring

String.

Specifies whether online monitoring data is collected, and if so, the rate at which the data is collected.

The value is one of the following values:

off

Specifies that online monitoring data is not collected for the queue.

asQmgr

Specifies that the queue inherits the value from the queue manager MONQ MQSC parameter.

low

Specifies that online monitoring data is collected for the queue if the MONQ MQSC parameter on the queue manager is not set to none. The rate of data collection is low.

medium

Specifies that online monitoring data is collected for the queue if the MONQ MQSC parameter on the queue manager is not set to none. The rate of data collection is moderate.

high

Specifies that online monitoring data is collected for the queue if the MONQ MQSC parameter on the queue manager is not set to none. The rate of data collection is high.

statistics

MQ Appliance

ALW

This attribute is only available on the IBM MQ Appliance, AIX, Linux, and Windows.

String.

Specifies whether statistics data is collected for the queue.

The value is one of the following values:

asQmgr

Specifies that the queue inherits the value from the queue manager STATQ MQSC parameter.

off

Specifies that statistics data is not collected for the queue.

on

Specifies that statistics data is collected for the queue if the STATQ MQSC parameter on the queue manager is not set to none.

storage

The `storage` object contains attributes that are related to message storage, such as the maximum depth of the queue, and the maximum length of messages that are allowed on the queue:

indexType

z/OS

This attribute is only available on z/OS.

String.

Specifies the type of index that is maintained by the queue manager to expedite MQGET operations on the queue. For shared queues, the type of index determines what type of MQGET calls can be used.

The value is one of the following values:

none

Specifies that there is no index. Messages are retrieved sequentially.

correlationId

Specifies that the queue is indexed by using correlation identifiers.

groupId

Specifies that the queue is indexed by using group identifiers.

messageId

Specifies that the queue is indexed by using message identifiers.

messageToken

Specifies that the queue is indexed by using message tokens.

maximumMessageLength

Integer.

Specifies the maximum message length that is allowed, in bytes, for messages on the queue.

maximumDepth

Integer.

Specifies the maximum number of messages that are allowed on the queue.

messageDeliverySequence

String.

Specifies whether messages are delivered in priority order or by sequence.

The value is one of the following values:

priority

Specifies that messages are returned in priority order.

fifo

Specifies that messages are returned in first in, first out order.

nonPersistentMessageClass

MQ Appliance

ALW

This attribute is only available on the IBM MQ Appliance, AIX, Linux, and Windows.

String.

This attribute is valid only on local and model queues.

Specifies the level of reliability that is assigned to non-persistent messages that are put to the queue.

The value is one of the following values:

normal

Specifies that non-persistent messages persist for the lifetime of the queue manager session. They are discarded if the queue manager restarts.

high

Specifies that the queue manager attempts to retain non-persistent messages for the lifetime of the queue. Non-persistent messages might still be lost if a failure occurs.

pageSet

z/OS

This attribute is only available on z/OS.

Integer.

Specifies the ID of the page set.

storageClass

z/OS

This attribute is only available on z/OS.

String.

Specifies the name of the storage class.

general

The `general` object contains attributes that are related to general queue properties, such as whether get or put operations are inhibited, the description of the queue, and transmission queue settings:

description

String.

Specifies the description of the queue.

inhibitGet

Boolean.

Specifies whether get operations are allowed on the queue.

If the value is set to `true`, get operations are not allowed on the queue.

inhibitPut

Boolean.

Specifies whether put operations are allowed on the queue.

If the value is set to `true`, put operations are not allowed on the queue.

isTransmissionQueue

String.

Specifies whether the queue is for normal usage or for transmitting messages to a remote queue manager.

If the value is set to `true`, the queue is a transmission queue for transmitting messages to a remote queue manager.

extended

The `extended` object contains attributes that are related to extended queue properties, such as backout queue settings, and shared input settings:

allowSharedInput

Boolean.

Specifies whether multiple instances of applications can open the queue for input.

If the value is set to `true`, multiple instances of applications can open the queue for input.

backoutRequeueQueueName

String.

Specifies the name of the queue to which a message is transferred if it is backed out more times than the value of **backoutThreshold**.

backoutThreshold

Integer.

Specifies the number of times that a message can be backed out before it is transferred to the backout queue that is specified by the **backoutRequeueQueueName** attribute.

custom

String.

Specifies custom attributes for new features.

enableMediaImageOperations

  This attribute is available only on the IBM MQ Appliance, AIX, Linux, and Windows.

Specifies whether a local or permanent dynamic queue object is recoverable from a media image, if linear logging is being used.

String.

The value is one of the following values:

yes

Specifies that this queue object is recoverable.

no

The `rcdmqimg` and `rcimqobj` commands are not permitted for these objects. If automatic media images are enabled, the media images are not written for these objects.

asQmgr

Specifies that the queue inherits the value from the queue manager `ImageRecoverQueue` attribute.

This is the default value for this attribute.

hardenGetBackout

 This attribute is only available on z/OS.

Boolean.

Specifies whether the count of the number of times that a message was backed out is saved, to ensure that it is accurate across restarts of the queue manager.

If the value is set to `true`, the backout count is always accurate across restarts of the queue manager.

supportDistributionLists

  This attribute is only available on the IBM MQ Appliance, AIX, Linux, and Windows.

Boolean.

Specifies whether distribution-list messages can be placed on the queue.

If the value is set to `true`, distribution lists can be placed on the queue.

timestamps

The `timestamps` object contains attributes that are related to date and time information.

altered

String.

Specifies the date and time at which the queue was last altered.

For more information about the time stamp format that is used to return the date and time, see [REST API time stamps](#).

clustered

String.

Specifies the date and time at which the information became available to the local queue manager.

For more information about the time stamp format that is used to return the date and time, see [REST API time stamps](#).

created

String.

Specifies the date and time at which the queue was created.

For more information about the time stamp format that is used to return the date and time, see [REST API time stamps](#).

status

The status object contains attributes that are related to queue status information:

currentDepth

Integer.

Specifies the current queue depth.

lastGet

String.

Specifies the date and time at which the last message was destructively read from the queue.

For more information about the time stamp format that is used to return the date and time, see [REST API time stamps](#).

lastPut

String.

Specifies the date and time at which the last message was successfully put to the queue.

For more information about the time stamp format that is used to return the date and time, see [REST API time stamps](#).

mediaRecoveryLogExtent

 This attribute is only available on the IBM MQ Appliance, AIX, Linux, and Windows.

String.

Specifies the name of the oldest log extent that is required to perform media recovery of the queue.

The name that is returned is of the form Snnnnnnn . LOG and is not a fully qualified path name.

oldestMessageAge

Integer.

Specifies the age, in seconds, of the oldest message on the queue.

If the queue is empty, 0 is returned. If the value is greater than 999 999 999, it is returned as 999 999 999. If no data is available, -1 is returned.

onQueueTime

JSON object.

A JSON object that can contain the following attributes that related to the amount of time that a message remains on the queue:

longSamplePeriod

Integer.

Specifies an indication of the time, in microseconds, that a message remains on the queue based on activity over a long period.

shortSamplePeriod

Integer.

Specifies an indication of the time, in microseconds, that a message remains on the queue based on activity over a short period.

This attribute cannot be used to filter results.

openInputCount

Integer.

Specifies the number of handles that are currently valid for removing messages from the queue by using the MQGET call.

openOutputCount

Integer.

Specifies the number of handles that are currently valid for putting messages to the queue by using the MQPUT call.

monitoringRate

String.

Specifies the rate at which monitoring data is collected for the queue.

The value is one of the following values:

off

Specifies that no data is collected.

low

Specifies a low rate of data collection.

medium

Specifies a medium rate of data collection.

high

Specifies a high rate of data collection.

tpipeName

 This attribute is only available on z/OS.

Array.

Specifies the TPIPE names that are used for communication with OTMA by using the IBM MQ IMS bridge, if the bridge is active.

This attribute cannot be used to filter results.

uncommittedMessages

Integer.

Specifies the number of uncommitted changes that are pending for the queue.

On z/OS, the value can be only either 0 or 1. A value of 1 indicates that there is at least one uncommitted message on the queue.

applicationHandle

The applicationHandle object contains attributes that are related to application handle information:

description

String.

Specifies a description for the application.

tag

z/OS This attribute is only available on z/OS.

String.

Specifies the tag of the open application.

type

String.

Specifies the type of application.

This value is one of the following values:

queueManagerProcess

Specifies that the open application is a queue manager process.

channelInitiator

Specifies that the open application is a channel initiator.

userApplication

Specifies that the open application is a user application.

batchConnection

z/OS This attribute is only available on z/OS.

Specifies that the open application is using a batch connection.

rrsBatchConnection

z/OS This attribute is only available on z/OS.

Specifies that the open application is an RRS-coordinated application that uses a batch connection.

cicsTransaction

z/OS This attribute is only available on z/OS.

Specifies that the open application is a CICS transaction.

imsTransaction

z/OS This attribute is only available on z/OS.

Specifies that the open application is an IMS transaction.

systemExtension

Specifies that the open application is an application that performs an extension of function that is provided by the queue manager.

asynchronousConsumerState

String.

Specifies the state of the asynchronous consumer on the queue.

The value is one of the following values:

active

Specifies that an MQCB call set up a function to call back to process messages asynchronously, and the connection handle has started so that asynchronous message consumption can proceed.

inactive

Specifies that an MQCB call set up a function to call back to process messages asynchronously, but the connection handle is not started, or is stopped or suspended.

suspended

Specifies that the asynchronous consumption callback is suspended so that asynchronous message consumption cannot proceed on the handle.

This situation can be either because an MQCB or MQCTL call with *Operation* MQOP_SUSPEND was issued against this object handle by the application, or because it was suspended by the system. If it was suspended by the system, as part of the process of suspending asynchronous message consumption the callback function is called with the reason code that describes the

problem that resulted in suspension. This situation is reported in the reason field in the MQCBC structure passed to the callback. In order for asynchronous message consumption to proceed, the application must issue an MQCB or MQCTL call with *Operation* MQOP_RESUME.

suspendedTemporarily

Specifies that the asynchronous consumption callback is temporarily suspended by the system so that asynchronous message consumption cannot proceed on this handle.

As part of the process of suspending asynchronous message consumption the callback function is called with the reason code that describes the problem that resulted in suspension. This situation is reported in the reason field in the MQCBC structure passed to the callback. The callback function is called again when asynchronous message consumption is resumed by the system after the temporary condition is resolved.

none

Specifies that an MQCB call was not issued against this handle, so asynchronous message consumption is not configured on the handle.

addressSpaceId

 This attribute is only available on z/OS.

String.

Specifies a four character address space identifier for the application.

channelName

String.

Specifies the channel name.

connectionName

String.

Specifies the connection name.

state

String.

Specifies the state of the handle.

This value is one of the following values:

active

Specifies that an API call from a connection is in progress for the queue. This state can occur when an MQGET WAIT call is in progress.

inactive

Specifies that no API call from a connection is in progress for the queue. This state can occur when no MQGET WAIT call is in progress.

openOptions

JSON array.

Specifies the open options that are in force for the queue.

Any of the valid MQOO options can be present in the array. For more information about the MQOO_* options, see [MQOO_* \(Open Options\)](#).

processId

  This attribute is only available on the IBM MQ Appliance, AIX, Linux, and Windows.

Integer.

Specifies the process ID of the open application.

processSpecificationBlockName

 This attribute is only available on z/OS.

String.

Specifies the eight character name of the program specification block that is associated with the running IMS transaction.

processSpecificationTableId

 This attribute is only available on z/OS.

String.

Specifies the four character identifier of the program specification table region identifier for the connected IMS region.

qmgrTransactionId

String.

Specifies the unit of recovery that is assigned by the queue manager.

This identifier is represented as 2 hexadecimal digits for each byte of the recovery identifier.

This attribute cannot be used to filter results.

cicsTaskNumber

 This attribute is only available on z/OS.

Integer.

Specifies a seven digit CICS task number.

threadId

  This attribute is only available on the IBM MQ Appliance, AIX, Linux, and Windows.

Integer.

Specifies the thread ID of the open application.

A value of 0 indicates that the handle was opened by a shared connection. A handle that is created by a shared connection is logically open to all threads.

cicsTransactionId

 This attribute is only available on z/OS.

String.

Specifies a four character CICS transaction ID.

unitOfWorkId

String.

Specifies the recovery identifier for the unit of recovery. The format of this value is determined by the value of **unitOfWorkType**.

This identifier is represented as 2 hexadecimal digits for each byte of the recovery identifier.

This attribute cannot be used to filter results.

unitOfWorkType

String.

Specifies the type of external unit of recovery identifier as perceived by the queue manager.

The value is one of the following values:

qmgr

cics

 This value is only available on z/OS.

ims

 This value is only available on z/OS.

rrs

 This value is only available on z/OS.

xa

userId

String.

Specifies the user identifier of the open application.

DELETE

Use the HTTP DELETE method with the queue resource to delete a specified queue on a specified queue manager.

Note:

- This resource URL is available only in version 1 of the REST API. To delete queues using version 2 of the REST API, use the [“/admin/action/qmgr/{qmgrName}/mqsc” on page 2190](#) resource.
- **V9.4.0** You cannot use this resource with the stand-alone IBM MQ Web Server. For more information about the installation options for the IBM MQ component that runs the administrative REST API, see [The IBM MQ Console and REST API](#).

This REST API command is similar to the [“MQCMD_DELETE_Q \(Delete Queue\)” on page 1175](#) PCF command, and the [“DELETE queues” on page 647](#) MQSC commands.

- [Resource URL](#)
- [Optional query parameters](#)
- [“Request headers” on page 2398](#)
- [Request body format](#)
- [“Security requirements” on page 2398](#)
- [Response status codes](#)
- [“Response headers” on page 2399](#)
- [Response body format](#)
- [Examples](#)

Resource URL

`https://host:port/ibmmq/rest/v1/admin/qmgr/{qmgrName}/queue/{queueName}`

qmgrName

Specifies the name of the queue manager on which the queue to delete exists.

You can specify a remote queue manager as the **qmgrName**. If you specify a remote queue manager, you must configure a gateway queue manager. For more information, see [Remote administration using the REST API](#).

The queue manager name is case-sensitive.

If the queue manager name includes a forward slash, a period, or a percent sign, these characters must be URL encoded:

- A forward slash (/) must be encoded as %2F.
- A percent sign (%) must be encoded as %25.
- A period (.) must be encoded as %2E.

queueName

Specifies the name of the queue to delete.

The queue name is case-sensitive.

If the queue name includes a forward slash or a percent sign, these characters must be URL encoded:

- A forward slash, /, must be encoded as %2F.
- A percent sign, %, must be encoded as %25.

You can use HTTP instead of HTTPS if you enable HTTP connections. For more information about enabling HTTP, see [Configuring HTTP and HTTPS ports](#).

Optional query parameters

keepAuthorityRecords

  This parameter is only available on the IBM MQ Appliance, AIX, Linux, and Windows.

Specifies that the associated authority records are not deleted.

commandScope=*scope*

 This parameter is only available on z/OS.

Specifies how the command is run when the queue manager is a member of a queue sharing group. You cannot specify this parameter if the queue manager is not a member of a queue sharing group. *scope* can be one of the following values:

The name of a queue manager

Specifies that the command is run on the queue manager that is named. The queue manager must be active within the same queue sharing group as the queue manager that is specified in the resource URL.

You cannot specify the queue manager name that is the queue manager that is specified in the resource URL.

If the queue manager name includes a percent sign, %, this character must be URL encoded as %25.

*

Specifies that the command is run on the local queue manager and also passed to every active queue manager in the queue sharing group.

If this option is used, an `ibm-mq-qmgrs` response header is returned with a comma-separated list of the queue managers that generated a response. For example, the header might look like the following header:

```
ibm-mq-qmgrs: MQ21, MQ22
```

purge

Specifies that all messages are purged from the queue.

If messages are on the queue, you must specify **purge**, or the queue cannot be deleted.

queueSharingGroupDisposition=*disposition*

 This parameter is only available on z/OS.

Specifies where the queue is defined and how it behaves. That is, it specifies the disposition of the queue.

disposition can be one of the following values:

copy

Specifies that the queue definition exists on the page set of the queue manager that runs the command. The queue was defined by a command that used the **MQQSGD_COPY** PCF parameter, or the **copy** REST API parameter.

Any queue in the shared repository, or any queue that is defined by using the **MQQSGD_Q_MGR** PCF parameter, or **qmgr** REST API parameter, is not affected by this command.

group

Specifies that the queue definition exists in the shared repository. The queue was defined by a command that used the **MQQSGD_GROUP** PCF parameter, or the **group** REST API parameter.

Any queue that exists on the page set of the queue manager that runs the command, except for a local copy of the queue, is not affected by this command.

If the deletion is successful, the following MQSC command is generated and sent to all active queue managers in the queue sharing group to delete local copies on page set zero:

```
DELETE queue(q-name) QSGDISP(COPY)
```

or for a local queue only:

```
DELETE QLOCAL(q-name) NOPURGE QSGDISP(COPY)
```

The deletion of the group object takes effect even if the generated command with QSGDISP(COPY) fails.

Note: You always get the NOPURGE option even if you specify the **purge** flag. To delete messages on local copies of the queues you must explicitly run, for each copy, a command to delete the queue with the **purge** flag, and a **queueSharingGroupDisposition** value of copy.

qmgr

Specifies that the queue definition exists on the page set of the queue manager that runs the command. The object was defined by a command that used the **MQQSGD_Q_MGR** PCF parameter or the **qmgr** REST API parameter.

Any queue that exists in the shared repository, or any local copy of such a queue, is not affected by this command.

shared

This value is only valid for local queues.

Specifies that the queue exists in the shared repository. The object was defined by a command that used the **MQQSGD_SHARED** PCF parameter or the **shared** REST API parameter.

Any queue that exists on the page set of the queue manager that runs the command, or any queue that is defined by a command that uses the parameter **MQQSGD_GROUP** is not affected by this command.

The default value is **qmgr**.

Request headers

The following headers must be sent with the request:

ibm-mq-rest-csrf-token

This header must be set, but the value can be anything, including being blank.

Authorization

This header must be sent if you are using basic authentication. For more information, see [Using HTTP basic authentication with the REST API](#).

The following headers can optionally be sent with the request:

ibm-mq-rest-gateway-qmgr

This header specifies the queue manager that is to be used as the gateway queue manager. The gateway queue manager is used to connect to a remote queue manager. For more information, see [Remote administration using the REST API](#).

Request body format

None.

Security requirements

The caller must be authenticated to the mqweb server and must be a member of one or more of the MQWebAdmin, MQWebAdminRO, or MQWebUser roles. For more information about security for the administrative REST API, see [IBM MQ Console and REST API security](#).

If token based security is used, the LTPA token that is used to authenticate the user must be provided with the request as a cookie. For more information about token-based authentication, see [Using token-based authentication with the REST API](#).

The security principal of the caller must be granted the ability to issue the following PCF commands for the specified queue manager:

- For the queue that is specified by the *{queueName}* portion of the resource URL, authority to issue the **MQCMD_DELETE_Q** PCF command must be granted.

ALW On AIX, Linux, and Windows, you can grant authority to security principals to use IBM MQ resources by using the **setmqaut** command. For more information, see [setmqaut \(grant or revoke authority\)](#).

On z/OS, see [Setting up security on z/OS](#).

Response status codes

204

Queue deleted successfully.

400

Invalid data provided.

For example, invalid queue data is specified, or the queue is not empty.

401

Not authenticated.

The caller must be authenticated to the mqweb server and must be a member of one or more of the MQWebAdmin, MQWebAdminRO, or MQWebUser roles. The `ibm-mq-rest-csrf-token` header must also be specified. For more information, see [“Security requirements” on page 2398](#).

403

Access prohibited for one of the following reasons:

- Not authorized. The caller is authenticated to the mqweb server and is associated with a valid principal. However, the principal does not have access to the required IBM MQ resources. For more information about the access that is required, see [“Security requirements” on page 2398](#).
- **V9.4.0** Access prohibited in the current server environment. You cannot use the administrative REST API with the stand-alone IBM MQ Web Server.

404

Queue does not exist.

500

Server issue or error code from IBM MQ.

503

Queue manager not running.

Response headers

The following headers are returned with the response:

z/OS **ibm-mq-qmgrs**

On z/OS, if the optional query parameter `commandScope=*` is used, this header is returned with a comma-separated list of the queue managers that generated a response. For example, the header might look like the following header:

```
ibm-mq-qmgrs: MQ21, MQ22
```

If an error occurs before the command is issued to the queue managers, the response header does not contain the list of queue managers. For example, a request that generates a 200 or 201 status code has the header because the command was successful. A request that generates a 401 (not authenticated) status code does not have the header because the request was rejected. A request that generates a 403 (not authorized) status code has the header because individual queue managers decide whether the command is authorized.

ibm-mq-rest-gateway-qmgr

This header is returned if a remote queue manager is specified in the resource URL. The value of this header is the name of the queue manager that is used as the gateway queue manager.

Response body format

The response body is empty if the queue is deleted successfully. If an error occurs, the response body contains an error message. For more information, see [REST API error handling](#).

Examples

The following example deletes the queue Q1 from the queue manager QM1, and purges all messages from the queue when used with the HTTP DELETE method:

```
https://localhost:9443/ibmmq/rest/v1/admin/qmgr/QM1/queue/Q1?purge
```

/admin/qmgr/{qmgrName}/subscription

You can use the HTTP GET method with the subscription resource to request information about subscriptions.

Note:

- This resource URL is available only in version 1 of the REST API. To query subscriptions using version 2 of the REST API, use the ["/admin/action/qmgr/{qmgrName}/mqsc"](#) on page 2190 resource.
- **V 9.4.0** You cannot use this resource with the stand-alone IBM MQ Web Server. For more information about the installation options for the IBM MQ component that runs the administrative REST API, see [The IBM MQ Console and REST API](#).

You can use the administrative REST API gateway with this resource URL.

For more information about the PCF equivalents to the subscription REST API parameters and attributes, see ["REST API and PCF equivalents for subscriptions"](#) on page 2419.

GET

Use the HTTP GET method with the subscription resource to request information about subscriptions.

Note:

- This resource URL is available only in version 1 of the REST API. To query subscriptions using version 2 of the REST API, use the ["/admin/action/qmgr/{qmgrName}/mqsc"](#) on page 2190 resource.
- **V 9.4.0** You cannot use the administrative REST API with the stand-alone IBM MQ Web Server. For more information about the installation options for the IBM MQ component that runs the administrative REST API, see [The IBM MQ Console and REST API](#).

The information that is returned is similar to the information returned by the ["MQCMD_INQUIRE_SUBSCRIPTION \(Inquire Subscription\)"](#) on page 1443 PCF command, and the ["DISPLAY SUB \(display subscription information\)"](#) on page 862 MQSC command.

- ["Resource URL"](#) on page 2401
- ["Optional query parameters"](#) on page 2401
- ["Request headers"](#) on page 2403
- ["Request body format"](#) on page 2403
- ["Security requirements"](#) on page 2403
- ["Response status codes"](#) on page 2404
- ["Response headers"](#) on page 2404
- ["Response body format"](#) on page 2404

- [“Examples” on page 2405](#)

Resource URL

`https://host:port/ibmmq/rest/v1/admin/qmgr/{qmgrName}/subscription/{subscriptionName}`

qmgrName

Specifies the name of the queue manager on which to query the subscriptions.

You can specify a remote queue manager as the **qmgrName**. If you specify a remote queue manager, you must configure a gateway queue manager. For more information, see [Remote administration using the REST API](#).

The queue manager name is case-sensitive.

If the queue manager name includes a forward slash, a period, or a percent sign, these characters must be URL encoded:

- A forward slash (/) must be encoded as %2F.
- A percent sign (%) must be encoded as %25.
- A period (.) must be encoded as %2E.

subscriptionName

Optionally specifies the name of a subscription that exists on the specified queue manager.

The subscription name is case-sensitive.

If the subscription name includes any non-alphanumeric characters, they must be URL encoded.

You can use HTTP instead of HTTPS if you enable HTTP connections. For more information about enabling HTTP, see [Configuring HTTP and HTTPS ports](#).

Optional query parameters

attributes={object,...[*|object.attributeName,...]}

object,...

Specifies a comma-separated list of JSON objects that contain related subscription attributes to return.

For example, to return all subscription attributes that are related to time stamps, specify `timestamps`. To return all subscription attributes that are related to the destination and user, specify `destination,user`.

You cannot specify the same object more than once.

For a full list of objects and associated attributes, see [Attributes for subscriptions](#).

Specifies all attributes.

object.attributeName,...

Specifies a comma-separated list of queue configuration attributes to return.

Each attribute must specify the JSON object that contains the attribute, in the form `object.attributeName`. For example, to return the `correlationId` attribute, which is contained in the destination object, specify `destination.correlationId`.

You cannot specify the same attribute more than once.

For a full list of attributes and associated objects, see [Attributes for subscriptions](#).

filter=filterValue

Specifies a filter for the subscription definitions that are returned.

This query parameter cannot be used if you specify a subscription name in the resource URL or if you use the ID query parameter.

You can specify only one filter.

filterValue has the following format:

```
attribute:operator:value
```

where:

attribute

Specifies one of the applicable attributes. For a full list of attributes, see [Attributes for subscriptions](#). The following attributes cannot be specified:

- name
- id

To filter on any attributes that are time stamps, the filter can specify any portion of the time stamp, with a trailing asterisk, *. The format of a time stamp is, YYYY-MM-DDThh:mm:ss. For example, you can specify 2001-11-1* to filter on dates in the range 2001-11-10 to 2001-11-19, or 2001-11-12T14:* to filter any minute in the specified hour of the specified day.

Valid values for the YYYY section of the date are in the range 1900 - 9999.

The time stamp is a string. Therefore, only the equalTo and notEqualTo operators can be used with the time stamp.

operator

Specifies one of the following operators:

lessThan

Use this operator only with integer attributes.

greaterThan

Use this operator only with integer attributes.

equalTo

Use this operator with any attribute.

notEqualTo

Use this operator with any attribute.

lessThanOrEqualTo

Use this operator only with integer attributes.

greaterThanOrEqualTo

Use this operator only with integer attributes.

value

Specifies the constant value to test against the attribute.

The value type is determined by the attribute type.

For string and boolean attributes, you can omit the value field after the colon. For string attributes, omit the value to return subscriptions with no value for the specified attribute. For boolean attributes, omit the value to return any subscriptions that have the specified attribute set to false. For example, the following filter returns all subscriptions where the topic name attribute is not specified:

```
filter=topic.name:equalTo:
```

A single asterisk, *, can be used for string attributes specified at the end of the value as a wildcard.

If the value includes non-alphanumeric characters, then they must be URL encoded. If the value contains a percent character or any asterisk that is not intended to be a wildcard, then the value must be URL encoded a second time. That is, a percent character must be encoded as %2525. An asterisk must be encoded as %252A.

id=id

Specifies the ID of a subscription that exists on the queue manager specified.

This query parameter cannot be used if you specify a subscription name in the resource URL or the name query parameter.

The ID is a string that contains a hexadecimal number. It can be comprised of a mixture of uppercase and lowercase characters.

name=*name*

Specifies a wildcard subscription name to filter on.

This query parameter cannot be used if you specify a subscription name in the resource URL or the `id` query parameter.

The *name* specified must either be blank or include an asterisk, *, as a wildcard. You can specify one of the following combinations:

Specifies that subscriptions that do have a blank name attribute are returned.

Specifies that all subscriptions are returned.

prefix*

Specifies that all subscriptions with the specified prefix in the subscription name are returned.

***suffix**

Specifies that all subscriptions with the specified suffix in the subscription name are returned.

prefix*suffix

Specifies that all subscriptions with the specified prefix and the specified suffix in the subscription name are returned.

Request headers

The following headers must be sent with the request:

Authorization

This header must be sent if you are using basic authentication. For more information, see [Using HTTP basic authentication with the REST API](#).

The following headers can optionally be sent with the request:

ibm-mq-rest-gateway-qmgr

This header specifies the queue manager that is to be used as the gateway queue manager. The gateway queue manager is used to connect to a remote queue manager. For more information, see [Remote administration using the REST API](#).

Request body format

None.

Security requirements

The caller must be authenticated to the mqweb server and must be a member of one or more of the MQWebAdmin, MQWebAdminRO, or MQWebUser roles. For more information about security for the administrative REST API, see [IBM MQ Console and REST API security](#).

If token based security is used, the LTPA token that is used to authenticate the user must be provided with the request as a cookie. For more information about token-based authentication, see [Using token-based authentication with the REST API](#).

The security principal of the caller must be granted the ability to issue the following PCF commands for the specified queue manager:

- For the subscription that is specified by the *{subscriptionName}* portion of the resource URL, the *id* query parameter, or for subscriptions that match the specified query parameters, authority to issue the **MQCMD_INQUIRE_SUBSCRIPTION** PCF command must be granted.

A principal has display authority if the principal can issue the **MQCMD_INQUIRE_SUBSCRIPTION** PCF command. If the principal has display authority for only some of the subscriptions that are specified by the resource URL and query parameters, then the array of subscriptions that is returned from the REST request is limited to those subscriptions that the principal has authority to display. No information is

returned about subscriptions that cannot be displayed. If the principal does not have display authority for any of the subscriptions that are specified by the resource URL and query parameters, an HTTP status code of 403 is returned.

ALW On AIX, Linux, and Windows, you can grant authority to security principals to use IBM MQ resources by using the **setmqaut** command. For more information, see [setmqaut \(grant or revoke authority\)](#).

On z/OS, see [Setting up security on z/OS](#).

Response status codes

200

Subscriptions retrieved successfully.

400

Invalid data provided.

For example, invalid subscription attributes specified.

401

Not authenticated.

The caller must be authenticated to the mqweb server and must be a member of one or more of the MQWebAdmin, MQWebAdminRO, or MQWebUser roles. For more information, see [“Security requirements” on page 2403](#).

403

Access prohibited for one of the following reasons:

- Not authorized. The caller is authenticated to the mqweb server and is associated with a valid principal. However, the principal does not have access to the required IBM MQ resources. For more information about the access that is required, see [“Security requirements” on page 2403](#).
- **V9.4.0** Access prohibited in the current server environment. You cannot use the administrative REST API with the stand-alone IBM MQ Web Server.

404

Subscription does not exist.

500

Server issue or error code from IBM MQ.

503

Queue manager not running.

Response headers

The following headers are returned with the response:

Content-Type

This header is returned with a value of `application/json; charset=utf-8`.

ibm-mq-rest-gateway-qmgr

This header is returned if a remote queue manager is specified in the resource URL. The value of this header is the name of the queue manager that is used as the gateway queue manager.

Response body format

The response is in JSON format in UTF-8 encoding. The response contains an outer JSON object that contains a single JSON array called `subscription`. Each element in the array is a JSON object that represents information about a subscription. Each of these JSON objects contains the following attributes:

id

Hexadecimal string

Specifies the unique key that identifies the subscription.

This attribute is always returned.

name

String

Specifies the name of the subscription.

This attribute is always returned.

resolvedTopicString

String

Specifies the fully resolved topic string using the combined values from the topic name and defined string when the subscription was created.

This attribute is always returned.

The following objects can be included in the JSON object that represents information about a subscription. Which objects and attributes are returned depends on the URL that was specified for the request:

topic

Contains attributes that are related to a defined topic.

selector

Contains attributes that are related to the message selector.

destination

Contains attributes that are related to the destination queue / queue manager.

user

Contains attributes that are related to user, such as the accounting token, the user ID that owns the subscription and the user data.

general

Contains attributes that are related to general subscription properties, such whether the subscription is durable, how the subscription was created and whether wildcards should be interpreted in the topic string.

extended

Contains attributes that are related to extended subscription properties, such as the expiry time, the message priority, and the network scope.

timestamps

Contains attributes that are related to date and time information, such as the time stamp of when the subscription was created.

For more information, see [“Response body attributes for subscriptions” on page 2406](#).

If an error occurs, the response body contains an error message. For more information, see [REST API error handling](#).

Examples

- The following example lists all subscriptions on the queue manager QM1. The following URL is used with the HTTP GET method:

```
https://localhost:9443/ibmmq/rest/v1/admin/qmgr/QM1/subscription
```

The following JSON response is returned:

```
{
  "subscription":
  [
    {
      "id": "414D5120514D332020202020202020A878195911AFD206",
      "name": "SYSTEM.DEFAULT.SUB",
      "resolvedTopicString": ""
    }
  ],
}
```

topic

The `topic` object contains attributes that are related to a defined topic.

name

String.

Specifies the name of a previously defined topic object from which the topic string prefix is obtained for the subscription.

definedString

String.

Specifies the topic string that contains the application part of the topic string only.

selector

The `selector` object contains attributes that are related to the message selector.

value

String.

Specifies the selector applied to messages published to the topic.

Only those messages that satisfy the selection criteria are put to the destination specified by this subscription.

type

String.

Specifies type of selector.

The value is one of the following values:

none

Specifies that no selector is present.

standard

Specifies that the selector references only the properties of the message, not its content, using the standard IBM MQ selector syntax. Selectors of this type are to be handled internally by the queue manager.

extended

Specifies that the selector uses extended selector syntax, typically referencing the content of the message. Selectors of this type cannot be handled internally by the queue manager; extended selectors can be handled only by another program such as IBM Integration Bus.

destination

The `destination` object contains attributes that are related to the destination queue / queue manager.

isManaged

Boolean.

Specifies whether the destination is managed.

qmgrName

String.

Specifies the name of the destination queue manager, either local or remote, to which messages for the subscription are forwarded.

name

String.

Specifies the name of the alias, local, remote, or cluster queue to which messages for this subscription are put.

correlationId

Hexadecimal.

Specifies the correlation identifier that is placed in the CorrelId field of the message descriptor for all the messages sent to this subscription.

user

The `user` object contains attributes that are related to user that created the subscription, such as the accounting token, the user ID that owns the subscription and the user data.

accountingToken

Hexadecimal.

Specifies the accounting token used in the AccountingToken field of the message descriptor.

applicationIdentityData

String.

Specifies the application identity data used in the ApplIdentityData field of the message descriptor.

data

String.

Specifies the user data associated with the subscription.

name

String.

Specifies the userid that 'owns' this subscription. This parameter is either the userid associated with the creator of the subscription, or, if subscription takeover is permitted, the userid which last took over the subscription.

isVariable

Boolean.

Specifies whether any user other than the one who created the subscription can take over ownership.

general

The `general` object contains attributes that are related to general subscription properties, such as whether the subscription is durable, how the subscription was created and whether wildcards should be interpreted in the topic string.

isDurable

Boolean.

Specifies whether this subscription is a durable subscription.

If the subscription is durable, the subscription persists, even if the creating application disconnects from the queue manager or issues an MQCLOSE call for the subscription. The queue manager reinstates the subscription during restart.

If the subscription is non-durable, the queue manager removes the subscription when the creating application disconnects from the queue manager or issues an MQCLOSE call for the subscription. If the subscription has a **destination.class** of managed, the queue manager removes any messages not yet consumed when it closes the subscription.

type

String.

Specifies how the subscription was created.

The value is one of the following values:

administrative

Created using DEF SUB MQSC, REST or PCF command. It also indicates that a subscription has been modified using an administrative command.

api

Created using an MQSUB API request.

proxy

Created internally and used for routing publications through a queue manager.

usesCharacterWildcard

Boolean.

Specifies the schema to be used when any wildcard characters that are contained in the topic string are interpreted.

If the value is set to `true`, wildcard characters represent portions of strings; this is for compatibility with IBM MQ V6.0 brokers.

If the value is set to `false`, wildcard characters represent portions of the topic hierarchy; this value is for compatibility with IBM Integration Bus brokers.

extended

The extended object contains attributes that are related to extended subscription properties, such as the expiry time, the message priority and the network scope.

expiry

Integer.

Specifies the time, in tenths of seconds, at which a subscription expires after its creation date.

A value of `-1` can be used to represent unlimited.

level

Integer.

Specifies the level within the subscription interception hierarchy at which this subscription is made.

messagePriority

String.

Specifies the priority of messages sent to this subscription. It has the range 0-9.

Additionally, the value can be one of the following values:

asPublished

The priority of messages sent to this subscription is taken from that priority supplied to the published message.

asQueue

The priority of messages sent to this subscription is determined by the default priority of the queue defined as a destination.

messagePropertyControl

String.

Specifies how publish/subscribe related message properties are added to messages sent to this subscription.

The value is one of the following values:

none

Specifies that publish/subscribe properties are not added to the messages.

compatible

Specifies that if the original publication is a PCF message, then the publish/subscribe properties are added as PCF attributes. Otherwise, publish/subscribe properties are added within an MQRFH version 1 header. This method is compatible with applications coded for use with previous versions of IBM MQ.

pcf

Specifies that publish/subscribe properties are added as PCF attributes.

rfh2

Specifies that publish/subscribe properties are added within an MQRFH version 2 header. This method is compatible with applications coded for use with IBM Integration Bus brokers.

deliverOnRequest

Boolean.

Specifies whether the subscriber polls for updates using the MQSUBRQ API call, or whether all publications are delivered to this subscription.

If the value is set to `true`, publications are only delivered to this subscription in response to an MQSUBRQ API call.

If the value is set to `false`, all publications on the topic are delivered to this subscription.

networkScope

String.

Specifies whether this subscription is passed to other queue managers in the network.

The value is one of the following values:

all

Specifies that the subscription is forwarded to all queue managers directly connected through a publish/subscribe collective or hierarchy.

qmgr

Specifies that the subscription forwards only messages that are published on the topic within this queue manager.

timestamps

The `timestamps` object contains attributes that are related to date and time information.

altered

String.

Specifies the date and time at which the subscription was last altered.

For more information about the time stamp format that is used to return the date and time, see [REST API time stamps](#).

created

String.

Specifies the date and time at which the subscription was created.

For more information about the time stamp format that is used to return the date and time, see [REST API time stamps](#).

REST API and PCF equivalents

For most REST API optional query parameters and attributes, an equivalent PCF parameter or attribute exists. Use these topics to understand these equivalents.

REST API and PCF equivalents for queue managers

For most REST API optional query parameters and attributes for queue managers, an equivalent PCF parameter or attribute exists. Use the tables that are provided to understand these equivalents.

- [“Queue manager attribute equivalents” on page 2410](#)
- [“Unsupported PCF attributes” on page 2411](#)

Queue manager attribute equivalents

REST API attribute	PCF attribute	Related values (REST API)	Related values (PCF)
name	MQCA_Q_MGR_NAME		
state	MQIACF_Q_MGR_STATU S		

Table 354. Queue manager attributes for the REST API and equivalent PCF attributes. (continued)

REST API attribute	PCF attribute	Related values (REST API)	Related values (PCF)
status.started	MQCACF_Q_MGR_START_DATE MQCACF_Q_MGR_START_TIME		
status.channelInitiatorState	MQIACF_CHINIT_STATUS	MQSVC_STATUS_STOPPED MQSVC_STATUS_STARTING MQSVC_STATUS_RUNNING MQSVC_STATUS_STOPPING	stopped starting running stopping
status.ldapConnectionState	MQIACF_LDAP_CONNECTION_STATUS	MQLDAPC_CONNECTED MQLDAPC_ERROR MQLDAPC_INACTIVE	connected error disconnected
status.connectionCount	MQIACF_CONNECTION_COUNT		

Unsupported PCF attributes

The following queue manager PCF attributes are not supported by the administrative REST API qmgr resource:

- MQCA_INSTALLATION_DESC
- MQCA_INSTALLATION_NAME
- MQCA_INSTALLATION_PATH
- MQCACF_CURRENT_LOG_EXTENT_NAME
- MQCACF_LOG_PATH
- MQCACF_MEDIA_LOG_EXTENT_NAME
- MQCACF_RESTART_LOG_EXTENT_NAME

REST API and PCF equivalents for queues

For most REST API optional query parameters and attributes for queues, an equivalent PCF parameter or attribute exists. Use the tables that are provided to understand these equivalents.

- [“Optional query parameter equivalents” on page 2412](#)
- [“Queue attribute equivalents” on page 2412](#)
- [“Unsupported PCF attributes” on page 2419](#)

Optional query parameter equivalents

timestamps.created	MQCA_CREATION_DATE MQCA_CREATION_TIME		

Unsupported PCF parameters

The following subscription PCF inquire parameters are not supported by the administrative REST API:

- MQIA_DISPLAY_TYPE
- MQIACF_SUB_TYPE
- MQIACF_SUB_ATTRS

REST API and PCF equivalents for channels

For most REST API optional query parameters and attributes for channels, an equivalent PCF parameter or attribute exists. Use the tables that are provided to understand these equivalents.

- [“Optional query parameter equivalents” on page 2422](#)
- [“Channel attribute equivalents” on page 2422](#)
- [“Unsupported PCF parameters” on page 2434](#)

Optional query parameter equivalents

Multi IBM MQ Administration Interface reference

Reference information for the IBM MQ Administration Interface (MQAI).

Related tasks

[Using the MQAI to simplify the use of PCFs](#)

Multi MQAI calls

Reference information for MQAI calls.

There are two types of selector: *user selector* and *system selector*. These are described in [“MQAI selectors”](#) on page 2516.

There are three types of call:

- Data-bag manipulation calls for configuring data bags:

- [“mqAddBag” on page 2436](#)
- [“mqAddByteString” on page 2437](#)
- [“mqAddByteStringFilter” on page 2439](#)
- [“mqAddInquiry” on page 2441](#)
- [“mqAddInteger” on page 2443](#)
- [“mqAddInteger64” on page 2444](#)
- [“mqAddIntegerFilter” on page 2446](#)
- [“mqAddString” on page 2448](#)
- [“mqAddStringFilter” on page 2450](#)
- [“mqClearBag” on page 2455](#)
- [“mqCountItems” on page 2456](#)
- [“mqCreateBag” on page 2458](#)
- [“mqDeleteBag” on page 2461](#)
- [“mqDeleteItem” on page 2462](#)
- [“mqInquireBag” on page 2471](#)
- [“mqInquireByteString” on page 2473](#)
- [“mqInquireByteStringFilter” on page 2476](#)
- [“mqInquireInteger” on page 2478](#)
- [“mqInquireInteger64” on page 2481](#)
- [“mqInquireIntegerFilter” on page 2483](#)
- [“mqInquireItemInfo” on page 2485](#)
- [“mqInquireString” on page 2487](#)
- [“mqInquireStringFilter” on page 2490](#)

- [“mqSetString” on page 2508](#)
- [“mqSetStringFilter” on page 2511](#)
- [“mqTruncateBag” on page 2514](#)
- Command calls for sending and receiving administration commands and PCF messages:
 - [“mqBagToBuffer” on page 2452](#)
 - [“mqBufferToBag” on page 2454](#)
 - [“mqExecute” on page 2464](#)
 - [“mqGetBag” on page 2469](#)
 - [“mqPutBag” on page 2494](#)
- Utility calls for handling blank-padded and null-terminated strings:
 - [“mqPad” on page 2493](#)
 - [“mqTrim” on page 2513](#)

These calls are described in alphabetical order in the following sections.

Multi **mqAddBag**

The `mqAddBag` call nests a bag in another bag.

Syntax for `mqAddBag`

`mqAddBag` (*Bag, Selector, ItemValue, CompCode, Reason*)

Parameters for `mqAddBag`

Bag (MQHBAG) - input

Bag handle into which the item is to be added.

The bag must be a user bag. This means that it must have been created using the `MQCBO_USER_BAG` option on the `mqCreateBag` call. If the bag was not created in this way, `MQRC_WRONG_BAG_TYPE` results.

Selector (MQLONG) - input

Selector identifying the item to be nested.

If the selector is less than zero (that is, a system selector), `MQRC_SELECTOR_OUT_OF_RANGE` results.

If the selector is zero or greater (that is, a user selector) and the bag was created with the `MQCBO_CHECK_SELECTORS` option, the selector must be in the range `MQGA_FIRST` through `MQGA_LAST`; if not, again `MQRC_SELECTOR_OUT_OF_RANGE` results.

If `MQCBO_CHECK_SELECTORS` was not specified, the selector can be any value of zero or greater.

If the call is creating a second or later occurrence of a selector that is already in the bag, the data type of this occurrence must be the same as the data type of the first occurrence; `MQRC_INCONSISTENT_ITEM_TYPE` results if it is not.

ItemValue (MQHBAG) - input

The bag which is to be nested.

If the bag is not a group bag, `MQRC_BAG_WRONG_TYPE` results. If an attempt is made to add a bag to itself, `MQRC_HBAG_ERROR` results.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicate error conditions that can be returned from the `mqAddBag` call:

MQRC_BAG_WRONG_TYPE

Wrong type of bag for intended use (either Bag or ItemValue).

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_INCONSISTENT_ITEM_TYPE

Data type of this occurrence of selector differs from data type of first occurrence.

MQRC_SELECTOR_OUT_OF_RANGE

Selector not within valid range for call.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

Usage notes for mqAddBag

If a bag with the specified selector is already present in the bag, an additional instance of that selector is added to the end of the bag. The new instance is not necessarily adjacent to the existing instance.

C language invocation for mqAddBag

```
mqAddBag (Bag, Selector, ItemValue, &CompCode, &Reason)
```

Declare the parameters as follows:

```
MQHBAG  Bag;          /* Bag handle */
MQLONG  Selector;     /* Selector */
MQHBAG  ItemValue;    /* Nested bag handle */
MQLONG  CompCode;     /* Completion code */
MQLONG  Reason;       /* Reason code qualifying CompCode */
```

Visual Basic invocation for mqAddBag

(Supported on Windows only.)

```
mqAddGroup Bag, Selector, ItemValue, CompCode, Reason
```

Declare the parameters as follows:

```
Dim Bag      As Long 'Bag handle'
Dim Selector As Long 'Selector'
Dim ItemValue As Long 'Nested bag handle'
Dim CompCode As Long 'Completion code'
Dim Reason   As Long 'Reason code qualifying CompCode'
```

Note: The mqAddBag call can be used with user bags only; you cannot add nested bags to administration or command bags. You can only nest group bags.

mqAddByteString

The mqAddByteString call adds a byte string identified by a user selector to the end of a specified bag.

Syntax for mqAddByteString

```
mqAddByteString (Bag, Selector, BufferLength, Buffer, CompCode, Reason)
```

Parameters for mqAddByteString

Bag (MQHBAG) - input

Handle of the bag to be modified.

This value must be the handle of a bag created by the user, not the handle of a system bag. MQRC_SYSTEM_BAG_NOT_ALTERABLE results if the value you specify relates to a system bag.

Selector (MQLONG) - input

Selector identifying the item to be added to the bag.

If the selector is less than zero (that is, a system selector), MQRC_SELECTOR_OUT_OF_RANGE results.

If the selector is zero or greater (that is, a user selector), and the bag was created with the MQCBO_CHECK_SELECTORS option or as an administration bag (MQCBO_ADMIN_BAG), the selector must be in the range MQBA_FIRST through MQBA_LAST. MQRC_SELECTOR_OUT_OF_RANGE results if it is not in the correct range.

If MQCBO_CHECK_SELECTORS was not specified, the selector can be any value zero or greater.

If the call is creating a second or later occurrence of a selector that is already in the bag, the data type of this occurrence must be the same as the data type of the first occurrence; MQRC_INCONSISTENT_ITEM_TYPE results if it is not.

BufferLength (MQLONG) - input

The length in bytes of the string contained in the **Buffer** parameter. The value must be zero or greater.

Buffer (MQBYTE - BufferLength) - input

Buffer containing the byte string.

The length is given by the **BufferLength** parameter. If zero is specified for **BufferLength**, the null pointer can be specified for the address of the **Buffer** parameter. In all other cases, a valid (nonnull) address must be specified for the **Buffer** parameter.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating error conditions can be returned from the mqAddByteString call:

MQRC_BUFFER_ERROR

Buffer parameter not valid (invalid parameter address or buffer not completely accessible).

MQRC_BUFFER_LENGTH_ERROR

Buffer length not valid.

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_INCONSISTENT_ITEM_TYPE

Data type of this occurrence of selector differs from data type of first occurrence.

MQRC_SELECTOR_OUT_OF_RANGE

Selector not within valid range for call.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

MQRC_SYSTEM_BAG_NOT_ALTERABLE

System bag cannot be altered or deleted.

Usage notes for mqAddByteString

1. If a data item with the specified selector is already present in the bag, an additional instance of that selector is added to the end of the bag. The new instance is not necessarily adjacent to the existing instance.
2. This call cannot be used to add a system selector to a bag.

C language invocation for mqAddByteString

```
mqAddByteString (hBag, Selector, BufferLength, Buffer, &CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHBAG   Bag;           /* Bag handle */  
MQLONG   Selector;     /* Selector */
```

```

MQLONG  BufferLength; /* Buffer length */
MQBYTE  Buffer        /* Buffer containing item value */
MQLONG  CompCode;    /* Completion code */
MQLONG  Reason;      /* Reason code qualifying CompCode */

```

Visual Basic invocation for mqAddByteString

(Supported on Windows only.)

```
mqAddByteString Bag, Selector, BufferLength, Buffer, CompCode, Reason
```

Declare the parameters as follows:

```

Dim Bag           As Long 'Bag handle'
Dim Selector      As Long 'Selector'
Dim BufferLength  As Long 'Buffer length'
Dim Buffer        As Byte  'Buffer containing item value'
Dim CompCode     As Long  'Completion code'
Dim Reason       As Long  'Reason code qualifying CompCode'

```

Multi mqAddByteStringFilter

The mqAddByteStringFilter call adds a byte string filter identified by a user selector to the end of a specified bag.

Syntax for mqAddByteStringFilter

mqAddByteStringFilter (*Bag, Selector, BufferLength, Buffer, Operator, CompCode, Reason*)

Parameters for mqAddByteStringFilter

Bag (MQHBAG) - input

Handle of the bag to be modified.

This value must be the handle of a bag created by the user, not the handle of a system bag. MQRC_SYSTEM_BAG_NOT_ALTERABLE results if the value you specify relates to a system bag.

Selector (MQLONG) - input

Selector identifying the item to be added to the bag.

If the selector is less than zero (that is, a system selector), MQRC_SELECTOR_OUT_OF_RANGE results.

If the selector is zero or greater (that is, a user selector), and the bag was created with the MQCBO_CHECK_SELECTORS option or as an administration bag (MQCBO_ADMIN_BAG), the selector must be in the range MQBA_FIRST through MQBA_LAST. MQRC_SELECTOR_OUT_OF_RANGE results if it is not in the correct range.

If MQCBO_CHECK_SELECTORS was not specified, the selector can be any value zero or greater.

If the call is creating a second or later occurrence of a selector that is already in the bag, the data type of this occurrence must be the same as the data type of the first occurrence; MQRC_INCONSISTENT_ITEM_TYPE results if it is not.

BufferLength (MQLONG) - input

The length in bytes of the condition byte string contained in the **Buffer** parameter. The value must be zero or greater.

Buffer (MQBYTE x BufferLength) - input

Buffer containing the condition byte string.

The length is given by the **BufferLength** parameter. If zero is specified for **BufferLength**, the null pointer can be specified for the address of the **Buffer** parameter. In all other cases, a valid (nonnull) address must be specified for the **Buffer** parameter.

Operator (MQLONG) - input

The byte string filter operator to be placed in the bag. Valid operators are of the form MQCFOP_*.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating error conditions can be returned from the mqAddByteStringFilter call:

MQRC_BUFFER_ERROR

Buffer parameter not valid (invalid parameter address or buffer not accessible).

MQRC_BUFFER_LENGTH_ERROR

Buffer length not valid.

MQRC_FILTER_OPERATOR_ERROR

Filter operator not valid.

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_INCONSISTENT_ITEM_TYPE

Data type of this occurrence of selector differs from data type of first occurrence.

MQRC_SELECTOR_OUT_OF_RANGE

Selector not within valid range for call.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

MQRC_SYSTEM_BAG_NOT_ALTERABLE

System bag cannot be altered or deleted.

Usage notes for mqAddByteStringFilter

1. If a data item with the specified selector is already present in the bag, an additional instance of that selector is added to the end of the bag. The new instance is not necessarily adjacent to the existing instance.
2. This call cannot be used to add a system selector to a bag.

C language invocation for mqAddByteStringFilter

```
mqAddByteStringFilter (hBag, Selector, BufferLength, Buffer, Operator,  
&CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHBAG    hBag;           /* Bag handle */  
MQLONG    Selector;      /* Selector */  
MQLONG    BufferLength;  /* Buffer length */  
PMQBYTE   Buffer         /* Buffer containing item value */  
MQLONG    Operator      /* Operator */  
PMQLONG   CompCode;     /* Completion code */  
PMQLONG   Reason;       /* Reason code qualifying CompCode */
```

Visual Basic invocation for mqAddByteStringFilter

(Supported on Windows only.)

```
mqAddByteStringFilter Bag, Selector, BufferLength, Buffer, Operator, CompCode,  
Reason
```

Declare the parameters as follows:

```
Dim Bag           As Long 'Bag handle'  
Dim Selector      As Long 'Selector'  
Dim BufferLength  As Long 'Buffer length'  
Dim Buffer        As String 'Buffer containing item value'  
Dim Operator      As Long 'Operator'  
Dim CompCode     As Long 'Completion code'  
Dim Reason       As Long 'Reason code qualifying CompCode'
```

Multi mqAddInquiry

The mqAddInquiry call can be used with administration bags only; it is specifically for administration purposes.

The mqAddInquiry call adds a selector to an administration bag. The selector refers to an IBM MQ object attribute that is to be returned by a PCF INQUIRE command. The value of the **Selector** parameter specified on this call is added to the end of the bag, as the value of a data item that has the selector value MQIACF_INQUIRY.

Syntax for mqAddInquiry

mqAddInquiry (Bag, Selector, CompCode, Reason)

Parameters for mqAddInquiry

Bag (MQHBAG) - input

Bag handle.

The bag must be an administration bag; that is, it must have been created with the MQCBO_ADMIN_BAG option on the mqCreateBag call. If the bag was not created this way, MQRC_BAG_WRONG_TYPE results.

Selector (MQLONG) - input

Selector of the IBM MQ object attribute that is to be returned by the appropriate INQUIRE administration command.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicate error conditions that can be returned from the mqAddInquiry call:

MQRC_BAG_WRONG_TYPE

Wrong type of bag for intended use.

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_SELECTOR_OUT_OF_RANGE

Selector not within valid range for call.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

MQRC_SYSTEM_BAG_NOT_ALTERABLE

System bag cannot be altered or deleted.

Usage notes for mqAddInquiry

1. When the administration message is generated, the MQAI constructs an integer list with the MQIACF_*_ATTRS or MQIACH_*_ATTRS selector that is appropriate to the Command value specified on the mqExecute, mqPutBag, or mqBagToBuffer call. It then adds the values of the attribute selectors specified by the mqAddInquiry call.
2. If the Command value specified on the mqExecute, mqPutBag, or mqBagToBuffer call is not recognized by the MQAI, MQRC_INQUIRY_COMMAND_ERROR results. Instead of using the mqAddInquiry call, this can be overcome by using the mqAddInteger call with the appropriate MQIACF_*_ATTRS or MQIACH_*_ATTRS selector and the **ItemValue** parameter of the selector being inquired.

C language invocation for mqAddInquiry

```
mqAddInquiry (Bag, Selector, &CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHBAG   Bag;           /* Bag handle */
MQLONG   Selector;      /* Selector */
MQLONG   CompCode;      /* Completion code */
MQLONG   Reason;        /* Reason code qualifying CompCode */
```

Visual Basic invocation for mqAddInquiry

(Supported on Windows only.)

```
mqAddInquiry Bag, Selector, CompCode, Reason
```

Declare the parameters as follows:

```
Dim Bag      As Long 'Bag handle'
Dim Selector As Long 'Selector'
Dim CompCode As Long 'Completion code'
Dim Reason   As Long 'Reason code qualifying CompCode'
```

Supported INQUIRE command codes

- MQCMD_INQUIRE_AUTH_INFO
- MQCMD_INQUIRE_AUTH_RECS
- MQCMD_INQUIRE_AUTH_SERVICE
- MQCMD_INQUIRE_CHANNEL
- MQCMD_INQUIRE_CHANNEL_STATUS
- MQCMD_INQUIRE_CLUSTER_Q_MGR
- MQCMD_INQUIRE_CONNECTION
- MQCMD_INQUIRE_LISTENER
- MQCMD_INQUIRE_LISTENER_STATUS
- MQCMD_INQUIRE_NAMELIST
- MQCMD_INQUIRE_PROCESS
- MQCMD_INQUIRE_Q

- MQCMD_INQUIRE_Q_MGR
- MQCMD_INQUIRE_Q_MGR_STATUS
- MQCMD_INQUIRE_Q_STATUS
- MQCMD_INQUIRE_SECURITY

For an example that demonstrates the use of supported INQUIRE command codes, see [Inquiring about queues and printing information \(amqsailq.c\)](#).

Multi mqAddInteger

The mqAddInteger call adds an integer item identified by a user selector to the end of a specified bag.

Syntax for mqAddInteger

mqAddInteger (*Bag, Selector, ItemValue, CompCode, Reason*)

Parameters for mqAddInteger

Bag (MQHBAG) - input

Handle of the bag to be modified.

This must be the handle of a bag created by the user, not the handle of a system bag. MQRC_SYSTEM_BAG_NOT_ALTERABLE results if the value you specify identifies a system bag.

Selector (MQLONG)

Selector identifying the item to be added to the bag.

If the selector is less than zero (that is, a system selector), MQRC_SELECTOR_OUT_OF_RANGE results.

If the selector is zero or greater (that is, a user selector) and the bag was created with the MQCBO_CHECK_SELECTORS option or as an administration bag (MQCBO_ADMIN_BAG), the selector must be in the range MQIA_FIRST through MQIA_LAST; if not, again MQRC_SELECTOR_OUT_OF_RANGE results.

If MQCBO_CHECK_SELECTORS was not specified, the selector can be any value of zero or greater.

If the call is creating a second or later occurrence of a selector that is already in the bag, the data type of this occurrence must be the same as the data type of the first occurrence; MQRC_INCONSISTENT_ITEM_TYPE results if it is not.

ItemValue (MQLONG) - input

The integer value to be placed in the bag.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicate error conditions that can be returned from the mqAddInteger call:

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_INCONSISTENT_ITEM_TYPE

Data type of this occurrence of selector differs from data type of first occurrence.

MQRC_SELECTOR_OUT_OF_RANGE

Selector not within valid range for call.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

MQRC_SYSTEM_BAG_NOT_ALTERABLE

System bag cannot be altered or deleted.

Usage notes for mqAddInteger

1. If a data item with the specified selector is already present in the bag, an additional instance of that selector is added to the end of the bag. The new instance is not necessarily next to the existing instance.
2. This call cannot be used to add a system selector to a bag.

C language invocation for mqAddInteger

```
mqAddInteger (Bag, Selector, ItemValue, &CompCode, &Reason)
```

Declare the parameters as follows:

```
MQHBAG  Bag;          /* Bag handle */
MQLONG  Selector;     /* Selector */
MQLONG  ItemValue;    /* Integer value */
MQLONG  CompCode;     /* Completion code */
MQLONG  Reason;       /* Reason code qualifying CompCode */
```

Visual Basic invocation for mqAddInteger

(Supported on Windows only.)

```
mqAddInteger Bag, Selector, ItemValue, CompCode, Reason
```

Declare the parameters as follows:

```
Dim Bag      As Long 'Bag handle'
Dim Selector As Long 'Selector'
Dim ItemValue As Long 'Integer value'
Dim CompCode As Long 'Completion code'
Dim Reason   As Long 'Reason code qualifying CompCode'
```

Multi mqAddInteger64

The mqAddInteger64 call adds a 64-bit integer item identified by a user selector to the end of a specified bag.

Syntax for mqAddInteger64

```
mqAddInteger64 (Bag, Selector, ItemValue, CompCode, Reason)
```

Parameters for mqAddInteger64**Bag (MQHBAG) - input**

Handle of the bag to be modified.

This must be the handle of a bag created by the user, not the handle of a system bag.
MQRC_SYSTEM_BAG_NOT_ALTERABLE results if the value you specify identifies a system bag.

Selector (MQLONG) - input

Selector identifying the item to be added to the bag.

If the selector is less than zero (that is, a system selector), MQRC_SELECTOR_OUT_OF_RANGE results.

If the selector is zero or greater (that is, a user selector) and the bag was created with the MQCBO_CHECK_SELECTORS option or as an administration bag (MQCBO_ADMIN_BAG), the selector must be in the range MQIA_FIRST through MQIA_LAST; if not, again MQRC_SELECTOR_OUT_OF_RANGE results.

If MQCBO_CHECK_SELECTORS was not specified, the selector can be any value of zero or greater.

If the call is creating a second or later occurrence of a selector that is already in the bag, the data type of this occurrence must be the same as the data type of the first occurrence; MQRC_INCONSISTENT_ITEM_TYPE results if it is not.

ItemValue (MQINT64) - input

The 64-bit integer value to be placed in the bag.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicate error conditions that can be returned from the mqAddInteger64 call:

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_INCONSISTENT_ITEM_TYPE

Data type of this occurrence of selector differs from data type of first occurrence.

MQRC_SELECTOR_OUT_OF_RANGE

Selector not within valid range for call.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

MQRC_SYSTEM_BAG_NOT_ALTERABLE

System bag cannot be altered or deleted.

Usage notes for mqAddInteger64

1. If a data item with the specified selector is already present in the bag, an additional instance of that selector is added to the end of the bag. The new instance is not necessarily adjacent to the existing instance.
2. This call cannot be used to add a system selector to a bag.

C language invocation for mqAddInteger64

```
mqAddInteger64 (Bag, Selector, ItemValue, &CompCode, &Reason)
```

Declare the parameters as follows:

```

MQHBAG  Bag;          /* Bag handle */
MQLONG  Selector;     /* Selector */
MQINT64 ItemValue;    /* Integer value */
MQLONG  CompCode;     /* Completion code */
MQLONG  Reason;       /* Reason code qualifying CompCode */

```

Visual Basic invocation for mqAddInteger64

(Supported on Windows only.)

```
mqAddInteger64 Bag, Selector, ItemValue, CompCode, Reason
```

Declare the parameters as follows:

```

Dim Bag          As Long 'Bag handle'
Dim Selector     As Long 'Selector'
Dim Item Value   As Long 'Integer value'
Dim CompCode     As Long 'Completion code'
Dim Reason       As Long 'Reason code qualifying CompCode'

```

Multi

mqAddIntegerFilter

The mqAddIntegerFilter call adds an integer filter identified by a user selector to the end of a specified bag.

Syntax for mqAddIntegerFilter

mqAddIntegerFilter (*Bag, Selector, ItemValue, Operator, CompCode, Reason*)

Parameters for mqAddIntegerFilter

Bag (MQHBAG) - input

Handle of the bag to be modified.

This must be the handle of a bag created by the user, not the handle of a system bag.

MQRC_SYSTEM_BAG_NOT_ALTERABLE results if the value you specify identifies a system bag.

Selector (MQLONG) - input

Selector identifying the item to be added to the bag.

If the selector is less than zero (that is, a system selector), MQRC_SELECTOR_OUT_OF_RANGE results.

If the selector is zero or greater (that is, a user selector) and the bag was created with the MQCBO_CHECK_SELECTORS option or as an administration bag (MQCBO_ADMIN_BAG), the selector must be in the range MQIA_FIRST through MQIA_LAST; if not, again MQRC_SELECTOR_OUT_OF_RANGE results.

If MQCBO_CHECK_SELECTORS was not specified, the selector can be any value of zero or greater.

If the call is creating a second or later occurrence of a selector that is already in the bag, the data type of this occurrence must be the same as the data type of the first occurrence; MQRC_INCONSISTENT_ITEM_TYPE results if it is not.

ItemValue (MQLONG) - input

The integer condition value to be placed in the bag.

Operator (MQLONG) - input

The integer filter operator to be placed in the bag. Valid operators take the form MQCFOP_*

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicate error conditions that can be returned from the `mqAddIntegerFilter` call:

MQRC_FILTER_OPERATOR_ERROR

Filter operator not valid.

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_INCONSISTENT_ITEM_TYPE

Data type of this occurrence of selector differs from data type of first occurrence.

MQRC_SELECTOR_OUT_OF_RANGE

Selector not within valid range for call.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

MQRC_SYSTEM_BAG_NOT_ALTERABLE

System bag cannot be altered or deleted.

Usage notes for `mqAddIntegerFilter`

1. If a data item with the specified selector is already present in the bag, an additional instance of that selector is added to the end of the bag. The new instance is not necessarily adjacent to the existing instance.
2. This call cannot be used to add a system selector to a bag.

C language invocation for `mqAddIntegerFilter`

```
mqAddIntegerFilter (Bag, Selector, ItemValue, Operator, &CompCode, &Reason)
```

Declare the parameters as follows:

```
MQHBAG   Bag;           /* Bag handle */
MQLONG   Selector;      /* Selector */
MQLONG   ItemValue;     /* Integer value */
MQLONG   Operator;      /* Item operator */
MQLONG   CompCode;      /* Completion code */
MQLONG   Reason;        /* Reason code qualifying CompCode */
```

Visual Basic invocation for `mqAddIntegerFilter`

(Supported on Windows only.)

```
mqAddIntegerFilter Bag, Selector, ItemValue, Operator, CompCode, Reason
```

Declare the parameters as follows:

```
Dim Bag           As Long 'Bag handle'
Dim Selector      As Long 'Selector'
Dim ItemValue     As Long 'Integer value'
```

```
Dim Operator As Long 'Item Operator'
Dim CompCode As Long 'Completion code'
Dim Reason As Long 'Reason code qualifying CompCode'
```

Multi

mqAddString

The `mqAddString` call adds a character data item identified by a user selector to the end of a specified bag.

Syntax for `mqAddString`

`mqAddString` (*Bag*, *Selector*, *BufferLength*, *Buffer*, *CompCode*, *Reason*)

Parameters for `mqAddString`

Bag (MQHBAG) - input

Handle of the bag to be modified.

This value must be the handle of a bag created by the user, not the handle of a system bag. MQRC_SYSTEM_BAG_NOT_ALTERABLE results if the value you specify relates to a system bag.

Selector (MQLONG) - input

Selector identifying the item to be added to the bag.

If the selector is less than zero (that is, a system selector), MQRC_SELECTOR_OUT_OF_RANGE results.

If the selector is zero or greater (that is, a user selector), and the bag was created with the MQCBO_CHECK_SELECTORS option or as an administration bag (MQCBO_ADMIN_BAG), the selector must be in the range MQCA_FIRST through MQCA_LAST. MQRC_SELECTOR_OUT_OF_RANGE results if it is not in the correct range.

If MQCBO_CHECK_SELECTORS was not specified, the selector can be any value zero or greater.

If the call is creating a second or later occurrence of a selector that is already in the bag, the data type of this occurrence must be the same as the data type of the first occurrence; MQRC_INCONSISTENT_ITEM_TYPE results if it is not.

BufferLength (MQLONG) - input

The length in bytes of the string contained in the **Buffer** parameter. The value must be zero or greater, or the special value MQBL_NULL_TERMINATED:

- If MQBL_NULL_TERMINATED is specified, the string is delimited by the first null encountered in the string. The null is not added to the bag as part of the string.
- If MQBL_NULL_TERMINATED is not specified, *BufferLength* characters are inserted into the bag, even if null characters are present. Nulls do not delimit the string.

Buffer (MQCHAR x BufferLength) - input

Buffer containing the character string.

The length is given by the **BufferLength** parameter. If zero is specified for **BufferLength**, the null pointer can be specified for the address of the **Buffer** parameter. In all other cases, a valid (nonnull) address must be specified for the **Buffer** parameter.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating error conditions can be returned from the mqAddString call:

MQRC_BUFFER_ERROR

Buffer parameter not valid (invalid parameter address or buffer not completely accessible).

MQRC_BUFFER_LENGTH_ERROR

Buffer length not valid.

MQRC_CODED_CHAR_SET_ID_ERROR

Bag CCSID is MQCCSI_EMBEDDED.

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_INCONSISTENT_ITEM_TYPE

Data type of this occurrence of selector differs from data type of first occurrence.

MQRC_SELECTOR_OUT_OF_RANGE

Selector not within valid range for call.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

MQRC_SYSTEM_BAG_NOT_ALTERABLE

System bag cannot be altered or deleted.

Usage notes for mqAddString

1. If a data item with the specified selector is already present in the bag, an additional instance of that selector is added to the end of the bag. The new instance is not necessarily adjacent to the existing instance.
2. This call cannot be used to add a system selector to a bag.
3. The Coded Character Set ID associated with this string is copied from the current CCSID of the bag.

C language invocation for mqAddString

```
mqAddString (hBag, Selector, BufferLength, Buffer, &CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHBAG    hBag;           /* Bag handle */
MQLONG    Selector;      /* Selector */
MQLONG    BufferLength;   /* Buffer length */
PMQCHAR   Buffer;        /* Buffer containing item value */
MQLONG    CompCode;      /* Completion code */
MQLONG    Reason;       /* Reason code qualifying CompCode */
```

Visual Basic invocation for mqAddString

(Supported on Windows only.)

```
mqAddString Bag, Selector, BufferLength, Buffer, CompCode, Reason
```

Declare the parameters as follows:

```
Dim Bag           As Long 'Bag handle'
Dim Selector      As Long 'Selector'
Dim BufferLength   As Long 'Buffer length'
Dim Buffer         As String 'Buffer containing item value'
Dim CompCode      As Long 'Completion code'
Dim Reason        As Long 'Reason code qualifying CompCode'
```

mqAddStringFilter

The `mqAddStringFilter` call adds a string filter identified by a user selector to the end of a specified bag.

Syntax for `mqAddStringFilter`

`mqAddStringFilter (Bag, Selector, BufferLength, Buffer, Operator, CompCode, Reason)`

Parameters for `mqAddStringFilter`

Bag (MQHBAG) - input

Handle of the bag to be modified.

This value must be the handle of a bag created by the user, not the handle of a system bag. `MQRC_SYSTEM_BAG_NOT_ALTERABLE` results if the value you specify relates to a system bag.

Selector (MQLONG) - input

Selector identifying the item to be added to the bag.

If the selector is less than zero (that is, a system selector), `MQRC_SELECTOR_OUT_OF_RANGE` results.

If the selector is zero or greater (that is, a user selector), and the bag was created with the `MQCBO_CHECK_SELECTORS` option or as an administration bag (`MQCBO_ADMIN_BAG`), the selector must be in the range `MQCA_FIRST` through `MQCA_LAST`. `MQRC_SELECTOR_OUT_OF_RANGE` results if it is not in the correct range.

If `MQCBO_CHECK_SELECTORS` was not specified, the selector can be any value zero or greater.

If the call is creating a second or later occurrence of a selector that is already in the bag, the data type of this occurrence must be the same as the data type of the first occurrence; `MQRC_INCONSISTENT_ITEM_TYPE` results if it is not.

BufferLength (MQLONG) - input

The length in bytes of the character condition string contained in the **Buffer** parameter. The value must be zero or greater, or the special value `MQBL_NULL_TERMINATED`:

- If `MQBL_NULL_TERMINATED` is specified, the string is delimited by the first null encountered in the string. The null is not added to the bag as part of the string.
- If `MQBL_NULL_TERMINATED` is not specified, *BufferLength* characters are inserted into the bag, even if null characters are present. Nulls do not delimit the string.

Buffer (MQCHAR x BufferLength) - input

Buffer containing the character condition string.

The length is given by the **BufferLength** parameter. If zero is specified for **BufferLength**, the null pointer can be specified for the address of the **Buffer** parameter. In all other cases, a valid (nonnull) address must be specified for the **Buffer** parameter.

Operator (MQLONG) - input

The string filter operator to be placed in the bag. Valid operators are of the form `MQCFOP_*`.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating error conditions can be returned from the `mqAddStringFilter` call:

MQRC_BUFFER_ERROR

Buffer parameter not valid (invalid parameter address or buffer not completely accessible).

MQRC_BUFFER_LENGTH_ERROR

Buffer length not valid.

MQRC_CODED_CHAR_SET_ID_ERROR

Bag CCSID is MQCCSI_EMBEDDED.

MQRC_FILTER_OPERATOR_ERROR

Filter operator not valid.

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_INCONSISTENT_ITEM_TYPE

Data type of this occurrence of selector differs from data type of first occurrence.

MQRC_SELECTOR_OUT_OF_RANGE

Selector not within valid range for call.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

MQRC_SYSTEM_BAG_NOT_ALTERABLE

System bag cannot be altered or deleted.

Usage notes for `mqAddStringFilter`

1. If a data item with the specified selector is already present in the bag, an additional instance of that selector is added to the end of the bag. The new instance is not necessarily adjacent to the existing instance.
2. This call cannot be used to add a system selector to a bag.
3. The Coded Character Set ID associated with this string is copied from the current CCSID of the bag.

C language invocation for `mqAddStringFilter`

```
mqAddStringFilter (hBag, Selector, BufferLength, Buffer, &CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHBAG    hBag;           /* Bag handle */
MQLONG    Selector;      /* Selector */
MQLONG    BufferLength;   /* Buffer length */
PMQCHAR   Buffer;        /* Buffer containing item value */
MQLONG    Operator;      /* Operator */
MQLONG    CompCode;     /* Completion code */
MQLONG    Reason;       /* Reason code qualifying CompCode */
```

Visual Basic invocation for `mqAddStringFilter`

(Supported on Windows only.)

```
mqAddStringFilter Bag, Selector, BufferLength, Buffer, Operator, CompCode, Reason
```

Declare the parameters as follows:

```
Dim Bag           As Long 'Bag handle'
Dim Selector      As Long 'Selector'
Dim BufferLength  As Long 'Buffer length'
```

Dim Buffer	As String 'Buffer containing item value'
Dim Operator	As Long 'Item operator'
Dim CompCode	As Long 'Completion code'
Dim Reason	As Long 'Reason code qualifying CompCode'

Multi mqBagToBuffer

The mqBagToBuffer call converts the bag into a PCF message in the supplied buffer.

Syntax for mqBagToBuffer

mqBagToBuffer (*OptionsBag, DataBag, BufferLength, Buffer, DataLength, CompCode, Reason*)

Parameters for mqBagToBuffer

OptionsBag (MQHBAG) - input

Handle of the bag containing options that control the processing of the call. This is a reserved parameter; the value must be MQHB_NONE.

DataBag (MQHBAG) - input

The handle of the bag to convert.

If the bag contains an administration message and mqAddInquiry was used to insert values into the bag, the value of the MQIASY_COMMAND data item must be an INQUIRE command that is recognized by the MQAI; MQRC_INQUIRY_COMMAND_ERROR results if it is not.

If the bag contains nested system bags, MQRC_NESTED_BAG_NOT_SUPPORTED results.

BufferLength (MQLONG) - input

Length in bytes of the buffer supplied.

If the buffer is too small to accommodate the message generated, MQRC_BUFFER_LENGTH_ERROR results.

Buffer (MQBYTE x BufferLength) - output

The buffer to hold the message.

DataLength (MQLONG) - output

The length in bytes of the buffer required to hold the entire bag. If the buffer is not long enough, the contents of the buffer are undefined but the DataLength is returned.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating error conditions can be returned from the mqBagToBuffer call:

MQRC_BAG_WRONG_TYPE

Input data bag is a group bag.

MQRC_BUFFER_ERROR

Buffer parameter not valid (invalid parameter address or buffer not accessible).

MQRC_BUFFER_LENGTH_ERROR

Buffer length not valid or buffer too small. (Required length returned in *DataLength*.)

MQRC_DATA_LENGTH_ERROR

DataLength parameter not valid (invalid parameter address).

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_INQUIRY_COMMAND_ERROR

mqAddInquiry used with a command code that is not recognized as an INQUIRE command.

MQRC_NESTED_BAG_NOT_SUPPORTED

Input data bag contains one or more nested system bags.

MQRC_OPTIONS_ERROR

Options bag contains unsupported data items or a supported option has an invalid value.

MQRC_PARAMETER_MISSING

An administration message requires a parameter that is not present in the bag.

Note: This reason code occurs for bags created with the MQCBO_ADMIN_BAG or MQCBO_REORDER_AS_REQUIRED options only.

MQRC_SELECTOR_WRONG_TYPE

mqAddString or mqSetString was used to add the MQIACF_INQUIRY selector to the bag.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

Usage notes for mqBagToBuffer

1. The PCF message is generated with an encoding of MQENC_NATIVE for the numeric data.
2. The buffer that holds the message can be null if the BufferLength is zero. This is useful if you use the mqBagToBuffer call to calculate the size of buffer necessary to convert your bag.

C language invocation for mqBagToBuffer

```
mqBagToBuffer (OptionsBag, DataBag, BufferLength, Buffer, &DataLength,
&CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHBAG OptionsBag;      /* Options bag handle */
MQHBAG DataBag;        /* Data bag handle */
MQLONG BufferLength;   /* Buffer length */
MQBYTE Buffer[n];      /* Buffer to contain PCF */
MQLONG DataLength;    /* Length of PCF returned in buffer */
MQLONG CompCode;      /* Completion code */
MQLONG Reason;        /* Reason code qualifying CompCode */
```

Visual Basic invocation for mqBagToBuffer

(Supported on Windows only.)

```
mqBagToBuffer OptionsBag, DataBag, BufferLength, Buffer, DataLength,
CompCode, Reason
```

Declare the parameters as follows:

```
Dim OptionsBag As Long 'Options bag handle'
Dim DataBag As Long 'Data bag handle'
Dim BufferLength As Long 'Buffer length'
Dim Buffer As Long 'Buffer to contain PCF'
Dim DataLength As Long 'Length of PCF returned in buffer'
```

Dim CompCode	As Long 'Completion code'
Dim Reason	As Long 'Reason code qualifying CompCode'

Multi **mqBufferToBag**

The `mqBufferToBag` call converts the supplied buffer into bag form.

Syntax for `mqBufferToBag`

`mqBufferToBag (OptionsBag, BufferLength, Buffer, DataBag, CompCode, Reason)`

Parameters for `mqBufferToBag`

OptionsBag (MQHBAG) - input

Handle of the bag containing options that control the processing of the call. This is a reserved parameter; the value must be `MQHB_NONE`.

BufferLength (MQLONG) - input

Length in bytes of the buffer.

Buffer (MQBYTE x BufferLength) - input

Pointer to the buffer containing the message to be converted.

DataBag (MQHBAG) - input/output

Handle of the bag to receive the message. The `MQAI` performs an `mqClearBag` call on the bag before placing the message in the bag.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating error conditions can be returned from the `mqBufferToBag` call:

MQRC_BAG_CONVERSION_ERROR

Data could not be converted into a bag. This indicates a problem with the format of the data to be converted into a bag (for example, the message is not a valid PCF).

MQRC_BUFFER_ERROR

Buffer parameter not valid (invalid parameter address or buffer not accessible).

MQRC_BUFFER_LENGTH_ERROR

Buffer length not valid.

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_INCONSISTENT_ITEM_TYPE

Data type of second occurrence of selector differs from data type of first occurrence.

MQRC_OPTIONS_ERROR

Options bag contains unsupported data items, or a supported option has a value that is not valid.

MQRC_SELECTOR_OUT_OF_RANGE

Selector not within valid range for call.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

MQRC_SYSTEM_BAG_NOT_ALTERABLE

System bag cannot be altered or deleted.

Usage notes for mqBufferToBag

The buffer must contain a valid PCF message. The encoding of numeric data in the buffer must be MQENC_NATIVE.

The Coded Character Set ID of the bag is unchanged by this call.

C language invocation for mqBufferToBag

```
mqBufferToBag (OptionsBag, BufferLength, Buffer, DataBag,  
&CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHBAG  OptionsBag;    /* Options bag handle */  
MQLONG  BufferLength; /* Buffer length */  
MQBYTE  Buffer[n];    /* Buffer containing PCF */  
MQHBAG  DataBag;     /* Data bag handle */  
MQLONG  CompCode;    /* Completion code */  
MQLONG  Reason;      /* Reason code qualifying CompCode */
```

Visual Basic invocation for mqBufferToBag

(Supported on Windows only.)

```
mqBufferToBag OptionsBag, BufferLength, Buffer, DataBag,  
CompCode, Reason
```

Declare the parameters as follows:

```
Dim OptionsBag As Long 'Options bag handle'  
Dim BufferLength As Long 'Buffer length'  
Dim Buffer As Long 'Buffer containing PCF'  
Dim DataBag As Long 'Data bag handle'  
Dim CompCode As Long 'Completion code'  
Dim Reason As Long 'Reason code qualifying CompCode'
```

Multi **mqClearBag**

The mqClearBag call deletes all user items from the bag, and resets system items to their initial values.

Syntax for mqClearBag

mqClearBag (*Bag*, *CompCode*, *Reason*)

Parameters for mqClearBag

Bag (MQHBAG) - input

Handle of the bag to be cleared. This must be the handle of a bag created by the user, not the handle of a system bag. MQRC_SYSTEM_BAG_NOT_ALTERABLE results if you specify the handle of a system bag.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating error conditions can be returned from the mqClearBag call:

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_SYSTEM_BAG_NOT_ALTERABLE

System bag cannot be altered or deleted.

Usage notes for mqClearBag

1. If the bag contains system bags, they are also deleted.
2. The call cannot be used to clear system bags.

C language invocation for mqClearBag

```
mqClearBag (Bag, &CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHBAG   Bag;           /* Bag handle */
MQLONG   CompCode;      /* Completion code */
MQLONG   Reason;        /* Reason code qualifying CompCode */
```

Visual Basic invocation for mqClearBag

(Supported on Windows only.)

```
mqClearBag Bag, CompCode, Reason
```

Declare the parameters as follows:

```
Dim Bag      As Long 'Bag handle'
Dim CompCode As Long 'Completion code'
Dim Reason   As Long 'Reason code qualifying CompCode'
```

mqCountItems

The mqCountItems call returns the number of occurrences of user items, system items, or both, that are stored in a bag with the same specific selector.

Syntax for mqCountItems

mqCountItems (Bag, Selector, ItemCount, CompCode, Reason)

Parameters for mqCountItems

Bag (MQHBAG) - input

Handle of the bag with items that are to be counted. This can be a user bag or a system bag.

Selector (MQLONG) - input

Selector of the data items to count.

If the selector is less than zero (a system selector), the selector must be one that is supported by the MQAI. MQRC_SELECTOR_NOT_SUPPORTED results if it is not.

If the specified selector is not present in the bag, the call succeeds and zero is returned for *ItemCount*.

The following special values can be specified for *Selector*:

MQSEL_ALL_SELECTORS

All user and system items are to be counted.

MQSEL_ALL_USER_SELECTORS

All user items are to be counted; system items are excluded from the count.

MQSEL_ALL_SYSTEM_SELECTORS

All system items are to be counted; user items are excluded from the count.

ItemCount (MQLONG) - output

Number of items of the specified type in the bag (can be zero).

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating error conditions can be returned from the *mqCountItems* call:

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_ITEM_COUNT_ERROR

ItemCount parameter not valid (invalid parameter address).

MQRC_SELECTOR_NOT_SUPPORTED

Specified system selector not supported by the MQAI.

MQRC_SELECTOR_OUT_OF_RANGE

Selector not within valid range for call.

Usage notes for mqCountItems

This call counts the number of data items, not the number of unique selectors in the bag. A selector can occur multiple times, so there might be fewer unique selectors in the bag than data items.

C language invocation for mqCountItems

```
mqCountItems (Bag, Selector, &ItemCount, &CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHBAG Bag;           /* Bag handle */
MQLONG Selector;      /* Selector */
MQLONG ItemCount;     /* Number of items */
MQLONG CompCode;     /* Completion code */
MQLONG Reason;       /* Reason code qualifying CompCode */
```

Visual Basic invocation for mqCountItems

(Supported on Windows only.)

```
mqCountItems Bag, Selector, ItemCount, CompCode, Reason
```

Declare the parameters as follows:

```
Dim Bag;           As Long 'Bag handle'
Dim Selector      As Long 'Selector'
Dim ItemCount    As Long 'Number of items'
Dim CompCode     As Long 'Completion code'
Dim Reason       As Long 'Reason code qualifying CompCode'
```

Multi **mqCreateBag**

The mqCreateBag call creates a new bag.

Syntax for mqCreateBag

mqCreateBag (*Options, Bag, CompCode, Reason*)

Parameters for mqCreateBag

Options (MQLONG) - input

Options for creation of the bag.

The following values are valid:

MQCBO_ADMIN_BAG

Specifies that the bag is for administering IBM MQ objects. MQCBO_ADMIN_BAG automatically implies the MQCBO_LIST_FORM_ALLOWED, MQCBO_REORDER_AS_REQUIRED, and MQCBO_CHECK_SELECTORS options.

Administration bags are created with the MQIASY_TYPE system item set to MQCFT_COMMAND.

MQCBO_COMMAND_BAG

Specifies that the bag is a command bag. MQCBO_COMMAND_BAG is an alternative to the administration bag (MQCBO_ADMIN_BAG) and MQRC_OPTIONS_ERROR results if both are specified.

A command bag is processed in the same way as a user bag except that the value of the MQIASY_TYPE system item is set to MQCFT_COMMAND when the bag is created.

The command bag is also created for administering objects but they are not used to send administration messages to a command server as an administration bag is. The bag options assume the following default values:

- MQCBO_LIST_FORM_INHIBITED
- MQCBO_DO_NOT_REORDER
- MQCBO_DO_NOT_CHECK_SELECTORS

Therefore, the MQAI does not change the order of data items or create lists within a message as with administration bags.

MQCBO_GROUP_BAG

Specifies that the bag is a group bag. This means that the bag is used to hold a set of grouped items. Group bags cannot be used for the administration of IBM MQ objects. The bag options assume the following default values:

- MQCBO_LIST_FORM_ALLOWED
- MQCBO_REORDER_AS_REQUIRED
- MQCBO_DO_NOT_CHECK_SELECTORS

Therefore, the MQAI can change the order of data items or create lists within a bag of grouped items.

Group bags are created with two system selectors: MQIASY_BAG_OPTIONS and MQIASY_CODED_CHAR_SET_ID.

If a group bag is nested in a bag in which MQCBO_CHECK_SELECTORS was specified, the group bag to be nested has its selectors checked at that point whether MQCBO_CHECK_SELECTORS was specified when the group bag was created.

MQCBO_USER_BAG

Specifies that the bag is a user bag. MQCBO_USER_BAG is the default bag-type option. User bags can also be used for the administration of IBM MQ objects, but the MQCBO_LIST_FORM_ALLOWED and MQCBO_REORDER_AS_REQUIRED options must be specified to ensure correct generation of the administration messages.

User bags are created with the MQIASY_TYPE system item set to MQCFT_USER.

For user bags, one or more of the following options can be specified:

MQCBO_LIST_FORM_ALLOWED

Specifies that the MQAI can use the more compact list form in the message sent whenever there are two or more adjacent occurrences of the same selector in the bag. However, the items cannot be reordered if this option is used. Therefore, if the occurrences of the selector are not adjacent in the bag, and MQCBO_REORDER_AS_REQUIRED is not specified, the MQAI cannot use the list form for that particular selector.

If the data items are character strings, these strings must have the same Character Set ID and the same selector, in order to be compacted into list form. If the list form is used, the shorter strings are padded with blanks to the length of the longest string.

This option must be specified if the message to be sent is an administration message but MQCBO_ADMIN_BAG is not specified.

Note: MQCBO_LIST_FORM_ALLOWED does not imply that the MQAI definitely uses the list form. The MQAI considers various factors in deciding whether to use the list form.

MQCBO_LIST_FORM_INHIBITED

Specifies that the MQAI cannot use the list form in the message sent, even if there are adjacent occurrences of the same selector in the bag. MQCBO_LIST_FORM_INHIBITED is the default list-form option.

MQCBO_REORDER_AS_REQUIRED

Specifies that the MQAI can change the order of the data items in the message sent. This option does not affect the order of the items in the sending bag.

This option means that you can insert items into a data bag in any order. That is, the items do not need to be inserted in the way that they must be in the PCF message, because the MQAI can reorder these items as required.

If the message is a user message, the order of the items in the receiving bag is the same as the order of the items in the message. This order can be different from the order of the items in the sending bag.

If the message is an administration message, the order of the items in the receiving bag is determined by the message received.

This option must be specified if the message to be sent is an administration message but MQCBO_ADMIN is not specified.

MQCBO_DO_NOT_REORDER

Specifies that the MQAI cannot change the order of data items in the message sent. Both the message sent and the receiving bag contain the items in the same order as they occur in the sending bag. This option is the default ordering option.

MQCBO_CHECK_SELECTORS

Specifies that user selectors (selectors that are zero or greater) must be checked to ensure that the selector is consistent with the data type implied by the mqAddInteger, mqAddInteger64, mqAddIntegerFilter, mqAddString, mqAddStringFilter, mqAddByteString, mqAddByteStringFilter, mqSetInteger, mqSetInteger64, mqSetIntegerFilter, mqSetString, mqSetStringFilter, mqSetByteString, or mqSetByteStringFilter call:

- For the integer, 64-bit integer, and integer filter calls, the selector must be in the range MQIA_FIRST through MQIA_LAST.
- For the string and string filter calls, the selector must be in the range MQCA_FIRST through MQCA_LAST.
- For byte string and byte string filter calls, the selector must be in the range MQBA_FIRST through MQBA_LAST.
- For group bag calls, the selector must be in the range MQGA_FIRST through MQGA_LAST.
- For the handle calls, the selector must be in the range MQHA_FIRST through MQHA_LAST.

The call fails if the selector is outside the valid range. System selectors (selectors less than zero) are always checked, and if a system selector is specified, it must be one that is supported by the MQAI.

MQCBO_DO_NOT_CHECK_SELECTORS

Specifies that user selectors (selectors that are zero or greater) are not checked. Any selector that is zero or positive can be used with any call. This option is the default selectors option. System selectors (selectors less than zero) are always checked.

MQCBO_NONE

Specifies that all options must have their default values. This option is provided to aid program documentation, and must not be specified with any of the options that have a nonzero value.

The following list summarizes the default option values:

- MQCBO_USER_BAG
 - MQCBO_LIST_FORM_INHIBITED
 - MQCBO_DO_NOT_REORDER
 - MQCBO_DO_NOT_CHECK_SELECTORS

Bag (MQHBAG) - output

The handle of the bag created by the call.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating error conditions can be returned from the mqCreateBag call:

MQRC_HBAG_ERROR

Bag handle not valid (invalid parameter address or the parameter location is read-only).

MQRC_OPTIONS_ERROR

Options not valid or not consistent.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

Usage notes for mqCreateBag

Any options used for creating your bag are contained in a system item within the bag when it is created.

C language invocation for mqCreateBag

```
mqCreateBag (Options, &Bag, &CompCode, &Reason);
```

Declare the parameters as follows:

```

MQLONG Options;          /* Bag options */
MQHBAG Bag;              /* Bag handle */
MQLONG CompCode;        /* Completion code */
MQLONG Reason;          /* Reason code qualifying CompCode */

```

Visual Basic invocation for mqCreateBag

(Supported on Windows only.)

```
mqCreateBag Options, Bag, CompCode, Reason
```

Declare the parameters as follows:

```

Dim Options As Long 'Bag options'
Dim Bag As Long 'Bag handle'
Dim CompCode As Long 'Completion code'
Dim Reason As Long 'Reason code qualifying CompCode'

```

mqDeleteBag

The mqDeleteBag call deletes the specified bag.

Syntax for mqDeleteBag

mqDeleteBag (*Bag*, *CompCode*, *Reason*)

Parameters for mqDeleteBag

Bag (MQHBAG) - input/output

The handle of the bag to be deleted. This must be the handle of a bag created by the user, not the handle of a system bag. MQRC_SYSTEM_BAG_NOT_DELETABLE results if you specify the handle of a system bag. The handle is reset to MQHB_UNUSABLE_HBAG.

If the bag contains system-generated bags, they are also deleted.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating error conditions can be returned from the mqDeleteBag call:

MQRC_HBAG_ERROR

Bag handle not valid, or invalid parameter address, or parameter location is read only.

MQRC_SYSTEM_BAG_NOT_DELETABLE

System bag cannot be deleted.

Usage notes for mqDeleteBag

1. Delete any bags created with mqCreateBag.
2. Nested bags are deleted automatically when the containing bag is deleted.

C language invocation for mqDeleteBag

```
mqDeleteBag (&Bag, CompCode, Reason);
```

Declare the parameters as follows:

```
MQHBAG  Bag;           /* Bag handle */
MQLONG  CompCode;     /* Completion code */
MQLONG  Reason;       /* Reason code qualifying CompCode */
```

Visual Basic invocation for mqDeleteBag

(Supported on Windows only.)

```
mqDeleteBag Bag, CompCode, Reason
```

Declare the parameters as follows:

```
Dim Bag;           As Long 'Bag handle'
Dim CompCode As Long 'Completion code'
Dim Reason As Long 'Reason code qualifying CompCode'
```

mqDeleteItem

The mqDeleteItem call removes one or more user items from a bag.

Syntax for mqDeleteItem

mqDeleteItem (Bag, Selector, ItemIndex, CompCode, Reason)

Parameters for mqDeleteItem

Hbag (MQHBAG) - input

Handle of the bag to be modified.

This must be the handle of a bag created by the user, and not the handle of a system bag; MQRC_SYSTEM_BAG_NOT_ALTERABLE results if it is a system bag.

Selector (MQLONG) - input

Selector identifying the user item to be deleted.

If the selector is less than zero (that is, a system selector), MQRC_SELECTOR_OUT_OF_RANGE results.

The following special values are valid:

MQSEL_ANY_SELECTOR

The item to be deleted is a user item identified by the **ItemIndex** parameter, the index relative to the set of items that contains both user and system items.

MQSEL_ANY_USER_SELECTOR

The item to be deleted is a user item identified by the **ItemIndex** parameter, the index relative to the set of user items.

If an explicit selector value is specified, but the selector is not present in the bag, the call succeeds if MQIND_ALL is specified for **ItemIndex**, and fails with reason code MQRC_SELECTOR_NOT_PRESENT if MQIND_ALL is not specified.

ItemIndex (MQLONG) - input

Index of the data item to be deleted.

The value must be zero or greater, or one of the following special values:

MQIND_NONE

This specifies that there must be one occurrence only of the selector in the bag. If there is more than one occurrence, MQRC_SELECTOR_NOT_UNIQUE results. If MQIND_NONE is specified with one of the MQSEL_XXX_SELECTOR values, MQRC_INDEX_ERROR results.

MQIND_ALL

This specifies that all occurrences of the selector in the bag are to be deleted. If MQIND_ALL is specified with one of the MQSEL_XXX_SELECTOR values, MQRC_INDEX_ERROR results. If MQIND_ALL is specified when the selector is not present within the bag, the call succeeds.

If MQSEL_ANY_SELECTOR is specified for the **Selector** parameter, the **ItemIndex** parameter is the index relative to the set of items that contains both user items and system items, and must be zero or greater. If **ItemIndex** identifies a system selector MQRC_SYSTEM_ITEM_NOT_DELETABLE results. If MQSEL_ANY_USER_SELECTOR is specified for the **Selector** parameter, the **ItemIndex** parameter is the index relative to the set of user items, and must be zero or greater.

If an explicit selector value is specified, **ItemIndex** is the index relative to the set of items that have that selector value, and can be MQIND_NONE, MQIND_ALL, zero, or greater.

If an explicit index is specified (that is, not MQIND_NONE or MQIND_ALL) and the item is not present in the bag, MQRC_INDEX_NOT_PRESENT results.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating error conditions can be returned from the mqDeleteItem call:

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_INDEX_ERROR

MQIND_NONE or MQIND_ALL specified with one of the MQSEL_ANY_XXX_SELECTOR values.

MQRC_INDEX_NOT_PRESENT

No item with the specified index is present within the bag.

MQRC_SELECTOR_NOT_PRESENT

No item with the specified selector is present within the bag.

MQRC_SELECTOR_NOT_UNIQUE

MQIND_NONE specified when more than one occurrence of the specified selector is present in the bag.

MQRC_SELECTOR_OUT_OF_RANGE

Selector not within valid range for call.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

MQRC_SYSTEM_BAG_NOT_ALTERABLE

System bag is read only and cannot be altered.

MQRC_SYSTEM_ITEM_NOT_DELETABLE

System item is read only and cannot be deleted.

Usage notes for mqDeleteItem

1. Either a single occurrence of the specified selector can be removed, or all occurrences of the specified selector.
2. The call cannot remove system items from the bag, or remove items from a system bag. However, the call can remove the handle of a system bag from a user bag. This way, a system bag can be deleted.

C language invocation for mqDeleteItem

```
mqDeleteItem (Bag, Selector, ItemIndex, &CompCode, &Reason)
```

Declare the parameters as follows:

```
MQHBAG   Hbag;           /* Bag handle */
MQLONG   Selector;       /* Selector */
MQLONG   ItemIndex;      /* Index of the data item */
MQLONG   CompCode;       /* Completion code */
MQLONG   Reason;         /* Reason code qualifying CompCode */
```

Visual Basic invocation for mqDeleteItem

(Supported on Windows only.)

```
mqDeleteItem Bag, Selector, ItemIndex, CompCode, Reason
```

Declare the parameters as follows:

```
Dim Bag      As Long 'Bag handle'
Dim Selector As Long 'Selector'
Dim ItemIndex As Long 'Index of the data item'
Dim CompCode As Long 'Completion code'
Dim Reason   As Long 'Reason code qualifying CompCode'
```

Multi mqExecute

The mqExecute call sends an administration command message and waits for the reply (if expected).

Syntax for mqExecute

mqExecute (Hconn, Command, OptionsBag, AdminBag, ResponseBag, AdminQ, ResponseQ, CompCode, Reason)

Parameters for mqExecute

Hconn (MQHCONN) - input

MQI Connection handle.

This is returned by a preceding MQCONN call issued by the application.

Command (MQLONG) - input

The command to be executed.

This should be one of the MQCMD_* values. If it is a value that is not recognized by the MQAI servicing the mqExecute call, the value is still accepted. However, if mqAddInquiry was used to insert values in the bag, the **Command** parameter must be an INQUIRE command recognized by the MQAI; MQRC_INQUIRY_COMMAND_ERROR results if it is not.

OptionsBag (MQHBAG) - input

Handle of a bag containing options that affect the operation of the call.

This must be the handle returned by a preceding mqCreateBag call or the following special value:

MQHB_NONE

No options bag; all options assume their default values.

Only the options listed in this topic can be present in the options bag (MQRC_OPTIONS_ERROR results if other data items are present).

The appropriate default value is used for each option that is not present in the bag. The following option can be specified:

MQIACF_WAIT_INTERVAL

This data item specifies the maximum time in milliseconds that the MQAI should wait for each reply message. The time interval must be zero or greater, or the special value MQWI_UNLIMITED; the default is thirty seconds. The mqExecute call completes either when all of the reply messages are received or when the specified wait interval expires without the expected reply message having been received.

Note: The time interval is an approximate quantity.

If the MQIACF_WAIT_INTERVAL data item has the wrong data type, or there is more than one occurrence of that selector in the options bag, or the value of the data item is not valid, MQRC_WAIT_INTERVAL_ERROR results.

AdminBag (MQHBAG) - input

Handle of the bag containing details of the administration command to be issued.

All user items placed in the bag are inserted into the administration message that is sent. It is the application's responsibility to ensure that only valid parameters for the command are placed in the bag.

If the value of the MQIASY_TYPE data item in the command bag is not MQCFT_COMMAND, MQRC_COMMAND_TYPE_ERROR results. If the bag contains nested system bags, MQRC_NESTED_BAG_NOT_SUPPORTED results.

ResponseBag (MQHBAG) - input

Handle of the bag where reply messages are placed.

The MQAI performs an mqClearBag call on the bag before placing reply messages in the bag. To retrieve the reply messages, the selector, MQIACF_CONVERT_RESPONSE, can be specified.

Each reply message is placed into a separate system bag, with a handle that is then placed in the response bag. Use the mqInquireBag call with selector MQHA_BAG_HANDLE to determine the handles of the system bags within the reply bag, and those bags can then be inquired to determine their contents.

If some but not all of the expected reply messages are received, MQCC_WARNING with MQRC_NO_MSG_AVAILABLE results. If none of the expected reply messages is received, MQCC_FAILED with MQRC_NO_MSG_AVAILABLE results.

Group bags cannot be used as response bags.

AdminQ (MQHOBJ) - input

Object handle of the queue on which the administration message is to be placed.

This handle was returned by a preceding MQOPEN call issued by the application. The queue must be open for output.

The following special value can be specified:

MQHO_NONE

This indicates that the administration message should be placed on the SYSTEM.ADMIN.COMMAND.QUEUE belonging to the currently connected queue manager. If MQHO_NONE is specified, the application need not use MQOPEN to open the queue.

ResponseQ

Object handle of the queue on which reply messages are placed.

This handle was returned by a preceding MQOPEN call issued by the application. The queue must be open for input and for inquiry.

The following special value can be specified:

MQHO_NONE

This indicates that the reply messages should be placed on a dynamic queue created automatically by the MQAI. The queue is created by opening SYSTEM.DEFAULT.MODEL.QUEUE, that must therefore have suitable characteristics. The queue created exists for the duration of the call only, and is deleted by the MQAI on exit from the mqExecute call.

CompCode

Completion code.

Reason

Reason code qualifying *CompCode*.

The following reason codes indicating error conditions can be returned from the mqExecute call:

MQRC_*

Anything from the MQINQ, MQPUT, MQGET, or MQOPEN calls.

MQRC_BAG_WRONG_TYPE

Input data bag is a group bag.

MQRC_CMD_SERVER_NOT_AVAILABLE

The command server that processes administration commands is not available.

MQRC_COMMAND_TYPE_ERROR

The value of the MQIASY_TYPE data item in the request bag is not MQCFT_COMMAND.

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_INQUIRY_COMMAND_ERROR

mqAddInteger call used with a command code that is not a recognized INQUIRE command.

MQRC_NESTED_BAG_NOT_SUPPORTED

Input data bag contains one or more nested system bags.

MQRC_NO_MSG_AVAILABLE

Some reply messages received, but not all. Reply bag contains system-generated bags for messages that were received.

MQRC_NO_MSG_AVAILABLE

No reply messages received during the specified wait interval.

MQRC_OPTIONS_ERROR

Options bag contains unsupported data items, or a supported option has a value which is not valid.

MQRC_PARAMETER_MISSING

Administration message requires a parameter which is not present in the bag. This reason code occurs for bags created with the MQCBO_ADMIN_BAG or MQCBO_REORDER_AS_REQUIRED options only.

MQRC_SELECTOR_NOT_UNIQUE

Two or more instances of a selector exist within the bag for a mandatory parameter that permits one instance only.

MQRC_SELECTOR_WRONG_TYPE

mqAddString or mqSetString was used to add the MQIACF_INQUIRY selector to the bag.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

MQRCCF_COMMAND_FAILED

Command failed; details of failure are contained in system-generated bags within the reply bag.

Usage notes for mqExecute

1. If no *AdminQ* is specified, the MQAI checks to see if the command server is active before sending the administration command message. However, if the command server is not active, the MQAI does not start it. If you are sending many administration command messages, you are recommended to open the SYSTEM.ADMIN.COMMAND.QUEUE yourself and pass the handle of the administration queue on each administration request.
2. Specifying the MQHO_NONE value in the **ResponseQ** parameter simplifies the use of the mqExecute call, but if mqExecute is issued repeatedly by the application (for example, from within a loop), the response queue will be created and deleted repeatedly. In this situation, it is better for the application itself to open the response queue before any mqExecute call, and close it after all mqExecute calls have been issued.
3. If the administration command results in a message being sent with a message type of MQMT_REQUEST, the call waits for the time given by the MQIACF_WAIT_INTERVAL data item in the options bag.
4. If an error occurs during the processing of the call, the response bag might contain some data from the reply message, but the data will typically be incomplete.

C language invocation for mqExecute

```
mqExecute (Hconn, Command, OptionsBag, AdminBag, ResponseBag,
AdminQ, ResponseQ, CompCode, Reason);
```

Declare the parameters as follows:

```
MQHCONN  Hconn;           /* MQI connection handle */
MQLONG   Command;        /* Command to be executed */
MQHBAG   OptionsBag;     /* Handle of a bag containing options */
MQHBAG   AdminBag;       /* Handle of administration bag containing
                          /* details of administration command */
MQHBAG   ResponseBag;    /* Handle of bag for response messages */
MQHOBJ   AdminQ;         /* Handle of administration queue for
                          /* administration messages */
MQHOBJ   ResponseQ;      /* Handle of response queue for response
                          /* messages */
MQLONG   pCompCode;      /* Completion code */
MQLONG   pReason;        /* Reason code qualifying CompCode */
```

Visual Basic invocation for mqExecute

(Supported on Windows only.)

```
mqExecute (Hconn, Command, OptionsBag, AdminBag, ResponseBag,
AdminQ, ResponseQ, CompCode, Reason);
```

Declare the parameters as follows:

```

Dim HConn      As Long 'MQI connection handle'
Dim Command    As Long 'Command to be executed'
Dim OptionsBag As Long 'Handle of a bag containing options'
Dim AdminBag   As Long 'Handle of command bag containing details of
                        administration command'
Dim ResponseBag As Long 'Handle of bag for reply messages'
Dim AdminQ     As Long 'Handle of command queue for
                        administration messages'
Dim ResponseQ  As Long 'Handle of response queue for reply messages'
Dim CompCode   As Long 'Completion code'
Dim Reason     As Long 'Reason code qualifying CompCode'

```

Multi Example code for using the mqExecute call

Two code examples showing how to use mqExecute to create a local queue and to inquire about queue attributes.

Example: Using mqExecute to create a local queue

The following example creates a local queue, with a maximum message length of 100 bytes, on a queue manager:

```

/* Create a bag for the data you want in your PCF message */
mqCreateBag(MQCBO_ADMIN_BAG, &hbagRequest)

/* Create a bag to be filled with the response from the command server */
mqCreateBag(MQCBO_ADMIN_BAG, &hbagResponse)

/* Create a queue */
/* Supply queue name */
mqAddString(hbagRequest, MQCA_Q_NAME, "QBERT")

/* Supply queue type */
mqAddString(hbagRequest, MQIA_Q_TYPE, MQQT_LOCAL)

/* Maximum message length is an optional parameter */
mqAddString(hbagRequest, MQIA_MAX_MSG_LENGTH, 100)

/* Ask the command server to create the queue */
mqExecute(MQCMD_CREATE_Q, hbagRequest, hbagResponse)

/* Tidy up memory allocated */
mqDeleteBag(hbagRequest)
mqDeleteBag(hbagResponse)

```

Example: Using mqExecute to inquire about queue attributes

The following example inquires about all attributes of a particular queue. The mqAddInquiry call identifies all IBM MQ object attributes of a queue to be returned by the Inquire parameter on mqExecute:

```

/* Create a bag for the data you want in your PCF message */
mqCreateBag(MQCBO_ADMIN_BAG, &hbagRequest)

/* Create a bag to be filled with the response from the command server */
mqCreateBag(MQCBO_ADMIN_BAG, &hbagResponse)

/* Inquire about a queue by supplying its name */
/* (other parameters are optional) */
mqAddString(hbagRequest, MQCA_Q_NAME, "QBERT")

/* Request the command server to inquire about the queue */
mqExecute(MQCMD_INQUIRE_Q, hbagRequest, hbagResponse)

/* If it worked, the attributes of the queue are returned */
/* in a system bag within the response bag */
mqInquireBag(hbagResponse, MQHA_BAG_HANDLE, 0, &hbagAttributes)

/* Inquire the name of the queue and its current depth */
mqInquireString(hbagAttributes, MQCA_Q_NAME, &stringAttribute)
mqInquireString(hbagAttributes, MQIA_CURRENT_Q_DEPTH, &integerAttribute)

```

```
/* Tidy up memory allocated */  
mqDeleteBag(hbagRequest)  
mqDeleteBag(hbagResponse)
```

Using `mqExecute` is the simplest way of administering IBM MQ, but lower-level calls, `mqBagToBuffer` and `mqBufferToBag`, can be used. For more information about the use of these calls, see [Using the MQAI to simplify the use of PCFs](#).

mqGetBag

The `mqGetBag` call removes a message from the specified queue and converts the message data into a data bag.

Syntax for `mqGetBag`

`mqGetBag (Hconn, Hobj, MsgDesc, GetMsgOpts, HBag, CompCode, Reason)`

Parameters for `mqGetBag`

Hconn (MQHCONN) - input

MQI connection handle.

Hobj (MQHOBJ) - input

Object handle of the queue from which the message is to be retrieved. This handle was returned by a preceding `MQOPEN` call issued by the application. The queue must be open for input.

MsgDesc (MQMD) - input/output

Message descriptor (for more information, see [MQMD - Message descriptor](#)).

If the *Format* field in the message has a value other than `MQFMT_ADMIN`, `MQFMT_EVENT`, or `MQFMT_PCF`, `MQRC_FORMAT_NOT_SUPPORTED` results.

If, on entry to the call, the *Encoding* field in the application's `MQMD` has a value other than `MQENC_NATIVE` and `MQGMO_CONVERT` is specified, `MQRC_ENCODING_NOT_SUPPORTED` results. Also, if `MQGMO_CONVERT` is not specified, the value of the **Encoding** parameter must be the retrieving application's `MQENC_NATIVE`; if not, again `MQRC_ENCODING_NOT_SUPPORTED` results.

GetMsgOpts (MQGMO) - input/output

Get-message options (for more information, see [MQGMO - Get-message options](#)).

`MQGMO_ACCEPT_TRUNCATED_MSG` cannot be specified; `MQRC_OPTIONS_ERROR` results if it is. `MQGMO_LOCK` and `MQGMO_UNLOCK` are not supported in a 16-bit or 32-bit Window environment. `MQGMO_SET_SIGNAL` is supported in a 32-bit Window environment only.

HBag (MQHBAG) - input/output

Handle of a bag into which the retrieved message is placed. The MQAI performs an `mqClearBag` call on the bag before placing the message in the bag.

MQHB_NONE

Gets the retrieved message. This provides a means of deleting messages from the queue.

If an option of `MQGMO_BROWSE_*` is specified, this value sets the browse cursor to the selected message; it is not deleted in this case.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating warning and error conditions can be returned from the `mqGetBag` call:

MQRC_*

Anything from the MQGET call or bag manipulation.

MQRC_BAG_CONVERSION_ERROR

Data could not be converted into a bag.

This indicates a problem with the format of the data to be converted into a bag (for example, the message is not a valid PCF).

If the message was retrieved destructively from the queue (that is, not browsing the queue), this reason code indicates that it has been discarded.

MQRC_BAG_WRONG_TYPE

Input data bag is a group bag.

MQRC_ENCODING_NOT_SUPPORTED

Encoding not supported; the value in the *Encoding* field of the MQMD must be MQENC_NATIVE.

MQRC_FORMAT_NOT_SUPPORTED

Format not supported; the *Format* name in the message is not MQFMT_ADMIN, MQFMT_EVENT, or MQFMT_PCF. If the message was retrieved destructively from the queue (that is, not browsing the queue), this reason code indicates that it has been discarded.

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_INCONSISTENT_ITEM_TYPE

Data type of second occurrence of selector differs from data type of first occurrence.

MQRC_SELECTOR_OUT_OF_RANGE

Selector not within valid range for call.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

MQRC_SYSTEM_BAG_NOT_ALTERABLE

System bag cannot be altered or deleted.

Usage notes for `mqGetBag`

1. Only messages that have a supported format can be returned by this call. If the message has a format that is not supported, the message is discarded, and the call completes with an appropriate reason code.
2. If the message is retrieved within a unit of work (that is, with the MQGMO_SYNCPOINT option), and the message has an unsupported format, the unit of work can be backed out, reinstating the message on the queue. This allows the message to be retrieved by using the MQGET call in place of the `mqGetBag` call.

C language invocation for `mqGetBag`

```
mqGetBag (hConn, hObj, &MsgDesc, &GetMsgOpts, hBag, CompCode, Reason);
```

Declare the parameters as follows:

```
MQHCONN  hConn;          /* MQI connection handle */
MQHOBJ   hObj;          /* Object handle */
MQMD     MsgDesc;       /* Message descriptor */
MQGMO    GetMsgOpts;    /* Get-message options */
MQHBAG   hBag;         /* Bag handle */
MQLONG   CompCode;     /* Completion code */
MQLONG   Reason;       /* Reason code qualifying CompCode */
```

Visual Basic invocation for mqGetBag

(Supported on Windows only.)

```
mqGetBag (HConn, HObj, MsgDesc, GetMsgOpts, Bag, CompCode, Reason);
```

Declare the parameters as follows:

```
Dim HConn      As Long 'MQI connection handle'  
Dim HObj       As Long 'Object handle'  
Dim MsgDesc    As Long 'Message descriptor'  
Dim GetMsgOpts As Long 'Get-message options'  
Dim Bag        As Long 'Bag handle'  
Dim CompCode   As Long 'Completion code'  
Dim Reason     As Long 'Reason code qualifying CompCode'
```

Multi

mqInquireBag

The mqInquireBag call inquires the value of a bag handle that is present in the bag. The data item can be a user item or a system item.

Syntax for mqInquireBag

mqInquireBag (*Bag*, *Selector*, *ItemIndex*, *ItemValue*, *CompCode*, *Reason*)

Parameters for mqInquireBag

Bag (MQHBAG) - input

Bag handle to be inquired. The bag can be a user bag or a system bag.

Selector (MQLONG) - input

Selector identifying the item to be inquired.

If the selector is less than zero (that is, a system selector), the selector must be one that is supported by the MQAI; MQRC_SELECTOR_NOT_SUPPORTED results if it is not.

The specified selector must be present in the bag; MQRC_SELECTOR_NOT_PRESENT results if it is not.

The data type of the item must agree with the data type implied by the call; MQRC_SELECTOR_WRONG_TYPE results if it is not.

The following special values can be specified for **Selector**:

MQSEL_ANY_SELECTOR

The item to be inquired is a user or system item identified by the **ItemIndex** parameter.

MQSEL_ANY_USER_SELECTOR

The item to be inquired is a user item identified by the **ItemIndex** parameter.

MQSEL_ANY_SYSTEM_SELECTOR

The item to be inquired is a system item identified by the **ItemIndex** parameter.

ItemIndex (MQLONG) - input

Index of the data item to be inquired.

The value must be zero or greater, or the special value MQIND_NONE. If the value is less than zero and not MQIND_NONE, MQRC_INDEX_ERROR results. If the item is not already present in the bag, MQRC_INDEX_NOT_PRESENT results.

The following special value can be specified:

MQIND_NONE

This specifies that there must be one occurrence only of the selector in the bag. If there is more than one occurrence, MQRC_SELECTOR_NOT_UNIQUE results.

If MQSEL_ANY_SELECTOR is specified for the **Selector** parameter, the **ItemIndex** parameter is the index relative to the set of items that contains both user items and system items, and must be zero or greater.

If MQSEL_ANY_USER_SELECTOR is specified for the **Selector** parameter, the **ItemIndex** parameter is the index relative to the set of system items, and must be zero or greater.

If MQSEL_ANY_SYSTEM_SELECTOR is specified for the **Selector** parameter, the **ItemIndex** parameter is the index relative to the set of system items, and must be zero or greater.

If an explicit selector value is specified, the **ItemIndex** parameter is the index relative to the set of items that have that selector value and can be MQIND_NONE, zero, or greater.

ItemValue (MQHBAG) - output

Value of the item in the bag.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating error conditions can be returned from the mqInquireBag call:

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_INDEX_ERROR

Index not valid (index negative and not MQIND_NONE, or MQIND_NONE specified with one of the MQSEL_ANY_xxx_SELECTOR values).

MQRC_INDEX_NOT_PRESENT

No item with the specified index is present within the bag for the selector given.

MQRC_ITEM_VALUE_ERROR

The **ItemValue** parameter is not valid (invalid parameter address).

MQRC_SELECTOR_NOT_PRESENT

No item with the specified selector is present within the bag.

MQRC_SELECTOR_NOT_SUPPORTED

Specified system selector not supported by the MQAI.

MQRC_SELECTOR_NOT_UNIQUE

MQIND_NONE specified when more than one occurrence of the specified selector is present within the bag.

MQRC_SELECTOR_OUT_OF_RANGE

Selector not within valid range for call.

MQRC_SELECTOR_WRONG_TYPE

Data item has wrong data type for call.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

C language invocation for mqInquireBag

```
mqInquireBag (Bag, Selector, ItemIndex, &ItemValue, &CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHBAG   Bag;           /* Bag handle */
MQLONG   Selector;      /* Selector */
MQLONG   ItemIndex;     /* Index of the data item to be inquired */
MQHBAG   ItemValue;     /* Value of item in the bag */
MQLONG   CompCode;     /* Completion code */
MQLONG   Reason;       /* Reason code qualifying CompCode */
```

Visual Basic invocation for mqInquireBag

(Supported on Windows only.)

```
mqInquireBag (Bag, Selector, ItemIndex, ItemValue, CompCode, Reason
```

Declare the parameters as follows:

```
Dim Bag      As Long 'Bag handle'
Dim Selector As Long 'Selector'
Dim ItemIndex As Long 'Index of the data item to be inquired'
Dim ItemValue As Long 'Value of item in the bag'
Dim CompCode As Long 'Completion code'
Dim Reason   As Long 'Reason code qualifying CompCode'
```

mqInquireByteString

The mqInquireByteString call requests the value of a byte string data item that is present in the bag. The data item can be a user item or a system item.

Syntax for mqInquireByteString

mqInquireByteString (*Bag, Selector, ItemIndex, Bufferlength, Buffer, ByteStringLength, CompCode, Reason*)

Parameters for mqInquireByteString

Bag (MQHBAG) - input

Handle of the bag to which the inquiry relates. The bag can be a user bag or a system bag.

Selector (MQLONG) - input

Selector of the item to which the inquiry relates.

If the selector is less than zero (that is, a system selector), the selector must be one that is supported by the MQAI; MQRC_SELECTOR_NOT_SUPPORTED results if it is not.

The specified selector must be present in the bag; MQRC_SELECTOR_NOT_PRESENT results if it is not.

The data type of the item must be the same as the data type implied by the call; MQRC_SELECTOR_WRONG_TYPE results if it is not.

The following special values can be specified for *Selector*:

MQSEL_ANY_SELECTOR

The item to be inquired about is a user or system item identified by *ItemIndex*.

MQSEL_ANY_USER_SELECTOR

The item to be inquired about is a user item identified by *ItemIndex*.

MQSEL_ANY_SYSTEM_SELECTOR

The item to be inquired about is a system item identified by *ItemIndex*.

ItemIndex (MQLONG) - input

Index of the data item to which the inquiry relates. The value must be zero or greater, or the special value MQIND_NONE. If the value is less than zero and not MQIND_NONE, MQRC_INDEX_ERROR results. If the item is not already present in the bag, MQRC_INDEX_NOT_PRESENT results. The following special value can be specified:

MQIND_NONE

This specifies that there must be one occurrence only of the selector in the bag. If there is more than one occurrence, MQRC_SELECTOR_NOT_UNIQUE results.

If MQSEL_ANY_SELECTOR is specified for the **Selector** parameter, **ItemIndex** is the index relative to the set of items that contains both user items and system items, and must be zero or greater.

If MQSEL_ANY_USER_SELECTOR is specified for the **Selector** parameter, **ItemIndex** is the index relative to the set of user items, and must be zero or greater.

If MQSEL_ANY_SYSTEM_SELECTOR is specified for **Selector**, **ItemIndex** is the index relative to the set of system items, and must be zero or greater.

If an explicit selector value is specified, **ItemIndex** is the index relative to the set of items that have that selector value, and can be MQIND_NONE, zero, or greater.

BufferLength (MQLONG) - input

Length in bytes of the buffer to receive the byte string. Zero is a valid value.

Buffer (MQBYTE x BufferLength) - output

Buffer to receive the byte string. The length is given by the **BufferLength** parameter. If zero is specified for **BufferLength**, the null pointer can be specified for the address of the **Buffer** parameter; in all other cases, a valid (non-null) address must be specified for the **Buffer** parameter.

The string is padded with nulls to the length of the buffer. If the string is longer than the buffer, the string is truncated to fit; in this case *ByteStringLength* indicates the size of the buffer needed to accommodate the string without truncation.

ByteStringLength (MQLONG) - output

The length in bytes of the string contained in the bag. If the **Buffer** parameter is too small, the length of the string returned is less than *ByteStringLength*.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating error and warning conditions can be returned from the mqInquireByteString call:

MQRC_BUFFER_ERROR

Buffer parameter not valid (invalid parameter address or buffer not completely accessible).

MQRC_BUFFER_LENGTH_ERROR

Buffer length not valid.

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_INDEX_ERROR

Index not valid (index negative and not MQIND_NONE, or MQIND_NONE specified with one of the MQSEL_ANY_XXX_SELECTOR values).

MQRC_INDEX_NOT_PRESENT

No item with the specified index is present within the bag for the selector given.

MQRC_SELECTOR_NOT_PRESENT

No item with the specified selector is present within the bag.

MQRC_SELECTOR_NOT_SUPPORTED

Specified system selector not supported by the MQAI.

MQRC_SELECTOR_NOT_UNIQUE

MQIND_NONE specified when more than one occurrence of the specified selector is present in the bag.

MQRC_SELECTOR_OUT_OF_RANGE

Selector not within valid range for call.

MQRC_SELECTOR_WRONG_TYPE

Data item has wrong data type for call.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

MQRC_STRING_LENGTH_ERROR

ByteStringLength parameter not valid (invalid parameter address).

MQRC_STRING_TRUNCATED

Data too long for output buffer and has been truncated.

C language invocation for mqInquireByteString

```
mqInquireByteString (Bag, Selector, ItemIndex,
  BufferLength, Buffer, &StringLength, &CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHBAG   Bag;           /* Bag handle */
MQLONG   Selector;      /* Selector */
MQLONG   ItemIndex;     /* Item index */
MQLONG   BufferLength;  /* Buffer length */
PMQBYTE  Buffer;        /* Buffer to contain string */
MQLONG   ByteStringLength; /* Length of byte string returned */
MQLONG   CompCode;     /* Completion code */
MQLONG   Reason;       /* Reason code qualifying CompCode */
```

Visual Basic invocation for mqInquireByteString

(Supported on Windows only.)

```
mqInquireByteString Bag, Selector, ItemIndex,
  BufferLength, Buffer, StringLength, CompCode, Reason
```

Declare the parameters as follows:

```
Dim Bag           As Long   'Bag handle'
Dim Selector      As Long   'Selector'
Dim ItemIndex     As Long   'Item index'
```

Dim BufferLength	As Long	'Buffer length'
Dim Buffer	As Byte	'Buffer to contain string'
Dim ByteStringLength	As Long	'Length of byte string returned'
Dim CompCode	As Long	'Completion code'
Dim Reason	As Long	'Reason code qualifying CompCode'

Multi **mqInquireByteStringFilter**

The `mqInquireByteStringFilter` call requests the value and operator of a byte string filter item that is present in the bag. The data item can be a user item or a system item.

Syntax for `mqInquireByteStringFilter`

`mqInquireByteStringFilter` (*Bag*, *Selector*, *ItemIndex*, *Bufferlength*, *Buffer*, *ByteStringLength*, *Operator*, *CompCode*, *Reason*)

Parameters for `mqInquireByteStringFilter`

Bag (MQHBAG) - input

Handle of the bag to which the inquiry relates. The bag can be a user bag or a system bag.

Selector (MQLONG) - input

Selector of the item to which the inquiry relates.

If the selector is less than zero (that is, a system selector), the selector must be one that is supported by the MQAI; MQRC_SELECTOR_NOT_SUPPORTED results if it is not.

The specified selector must be present in the bag; MQRC_SELECTOR_NOT_PRESENT results if it is not.

The data type of the item must be the same as the data type implied by the call; MQRC_SELECTOR_WRONG_TYPE results if it is not.

The following special values can be specified for *Selector*:

MQSEL_ANY_SELECTOR

The item to be inquired about is a user or system item identified by *ItemIndex*.

MQSEL_ANY_USER_SELECTOR

The item to be inquired about is a user item identified by *ItemIndex*.

MQSEL_ANY_SYSTEM_SELECTOR

The item to be inquired about is a system item identified by *ItemIndex*.

ItemIndex (MQLONG) - input

Index of the data item to which the inquiry relates. The value must be zero or greater, or the special value MQIND_NONE. If the value is less than zero and not MQIND_NONE, MQRC_INDEX_ERROR results. If the item is not already present in the bag, MQRC_INDEX_NOT_PRESENT results. The following special value can be specified:

MQIND_NONE

This specifies that there must be one occurrence only of the selector in the bag. If there is more than one occurrence, MQRC_SELECTOR_NOT_UNIQUE results.

If MQSEL_ANY_SELECTOR is specified for the **Selector** parameter, **ItemIndex** is the index relative to the set of items that contains both user items and system items, and must be zero or greater.

If MQSEL_ANY_USER_SELECTOR is specified for the **Selector** parameter, **ItemIndex** is the index relative to the set of user items, and must be zero or greater.

If MQSEL_ANY_SYSTEM_SELECTOR is specified for **Selector**, **ItemIndex** is the index relative to the set of system items, and must be zero or greater.

If an explicit selector value is specified, **ItemIndex** is the index relative to the set of items that have that selector value, and can be MQIND_NONE, zero, or greater.

BufferLength (MQLONG) - input

Length in bytes of the buffer to receive the condition byte string. Zero is a valid value.

Buffer (MQBYTE x BufferLength) - output

Buffer to receive the condition byte string. The length is given by the **BufferLength** parameter. If zero is specified for **BufferLength**, the null pointer can be specified for the address of the **Buffer** parameter; in all other cases, a valid (non-null) address must be specified for the **Buffer** parameter.

The string is padded with blanks to the length of the buffer; the string is not null-terminated. If the string is longer than the buffer, the string is truncated to fit; in this case **ByteStringLength** indicates the size of the buffer needed to accommodate the string without truncation.

ByteStringLength (MQLONG) - output

The length in bytes of the condition string contained in the bag. If the **Buffer** parameter is too small, the length of the string returned is less than **StringLength**.

Operator (MQLONG) - output

Byte string filter operator in the bag.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating error and warning conditions can be returned from the mqInquireByteStringFilter call:

MQRC_BUFFER_ERROR

Buffer parameter not valid (invalid parameter address or buffer not completely accessible).

MQRC_BUFFER_LENGTH_ERROR

Buffer length not valid.

MQRC_FILTER_OPERATOR_ERROR

Filter operator not valid.

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_INDEX_ERROR

Index not valid (index negative and not MQIND_NONE, or MQIND_NONE specified with one of the MQSEL_ANY_xxx_SELECTOR values).

MQRC_INDEX_NOT_PRESENT

No item with the specified index is present within the bag for the selector given.

MQRC_SELECTOR_NOT_PRESENT

No item with the specified selector is present within the bag.

MQRC_SELECTOR_NOT_SUPPORTED

Specified system selector not supported by the MQAI.

MQRC_SELECTOR_NOT_UNIQUE

MQIND_NONE specified when more than one occurrence of the specified selector is present in the bag.

MQRC_SELECTOR_OUT_OF_RANGE

Selector not within valid range for call.

MQRC_SELECTOR_WRONG_TYPE

Data item has wrong data type for call.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

MQRC_STRING_LENGTH_ERROR

ByteStringLength parameter not valid (invalid parameter address).

MQRC_STRING_TRUNCATED

Data too long for output buffer and has been truncated.

C language invocation for mqInquireByteStringFilter

```
mqInquireByteStringFilter (Bag, Selector, ItemIndex,
    BufferLength, Buffer, &ByteStringLength, &Operator, &CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHBAG   Bag;           /* Bag handle */
MQLONG   Selector;      /* Selector */
MQLONG   ItemIndex;     /* Item index */
MQLONG   BufferLength;  /* Buffer length */
PMQBYTE  Buffer;         /* Buffer to contain string */
MQLONG   ByteStringLength; /* Length of string returned */
MQLONG   Operator;     /* Item operator */
PMQLONG  CompCode;     /* Completion code */
PMQLONG  Reason;       /* Reason code qualifying CompCode */
```

Visual Basic invocation for mqInquireByteStringFilter

(Supported on Windows only.)

```
mqInquireByteStringFilter Bag, Selector, ItemIndex,
    BufferLength, Buffer, ByteStringLength,
    Operator, CompCode, Reason
```

Declare the parameters as follows:

```
Dim Bag           As Long   'Bag handle'
Dim Selector      As Long   'Selector'
Dim ItemIndex     As Long   'Item index'
Dim BufferLength  As Long   'Buffer length'
Dim Buffer        As String  'Buffer to contain string'
Dim ByteStringLength As Long 'Length of byte string returned'
Dim Operator      As Long   'Operator'
Dim CompCode     As Long   'Completion code'
Dim Reason       As Long   'Reason code qualifying CompCode'
```

mqInquireInteger

The `mqInquireInteger` call requests the value of an integer data item that is present in the bag. The data item can be a user item or a system item.

Syntax for mqInquireInteger

mqInquireInteger (*Bag, Selector, ItemIndex, ItemValue, CompCode, Reason*)

Parameters for mqInquireInteger

Bag (MQHBAG) - input

Handle of the bag to which the inquiry relates. The bag can be a user bag or a system bag.

Selector (MQLONG) - input

Selector identifying the item to which the inquiry relates.

If the selector is less than zero (a system selector), the selector must be one that is supported by the MQAI; MQRC_SELECTOR_NOT_SUPPORTED results if it is not.

The specified selector must be present in the bag; MQRC_SELECTOR_NOT_PRESENT results if it is not.

The data type of the item must agree with the data type implied by the call; MQRC_SELECTOR_WRONG_TYPE results if it is not.

The following special values can be specified for *Selector*:

MQSEL_ANY_SELECTOR

The item to be inquired about is a user or system item identified by *ItemIndex*.

MQSEL_ANY_USER_SELECTOR

The item to be inquired about is a user item identified by *ItemIndex*.

MQSEL_ANY_SYSTEM_SELECTOR

The item to be inquired about is a system item identified by *ItemIndex*.

ItemIndex (MQLONG) - input

Index of the data item to which the inquiry relates. The value must be zero or greater, or the special value MQIND_NONE. If the value is less than zero and is not MQIND_NONE, MQRC_INDEX_ERROR results. If the item is not already present in the bag, MQRC_INDEX_NOT_PRESENT results. The following special value can be specified:

MQIND_NONE

This specifies that there must be one occurrence only of the selector in the bag. If there is more than one occurrence, MQRC_SELECTOR_NOT_UNIQUE results.

If MQSEL_ANY_SELECTOR is specified for *Selector*, *ItemIndex* is the index relative to the set of items that contains both user items and system items, and must be zero or greater.

If MQSEL_ANY_USER_SELECTOR is specified for *Selector*, *ItemIndex* is the index relative to the set of user items, and must be zero or greater.

If MQSEL_ANY_SYSTEM_SELECTOR is specified for *Selector*, *ItemIndex* is the index relative to the set of system items, and must be zero or greater.

If an explicit selector value is specified, *ItemIndex* is the index relative to the set of items that have that selector value, and can be MQIND_NONE, zero, or greater.

ItemValue (MQLONG) - output

The value of the item in the bag.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating error conditions can be returned from the mqInquireInteger call:

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_INDEX_ERROR

Index not valid (index negative and not MQIND_NONE, or MQIND_NONE specified with one of the MQSEL_ANY_XXX_SELECTOR values).

MQRC_INDEX_NOT_PRESENT

No item with the specified index is present within the bag for the selector given.

MQRC_ITEM_VALUE_ERROR

ItemValue parameter not valid (invalid parameter address).

MQRC_SELECTOR_NOT_PRESENT

No item with the specified selector is present within the bag.

MQRC_SELECTOR_NOT_SUPPORTED

Specified system selector not supported by the MQAI.

MQRC_SELECTOR_NOT_UNIQUE

MQIND_NONE specified when more than one occurrence of the specified selector is present in the bag.

MQRC_SELECTOR_OUT_OF_RANGE

Selector not within valid range for call.

MQRC_SELECTOR_WRONG_TYPE

Data item has wrong data type for call.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

C language invocation for mqInquireInteger

```
mqInquireInteger (Bag, Selector, ItemIndex, &ItemValue,
&CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHBAG   Bag;           /* Bag handle */
MQLONG   Selector;      /* Selector */
MQLONG   ItemIndex;     /* Item index */
MQLONG   ItemValue;     /* Item value */
MQLONG   CompCode;      /* Completion code */
MQLONG   Reason;        /* Reason code qualifying CompCode */
```

Visual Basic invocation for mqInquireInteger

(Supported on Windows only.)

```
mqInquireInteger Bag, Selector, ItemIndex, ItemValue,
CompCode, Reason
```

Declare the parameters as follows:

```
Dim Bag       As Long 'Bag handle'
Dim Selector  As Long 'Selector'
Dim ItemIndex As Long 'Item index'
Dim ItemValue As Long 'Item value'
Dim CompCode  As Long 'Completion code'
Dim Reason    As Long 'Reason code qualifying CompCode'
```

mqInquireInteger64

The `mqInquireInteger64` call requests the value of a 64-bit integer data item that is present in the bag. The data item can be a user item or a system item.

Syntax for `mqInquireInteger64`

`mqInquireInteger64` (*Bag*, *Selector*, *ItemIndex*, *ItemValue*, *CompCode*, *Reason*)

Parameters for `mqInquireInteger64`

Bag (MQHBAG) - input

Handle of the bag to which the inquiry relates. The bag can be a user bag or a system bag.

Selector (MQLONG) - input

Selector identifying the item to which the inquiry relates.

If the selector is less than zero (a system selector), the selector must be one that is supported by the MQAI; MQRC_SELECTOR_NOT_SUPPORTED results if it is not.

The specified selector must be present in the bag; MQRC_SELECTOR_NOT_PRESENT results if it is not.

The data type of the item must agree with the data type implied by the call; MQRC_SELECTOR_WRONG_TYPE results if it is not.

The following special values can be specified for *Selector*:

MQSEL_ANY_SELECTOR

The item to be inquired about is a user or system item identified by *ItemIndex*.

MQSEL_ANY_USER_SELECTOR

The item to be inquired about is a user item identified by *ItemIndex*.

MQSEL_ANY_SYSTEM_SELECTOR

The item to be inquired about is a system item identified by *ItemIndex*.

ItemIndex (MQLONG) - input

Index of the data item to which the inquiry relates. The value must be zero or greater, or the special value MQIND_NONE. If the value is less than zero and is not MQIND_NONE, MQRC_INDEX_ERROR results. If the item is not already present in the bag, MQRC_INDEX_NOT_PRESENT results. The following special value can be specified:

MQIND_NONE

This specifies that there must be one occurrence only of the selector in the bag. If there is more than one occurrence, MQRC_SELECTOR_NOT_UNIQUE results.

If MQSEL_ANY_SELECTOR is specified for *Selector*, *ItemIndex* is the index relative to the set of items that contains both user items and system items, and must be zero or greater.

If MQSEL_ANY_USER_SELECTOR is specified for *Selector*, *ItemIndex* is the index relative to the set of user items, and must be zero or greater.

If MQSEL_ANY_SYSTEM_SELECTOR is specified for *Selector*, *ItemIndex* is the index relative to the set of system items, and must be zero or greater.

If an explicit selector value is specified, *ItemIndex* is the index relative to the set of items that have that selector value, and can be MQIND_NONE, zero, or greater.

ItemValue (MQINT64) - output

The value of the item in the bag.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating error conditions can be returned from the `mqInquireInteger64` call:

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_INDEX_ERROR

Index not valid (index negative and not `MQIND_NONE`, or `MQIND_NONE` specified with one of the `MQSEL_ANY_xxx_SELECTOR` values).

MQRC_INDEX_NOT_PRESENT

No item with the specified index is present within the bag for the selector given.

MQRC_ITEM_VALUE_ERROR

`ItemValue` parameter not valid (invalid parameter address).

MQRC_SELECTOR_NOT_PRESENT

No item with the specified selector is present within the bag.

MQRC_SELECTOR_NOT_SUPPORTED

Specified system selector not supported by the MQAI.

MQRC_SELECTOR_NOT_UNIQUE

`MQIND_NONE` specified when more than one occurrence of the specified selector is present in the bag.

MQRC_SELECTOR_OUT_OF_RANGE

Selector not within valid range for call.

MQRC_SELECTOR_WRONG_TYPE

Data item has wrong data type for call.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

C language invocation for `mqInquireInteger64`

```
mqInquireInteger64 (Bag, Selector, ItemIndex, &ItemValue,  
&CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHBAG    Bag;           /* Bag handle */  
MQLONG    Selector;      /* Selector */  
MQLONG    ItemIndex;     /* Item index */  
MQINT64   ItemValue;     /* Item value */  
MQLONG    CompCode;      /* Completion code */  
MQLONG    Reason;        /* Reason code qualifying CompCode */
```

Visual Basic invocation for `mqInquireInteger64`

(Supported on Windows only.)

```
mqInquireInteger64 Bag, Selector, ItemIndex, ItemValue,  
CompCode, Reason
```

Declare the parameters as follows:

```
Dim Bag      As Long 'Bag handle'  
Dim Selector As Long 'Selector'
```

```
Dim ItemIndex As Long 'Item index'  
Dim ItemValue As Long 'Item value'  
Dim CompCode As Long 'Completion code'  
Dim Reason As Long 'Reason code qualifying CompCode'
```

Multi **mqInquireIntegerFilter**

The `mqInquireIntegerFilter` call requests the value and operator of an integer filter item that is present in the bag. The data item can be a user item or a system item.

Syntax for `mqInquireIntegerFilter`

`mqInquireIntegerFilter (Bag, Selector, ItemIndex, ItemValue, Operator, CompCode, Reason)`

Parameters for `mqInquireIntegerFilter`

Bag (MQHBAG) - input

Handle of the bag to which the inquiry relates. The bag can be a user bag or a system bag.

Selector (MQLONG) - input

Selector identifying the item to which the inquiry relates.

If the selector is less than zero (a system selector), the selector must be one that is supported by the MQAI; MQRC_SELECTOR_NOT_SUPPORTED results if it is not.

The specified selector must be present in the bag; MQRC_SELECTOR_NOT_PRESENT results if it is not.

The data type of the item must agree with the data type implied by the call; MQRC_SELECTOR_WRONG_TYPE results if it is not.

The following special values can be specified for *Selector*:

MQSEL_ANY_SELECTOR

The item to be inquired about is a user or system item identified by *ItemIndex*.

MQSEL_ANY_USER_SELECTOR

The item to be inquired about is a user item identified by *ItemIndex*.

MQSEL_ANY_SYSTEM_SELECTOR

The item to be inquired about is a system item identified by *ItemIndex*.

ItemIndex (MQLONG) - input

Index of the data item to which the inquiry relates. The value must be zero or greater, or the special value MQIND_NONE. If the value is less than zero and is not MQIND_NONE, MQRC_INDEX_ERROR results. If the item is not already present in the bag, MQRC_INDEX_NOT_PRESENT results. The following special value can be specified:

MQIND_NONE

This specifies that there must be one occurrence only of the selector in the bag. If there is more than one occurrence, MQRC_SELECTOR_NOT_UNIQUE results.

If MQSEL_ANY_SELECTOR is specified for *Selector*, *ItemIndex* is the index relative to the set of items that contains both user items and system items, and must be zero or greater.

If MQSEL_ANY_USER_SELECTOR is specified for *Selector*, *ItemIndex* is the index relative to the set of user items, and must be zero or greater.

If MQSEL_ANY_SYSTEM_SELECTOR is specified for *Selector*, *ItemIndex* is the index relative to the set of system items, and must be zero or greater.

If an explicit selector value is specified, *ItemIndex* is the index relative to the set of items that have that selector value, and can be MQIND_NONE, zero, or greater.

ItemValue (MQLONG) - output

The condition value.

Operator (MQLONG) - output

Integer filter operator in the bag.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating error conditions can be returned from the mqInquireIntegerFilter call:

MQRC_FILTER_OPERATOR_ERROR

Filter operator not valid.

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_INDEX_ERROR

Index not valid (index negative and not MQIND_NONE, or MQIND_NONE specified with one of the MQSEL_ANY_xxx_SELECTOR values).

MQRC_INDEX_NOT_PRESENT

No item with the specified index is present within the bag for the selector given.

MQRC_ITEM_VALUE_ERROR

ItemValue parameter not valid (invalid parameter address).

MQRC_SELECTOR_NOT_PRESENT

No item with the specified selector is present within the bag.

MQRC_SELECTOR_NOT_SUPPORTED

Specified system selector not supported by the MQAI.

MQRC_SELECTOR_NOT_UNIQUE

MQIND_NONE specified when more than one occurrence of the specified selector is present in the bag.

MQRC_SELECTOR_OUT_OF_RANGE

Selector not within valid range for call.

MQRC_SELECTOR_WRONG_TYPE

Data item has wrong data type for call.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

C language invocation for mqInquireIntegerFilter

```
mqInquireIntegerFilter (Bag, Selector, ItemIndex, &ItemValue,  
&Operator, &CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHBAG   Bag;           /* Bag handle */  
MQLONG   Selector;     /* Selector */  
MQLONG   ItemIndex;    /* Item index */  
MQLONG   ItemValue;    /* Item value */  
MQLONG   Operator;     /* Item operator */
```

```
MQLONG  CompCode;      /* Completion code */
MQLONG  Reason;        /* Reason code qualifying CompCode */
```

Visual Basic invocation for mqInquireIntegerFilter

(Supported on Windows only.)

```
mqInquireIntegerFilter Bag, Selector, ItemIndex, ItemValue,
Operator, CompCode, Reason
```

Declare the parameters as follows:

```
Dim Bag      As Long 'Bag handle'
Dim Selector As Long 'Selector'
Dim ItemIndex As Long 'Item index'
Dim ItemValue As Long 'Item value'
Dim Operator As Long 'Item operator'
Dim CompCode As Long 'Completion code'
Dim Reason   As Long 'Reason code qualifying CompCode'
```

Multi

mqInquireItemInfo

The mqInquireItemInfo call returns information about a specified item in a bag. The data item can be a user item or a system item.

Syntax for mqInquireItemInfo

mqInquireItemInfo (*Bag, Selector, ItemIndex, ItemType, OutSelector, CompCode, Reason*)

Parameters for mqInquireItemInfo

Bag (MQHBAG) - input

Handle of the bag to be inquired.

The bag can be a user bag or a system bag.

Selector (MQLONG) - input

Selector identifying the item to be inquired.

If the selector is less than zero (that is, a system selector), the selector must be one that is supported by the MQAI; MQRC_SELECTOR_NOT_SUPPORTED results if it is not.

The specified selector must be present in the bag; MQRC_SELECTOR_NOT_PRESENT results if it is not.

The following special values can be specified for **Selector**:

MQSEL_ANY_SELECTOR

The item to be inquired is a user or system item identified by the **ItemIndex** parameter.

MQSEL_ANY_USER_SELECTOR

The item to be inquired is a user item identified by the **ItemIndex** parameter.

MQSEL_ANY_SYSTEM_SELECTOR

The item to be inquired is a system item identified by the **ItemIndex** parameter.

ItemIndex (MQLONG) - input

Index of the data item to be inquired.

The item must be present within the bag; MQRC_INDEX_NOT_PRESENT results if it is not. The value must be zero or greater, or the following special value:

MQIND_NONE

This specifies that there must be one occurrence only of the selector in the bag. If there is more than one occurrence, MQRC_SELECTOR_NOT_UNIQUE results.

If MQSEL_ANY_SELECTOR is specified for the **Selector** parameter, the **ItemIndex** parameter is the index relative to the set of items that contains both user items and system items, and must be zero or greater.

If MQSEL_ANY_USER_SELECTOR is specified for the **Selector** parameter, the **ItemIndex** parameter is the index relative to the set of system items, and must be zero or greater.

If MQSEL_ANY_SYSTEM_SELECTOR is specified for the **Selector** parameter, the **ItemIndex** parameter is the index relative to the set of system items, and must be zero or greater. If an explicit selector value is specified, the **ItemIndex** parameter is the index relative to the set of items that have that selector value and can be MQIND_NONE, zero, or greater.

ItemType (MQLONG) - output

The data type of the specified data item.

The following can be returned:

MQITEM_BAG

Bag handle item.

MQITEM_BYTE_STRING

Byte string.

MQITEM_INTEGER

Integer item.

MQITEM_INTEGER_FILTER

Integer filter.

MQITEM_INTEGER64

64-bit integer item.

MQITEM_STRING

Character-string item.

MQITEM_STRING_FILTER

String filter.

OutSelector (MQLONG) - output

Selector of the specified data item.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating error conditions can be returned from the mqInquireItemInfo call:

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_INDEX_ERROR

MQIND_NONE specified with one of the MQSEL_ANY_XXX_SELECTOR values.

MQRC_INDEX_NOT_PRESENT

No item with the specified index is present within the bag for the selector given.

MQRC_ITEM_TYPE_ERROR

ItemType parameter not valid (invalid parameter address).

MQRC_OUT_SELECTOR_ERROR

OutSelector parameter not valid (invalid parameter address).

MQRC_SELECTOR_NOT_PRESENT

No item with the specified selector is present within the bag.

MQRC_SELECTOR_NOT_SUPPORTED

Specified system selector not supported by the MQAI.

MQRC_SELECTOR_NOT_UNIQUE

MQIND_NONE specified when more than one occurrence of the specified selector is present in the bag.

MQRC_SELECTOR_OUT_OF_RANGE

Selector not within valid range for call.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

C language invocation for mqInquireItemInfo

```
mqInquireItemInfo (Bag, Selector, ItemIndex, &OutSelector, &ItemType,  
&CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHBAG   Bag;           /* Bag handle */  
MQLONG   Selector;     /* Selector identifying item */  
MQLONG   ItemIndex;    /* Index of data item */  
MQLONG   OutSelector;  /* Selector of specified data item */  
MQLONG   ItemType;     /* Data type of data item */  
MQLONG   CompCode;     /* Completion code */  
MQLONG   Reason;       /* Reason code qualifying CompCode */
```

Visual Basic invocation for mqInquireItemInfo

(Supported on Windows only.)

```
mqInquireItemInfo Bag, Selector, ItemIndex, OutSelector, ItemType,  
CompCode, Reason
```

Declare the parameters as follows:

```
Dim Bag           As Long 'Bag handle'  
Dim Selector      As Long 'Selector identifying item'  
Dim ItemIndex     As Long 'Index of data item'  
Dim OutSelector   As Long 'Selector of specified data item'  
Dim ItemType      As Long 'Data type of data item'  
Dim CompCode      As Long 'Completion code'  
Dim Reason        As Long 'Reason code qualifying CompCode'
```

mqInquireString

The mqInquireString call requests the value of a character data item that is present in the bag. The data item can be a user item or a system item.

Syntax for mqInquireString

mqInquireString (*Bag, Selector, ItemIndex, Bufferlength, Buffer, StringLength, CodedCharSetId, CompCode, Reason*)

Parameters for mqInquireString

Bag (MQHBAG) - input

Handle of the bag to which the inquiry relates. The bag can be a user bag or a system bag.

Selector (MQLONG) - input

Selector of the item to which the inquiry relates.

If the selector is less than zero (that is, a system selector), the selector must be one that is supported by the MQAI; MQRC_SELECTOR_NOT_SUPPORTED results if it is not.

The specified selector must be present in the bag; MQRC_SELECTOR_NOT_PRESENT results if it is not.

The data type of the item must be the same as the data type implied by the call; MQRC_SELECTOR_WRONG_TYPE results if it is not.

The following special values can be specified for *Selector*:

MQSEL_ANY_SELECTOR

The item to be inquired about is a user or system item identified by *ItemIndex*.

MQSEL_ANY_USER_SELECTOR

The item to be inquired about is a user item identified by *ItemIndex*.

MQSEL_ANY_SYSTEM_SELECTOR

The item to be inquired about is a system item identified by *ItemIndex*.

ItemIndex (MQLONG) - input

Index of the data item to which the inquiry relates. The value must be zero or greater, or the special value MQIND_NONE. If the value is less than zero and not MQIND_NONE, MQRC_INDEX_ERROR results. If the item is not already present in the bag, MQRC_INDEX_NOT_PRESENT results. The following special value can be specified:

MQIND_NONE

This specifies that there must be one occurrence only of the selector in the bag. If there is more than one occurrence, MQRC_SELECTOR_NOT_UNIQUE results.

If MQSEL_ANY_SELECTOR is specified for the **Selector** parameter, **ItemIndex** is the index relative to the set of items that contains both user items and system items, and must be zero or greater.

If MQSEL_ANY_USER_SELECTOR is specified for the **Selector** parameter, **ItemIndex** is the index relative to the set of user items, and must be zero or greater.

If MQSEL_ANY_SYSTEM_SELECTOR is specified for **Selector**, **ItemIndex** is the index relative to the set of system items, and must be zero or greater.

If an explicit selector value is specified, **ItemIndex** is the index relative to the set of items that have that selector value, and can be MQIND_NONE, zero, or greater.

BufferLength (MQLONG) - input

Length in bytes of the buffer to receive the string. Zero is a valid value.

Buffer (MQCHAR x BufferLength) - output

Buffer to receive the character string. The length is given by the **BufferLength** parameter. If zero is specified for **BufferLength**, the null pointer can be specified for the address of the **Buffer** parameter; in all other cases, a valid (non-null) address must be specified for the **Buffer** parameter.

The string is padded with blanks to the length of the buffer; the string is not null-terminated. If the string is longer than the buffer, the string is truncated to fit; in this case **StringLength** indicates the size of the buffer needed to accommodate the string without truncation.

StringLength (MQLONG) - output

The length in bytes of the string contained in the bag. If the **Buffer** parameter is too small, the length of the string returned is less than *StringLength*.

CodedCharSetId (MQLONG) - output

The coded character set identifier for the character data in the string. This parameter can be set to a null pointer if not required.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating error and warning conditions can be returned from the *mqInquireString* call:

MQRC_BUFFER_ERROR

Buffer parameter not valid (invalid parameter address or buffer not completely accessible).

MQRC_BUFFER_LENGTH_ERROR

Buffer length not valid.

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_INDEX_ERROR

Index not valid (index negative and not MQIND_NONE, or MQIND_NONE specified with one of the MQSEL_ANY_XXX_SELECTOR values).

MQRC_INDEX_NOT_PRESENT

No item with the specified index is present within the bag for the selector given.

MQRC_SELECTOR_NOT_PRESENT

No item with the specified selector is present within the bag.

MQRC_SELECTOR_NOT_SUPPORTED

Specified system selector not supported by the MQAI.

MQRC_SELECTOR_NOT_UNIQUE

MQIND_NONE specified when more than one occurrence of the specified selector is present in the bag.

MQRC_SELECTOR_OUT_OF_RANGE

Selector not within valid range for call.

MQRC_SELECTOR_WRONG_TYPE

Data item has wrong data type for call.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

MQRC_STRING_LENGTH_ERROR

StringLength parameter not valid (invalid parameter address).

MQRC_STRING_TRUNCATED

Data too long for output buffer and has been truncated.

C language invocation for mqInquireString

```
mqInquireString (Bag, Selector, ItemIndex,  
BufferLength, Buffer, &StringLength, &CodedCharSetId,  
&CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHBAG   Bag;           /* Bag handle */  
MQLONG   Selector;      /* Selector */  
MQLONG   ItemIndex;     /* Item index */  
MQLONG   BufferLength;  /* Buffer length */  
PMQCHAR  Buffer;        /* Buffer to contain string */  
MQLONG   StringLength; /* Length of string returned */  
MQLONG   CodedCharSetId /* Coded Character Set ID */  
MQLONG   CompCode;     /* Completion code */  
MQLONG   Reason;       /* Reason code qualifying CompCode */
```

Visual Basic invocation for mqInquireString

(Supported on Windows only.)

```
mqInquireString Bag, Selector, ItemIndex,  
BufferLength, Buffer, StringLength, CodedCharSetId,  
CompCode, Reason
```

Declare the parameters as follows:

```
Dim Bag           As Long 'Bag handle'  
Dim Selector      As Long 'Selector'  
Dim ItemIndex     As Long 'Item index'  
Dim BufferLength  As Long 'Buffer length'  
Dim Buffer         As String 'Buffer to contain string'  
Dim StringLength As Long 'Length of string returned'  
Dim CodedCharSetId As Long 'Coded Character Set ID'  
Dim CompCode     As Long 'Completion code'  
Dim Reason       As Long 'Reason code qualifying CompCode'
```

mqInquireStringFilter

The mqInquireStringFilter call requests the value and operator of a string filter item that is present in the bag. The data item can be a user item or a system item.

Syntax for mqInquireStringFilter

```
mqInquireStringFilter (Bag, Selector, ItemIndex, Bufferlength, Buffer,  
StringLength, CodedCharSetId, Operator, CompCode, Reason)
```

Parameters for mqInquireStringFilter

Bag (MQHBAG) - input

Handle of the bag to which the inquiry relates. The bag can be a user bag or a system bag.

Selector (MQLONG) - input

Selector of the item to which the inquiry relates.

If the selector is less than zero (that is, a system selector), the selector must be one that is supported by the MQAI; MQRC_SELECTOR_NOT_SUPPORTED results if it is not.

The specified selector must be present in the bag; MQRC_SELECTOR_NOT_PRESENT results if it is not.

The data type of the item must be the same as the data type implied by the call; MQRC_SELECTOR_WRONG_TYPE results if it is not.

The following special values can be specified for *Selector*:

MQSEL_ANY_SELECTOR

The item to be inquired about is a user or system item identified by *ItemIndex*.

MQSEL_ANY_USER_SELECTOR

The item to be inquired about is a user item identified by *ItemIndex*.

MQSEL_ANY_SYSTEM_SELECTOR

The item to be inquired about is a system item identified by *ItemIndex*.

ItemIndex (MQLONG) - input

Index of the data item to which the inquiry relates. The value must be zero or greater, or the special value MQIND_NONE. If the value is less than zero and not MQIND_NONE, MQRC_INDEX_ERROR results. If the item is not already present in the bag, MQRC_INDEX_NOT_PRESENT results. The following special value can be specified:

MQIND_NONE

This specifies that there must be one occurrence only of the selector in the bag. If there is more than one occurrence, MQRC_SELECTOR_NOT_UNIQUE results.

If MQSEL_ANY_SELECTOR is specified for the **Selector** parameter, *ItemIndex* is the index relative to the set of items that contains both user items and system items, and must be zero or greater.

If MQSEL_ANY_USER_SELECTOR is specified for the **Selector** parameter, *ItemIndex* is the index relative to the set of user items, and must be zero or greater.

If MQSEL_ANY_SYSTEM_SELECTOR is specified for *Selector*, *ItemIndex* is the index relative to the set of system items, and must be zero or greater.

If an explicit selector value is specified, *ItemIndex* is the index relative to the set of items that have that selector value, and can be MQIND_NONE, zero, or greater.

BufferLength (MQLONG) - input

Length in bytes of the buffer to receive the condition string. Zero is a valid value.

Buffer (MQCHAR x BufferLength) - output

Buffer to receive the character condition string. The length is given by the **BufferLength** parameter. If zero is specified for **BufferLength**, the null pointer can be specified for the address of the **Buffer** parameter; in all other cases, a valid (nonnull) address must be specified for the **Buffer** parameter.

The string is padded with blanks to the length of the buffer; the string is not null-terminated. If the string is longer than the buffer, the string is truncated to fit; in this case *StringLength* indicates the size of the buffer needed to accommodate the string without truncation.

StringLength (MQLONG) - output

The length in bytes of the condition string contained in the bag. If the **Buffer** parameter is too small, the length of the string returned is less than *StringLength*.

CodedCharSetId (MQLONG) - output

The coded character set identifier for the character data in the string. This parameter can be set to a null pointer if not required.

Operator (MQLONG) - output

String filter operator in the bag.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating error and warning conditions can be returned from the `mqInquireStringFilter` call:

MQRC_BUFFER_ERROR

Buffer parameter not valid (invalid parameter address or buffer not completely accessible).

MQRC_BUFFER_LENGTH_ERROR

Buffer length not valid.

MQRC_FILTER_OPERATOR_ERROR

Filter operator not valid.

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_INDEX_ERROR

Index not valid (index negative and not MQIND_NONE, or MQIND_NONE specified with one of the MQSEL_ANY_XXX_SELECTOR values).

MQRC_INDEX_NOT_PRESENT

No item with the specified index is present within the bag for the selector given.

MQRC_SELECTOR_NOT_PRESENT

No item with the specified selector is present within the bag.

MQRC_SELECTOR_NOT_SUPPORTED

Specified system selector not supported by the MQAI.

MQRC_SELECTOR_NOT_UNIQUE

MQIND_NONE specified when more than one occurrence of the specified selector is present in the bag.

MQRC_SELECTOR_OUT_OF_RANGE

Selector not within valid range for call.

MQRC_SELECTOR_WRONG_TYPE

Data item has wrong data type for call.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

MQRC_STRING_LENGTH_ERROR

`StringLength` parameter not valid (invalid parameter address).

MQRC_STRING_TRUNCATED

Data too long for output buffer and has been truncated.

C language invocation for `mqInquireStringFilter`

```
mqInquireStringFilter (Bag, Selector, ItemIndex,
    BufferLength, Buffer, &StringLength, &CodedCharSetId,
    &Operator, &CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHBAG    Bag;          /* Bag handle */
```

```

MQLONG Selector;      /* Selector */
MQLONG ItemIndex;    /* Item index */
MQLONG BufferLength;  /* Buffer length */
PMQCHAR Buffer;       /* Buffer to contain string */
MQLONG StringLength; /* Length of string returned */
MQLONG CodedCharSetId /* Coded Character Set ID */
MQLONG Operator      /* Item operator */
MQLONG CompCode;     /* Completion code */
MQLONG Reason;       /* Reason code qualifying CompCode */

```

Visual Basic invocation for mqInquireStringFilter

(Supported on Windows only.)

```

mqInquireStringFilter Bag, Selector, ItemIndex,
BufferLength, Buffer, StringLength, CodedCharSetId,
Operator, CompCode, Reason

```

Declare the parameters as follows:

```

Dim Bag           As Long   'Bag handle'
Dim Selector      As Long   'Selector'
Dim ItemIndex     As Long   'Item index'
Dim BufferLength   As Long   'Buffer length'
Dim Buffer         As String 'Buffer to contain string'
Dim StringLength  As Long   'Length of string returned'
Dim CodedCharSetId As Long   'Coded Character Set ID'
Dim Operator      As Long   'Item operator'
Dim CompCode      As Long   'Completion code'
Dim Reason        As Long   'Reason code qualifying CompCode'

```

Multi mqPad

The mqPad call pads a null-terminated string with blanks.

Syntax for mqPad

mqPad (*String*, *BufferLength*, *Buffer*, *CompCode*, *Reason*)

Parameters for mqPad

String (PMQCHAR) - input

Null-terminated string. The null pointer is valid for the address of the **String** parameter, and denotes a string of zero length.

BufferLength (MQLONG) - input

Length in bytes of the buffer to receive the string padded with blanks. Must be zero or greater.

Buffer (MQCHAR x BufferLength) - output

Buffer to receive the blank-padded string. The length is given by the **BufferLength** parameter. If zero is specified for **BufferLength**, the null pointer can be specified for the address of the **Buffer** parameter; in all other cases, a valid (nonnull) address must be specified for the **Buffer** parameter.

If the number of characters preceding the first null in the **String** parameter is greater than the **BufferLength** parameter, the excess characters are omitted and MQRC_DATA_TRUNCATED results.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating error and warning conditions can be returned from the mqPad call:

MQRC_BUFFER_ERROR

Buffer parameter not valid (invalid parameter address or buffer not completely accessible).

MQRC_BUFFER_LENGTH_ERROR

Buffer length not valid.

MQRC_STRING_ERROR

String parameter not valid (invalid parameter address or buffer not completely accessible).

MQRC_STRING_TRUNCATED

Data too long for output buffer and has been truncated.

Usage notes for mqPad

1. If the buffer pointers are the same, the padding is done in place. If not, at most *BufferLength* characters are copied into the second buffer; any space remaining, including the null-termination character, is overwritten with spaces.
2. If the *String* and **Buffer** parameters partially overlap, the result is undefined.

C language invocation for mqPad

```
mqPad (String, BufferLength, Buffer, &CompCode, &Reason);
```

Declare the parameters as follows:

```
MQCHAR   String;           /* String to be padded */
MQLONG   BufferLength;     /* Buffer length */
PMQCHAR  Buffer;           /* Buffer to contain padded string */
MQLONG   CompCode;        /* Completion code */
MQLONG   Reason;          /* Reason code qualifying CompCode */
```

Note: This call is not supported in Visual Basic.

mqPutBag

The mqPutBag call converts the contents of the specified bag into a PCF message and sends the message to the specified queue. The contents of the bag are unchanged after the call.

Syntax for mqPutBag

mqPutBag (*Hconn*, *Hobj*, *MsgDesc*, *PutMsgOpts*, *Bag*, *CompCode*, *Reason*)

Parameters for mqPutBag

Hconn (MQHCONN) - input

MQI connection handle.

Hobj (MQHOBJ) - input

Object handle of the queue on which the message is to be placed. This handle was returned by a preceding MQOPEN call issued by the application. The queue must be open for output.

MsgDesc (MQMD) - input/output

Message descriptor. (For more information, see [MQMD - Message descriptor](#).)

If the *Format* field has a value other than MQFMT_ADMIN, MQFMT_EVENT, or MQFMT_PCF, MQRC_FORMAT_NOT_SUPPORTED results.

If the *Encoding* field has a value other than MQENC_NATIVE, MQRC_ENCODING_NOT_SUPPORTED results.

PutMsgOpts (MQPMO) - input/output

Put-message options. (For more information, see [MQPMO - Put-message options](#).)

Bag (MQHBAG) - input

Handle of the data bag to be converted to a message.

If the bag contains an administration message, and mqAddInquiry was used to insert values into the bag, the value of the MQIASY_COMMAND data item must be an INQUIRE command recognized by the MQAI; MQRC_INQUIRY_COMMAND_ERROR results if it is not.

If the bag contains nested system bags, MQRC_NESTED_BAG_NOT_SUPPORTED results.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*. The following reason codes indicating error and warning conditions can be returned from the mqPutBag call:

MQRC_*

Anything from the MQPUT call or bag manipulation.

MQRC_BAG_WRONG_TYPE

Input data bag is a group bag.

MQRC_ENCODING_NOT_SUPPORTED

Encoding not supported (value in *Encoding* field in MQMD must be MQENC_NATIVE).

MQRC_FORMAT_NOT_SUPPORTED

Format not supported (name in *Format* field in MQMD must be MQFMT_ADMIN, MQFMT_EVENT, or MQFMT_PCF).

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_INQUIRY_COMMAND_ERROR

mqAddInquiry call used with a command code that is not a recognized INQUIRE command.

MQRC_NESTED_BAG_NOT_SUPPORTED

Input data bag contains one or more nested system bags.

MQRC_PARAMETER_MISSING

Administration message requires a parameter that is not present in the bag. This reason code occurs for bags created with the MQCBO_ADMIN_BAG or MQCBO_REORDER_AS_REQUIRED options only.

MQRC_SELECTOR_WRONG_TYPE

mqAddString or mqSetString was used to add the MQIACF_INQUIRY selector to the bag.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

C language invocation for mqPutBag

```
mqPutBag (HConn, HObj, &MsgDesc, &PutMsgOpts, Bag,  
&CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHCONN  HConn;          /* MQI connection handle */
MQHOBJ   HObj;          /* Object handle */
MQMD     MsgDesc;       /* Message descriptor */
MQPMO    PutMsgOpts;    /* Put-message options */
MQHBAG   Bag;           /* Bag handle */
MQLONG   CompCode;      /* Completion code */
MQLONG   Reason;        /* Reason code qualifying CompCode */
```

Visual Basic invocation for mqPutBag

(Supported on Windows only.)

```
mqPutBag (HConn, HObj, MsgDesc, PutMsgOpts, Bag,
CompCode, Reason);
```

Declare the parameters as follows:

```
Dim HConn      As Long 'MQI connection handle'
Dim HObj       As Long 'Object handle'
Dim MsgDesc    As MQMD 'Message descriptor'
Dim PutMsgOpts As MQPMO 'Put-message options'
Dim Bag        As Long 'Bag handle'
Dim CompCode   As Long 'Completion code'
Dim Reason     As Long 'Reason code qualifying CompCode'
```

Multi

mqSetByteString

The mqSetByteString call either modifies a byte string data item that is already present in the bag, or deletes all existing occurrences of the specified selector and adds a new occurrence at the end of the bag. The data item is usually a user item, but certain system-data items can also be modified.

Syntax for mqSetByteString

mqSetByteString (*Bag*, *Selector*, *ItemIndex*, *Bufferlength*, *Buffer*, *CompCode*, *Reason*)

Parameters for mqSetByteString

Bag (MQHBAG) - input

Handle of the bag to be set. This must be the handle of a bag created by the user, not the handle of a system bag; MQRC_SYSTEM_BAG_NOT_ALTERABLE results if you specify the handle of a system bag.

Selector (MQLONG) - input

Selector of the item to be modified.

If the selector is less than zero (that is, a system selector), the selector must be one that is supported by the MQAI; MQRC_SELECTOR_NOT_SUPPORTED results if it is not.

If the selector is a supported system selector, but is one that is read only, MQRC_SYSTEM_ITEM_NOT_ALTERABLE results.

If the selector is an alterable system selector, but is always a single-instance selector and the application attempts to create a second instance in the bag, MQRC_MULTIPLE_INSTANCE_ERROR results.

If the selector is zero or greater (that is, a user selector), and the bag was created with the MQCBO_CHECK_SELECTORS option or as an administration bag (MQCBO_ADMIN_BAG), the selector must be in the range MQBA_FIRST through MQBA_LAST; MQRC_SELECTOR_OUT_OF_RANGE results

if it is not. If MQCBO_CHECK_SELECTORS was not specified, the selector can be any value zero or greater.

If MQIND_ALL is not specified for the **ItemIndex** parameter, the specified selector must already be present in the bag; MQRC_SELECTOR_NOT_PRESENT results if it is not.

If MQIND_ALL is not specified for the **ItemIndex** parameter, the data type of the item must be the same as the data type implied by the call; MQRC_SELECTOR_WRONG_TYPE results if it is not.

ItemIndex (MQLONG) - input

This identifies which occurrence of the item with the specified selector is to be modified. The value must be zero or greater, or one of the special values described in this topic; if it is none of these, MQRC_INDEX_ERROR results.

Zero or greater

The item with the specified index must already be present in the bag; MQRC_INDEX_NOT_PRESENT results if it is not. The index is counted relative to the items in the bag that have the specified selector. For example, if there are five items in the bag with the specified selector, the valid values for *ItemIndex* are 0 through 4.

MQIND_NONE

This specifies that there must be only one occurrence of the specified selector in the bag. If there is more than one occurrence, MQRC_SELECTOR_NOT_UNIQUE results.

MQIND_ALL

This specifies that all existing occurrences of the specified selector (if any) are to be deleted from the bag, and a new occurrence of the selector created at the end of the bag.

BufferLength (MQLONG) - input

The length in bytes of the byte string contained in the **Buffer** parameter. The value must be zero or greater.

Buffer (MQBYTE x BufferLength) - input

Buffer containing the byte string. The length is given by the **BufferLength** parameter. If zero is specified for **BufferLength**, the null pointer can be specified for the address of the **Buffer** parameter; in all other cases, a valid (nonnull) address must be specified for the **Buffer** parameter.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating error conditions can be returned from the mqSetByteString call:

MQRC_BUFFER_ERROR

Buffer parameter not valid (invalid parameter address or buffer not completely accessible).

MQRC_BUFFER_LENGTH_ERROR

Buffer length not valid.

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_INDEX_ERROR

Index not valid (index negative and not MQIND_NONE or MQIND_ALL).

MQRC_INDEX_NOT_PRESENT

No item with the specified index is present within the bag for the selector given.

MQRC_MULTIPLE_INSTANCE_ERROR

Multiple instances of system selector not valid.

MQRC_SELECTOR_NOT_PRESENT

No item with the specified selector is present within the bag.

MQRC_SELECTOR_NOT_SUPPORTED

Specified system selector not supported by the MQAI.

MQRC_SELECTOR_NOT_UNIQUE

MQIND_NONE specified when more than one occurrence of the specified selector is present in the bag.

MQRC_SELECTOR_OUT_OF_RANGE

Selector not within valid range for call.

MQRC_SELECTOR_WRONG_TYPE

Data item has wrong data type for call.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

MQRC_SYSTEM_BAG_NOT_ALTERABLE

System bag cannot be altered or deleted.

MQRC_SYSTEM_ITEM_NOT_ALTERABLE

System item is read-only and cannot be altered.

C language invocation for mqSetByteString

```
mqSetByteString (Bag, Selector, ItemIndex, BufferLength, Buffer,
&CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHBAG   Bag;           /* Bag handle */
MQLONG   Selector;      /* Selector */
MQLONG   ItemIndex;     /* Item index */
MQLONG   BufferLength;   /* Buffer length */
PMQBYTE  Buffer;         /* Buffer containing string */
MQLONG   CompCode;      /* Completion code */
MQLONG   Reason;        /* Reason code qualifying CompCode */
```

Visual Basic invocation for mqSetByteString

(Supported on Windows only.)

```
mqSetByteString Bag, Selector, ItemIndex, BufferLength, Buffer,
CompCode, Reason
```

Declare the parameters as follows:

```
Dim Bag           As Long   'Bag handle'
Dim Selector      As Long   'Selector'
Dim ItemIndex     As Long   'Item index'
Dim BufferLength  As Long   'Buffer length'
Dim Buffer        As Byte    'Buffer containing string'
Dim CompCode     As Long   'Completion code'
Dim Reason       As Long   'Reason code qualifying CompCode'
```

The `mqSetByteStringFilter` call either modifies a byte string filter item that is already present in the bag, or deletes all existing occurrences of the specified selector and adds a new occurrence at the end of the bag. The data item is usually a user item, but certain system-data items can also be modified.

Syntax for `mqSetByteStringFilter`

`mqSetByteStringFilter` (*Bag, Selector, ItemIndex, Bufferlength, Buffer, Operator, CompCode, Reason*)

Parameters for `mqSetByteStringFilter`

Bag (MQHBAG) - input

Handle of the bag to be set. This must be the handle of a bag created by the user, not the handle of a system bag; `MQRC_SYSTEM_BAG_NOT_ALTERABLE` results if you specify the handle of a system bag.

Selector (MQLONG) - input

Selector of the item to be modified.

If the selector is less than zero (that is, a system selector), the selector must be one that is supported by the MQAI; `MQRC_SELECTOR_NOT_SUPPORTED` results if it is not.

If the selector is a supported system selector, but is one that is read only, `MQRC_SYSTEM_ITEM_NOT_ALTERABLE` results.

If the selector is an alterable system selector, but is always a single-instance selector and the application attempts to create a second instance in the bag, `MQRC_MULTIPLE_INSTANCE_ERROR` results.

If the selector is zero or greater (that is, a user selector), and the bag was created with the `MQCBO_CHECK_SELECTORS` option or as an administration bag (`MQCBO_ADMIN_BAG`), the selector must be in the range `MQBA_FIRST` through `MQBA_LAST`; `MQRC_SELECTOR_OUT_OF_RANGE` results if it is not. If `MQCBO_CHECK_SELECTORS` was not specified, the selector can be any value zero or greater.

If `MQIND_ALL` is not specified for the **ItemIndex** parameter, the specified selector must already be present in the bag; `MQRC_SELECTOR_NOT_PRESENT` results if it is not.

If `MQIND_ALL` is not specified for the **ItemIndex** parameter, the data type of the item must be the same as the data type implied by the call; `MQRC_SELECTOR_WRONG_TYPE` results if it is not.

ItemIndex (MQLONG) - input

This identifies which occurrence of the item with the specified selector is to be modified. The value must be zero or greater, or one of the special values described in this topic; if it is none of these, `MQRC_INDEX_ERROR` results.

Zero or greater

The item with the specified index must already be present in the bag; `MQRC_INDEX_NOT_PRESENT` results if it is not. The index is counted relative to the items in the bag that have the specified selector. For example, if there are five items in the bag with the specified selector, the valid values for *ItemIndex* are 0 through 4.

MQIND_NONE

This specifies that there must be only one occurrence of the specified selector in the bag. If there is more than one occurrence, `MQRC_SELECTOR_NOT_UNIQUE` results.

MQIND_ALL

This specifies that all existing occurrences of the specified selector (if any) are to be deleted from the bag, and a new occurrence of the selector created at the end of the bag.

BufferLength (MQLONG) - input

The length in bytes of the condition byte string contained in the **Buffer** parameter. The value must be zero or greater.

Buffer (MQBYTE x BufferLength) - input

Buffer containing the condition byte string. The length is given by the **BufferLength** parameter. If zero is specified for **BufferLength**, the null pointer can be specified for the address of the **Buffer** parameter; in all other cases, a valid (nonnull) address must be specified for the **Buffer** parameter.

Operator (MQLONG x Operator) - input

Byte string filter operator to be placed in the bag. Valid operators are of the form MQCFOP_*

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating error conditions can be returned from the mqSetByteStringFilter call:

MQRC_BUFFER_ERROR

Buffer parameter not valid (invalid parameter address or buffer not completely accessible).

MQRC_BUFFER_LENGTH_ERROR

Buffer length not valid.

MQRC_FILTER_OPERATOR_ERROR

Bag handle not valid.

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_INDEX_ERROR

Index not valid (index negative and not MQIND_NONE or MQIND_ALL).

MQRC_INDEX_NOT_PRESENT

No item with the specified index is present within the bag for the selector given.

MQRC_MULTIPLE_INSTANCE_ERROR

Multiple instances of system selector not valid.

MQRC_SELECTOR_NOT_PRESENT

No item with the specified selector is present within the bag.

MQRC_SELECTOR_NOT_SUPPORTED

Specified system selector not supported by the MQAI.

MQRC_SELECTOR_NOT_UNIQUE

MQIND_NONE specified when more than one occurrence of the specified selector is present in the bag.

MQRC_SELECTOR_OUT_OF_RANGE

Selector not within valid range for call.

MQRC_SELECTOR_WRONG_TYPE

Data item has wrong data type for call.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

MQRC_SYSTEM_BAG_NOT_ALTERABLE

System bag cannot be altered or deleted.

MQRC_SYSTEM_ITEM_NOT_ALTERABLE

System item is read-only and cannot be altered.

C language invocation for mqSetByteStringFilter

```
mqSetByteStringFilter (Bag, Selector, ItemIndex, BufferLength, Buffer,  
Operator, &CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHBAG   Bag;           /* Bag handle */  
MQLONG   Selector;      /* Selector */  
MQLONG   ItemIndex;     /* Item index */  
MQLONG   BufferLength;  /* Buffer length */  
PMQBYTE  Buffer;        /* Buffer containing string */  
MQLONG   Operator;     /* Operator */  
PMQLONG  CompCode;     /* Completion code */  
PMQLONG  Reason;       /* Reason code qualifying CompCode */
```

Visual Basic invocation for mqSetByteStringFilter

(Supported on Windows only.)

```
mqSetByteStringFilter Bag, Selector, ItemIndex, BufferLength, Buffer,  
Operator, CompCode, Reason
```

Declare the parameters as follows:

```
Dim Bag           As Long 'Bag handle'  
Dim Selector      As Long 'Selector'  
Dim ItemIndex     As Long 'Item index'  
Dim BufferLength  As Long 'Buffer length'  
Dim Buffer        As String 'Buffer containing string'  
Dim Operator      As Long 'Item operator'  
Dim CompCode     As Long 'Completion code'  
Dim Reason       As Long 'Reason code qualifying CompCode'
```

mqSetInteger

The mqSetInteger call either modifies an integer item that is already present in the bag, or deletes all existing occurrences of the specified selector and adds a new occurrence at the end of the bag. The data item is usually a user item, but specific system-data items can also be modified.

Syntax for mqSetInteger

mqSetInteger (Bag, Selector, ItemIndex, ItemValue, CompCode, Reason)

Parameters for mqSetInteger

Bag (MQHBAG) - input

Handle of the bag to be set. This must be the handle of a bag created by the user, and not the handle of a system bag; MQRC_SYSTEM_BAG_NOT_ALTERABLE results if the handle you specify refers to a system bag.

Selector (MQLONG) - input

Selector of the item to be modified. If the selector is less than zero (that is, a system selector), the selector must be one that is supported by the MQAI; MQRC_SELECTOR_NOT_SUPPORTED results if it is not.

If the selector is a supported system selector, but is one that is read-only, MQRC_SYSTEM_ITEM_NOT_ALTERABLE results.

If the selector is an alterable system selector, but is always a single-instance selector and the application attempts to create a second instance in the bag, MQRC_MULTIPLE_INSTANCE_ERROR results.

If the selector is zero or greater (that is, a user selector), and the bag was created with the MQCBO_CHECK_SELECTORS option or as an administration bag (MQCBO_ADMIN_BAG), the selector must be in the range MQIA_FIRST through MQIA_LAST; MQRC_SELECTOR_OUT_OF_RANGE results if it is not. If MQCBO_CHECK_SELECTORS was not specified, the selector can be any value zero or greater.

If MQIND_ALL is not specified for the **ItemIndex** parameter, the specified selector must already be present in the bag; MQRC_SELECTOR_NOT_PRESENT results if it is not.

If MQIND_ALL is not specified for the **ItemIndex** parameter, the data type of the item must agree with the data type implied by the call; MQRC_SELECTOR_WRONG_TYPE results if it is not.

ItemIndex (MQLONG) - input

This value identifies the occurrence of the item with the specified selector that is to be modified. The value must be zero or greater, or one of the special values described in this topic; if it is none of these, MQRC_INDEX_ERROR results.

Zero or greater

The item with the specified index must already be present in the bag; MQRC_INDEX_NOT_PRESENT results if it is not. The index is counted relative to the items in the bag that have the specified selector. For example, if there are five items in the bag with the specified selector, the valid values for *ItemIndex* are 0 through 4.

MQIND_NONE

This specifies that there must be one occurrence only of the specified selector in the bag. If there is more than one occurrence, MQRC_SELECTOR_NOT_UNIQUE results.

MQIND_ALL

This specifies that all existing occurrences of the specified selector (if any) are to be deleted from the bag, and a new occurrence of the selector created at the end of the bag.

Note: For system selectors, the order is not changed.

ItemValue (MQLONG) - input

The integer value to be placed in the bag.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating error and warning conditions can be returned from the mqSetInteger call:

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_INDEX_ERROR

Index not valid (index negative and not MQIND_NONE or MQIND_ALL).

MQRC_INDEX_NOT_PRESENT

No item with the specified index is present within the bag for the selector given.

MQRC_MULTIPLE_INSTANCE_ERROR

Multiple instances of system selector not valid.

MQRC_SELECTOR_NOT_PRESENT

No item with the specified selector is present within the bag.

MQRC_SELECTOR_NOT_SUPPORTED

Specified system selector not supported by the MQAI.

MQRC_SELECTOR_NOT_UNIQUE

MQIND_NONE specified when more than one occurrence of the specified selector is present in the bag.

MQRC_SELECTOR_OUT_OF_RANGE

Selector not in valid range for call.

MQRC_SELECTOR_WRONG_TYPE

Data item has wrong data type for call.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

MQRC_SYSTEM_BAG_NOT_ALTERABLE

System bag cannot be altered or deleted.

MQRC_SYSTEM_ITEM_NOT_ALTERABLE

System item is read only and cannot be altered.

C language invocation for mqSetInteger

```
mqSetInteger (Bag, Selector, ItemIndex, ItemValue, &CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHBAG   Bag;           /* Bag handle */
MQLONG   Selector;     /* Selector */
MQLONG   ItemIndex;    /* Item index */
MQLONG   ItemValue;    /* Integer value */
MQLONG   CompCode;     /* Completion code */
MQLONG   Reason;       /* Reason code qualifying CompCode */
```

Visual Basic invocation for mqSetInteger

(Supported on Windows only.)

```
mqSetInteger Bag, Selector, ItemIndex, ItemValue, CompCode, Reason
```

Declare the parameters as follows:

```
Dim Bag       As Long 'Bag handle'
Dim Selector  As Long 'Selector'
Dim ItemIndex As Long 'Item index'
Dim ItemValue As Long 'Integer value'
Dim CompCode  As Long 'Completion code'
Dim Reason    As Long 'Reason code qualifying CompCode'
```

Multi mqSetInteger64

The mqSetInteger64 call either modifies a 64-bit integer item that is already present in the bag, or deletes all existing occurrences of the specified selector and adds a new occurrence at the end of the bag. The data item is usually a user item, but specific system-data items can also be modified.

Syntax for mqSetInteger64

```
mqSetInteger64 (Bag, Selector, ItemIndex, ItemValue, CompCode, Reason)
```

Parameters for mqSetInteger64

Bag (MQHBAG) - input

Handle of the bag to be set. This must be the handle of a bag created by the user, and not the handle of a system bag; MQRC_SYSTEM_BAG_NOT_ALTERABLE results if the handle you specify refers to a system bag.

Selector (MQLONG) - input

Selector of the item to be modified. If the selector is less than zero (that is, a system selector), the selector must be one that is supported by the MQAI; MQRC_SELECTOR_NOT_SUPPORTED results if it is not.

If the selector is a supported system selector, but is one that is read-only, MQRC_SYSTEM_ITEM_NOT_ALTERABLE results.

If the selector is an alterable system selector, but is always a single-instance selector and the application attempts to create a second instance in the bag, MQRC_MULTIPLE_INSTANCE_ERROR results.

If the selector is zero or greater (that is, a user selector), and the bag was created with the MQCBO_CHECK_SELECTORS option or as an administration bag (MQCBO_ADMIN_BAG), the selector must be in the range MQIA_FIRST through MQIA_LAST; MQRC_SELECTOR_OUT_OF_RANGE results if it is not. If MQCBO_CHECK_SELECTORS was not specified, the selector can be any value zero or greater.

If MQIND_ALL is not specified for the **ItemIndex** parameter, the specified selector must already be present in the bag; MQRC_SELECTOR_NOT_PRESENT results if it is not.

If MQIND_ALL is not specified for the **ItemIndex** parameter, the data type of the item must agree with the data type implied by the call; MQRC_SELECTOR_WRONG_TYPE results if it is not.

ItemIndex (MQLONG) - input

This value identifies the occurrence of the item with the specified selector that is to be modified. The value must be zero or greater, or one of the special values described in this topic; if it is none of these, MQRC_INDEX_ERROR results.

Zero or greater

The item with the specified index must already be present in the bag; MQRC_INDEX_NOT_PRESENT results if it is not. The index is counted relative to the items in the bag that have the specified selector. For example, if there are five items in the bag with the specified selector, the valid values for *ItemIndex* are 0 through 4.

MQIND_NONE

This specifies that there must be one occurrence only of the specified selector in the bag. If there is more than one occurrence, MQRC_SELECTOR_NOT_UNIQUE results.

MQIND_ALL

This specifies that all existing occurrences of the specified selector (if any) are to be deleted from the bag, and a new occurrence of the selector created at the end of the bag.

Note: For system selectors, the order is not changed.

ItemValue (MQINT64) - input

The integer value to be placed in the bag.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating error and warning conditions can be returned from the mqSetInteger64 call:

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_INDEX_ERROR

Index not valid (index negative and not MQIND_NONE or MQIND_ALL).

MQRC_INDEX_NOT_PRESENT

No item with the specified index is present within the bag for the selector given.

MQRC_MULTIPLE_INSTANCE_ERROR

Multiple instances of system selector not valid.

MQRC_SELECTOR_NOT_PRESENT

No item with the specified selector is present within the bag.

MQRC_SELECTOR_NOT_SUPPORTED

Specified system selector not supported by the MQAI.

MQRC_SELECTOR_NOT_UNIQUE

MQIND_NONE specified when more than one occurrence of the specified selector is present in the bag.

MQRC_SELECTOR_OUT_OF_RANGE

Selector not in valid range for call.

MQRC_SELECTOR_WRONG_TYPE

Data item has wrong data type for call.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

MQRC_SYSTEM_BAG_NOT_ALTERABLE

System bag cannot be altered or deleted.

MQRC_SYSTEM_ITEM_NOT_ALTERABLE

System item is read only and cannot be altered.

C language invocation for mqSetInteger64

```
mqSetInteger64 (Bag, Selector, ItemIndex, ItemValue, &CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHBAG   Bag;           /* Bag handle */
MQLONG   Selector;      /* Selector */
MQLONG   ItemIndex;     /* Item index */
MQINT64  ItemValue;     /* Integer value */
MQLONG   CompCode;      /* Completion code */
MQLONG   Reason;        /* Reason code qualifying CompCode */
```

Visual Basic invocation for mqSetInteger64

(Supported on Windows only.)

```
mqSetInteger64 Bag, Selector, ItemIndex, ItemValue, CompCode, Reason
```

Declare the parameters as follows:

```
Dim Bag      As Long 'Bag handle'
Dim Selector As Long 'Selector'
Dim ItemIndex As Long 'Item index'
Dim ItemValue As Long 'Integer value'
Dim CompCode As Long 'Completion code'
Dim Reason   As Long 'Reason code qualifying CompCode'
```

Multi **mqSetIntegerFilter**

The `mqSetIntegerFilter` call either modifies an integer filter item that is already present in the bag, or deletes all existing occurrences of the specified selector and adds a new occurrence at the end of the bag. The data item is usually a user item, but specific system-data items can also be modified.

Syntax for `mqSetIntegerFilter`

`mqSetIntegerFilter (Bag, Selector, ItemIndex, ItemValue, Operator, CompCode, Reason)`

Parameters for `mqSetIntegerFilter`

Bag (MQHBAG) - input

Handle of the bag to be set. This must be the handle of a bag created by the user, and not the handle of a system bag; `MQRC_SYSTEM_BAG_NOT_ALTERABLE` results if the handle you specify refers to a system bag.

Selector (MQLONG) - input

Selector of the item to be modified. If the selector is less than zero (that is, a system selector), the selector must be one that is supported by the MQAI; `MQRC_SELECTOR_NOT_SUPPORTED` results if it is not.

If the selector is a supported system selector, but is one that is read-only, `MQRC_SYSTEM_ITEM_NOT_ALTERABLE` results.

If the selector is an alterable system selector, but is always a single-instance selector and the application attempts to create a second instance in the bag, `MQRC_MULTIPLE_INSTANCE_ERROR` results.

If the selector is zero or greater (that is, a user selector), and the bag was created with the `MQCBO_CHECK_SELECTORS` option or as an administration bag (`MQCBO_ADMIN_BAG`), the selector must be in the range `MQIA_FIRST` through `MQIA_LAST`; `MQRC_SELECTOR_OUT_OF_RANGE` results if it is not. If `MQCBO_CHECK_SELECTORS` was not specified, the selector can be any value zero or greater.

If `MQIND_ALL` is not specified for the **ItemIndex** parameter, the specified selector must already be present in the bag; `MQRC_SELECTOR_NOT_PRESENT` results if it is not.

If `MQIND_ALL` is not specified for the **ItemIndex** parameter, the data type of the item must agree with the data type implied by the call; `MQRC_SELECTOR_WRONG_TYPE` results if it is not.

ItemIndex (MQLONG) - input

This value identifies the occurrence of the item with the specified selector that is to be modified. The value must be zero or greater, or one of the special values described in this topic; if it is none of these, `MQRC_INDEX_ERROR` results.

Zero or greater

The item with the specified index must already be present in the bag; `MQRC_INDEX_NOT_PRESENT` results if it is not. The index is counted relative to the items in the bag that have the specified selector. For example, if there are five items in the bag with the specified selector, the valid values for *ItemIndex* are 0 through 4.

MQIND_NONE

This specifies that there must be one occurrence only of the specified selector in the bag. If there is more than one occurrence, `MQRC_SELECTOR_NOT_UNIQUE` results.

MQIND_ALL

This specifies that all existing occurrences of the specified selector (if any) are to be deleted from the bag, and a new occurrence of the selector created at the end of the bag.

Note: For system selectors, the order is not changed.

ItemValue (MQLONG) - input

The integer condition value to be placed in the bag.

Operator (MQLONG) - input

The integer filter operator to be placed in the bag. Valid operators are of the form MQCFOP_*

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating error and warning conditions can be returned from the `mqSetIntegerFilter` call:

MQRC_FILTER_OPERATOR_ERROR

Filter operator not valid.

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_INDEX_ERROR

Index not valid (index negative and not MQIND_NONE or MQIND_ALL).

MQRC_INDEX_NOT_PRESENT

No item with the specified index is present within the bag for the selector given.

MQRC_MULTIPLE_INSTANCE_ERROR

Multiple instances of system selector not valid.

MQRC_SELECTOR_NOT_PRESENT

No item with the specified selector is present within the bag.

MQRC_SELECTOR_NOT_SUPPORTED

Specified system selector not supported by the MQAI.

MQRC_SELECTOR_NOT_UNIQUE

MQIND_NONE specified when more than one occurrence of the specified selector is present in the bag.

MQRC_SELECTOR_OUT_OF_RANGE

Selector not in valid range for call.

MQRC_SELECTOR_WRONG_TYPE

Data item has wrong data type for call.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

MQRC_SYSTEM_BAG_NOT_ALTERABLE

System bag cannot be altered or deleted.

MQRC_SYSTEM_ITEM_NOT_ALTERABLE

System item is read only and cannot be altered.

C language invocation for `mqSetIntegerFilter`

```
mqSetIntegerFilter (Bag, Selector, ItemIndex, ItemValue, Operator,
&CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHBAG   Bag;           /* Bag handle */
MQLONG   Selector;      /* Selector */
MQLONG   ItemIndex;     /* Item index */
MQLONG   ItemValue;     /* Integer value */
```

```

MQLONG  Operator;      /* Item operator */
MQLONG  CompCode;     /* Completion code */
MQLONG  Reason;       /* Reason code qualifying CompCode */

```

Visual Basic invocation for mqSetIntegerFilter

(Supported on Windows only.)

```

mqSetIntegerFilter Bag, Selector, ItemIndex, ItemValue, Operator,
CompCode, Reason

```

Declare the parameters as follows:

```

Dim Bag      As Long 'Bag handle'
Dim Selector As Long 'Selector'
Dim ItemIndex As Long 'Item index'
Dim ItemValue As Long 'Integer value'
Dim Operator As Long 'Item operator'
Dim CompCode As Long 'Completion code'
Dim Reason   As Long 'Reason code qualifying CompCode'

```

Multi

mqSetString

The mqSetString call either modifies a character data item that is already present in the bag, or deletes all existing occurrences of the specified selector and adds a new occurrence at the end of the bag. The data item is usually a user item, but certain system-data items can also be modified.

Syntax for mqSetString

mqSetString (*Bag, Selector, ItemIndex, Bufferlength, Buffer, CompCode, Reason*)

Parameters for mqSetString

Bag (MQHBAG) - input

Handle of the bag to be set. This must be the handle of a bag created by the user, not the handle of a system bag; MQRC_SYSTEM_BAG_NOT_ALTERABLE results if you specify the handle of a system bag.

Selector (MQLONG) - input

Selector of the item to be modified.

If the selector is less than zero (that is, a system selector), the selector must be one that is supported by the MQAI; MQRC_SELECTOR_NOT_SUPPORTED results if it is not.

If the selector is a supported system selector, but is one that is read only, MQRC_SYSTEM_ITEM_NOT_ALTERABLE results.

If the selector is an alterable system selector, but is always a single-instance selector and the application attempts to create a second instance in the bag, MQRC_MULTIPLE_INSTANCE_ERROR results.

If the selector is zero or greater (that is, a user selector), and the bag was created with the MQCBO_CHECK_SELECTORS option or as an administration bag (MQCBO_ADMIN_BAG), the selector must be in the range MQCA_FIRST through MQCA_LAST; MQRC_SELECTOR_OUT_OF_RANGE results if it is not. If MQCBO_CHECK_SELECTORS was not specified, the selector can be any value zero or greater.

If MQIND_ALL is not specified for the **ItemIndex** parameter, the specified selector must already be present in the bag; MQRC_SELECTOR_NOT_PRESENT results if it is not.

If MQIND_ALL is not specified for the **ItemIndex** parameter, the data type of the item must be the same as the data type implied by the call; MQRC_SELECTOR_WRONG_TYPE results if it is not.

ItemIndex (MQLONG) - input

This identifies which occurrence of the item with the specified selector is to be modified. The value must be zero or greater, or one of the special values described in this topic; if it is none of these, MQRC_INDEX_ERROR results.

Zero or greater

The item with the specified index must already be present in the bag; MQRC_INDEX_NOT_PRESENT results if it is not. The index is counted relative to the items in the bag that have the specified selector. For example, if there are five items in the bag with the specified selector, the valid values for *ItemIndex* are 0 through 4.

MQIND_NONE

This specifies that there must be only one occurrence of the specified selector in the bag. If there is more than one occurrence, MQRC_SELECTOR_NOT_UNIQUE results.

MQIND_ALL

This specifies that all existing occurrences of the specified selector (if any) are to be deleted from the bag, and a new occurrence of the selector created at the end of the bag.

BufferLength (MQLONG) - input

The length in bytes of the string contained in the **Buffer** parameter. The value must be zero or greater, or the special value MQBL_NULL_TERMINATED.

If MQBL_NULL_TERMINATED is specified, the string is delimited by the first null encountered in the string.

If MQBL_NULL_TERMINATED is not specified, *BufferLength* characters are inserted into the bag, even if null characters are present; the nulls do not delimit the string.

Buffer (MQCHAR x BufferLength) - input

Buffer containing the character string. The length is given by the **BufferLength** parameter. If zero is specified for **BufferLength**, the null pointer can be specified for the address of the **Buffer** parameter; in all other cases, a valid (nonnull) address must be specified for the **Buffer** parameter.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating error conditions can be returned from the mqSetString call:

MQRC_BUFFER_ERROR

Buffer parameter not valid (invalid parameter address or buffer not completely accessible).

MQRC_BUFFER_LENGTH_ERROR

Buffer length not valid.

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_INDEX_ERROR

Index not valid (index negative and not MQIND_NONE or MQIND_ALL).

MQRC_INDEX_NOT_PRESENT

No item with the specified index is present within the bag for the selector given.

MQRC_MULTIPLE_INSTANCE_ERROR

Multiple instances of system selector not valid.

MQRC_SELECTOR_NOT_PRESENT

No item with the specified selector is present within the bag.

MQRC_SELECTOR_NOT_SUPPORTED

Specified system selector not supported by the MQAI.

MQRC_SELECTOR_NOT_UNIQUE

MQIND_NONE specified when more than one occurrence of the specified selector is present in the bag.

MQRC_SELECTOR_OUT_OF_RANGE

Selector not within valid range for call.

MQRC_SELECTOR_WRONG_TYPE

Data item has wrong data type for call.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

MQRC_SYSTEM_BAG_NOT_ALTERABLE

System bag cannot be altered or deleted.

MQRC_SYSTEM_ITEM_NOT_ALTERABLE

System item is read-only and cannot be altered.

Usage notes for mqSetString

The Coded Character Set ID (CCSID) associated with this string is copied from the current CCSID of the bag.

C language invocation for mqSetString

```
mqSetString (Bag, Selector, ItemIndex, BufferLength, Buffer,
&CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHBAG   Bag;           /* Bag handle */
MQLONG   Selector;     /* Selector */
MQLONG   ItemIndex;    /* Item index */
MQLONG   BufferLength;  /* Buffer length */
PMQCHAR  Buffer;        /* Buffer containing string */
MQLONG   CompCode;     /* Completion code */
MQLONG   Reason;       /* Reason code qualifying CompCode */
```

Visual Basic invocation for mqSetString

(Supported on Windows only.)

```
mqSetString Bag, Selector, ItemIndex, BufferLength, Buffer,
CompCode, Reason
```

Declare the parameters as follows:

```
Dim Bag           As Long   'Bag handle'
Dim Selector      As Long   'Selector'
Dim ItemIndex     As Long   'Item index'
Dim BufferLength   As Long   'Buffer length'
Dim Buffer         As String  'Buffer containing string'
Dim CompCode      As Long   'Completion code'
Dim Reason        As Long   'Reason code qualifying CompCode'
```

Multi **mqSetStringFilter**

The `mqSetStringFilter` call either modifies a string filter item that is already present in the bag, or deletes all existing occurrences of the specified selector and adds a new occurrence at the end of the bag. The data item is usually a user item, but certain system-data items can also be modified.

Syntax for `mqSetStringFilter`

`mqSetStringFilter (Bag, Selector, ItemIndex, Bufferlength, Buffer, Operator, CompCode, Reason)`

Parameters for `mqSetStringFilter`

Bag (MQHBAG) - input

Handle of the bag to be set. This must be the handle of a bag created by the user, not the handle of a system bag; `MQRC_SYSTEM_BAG_NOT_ALTERABLE` results if you specify the handle of a system bag.

Selector (MQLONG) - input

Selector of the item to be modified.

If the selector is less than zero (that is, a system selector), the selector must be one that is supported by the MQAI; `MQRC_SELECTOR_NOT_SUPPORTED` results if it is not.

If the selector is a supported system selector, but is one that is read only, `MQRC_SYSTEM_ITEM_NOT_ALTERABLE` results.

If the selector is an alterable system selector, but is always a single-instance selector and the application attempts to create a second instance in the bag, `MQRC_MULTIPLE_INSTANCE_ERROR` results.

If the selector is zero or greater (that is, a user selector), and the bag was created with the `MQCBO_CHECK_SELECTORS` option or as an administration bag (`MQCBO_ADMIN_BAG`), the selector must be in the range `MQCA_FIRST` through `MQCA_LAST`; `MQRC_SELECTOR_OUT_OF_RANGE` results if it is not. If `MQCBO_CHECK_SELECTORS` was not specified, the selector can be any value zero or greater.

If `MQIND_ALL` is not specified for the **ItemIndex** parameter, the specified selector must already be present in the bag; `MQRC_SELECTOR_NOT_PRESENT` results if it is not.

If `MQIND_ALL` is not specified for the **ItemIndex** parameter, the data type of the item must be the same as the data type implied by the call; `MQRC_SELECTOR_WRONG_TYPE` results if it is not.

ItemIndex (MQLONG) - input

This identifies which occurrence of the item with the specified selector is to be modified. The value must be zero or greater, or one of the special values described in this topic; if it is none of these, `MQRC_INDEX_ERROR` results.

Zero or greater

The item with the specified index must already be present in the bag; `MQRC_INDEX_NOT_PRESENT` results if it is not. The index is counted relative to the items in the bag that have the specified selector. For example, if there are five items in the bag with the specified selector, the valid values for *ItemIndex* are 0 through 4.

MQIND_NONE

This specifies that there must be only one occurrence of the specified selector in the bag. If there is more than one occurrence, `MQRC_SELECTOR_NOT_UNIQUE` results.

MQIND_ALL

This specifies that all existing occurrences of the specified selector (if any) are to be deleted from the bag, and a new occurrence of the selector created at the end of the bag.

BufferLength (MQLONG) - input

The length in bytes of the condition string contained in the **Buffer** parameter. The value must be zero or greater, or the special value MQBL_NULL_TERMINATED.

If MQBL_NULL_TERMINATED is specified, the string is delimited by the first null encountered in the string.

If MQBL_NULL_TERMINATED is not specified, *BufferLength* characters are inserted into the bag, even if null characters are present; the nulls do not delimit the string.

Buffer (MQCHAR x BufferLength) - input

Buffer containing the character condition string. The length is given by the **BufferLength** parameter. If zero is specified for **BufferLength**, the null pointer can be specified for the address of the **Buffer** parameter; in all other cases, a valid (nonnull) address must be specified for the **Buffer** parameter.

Operator (MQLONG x Operator) - input

String filter operator to be placed in the bag. Valid operators are of the form MQCFOP_*

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating error conditions can be returned from the mqSetStringFilter call:

MQRC_BUFFER_ERROR

Buffer parameter not valid (invalid parameter address or buffer not completely accessible).

MQRC_BUFFER_LENGTH_ERROR

Buffer length not valid.

MQRC_FILTER_OPERATOR_ERROR

Bag handle not valid.

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_INDEX_ERROR

Index not valid (index negative and not MQIND_NONE or MQIND_ALL).

MQRC_INDEX_NOT_PRESENT

No item with the specified index is present within the bag for the selector given.

MQRC_MULTIPLE_INSTANCE_ERROR

Multiple instances of system selector not valid.

MQRC_SELECTOR_NOT_PRESENT

No item with the specified selector is present within the bag.

MQRC_SELECTOR_NOT_SUPPORTED

Specified system selector not supported by the MQAI.

MQRC_SELECTOR_NOT_UNIQUE

MQIND_NONE specified when more than one occurrence of the specified selector is present in the bag.

MQRC_SELECTOR_OUT_OF_RANGE

Selector not within valid range for call.

MQRC_SELECTOR_WRONG_TYPE

Data item has wrong data type for call.

MQRC_STORAGE_NOT_AVAILABLE

Insufficient storage available.

MQRC_SYSTEM_BAG_NOT_ALTERABLE

System bag cannot be altered or deleted.

MQRC_SYSTEM_ITEM_NOT_ALTERABLE

System item is read-only and cannot be altered.

Usage notes for mqSetStringFilter

The Coded Character Set ID (CCSID) associated with this string is copied from the current CCSID of the bag.

C language invocation for mqSetStringFilter

```
mqSetStringFilter (Bag, Selector, ItemIndex, BufferLength, Buffer,  
Operator, &CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHBAG    Bag;           /* Bag handle */  
MQLONG    Selector;      /* Selector */  
MQLONG    ItemIndex;     /* Item index */  
MQLONG    BufferLength;  /* Buffer length */  
PMQCHAR   Buffer;        /* Buffer containing string */  
MQLONG    Operator;      /* Item operator */  
MQLONG    CompCode;     /* Completion code */  
MQLONG    Reason;       /* Reason code qualifying CompCode */
```

Visual Basic invocation for mqSetStringFilter

(Supported on Windows only.)

```
mqSetStringFilter Bag, Selector, ItemIndex, BufferLength, Buffer,  
Operator, CompCode, Reason
```

Declare the parameters as follows:

```
Dim Bag           As Long   'Bag handle'  
Dim Selector      As Long   'Selector'  
Dim ItemIndex     As Long   'Item index'  
Dim BufferLength  As Long   'Buffer length'  
Dim Buffer         As String 'Buffer containing string'  
Dim Operator      As Long   'Item operator'  
Dim CompCode     As Long   'Completion code'  
Dim Reason       As Long   'Reason code qualifying CompCode'
```

Multi mqTrim

The mqTrim call trims the blanks from a blank-padded string, then terminates it with a null.

Syntax for mqTrim

mqTrim (BufferLength, Buffer, String, CompCode, Reason)

Parameters for mqTrim

BufferLength (MQLONG) - input

Length in bytes of the buffer containing the string padded with blanks. Must be zero or greater.

Buffer (MQCHAR × *BufferLength*) - input

Buffer containing the blank-padded string. The length is given by the **BufferLength** parameter. If zero is specified for **BufferLength**, the null pointer can be specified for the address of the **Buffer** parameter; in all other cases, a valid (nonnull) address must be specified for the **Buffer** parameter.

String (MQCHAR × (*BufferLength* +1)) - output

Buffer to receive the null-terminated string. The length of this buffer must be at least one byte greater than the value of the **BufferLength** parameter.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating error conditions can be returned from the mqTrim call:

MQRC_BUFFER_ERROR

Buffer parameter not valid (invalid parameter address or buffer not completely accessible).

MQRC_BUFFER_LENGTH_ERROR

Buffer length not valid.

MQRC_STRING_ERROR

String parameter not valid (invalid parameter address or buffer not completely accessible).

Usage notes for mqTrim

1. If the two buffer pointers are the same, the trimming is done in place. If they are not the same, the blank-padded string is copied into the null-terminated string buffer. After copying, the buffer is scanned backwards from the end until a nonspace character is found. The byte following the nonspace character is then overwritten with a null character.
2. If *String* and *Buffer* partially overlap, the result is undefined.

C language invocation for mqTrim

```
mqTrim (BufferLength, Buffer, String, &CompCode, &Reason);
```

Declare the parameters as follows:

```
MQLONG  BufferLength;    /* Buffer length */
PMQCHAR Buffer;         /* Buffer containing blank-padded string */
MQCHAR  String[n+1];   /* String with blanks discarded */
MQLONG  CompCode;      /* Completion code */
MQLONG  Reason;        /* Reason code qualifying CompCode */
```

Note: This call is not supported in Visual Basic.

mqTruncateBag

The mqTruncateBag call reduces the number of user items in a user bag to the specified value, by deleting user items from the end of the bag.

Syntax for mqTruncateBag

mqTruncateBag (*Bag*, *ItemCount*, *CompCode*, *Reason*)

Parameters for mqTruncateBag

Bag (MQHBAG) - input

Handle of the bag to be truncated. This must be the handle of a bag created by the user, not the handle of a system bag; MQRC_SYSTEM_BAG_NOT_ALTERABLE results if you specify the handle of a system bag.

ItemCount (MQLONG) - input

The number of user items to remain in the bag after truncation. Zero is a valid value.

Note: The **ItemCount** parameter is the number of data items, not the number of unique selectors. (If there are one or more selectors that occur multiple times in the bag, there will be fewer selectors than data items before truncation.) Data items are deleted from the end of the bag, in the opposite order to which they were added to the bag.

If the number specified exceeds the number of user items currently in the bag, MQRC_ITEM_COUNT_ERROR results.

CompCode (MQLONG) - output

Completion code.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

The following reason codes indicating error conditions can be returned from the mqTruncateBag call:

MQRC_HBAG_ERROR

Bag handle not valid.

MQRC_ITEM_COUNT_ERROR

ItemCount parameter not valid (value exceeds the number of user data items in the bag).

MQRC_SYSTEM_BAG_NOT_ALTERABLE

System bag cannot be altered or deleted.

Usage notes for mqTruncateBag

1. System items in a bag are not affected by mqTruncateBag; the call cannot be used to truncate system bags.
2. mqTruncateBag with an *ItemCount* of zero is not the same as the mqClearBag call. The former deletes all of the user items but leaves the system items intact, and the latter deletes all of the user items and resets the system items to their initial values.

C language invocation for mqTruncateBag

```
mqTruncateBag (Bag, ItemCount, &CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHBAG    hBag;           /* Bag handle */
MQLONG    ItemCount;      /* Number of items to remain in bag */
MQLONG    CompCode;      /* Completion code */
MQLONG    Reason;        /* Reason code qualifying CompCode */
```

Visual Basic invocation for mqTruncateBag

(Supported on Windows only.)

```
mqTruncateBag Bag, ItemCount, CompCode, Reason
```

Declare the parameters as follows:

```
Dim Bag           As Long 'Bag handle'  
Dim ItemCount    As Long 'Number of items to remain in bag'  
Dim CompCode     As Long 'Completion code'  
Dim Reason       As Long 'Reason code qualifying CompCode'
```

Multi MQAI selectors

Items in bags are identified by a *selector* that acts as an identifier for the item. There are two types of selector, *user selector* and *system selector*.

User selectors

User selectors have values that are zero or positive. For the administration of MQSeries objects, valid user selectors are already defined by the following constants:

- MQCA_* and MQIA_* (object attributes)
- MQCACF_* and MQIACF_* (items relating specifically to PCF)
- MQCACH_* and MQIACH_* (channel attributes)

For user messages, the meaning of a user selector is defined by the application.

The following additional user selectors are introduced by the MQAI:

MQIACF_INQUIRY

Identifies an IBM MQ object attribute to be returned by an Inquire command.

MQHA_BAG_HANDLE

Identifies a bag handle residing within another bag.

MQHA_FIRST

Lower limit for handle selectors.

MQHA_LAST

Upper limit for handle selectors.

MQHA_LAST_USED

Upper limit for last handle selector allocated.

MQCA_USER_LIST

Default user selector. Supported on Visual Basic only. This selector supports character type and represents the default value used if the **Selector** parameter is omitted on the mqAdd*, mqSet*, or mqInquire* calls.

MQIA_USER_LIST

Default user selector. Supported on Visual Basic only. This selector supports integer type and represents the default value used if the **Selector** parameter is omitted on the mqAdd*, mqSet*, or mqInquire* calls.

System selectors

System selectors have negative values. The following system selectors are included in the bag when it is created:

MQIASY_BAG_OPTIONS

Bag-creation options. A summation of the options used to create the bag. This selector cannot be changed by the user.

MQIASY_CODED_CHAR_SET_ID

Character-set identifier for the character data items in the bag. The initial value is the queue manager's character set.

The value in the bag is used on entry to the mqExecute call and set on exit from the mqExecute call. This also applies when character strings are added to or modified in the bag.

MQIASY_COMMAND

PCF command identifier. Valid values are the MQCMD_* constants. For user messages, the value MQCMD_NONE should be used. The initial value is MQCMD_NONE.

The value in the bag is used on entry to the mqPutBag and mqBagToBuffer calls, and set on exit from the mqExecute, mqGetBag and mqBufferToBag calls.

MQIASY_COMP_CODE

Completion code. Valid values are the MQCC_* constants. The initial value is MQCC_OK.

The value in the bag is used on entry to the mqExecute, mqPutBag, and mqBagToBuffer calls, and set on exit from the mqExecute, mqGetBag, and mqBufferToBag calls.

MQIASY_CONTROL

PCF control options. Valid values are the MQCFC_* constants. The initial value is MQCFC_LAST.

The value in the bag is used on entry to the mqExecute, mqPutBag, and mqBagToBuffer calls, and set on exit from the mqExecute, mqGetBag, and mqBufferToBag calls.

MQIASY_MSG_SEQ_NUMBER

PCF message sequence number. Valid values are 1 or greater. The initial value is 1.

The value in the bag is used on entry to the mqExecute, mqPutBag, and mqBagToBuffer calls, and set on exit from the mqExecute, mqGetBag, and mqBufferToBag calls.

MQIASY_REASON

Reason code. Valid values are the MQRC_* constants. The initial value is MQRC_NONE.

The value in the bag is used on entry to the mqExecute, mqPutBag, and mqBagToBuffer calls, and set on exit from the mqExecute, mqGetBag, and mqBufferToBag calls.

MQIASY_TYPE

PCF command type. Valid values are the MQCFT_* constants. For user messages, the value MQCFT_USER should be used. The initial value is MQCFT_USER for bags created as user bags and MQCFT_COMMAND for bags created as administration or command bags.

The value in the bag is used on entry to the mqExecute, mqPutBag, and mqBagToBuffer calls, and set on exit from the mqExecute, mqGetBag, and mqBufferToBag calls.

MQIASY_VERSION

PCF version. Valid values are the MQCFH_VERSION_* constants. The initial value is MQCFH_VERSION_1.

If the value in the bag is set to a value other than MQCFH_VERSION_1, the value is used on entry to the mqExecute, mqPutBag, and mqBagToBuffer calls. If the value in the bag is MQCFH_VERSION_1, the PCF version is the lowest value required for the parameter structures that are present in the message.

The value in the bag is set on exit from the mqExecute, mqGetBag, and mqBufferToBag calls.

Managed File Transfer administration reference

Use the following reference information to help you administer Managed File Transfer.

Related reference

[“MFT commands reference” on page 2008](#)

All Managed File Transfer (MFT) commands are listed with links to their detailed descriptions.

How MFT agents allocate source transfer slots to new requests

A managed file transfer (MFT) agent contains a number of source transfer slots. Each source transfer slot holds either details of a managed transfer that the agent is currently acting as the source agent for, or details of a managed call that the agent is currently processing.

The number of source transfer slots on an agent is specified by the agent property

maxSourceTransfers, which has a default value of 25.

An agent also has a number of queued transfer slots as well. These slots are used to hold managed transfer or managed call requests that are currently on the agent's backlog waiting to be processed. The number of queued transfer slots is specified by the agent property **maxQueuedTransfers**. The default value of this property is 1000.

When an agent receives either a managed transfer request asking it to act as the source agent or a managed call request, it checks to see if it has a free source transfer slot.

If the agent does have a free transfer slot, the managed transfer or managed calls is assigned to one of the slots and the agent starts processing it.

If all of the source transfer slots are occupied, the agent assigns the managed transfer or managed call a queued transfer slot, so that it can be processed later.

However, if all of the queued transfer slots are full, the managed transfer request is rejected and the agent writes the following message to its event log:

```
BFGSS0030W: The agent is already acting as the source agent for the maximum number of file transfer operations and unable to queue further requests, due to the queued transfer limit of <maxQueuedTransfers> being reached. The new transfer request will not be carried out.
```

When a managed transfer or managed call completes (either successfully, or due to an error), its source transfer slot is released. The agent then moves a managed transfer or managed call from a queued transfer slot to the free source transfer slot, and starts processing it.

See the [Advanced agent properties: Transfer limit](#) section of the topic [The MFT agent.properties file](#) for more information about the **maxSourceTransfers** and **maxQueuedTransfers** properties.

MFT agent status values

The **fteListAgents** and **fteShowAgentDetails** commands produce agent status information. There are several possible values for this status.

ACTIVE

The agent is running and is sending or receiving files. The agent is publishing its status at regular intervals. The last update was received within the expected time period.

ENDED UNEXPECTEDLY

The agent has ended unexpectedly. The agent will be automatically restarted, unless there have been more than **maxRestartCount** restarts within the **maxRestartInterval** time period and the **maxRestartDelay** value is less than or equal to 0. For more information about these properties, see [The agent.properties file](#).

NO_INFORMATION

The agent is not publishing updates in a form that this command can process.

PROBLEM

The agent command handler might not be working. The agent is publishing status messages, but these status messages are out of date.

READY

The agent is running, but is not sending or receiving files. The agent is publishing its status at regular intervals. The last update was received within the expected time period.

STARTING

The agent is starting, but is not yet ready to perform transfers.

STOPPED

The agent has been stopped.

STOPPING

The agent has been stopped in a controlled manner and is in a transient state. While the agent is in this state, it does not accept any new managed transfer requests and waits for any in-progress transfers to complete before it shuts itself down. For more information, see [Stopping an MFT agent](#).

UNKNOWN

The status of the agent cannot be determined. It might have published a status which is not recognized by this tool. If you have mixed product versions on your network, upgrading the installation version of this tool might fix this problem.

When you run commands or look at the list of agents connecting to a coordination manager and their individual properties, you can see a new **Status Age** value for the agent that shows the age of their last reported status. For more information, see [What to do if an agent is shown as being in an UNKNOWN state](#).

Use the **fteListAgents** command to list all of the Managed File Transfer agents that are registered with a particular coordination queue manager.

[“fteShowAgentDetails \(display MFT agent details\)” on page 2159](#)

Use the **fteShowAgentDetails** command to display the details of a particular Managed File Transfer Agent. These are the details that are stored by the agent's Managed File Transfer coordination queue manager.

Multi

MFT process controller overview

The IBM MQ Managed File Transfer (MFT) process controller is responsible for starting an MFT agent, and restarting that process if it ends for any reason. There is one process controller for every agent process.

Note: The process controller is applicable to IBM MQ for Multiplatforms only.

 On IBM MQ for z/OS the agent process is restarted by Automatic Restart Manager (ARM). For more information on this, see [Configuring MFT for the z/OS Automatic Restart Manager \(ARM\)](#)

How the process controller works

When the **fteStartAgent** command is run, it starts up an instance of the process controller for that agent and the process controller then starts the agent process.

When the **fteStopAgent** command is run, it connects to the process controller for that agent and sends it a stop request. The process controller receives the request, stops the agent process and then shuts itself down.

The process controller monitors the agent process. If the agent process stops unexpectedly, the process controller restarts it.

By default, if an agent process stops five times within a two minute period, the process controller shuts itself down and does not try to restart the agent again. In this situation, you need to restart the agent manually, using the **fteStartAgent** command.

You can change this behavior by modifying the following agent properties:

- **maxRestartCount**
- **maxRestartDelay**
- **maxRestartInterval**

If you have configured an agent to connect to its agent queue manager using the BINDINGS transport, the process controller creates a connection to this queue manager when it starts up. The process controller then monitors this connection.

If the connection is broken because the queue manager has become unavailable, the process controller stops the agent and then attempts to re-establish the connection at regular intervals.

The time period between reconnection attempts is determined by the agent property **agentQMgrRetryInterval**. Once the queue manager is available again and the process controller has been able to connect to it, the process controller restarts the agent process.

Note: When an agent is configured to connect to its agent queue manager using the CLIENT transport, the agent process remains active if it becomes disconnected from the queue manager. In this situation, the agent process tries to reconnect itself at regular intervals.

For more information on the four properties mentioned in this section, see the [Advanced agent properties: Process controller](#) section of *The MFT agent.properties* file topic.

Process controller log files

The process controller writes informational messages to its event log. This is a file called pceventN.log, where N is a number, which can be found in the following directory: MQ_DATA_PATH/mqft/logs/coordination_qmgr_name/agents/agent_name/logs/

The size of each process controller event log file, and the number of historical files, is determined by the agent properties **outputLogSize** and **outputLogFiles**.

For more information on the properties mentioned in this section, see the [Advanced agent properties: Tracing and logging](#) section of *The MFT agent.properties* file topic.

Note: These properties are also used to determine the size and number of agent log files (called outputN.log) as well as the process controller log files.

The messages written to the process controller event log include the process identifier of the process controller, and the process identifier of the agent process. Some examples of these messages are shown here:

```
[21/06/2022 16:17:40.000 GMT Daylight Time] 00000000000049e0
ProcessContro I BFGPC0003I: IBM MQ Managed File Transfer process controller started.
Log files located at: C:\ProgramData\IBM\MQ\mqft\logs\QM1\agents\AGENT1.

[21/06/2022 16:17:55.000 GMT Daylight Time] 00000000000049e0
ProcessContro I BFGPC0007I: IBM MQ Managed File Transfer process controller with process
identifier 18736 started AGENT1@QM1 with process identifier 1748.

[21/06/2022 16:19:20.000 GMT Daylight Time] 00000000000049e0
ProcessContro I BFGPC0027W: Process has ended with return code 1 and will be
restarted to attempt to recover the problem.

[21/06/2022 16:19:20.000 GMT Daylight Time] 00000000000049e0
ProcessContro I BFGPC0007I: IBM MQ Managed File Transfer process controller with process
identifier 18736 started AGENT1@QM1 with process identifier 1304.
```

Here, the process controller associated with the agent AGENT1 was running with process identifier 18736.

Initially, it started the agent process – the process identifier for this process was 1748.

Shortly after the agent started, the process controller detected that it had stopped unexpectedly and so restarted it. Following the restart, the process identifier for the agent process is 1304.

[“MFT process controller exit codes” on page 2523](#)

If the Managed File Transfer process controller ends, a BFGPC0004I message is generated with an exit code that gives the reason why the process controller ended.

MFT agent process controller status values

The **fteShowAgentDetails** command produces agent process controller status information. There are several possible values for this status.

WAITING

The agent process controller is waiting for the queue manager to become available before starting the agent.

STARTED

The agent process controller has started the agent process.

STOPPED

The agent process controller has been stopped, either because of a request to stop the agent or because there have been too many agent process restarts within the restart interval.

RECOVERING

The agent process unexpectedly stopped and the process controller will attempt to restart it.

ISTOPPING

The agent process has received a request to shut down immediately. When the agent process has stopped, the process controller will stop.

CSTOPPING

The agent process has received a request to shut down in a controlled manner. When the agent process has stopped, the process controller will stop.

UNKNOWN

The agent process controller status cannot be determined. It might be that the agent process controller is not running, or that it is running on a different system from where the **fteShowAgentDetails** command was run.

Related reference

fteShowAgentDetails

Use the **fteShowAgentDetails** command to display the details of a particular Managed File Transfer Agent. These are the details that are stored by the agent's Managed File Transfer coordination queue manager.

MFT logger status values

The **fteShowLoggerDetails** commands produce logger status information. There are several possible values for this status.

ACTIVE

The logger is running and is sending or receiving files. The logger is publishing its status at regular intervals. The last update was received within the expected time period.

READY

The logger is running, but is not sending or receiving files. The logger is publishing its status at regular intervals. The last update was received within the expected time period.

STARTING

The logger is starting, but is not yet ready to perform transfers.

UNREACHABLE

Logger status updates were not received at the expected time intervals. The logger might have stopped running due to an error, or have been shut down abruptly, or be running but experiencing communication problems.

STOPPED

The logger has been stopped. It was shut down in a controlled manner.

ENDED UNEXPECTEDLY

The logger has ended unexpectedly. The logger will be automatically restarted, unless there have been more than `maxRestartCount` restarts within the `maxRestartInterval` time period and the `maxRestartDelay` value is less than or equal to 0. For more information about these properties, see [MFT logger configuration properties](#).

For the **`fteShowLoggerDetails`** command the details for the this status will include a status code, which is the logger process exit code. See "Process Exit Codes" for a list of known exit codes.

NO_INFORMATION

The logger version might be IBM WebSphere MQ File Transfer Edition 7.0.2 earlier. The logger is not publishing updates in a form that this command can process.

UNKNOWN

The status of the logger cannot be determined. It might have published a status which is not recognized by this tool. If you have mixed product versions on your network, upgrading the installation version of this tool might fix this problem.

PROBLEM

The logger command handler might not be working. The logger is publishing status messages, but these status messages are out of date.

MFT process controller exit codes

If the Managed File Transfer process controller ends, a BFGPC0004I message is generated with an exit code that gives the reason why the process controller ended.

The following message appears to indicate that process controller has ended:

```
BFGPC0004I IBM MQ Managed File Transfer process controller ended with exit code reason_code.
```

where *reason_code* shows the reason why the process controller has ended.

Note: Exit codes from the process controller mostly reflect the standard operating system exit codes, but some exit codes are defined for specific purposes and are always accompanied with a specific message in the process controller log file.

Reason code	Description
RC_SUCCESS = 0	The process controller ended successfully.
RC_FAILURE = 1	General process controller failure return code (should in general not be returned).
RC_EXIT = 2	The process controller was forced to exit (for example, a diagnostic system requested the process controller to terminate).
RC_ABEND = 70	The process controller has had an unrecoverable problem and is forcibly terminating.
RC_QMUNAVAIL = 75	The process controller cannot continue because the queue manager for the process controller is unavailable.
RC_CONFIG = 78	The process controller cannot continue because there is a problem with the startup configuration data.

These exit codes are written to pceventX.log, where X can be any number, for example the log file name can be pcevent0.log.

If you transfer files to or from IBM i systems using Managed File Transfer in text mode and you want to convert the data in the files, consider the information in this topic.

[“Transferring save files located in QSYS.LIB on IBM i” on page 2548](#)

Managed File Transfer supports the transfer of save files located in the QSYS.LIB file system between two IBM i systems. Consider the following information when requesting file transfers of save files.

[“Transferring generation data groups \(GDGs\)” on page 2550](#)

Managed File Transfer supports generation data groups (GDGs) for source and destination data sets on z/OS. Absolute and relative GDG names are supported. When you write to a new generation, the base GDG must exist.

[“Using wildcard characters with MFT” on page 2551](#)

You can use wildcard characters when you specify source file names and source file paths for file transfers. This allows you to select multiple files simultaneously.

Transferring files and data sets between z/OS and distributed systems

You can transfer files and supported data set types between z/OS and distributed file systems by using Managed File Transfer. Review the following behavior carefully, which is dependent on the type of system you are transferring from and to.

Managed File Transfer supports generation data groups (GDGs) for source and destination data sets on z/OS. Absolute and relative GDG names are supported. When you write to a new generation, the base GDG must exist.

When you transfer a file or data set to tape, any existing data set that is already on the tape is replaced. The attributes for the new data set are set from attributes passed in the transfer definition. If no attributes are specified, attributes are set to the same as those attributes for the source data set or are set to the default values when the source is a file. The attributes of an existing tape data set are ignored.

Transferring from a file to a data set - binary transfers

The format of the destination data set determines the destination record length. Ensure the data set exists on the destination system or specify the destination data set with the correct attributes so that the

data set is created properly. If you do not specify attributes, the system specifies the following default: a physical sequential data set with an undefined record format and the maximum block size (BLKSIZE) for the device (as returned by the DEVTYPE macro). For example, for DASD the size is 6144 and for tape the size is 32760. If you want to transfer a file on a distributed system to a z/OS data set in binary mode, note the following behavior:

Physical sequential (PS) destination data sets:

- The source file on the distributed system is read sequentially to fill each record or block.
- On variable format data sets, each record is filled to capacity.

Partitioned data set (PDS) destination data sets:

- Each source file is copied to a PDS member with the same or equivalent name. If the file name is longer than the maximum allowed length of a member name, the file name is converted to a valid member name. For more information about member names, see [Object naming conventions](#). If the source file is a directory, each file in that directory becomes a member of the PDS.
- If a PDS member exists, the member is overwritten if you have specified overwrite existing destination files for the transfer. If you do not specify overwrite, the transfer fails.
- The source file on the distributed system's is read sequentially to fill each record or block for the member.
- On variable format PDS members, each record is filled to capacity.

Transferring from a file to a data set - text transfers

The format of the destination data set determines the destination record length. Ensure the data set exists on the destination system or specify the destination data set with the correct attributes so the data set is created properly. If you want to transfer from a file on a distributed system to a z/OS data set as text, note the following behavior:

Physical sequential (PS) destination data sets:

- Each line of text becomes a record (or a block for undefined record format (RECFM=U) data sets). End-of-line characters are not present in data set records (for non-ASA data sets only).
- When ASA format control characters are used in the destination data set, end-of-line characters are effectively converted to equivalent ASA format control code.
- When a line is longer than a record, the line is split at the record boundary and flows onto the next record.

PDS destination data sets:

- Each source file is copied to a PDS member with the same or equivalent name. If the file name is longer than the maximum allowed length of a member name, the file name is converted to a valid member name. For more information about member names, see [Object naming conventions](#). If the source file is a directory, each file in that directory becomes a member of the PDS.
- If a PDS member exists, the member is overwritten if you have specified overwrite existing destination files for the transfer. If you do not specify overwrite, the transfer fails.
- Each line of text becomes a record (or a block for undefined record format (RECFM=U) data sets). End-of-line characters are not present in member records (for non-ASA data sets only).
- When ASA format control characters are used in the destination data set, end-of-line characters are effectively converted to equivalent ASA format control code.
- When a line is longer than a record, the line is split at the record boundary and flows onto the next record.

Transferring from a data set to a file - binary and text transfers

If you want to transfer from a data set to a file as binary or text, note the following behavior:

- The content of each record is transferred in binary form to a file; no record, block format information, or ASA format control characters are transferred.
- For text transfers only, each data set record becomes a line with text converted to the code page of the destination agent. That is, a carriage return-line feed (CRLF) is appended for a Windows destination system and carriage return (CR) is appended for an AIX destination system.
- **Non-VSAM and PS source data sets.** The records for the source data set are transferred to the destination file and concatenated together. If the destination file exists, the file is overwritten, depending on the destination file behavior option you have specified for the file transfer. If the destination is specified as a directory rather than a file, the destination filename will be the data set name excluding the high-level qualifier (HLQ).
- **PDS source data sets.** Each specified member, or all members if no member is specified, is extracted to the destination. If the destination specifies a directory, members are extracted to separate files. Otherwise each specified member is written to the destination file, resulting in effectively only one member being transferred. If the destination file exists for a member, the file is overwritten, depending on the destination file behavior option you have specified for the file transfer.

Related reference

[“Guidelines for transferring files” on page 2523](#)

Depending on the operating system you are transferring from and to and whether you are transferring in binary or text mode, there are guidelines on what behavior to expect.

[“Transferring between data sets on z/OS” on page 2526](#)

You can transfer between z/OS data sets using Managed File Transfer. Review the following behavior carefully to ensure your data sets are transferred correctly.

[“fteCreateTransfer \(start a new file transfer\)” on page 2079](#)

The **fteCreateTransfer** command creates and starts a new file transfer from the command line. This command can start a file transfer immediately, schedule a file transfer for a future time and date, repeat a scheduled transfer one or more times, and trigger a file transfer based on certain conditions.

Transferring between data sets on z/OS

You can transfer between z/OS data sets using Managed File Transfer. Review the following behavior carefully to ensure your data sets are transferred correctly.

Managed File Transfer does not support uncataloged data sets either on disk or tape. Existing data sets must be cataloged and new data sets will be cataloged.

Managed File Transfer can transfer most data set types, with some restrictions which are described below. If a particular data set type, or set of characteristics is not supported, you can use the alternative methods described in [“Using Managed File Transfer in combination with z/OS utilities to transfer files” on page 2528](#).

Consider the following cases:

If you copy or move a data set between z/OS systems and the destination does not exist.

By default, the destination data set is created with the identical characteristics to the source. You can specify attributes for the destination data set to override the default characteristics. If you do this, a compatibility check is performed to ensure the transfer is possible.

If you copy or move a data set between z/OS systems and the destination already exists.

If you specify attributes for the destination data set to override the default characteristics, a compatibility check is performed to ensure the destination data set can be accessed in the required way. However, you cannot override the following attributes:

- Base data set organization and type
- Logical record length (LRECL)
- Block size (BLKSIZE)

If you are transferring a data set to tape.

When you transfer a data set to tape, any existing data set that is already on the tape is replaced. The attributes for the new data set are set from attributes passed in the transfer definition. If no attributes are specified, attributes are set to the same as those for the source data set or are set to the default values when the source is a file. The attributes of an existing tape data set are ignored.

In addition, the user identifier that the destination agent is running as needs to have the correct authority to mount tapes. Refer to the documentation for the external security manager being used by your enterprise for information on how to do this.

If you are transferring from tape to a data set.

In order to access a dataset on tape, the user identifier that the source agent is running as needs to have the appropriate authority to mount tapes. Refer to the documentation for the external security manager being used by your enterprise for information on how to do this.

Data set compatibility

Review the following behavior and restrictions for data set compatibility:

Record format and length differences:

Variable-format records use a 4 byte record length field in the record data. Therefore for a transfer from a fixed record to a variable record data set, the variable record length must be greater than or equal to the fixed record length plus 4. For a transfer from a variable format record data set to a fixed format record data set, the fixed format record data set record length must be greater than or equal to the variable record length minus 4.

Block size differences:

- For fixed- and variable-format record data, block size differences makes the source and destination data set layout different.
- For undefined format records, provided the destination block size is greater or equal to the source data set block size, you can transfer a data set.
- For undefined format data sets, you cannot transfer if the source block size is greater than the destination block size.

Partitioned data sets (PDS) and partitioned data set extended (PDSE) data sets

The following behavior and restrictions apply equally to PDS and PDSE:

- When you transfer a PDS or PDSE to a destination PDS or PDSE, the member information and statistics are not preserved. For example, if you transfer a load library that is stored as a PDSE, the destination PDSE is not usable as a load library. See [“Using Managed File Transfer in combination with z/OS utilities to transfer files” on page 2528](#) for methods that can be used to transfer the PDSE so that it can be used as a load library.
- If you transfer a PDS or PDSE member to a destination PDS or PDSE, a member of the destination PDS or PDSE is created. If the destination PDS or PDSE member already exists, the member is overwritten. If you transfer a PDS or PDSE member to a non-PDS or non-PDSE destination data set, the destination data set is created to contain the member data. If the destination data set already exists, the data set is overwritten.
- If you attempt to transfer a PDS or PDSE to a non-PDS or non-PDSE destination, this results in all members of the PDS or PDSE being written to the non-PDSE destination. Each subsequent member transfer overwrites the previous contents of the non-PDSE destination or fails, depending on the transfer options.
- When you transfer a PDS or PDSE to a destination PDS or PDSE, a copy of the entire PDS or PDSE is created at the destination. If the destination PDS or PDSE already exists, members from the source are added. If a PDS or PDSE member already exists at the destination, the member is overwritten.
- The transfer of a non-PDS or non-PDSE to a destination PDS or PDSE, adds the contents of the non-PDS or non-PDSE as a new member of the PDS or PDSE. If the PDS member already exists, the member is overwritten. If you do not specify a name for a new member, a name is generated from the source data set or DD name.

- There is a known limitation with transfers to PDS and PDSE data sets on systems where disk space is limited. See [Troubleshooting common MFT problems](#).

VSAM data sets

Managed File Transfer does not support transfers to, or from, VSAM data sets.

Sequential data sets

Managed File Transfer supports logical record lengths (LRECL) only in the range of 4 – 32756 for variable format data sets.

Managed File Transfer supports logical record lengths (LRECL) only in the range of 0 – 32760 for fixed format data sets.

Binary and text transfers

Binary transfer for data sets is defined as the record data in its binary form, as read from the data set using the default record format (type=record). Data is read and written on a record by record basis. The system service performs the necessary record and block conversion (where the data sets have different record and block settings) and the necessary ASA and machine control code conversion. If one data set is defined for ASA format control characters and the other is not appropriate, conversion to normal control codes is performed using the C/C++ system library function behavior.

Generation data groups (GDGs)

Managed File Transfer supports generation data groups (GDGs) for source and destination data sets on z/OS. Absolute and relative GDG names are supported. When you write to a new generation, the base GDG must already exist.

Depending on the operating system you are transferring from and to and whether you are transferring in binary or text mode, there are guidelines on what behavior to expect.

[“Transferring generation data groups \(GDGs\)” on page 2550](#)

Managed File Transfer supports generation data groups (GDGs) for source and destination data sets on z/OS. Absolute and relative GDG names are supported. When you write to a new generation, the base GDG must exist.

[“Transferring data sets to and from Connect:Direct nodes” on page 2532](#)

You can transfer data sets between Managed File Transfer agents and IBM Sterling Connect:Direct nodes using the Connect:Direct bridge. You can specify a data set as the transfer source, transfer destination, or both.

[“Transferring files and data sets between z/OS and distributed systems” on page 2524](#)

You can transfer files and supported data set types between z/OS and distributed file systems by using Managed File Transfer. Review the following behavior carefully, which is dependent on the type of system you are transferring from and to.

Using Managed File Transfer in combination with z/OS utilities to transfer files

The various methods you can use with Managed File Transfer (MFT) to transfer a wide range of data sets between z/OS systems.

You can use these methods for all data sets that MFT supports, but these methods are particularly useful when used to transfer data sets for which MFT supports with restrictions, or has no support for at all. These approaches work for all supported versions of MFT.

For example, these methods can be used to transfer PDSE data sets between systems without losing directory information.

Each of the methods use the same general approach of using JCL to:

- Run one or more z/OS utilities to convert the source data set into a format that MFT can transfer.

- Schedule MFT to transfer the converted data set to the target system, and wait until the transfer is complete.
- Schedule JCL on the target system to run one or more z/OS utilities to convert the converted data set into a target data set that is the same as the original source data set.

As well as the methods described in this topic, there is an alternative approach described in [vsamtransfer](#), which describes how Ant tasks can be used to run commands before and after a transfer to do a similar thing. While the sample demonstrates the transfer of VSAM data sets, the approach can be extended to other data set types, subject to the limitations of the [REPRO](#) command.

Method 1: Using the TRANSMIT (XMIT) and RECEIVE commands with MFT

This method uses the [TRANSMIT \(XMIT\)](#) TSO command to convert a data set into a sequential data set, and transfer it using MFT. Once the transfer is complete the sequential data set is converted back into the original data set type using the [RECEIVE](#) command.

This method can be used with any data set supported by the XMIT command. A list of supported data sets, and attributes are listed in [Transmitting data sets](#). For example, this method can be used to transfer PDSEs while preserving directory information, but it cannot be used to transfer VSAM data sets.

This method is implemented using two JCL jobs and you need to adjust these jobs so that they are suitable for your environment, and the type of data being transferred. You need to change the values inside < >. In most environments extra job steps need to be added to delete earlier versions of the data sets, or alternatively you can use generation data groups.

You submit the first of these jobs, XMITJOB1 shown in the following example, on the sending side.

The XMIT step runs the XMIT command to convert the source data set into a sequential format data set. X.X is specified for the node and user name to pass the command validation checks, but a proper node and user name are not needed.

The MFT step initiates a file transfer from the source agent, SRC, to the destination agent, DEST. The **-w** flag means that the [fteCreatetransfer](#) command waits until the transfer has completed. The **-ds** flag indicates that a sequential data set is to be created on the destination agent and provides the correct DCB characteristics, so that there is sufficient space when the data set is dynamically allocated.

In this case, both data set names are surrounded with double quotes, indicating that fully qualified data set names are used. If double quotes are not used, the default high level qualifier of the source or destination agent is used.

The SUBMIT step only runs if the MFT step successfully completes. This step submits the RECVJOB1 job which restores the transferred data set to its original format on the destination system.

Example XMITJOB1 JCL

```
//XMITJOB1 JOB NOTIFY=&SYSUID
//*
//*****
//* Use the XMIT command to unload the data set to fix block,
//* 80 logical record format
//*****
//XMIT EXEC PGM=IKJEFT01
//SYSTSPRT DD SYSOUT=*
//SYSTSIN DD *
XMIT X.X DSN('USER1.SOURCE.DATASET')          +
OUTDATA('USER1.SOURCE.DATASET.UNLOADED')
/*
//*****
//* Invoke MFT fteCreateTransfer
//*****
//MFT EXEC PGM=IKJEFT01,REGION=0M
//STDERR DD SYSOUT=*
//STDOUT DD SYSOUT=*
//SYSTSPRT DD SYSOUT=*
//SYSTSIN DD *
BPXBATCH SH <MFT path>/fteCreateTransfer      +
```

```

-w                                     +
-sa SRC
+
-da DEST
+
-ds "'USER1.TARGET.DATASET.UNLOADED' ;      +
RECFM(F,B);BLKSIZE(3120);LRECL(80);SPACE(10,10); +
CYL;RELEASE"                                +
"'"USER1.SOURCE.DATASET.UNLOADED'"
/*
//*****
//* Submit the restore job to the internal reader
//
//*****
//SUBMIT EXEC PGM=IEBGENER,COND=(0,NE)
//SYSPRINT DD SYSOUT=*
//SYSUT1 DD DISP=SHR,DSN=USER1.JCL.MFT(RECVJOB1)
//SYSUT2 DD SYSOUT=(A,INTRDR),DCB=BLKSIZE=80
//SYSIN DD DUMMY

```

The RECVJOB1 JCL is shown in the following example. When it is submitted by XMITJOB1, it is routed by JES2 to the target node as indicated on the ROUTE command on the second line of the job. Depending on the settings of your installation, you might need to provide USER and PASSWORD parameters on the JOB step.

The RECEIVE step takes the data set that has been transferred by MFT and uses the TSO RECEIVE command to convert it back into its original format.

Example RECVJOB1 JCL

```

//RECVJOB1 JOB NOTIFY=&SYSUID
/*ROUTE XEQ NODE2
//*
//*****
//* Convert the data set back into its original format
//*****
//RECEIVE EXEC PGM=IKJEFT01
//SYSTSPRT DD SYSOUT=*
//UNLOAD DD DISP=SHR,DSN='USER1.TARGET.DATASET.UNLOADED'
//SYSTSIN DD *
RECEIVE INFILE(UNLOAD)
DSN('USER1.TARGET.DATASET')
/*

```

Method 2: Using the ADDRSSU utility with MFT

This method uses the [DUMP](#) and [RESTORE](#) commands of the ADDRSSU utility to convert data sets to and from a format that MFT can transfer. This method can be used with a wider range of data sets than method one, including VSAM data sets, and for transfer of multiple data sets at the same time.

Information on data sets that are not supported with DUMP is described in [Special considerations for DUMP](#).

As before, this method is implemented using two JCL jobs and you need to adjust these jobs so that they are suitable for your environment, and the type of data being transferred. You need to change the values inside < >. In most environments extra job steps need to be added to delete earlier versions of the data sets, or alternatively you can use generation data groups.

You submit the first of these jobs, DUMPJOB1 shown in the following example, on the sending side.

The DUMP step runs the ADDRSSU DUMP command to convert the source data set into a sequential data set. This step can be adjusted to dump multiple data sets if needed.

The XMIT step converts the dumped data set into a fix block, 80 logical record format. This step is not strictly necessary but provides consistency with the approach used in XMITJOB1. X.X is specified for the node and user name to pass the command validation checks, but a proper node and user name are not needed.

The MFT step initiates a file transfer from the source agent, SRC, to the destination agent, DEST. The **-w** flag means that the `fteCreateTransfer` command waits until the transfer has completed. The **-ds** flag indicates that a sequential data set is to be created on the destination agent and provides the correct DCB characteristics, so that there is sufficient space when the data set is dynamically allocated.

In this case, both data set names are surrounded with double quotes, indicating that fully qualified data set names are used. If double quotes are not used, the default high level qualifier of the source or destination agent is used.

The SUBMIT step only runs if the MFT step successfully completes. This step submits the RESTJOB1 job which restores the transferred data set to its original format on the destination system.

Example DUMPJOB1 JCL

```
//DUMPJOB1 JOB NOTIFY=&SYSUID,REGION=0M
//*
//*****
//* Invoke ADRDSSU to unload the selected data sets
//
//*****

//DUMP EXEC PGM=ADRDSSU,REGION=2048K
//SYSPRINT DD SYSOUT=*
//DUMPDD DD DSN=USER1.SOURCE.DATASET.BACKUP,DISP=(NEW,CATLG),
// UNIT=SYSDA,SPACE=(CYL,(200,100,0),RLSE)
//SYSIN DD *
    DUMP DATASET(INCLUDE(USER1.SOURCE.DATASET)) -
    OPTIMIZE(4) OUTDDNAME(DUMPDD) TOLERATE(ENQF)
/*
//*****
//* Convert the contents to fix block, 80 logical record format
//
//*****

//XMIT EXEC PGM=IKJEFT01
//SYSTSPRT DD SYSOUT=*
//DUMPDD DD DISP=SHR,DSN=USER1.SOURCE.DATASET.BACKUP
//XMITDD DD DISP=(,CATLG),DSN=USER1.SOURCE.DATASET.BACKUP.UNLOAD,
// DCB=(LRECL=80,RECFM=FB,BLKSIZE=3120),
// UNIT=SYSDA,SPACE=(CYL,(200,100,0),RLSE)
//SYSTSIN DD *
    XMIT X.X DDNAME(DUMPDD) +
    OUTDD(XMITDD)
/*
//*****
//* Invoke MFT fteCreateTransfer
//
//*****

//MFT EXEC PGM=IKJEFT01,REGION=0M
//STDERR DD SYSOUT=*
//STDOUT DD SYSOUT=*
//SYSTSPRT DD SYSOUT=*
//SYSTSIN DD *
    BPXBATCH SH <MFT path>/fteCreateTransfer      +
    -w                                             +
    -sa SRC                                       +
    -da DEST                                       +
    -ds "'USER1.TARGET.DATASET.BACKUP.UNLOAD' ;   +
    RECFM(F,B);BLKSIZE(3120);LRECL(80);SPACE(50,50); +
    CYL;RELEASE;UNIT(SYSDA)"                     +
    "'USER1.SOURCE.DATASET.BACKUP.UNLOAD'"
/*
//*****
//* Submit the restore job to the internal reader
//
//*****

//SUBMIT EXEC PGM=IEBGENER,COND=(0,NE)
//SYSPRINT DD SYSOUT=*
//SYSUT1 DD DISP=SHR,DSN=USER1.JCL.MFT(RESTJOB1)
//SYSUT2 DD SYSOUT=(A,INTRDR),DCB=BLKSIZE=80
//SYSIN DD DUMMY
```

The RESTJOB1 JCL is shown in the following example. When the job is submitted by DUMPJOB1, it is routed by JES2 to the target node as indicated on the ROUTE command on the second line of the job. Depending on the settings of your installation, you might need to provide USER and PASSWORD parameters on the JOB step.

The RECEIVE step takes the data set that has been transferred by MFT and uses the TSO RECEIVE command to convert it back into the format expected by the ADRDSSU RECEIVE command.

The RESTORE step then uses ADRDSSU RECEIVE to convert the data set into its original format. The RENAMEU parameter could be used here to change the data set prefixes if needed.

Example RESTJOB1 JCL

```
//RESTJOB1 JOB NOTIFY=&SYSUID,REGION=0M
//*

//*****
/* Convert the data set back into the form accepted by
/* RECEIVE
//*****
//RECEIVE EXEC PGM=IKJEFT01
//SYSTSPRT DD SYSOUT=*
//UNLOAD DD DISP=SHR,DSN=USER1.TARGET.DATASET.BACKUP.UNLOAD
//SYSTSIN DD *
RECEIVE INFILE(UNLOAD)
DSN('USER1.TARGET.DATASET.BACKUP')
/*
//*****
/* Convert the data set back into its original format
//
*****

//RESTORE EXEC PGM=ADRDSSU,REGION=2048K
//SYSPPRINT DD SYSOUT=*
//DUMPDD DD DISP=SHR,DSN=USER1.TARGET.DATASET.BACKUP
//SYSIN DD *
RESTORE DATASET(INCLUDE(**)) -
INDDNAME(DUMPDD) -
CATALOG
/*
```

[“Guidelines for transferring files” on page 2523](#)

Depending on the operating system you are transferring from and to and whether you are transferring in binary or text mode, there are guidelines on what behavior to expect.

[“Transferring files and data sets between z/OS and distributed systems” on page 2524](#)

You can transfer files and supported data set types between z/OS and distributed file systems by using Managed File Transfer. Review the following behavior carefully, which is dependent on the type of system you are transferring from and to.

Transferring data sets to and from Connect:Direct nodes

You can transfer data sets between Managed File Transfer agents and IBM Sterling Connect:Direct nodes using the Connect:Direct bridge. You can specify a data set as the transfer source, transfer destination, or both.

Specifying data set names

To specify a data set on a Connect:Direct node in a transfer request, use the syntax that is used for data set transfers between Managed File Transfer agents, but with two changes:

- You must prefix the data set name with the Connect:Direct node name and a colon (:). The syntax is as follows:

```
cdNode:data_set_name{;attrib1;...;attribN}
```

For example, to specify a partitioned data set called OBJECT.LIB on the system where the Connect:Direct node CD_NODE1 is located, use the following syntax:

```
CD_NODE1:// 'OBJECT.LIB' ;RECFM(F,B);BLKSIZE(800);LRECL(80)
```

In this example, three optional attributes are specified by the text RECFM(F,B);BLKSIZE(800);LRECL(80).

- The specified data set name is interpreted as a fully qualified data set name, regardless of whether it is enclosed by single quotation mark characters. The system never adds any prefix. If you want to specify a prefix, such as the user ID that the agent runs under, you must specify it as part of the data set name. This differs from the behavior for data set transfers that involve only Managed File Transfer agents, where if the specified data set name is not enclosed by single quotation mark characters, the system adds a prefix of the default high-level qualifier for the destination agent.

Except for these two changes, specify the data set name and any optional attributes using the same syntax that is used for data set transfers between Managed File Transfer agents, which has the following rules:

- You must prefix the data set name with two forward slash characters (//).
- If you want to specify data set attributes, provide these after the data set name, separated by semicolons. Attributes must be provided in the format *key (value)*, which is suitable for BPXWDYN.

For more information about specifying data sets in a transfer request, see [“fteCreateTransfer \(start a new file transfer\)”](#) on page 2079 and [“fteCreateTemplate \(create new file transfer template\)”](#) on page 2064.

Parameters to use in your transfer request

For most transfer requests that involve data sets on Connect:Direct nodes, you can specify the source and destination data sets in the same way as you would for a data set transfer that involves only Managed File Transfer agents. Use the **source_specification**, **-ds**, and **-dp** parameters with the **fteCreateTransfer** or **fteCreateTemplate** commands.

Note: If the destination of the transfer is a PDS and the destination agent is the Connect:Direct bridge agent, you must specify the **-de** parameter with the value of **overwrite**.

Specifying data set attributes

Certain data set attributes are set by Managed File Transfer and passed through as parameters to the Connect:Direct **COPY** process. You can also supply certain attributes in the transfer request, by specifying the appropriate BPXWDYN key. The Connect:Direct bridge converts keys that have equivalent Connect:Direct properties to the format that is required by Connect:Direct. For example, in the data set specification CD_NODE1:// 'OBJECT.LIB' ;RECFM(F,B);BLKSIZE(800);LRECL(80), the attributes RECFM(F,B);BLKSIZE(800);LRECL(80) are converted to DCB=(RECFM=FB,BLKSIZE=800,LRECL=80).

For details of the mappings between these two types of parameter, including details of the BPXWDYN keys that are supported for use with a Connect:Direct transfer, see [“Mappings between Connect:Direct process statement parameters and BPXWDYN keys”](#) on page 2534. Not all BPXWDYN keys have an equivalent Connect:Direct process parameter, and not all Connect:Direct process parameters have an equivalent BPXWDYN key.

Additional considerations

- If your transfer destination is a partitioned data set at a Connect:Direct node, you must create the partitioned data set before the transfer, because the Connect:Direct node does not create it for you.

Related concepts

[Connect:Direct file paths specified with a double forward slash](#)

Related tasks

 [Transferring a data set to a Connect:Direct node on z/OS](#)

Related reference

[The Connect:Direct bridge](#)

[“Transferring between data sets on z/OS” on page 2526](#)

You can transfer between z/OS data sets using Managed File Transfer. Review the following behavior carefully to ensure your data sets are transferred correctly.

[“fteCreateTransfer \(start a new file transfer\)” on page 2079](#)

The **fteCreateTransfer** command creates and starts a new file transfer from the command line. This command can start a file transfer immediately, schedule a file transfer for a future time and date, repeat a scheduled transfer one or more times, and trigger a file transfer based on certain conditions.

[“fteCreateTemplate \(create new file transfer template\)” on page 2064](#)

The **fteCreateTemplate** command creates a file transfer template that you can keep for future use. The only required parameter is the **-tn *template_name*** parameter. All other parameters are optional, although if you specify a source file specification, you must also provide a destination file. Similarly, if you specify a destination file, you must also specify a source file specification.

Mappings between Connect:Direct process statement parameters and BPXWDYN keys

When you submit a transfer request for a data set where either the source or destination is a Connect:Direct node, any supported BPXWDYN keys that you provide are converted to a format that is accepted by Connect:Direct processes.

For more information about IBM Sterling Connect:Direct process statements, download the [Connect:Direct Process Language Reference Guide](#).

Parameter to Connect:Direct COPY statement	BPXWDYN key
DSN	DSN (valid for transfers to and from data sets). Specifying this key overrides the parameter value that is assigned by Managed File Transfer, which is based on the source or destination file specifications that are provided in the transfer request.
FILE	No mapping for data sets.
PNODE	No mapping. The primary node for the transfer is identified by Managed File Transfer. If you attempt to provide a value for this parameter, an error is produced.
SNODE	No mapping. The secondary node for the transfer is identified by Managed File Transfer. If you attempt to provide a value for this parameter, an error is produced.
DCB	See Mappings for subparameters of DCB

Table 362. Parameters to the Connect:Direct **COPY** statement, and the equivalent BPXWDYN keys used by Managed File Transfer (continued)

Parameter to Connect:Direct COPY statement	BPXWDYN key
DISP	See Mappings for subparameters of DISP for a COPY From statement and Mappings for subparameters of DISP for a COPY To statement
RESGDG	No mapping
LABEL	See Mappings for subparameters of LABEL
MSVGP	No mapping
UNIT	UNIT
VOL	See Mappings for subparameters of VOL
ALIAS	No mapping
EXCLUDE	No mapping
PDS.DIR	No mapping. Managed File Transfer sets the value of this process parameter to N, so no user-related information that is in the directory is sent.
REPLACE NOREPLACE	No BPXWDYN equivalent. The behavior when a destination data set already exists on the destination system is defined by the value of the -de (destination_file_behavior) parameter in the transfer request. For more information about the default behavior of Managed File Transfer when a destination data set already exists, see “ Transferring between data sets on z/OS ” on page 2526.
SELECT	No BPXWDYN equivalent. The data set members that are selected for copying are defined by the source file specification in the transfer request.
BUFND	No mapping
IOEXIT	No mapping
DATAEXIT	No mapping
SYSOPTS	See Mappings for subparameters of SYSOPTS
TYPE	No mapping
AVGREC	No mapping
DATACLAS	DATACLAS
DSNTYPE	DSNTYPE. Specifying a value of PDS for this key overrides the parameter value that is assigned by Managed File Transfer, which is LIBRARY. There are no mappings for any other value - EXTPREF, EXTREQ, BASIC, or LARGE. Specifying any of these unsupported values produces an error. Specifying PDS or LIBRARY for a sequential data set produces an error.
KEYLEN	No mapping
KEYOFF	No mapping
LIKE	LIKE

You can transfer data sets between Managed File Transfer agents and IBM Sterling Connect:Direct nodes using the Connect:Direct bridge. You can specify a data set as the transfer source, transfer destination, or both.

[The Connect:Direct bridge](#)

BPXWDYN properties you must not use with MFT

Some BPXWDYN options must not be specified when using the **fteCreateTemplate** command, the **fteCreateTransfer** command or the **bpxwdynAllocAdditionalOptions** property in the `agent.properties` file.

There are a number of BPXWDYN options that must not be specified with Managed File Transfer because they are used by the agent or they are not supported. If you use these options they can cause unpredictable behavior; the options are listed in the following table.

Table 370. BPXWDYN options that must not be specified with Managed File Transfer

BPXWDYN options	Description
DA DSN	Specifies the data set name to allocate.
FI DD	Specifies the ddname to allocate.
FILEDATA	Specifies, to the sequential access method services, whether the data is treated as text or binary.
OLD SHR MOD NEW SYSOUT	Specifies the data set status.

<i>Table 370. BPXWDYN options that must not be specified with Managed File Transfer (continued)</i>	
BPXWDYN options	Description
REUSE	Specifies that the named data set is freed before the function is performed.
HOLD	Specifies that the output data set is to be held until released by the user or operator.
KEEP DELETE CATALOG UNCATALOG	Specifies the data set disposition after it is freed.
RECOrg(LS)	Creates a VSAM linear data set.
MSG	Directs allocation messages. Note: This option can be used, but because Managed File Transfer uses this option to direct error information to the transfer log, using it can cause unpredictable behavior.

The **fteCreateTransfer** command creates and starts a new file transfer from the command line. This command can start a file transfer immediately, schedule a file transfer for a future time and date, repeat a scheduled transfer one or more times, and trigger a file transfer based on certain conditions.

[“fteCreateTemplate \(create new file transfer template\)” on page 2064](#)

The **fteCreateTemplate** command creates a file transfer template that you can keep for future use. The only required parameter is the **-tn** *template_name* parameter. All other parameters are optional, although if you specify a source file specification, you must also provide a destination file. Similarly, if you specify a destination file, you must also specify a source file specification.

[The agent.properties file](#)

Transferring text files with MFT

Text file transfer involves converting the code page of a file from one code page to another. Text file transfer also involves converting CRLF (carriage return-line feed) characters between systems. This topic summarizes text file transfer behavior of Managed File Transfer.

Unless you specify otherwise, conversion is from the default code page of the file's source system to the default code page of its destination system. Additionally, text file transfer performs new line conversion, which means that new line characters for the destination file are those native to its destination platform. You can override the use of the default code pages on a system by specifying the code page to use for reading the source file and writing the destination file. You can also specify the end-of-line character sequence to use for the destination file. For more information, see the topics [“fteCreateTransfer \(start a new file transfer\)” on page 2079](#).

Text file transfers perform simple code point substitutions between code pages. Text file transfers do not perform complex transfers or translations of data, for example, conversions between visual and logical forms of bidi data or text shaping.

Table 371. Text file transfer behavior for all platforms

Area	Default behavior	Can you change this behavior?
Source file encoding	Source platform encoding	Yes When you specify source file encoding and the source is a data set, the encoding must be an EBCDIC code page, otherwise the transfer fails. Similarly, if the destination is a data set, the destination encoding must be an EBCDIC code page.
Source file end of line character sequence	Convert a single (LF) or (CRLF) sequence to the destination end of line character sequence	No
Destination file encoding	Destination platform encoding	Yes When you specify source file encoding and the source is a data set, the encoding must be an EBCDIC code page, otherwise the transfer fails. Similarly, if the destination is a data set, the destination encoding must be an EBCDIC code page.
Destination file end of line character sequence	Destination platform EOL	Yes
Text replacement character sequence for unmappable or malformed characters in the source or destination	Blank, meaning the transfer fails if unmappable characters or malformed characters are present. You can use the <code>textReplacementCharacterSequence</code> property to specify the replacement text, which is described in The agent.properties file .	Yes

z/OS data sets

When data set records are accessed in text mode, each record represents a single line. New line characters do not exist in the record but for ASA format data sets an ASA format control code character is set that represents a new line (or other control character). When a line of text with a terminating new line character is written to a record, the new line character is either automatically removed or an appropriate ASA control code is set, as appropriate. When a record is read a new line character is automatically appended to the return data. For ASA format data sets this character can be multiple new lines or a form feed, as appropriate for the ASA control code of the record.

Additionally, for fixed-format data sets when a record is read the new line is appended after the last character in the record that is not a space character, thus making fixed-format data sets suitable for storing text.

Area	Default behavior	Can you change this behavior?
Maximum line length	Destination data set LRECL or BLKSIZE setting, as appropriate	No
Wrap over length lines	Wrap. The line is split over multiple records and blocks as required.	No

When the Managed File Transfer agent is run, the environment variable `_EDC_ZERO_RECLLEN` is always set to "Y". This setting makes Managed File Transfer text transfer behavior the same as FTP for variable and fixed block data sets. However, for undefined format data sets, Managed File Transfer converts single space lines to an empty line and preserves empty lines. FTP converts empty lines to single space lines and preserves single space lines. Table 3 describes the Managed File Transfer behavior and how FTP behavior differs.

The format of the data set also determines how each line of text is written to a record. For non-ASA format data sets newline and carriage-return characters are not written to the record. For ASA format data sets, the first byte of each record is an ASA control code representing end of lines, a form feed, and other codes, as appropriate. Because ASA control codes are at the start of each record, if the source text file does not start with a new line character sequence, a blank (' ') ASA control character sequence (which equates to a newline) is inserted. This means that if the ASA data set is transferred to a file, a blank line is present at the start of the file.

Data set format	Original text line in file	Data set record	Read of data set record	FTP Read behavior
Fixed block	Empty line	Space filled record	Empty line	Same as MFT
Fixed block	Single space	Space filled record	Empty line	Same as MFT
Variable block	Empty line	Empty record	Empty line	Same as MFT
Variable block	Single space	Single space record	Single space	Same as MFT
Undefined	Empty line	Single space record	Empty line	Single space
Undefined	Single space	Single space record	Empty line	Single space

Depending on the operating system you are transferring from and to and whether you are transferring in binary or text mode, there are guidelines on what behavior to expect.

[“Available code pages for MFT” on page 2587](#)

This reference topic lists all character encoding formats available for text file conversion on the various platforms supported by Managed File Transfer.

Transferring text files between Connect:Direct and MFT

Text transfer involves converting the text of a file from one code page to another, and converting CRLF (carriage return line feed) characters between systems.

About this task

Ensure that the network map of the Connect:Direct bridge node and any Connect:Direct nodes that are used as a transfer destination include the correct platform description.

For information about the behavior of text transfers in Managed File Transfer, see [“Transferring text files with MFT” on page 2540](#).

Procedure

- For each remote node in your network map, select the correct operating system value.

For example, if your Connect:Direct bridge node is on a Windows system, ensure that for each remote node in your network map you select the correct value from the **Operating System** list:

-  If the remote node is on a Windows system, select Windows.
-   If the remote node is on an AIX or Linux system, select UNIX.
-  If the remote node is on a z/OS system, select OS/390.

Transfers to remote nodes on other operating systems are not supported by the Connect:Direct bridge.

- For each remote node you transfer a file to or from, specify the operating system type of the remote Connect:Direct node in the `ConnectDirectNodeProperties.xml` file in the Connect:Direct bridge agent configuration directory.

For more information, see [Configure the ConnectDirectNodeProperties.xml file to include information about the remote Connect:Direct nodes](#) and [Connect:Direct node properties file format](#).

Transferring files to or from protocol bridge agents

You can transfer files to and from an FTP or SFTP file server outside your Managed File Transfer network using a protocol bridge agent.

When you transfer files using the protocol bridge, the bridge must have permission to read the source or destination directory containing the files you want to transfer. For example, if you want to transfer files from the directory `/home/fte/bridge` that has only execute permissions (`d--x--x--x`), any transfers you attempt from this directory fail with the following error message:

```
BFGBR0032E: Attempt to read filename from the protocol file server has failed with server error 550
Failed to open file.
```

During file transfer, files are typically written as temporary files at the destination and are then renamed when the transfer is complete. However, if the transfer destination is a protocol file server that is configured as limited write (users can upload files to the protocol file server but cannot change those uploaded files in any way; effectively users can write once only), transferred files are written to the destination directly. This means that if a problem occurs during the transfer, the partially-written files remain on the destination protocol file server and Managed File Transfer cannot delete or edit these files. In this situation the transfer fails.

Ensure that you have another agent in your Managed File Transfer network in addition to the protocol bridge agent. The protocol bridge agent is a bridge to the FTP or SFTP server only and does not write transferred files to the local disk. If you want to transfer files to or from the FTP or SFTP server you must

use the protocol bridge agent as the destination or source for the file transfer (representing the FTP or SFTP server) and another standard agent as the corresponding source or destination.

Managed transfer requests that require a new directory to be created on an SFTP file server

Managed File Transfer protocol bridge agents use the third-party JSch library to communicate with file servers using the SFTP protocol. If the protocol bridge agent attempts to transfer a file into a directory that does not exist on a file server and JSch is unable to perform the requested SFTP operation to create that directory, because the user that the protocol bridge agent logs into the file server with does not have permission to do so, JSch throws an exception back to the protocol bridge agent. The protocol bridge agent then marks the managed transfer as "Failed" and generates a supplementary message. If JSch has provided more information about the failure, the protocol bridge agent includes this information in the supplementary message:

```
BFGTR0072E: The transfer failed to complete due to the exception:  
BFGBR0119E: Bridge agent was unable to create directory directory name because message from JSch  
exception
```

If the JSch exception does not contain any more information about the failure, the protocol bridge agent generates the following supplementary message:

```
BFGTR0072E: The transfer failed to complete due to the exception:  
BFGBR0209E: Bridge agent was unable to create directory directory name
```

[The protocol bridge](#)

Transferring files to or from IBM i systems

If you transfer files to or from IBM i systems using Managed File Transfer in text mode and you want to convert the data in the files, consider the information in this topic.

Each file on an IBM i system is tagged with a coded character set ID (CCSID) value that identifies the data encoding of the file. For example, a file containing EBCDIC data might have a CCSID value of 037 and a file containing ASCII data might have a CCSID value of 819.

For text mode transfers, Managed File Transfer converts data when there are file encoding differences between source and destination files. However, Managed File Transfer currently ignores CCSID tags associated with files on IBM i systems. Instead, it uses the JVM file encoding property of the JVMs running the source agent and destination agent. The default value of this property is based on locale (but you can override this default on your IBM i system using the `SystemDefault.properties` file described in the following section: [“Changing the file.encoding record in the SystemDefault.properties file”](#) on page 2545). With this default implementation, an agent that transfers files in text mode is limited in its ability to handle text files with different file encodings. For example, you cannot use the same agent to transfer files containing EBCDIC text and also files containing ASCII text without stopping and restarting the agent with the appropriate (that is, EBCDIC or ASCII) file encoding override in place. On IBM i V6R1 systems, you can check the file encoding value of the JVM that is running the agent job by using WRKJVMJOB, option 7 to Display Current® Java System Properties. (The WRKJVMJOB command does not exist on IBM i V5R4 systems.)

If you plan to use Managed File Transfer to transfer text files with different file encodings, consider creating multiple agents and multiple users who start those agents, so that each unique encoding has an agent that is ready and enabled to transfer that type of data.

For example, if you want to transfer a file containing EBCDIC text with CCSID value of 037 from an IBM i system (source) to another IBM i V6R1 system (destination) where you want the file content at the destination to be converted to ASCII text with CCSID value of 819, complete the following steps:

1. Select a source agent with a JVM file encoding of Cp037.
2. Select a destination agent with a JVM file encoding of ISO8859_1.
3. Select text mode transfer, and other specifications as needed.

Changing the file.encoding record in the SystemDefault.properties file

To enable a JVM running an agent for a particular encoding, complete the following steps:

1. Determine which user starts the agent that runs on the IBM i system. This is the agent that services the Managed File Transfer file transfer request.

Create a `SystemDefault.properties` file in the home directory of that user as needed. For example, if you start the agent, use Qshell to run the following command:

```
touch -C 819 /home/your_userID/SystemDefault.properties
```

2. Using Qshell, run the `/qibm/proddata/mqm/bin/fteStopAgent` command to stop the agent as needed.
3. Update the `SystemDefault.properties` file that is described in step 1 to ensure that the file contains a record like the following:

```
file.encoding=java_encoding
```

where *java encoding* corresponds to the type of data that is contained in the file, and matches a `file.encoding` value from the following table: [File.encoding values and System i5® CCSID](#).

4. The user identified in step 1 must complete the following steps:
 - a. On IBM i V5R4 only: add the `QIBM_PASE_DESCRIPTOR_STDIO` environment variable (*JOB scope) to 'B' if using EBCDIC file encoding, or 'T' if using ASCII encoding. For example:

```
ADDENVVAR ENVVAR('QIBM_PASE_DESCRIPTOR_STDIO') VALUE('B') REPLACE(*YES)
```

- b. If Qshell is active, press **F3=Exit** to end Qshell.
- c. Start Qshell and run the `/qibm/proddata/mqm/bin/fteStartAgent` command as appropriate to restart the agent.

When the file encoding of the JVM running the agent has been changed, the agent log is written with that encoding. If you want to read the contents of the agent log, you must use a viewer that is enabled for that encoding.

Using a transfer definition for data conversion

An alternative way to convert data when files are being transferred is to create a transfer definition that specifies file encoding, or to use the `-sce` and `-dce` parameters of the `fteCreateTransfer` command. If you use these parameters when the destination is an IBM i system, this can result in files that have incorrect CCSID tags. For this reason, the recommended approach for controlling data conversion with files that are located on IBM i systems is to use `SystemDefault.properties` as described in the preceding section.

Protocol bridge limitation

On IBM i, you cannot transfer EBCDIC files to or from an SFTP server using a protocol bridge agent.

“Guidelines for transferring files” on page 2523

Depending on the operating system you are transferring from and to and whether you are transferring in binary or text mode, there are guidelines on what behavior to expect.

[“Transferring save files located in QSYS.LIB on IBM i” on page 2548](#)

Managed File Transfer supports the transfer of save files located in the QSYS.LIB file system between two IBM i systems. Consider the following information when requesting file transfers of save files.

IBM i Transferring physical files located in QSYS.LIB on IBM i

Managed File Transfer supports the transfer of physical file members in the QSYS.LIB file system between two IBM i systems. Consider the following information when you request file transfers of physical file members.

This support is limited to transferring file members in program-described files only and does not support the use of externally-described files or source physical files. You can transfer file members to a destination file member on another IBM i system, or to a stream file residing in an IBM i system, or other platforms, such as Windows or AIX. You can also transfer stream files to a destination file member.

When transferring to a file that does not exist, a program-described file is created with a record length of 5000. There is currently no support for specifying the record length, CCSID, or other attributes for creating the file during the transfer. If you want to specify a value or attribute, you must create the destination file before the transfer occurs, although you can also do this using a predestination transfer task.

You can transfer file members in text mode only. The data is automatically converted from EBCDIC.

A physical file member on IBM i is located in a physical file, which in turn is located in a library on IBM i. A library can be one of the standard libraries that ship with the operating system (for example, QSYS or QGPL) or it can be a library that you have created.

Physical files in the QSYS.LIB file system are identified in two different ways on IBM i. When you run CL commands on an IBM i command line, use the following naming syntax:

```
FILE(library name/file name) MBR(member name)
```

For example, a physical file member that is called MYMBR is in a file that called MYFILE in a library that is called SOMELIB is identified as FILE(SOMELIB/MYFILE) MBR(MYMBR). You can also identify the same physical file member by specifying a UNIX-like path name that follows the Integrated File System (IFS) naming convention. Using the IFS naming convention, MYMBR in MYFILE in SOMELIB has the following path name:

```
/QSYS.LIB/SOMELIB.LIB/MYFILE.FILE/MYMBR.MBR
```

For more information, see [Path names in the QSYS.LIB file system](#).

Managed File Transfer on IBM i recognizes the IFS naming convention but does not support the syntax used by CL commands. The following examples illustrate valid and invalid path names for MFT. The following example is a valid path name for a physical file member:

```
/QSYS.LIB/SOMELIB.LIB/MYFILE.FILE/MYMBR.MBR
```

This example assumes MYFILE is a physical file in the library SOMELIB and contains a member that is called MYMBR.

The following examples are invalid path names for physical file member transfers:

- /QSYS.LIB/SOMELIB.LIB/MYFILE.FILE (.FILE assumes a SAVF, not a physical file. If MYFILE is a physical file, the transfer fails with an invalid file type error)
- /QSYS.LIB/MYLIB.LIB/ (physical file and member names are required)
- /QSYS.LIB/SOMELIB.LIB/MYFILE.FILE/MYMBR (the member name must contain an extension of .MBR)
- /QSYS.LIB/SOMELIB.LIB/MYFILE/MYMBR.MBR (the physical file name extension must be .FILE)

Transferring multiple physical file members from a physical file in a single transfer request

Managed File Transfer on IBM i supports the transfer of multiple physical file members from a single physical file as a single transfer request. You can specify an appropriate path name that includes wildcard characters as shown in the following examples:

- ABCLIB contains a physical file MYFILE with multiple members. To transfer all these members in a single request, specify the following path name: /QSYS.LIB/ABCLIB.LIB/MYFILE.FILE/* .MBR
- XYZLIB contains a physical file MYFILE whose member names differ by a single character, that is: TEST1.MBR, TEST2.MBR, TEST3.MBR, and so on. To transfer all these members in a single request, specify the following path name: /QSYS.LIB/XYZLIB.LIB/MYFILE.FILE/TEST? .MBR.

The following types of transfer requests are not supported for transferring multiple physical file members and result in an error:

- /QSYS.LIB/MYLIB.LIB/*.*
- /QSYS.LIB/MYLIB.LIB/*
- /QSYS.LIB/MYLIB.LIB/* .FILE/MYMBR.MBR
- /QSYS.LIB/MYLIB.LIB/MYFILE*.FILE/* .MBR (there is no support for wildcarding on file names, only on member names)
- /QSYS.LIB/MYLIB.LIB/* .FILE/* .MBR
- /QSYS.LIB/MYLIB.LIB/MYFILE.FILE (.FILE assumes a SAVF not a physical file, so if MYFILE is a physical file, the transfer fails with invalid file type error)

Transferring physical file members to and from non-IBM i systems

MFT supports the transfer of physical file members to and from non-IBM i systems, such as AIX, Linux, and Windows. All transfers must be done in text mode. The following examples illustrate some of the supported **fteCreateTransfer** requests when working with non-IBM i systems:

- This command transfers physical file member FILE(FROMIBMI/FILE1) MBR(FILE1) on IBM i to text file /home/qfte/fromibmi/linux.mbr.txt on Linux:

```
fteCreateTransfer -da linux -dm QM1 -sa ibmi -sm QM1 -t text -df /home/qfte/fromibmi/  
linux.mbr.txt /qsys.lib/fromibmi.lib/file1.file/file1.mbr
```

- This command transfers physical file member FILE(FROMIBMI/FILE1) MBR(FILE1) on IBM i to text file C:\FTE\fromibmi\windows.mbr.txt on Windows:

```
fteCreateTransfer -da windows -dm QM1 -sa ibmi -sm QM1 -t text -df  
C:\FTE\fromibmi\windows.mbr.txt /qsys.lib/fromibmi.lib/file1.file/file1.mbr
```

- This command transfers text file C:\FTE\toibmi\file.txt on Windows to physical file member FILE(TOIBMI/EXISTS) MBR(WINDOWS) on IBM i:

```
fteCreateTransfer -da ibmi -dm QM1 -sa windows -sm QM1 -t text -df /qsys.lib/toibmi.lib/  
exists.file/windows.mbr C:\FTE\toibmi\file.txt
```

The following commands are examples of invalid physical file member transfers with non-IBM i systems:

- This command fails because the source file on Windows has a .txt file extension but a destination directory of .file has been specified. When transferring using the destination directory parameter

to specify a destination physical file, the source file extension must be .mbr file, for example, C:\FTE\toibmi\file.mbr

```
fteCreateTransfer -da ibmi -dm QM1 -sa windows -sm QM1 -t text -dd /qsys.lib/toibmi.lib/windows.file C:\FTE\toibmi\file.txt
```

- The default transfer mode is binary and text mode must be specified when transferring physical file members.

```
fteCreateTransfer -da windows -dm QM1 -sa ibmi -sm QM1 -df C:\FTE\fromibmi\file.bin /qsys.lib/fromibmi.lib/file1.file/file1.mbr
```

MFT supports the transfer of physical file members that are in the QSYS.LIB file system but does not support the transfer of source physical file members that are in the QSYS.LIB file system. File transfers in the QDLS file system are supported using the provided sample user exits. You can use the user exit samples provided in MFT for the following tasks:

- Transfer files in the QDLS file system.
- Automatically transfer physical file members from an IBM i library in the same way as an MFT file monitor.
- Delete an empty file object when the source file member is deleted as part of the transfer.

For more information, see [Sample MFT on IBM i user exits](#).

Depending on the operating system you are transferring from and to and whether you are transferring in binary or text mode, there are guidelines on what behavior to expect.

[“Transferring files to or from IBM i systems” on page 2544](#)

If you transfer files to or from IBM i systems using Managed File Transfer in text mode and you want to convert the data in the files, consider the information in this topic.

IBM i Transferring save files located in QSYS.LIB on IBM i

Managed File Transfer supports the transfer of save files located in the QSYS.LIB file system between two IBM i systems. Consider the following information when requesting file transfers of save files.

A save file on IBM i is located in a library on IBM i. A library can be one of the standard libraries that ship with the operating system for example QSYS or QGPL or it can be a library that is created by the user. Save files in the QSYS.LIB file system are identified in two different ways on IBM i. When working with CL commands on an IBM i command line, the naming syntax used is as follows:

```
FILE(library name/file name)
```

For example, a save file called MYSAVF is located in a library called SOMELIB is identified as FILE(SOMELIB/MYSAVF).

You can also identify the same save file by specifying a UNIX-like path name that follows the Integrated File System (IFS) naming convention. See [Path names in the QSYS.LIB file system](#) for more information. Using the IFS naming convention, MYSAVF in SOMELIB has the following path name:

```
/QSYS.LIB/SOMELIB.LIB/MYSAVF.FILE
```

Managed File Transfer on IBM i recognizes the IFS naming convention but does not support the syntax used by CL commands. The following examples illustrate valid and invalid path names for Managed File Transfer.

Some examples of valid path names for save file transfers are as follows:

- /QSYS.LIB/SOMELIB.LIB/MYSAVF.FILE (assuming MYSAVF save file is located in the library SOMELIB)
- /QSYS.LIB/MYSAVF.FILE (assuming MYSAVF is located in the library QSYS)

Some examples of invalid path names for save file transfers are as follows:

- SOMELIB.LIB/MYSAVF.FILE (Path name must start with /QSYS.LIB)
- /QSYS.LIB/MYLIB.LIB (Path must end in a save file name, not a library name)
- /QSYS.LIB/MYLIB.LIB/ (Save file name is required)
- /QSYS.LIB/SOMELIB.LIB/MYSAVF (Save file name must have a .FILE extension in name)
- /QSYS.LIB/SOMELIB.LIB/MYSAVF.SAVF (Save file name extension must be .FILE)

Transferring multiple save files from a library in a single transfer request

Managed File Transfer on IBM i supports the transfer of multiple save files from a library as a single transfer request. You can specify an appropriate path name that includes wildcard characters as shown in the following examples:

- ABCLIB contains many save files. To transfer all these files in a single request, specify the following path name:

```
/QSYS.LIB/ABCLIB.LIB/*.FILE
```

- XYZLIB contains several save files whose names differ by a single character, that is: TEST1.FILE, TEST2.FILE, TEST3.FILE, and so on. To transfer all of these files in a single request, specify the following path name:

```
/QSYS.LIB/XYZLIB.LIB/TEST?.FILE
```

The following types of transfer requests are not supported for transferring multiple save files and result in an error:

- /QSYS.LIB/MYLIB.LIB/*.*
- /QSYS.LIB/MYLIB.LIB/*

Managed File Transfer supports the transfer of save files that are located in the QSYS.LIB file system but the transfer of other types of files that are located in the QSYS.LIB file system is not supported. However, Managed File Transfer provides samples that use the save file support and use predefined fteAnt tasks to demonstrate how a complete library, a source physical file, or database file can be transferred between two IBM i systems. See [Getting started using Ant scripts with MFT](#) for details on how to customize and use these samples.

[“Transferring files to or from IBM i systems” on page 2544](#)

If you transfer files to or from IBM i systems using Managed File Transfer in text mode and you want to convert the data in the files, consider the information in this topic.

Transferring generation data groups (GDGs)

Managed File Transfer supports generation data groups (GDGs) for source and destination data sets on z/OS. Absolute and relative GDG names are supported. When you write to a new generation, the base GDG must exist.

Note: When creating a GDG entry in a batch environment using BASEGDG(+n), it cannot be referred to later in the same job by using the same positive generation number. Maintaining the same GDG entry numbers between steps of a job is a function of JCL and is not available to utility functions that update the GDG by using dynamic allocation. Therefore, a job that creates a new generation using BASEGDG(+1) would find the GDG updated as soon as the transfer successfully completes and would then need to refer to the same data set as BASEGDG(0).

GDG examples

The following examples show the **fteCreateTransfer** command using GDGs. In the examples, the name BASEGDG refers to an existing base GDG name. The name DSET refers to a sequential data set that is to be created. The name /u/user/file.dat refers to the name of a source data file.

This command copies file.dat into a new generation in BASEGDG. The absolute name of the new generation is reported in the transfer log:

```
fteCreateTransfer -sa A1 -da A2 -ds "//BASEGDG(+1)" /u/user/file.dat
```

This command copies file.dat into the generation with the absolute name specified in BASEGDG:

```
fteCreateTransfer -sa A1 -da A2 -ds "//BASEGDG.G0009V00" /u/user/file.dat
```

This command copies the most recent generation in BASEGDG to DSET. The absolute name of the generation is reported in the transfer log:

```
fteCreateTransfer -sa A1 -da A2 -ds "//DSET" "//BASEGDG(0)"
```

This command copies the next most recent generation in BASEGDG to DSET. The absolute name of the generation is reported in the transfer log:

```
fteCreateTransfer -sa A1 -da A2 -ds "//DSET" "//BASEGDG(-1)"
```

Related reference

[“Guidelines for transferring files” on page 2523](#)

Depending on the operating system you are transferring from and to and whether you are transferring in binary or text mode, there are guidelines on what behavior to expect.

[“fteCreateTransfer \(start a new file transfer\)” on page 2079](#)

The **fteCreateTransfer** command creates and starts a new file transfer from the command line. This command can start a file transfer immediately, schedule a file transfer for a future time and date, repeat a scheduled transfer one or more times, and trigger a file transfer based on certain conditions.

[“Transferring between data sets on z/OS” on page 2526](#)

You can transfer between z/OS data sets using Managed File Transfer. Review the following behavior carefully to ensure your data sets are transferred correctly.

Using wildcard characters with MFT

You can use wildcard characters when you specify source file names and source file paths for file transfers. This allows you to select multiple files simultaneously.

Multiplatforms

You can use the following wildcard characters on [Multiplatforms](#):

?

Use the question mark (?) to represent exactly one character. All of the other characters specified are required in matching file names.

For example, `ab?d.jpg` matches the files `abcd.jpg`, `abed.jpg`, and `abfd.jpg`.

*

Use the asterisk character (*) to represent zero or more characters.

For example `*.txt` matches the files `abc.txt` and `x.txt`, but not `newtxt` because the period (.) in the file names is a required character.

The pattern `*txt` matches the files `abc.txt`, `x.txt`, and `newtxt`.

You must enclose the asterisk character (*) in double quotation marks. If you do not, the character will be interpreted by the command shell and might cause the command to fail.

 On AIX and Linux, using the asterisk character (*) will not include the pseudo hidden files, for example `.bashrc`.

If the operating system is case-insensitive for file and path names, for example Windows, the pattern match is case-insensitive. You can use wildcard characters to specify file names only: you cannot use wildcards in directory names.

Protocol bridge agent

If you are using a protocol bridge agent to transfer files from an FTP, FTPS, or SFTP file server, wildcard matching is case sensitive, regardless of the platform that the file server is actually running on.

Connect:Direct bridge

When the source of a transfer is a Connect:Direct bridge agent that is requesting files from a Connect:Direct node, wildcards are not supported.

IBM i

You can use the following wildcard characters on IBM i platforms:

?

Use the question mark (?) to represent exactly one character. All of the other characters specified are required in matching file names.

For example, `ab?d.jpg` matches the files `abcd.jpg`, `abed.jpg`, and `abfd.jpg`.

*

Use the asterisk character (*) to represent zero or more characters.

For example `*.txt` matches the files `abc.txt` and `x.txt`.

The pattern `*txt` matches the files `abc.txt`, `x.txt`, and `newtxt` because the period (.) in the pattern is a required character.

For additional considerations regarding the use of wildcard characters with save file transfers, see [Transferring save files that reside in QSYS.LIB file system on IBM i systems](#).

z/OS

 For z/OS systems the wildcard character rules for Managed File Transfer follow the standard ISPF wildcard conventions in general. There are specific rules for both sequential and partitioned data sets as follows:

Sequential data sets

 When you reference sequential data sets, you can use data set name qualifiers containing asterisks (*) and percent signs (%) as follows:

- ***
Use a single asterisk (*) to represent at least one qualifier. A single asterisk within a qualifier represents zero or more characters.
- ****
Use double asterisks (**) to represent zero or more qualifiers. You cannot use a double asterisk within a qualifier.
- %**
Use a single percent sign (%) to represent one single alphanumeric or national language character.
- %%**
Use between one and eight percent signs to represent zero or more characters.

Partitioned data sets

 When you reference partitioned data sets, you can specify wildcard characters for the member names only. You can use data set name qualifiers containing asterisks (*), underscores (_), and question marks (?) as follows:

- ***
Use the asterisk (*) character to represent zero or more characters.
- _**
Use the underscore (_) character to represent exactly one character.
- ?**
Use the question mark (?) character to represent exactly one character. The question mark is an alternative to the underscore character and is provided as an addition to ISPF conventions.

Directories

By default if you create a file transfer with a wildcard pattern that matches subdirectories, the subdirectories are not transferred. You can specify the `-x` parameter on the `fteCreateTransfer` command to include subdirectories that match the wildcard pattern. When you transfer a subdirectory, the entire contents and structure of the subdirectory are transferred: including all of its files, subdirectories, and hidden files.

For example, if you have a directory called `abc`, there is a difference in behavior between specifying a source file path of `/opt/abc` and `/opt/abc/*`. In the case of `/opt/abc` because the directory is transferred, a directory called `abc` is created at the destination and all of the file contents are transferred. In the case of `/opt/abc/*`, the contents of `abc` are transferred into the destination path.

Hidden files

Wildcards do not match hidden files except on UNIX-type platforms when the wildcard pattern starts with a dot character (.). For example: `/opt/.*` transfers all hidden files in the `opt` directory.

On Windows if you want to transfer a hidden file, either specify the file name exactly or transfer the directory containing the hidden file.

Symbolic links

Symbolic links are a type of file that contain a pointer to another file or directory and are known as shortcuts on Windows. You can match symbolic link files with wildcard characters. However, when a destination file is created from a source that is a symbolic link, the destination file becomes a hard link (that is, a regular file). You cannot successfully transfer symbolic links to directories because this could potentially create a recursive path.

Transferring files with wildcard characters in their file names

You can transfer a file if the file name itself contains a wildcard character. If you specify that file name exactly, only that file is transferred, and not the set of files that match the wildcard.

For example, if you have a file called `/opt/abc*.txt` and you create a file transfer for `/opt/abc*.txt`, the only file transferred is `/opt/abc*.txt`. But if you create a file transfer for `/opt/ab*.txt`, all files matching the pattern `/opt/ab*.txt` are transferred, including the file `/opt/abc*.txt`.

Transferring directory paths that contain wildcard characters

Enclose any directory path that includes a wildcard character in quotation marks (") or single quotation marks (') to avoid shell expansion. Shell expansion happens when the operating system expands the wildcard character before the character is passed to the Managed File Transfer command and this might cause unexpected behavior.

For example, if you run the following **fteCreateTransfer** command with the **-gt** parameter on AIX and Linux, where `${..}` is a variable substitution from a resource monitor:

```
fteCreateTransfer -p QM_VENUS -sa AGT.QM_JUPITER -sm QM_JUPITER -da AGT.QM_NEPTUNE -dm QM_NEPTUNE -r -sd
delete
-t binary -de overwrite -jn MONTASK -gt /home/ftadmin/bin/TransferTask.xml -df "${FilePath}" "${
FilePath}"
```

the shell parses `${FilePath}` and does not pass it to the command. The workaround is to enclose `${FilePath}` in double quotation marks, that is, `"${FilePath}"`.

Transfer is reported as successful even though wildcard matches zero files

If you attempt to transfer a file that does not exist, Managed File Transfer treats this attempt as a failed transfer. If you specify a file name explicitly (for example, `/a/missing/filename.txt`) and MFT is unable to find that file, the following error message is reported in the log:

```
BFGI00001E: File "/a/missing/filename.txt" does not exist
```

As part of this process the source agent, which could not find the file, notifies the destination agent that this file transfer has been canceled (because the source agent cannot find the source file to read). If you had planned to trigger an exit after the transfer at this point, the destination agent triggers its `DestinationTransferEndExit` with a `FileExitResultCode` of `CANCEL_FILE` for that file name.

However, if you attempt to transfer a wildcard (for example, `/a/missing/*.txt`) and the source agent does not find any files that match that wildcard, MFT reports this as a successful transfer. This is because technically the source agent was asked to transfer 0 files. The following error message is reported in the log:

```
The transfer request has successfully completed, although no files were transferred.
```

In this example, because the destination agent was never involved in the transfer, its exit is not called.

[“Guidelines for transferring files” on page 2523](#)

Depending on the operating system you are transferring from and to and whether you are transferring in binary or text mode, there are guidelines on what behavior to expect.

[“fteCreateTransfer \(start a new file transfer\)” on page 2079](#)

The **fteCreateTransfer** command creates and starts a new file transfer from the command line. This command can start a file transfer immediately, schedule a file transfer for a future time and date, repeat a scheduled transfer one or more times, and trigger a file transfer based on certain conditions.

Transferring between two different MFT topologies

Managed File Transfer (MFT) agents can only perform managed transfers between other agents in the same topology. However, if you have multiple topologies, it can be useful to transfer data between them. The following text provides some high level guidance on how to do this.

Here is a diagram that shows two different topologies:

Figure 6. AGENT1 and AGENT2 are part of a topology in the Production environment, and AGENT3 and AGENT4 are part of the Development environment topology.

The Production topology is separate from the Development topology. This means that it is not possible for the agents in Production to directly participate in managed transfers with the agents in the Development environment (for example, AGENT2 cannot perform a managed transfer to AGENT3). To transfer data between the environments, you can use either a shared file system, or file-to-message and message-to-file transfers.

Transferring data using a shared file system

In this solution, the agents in both topologies have access to the same shared file system.

An agent in one topology acts as the destination agent for a managed transfer and writes a file to a known location on the file system. Another agent in the second topology uses a resource monitor or a scheduled transfer to detect when a file appears in that location, and then processes it.

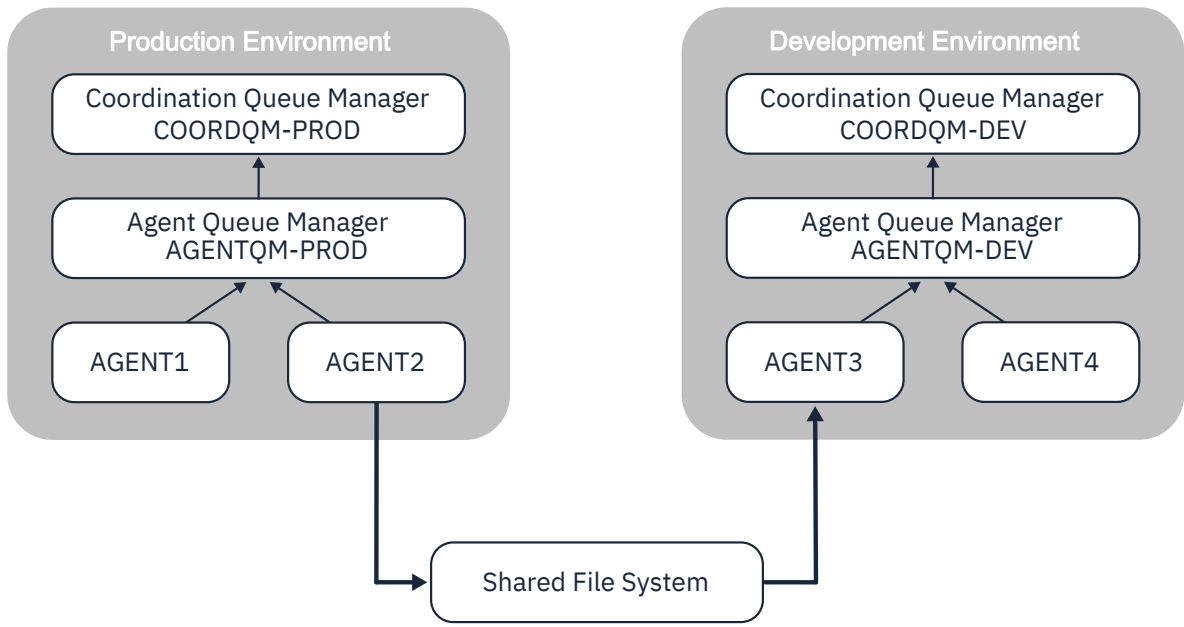

Figure 7. Here, AGENT2 is the destination agent for a managed transfer running in the Production Environment topology, and writes a file to a location on the shared file system. A resource monitor running inside of AGENT3 polls that location. When it detects the file written by AGENT2, it submits a managed transfer request to AGENT3 to process it and bring it into the Development Environment topology.

Note that the shared file system should be reliable, to ensure that data is not lost.

Transferring data using message-to-file and file-to-message transfers

An alternative approach is to use a gateway queue manager in between the two topologies. This queue manager is connected to agent queue managers in the topologies using sender and receiver channels, to allow data to pass between the two.

An agent in one of the topologies performs a file-to-message transfer, to write data to a remote queue. The message is then routed through the gateway queue manager to a local queue on a queue manager in the other topology. An agent in that topology then performs a message-to-file transfer to get the message and process it.

Figure 8. Here, AGENT2 is connected to its agent queue manager AGENTQM-PROD and performs a file-to-message transfer to write a message to a queue called Q1. Q1 is a remote queue, and so the message gets routed via the Gateway Queue Manager and sender/receiver channels to the local queue Q1 on the queue manager AGENTQM-DEV. AGENT3 then performs a message-to-file transfer to get the message and bring it into the Development Environment topology.

This solution uses standard IBM MQ networking to transfer messages from one topology to another via the gateway queue manager. This means that if a channel between the gateway queue manager and one of the agent queue managers is unavailable for some reason, messages might get stuck and not arrive on the destination queue. In this situation, you should check the channels to ensure that they are all running.

Regular expressions used by MFT

Managed File Transfer uses regular expressions in a number of scenarios. For example, regular expressions are used to match user IDs for Connect:Direct security credentials, or to split a file into multiple messages by creating a new message each time a regular expression is matched. The regular expression syntax used by Managed File Transfer is the syntax supported by the `java.util.regex` API. This regular expression syntax is similar to, but not the same as, the regular expression syntax used by the Perl language.

For more information about Java regular expressions, see the Java tutorial [Regular Expressions](#).

Examples

To match all patterns, use the following regular expression:

```
.*
```

To match all patterns that begin with the string `fte`, use the following regular expression:

```
fte.*
```

To match all patterns that begin with the string `accounts` followed by a single digit, and end with `.txt`, use the following regular expression:

```
accounts[0-9]\.txt
```

Substitution variables for use with user-defined Connect:Direct processes

You can define values to substitute in to user-defined Connect:Direct processes by using intrinsic symbolic variables that are specific to Managed File Transfer.

To follow the Connect:Direct naming convention, all intrinsic symbolic variables used by Managed File Transfer have the format `%FTE` followed by five uppercase alphanumeric characters. For more information about intrinsic symbolic variables, see the Connect:Direct product documentation.

When creating a process to transfer files from a Connect:Direct node to the Connect:Direct bridge system, you must use the intrinsic variable `%FTETFILE` as the value of `TO FILE` in the Connect:Direct process.

When creating a process to transfer files to a Connect:Direct node from the Connect:Direct bridge system, you must use the intrinsic variable `%FTEFFILE` as the value of `FROM FILE` in the Connect:Direct process.

These variables contain the temporary file paths that the Connect:Direct bridge agent uses for transfers into and out of the Managed File Transfer network.

Variable name	Description
<code>%FTESAGNT</code>	The name of the Managed File Transfer source agent. This variable is set only for transfers from a Managed File Transfer Agent to a Connect:Direct node.

Table 374. Intrinsic symbolic variables used by Managed File Transfer and Connect:Direct (continued)

Variable name	Description
%FTEDAGNT	The name of the Managed File Transfer destination agent. This variable is set only for transfers from a Connect:Direct node to a Managed File Transfer Agent.
%FTEPNODE	The Connect:Direct primary node name. The value is always the name of the Connect:Direct node that is part of the Connect:Direct bridge.
%FTEPPLAT	The platform that the Connect:Direct primary node runs on. Possible values for this variable are UNIX and WINDOWS. This information is provided by the Connect:Direct bridge agent.
%FTEPUSER	The Connect:Direct primary node user identifier to use in the Connect:Direct process. This information is taken from the ConnectDirectCredentials.xml file.
%FTEPPASS	The password to use with the user name defined by the %FTEPUSER variable. This information is taken from the ConnectDirectCredentials.xml file.
%FTESNODE	The Connect:Direct secondary node name. The value is always the name of the Connect:Direct node that the file is transferred to or from.
%FTESPLAT	The platform that the Connect:Direct secondary node runs on. Possible values for this variable are UNIX, WINDOWS, and ZOS. This information is taken from the ConnectDirectNodeProperties.xml file.
%FTESUSER	The Connect:Direct secondary node user identifier to use in the Connect:Direct process. This information is taken from the ConnectDirectCredentials.xml file.
%FTESPASS	The password to use with the user name defined by the %FTESUSER variable. This information is taken from the ConnectDirectCredentials.xml file.
%FTEFFILE	<p>The source file name. This variable is set only for Connect:Direct processes that are submitted at a per-file scope.</p> <p>When transferring files from a Managed File Transfer Agent to a Connect:Direct node, the value is the fully qualified location of the file on the same system as the Connect:Direct bridge.</p> <p>When transferring files from a Connect:Direct node to a Managed File Transfer Agent, the value is the name of the file that is specified as the source file in the Managed File Transfer transfer request.</p>
%FTEFDISP	<p>The disposition of the source file when the process is complete. The value of this variable is platform dependent and equivalent to the values for MFT transfer request. This variable is set only for Connect:Direct processes that are submitted at a per-file scope.</p> <p>When transferring files from a Managed File Transfer Agent to a Connect:Direct node, the action of deleting or not deleting the source file is performed by the Managed File Transfer bridge agent.</p> <p>When transferring files from a Connect:Direct node to a Managed File Transfer Agent, the action of deleting or not deleting the source file must be performed by the Connect:Direct process.</p>

Table 374. Intrinsic symbolic variables used by Managed File Transfer and Connect:Direct (continued)

Variable name	Description
%FTEFCP	<p>The code page to use for the source file. This variable is set only for Connect:Direct processes that are submitted at a per-file scope.</p> <p>When transferring files from a Managed File Transfer Agent to a Connect:Direct node, this value is UTF-8 or, if the transfer is a binary transfer, the value is not set.</p> <p>When transferring files from a Connect:Direct node to a Managed File Transfer Agent, this value is specified by Connect:Direct or, if the transfer is a binary transfer, the value is not set.</p>
%FTEFSYSO	<p>The Connect:Direct SYSOPTS for the source of the transfer. If the remote Connect:Direct node is on AIX, Linux, and Windows, this value contains information about the code page and data type of the source of the transfer. z/OS If the remote node is on z/OS, this value contains additional information.</p>
%FTEFNODE	<p>Identifies the Connect:Direct node where the source file resides. This will be set to a value of either: PNODE or SNODE.</p>
%FTETFILE	<p>The destination file name. This variable is set only for Connect:Direct processes that are submitted at a per-file scope.</p> <p>When transferring files from a Managed File Transfer Agent to a Connect:Direct node, the value is the name of the file that is specified as the destination file in the Managed File Transfer transfer request.</p> <p>When transferring files from a Connect:Direct node to a Managed File Transfer Agent, the value is the fully qualified name of the location to write the file to on the same system as the Connect:Direct bridge.</p>
%FTETDISP	<p>The disposition of the destination file. The value of this variable is platform dependent and equivalent to the values for Connect:Direct transfer request. This variable is set only for Connect:Direct processes that are submitted at a per-file scope.</p> <p>When transferring files from a Managed File Transfer Agent to a Connect:Direct node, the action of creating a file or replacing an existing file must be performed by the Connect:Direct process.</p> <p>When transferring files from a Connect:Direct node to a Managed File Transfer Agent, the action of creating a file or replacing an existing file is performed by the Managed File Transfer bridge agent.</p>
%FTETCP	<p>The code page to use for the destination file. This variable is set only for Connect:Direct processes that are submitted at a per-file scope.</p> <p>When transferring files from a Managed File Transfer Agent to a Connect:Direct node, this value is specified by Connect:Direct or, if the transfer is a binary transfer, the value is not set.</p> <p>When transferring files from a Connect:Direct node to a Managed File Transfer Agent, this value is UTF-8 or, if the transfer is a binary transfer, the value is not set.</p>
%FTETSYSO	<p>The Connect:Direct SYSOPTS for the destination of the transfer. If the remote Connect:Direct node is on AIX, Linux, and Windows, this value contains information about the code page and data type of the destination of the transfer. z/OS If the remote node is on Windows, this value contains additional information.</p>
%FTETNODE	<p>Identifies the Connect:Direct node where the destination file is to reside. This will be set to a value of either: PNODE or SNODE.</p>

Table 374. Intrinsic symbolic variables used by Managed File Transfer and Connect:Direct (continued)

Variable name	Description
%FTEDTYPE	The data type or mode of the transfer. Possible values for this variable are text or binary. This variable is set only for Connect:Direct processes that are submitted at a per-file scope.
%FTETRID	The 48-character hexadecimal transfer ID from the Managed File Transfer transfer.
%FTEJOB	The job name from the Managed File Transfer transfer request. The value of this variable is truncated to 256 characters and can be used in the process accounting data.
%FTEPNAME	The Connect:Direct process name generated by the Managed File Transfer bridge agent. The value of this variable is 8 alphanumeric characters. The value always starts with an alphabetic character.
%FTEMETA(key)	A metadata from the Managed File Transfer transfer request. The value of <i>key</i> is the key of the metadata. The value of <i>key</i> is not case sensitive. A key of ABC is treated the same as a key of abc. If both ABC and abc are defined as metadata keys, the value of the second metadata defined overwrites the value of the first metadata defined.

 The following table contains information about additional intrinsic symbolic variables that are used when the remote Connect:Direct node in the transfer is on a z/OS platform.

Table 375. Additional intrinsic symbolic variables used when the remote Connect:Direct is on z/OS

Variable name	Description
%FTEFDCB	The value of the DCB parameter at the source of the transfer.
%FTEFSPACE	The value of the SPACE parameter at the source of the transfer.
%FTEFLBEL	The value of the LABEL parameter at the source of the transfer.
%FTEFUNIT	The value of the UNIT parameter at the source of the transfer.
%FTEFVOL	The value of the VOL parameter at the source of the transfer.
%FTEFDAACL	The value of the DATACLAS parameter at the source of the transfer.
%FTETDCB	The value of the DCB parameter at the destination of the transfer.
%FTETSPACE	The value of the SPACE parameter at the destination of the transfer.
%FTETLBEL	The value of the LABEL parameter at the destination of the transfer.
%FTETUNIT	The value of the UNIT parameter at the destination of the transfer.
%FTETVOL	The value of the VOL parameter at the destination of the transfer.

Table 375. Additional intrinsic symbolic variables used when the remote Connect:Direct is on z/OS (continued)

Variable name	Description
%FTETDACL	The value of the DATACLAS parameter at the destination of the transfer.
%FTETDSTY	The value of the DSNTYPE parameter at the destination of the transfer.
%FTETLIKE	The value of the LIKE parameter at the destination of the transfer.
%FTETMGCL	The value of the MGMTCLAS parameter at the destination of the transfer.
%FTETSTCL	The value of the STORCLAS parameter at the destination of the transfer.

Example: A Connect:Direct process file that calls MFT commands

An example Connect:Direct process file that calls the Managed File Transfer **ftetag** command and the **ftecxfer** command.

In this example, the following actions occur:

1. A Connect:Direct COPY statement transfers the file from C:\test\from\sent.txt on the system where the secondary node runs to C:\test\tmp\midpoint.txt on the system where the primary node runs.
2. The Connect:Direct process calls the **ftetag** command to create audit information in MFT.
3. The Connect:Direct process calls the **ftecxfer** command.
4. The **ftecxfer** command transfers the file from C:\test\tmp\midpoint.txt on the system where the primary node runs and the agent CD_BRIDGE runs to /test/to/arrived.txt on the system where the agent LINUX_AGENT is located.

```

/*BEGIN_REQUESTER_COMMENTS
 $PNODE$="cd_win01" $PNODE_OS$="Windows"
 $SNODE$="CD_WIN01" $SNODE_OS$="Windows"
 $OPTIONS$="WDOS"

[Using Connect:Direct processes to submit Managed File Transfer transfer requests](#)

Restrictions of the Connect:Direct bridge agent

The Connect:Direct bridge agent is configured to transfer files to and from Connect:Direct nodes. There are some functions that the Connect:Direct bridge agent is not capable of performing.

- The Connect:Direct bridge agent cannot read messages from a queue or write messages to a queue. It cannot act as the destination agent in a file-to-message transfer or as the source agent in a message-to-file transfer.
- You cannot define a resource monitor on the Connect:Direct bridge agent.
- You cannot have a Connect:Direct bridge agent as both the source and destination of a transfer. You cannot transfer from Connect:Direct node to Connect:Direct node through the Connect:Direct bridge.
- The Connect:Direct bridge agent does not support user exits that are called before or after the transfer. The Connect:Direct bridge agent does support a credential mapping exit. For more information, see [Mapping credentials for Connect:Direct by using exit classes](#).
- You cannot define `presrc` or `postsrc` program invocations for a transfer that has the Connect:Direct bridge agent as the source agent. For more information, see [Program invocation nested elements](#).
- You cannot define `predst` or `postdst` program invocations for a transfer that has the Connect:Direct bridge agent as the destination agent. For more information, see [Program invocation nested elements](#).
- You cannot specify a wildcard character in the source specification if the source agent is the Connect:Direct bridge agent.
- If you specify a source disposition (**-sd**) of `deLeTe` when transferring a file  or data set from a Connect:Direct node, the behavior is different to the usual source disposition behavior. One of the following cases occurs:
 - If Connect:Direct uses a process that is generated by Managed File Transfer to move the file or data set from the source, specifying the `deLeTe` option causes the transfer to fail. To specify that the source file is deleted, you must submit a user-defined Connect:Direct process. For more information, see [Submitting a user-defined Connect:Direct process from a file transfer request](#).
 - If Connect:Direct uses a user-defined process to move the file or data set from the source, this parameter is passed to the process through the `%FTEFDISP` intrinsic symbolic variable. The user-defined process determines whether the source is deleted. The result that the transfer returns depends on the result that is returned by the user-defined process.

FTPS server support by the protocol bridge

The protocol bridge supports a subset of the FTPS protocol as defined by RFC-2228, RFC-4217, and the Internet-Draft entitled *Secure FTP over SSL*.

For a list of valid cipher suite values for connections between protocol bridge agents and FTPS servers, see [Cipher suites](#) in the IBM SDK and Runtime Environment Java Technology Edition 7 product documentation.

The following features of the FTPS protocol are supported:

- Implicit and explicit modes of operation.
- Validation of the server certificate.
- Optional mutual authentication using client certificate checks.

- Optional use of a clear control channel after the initial authentication and level of protection for the data channel has been selected.
- SHA-2 cipher suites and FIPS 140-2 compliance are supported. The following versions of Java are required: IBM JREs 6.0 SR13 FP2, 7.0 SR4 FP2, or later.

The following features of the FTPS protocol and runtime environment are not supported:

- Use of the **ADAT** command for additional security data exchange.
- Use of FTPS for channel encryption only that is, where the servers certificate is not validated.
- Selection of the Clear, Secure, or Confidential levels of protection using the **PROT** command.
- Encryption for each command using the **MIC**, **CONF**, and **ENC** commands.
- Fallback to the FTP protocol if the server does not support explicit FTPS. Use the FTP support provided by the protocol bridge to work with such a server.
- Use of the **FEAT** command to determine the available capabilities of the FTPS server.
- Validation of certificates using pattern matching against the DN field.
- Certificate revocation checking.
- Validation of certificates with the issuing trusted certificate authority.
- Explicit selection of the cipher suites available to the SSL negotiation phase of establishing a session.
-  Use of extensions specific to z/OS  or IBM i that integrate cryptography with the operating system. Specifically, the use of the z/OS keyring or non-hierarchical file systems for storing key and trust information, for example, data sets. Cryptographic hardware and offload engines are used if these functions are managed transparently by the JVM and do not require explicit application code.

[The protocol bridge](#)

SFTP server support by the protocol bridge

The protocol bridge supports the SFTP protocol as defined by the IETF Internet Draft entitled SSH File Transfer Protocol, version 6 draft 13.

Protocol bridge agents support the following ciphers when connecting to a file server using the SFTP protocol:

- blowfish-cbc
- 3des-cbc
- aes128-cbc
- aes192-cbc
- aes256-cbc
- aes128-ctr
- aes192-ctr
- aes256-ctr
- 3des-ctr
- arcfour
- arcfour128
- arcfour256

By default, the list of ciphers used by protocol bridge agents is aes128-cbc,aes192-cbc,aes256-cbc. For information on how to configure a protocol bridge agent to use specify different ciphers, see [“Protocol bridge properties file format” on page 2737](#).

Methods of authentication

If you have provided the IBM MQ Managed File Transfer (MFT) protocol bridge agent code with a private key and a server password, for a single user within the `ProtocolBridgeCredentials.xml` file, the MFT protocol bridge agent by default, configures the JSch library to use both methods of authentication, if required by the SFTP file server, when establishing a connection.

Should both a private key and a server password be configured for a single user within the `ProtocolBridgeCredentials.xml` file, but the SFTP file server requires only one of these authentication methods, the MFT protocol bridge agent configures the JSch library to use public/private-key authentication in preference to password based authentication.

Should the SFTP file server reject the attempt to use public/private-key authentication, then the MFT protocol bridge agent, using the JSch library, attempts username and password based authentication.

If either of these authentications alone is successful, a connection is established to the SFTP file server.

To configure both private key and a password authentication for the `ProtocolBridgeCredentials.xml` file, associated with the MFT protocol bridge agent, you need to specify:

- The **serverPassword** attribute (with associated value) in the element that maps from an MFT user name to a protocol server user name, and
- The element for the MFT user defined by the parent element.

For example, the syntax could be as follows:

```
-----BEGIN RSA PRIVATE KEY-----  
...  
-----END RSA PRIVATE KEY-----
```

Keyboard interactive method

The MFT protocol bridge agent uses the JSch, third-party library, to connect to SFTP file servers. You can configure the JSch library so that it can attempt to authenticate with an SFTP file server using the *keyboard-interactive* method when no private key is specified in the `ProtocolBridgeCredentials.xml` file.

Note that authentication using the *keyboard-interactive* method works only if the SFTP file server prompts for the password using the string `password:` (in either upper, lower or mixed case). In the situation where you use the *keyboard-interactive* authentication method, and the SFTP file server responds with a string different from `password:`, the connection attempt fails.

When the SFTP file server responds to the initial connection attempt with this string, the protocol bridge agent, using the JSch library, sends the password configured in the **serverPassword** attribute of the user element within the `ProtocolBridgeCredentials.xml` file.

[The protocol bridge](#)

FIPS support in MFT

Managed File Transfer supports the use of FIPS-compliant cryptography modules in client connections from agents, commands, and the IBM MQ Explorer to queue managers. All SSL connections to the queue manager use the TLS protocol only. Support is provided for JKS and PKCS#12 keystore types.

Note: On AIX, Linux, and Windows, IBM MQ provides FIPS 140-2 compliance through the IBM Crypto for C (ICC) cryptographic module. The certificate for this module has been moved to the Historical status. Customers should view the [IBM Crypto for C \(ICC\) certificate](#) and be aware of any advice provided by NIST. A replacement FIPS 140-3 module is currently in progress and its status can be viewed by searching for it in the [NIST CMVP modules in process list](#).

The IBM MQ Operator 3.2.0 and queue manager container image 9.4.0.0 onwards are based on UBI 9. FIPS 140-3 compliance is currently pending and its status can be viewed by searching for "Red Hat Enterprise Linux 9 - OpenSSL FIPS Provider" in the [NIST CMVP modules in process list](#).

Specify whether you want to enable FIPS support for an agent, a coordination queue manager, or a command queue manager as follows:

- If you want to enable FIPS for a specific agent, set the appropriate agentSsl properties in the `agent.properties` file for that agent. For more information, see [SSL/TLS properties for MFT](#).
- If you want to enable FIPS for a specific coordination queue manager, set the appropriate coordinationSsl properties in the `coordination.properties` file for that coordination queue manager. For more information, see [SSL/TLS properties for MFT](#).
- If you want to enable FIPS for a specific command queue manager, set the appropriate connectionSsl properties in the `command.properties` file for that command queue manager. For more information, see [SSL/TLS properties for MFT](#).

 FIPS is not supported on Managed File Transfer for  IBM i.

FIPS is not supported on connections to or from a protocol bridge or a Connect:Direct bridge.

For more information about IBM MQ and FIPS and the configuration steps required, see [Federal Information Processing Standards \(FIPS\)](#).

If you want to use FIPS, the CipherSuite must be FIPS-compliant or the connection fails. For more information about the CipherSpecs supported by IBM MQ, see [SSL/TLS CipherSpecs and CipherSuites in IBM MQ classes for Java](#) and [SSL/TLS CipherSpecs and CipherSuites in IBM MQ classes for JMS](#).

MFT database logger tables

When you have installed and configured the logger, a number of database tables are created.

MFT Logger database schema updates

From IBM MQ 9.1, certain data types have been modified in the database schema, causing a change to the widths of columns in those tables:

Db2 schema

LONG VARCHAR in the following tables has been modified to VARCHAR in the Db2 schema, with a fixed length of 2000 bytes, or 256 characters.

- SCHEDULE_ACTION
- TRANSFER_ITEM
- SCHEDULE_ITEM
- TRIGGER_CONDITION
- CALL_ARGUMENT
- CALL
- CALL_REQUEST
- TRANSFER
- CALL_RESULT
- MONITOR_METADATA
- MONITOR_EXIT_RESULT
- MONITOR_ACTION
- AUTH_EVENT
- FILE_SPACE_ENTRY

By default, LONG VARCHAR allowed you to store 32700 bytes, but VARCHAR(*Size*) limits the modified column size to 2000 characters, or 256 characters.

See “[Migrating a Db2 database to the new schema](#)” on page 2576 for more information on migrating a Db2 database to the new schema.

Oracle schema

NCLOB in the following tables has been modified to NVARCHAR(Size), where Size can be 2000 bytes or 256 bytes:

- SCHEDULE_ACTION
- TRANSFER_ITEM
- SCHEDULE_ITEM
- TRIGGER_CONDITION
- CALL_ARGUMENT
- CALL
- CALL_REQUEST
- TRANSFER
- CALL_RESULT
- MONITOR_METADATA
- MONITOR_EXIT_RESULT
- MONITOR_ACTION
- AUTH_EVENT
- FILE_SPACE_ENTRY

By default, NVARCHAR2 allows you to store only 4000 bytes. You must set the MAX_STRING_SIZE property to *extended* for the database to extend the storage to 32767 bytes.

See “[Migrating an Oracle database to the new schema](#)” on page 2579 for more information on migrating an Oracle database to the new schema.

In the SOURCE_FILENAME and DESTINATION_FILENAME columns, in the TRANSFER_ITEM and SCHEDULE_ITEM tables, a datatype of 2000 characters, (VARCHAR(2000)) brings commonality in both the Db2 and Oracle schemas.

AUTH_EVENT

An event related to authority checking, typically the rejection of a request due to insufficient privileges.

- **ID:** Row ID.
- **ACTION:** The type of action that took place.
- **COMMAND_ID:** The IBM MQ message ID of the original message that requested the event. In the case of a transfer request, this will also be the transfer ID.
- **TIME:** The time at which the event occurred.
- **ORIGINATOR_MQ_USER:** The user ID contained in the IBM MQ message, against which the authority check was performed.
- **AUTHORITY:** The authority that was required for the requested action.
- **ORIGINAL_XML_REQUEST:** The payload of the command message, indicating what action was refused.
- **RESULTCODE:** The numeric code identifying the result.
- **RESULT_TEXT:** A message explaining the result of the authority event.

CALL

The remote running of an operating system command, or Ant script , or z/OS JCL job, managed by Managed File Transfer. Calls can be embedded in transfers, or referred to by call_request rows.

A CALL (that is, a row in this table) can either be part of a normal transfer (in which case TRANSFER_CALLS is used to link it to the relevant entry in TRANSFERS) or it can be a stand-alone managed call on its own (available only from Ant or by directly inserting messages). In the latter case, the CALL_REQUEST table is used instead of the TRANSFERS table; an equivalent to TRANSFER_CALLS is not needed because there can be only one call per call request.

- **ID:** Row ID.
- **COMMAND:** The command that was run. This field does not include any arguments passed to the command or the path where the command is located.
- **TYPE:** The type of command, such as Ant or JCL.
- **RETRIES:** The number of retries that were requested.
- **RETRY_WAIT:** The interval to wait between retries as originally requested, in seconds.
- **SUCCESS_RC:** The return code that indicates a successful completion of the command. If any other code is received, the run is reported to have failed.
- **EXECUTED_COMMAND:** The full name of the command that was run, including path.
- **CAPPED_RETRIES:** The number of retries available; this number might be less than requested if the retry limit of the agent is lower than the number of retries requested.
- **CAPPED_RETRY_WAIT:** The interval between retries that is used; this number might be less than requested if the configured limit of the agent is lower than the retry wait requested.
- **OUTCOME:** Whether the call was successful overall. If there were multiple tries the outcome of each one is recorded separately in the CALL_RESULT table.

CALL_ARGUMENT

An argument or parameter supplied to a command that is called.

- **ID:** Row ID.
- **CALL_ID:** The call that the argument is associated with.
- **KEY:** Where the argument is of a key-value-pair kind, the key, or name.
- **TYPE:** The type of the argument: some are position parameters to operating system commands and others are named properties used with Ant.
- **VALUE:** The value of the argument.

CALL_REQUEST

The vehicle for a command call that is not part of a file transfer. You can submit ManagedCall messages using Ant and using direct XML injection.

- **ID:** The hexadecimal ID of the managed call request.
- **CALL_ID:** The database ID of the row in the CALL table describing this call.
- **ACTION_TIME:** The time that the action occurred.
- **AGENT:** The agent that the command is run on.
- **AGENT_QM:** The queue manager used by the agent that the command is run on.
- **ARCHITECTURE:** The machine architecture of the system that the agent runs on.
- **OS_NAME:** The name of the operating system that the agent is running on.
- **OS_VERSION:** The version of the operating system.
- **ORIGINATOR_HOST:** The host name of the machine that the call request was submitted from.
- **ORIGINATOR_USER:** The name of the user who submitted the call request, as reported in the request XML.
- **ORIGINATOR_MQ_USER:** The name of the user who submitted the call request, as contained in the IBM MQ message descriptor of the request.

- **JOB_NAME:** A user-specified job name.
- **RESULTCODE:** The overall result code for the call.
- **RESULTTEXT:** The overall result message for the call.

CALL_RESULT

The detailed result of calling a command. A call can have multiple results if retries were enabled.

- **ID:** Row ID.
- **CALL_ID:** The database ID of the row in the CALL table that this result applies to.
- **SEQUENCE:** Which attempt this result applies to, where there have been multiple attempts.
- **OUTCOME:** The outcome (for example, success or failure) of the command.
- **RETURN_CODE:** The command return code.
- **TIME:** The time that the command completed.
- **STDOUT:** The standard output stream from the command, if it was started.
- **STDERR:** The standard error stream from the command, if it was started.
- **ERROR:** If the command could not be started, an error message produced by Managed File Transfer explaining the problem.

FILE_SPACE_ENTRY

Each row represents a file that has been sent to the named file space.

- **ID:** The ID of the file space entry.
- **FILE_SPACE_NAME:** The name of the file space. This is the name of the user that the file space belongs to.
- **TRANSFER_ITEM_ID:** The ID of the transfer item that this row relates to.
- **ALIAS:** The alias name for this file space entry. Typically this alias name is the name of the source file for the transfer.
- **DELETED:** The time when the file was deleted from the file space. If the file has not been deleted the value is null.

METADATA

Metadata associated with a transfer.

- **ID:** Row ID.
- **TRANSFER_EVENT_ID:** The transfer_event row that this metadata is associated with, if it relates to a transfer. This field is null if the metadata is associated with a stand-alone managed call.
- **STANDALONE_CALL_ID:** If the metadata is associated with a stand-alone managed call, the ID of the managed call request concerned.
- **KEY:** The name of the metadata item.
- **VALUE:** The value of the metadata item.

MONITOR

Resource monitors that trigger Managed File Transfer operations based on external conditions.

- **AGENT:** The agent that the monitor runs on.
- **ID:** The hexadecimal ID of the monitor.
- **NAME:** The name of the monitor.
- **QMGR:** The queue manager of the agent where the monitor runs.

MONITOR_ACTION

Each row represents an action (for example, creation and triggering) occurring in respect of a monitor

- **ID:** Row ID.
- **ACTION:** The type of action that took place.
- **JOB_NAME:** The name of the submitted job, where applicable.
- **MONITOR:** The monitor that this action occurred on. Might be null if the action failed because it was requested for a monitor that does not exist.
- **ORIGINAL_XML_REQUEST:** If this action was a *create* or *triggerSatisfied* action, the XML request that is started when the monitor is triggered.
- **ORIGINATOR_MQ_USER:** The user ID contained in the IBM MQ message that initiated the action
- **ORIGINATOR_USER:** The user name that submitted the request to perform the action.
- **ORIGINATOR_HOST:** The machine from which the user submitted the request to perform the action.
- **TIME:** The time that the action occurred.
- **UPDATED_XML_REQUEST:** If the action is *triggerSatisfied*, the XML request that was started. This request might vary from the XML request that was originally made because of variable substitution.

MONITOR_EXIT_RESULT

The result of running a resource monitor exit.

- **ID:** Row ID.
- **ACTION_ID:** The monitor action that the result is associated with.
- **EXIT_NAME:** The name of the exit that produced this result.
- **RESULTCODE:** The value that the exit returned, either cancel or proceed.
- **RESULTTEXT:** The text output from the exit, if provided.

MONITOR_METADATA

Items of metadata associated with a resource monitor.

- **ID:** Row ID.
- **ACTION_ID:** The monitor_action that the metadata is associated with.
- **KEY:** The name of the metadata item.
- **PHASE:** Whether this metadata item represents the data that was originally submitted or the updated version after variable substitution.
- **VALUE:** The value of the metadata item.

SCHEDULE

A transfer schedule registered with an agent.

- **AGENT:** The name of the agent that has this schedule.
- **CREATION_DATE:** The point in time that this schedule was created.
- **ID:** The unique database (not agent) ID for the schedule.
- **ID_ON_AGENT:** The ID that the agent uses for the database ID. This ID is not unique across agents and might not even be unique in an agent if the persistent state of the agent is reset.
- **LATEST_ACTION:** The most recent action that modified the state of this schedule.

SCHEDULE_ACTION

When an event occurs that modifies the schedule state, an action is recorded.

- **ACTION_TYPE:** The action that occurred.
- **ID:** Row ID
- **ORIGINATOR_HOST:** The machine that the request that caused the change was submitted from.
- **ORIGINATOR_USER:** The user whose name the request that caused the change was submitted in.
- **SCHEDULE_ID:** The schedule that this action applies to.
- **SPEC_AFTERWARDS:** The schedule_spec that represents the state of this schedule after the action occurred.
- **STATUS_CODE:** A numeric return code describing the outcome of the action
- **STATUS_TEXT:** A text description of the outcome of the action. Typically null if the action succeeded.
- **TIME:** The point in time that the action occurred

SCHEDULE_SPEC

The details of an individual scheduled transfer.

- **ID:** Row ID.
- **DESTINATION_AGENT:** The agent that the files are transferred to.
- **DESTINATION_QM:** The queue manager used by the destination agent.
- **REPEAT_COUNT:** How many times to repeat if the schedule repeats and is bound by the number of occurrences rather than an end time.
- **REPEAT_FREQUENCY:** How many repeat_intervals there are between scheduled transfers.
- **REPEAT_INTERVAL:** If the transfer repeats, what interval to repeat at (for example, minutes or weeks).
- **SOURCE_AGENT:** The agent that the files are transferred from.
- **SOURCE_QM:** The queue manager used by the source agent.
- **START_TIME:** The time that the first transfer in the schedule will take place.
- **START_TIMEBASE:** The time base for the times associated with the transfer. For example, whether to operate from the time zone of the agent or the time zone of the administrator.
- **START_TIMEZONE:** The time zone that the time base corresponds to and which will be used in operating the schedule.

SCHEDULE_ITEM

Each file (or pattern to match at transfer time) is represented by a schedule_item.

- **ID:** Row ID.
- **CHECKSUM_METHOD:** How the checksum for the file is calculated
- **DESTINATION_EXISTS_ACTION:** What action the destination agent takes if the file already exists at the destination.
- **DESTINATION_FILENAME:** The file or directory that the files are transferred into.
- **DESTINATION_QUEUE:** The destination queue name for a file-to-message transfer.
- **Multi DESTINATION_TYPE:** Whether the destination_filename column refers to a file or directory.
- **z/OS DESTINATION_TYPE:** Whether the destination_filename column refers to a file, directory, or data set.
- **FILE_MODE:** The mode (for example, *text* or *binary*) that the file is transferred in.
- **RECURSIVE:** When the agent creates the transfer according to the schedule, whether the agent recurses (Y) or not (N) the source directory.
- **SCHEDULE_SPEC_ID:** The schedule_spec that this item is associated with.

- **SOURCE_DISPOSITION:** What action to perform on source files after the transfer completes.
- **SOURCE_FILENAME:** The source file, directory name, or pattern.
- **SOURCE_QUEUE:** The source queue name for a message-to-file transfer

TRANSFER

A single transfer of one or more files.

- **TRANSFER_ID:** The hexadecimal ID for the transfer.
- **JOB_NAME:** A user-specified job name for the transfer.
- **SCHEDULE_ID:** If this transfer is the result of a schedule, the database row ID of the schedule concerned.
- **START_ID:** The row ID of the transfer_event that represents the start of the transfer.
- **COMPLETE_ID:** The row ID of the transfer_event that represents the end of the transfer.
- **RESULTCODE:** The overall result code for the transfer. The possible values for this column are listed in the following topic: [Return codes for MFT](#). These codes apply to the transfer as a whole; see [TRANSFER_ITEM.RESULTCODE](#) for the status of each individual item.
- **RESULTTEXT:** The overall result text for the transfer, if any.
- **STATUS:** The status of a transfer. The possible values for this column are started, success, partial success, failure, and cancelled.
- **RELATED_TRANSFER_ID:** The hexadecimal ID of a previous transfer that is related to this transfer. For example, if the transfer is a file download, this field will refer to the transfer that uploaded the file.

TRANSFER_CALLS

Links runnable command calls to transfers

- **ID:** Row ID.
- **POST_DESTINATION_CALL:** The call made at the destination after the transfer is complete.
- **POST_SOURCE_CALL:** The call made at the source agent after the transfer is complete.
- **PRE_DESTINATION_CALL:** The call made at the destination agent before the transfer starts.
- **PRE_SOURCE_CALL:** The call made at the source agent before the transfer starts.
- **TRANSFER_ID:** The transfer that the calls in this row are associated with.

TRANSFER_CD_NODE

Information about Connect:Direct nodes that are used in a transfer.

- **PNODE:** The primary node in the transfer.
- **SNODE:** The secondary node in the transfer.
- **BRIDGE_IS_PNODE:** Character indicating which node is the node that is part of the Connect:Direct bridge. If this value is Y, the primary node is the bridge node. If this value is N, the secondary node is the bridge node.
- **ID:** The ID of this row.

TRANSFER_CORRELATOR

Each row contains a correlation string and a number associated with a transfer item.

- **CORRELATION_BOOLEAN:** A boolean correlation value. Represented by a single character of Y for true and N for false.
- **CORRELATION_STRING:** A string correlation value.
- **CORRELATION_NUMBER:** A numeric correlation value.

- **ID:** The ID of this row.

TRANSFER_EVENT

An event (start or end) related to a transfer.

- **ID:** Row ID.
- **ACTION_TIME:** The time that the transfer action took place.
- **SOURCE_AGENT:** The name of the agent that the files are transferred from.
- **SOURCE_AGENT_TYPE:** The type of agent that the files are transferred from. The following values are possible: 1 = STANDARD, 2 = BRIDGE, 3 = WEB_GATEWAY, 4 = EMBEDDED, 5 = CD_BRIDGE, 6 = SFG.
Note: From IBM MQ 9.0, Managed File Transfer does not support the Web Gateway or web agents.
- **SOURCE_QM:** The queue manager used by the source agent.
- **SOURCE_ARCHITECTURE:** The machine architecture of the system hosting the source agent.
- **SOURCE_OS_NAME:** The operating system of the source agent machine.
- **SOURCE_OS_VERSION:** The version of operating system of the source agent machine.
- **SOURCE_BRIDGE_URL:** If the source agent is a protocol bridge agent, the URL of the data source to which it forms a bridge.
- **SOURCE_CD_NODE_ID:** The Connect:Direct node that is the source of the transfer.
- **DESTINATION_AGENT:** The name of the agent that the files are transferred to.
- **DESTINATION_AGENT_TYPE:** The type of agent that the files are transferred to. The following values are possible: 1 = STANDARD, 2 = BRIDGE, 3 = WEB_GATEWAY, 4 = EMBEDDED, 5 = CD_BRIDGE, 6 = SFG.
Note: From IBM MQ 9.0, Managed File Transfer does not support the Web Gateway or web agents.
- **DESTINATION_QM:** The queue manager used by the destination agent.
- **DESTINATION_BRIDGE_URL:** If the destination agent is a bridge agent, the URL of the data source to which it forms a bridge.
- **DESTINATION_CD_NODE_ID:** The Connect:Direct node that is the destination of the transfer.
- **ORIGINATOR_HOST:** The host name of the machine that the transfer request was submitted from.
- **ORIGINATOR_USER:** The name of the user who submitted the transfer request, as reported by the `fteCreateTransfer` command.
- **ORIGINATOR_MQ_USER:** The name of the user who submitted the transfer request, as contained in the IBM MQ message descriptor of the request.
- **TRANSFERSET_TIME:** The time that the transfer set was created.
- **TRANSFERSET_SIZE:** The number of items being transferred.
- **TRIGGER_LOG:** For transfer definitions involving a trigger, whether to log trigger evaluations that did not result in a transfer.

TRANSFER_EXIT

Each row represents a transfer exit which was executed as part of a file transfer.

- **ID:** Row ID.
- **EXIT_NAME:** The name of the exit.
- **TRANSFER_ID:** The ID of the completed or canceled transfer that this exit applies to.
- **TYPE:** The type of exit. This can be one of the following values: *SourceStart*, *SourceEnd*, *DestinationStart* or *DestinationEnd*.
- **STATUS:** The value that the exit returned. This can be *cancel* or *proceed*.
- **SUPPLEMENT:** An optional message explaining the status of the exit.

TRANSFER_ITEM

Each row represents a file that is sent as part of the transfer.

- **DESTINATION_CHECKSUM_METHOD:** The algorithm used to calculate a checksum of the destination file. Might be null if no checksum was calculated because the transfer did not complete successfully.
- **DESTINATION_CHECKSUM_VALUE:** The checksum value of the destination file. The value might be null if checksumming was disabled.
- **DESTINATION_ENCODING:** The character encoding used on the destination file, if the destination file is transferred as text.
- **DESTINATION_EXISTS_ACTION:** The action to perform if the file exists at the destination.
- **DESTINATION_FILE_SIZE:** The size of the file name `z/OS` or data set name to use at the destination.
- **DESTINATION_FILENAME:** The file name `z/OS` or data set name to use at the destination.
- **DESTINATION_LINEEND:** The line-end format used in the destination file, if the destination file is transferred as text.
- **DESTINATION_MESSAGE_QUEUE_NAME:** The destination queue for the messages that are produced from the source file during a file to message transfer.
- **DESTINATION_MESSAGE_GROUP_ID:** If more than one message is produced, the group ID used for the messages that are produced from the source file during a file to message transfer.
- **DESTINATION_MESSAGE_MESSAGE_ID:** If only one message is produced, The message ID of the message that is produced from the source file during a file to message transfer.
- **DESTINATION_MESSAGE_COUNT:** The number of messages that the source file was split into during a file to message transfer.
- **DESTINATION_MESSAGE_LENGTH:** The length of the message that is produced from the source file during a file to message transfer, in bytes. This value is only set if you specify a length for the output messages, for example by using the `-qs` option of the **fteCreateTransfer** command. If you specify `-qs 20K` and the size of your source file is 50 KB, the resulting three messages are 20 KB, 20 KB, and 10 KB in size. In this case the value of `DESTINATION_MESSAGE_LENGTH` is set to 20480.
- **DESTINATION_CORRELATOR_ID:** The ID of the correlator information for the destination.
- **FILE_MODE:** The file transfer mode, for example *text* or *binary*.
- **ID:** Row ID
- **RESULTCODE:** A numeric code indicating the outcome of the transfer of this item. The possible values for this column are listed in the following topic: [Return codes for files in a transfer](#). These codes apply to the individual items in the transfer; see [TRANSFER.RESULTCODE](#) for the result of the transfer as a whole.
- **RESULT_TEXT:** A textual explanation of the result of the transfer. Typically null if the transfer was successful.
- **SOURCE_CHECKSUM_METHOD:** The algorithm used to calculate a checksum of the source file.
- **SOURCE_CHECKSUM_VALUE:** The checksum value of the source file. The value might be null if checksumming was disabled.
- **SOURCE_DISPOSITION:** The action to perform on the source file when the transfer is complete.
- **SOURCE_ENCODING:** The character encoding used on the source file, if the source file is transferred as text.
- **SOURCE_FILE_SIZE:** The size of the file name `z/OS` or data set name to use at the source.
- **SOURCE_FILENAME:** The source file name `z/OS` or data set name .
- **SOURCE_LINEEND:** The line-end format used in the source file, if the source file is transferred as text.
- **SOURCE_MESSAGE_QUEUE_NAME:** The source queue for the messages that are included in the destination file for a message to file transfer.

- **SOURCE_MESSAGE_GROUP_ID:** The group ID of the messages that are included in the destination file for a message to file transfer.
- **SOURCE_MESSAGE_COUNT:** The number of messages that are included in the destination file for a message to file transfer.
- **SOURCE_CORRELATOR_ID:** The ID of the correlator information for the source.
- **TRANSFER_ID:** The transfer that this item is part of.
- **TRUNCATE_RECORDS:** Indicates whether over length data set records are to be truncated or wrapped.

TRANSFER_STATS

A set of statistics generated at the end of a transfer.

- **ID:** Row ID.
- **TRANSFER_ID:** The transfer to which the statistics refer.
- **START_TIME:** The time at which the transfer started. In a system that is busy or has intermittent connectivity, this time might be later than the time reported in the Started message, as that time represents the point at which initial processing began rather than the point at which the successful transfer of data began.
- **RETRY_COUNT:** The number of times that the transfer had to be retried because of load or availability issues.
- **FILE_FAILURES:** The number of files that failed to be transferred.
- **FILE_WARNINGS:** The number of files that had warnings reported for them when they were transferred.

TRIGGER_CONDITION

One condition in a basic Managed File Transfer conditional transfer. For example, "file example.file exists".

- **ID:** Row ID.
- **TRANSFER_EVENT_ID:** The transfer event that the trigger is related to.
- **CONDITION_TYPE:** The type of check used in the trigger. For example, the existence of a file or the size of a file.
- **COMPARISON:** The specific comparison to make. For example "greater than or equal to".
- **VALUE:** The value to compare against.
- **FILENAME:** The file name to examine.

Related reference

[“fteStartLogger \(start an MFT logger\)” on page 2171](#)

The **fteStartLogger** command starts a Managed File Transfer logging application.

[“fteModifyLogger \(run an MFT logger as a Windows service\)” on page 2130](#)

Use the **fteModifyLogger** command to modify a Managed File Transfer logger so that it can be run as a Windows service. You can use this command only on Windows platforms, must be run by a user who is an IBM MQ administrator and a member of the mqm group, and you must first stop the logger by using the **fteStopLogger** command.

[“fteStopLogger \(stop an MFT logger\)” on page 2177](#)

The **fteStopLogger** command stops a Managed File Transfer logger.

Db2 entity relationship diagram

A diagram showing the relationship of the entities in a Db2 database.

In the ERD, the #, *, and o symbols each has a specific meaning:

- # means a primary key
- * means that a value cannot be null
- o means that a value can be null

Figure 9. Db2 entity relationship diagram (ERD)

Related tasks

[“Migrating a Db2 database to the new schema” on page 2576](#)

How you migrate a database with the existing schema to the new schema, by using the sample SQL script file.

Migrating a Db2 database to the new schema

How you migrate a database with the existing schema to the new schema, by using the sample SQL script file.

Before you begin

Take a backup of the database, and its relevant configuration information, that you are going to migrate and refer to the [“Db2 entity relationship diagram” on page 2574](#).

Attention:

In the Db2 database, the LongVarchar data type now has a limit of :

- 2000 bytes in the SOURCE_FILENAME and DESTINATION_FILENAME columns, in the TRANSFER_ITEM and SCHEDULE_ITEM tables
- 4000 bytes, or 256 bytes for all the remaining columns, depending on the purpose of each column

If, for any reason, you want to increase the size of these database columns, you can change the script file and increase the size of the corresponding column.

About this task

The following four sample SQL script files are located in `<MQ_Installation_Directory>/mqft/sql`:

- `db2_varchar_migration_step_1.sql`
- `db2_varchar_migration_step_2.sql`
- `db2_varchar_migration_step_3.sql`
- `db2_varchar_migration_step_4.sql`

Procedure

1. Carry out the following tasks in order:

- a) Run **`db2_varchar_migration_step_1.sql`**
- b) Run **`db2_varchar_migration_step_2.sql`**
- c) Run **`db2_varchar_migration_step_3.sql`**
- d) Run **`db2_varchar_migration_step_4.sql`**

Important: Before running step [“1.c” on page 2576](#), ensure that steps [“1.a” on page 2576](#) and [“1.b” on page 2576](#) have run successfully.

2. Issue the command **`cd <MQ_Installation_Directory>/mqft/sql`**

3. Process the SQL script files, using the following commands in order:

- a) Run **`db2 -tvvf db2_varchar_migration_step_1.sql`**
- b) Run **`db2 -tvvf db2_varchar_migration_step_2.sql`**
- c) Run **`db2 -tvvf db2_varchar_migration_step_3.sql`**
- d) Run **`db2 -tvvf db2_varchar_migration_step_4.sql`**

What to do next

If you receive some errors while creating new tables or new columns, caused by temporary table spaces, you can resolve these problems as follows:

Error:

```
SQL State [54048], Error Code [-1585], Message [DB2 SQL Error: SQLCODE=1585 ,
SQLSTATE=54048, SQLERRMC=null in the trace file of logger
```

Explanation:

One of the following conditions could have occurred:

1. The row length of the system temporary table exceeded the limit that can be accommodated in the largest system temporary table space in the database.
2. The number of columns required in a system temporary table exceeded the limit that can be accommodated in the largest system temporary table space in the database.

Link:

Message [SQL1585N](#).

Solution:

Create a system temporary tablespace for each page as SMS (System Managed). In that case, your query always finds a tablespace with the appropriate page size.

Example:

The following SQL commands resolve the preceding issue:

```
CREATE BUFFERPOOL BP4K pagesize 4K
CREATE SYSTEM TEMPORARY TABLESPACE STB_4 PAGESIZE 4K BUFFERPOOL BP4K
CREATE BUFFERPOOL BP8K pagesize 8K
CREATE SYSTEM TEMPORARY TABLESPACE STB_8 PAGESIZE 8K BUFFERPOOL BP8K
CREATE BUFFERPOOL BP16K pagesize 16K
CREATE SYSTEM TEMPORARY TABLESPACE STB_16 PAGESIZE 16K BUFFERPOOL BP16K
CREATE BUFFERPOOL BP32K pagesize 32K
CREATE SYSTEM TEMPORARY TABLESPACE STB_32 PAGESIZE 32K BUFFERPOOL BP32K
```

Oracle entity relationship diagram

A diagram showing the relationship of the entities in an Oracle database.

In the ERD, the #, *, and o symbols each has a specific meaning:

- # means a primary key
- * means that a value cannot be null
- o means that a value can be null

Figure 10. Oracle Entity Relationship Diagram (ERD)

Related tasks

[“Migrating an Oracle database to the new schema” on page 2579](#)

How you migrate a database with the existing schema to the new schema, by using the sample SQL script file.

Migrating an Oracle database to the new schema

How you migrate a database with the existing schema to the new schema, by using the sample SQL script file.

Before you begin

Take a backup of the database, and its relevant configuration information, that you are going to migrate and refer to the [“Oracle entity relationship diagram” on page 2577](#).

Attention: The NCLOB data type has no limit on the length of the data that can be stored. However, VARCHAR2 has a limit of 4000 bytes, so there could be some data loss while migrating to a new schema if the existing database contains file names that are longer than 4000 bytes (or 32767 bytes for an extended string).

In this situation, only the last 2000 characters of the filename will be migrated, therefore, you should ensure that your file names do not exceed 2000 characters.

About this task

The following four sample SQL script files are located in `<MQ_Installation_Directory>/mqft/sql`:

- `oracle_nvarchar_migration_step_1.sql`
- `oracle_nvarchar_migration_step_2.sql`
- `oracle_nvarchar_migration_step_3.sql`
- `oracle_nvarchar_migration_step_4.sql`

Procedure

1. Carry out the following tasks in order:

- a) Run **`oracle_nvarchar_migration_step_1.sql`**
- b) Run **`oracle_nvarchar_migration_step_2.sql`**
- c) Run **`oracle_nvarchar_migration_step_3.sql`**
- d) Run **`oracle_nvarchar_migration_step_4.sql`**

Important: Before running step [“1.c” on page 2579](#), ensure that steps [“1.a” on page 2579](#) and [“1.b” on page 2579](#) have run successfully.

2. Issue the command `cd <MQ_Installation_Directory>/mqft/sql`

3. Process the SQL script files, using the following commands in order:

- a) Run **`sqlplus USERNAME/PASSWORD < oracle_nvarchar_migration_step1.sql`**
- b) Run **`sqlplus USERNAME/PASSWORD < oracle_nvarchar_migration_step2.sql`**
- c) Run **`sqlplus USERNAME/PASSWORD < oracle_nvarchar_migration_step3.sql`**
- d) Run **`sqlplus USERNAME/PASSWORD < oracle_nvarchar_migration_step4.sql`**

where USERNAME/PASSWORD refers to the user Id and password of a particular user.

Authorities for the MFT logger

The operating system user who runs the logger requires certain IBM MQ authorities on the logger queues and the SYSTEM.FTE topic.

The operating system user who runs the logger requires the following IBM MQ authorities:

- CONNECT and INQUIRE on the coordination queue manager.
- SUBSCRIBE permission on the SYSTEM.FTE topic.
- PUT permission on the SYSTEM.FTE.LOG.RJCT.*logger_name* queue.
- GET permission on the SYSTEM.FTE.LOG.CMD.*logger_name* queue.

File permissions for destination files

The file permissions for destination files written by Managed File Transfer destination agents are determined by the platform that the agent is running on.

Destination agents on z/OS, AIX and Linux platforms

You need to alter the value of **umask** on your system.

For example, assume that the default **umask** value for your user ID on your z/OS system is *0022*.

When an MFT agent is running as this user, and writes a destination file, the file has the following permissions:

```
-IW-I--I--
```

If you change the **umask** value to, for example, *0006*, by running the command

```
umask 0006
```

and the agent restarted, then any destination files that the agent writes has the permissions:

```
-IW-IW----
```

Note, that you must restart the agent after you have run the `umask` command in order for the agent to pick up the new value.

Although z/OS is used as an example here, the same information applies to AIX and Linux platforms.

Destination agents on Windows

By default, permissions are inherited from a root folder to the files and sub-folders beneath it, though this inheritance can be turned off.

Your Windows administrator or domain administrator should review and manage the permissions and change them if necessary. They can use the `icacls` command to view, add, update, and remove permissions.

MQ message properties set by MFT on messages written to destination queues

When transferring from file to message, Managed File Transfer can set IBM MQ message properties on the first message written to the destination queue. Additional IBM MQ message properties are set when a file to message transfer has failed.

IBM MQ message properties allow an application to select messages to process, or to retrieve information about a message without accessing MQ Message Descriptor (MQMD) or MQRFH2 headers. See [Message properties](#).

This topic describes the parameter used in the **fteCreateTransfer** and **fteCreateTemplate** commands to indicate that message properties should be added to the first message written to the destination queue. You can also specify that message properties should be added to the first message written to the destination queue using the *dstmsgprop* value of the **fte:filespec** parameter.

Standard properties

You can use the **-qmp** parameter on the **fteCreateTransfer** command or the **fteCreateTemplate** command to specify whether IBM MQ message properties are set on the first message written to the destination queue by the transfer. For an example of how to use this parameter, see the topic [Example: Setting IBM MQ message properties on a file-to-message transfer](#)

The IBM MQ message properties contain transfer metadata. The message property names are prefixed with **usr.WMQFTE**. The **usr.** prefix makes these message properties available to JMS applications.

usr.WMQFTETransferId

The unique hexadecimal transfer ID.

usr.WMQFTETransferMode

The type of file transfer: binary mode or text mode.

usr.WMQFTESourceAgent

The name of the source agent.

usr.WMQFTEDestinationAgent

The name of the destination agent.

usr.WMQFTEFileName

The name of the source file.

usr.WMQFTEFileSize

The size of the source file in bytes.

usr.WMQFTEFileLastModified

The last modified time of the source file. This value is in units of milliseconds, measured from 00:00:00 UTC, January 1, 1970.

usr.WMQFTEFileIndex

The index of the current file in the list of files that are being transferred. The first file in the list has index 0.

usr.WMQFTEMqmdUser

The MQMD user ID of the user that submitted the transfer request.

Failure properties

When a file to message transfer fails after the destination agent has written at least one message to the destination queue, Managed File Transfer writes a blank message to the destination queue. If the **-qmp** parameter is set to true, this blank message has two IBM MQ message properties set. For an example of a file to message transfer failure, see [Failure of a file-to-message transfer](#).

When a file to message transfer fails completely, Managed File Transfer writes a blank message to the destination queue. If the **-qmp** parameter is set to true, and the length of the message data is greater than the `maxInputOutputMessageLength` value, the following error message is displayed at the command line.

```
Name WMQFTEResultCode
Value 40
Name WMQFTESupplement
Value BFGTR0072E: The transfer failed to complete due to the exception BFGI00205E:The message
data length 1290843 being written
to the output queue "M2F@q2" is greater than the maximum allowed 1048576.
```

The IBM MQ message properties contain information about the failure. As with the standard message properties, the message property names are prefixed with **usr.WMQFTE** and are available to JMS applications.

usr.WMQFTEReturnCode

The return code of the transfer. For a list of possible values for this return code, see the topic [Return codes for MFT](#).

usr.WMQFTESupplement

A supplementary message describing in more detail why the transfer failed.

User-defined properties

Metadata specified using the **-md** parameter with the **fteCreateTransfer** command can be set as IBM MQ message properties. If the **-qmp** parameter is set to true, any metadata specified by the user will be added to the message header of the first message.

The metadata name is prefixed by **usr.**. For example, if the metadata is `department=accounts`, the IBM MQ message header is set to `usr.department=accounts`.

You cannot use metadata to specify headers that begin with `usr.WMQFTE` or `usr.com.ibm.wmqfte`. If you specify metadata with a name beginning with `WMQFTE` or `com.ibm.wmqfte` this metadata is not used in the message properties and is ignored.

[fte:filespec](#)

IBM MQ message properties read by MFT from messages on source queues

The agent reading messages from a source queue in a message to file transfer reads the IBM MQ message properties from the message. The value of these properties can be used to determine the behavior of a transfer.

Headers used to cancel message to file transfers

Set the following IBM MQ message properties on the last message in a group to cancel the message to file transfer of that group:

usr.UserReturnCode

Required. The return code of the transfer. Set this header as a non-zero value to indicate that the transfer is to be canceled.

usr.UserSupplement

Optional. Text describing why the transfer was canceled.

If the source agent of a message to file transfer reads a message from the source queue that has the **usr.UserReturnCode** message property set to a non-zero value, it stops reading messages from the queue and reports that the transfer failed in the transfer log XML. The transfer log XML contains the return code and supplementary text that is set in the message headers. If the destination agent has already written data to a temporary file this file is deleted from the destination.

Headers used by variable substitution

The value of any IBM MQ message property in the first message to be read from the monitored queue can be substituted into the task XML definition. User-defined message properties are prefixed with `usr.`, but do not include this prefix in the variable name. Variable names must be preceded by a dollar sign (\$) character and enclosed in braces ({}). For example, `${destFileName}` is replaced with the value of the `usr.destFileName` message property of the first message to be read from the source queue.

For example, the user or program putting messages to a monitored queue can set IBM MQ message properties on the first message in a group specifying which agent is to be used as the destination of the file transfer and what file name to transfer the data to.

For more information, see [Monitoring a queue and using variable substitution](#).

Guidance for setting MQ attributes and MFT properties associated with message size

You can change IBM MQ attributes and Managed File Transfer properties to affect the behavior of Managed File Transfer when reading or writing messages of various sizes.

If the size of messages being read from a source queue or written to a destination queue exceeds 1048576 bytes (1 MB), you must increase the value of the Managed File Transfer Agent property

maxInOutPutMessageLength to a value that is greater than or equal to the maximum message size to be read or written.

If the messages on the source queue are greater than 1048576 bytes, you must set the **maxInOutPutMessageLength** property on the source agent. If the messages on the destination queue are greater than 1048576 bytes you must set the **maxInOutPutMessageLength** property on the destination agent. For more information about the **maxInOutPutMessageLength** property, see [Advanced agent properties: File to message and message to file agent](#).

- If the queue that the agent is writing to or reading from is local to the agent queue manager, you might have to change the IBM MQ queue manager, queue, and channel **MAXMSGL** attributes.

Ensure that the value of the maximum message size of the source or destination queue is greater than or equal to the value of the **maxInOutPutMessageLength** agent property.

Ensure that the value of each of the following IBM MQ attributes, in bytes:

- The maximum message size of the agent queue manager
- The maximum message size of the `SYSTEM.FTE.STATE.agent_name` queue
- The client channel maximum message size, if your agent connects to the queue manager in client mode

is greater than or equal to the result of the following calculation:

The value of $(3 * \text{maxInOutPutMessageLength}) + 1048576$

(This calculation is derived from the fact that three checkpoints can be stored in a state message and each checkpoint might have to buffer up to the maximum size of a message amount of data.)

- If the queue that the agent is writing to is a remote queue, you might have to change the IBM MQ queue manager, queue, and channel **MAXMSGL** attributes.

Ensure that the value of each of the following IBM MQ attributes is greater than or equal to the value of the **maxInOutPutMessageLength** agent property:

- The maximum message size of the remote queue manager transmission queue on the agent queue manager
- The maximum message size of the channel from the agent queue manager to the remote queue manager
- The maximum message size of the destination queue on the remote queue manager
- The maximum message size of the remote queue manager

Ensure that the value of each of the following IBM MQ attributes, in bytes:

- The maximum message size of the agent queue manager
- The maximum message size of the `SYSTEM.FTE.STATE.agent_name` queue
- The client channel maximum message size, if your agent connects to the queue manager in client mode

is greater than or equal to the result of the following calculation:

The value of $(3 * \text{maxInOutPutMessageLength}) + 1048576$

This calculation is derived from the fact that three checkpoints can be stored in a state message and each checkpoint might have to buffer up to the maximum size of a message amount of data.

If you exceed the value of one of these properties, the agent stops with the following error in the agent event log:

```
BFGUT0002E: An internal error has occurred. Product failure data was captured in file
"FFDC.FTE.20100928170828514.8172766022149157013.log".
BFGSS0025E: An internal error has occurred. The exception is: cc=2 rc=2010 op=put - MQPUT to
SYSTEM.FTE.STATE.agent_name
BFGAG0061E: The agent ended abnormally
```

The following IBM MQ reason codes might be included in this message in the agent event log:

- `rc=2010` This reason code maps to `MQRC_DATA_LENGTH_ERROR` and indicates that the value of the client channel maximum message size was exceeded. To resolve this problem ensure that the client channel maximum message size of the agent queue manager is greater than or equal to the result of the following calculation:

$$3 * (\text{maxInputOutputMessageLength}) + 1048576$$

- `rc=2030` This reason code maps to `MQRC_MSG_TOO_BIG_FOR_Q` and indicates that the value of the maximum message size of the `SYSTEM.FTE.STATE.agent_name` queue was exceeded. To resolve this problem ensure that the maximum message size of the `SYSTEM.FTE.STATE.agent_name` queue is greater than or equal to the result of the following calculation:

$$3 * (\text{maxInputOutputMessageLength}) + 1048576$$

- `rc=2031` This reason code maps to `MQRC_MSG_TOO_BIG_FOR_Q_MGR` and indicates that the value of the maximum message size of the agent queue manager was exceeded. To resolve this problem ensure that the maximum message size of the agent queue manager is greater than or equal to the result of the following calculation:

$$3 * (\text{maxInputOutputMessageLength}) + 1048576$$

If you are transferring many small messages

If the average size of the messages that the agent is reading from or writing to a queue is less than 1310 bytes and the agent is reading or writing more than 10000 messages, you must increase the maximum number of uncommitted messages attribute on the queue manager or reduce the amount of data in a checkpoint interval.

When the agent is reading messages from or writing messages to a queue the corresponding **GETs** or **PUTs** are grouped together into transactions. The number of **GETs** or **PUTs** in a transaction is determined by the number required to process all of the data within a checkpoint interval. The approximate amount of the data in a checkpoint interval is determined from agent properties using the following calculation:

$$\text{Checkpoint interval data size (in bytes)} = \text{agentCheckpointInterval} * \text{agentFrameSize} * \text{agentWindowSize} * \text{agentChunkSize}.$$

The default checkpoint data size is $1 * 5 * 10 * 262144$ bytes = 13107200 bytes (12.5MB). The maximum number of uncommitted messages in a transaction that a queue manager supports is controlled by the **MaxUncommittedMsgs** queue manager attribute. The default value of this attribute is 10000 messages. If the average message size is less than approximately 1310 bytes the default maximum number of uncommitted messages is exceeded if there are more than 10000 messages to be written.

If you exceed the **MaxUncommittedMsgs** limit, the agent stops with the following error in the agent event log:

```
BFGSS0024E: The agent has received a reason code of '2024' from the message queue interface (MQI).
The agent cannot continue processing and will now end.
BFGAG0139I: The agent has suspended its current transfers and is now stopping.
```

The reason code 2024 maps to: `MQRC_SYNCPOINT_LIMIT_REACHED`.

To resolve this problem perform one of the following actions

- Increase the value of the **MaxUncommittedMsgs** queue manager attribute of the queue manager that the agent reading from or writing to a queue connects to. See [MaxUncommittedMsgs \(MQLONG\)](#).
- Reduce the amount of data in a checkpoint interval. To do this, decrease the value of one or more of the following agent properties:
 - `agentCheckpointInterval`

- agentFrameSize
- agentWindowSize
- agentChunkSize

For information about these agent properties, see [Advanced agent properties](#).

If you are writing messages to a queue persistently

If you are transferring to a queue and writing the messages to the queue persistently, you might have to increase the size of the queue manager log file space to be able to log all of the data in a checkpoint interval.

If you exceed the queue manager log file space, the agent stops with the following error in the agent event log:

```
BFGSS0024E: The agent has received a reason code of '2102' from the message queue interface (MQI).
The agent cannot continue processing and will now end.
BFGAG0062E: The agent has received MQI reason code '2102'. The agent cannot continue processing and
will now end.
BFGAG0061E: The agent ended abnormally
```

The reason code '2102' maps to: MQRC_RESOURCE_PROBLEM.

To resolve this problem increase the size of the destination agent queue manager log file space.

Guidance for specifying a wait time on a message-to-file transfer

When specifying a message-to-file transfer you can optionally specify a wait time on the transfer using the **-sqwt** parameter. The value of **-sqwt** is the amount of time that the source agent waits either for a message to appear on the source queue if the source queue is empty or becomes empty, or for a complete group to appear on the source queue if the **-sqgi** attribute is specified.

This topic describes the parameters used in the **fteCreateTransfer** command for specifying a wait time. You can also specify the wait time using the [srcqueuetimeout](#) value of the **fte:filespec** parameter.

If the value of the **-sqwt** parameter is greater than or equal to the amount of time the destination agent waits for the transfer to be completed by the source agent, the transfer does not complete. The amount of time the destination agent waits for the transfer to complete is given by the following calculation:

```
transferAckTimeout * transferAckTimeoutRetries
```

The properties `transferAckTimeout` and `transferAckTimeoutRetries` are set in the destination agent `agent.properties` file. For more information about these agent properties, see [The agent.properties file](#).

To prevent transfers from failing to complete, you must perform one of the following steps:

- Reduce the value of the **-sqwt** parameter so that it is less than the value of the destination agent `transferAckTimeout` property.

Note: The default value of the `transferAckTimeout` property is 60,000 milliseconds. The value of the **-sqwt** parameter is given in seconds, set the value to 59 or less.

- Increase the value of the destination agent `transferAckTimeout` property so that it is greater than the value of the **-sqwt** parameter.

Note: The value of the `transferAckTimeout` property is given in milliseconds. The value of the `-sqwt` parameter is given in seconds.

Available code pages for MFT

This reference topic lists all character encoding formats available for text file conversion on the various platforms supported by Managed File Transfer.

Common encodings

These character encoding formats are available on all supported platforms. If your source file is encoded using one of the formats in this table, and you want to use another of the formats in this table to write the destination file, you can do so without any consideration of platform. You can use either the canonical name or any of the aliases to specify an encoding format.

MacTurkish	ibm-1281

Source platform default encodings

If you do not specify an encoding for the source file or for the destination file, the default encoding for that platform will be used. The conversion is performed by the destination agent, and both source and destination encodings must be supported on the destination agent's platform for the conversion to take place. The destination default encoding will always be supported on the destination agent, so it is always safe to leave this unspecified. However, it might not be safe to use a default source encoding, because the destination agent might not support the source's default.

If you are using default source encodings, use the tables in this topic to make sure that the combination will be supported.

Table 377. Default encodings

Platform	Default encoding
 SUSE Linux Enterprise Server on x86-64	UTF-8
 IBM i	ISO-8859-1
 Linux for IBM Z	UTF-8
 AIX	ISO-8859-1
 Windows	windows-1252
 Red Hat® Enterprise Linux on x86-64	UTF-8
 z/OS	IBM-1047
 Linux on POWER Systems - Big Endian	UTF-8
HP (PA-RISC)	ISO-8859-1

Platform-specific encodings

Note: The following two tables contain the same information. It is organized in two different ways to help you find the correct information, depending whether you are looking up by platform or by encoding.

Encodings by Platform

Canonical names are listed in bold, followed by aliases in parentheses.

Platforms that support only encodings already listed in the Common Encodings table are not listed here.

Table 378. Platform-specific encodings by platform

Platform	Supported encodings (not in common encodings table)
 SUSE Linux Enterprise Server on x86-64	<p> windows-1256S (Cp1256s, ibm-1256s) UTF-8J (UTF8J) UTF-32LE (UTF_32LE, X-UTF-32LE, UTF32LE) UTF-32BE (UTF_32BE, X-UTF-32BE, UTF32BE) UTF-32 (UCS-4, UTF32, ISO-10646-UCS-4) PTCP154 (PT154, IBM-1169, Cyrillic-Asian, csPTCP154) KOI8-RU (ibm-1168, koi8_ru) ISO-8859-16 (8859-16, iso8859_16, iso8859-16) ISO-8859-14 (ISO_8859-14:1998, 8859-14, latin8, iso-ir-199, iso8859-14, l8, isoceltic, iso8859_14) IBM01141 (cp1141, ccsid01141, cp01141, 1141) IBM01142 (cp01142, cp1142, 1142, ccsid01142) IBM01143 (cp01143, 1143, ccsid01143, cp1143) IBM01144 (cp01144, cp1144, ccsid01144, 1144) IBM01145 (cp1145, cp01145, ccsid01145, 1145) IBM01146 (ccsid01146, cp01146, cp1146, 1146) IBM01147 (ccsid01147, cp1147, 1147, cp01147) IBM01148 (cp1148, ccsid01148, 1148, cp01148) IBM01149 (cp1149, cp01149, ccsid01149, 1149) IBM1047 (cp1047, 1047, ibm-1047) IBM918 (cp918, ebcdic-cp-ar2, ibm-918, 918) ISO-2022-JP-2 (csISO2022JP2, iso2022jp2) x-Big5-Solaris (Big5_Solaris) x-eucJP-Open (EUC_JP_Solaris, eucJP-open) x-IBM33722 (ibm33722, 33722, ibm-33722_vascii_vpua, ibm-5050, ibm-33722, cp33722) x-IBM930 (cp930, ibm930, ibm-930, 930) x-IBM939 (ibm-939, ibm939, cp939, 939) x-IBM964 (964, cp964, ibm-964, ibm964) x-ISO-2022-CN-CNS (ISO-2022-CN-CNS, ISO2022CN_CNS) x-iso-8859-11 (iso-8859-11, iso8859_11) x-JISAutoDetect (JISAutoDetect) x-MS932_0213 () x-MS950-HKSCS (MS950_HKSCS) x-PCK (pck) x-IBM1363C (ibm1363c, cp1363c, ibm-1363c) x-IBM420S (420s, ibm-420s, csibm420s, ibm420s, cp420s) x-IBM864S (csibm864s, ibm864s, cp864s, 864s, ibm-864s) x-IBM943C (cp943c, 943c, ibm-943c, ibm943c) x-IBM949C (ibm949c, cp949c, 949c, ibm-949c) x-IBM954C (cp954c, 954c, ibm-954c, ibm954c) x-ISO-8859-6S (8859_6s, iso8859-6s, iso8859_6s, iso-8859-6s) x-JIS0208 (jis_c6226-1983, jis_x0208-1983, csiso87jisx0208, x0208, iso-ir-87, jis0208) x-KSC5601 (ksc5601) x-MacDingbat (macdingbat) x-MacHebrew (machebrew) x-MacThai (macthai) x-MacUkraine (macukraine) x-IBM1046S (ibm-1046s, 1046s, cp1046s, ibm1046s) x-IBM-udcJP (IBM-udcJP) JIS_X0201 (jis_x0201, x0201, cshalfwidthkatakana, jis0201) IBM-939A (Cp939A, ibm939A) IBM-930A (ibm930A, Cp930A) IBM-33722A (Cp33722A, ibm33722A) x-windows-iso2022jp (windows-iso2022jp) x-windows-50221 (ms50221, cp50221) x-windows-50220 (cp50220, ms50220) X-UTF-32LE-BOM (UTF_32LE_BOM, UTF-32LE-BOM) X-UTF-32BE-BOM (UTF_32BE_BOM, UTF-32BE-BOM) x-SJIS_0213 () IBM01140 (ccsid01140, cp01140, 1140, cp1140) IBM00858 (cp858, ccsid00858, 858, cp00858) X-UnicodeLittle (UnicodeLittle) X-UnicodeBig (UnicodeBig) IBM-859 (Cp859, ibm859) </p>

[Using transfer definition files](#)

Related reference

[“Transferring text files with MFT” on page 2540](#)

Text file transfer involves converting the code page of a file from one code page to another. Text file transfer also involves converting CRLF (carriage return-line feed) characters between systems. This topic summarizes text file transfer behavior of Managed File Transfer.

[“fteCreateTransfer \(start a new file transfer\)” on page 2079](#)

The **fteCreateTransfer** command creates and starts a new file transfer from the command line. This command can start a file transfer immediately, schedule a file transfer for a future time and date, repeat a scheduled transfer one or more times, and trigger a file transfer based on certain conditions.

How MFT agents use Java heap and native heap memory

An IBM MQ Managed File Transfer agent runs as a Java process. As such, the agent runs in the virtualized environment of the Java Virtual Machine (JVM).

The JVM itself is a native process, is bounded by the hardware and operating system. The JVM maintains two memory areas:

- The Java heap

This contains the instances of Java objects and is managed by garbage collection processing. The maximum size of the Java heap is allocated during JVM startup using the **-Xmx** JVM option.

- The native heap

The native heap contains resources for the JVM itself; for example, the Just-In-Time Compiler, Classes, and ClassLoaders.

An agent primarily uses the Java heap. When performing managed transfers, the agent uses the Java heap to create Java objects that are required for the transfer. Any file data that is read into buffers by the agent is also stored in Java heap memory.

An agent does not itself contain any code that uses the native heap. However, there is native code in the Java message queuing interface (JMQUI) that the agent uses to communicate with its agent queue manager.

This native code is used when an agent connects to its agent queue manager using the BINDINGS transport. This is a local shared memory connection (sometimes referred to as interprocess communication, or IPC), rather than a TCP/IP connection which is used if an agent connects using the CLIENT transport. When an agent is configured to use the BINDINGS transport, the native heap is used to pass messages and commands between the agent and the agent queue manager.

This means that a heavily loaded agent that is connected to its agent queue manager using the BINDINGS transport makes more extensive use of the native heap, when compared to an equivalent agent which is connected using the CLIENT transport.

One common misconception is that the Java heap for an agent must be equal to (or greater than) the size of the largest file that is to be transferred. This is not correct as file data is read into memory in stages.

As a guide, the maximum amount of Java heap that is used to store file data for each transfer can be roughly calculated as follows:

```
Memory allocated for a transfer = agentCheckpointInterval *  
agentFrameSize * agentWindowSize * agentChunkSize
```

How Java heap and native heap usage affects agents

When a `java.lang.OutOfMemoryError` occurs, you might think it reasonable to increase the amount of Java heap available to the application, using the **-Xmx** Java System Property. For example, the following property setting attempts to allocate a maximum Java heap size of 2GB:

```
-Xmx2048M
```

However, allocating too much Java heap for an application can cause a `java.lang.OutOfMemoryError` to occur, due to native heap exhaustion. This is because, as the Java heap space grows, the native heap must shrink to accommodate it.

For information about how to prevent `java.lang.OutOfMemoryErrors` that are caused by native heap exhaustion, see [What to do if your MFT agent ABENDS with a java.lang.OutOfMemoryError due to native memory exhaustion](#).

XML message formats used by MFT

Managed File Transfer uses messages in XML format for a number of purposes: to command an agent; to log information about the monitors, schedules, and transfers; and to define information used for configuration. The logical structure of the XML formats used for these purposes described by XML schema.

Each version of Managed File Transfer uses an XML schema to validate messages written in XML. The agent extracts the XML schema version and determines whether the schema is supported.

After you have installed Managed File Transfer, you can find the Managed File Transfer message schema files in the following directory: *MQ_INSTALLATION_PATH/mqft/samples/schema*. The following schemas are included:

Schemas for XML messages that can be put on an agent command queue

- FileTransfer.xsd
- Internal.xsd
- Monitor.xsd
- PingAgent.xsd

For more information about putting XML messages on an agent command queue, see [Controlling MFT by putting messages on the agent command queue](#).

Schemas for XML messages that are published to the SYSTEM.FTE topic

- MonitorList.xsd
- MonitorLog.xsd
- ScheduleList.xsd
- ScheduleLog.xsd
- TransferLog.xsd
- TransferStatus.xsd

For more information about XML messages that are published to the SYSTEM.FTE topic and the structure of the SYSTEM.FTE topic, see [SYSTEM.FTE topic](#).

Other schemas used by Managed File Transfer

fteutils.xsd. This schema contains common element definitions and is included by some of the other schemas.

- Notification.xsd
- ProtocolBridgeCredentials.xsd
- ProtocolBridgeProperties.xsd
- ConnectDirectCredentials.xsd
- ConnectDirectNodeProperties.xsd
- ConnectDirectProcessDefinitions.xsd
- Reply.xsd
- UserSandboxes.xsd

[“MFT agent status message format” on page 2648](#)

When a Managed File Transfer Agent is created or started, the agent publishes its details to the SYSTEM.FTE topic on its coordination queue manager (on the SYSTEM.FTE/Agents/*agent name* topic).

[“File transfer request message format” on page 2698](#)

File transfers are initiated by XML messages arriving at an agent command queue, typically as a result of a user issuing a file transfer command or by using the IBM MQ Explorer. The transfer request XML must conform to the *FileTransfer.xsd* schema and have the <request> element as the root element. The *FileTransfer.xsd* schema document is located in the *MQ_INSTALLATION_PATH/mqft/samples/schema* directory. The *FileTransfer.xsd* schema imports *fteutils.xsd*, which is in the same directory.

[“File transfer status message format” on page 2660](#)

Messages are published to the coordination queue manager to indicate transfer status of each file in the transfer set. Every time a request for file transfer is processed by the agent, a transaction message is published to the coordination queue manager (on its SYSTEM.FTE/Transfers/*agent_name/transfer ID* topic), which conforms to the *TransferStatus.xsd* XML schema. The *TransferStatus.xsd* file is located in the *MQ_INSTALLATION_PATH/mqft/samples/schema* directory of your WMQMFT installation.

[“File transfer log message formats” on page 2664](#)

File transfer log messages are published to the SYSTEM.FTE topic with a topic string of `Log/agent_name/transfer_id`. These messages conform to the schema `TransferLog.xsd`, which is located in the `MQ_INSTALLATION_PATH/mqft/samples/schema` directory of your Managed File Transfer installation.

[“Scheduled file transfer log message formats” on page 2686](#)

Every time a request for a scheduled file transfer is processed by the agent, a schedule log message is published to the coordination queue manager (on its `SYSTEM.FTE/Log/agent_name/schedule ID` topic). This message conforms to the `ScheduleLog.xsd` XML schema.

[“MFT monitor request message formats” on page 2715](#)

Resource monitors are created when a suitable XML message arrives at an agent's command queue, typically as a result of a user issuing the **fteCreateMonitor** command or using the IBM MQ Explorer interface.

[“MFT message formats for security” on page 2728](#)

This topic describes the messages published to the Managed File Transfer coordination queue manager relevant to security.

[“Protocol bridge credentials file format” on page 2733](#)

The `ProtocolBridgeCredentials.xml` file in the Managed File Transfer Agent configuration directory defines the user names and credential information that the protocol bridge agent uses to authorize itself with the protocol server.

[“Protocol bridge properties file format” on page 2737](#)

The `ProtocolBridgeProperties.xml` file in the agent configuration directory defines properties for protocol file servers.

[“Connect:Direct credentials file format” on page 2750](#)

The `ConnectDirectCredentials.xml` file in the Managed File Transfer Agent configuration directory defines the user names and credential information that the Connect:Direct agent uses to authorize itself with a Connect:Direct node.

[“Connect:Direct node properties file format” on page 2757](#)

The `ConnectDirectNodeProperties.xml` file in the Connect:Direct bridge agent configuration directory specifies information about remote Connect:Direct nodes that are involved in a file transfer.

[“Connect:Direct process definitions file format” on page 2753](#)

The `ConnectDirectProcessDefinitions.xml` file in the Connect:Direct bridge agent configuration directory specifies the user-defined Connect:Direct process to start as part of the file transfer.

[“Ping MFT agent request message format” on page 2725](#)

You can ping an agent by issuing an **ftePingAgent** command or by putting an XML message on the agent command queue. The ping agent request XML must conform to the `PingAgent.xsd` schema. After you have installed Managed File Transfer, you can find the `PingAgent.xsd` schema file in the following directory: `MQ_INSTALLATION_PATH/mqft/samples/schema`. The `PingAgent.xsd` schema imports `fteutils.xsd`, which is in the same directory.

[“MFT agent reply message format” on page 2726](#)

When an agent receives an XML message on its agent command queue, if a response is required, the agent will send an XML reply message to the reply queue defined in the original message. The reply XML conforms to the `Reply.xsd` schema. The `Reply.xsd` schema document is located in the `MQ_INSTALLATION_PATH/mqft/samples/schema` directory. The `Reply.xsd` schema imports `fteutils.xsd`, which is in the same directory.

MFT agent status message format

When a Managed File Transfer Agent is created or started, the agent publishes its details to the SYSTEM.FTE topic on its coordination queue manager (on the `SYSTEM.FTE/Agents/agent name` topic).

The following information is included:

- Agent name
- Platform the agent is running on
- Agent description (if provided)

- Agent's queue manager
- Time zone that the agent is running in
- Agent version
- Agent transfer limits
- State of each of the agent's current transfers. These states are listed in [Agent transfer states](#)
- Type of agent

If the agent is a protocol bridge agent the following information is also included:

- Type of protocol bridge agent
- Host name or IP address of the protocol bridge server

The agent status is republished whenever the agent transfer states change, but by default no more than every 30 seconds. You can change this default setting using the `agentStatusPublishRateLimit` agent property, which is described in [Advanced agent properties: General](#).

The following example output shows the keys used for each data element in the agent status:

```
<?xml version="1.0" encoding="UTF-8"?>

Resource monitors are created when a suitable XML message arrives at an agent's command queue, typically as a result of a user issuing the **fteCreateMonitor** command or using the IBM MQ Explorer interface.

[“MFT message formats for security” on page 2728](#)

This topic describes the messages published to the Managed File Transfer coordination queue manager relevant to security.

MFT agent transfer states

A Managed File Transfer Agent that is started publishes its details to the SYSTEM.FTE topic on its coordination queue manager. These details include the states of each of the current transfers that involved that agent.

<i>Table 380. Agent transfer state names and explanations</i>	
Transfer state	Explanation
CancelledInProgressTransfer	A source agent has received a cancel message for an in-progress transfer.
CancelledNewTransfer	A source agent has received a cancel message for a new transfer.
CompletedTransfer	A destination agent has completed the transfer and has sent a completion message to the source agent. The destination agent is waiting for an acknowledgment message from the source agent.
CompleteReceivedTransfer	A source agent has received a completion message from the destination agent and has sent a message back to the destination agent to acknowledge the completion message.

Table 380. Agent transfer state names and explanations (continued)

Transfer state	Explanation
FailedTransferEnding	The transfer has failed but the completion log message has not been published and the transfer has not been removed from the state store. For example, this state can occur if an agent process is stopped after a failure response has been received from the destination agent but before the subsequent processing has been completed.
NegotiatingTransfer	A source agent is in negotiation with the destination agent before running a transfer.
NewReceiverTransfer	A new transfer has been created at the destination agent as part of negotiation, but the transfer is not yet running.
NewSenderTransfer	A new transfer from the source agent that the negotiation has not started for.
RecoveringTransfer	When either a source or destination agent starts the recovery process, any transfers in running state are moved into transfer state. Transfers are moved out of this state into ReSynchronisingTransfer state when a resynchronization message is sent to the peer agent. For example, if the destination agent starts the recovery process for a running transfer, the transfer is moved into the ReSynchronisingTransfer state when a resynchronization message is sent to its source agent.
RecoveryTimedOut	If a transfer recovery timeout is set for a transfer, the source agent moves the transfer into this state if transfer recovery times out. After the transfer has been resynchronized, the destination agent removes any part files that were created during the transfer and sends a completion message to the source agent.
RestartingTransfer	A source or destination agent has received a resynchronize request message and is waiting for the respective destination or source agent to restart.
ResumingTransfer	A source agent has received a resynchronize response message and now schedules the transfer to restart.
ReSynchronisingTransfer	A transfer source or destination agent has found a problem and has sent a resynchronization message to its respective destination or source agent.
RunningTransfer	A transfer from either a source agent or destination agent that is in the normal running state
WaitingForDestinationCapacity	A source agent has received a DESTINATION_CAPACITY_EXCEEDED error from the destination agent. The transfer is now in a waiting state to be retried after a period.

[“MFT agent status values” on page 2518](#)

The **fteListAgents** and **fteShowAgentDetails** commands produce agent status information. There are several possible values for this status.

MFT monitor list message format

The XML messages that are published as retained publications to the topic string `SYSTEM.FTE/monitors/agent_name/monitor_name` conform to the `MonitorList.xsd` schema. Each XML message lists an active monitor belonging to that agent. This information is used by the **fteListMonitors** command and the IBM MQ Explorer plug-in to display a list of monitors to the user. The `MonitorList.xsd` schema document is located in the `MQ_INSTALLATION_PATH/mqft/samples/schema` directory. The `MonitorList.xsd` schema imports `Monitor.xsd`, which is in the same directory.

Schema

The following schema describes which elements are valid in a monitor list XML message.

```
<xsd:schema xmlns:xsd="https://www.w3.org/2001/XMLSchema"
  targetNamespace="https://www.ibm.com/xmlns/wmqfte/7.0.1/MonitorDefinition"
  xmlns="https://www.ibm.com/xmlns/wmqfte/7.0.1/MonitorDefinition">

  <xsd:include schemaLocation="Monitor.xsd"/>

      <xsd:element name="taskXML" type="xsd:string" minOccurs="0" maxOccurs="1" />
    </xsd:sequence>
  </xsd:complexType>

</xsd:schema>
```

Understanding the monitor list message

The elements and attributes used in the monitor list messages are described in the following list:

<monitorList>

Group element containing the elements describe a monitor that is defined for the agent.

Attribute	Description
agent	Required. The name of the agent that the resource monitor is defined on.
monitor	Required. The name of the monitor. Unique for this agent.
version	Required. The version of the monitor list message format.

<status>

The status of the monitor.

Attribute	Description
state	The state of the monitor.

<configuration>

Group element containing the elements describe the configuration of the monitor.

<description>

A description of the monitor. (Not currently used.)

<resources>

The resource or resources being monitored.

<directory>

A directory to monitor.

Attribute	Description
recursionLevel	The number of directory levels down from the top level to monitor.
id	The ID of the resource.

<queue>

A queue to monitor.

Attribute	Description
id	The ID of the resource.

<triggerMatch>

Element that contains the <conditions> element.

<conditions>

Element that contains the condition or conditions that the resource monitor is monitoring for. This element can contain only one of the following elements: <allOf>, <anyOf>, or <condition>.

<allOf>

Element that contains the condition or conditions that the resource monitor is monitoring for. This element can contain one or many <condition> elements. For the resource monitor to be triggered all of the conditions inside of this element must be met.

<anyOf>

Element that contains the condition or conditions that the resource monitor is monitoring for. This element can contain one or many <condition> elements. For the resource monitor to be triggered only one of the conditions inside of this element must be met.

<condition>

Element that contains a single condition that the resource monitor is monitoring for. This element can contain only one of the following elements: <fileMatch>, <fileNoMatch>, <fileSize>, <queueNotEmpty>, <completeGroups>, or <fileSizeSame>. It can also contain a <name> element and a <resource> element.

If the resource that is being monitored is a directory, one of the following three elements must be specified in the condition:

- fileMatch
- fileNoMatch
- fileSize

If the resource that is being monitored is a queue, one of the following two elements must be specified in the condition:

- queueNotEmpty
- completeGroups

<fileMatch>

Group element for a file name match condition.

<pattern>

Specifies a file name match pattern. Files on the resource must match the pattern in order to satisfy the condition. The default pattern is * (any file will match).

<fileNoMatch>

Group element for an inverse file name match condition.

<pattern>

Specifies an inverse file name match pattern. If no files on the monitored resource match, the condition is satisfied. The default pattern is * (the absence of any file will match).

<fileSize>

Group element for a file size comparison.

<compare>

Specifies a file size comparison. The value must be a non-negative integer.

Attribute	Description
operator	Comparison operator to use. Only '>=' is supported.
units	Specifies file size units, which can be one of: <ul style="list-style-type: none"> • B - bytes • KB - kilobytes • MB - megabytes • GB - gigabytes The units value is case insensitive, so 'mb' works as well as 'MB'.

<pattern>

File name pattern to match. Default is * (any file will match).

<queueNotEmpty>

This can only be specified if the resource is a queue. Specifies that there must be a message on the queue for the monitor to be triggered.

<completeGroups>

This can only be specified if the resource is a queue. Specifies that there must be a complete group of messages present on the queue for the monitor to be triggered. A single transfer task is executed for each complete group on the queue.

<name>

Name of the condition.

<resource>

Identifies the resource definition to compare the condition against.

Attribute	Description
id	Unique identifier for the resource.

<tasks>

Group element to contain elements which specify the tasks to invoke when the monitor trigger conditions are satisfied.

<task>

Group element which defines an individual task that the monitor will invoke when the trigger conditions are satisfied. Currently only one task can be specified.

<name>

Name of the task. Accepts any alphanumeric characters.

<description>

Description of the task. Any text value is allowed.

<taskXML>

The XML message that describes the task that the monitor is to perform. The contents of this element are in an escaped XML format.

<pollInterval>

The time interval between each check of the resource against the trigger condition.

Attribute	Description
units	Specifies the time units for the poll interval. Valid values are: <ul style="list-style-type: none"> • seconds • minutes • hours • days • weeks • months • years

<batch>

The maximum number of trigger matches to include in a single batch.

Attribute	Description
maxSize	The maximum number of trigger matches to include in a single batch

The following XML shows an example of a retained publication which is published to the topic string SYSTEM.FTE/monitors/*agent_name*/MONITORTWO when the monitor called MONITORTWO is created on AGENT_JUPITER. The escaped XML within the <taskXML> element describes the task that is submitted when the monitor condition is met.

MFT schedule list message format

The XML message that is published to a retained publication to the topic string `SYSTEM.FTE/Scheduler/agent_name` conforms to the `ScheduleList.xsd` schema. This XML message lists all active schedules belonging to that agent. This information is used by the `fteListScheduledTransfers` command and the IBM MQ Explorer to display a list of schedules to the user. The `ScheduleList.xsd` schema document is located in the `MQ_INSTALLATION_PATH/mqft/samples/schema` directory. The `ScheduleList.xsd` schema imports `FileTransfer.xsd`, which is in the same directory.

Schema

The following schema describes which elements are valid in a monitor list XML message.

```

<?xml version="1.0" encoding="UTF-8"?>
<xsd:schema xmlns:xsd="https://www.w3.org/2001/XMLSchema">

  <xsd:include schemaLocation="FileTransfer.xsd"/>

  <xsd:element name="schedules">
    <xsd:complexType>
      <xsd:sequence>
        <xsd:element name="managedTransfer" type="scheduledManagedTransferType" minOccurs="0" maxOccurs="unbounded"/>
      </xsd:sequence>
      <xsd:attribute name="version" type="versionType" use="required"/>
      <xsd:attribute name="size" type="xsd:nonNegativeInteger" use="required"/>
      <xsd:attribute name="agent" type="xsd:string" use="required"/>
    </xsd:complexType>
  </xsd:element>

  <xsd:complexType name="scheduledManagedTransferType">
    <xsd:sequence>
      <xsd:element name="originator" type="origRequestType" maxOccurs="1" minOccurs="1"/>
      <xsd:element name="schedule" type="scheduleListType" maxOccurs="1" minOccurs="0"/>
      <xsd:element name="sourceAgent" type="agentType" maxOccurs="1" minOccurs="1"/>
      <xsd:element name="destinationAgent" type="agentClientType" maxOccurs="1" minOccurs="1"/>
      <xsd:element name="trigger" type="triggerType" maxOccurs="1" minOccurs="0"/>
      <xsd:element name="reply" type="replyType" maxOccurs="1" minOccurs="0"/>
      <xsd:element name="transferSet" type="transferSetType" maxOccurs="1" minOccurs="1"/>
      <xsd:element name="job" type="jobType" maxOccurs="1" minOccurs="0"/>
    </xsd:sequence>
    <xsd:attribute name="id" type="idType" use="required"/>
  </xsd:complexType>

  <xsd:complexType name="scheduleListType">
    <xsd:sequence>
      <xsd:element name="submit" type="submitType" maxOccurs="1" minOccurs="1"/>
      <xsd:element name="repeat" type="repeatType" maxOccurs="1" minOccurs="0"/>
      <xsd:element name="next" type="noZoneTimeType" maxOccurs="1" minOccurs="1"/>
    </xsd:sequence>
  </xsd:complexType>
</xsd:schema>

```

Understanding the schedule list message

The elements and attributes used in the schedule list messages are described in the following list:

<schedules>

Group element containing information about all of the schedules defined on a single agent.

Attribute	Description
agent	Required. The name of the source agent that the schedule is defined on.
size	Required. The number of schedules defined on this agent.
version	Required. The version of the schedule list message format.

<managedTransfer>

Group element containing information about a single schedule.

Attribute	Description
id	Required. The hexadecimal string ID of the schedule request message.

<originator>

The originator of the schedule request.

<hostName>

The host name of the machine that the schedule request was submitted from.

<userID>

The user ID of the user that submitted the schedule request.

<mqmdUserID>

The MQMD user ID of the user that submitted the schedule request.

<schedule>

Element that contains the elements that describe when the scheduled transfer occurs.

<submit>

Specifies the date and time that the scheduled transfer is due to start.

Attribute	Description
timebase	Specifies which time zone to use. The value of this attribute can be one of the following values: <ul style="list-style-type: none"> • source - use the time zone of the source agent • admin - use the time zone of the administrator issuing the command • UTC - use Coordinated Universal Time
timezone	The time zone description according to the timebase value

<repeat>

Group element that contains details about how often a scheduled transfer repeats, how many times a scheduled transfer repeats, and when a scheduled transfer stops repeating.

Attribute	Description
interval	The interval units, which must be one of the following values: <ul style="list-style-type: none"> • minutes • hours • days • weeks • months • years

<frequency>

The time period that must elapse before the transfer repeats.

Attribute	Description
interval	The interval units, which must be one of the following values: <ul style="list-style-type: none"> • minutes • hours

Attribute	Description
	<ul style="list-style-type: none"> • days • weeks • months • years

<expireTime>

Optional element that specifies the date and time that a repeating scheduled transfer stops. This element and the <expireCount> element are mutually exclusive.

<expireCount>

Optional element that specifies the number of times the scheduled file transfer occurs before stopping. This element and the <expireTime> element are mutually exclusive.

<next>

Specifies the date and time when the next scheduled transfer is due to start.

<sourceAgent>

Specifies the name of the agent on the system where the source file is located.

Attribute	Description
agent	Specifies the name of the agent.
QMgr	The name of the agent queue manager.

<destinationAgent>

Specifies the name of the agent on the system you want to transfer the file to.

Attribute	Description
agent	Specifies the name of the agent.
QMgr	The name of the agent queue manager.

<trigger>

Optional element that specifies a condition that must be true for the file transfer to take place.

Attribute	Description
log	A flag indicating whether trigger failures are logged. The following are valid values: <ul style="list-style-type: none"> • yes - log entries are created for failed triggered transfers • no - log entries are not created for failed triggered transfers

<reply>

Specifies the name of the temporary reply queue generated for synchronous file transfers (specified with the **-w** parameter on the command line). The name of the queue is defined by the key **dynamicQueuePrefix** in the `command.properties` configuration file or the default of `WMQFTE.*` if not specified.

Attribute	Description
QMGR	The name of the command queue manager on which the temporary dynamic queue is generated to receive replies.

<transferSet>

Specifies a group of file transfers you want the scheduled transfer to perform together. During transmission <transferSet> is a group element containing <item> elements.

Attribute	Description
priority	Priority level of the transfer. Priority is a value in the range 0-9, where 0 is the lowest priority. The default priority level is 0 and by default the transfer uses the priority level of the source agent.

<job>

Optional group element containing job information for the entire transfer specification. <job> is a user-defined job name identifier that is added to the log message when the transfer has started. This <job> element is the same as the <job> element that appears in the transfer log message, which is described in the following topic: [“File transfer log message formats”](#) on page 2664.

Example

```
<?xml version="1.0" encoding="UTF-8"?>
<schedules xmlns:xsi="https://www.w3.org/2001/XMLSchema-instance"
  size="2"
  version="4.00"
  agent="AGENT_JUPITER"
  xsi:noNamespaceSchemaLocation="ScheduleList.xsd">
  <managedTransfer id="1">
    <originator>
      <hostName>example.com.</hostName>
      <userID>mqm</userID>
    </originator>
    <schedule>
      <submit timebase="admin" timezone="Europe/London">2010-01-01T21:00+0000</
submit>
      <next>2010-01-01T21:00+0000</next>
    </schedule>
    <sourceAgent agent="AGENT_JUPITER" QMgr="QM_JUPITER"/>
    <destinationAgent agent="AGENT_SATURN" QMgr="QM_JUPITER"/>
    <reply QMgr="QM_JUPITER">WMQFTE.4D400F8B20004E06</reply>
    <transferSet>
      <item mode="binary" checksumMethod="MD5">
        <source recursive="false" disposition="leave">
          <file>/etc/passwd</file>
        </source>
        <destination type="directory" exist="overwrite">
          <file>/tmp</file>
        </destination>
      </item>
    </transferSet>
  </managedTransfer>
  <managedTransfer id="2">
    <originator>
      <hostName>example.com.</hostName>
      <userID>mqm</userID>
    </originator>
    <schedule>
      <submit timebase="admin" timezone="Europe/London">2010-12-31T09:00+0000</
submit>
      <next>2010-12-31T09:00+0000</next>
    </schedule>
    <sourceAgent agent="AGENT_JUPITER" QMgr="QM_JUPITER"/>
    <destinationAgent agent="AGENT_NEPTUNE" QMgr="QM_JUPITER"/>
    <reply QMgr="QM_JUPITER">WMQFTE.4D400F8B20004E09</reply>
    <transferSet>
      <item mode="binary" checksumMethod="MD5">
        <source recursive="false" disposition="leave">
          <file>/etc/passwd</file>
        </source>
        <destination type="directory" exist="overwrite">
          <file>/tmp</file>
        </destination>
      </item>
    </transferSet>
  </managedTransfer>
</schedules>
```

MFT example template XML message

When a template is created, a message is published to the SYSTEM.FTE topic with a topic string of `Templates/template_id`. This example XML describes a single template defined in your Managed File Transfer network.

```
<?xml version="1.0" encoding="UTF-8"?>
<transferTemplate version="4.00" id="baf9df73-45c2-4bb0-a085-292232ab66bc">
  <name>BASIC_TEMPLATE</name>
  <sourceAgentName>AGENT_JUPITER</sourceAgentName>
  <sourceAgentQMgr>QM_JUPITER</sourceAgentQMgr>
  <destinationAgentName>AGENT_SATURN</destinationAgentName>
  <destinationAgentQMgr>QM_JUPITER</destinationAgentQMgr>
  <fileSpecs>
    <item mode="binary" checksumMethod="MD5">
      <source recursive="false" disposition="leave">
        <file>/etc/passwd</file>
      </source>
      <destination type="directory" exist="overwrite">
        <file>/tmp</file>
      </destination>
    </item>
  </fileSpecs>
  <priority>0</priority>
</transferTemplate>
```

Related tasks

[Creating a file transfer template using IBM MQ Explorer](#)

Related reference

[“fteCreateTemplate \(create new file transfer template\)” on page 2064](#)

The **fteCreateTemplate** command creates a file transfer template that you can keep for future use. The only required parameter is the **-tn *template_name*** parameter. All other parameters are optional, although if you specify a source file specification, you must also provide a destination file. Similarly, if you specify a destination file, you must also specify a source file specification.

File transfer status message format

Messages are published to the coordination queue manager to indicate transfer status of each file in the transfer set. Every time a request for file transfer is processed by the agent, a transaction message is published to the coordination queue manager (on its `SYSTEM.FTE/Transfers/agent_name/transfer ID` topic), which conforms to the `TransferStatus.xsd` XML schema. The `TransferStatus.xsd` file is located in the `MQ_INSTALLATION_PATH/mqft/samples/schema` directory of your WMQMFT installation.

Schema

The following schema describes which elements are valid in a transfer status XML message.

```
<xsd:schema xmlns:xsd="https://www.w3.org/2001/XMLSchema">
  <xsd:include schemaLocation="fteutils.xsd"/>
  <xsd:element name="transaction">
    <xsd:complexType>
      <xsd:sequence>
        <xsd:element name="sourceAgent" type="agentType" maxOccurs="1" minOccurs="1"/>
        <xsd:element name="destinationAgent" type="agentType" maxOccurs="1" minOccurs="1"/>
        <xsd:element name="transferSet" type="transferSetType" maxOccurs="1" minOccurs="1"/>
      </xsd:sequence>
      <xsd:attribute name="version" type="versionType" use="required"/>
      <xsd:attribute name="ID" type="IDType" use="required"/>
    </xsd:complexType>
  </xsd:element>
  <xsd:complexType name="transferSetType">
```

```

<xsd:sequence>
  <xsd:element name="stats" type="statsType"
    maxOccurs="1" minOccurs="1" />
  <xsd:element name="current" type="currentType"
    maxOccurs="1" minOccurs="0" />
</xsd:sequence>
<xsd:attribute name="time" type="xsd:dateTime" use="required" />
</xsd:complexType>

<xsd:complexType name="currentType">
  <xsd:sequence>
    <xsd:element name="source" type="fileSourceType"
      maxOccurs="1" minOccurs="1" />
    <xsd:element name="destination" type="fileDestinationType"
      maxOccurs="1" minOccurs="1" />
  </xsd:sequence>
  <xsd:attribute name="transferred" type="xsd:nonNegativeInteger"
    use="required" />
  <xsd:attribute name="size" type="xsd:nonNegativeInteger" use="required" />
</xsd:complexType>

<xsd:complexType name="statsType">
  <xsd:attribute name="bytes" type="xsd:nonNegativeInteger"
    use="required" />
  <xsd:attribute name="seconds" type="xsd:decimal"
    use="required" />
  <xsd:attribute name="currentItem" type="xsd:nonNegativeInteger"
    use="required" />
  <xsd:attribute name="totalItems" type="xsd:nonNegativeInteger" use="required" />
</xsd:complexType>
</xsd:schema>

```

Understanding the transfer status message

The elements and attributes used in the transfer status messages are described in the following list:

<transaction>

Group element that contains all of the elements for the file transfers.

Attribute	Description
version	Specifies the version of this element as supplied by Managed File Transfer.
ID	The unique identifier for the file transfer.

<sourceAgent>

Specifies the name of the agent on the system where the source file is located.

Attribute	Description
agent	The name of the agent.
QMgr	The name of the agent queue manager.

<destinationAgent>

Specifies the name of the agent on the system you want to transfer the file to.

Attribute	Description
agent	The name of the agent.
QMgr	The name of the agent queue manager.

<transferset>

Specifies a group of file transfers being performed together. All of the files in the transfer must originate at the same source agent and end at the same destination agent.

Attribute	Description
time	Specifies the date and time (in date time format).

<stats>

Required. Defines metrics about the transfer, including the number of bytes copied so far, in the given number of seconds. Also supplies the current item number out of the total number of items in the <transferSet>.

Attribute	Description
bytes	Number of bytes copied so far.
seconds	Number of seconds taken to transfer those bytes.
currentItem	The index of the current item being transferred.
totalItems	The total number of items being transferred.

<current>

Optional element. Group element that contains elements that specify the file transfer currently in progress. The <current> element indicates how many bytes of data have been transferred so far for the current item and the expected total number of bytes

<source>

Group element that contains the element specifying the source file name.

<file>

Specifies the source path of the file that is being transferred. The path is as specified for the transfer. This path might differ from the path that is output as part of the transfer log, which is the absolute form the of path.

<destination>

Group element that contains the element specifying the destination file name or specification.

<file>

Specifies the destination path of the file that is being transferred. The path is as specified for the transfer. This path might differ from the path that is output as part of the transfer log, which is the absolute form the of path.

Attribute	Description
alias	Specifies an alias for the destination file. This alias is the name of the source file, excluding any directory path specified for the transfer.
filespace	Specifies the name of the file space where the destination file is written.

<queue>

When used with the <destination> element, specifies the name of the queue you want to transfer to. This name is in the format QUEUE or QUEUE@QUEUE_MANAGER.

Related reference

[“File transfer progress message examples” on page 2663](#)

When a transfer is in progress, messages are published to the SYSTEM.FTE topic with a topic string of *Transfers/agent_name/transfer_id*. The XML examples show the progress message for a single file transfer and for a multiple file transfer.

[“MFT agent status message format” on page 2648](#)

When a Managed File Transfer Agent is created or started, the agent publishes its details to the SYSTEM.FTE topic on its coordination queue manager (on the SYSTEM.FTE/Agents/*agent name* topic).

[“File transfer request message format” on page 2698](#)

File transfers are initiated by XML messages arriving at an agent command queue, typically as a result of a user issuing a file transfer command or by using the IBM MQ Explorer. The transfer request XML must

conform to the `FileTransfer.xsd` schema and have the `<request>` element as the root element. The `FileTransfer.xsd` schema document is located in the `MQ_INSTALLATION_PATH/mqft/samples/schema` directory. The `FileTransfer.xsd` schema imports `fteutils.xsd`, which is in the same directory.

“File transfer log message formats” on page 2664

File transfer log messages are published to the `SYSTEM.FTE` topic with a topic string of `Log/agent_name/transfer_id`. These messages conform to the schema `TransferLog.xsd`, which is located in the `MQ_INSTALLATION_PATH/mqft/samples/schema` directory of your Managed File Transfer installation.

“Scheduled file transfer log message formats” on page 2686

Every time a request for a scheduled file transfer is processed by the agent, a schedule log message is published to the coordination queue manager (on its `SYSTEM.FTE/Log/agent_name/schedule ID` topic). This message conforms to the `ScheduleLog.xsd` XML schema.

“MFT monitor request message formats” on page 2715

Resource monitors are created when a suitable XML message arrives at an agent's command queue, typically as a result of a user issuing the `fteCreateMonitor` command or using the IBM MQ Explorer interface.

“MFT message formats for security” on page 2728

This topic describes the messages published to the Managed File Transfer coordination queue manager relevant to security.

File transfer progress message examples

When a transfer is in progress, messages are published to the `SYSTEM.FTE` topic with a topic string of `Transfers/agent_name/transfer_id`. The XML examples show the progress message for a single file transfer and for a multiple file transfer.

Single file transfer

The following example shows the details of a single file transfer that is in progress.

```
<?xml version="1.0" encoding="UTF-8"?>
<transaction xmlns:xsi="https://www.w3.org/2001/XMLSchema-instance"
  version="4.00"
  ID="414d51205553322e42494e44494e47538b0f404d223d0020"
  xsi:noNamespaceSchemaLocation="TransferStatus.xsd">
  <sourceAgent agent="US2.BINDINGS.FILE" QMgr="US2.BINDINGS"/>
  <destinationAgent agent="US2.BINDINGS.FILE" QMgr="US2.BINDINGS"/>
  <transferSet time="2011-01-26T13:03:26.542Z">
  <stats bytes="1198" seconds="0.018" currentItem="1" totalItems="1"/>
  <current transferred="1151" size="1151">
    <source>
      <file>/etc/passwd</file>
    </source>
    <destination>
      <file>/tmp/passwd</file>
    </destination>
  </current>
</transferSet>
</transaction>
```

Multiple file transfer

If there were more files in the transfer set, the transfer status message indicates which one is being processed and how many bytes have been transferred so far.

```
<?xml version="1.0" encoding="UTF-8"?>
<transaction xmlns:xsi="https://www.w3.org/2001/XMLSchema-instance"
  version="4.00"
  ID="414d51205553322e42494e44494e47538b0f404d035c0020"
  xsi:noNamespaceSchemaLocation="TransferStatus.xsd">
  <sourceAgent agent="US2.BINDINGS.FILE" QMgr="US2.BINDINGS"/>
  <destinationAgent agent="US2.BINDINGS.FILE" QMgr="US2.BINDINGS"/>
  <transferSet time="2011-01-26T13:12:58.636Z">
    <stats bytes="440" seconds="0.082" currentItem="10" totalItems="10"/>
  </transferSet>
</transaction>
```

```

    <current transferred="0" size="0">
      <source>
        <file>/srv/nfs/incoming/file10.txt</file>
      </source>
      <destination>
        <file>/srv/nfs/outgoing/file10.txt</file>
      </destination>
    </current>
  </transferSet>
</transaction>

```

File transfer log message formats

File transfer log messages are published to the SYSTEM.FTE topic with a topic string of `Log/agent_name/transfer_id`. These messages conform to the schema `TransferLog.xsd`, which is located in the `MQ_INSTALLATION_PATH/mqft/samples/schema` directory of your Managed File Transfer installation.

If you want to monitor file transfers or collect data about them, set up a subscription to a wildcard topic tailored to the transfers you are interested in. For example:

```
Log/#
```

or,

```
Log/FTEAGENT/#
```

This subscription can be durable or non-durable. Durable subscriptions continue to exist when a subscribing application's connection to the queue manager is closed. Non-durable subscriptions exist only as long as a subscribing application's connection to the queue manager remains open.

Schema

The following schema describes which elements are valid in a transfer log XML message.

```

<xsd:schema xmlns:xsd="https://www.w3.org/2001/XMLSchema">
  <xsd:include schemaLocation="fteutils.xsd"/>
  <xsd:element name="transaction">
    <xsd:complexType>
      <xsd:sequence>
        <xsd:element name="action" type="actionType" maxOccurs="1" minOccurs="0"/>
        <xsd:element name="sourceAgent" type="agentExitStatusType" maxOccurs="1" minOccurs="0"/>
        <xsd:element name="sourceWebGateway" type="webGatewayType" maxOccurs="1" minOccurs="0"/>
        <xsd:element name="sourceWebUser" type="webUserType" maxOccurs="1" minOccurs="0"/>
        <xsd:element name="destinationAgent" type="agentExitStatusType" maxOccurs="1" minOccurs="0"/>
        <xsd:element name="destinationWebGateway" type="webGatewayType" maxOccurs="1" minOccurs="0"/>
        <xsd:element name="destinationWebUser" type="webUserType" maxOccurs="1" minOccurs="0"/>
        <xsd:element name="agent" type="agentExitStatusType" maxOccurs="1" minOccurs="0"/>
        <xsd:element name="originator" type="origRequestType" maxOccurs="1" minOccurs="1"/>
        <xsd:element name="status" type="statusType" maxOccurs="1" minOccurs="0"/>
        <xsd:element name="trigger" type="triggerType" maxOccurs="1" minOccurs="0"/>
        <xsd:element name="transferSet" type="transferSetType" maxOccurs="1" minOccurs="1"/>
        <xsd:element name="job" type="jobType" maxOccurs="1" minOccurs="0"/>
        <xsd:element name="scheduleLog" type="scheduleLogType" maxOccurs="1" minOccurs="0"/>
        <xsd:element name="statistics" type="statisticsType"

```

```

        maxOccurs="1"                minOccurs="0" />

Note: From IBM MQ 9.0, Managed File Transfer does not support the Web Gateway or web agents.

Understanding the transfer log message

<transaction>

Group element that specifies a group of transfers you want to perform together.

Attribute	Description
version	Specifies the version of this element as detailed by Managed File Transfer.
ID	Specifies the unique transaction ID. The ID can be a maximum of 48 alphanumeric characters.
relatedID	Optional. If the transaction is the delete or download of a file from a file space, relatedID specifies the transaction ID of the transfer that uploaded the file to the file space.
agentRole	Optional. Specifies whether the agent concerned is on the source or destination system
xmlns:xsi	Namespace declaration. Indicates that the elements and data types used in this schema derive from the "https://www.w3.org/2001/XMLSchema-instance" namespace.
xsi:noNamespaceSchemaLocation	Specifies the name and location of the XML schema document to validate this message against if there is no namespace declaration. The value you specify for this attribute must refer to a Managed File Transfer TransferLog.xsd document.

<action>

Describes the status of the file transfer at the time logged by the time attribute. The status can be one of the following values:

- started
- progress
- completed
- cancelled
- malformed (indicates the file transfer request message content can not be interpreted.)
- notAuthorized
- deleted

Attribute	Description
time	The time that the transfer status was captured, expressed in UTC format.

<sourceAgent>

Specifies the name of the agent on the system where the source file is located. Only <sourceAgent> or <sourceWebUser> can be specified.

<startExits>

Group element that contains one or more user exit elements. This element can occur once only.

<endExits>

Group element that contains one or more user exit elements. This element can occur once only.

<systemInfo>

Describes the system architecture, name, and version. This element can occur once only.

Attribute	Description
agent	The name of the agent on the source system.
QMgr	The name of the queue manager on the source system.
agentType	The type of the agent. Valid values are: <ul style="list-style-type: none"> • STANDARD - a normal agent • BRIDGE - a protocol bridge agent • CD_BRIDGE - a Connect:Direct bridge agent • EMBEDDED - an embedded agent • SFG - a Sterling File Gateway embedded agent
bridgeURL	Optional. If the agent is a protocol bridge agent, the host name of the system hosting the protocol server.
pnode	Optional. If the agent is a Connect:Direct bridge agent, the name of the Connect:Direct primary node involved in the transfer.
snode	Optional. If the agent is a Connect:Direct bridge agent, the name of the Connect:Direct secondary node involved in the transfer.
bridgeNode	Optional. If the agent is a Connect:Direct bridge agent, the name of the Connect:Direct node that is part of the Connect:Direct bridge. This is the same node as either the primary node or the secondary node.

<destinationAgent>

Specifies the name of the agent on the system the file was transferred to. Either <destinationAgent> or <destinationWebUser> can be specified.

Attribute	Description
agent	The name of the agent on the destination system.
QMgr	The name of the queue manager on the destination system.
agentType	The type of the agent. Valid values are: <ul style="list-style-type: none"> • STANDARD - a normal agent • BRIDGE - a protocol bridge agent • CD_BRIDGE - a Connect:Direct bridge agent • EMBEDDED - an embedded agent • SFG - a Sterling File Gateway embedded agent
bridgeURL	Optional. If the agent is a protocol bridge agent, the host name of the system hosting the protocol server.
pnode	Optional. If the agent is a Connect:Direct bridge agent, the name of the Connect:Direct primary node involved in the transfer.
snode	Optional. If the agent is a Connect:Direct bridge agent, the name of the Connect:Direct secondary node involved in the transfer.
bridgeNode	Optional. If the agent is a Connect:Direct bridge agent, the name of the Connect:Direct node that is part of the Connect:Direct bridge. This is the same node as either the primary node or the secondary node.

<startExits>

Group element that contains one or more user exit elements. This element can occur once only.

<endExits>

Group element that contains one or more user exit elements. This element can occur once only.

<systemInfo>

Describes the system architecture, name, and version. This element can occur once only.

<originator>

Group element that contains the elements specifying the originator of the request.

<hostName>

The host name of the system where the source file is located.

<userID>

The user ID that originated the file transfer.

<mqmdUserID>

The IBM MQ user ID that was supplied in the message descriptor (MQMD)

<webUserID>

Optional. The user ID that was supplied to the web browser submitting the transfer request.

<webBrowser>

Optional. The web browser that the transfer request was submitted from.

<status>

The result code and supplement messages.

<trigger>

Group element that contains the trigger elements defined in the original transfer request. These elements can be either or both of the following:

<fileExist>

Trigger condition based on whether a file exists

<fileSize>

Trigger condition based on whether a file meets or exceeds the specified size

<transferSet>

Specifies a group of file transfers you want to perform together. During transmission <transferSet> is a group element containing <item> elements.

Attribute	Description
startTime	Records the time that the set of transfers started, expressed in UTC format.
total	Specifies the total number of items in this set of transfers.
index	Optional attribute. Specifies the position of the first item in progress of the transfer set. The index attribute increments from zero. For example, if the index is set to 1, the progress message is the second of two items.
size	Optional attribute. Specifies the number of items in the progress report.
priority	Optional attribute. Priority level of the transfer. Priority is a value in the range 0-9, where 0 is the lowest priority. The default priority level is 0 and by default the transfer uses the source agent priority level.

<metaDataSet>

Group element containing one or more of the following attributes:

<metaData>

Attribute	Description
key	The key half of a metadata key-value pair. The <metaData> element content contains the value half of the pair. For example <metaData key="testkey1">testvalue1</metaData>

<job>

Group element that contains an element specifying job details. <job> is a user-defined job name identifier that is added to the log message when the transfer has started. This <job> element is the same as the <job> element that is included in the transfer request message, which is described in the following topic: [“File transfer request message format” on page 2698.](#)

<name>

The value of name can be any string.

<scheduleLog>

Group element that contains elements specifying the source and destination file names and locations.

Attribute	Description
ID	Matches the schedule ID if the transfer is a scheduled transfer.

<item>

Group element that contains elements specifying the source and destination file names and locations.

<source>

Group element that contains the <file> element or the <queue> element, and the <checksum> element for the file on the source system.

Attribute	Description
recursive	Specifies that files are transferred recursively in subdirectories when the <source> element is a directory or contains wildcard characters.
disposition	Specifies the action that is taken on the <source> element when <source> has successfully been transferred to its destination. The valid options are as follows: <ul style="list-style-type: none"> • leave - the source files are left unchanged. • delete - the source files are deleted from the source system after the source file is successfully transferred.
correlationBoolean	A boolean correlation value. If the source is a Connect:Direct bridge, this specifies whether the Connect:Direct process is user-defined.
correlationString1	A string correlation value. If the source is a Connect:Direct bridge, this specifies the name of the Connect:Direct process that occurs at the destination of the transfer.
correlationNum1	A numeric correlation value. If the source is a Connect:Direct bridge, this specifies the ID number of the Connect:Direct process that occurs at the destination of the transfer.

<queue>

When used with the <source> element, specifies the name of the queue that the transferred messages were read from, which is located on the source agent queue manager.

Attribute	Description
messageCount	The number of messages that were read from the queue.

Attribute	Description
groupId	The IBM MQ group ID of the messages read from the queue.

<destination>

Group element that contains the <file> element or the <queue> element, and <checksum> element for the destination.

Only one of <file> and <queue> is present as a child element of destination.

Attribute	Description
type	<p>The type of destination. The valid options are as follows:</p> <ul style="list-style-type: none"> • queue - specifies an IBM MQ queue as the destination • file - specifies a file as the destination • directory - specifies a directory as the destination • z/OS dataset - specifies a z/OS data set as the destination • z/OS pds - specifies a z/OS partitioned data set as the destination <p>The option queue can be present only when the <destination> element has a child element of <queue>. The other options can be present only when the <destination> element has a child element of <file>.</p>
exist	<p>Specifies the action that is taken if a destination file exists on the destination system. The valid options are as follows:</p> <ul style="list-style-type: none"> • error - reports an error and the file is not transferred. • overwrite - overwrites the existing destination file. <p>This attribute cannot be present if the <destination> element has a child element of <queue>.</p>
correlationBoolean	A boolean correlation value. If the destination is a Connect:Direct bridge, this specifies whether the Connect:Direct process is user-defined.
correlationString1	A string correlation value. If the destination is a Connect:Direct bridge, this specifies the name of the Connect:Direct process that occurs at the destination of the transfer.
correlationNum1	A numeric correlation value. If the destination is a Connect:Direct bridge, this specifies the ID number of the Connect:Direct process that occurs at the destination of the transfer.

<file>

Specifies the absolute path of the file that was transferred (both at the source and destination). The fully-qualified path is in the format consistent with your operating system, for example C:/from/here.txt. File URIs are not used.

<queue>

When used with the <destination> element, specifies the name of the queue that was transferred to, which is located on any queue manager that is connected to the destination agent queue manager.

Attribute	Description
messageCount	The number of messages that were written to the queue.
messageLength	The length of the messages written to the queue.

Attribute	Description
groupId	If the transfer request specified that the file is split into multiple messages, the value of this attribute is the IBM MQ group ID of the messages written to the queue.
messageId	If the transfer request did not specify that the file is split into multiple messages, the value of this attribute is the IBM MQ message ID of the message written to the queue.

<checksum>

Optional element.

Specifies the type of hash algorithm that generated the message digest to create the digital signature. Currently Managed File Transfer supports Message Digest algorithm 5 (MD5) only. The checksum provides a way for you to confirm the integrity of transferred files is intact.

<malformed>

Group element for malformed messages.

Attribute	Description
version	
ID	
agentRole	Either source agent or destination agent

<statistics>

Group element for statistical information for the transfer (when available).

<actualStartTime>

The actual time that the agent started running the transfer. Typically, the time is the same as (or very close to) the start time recorded for the transfer. However, when an agent is busy submitted transfers might be queued until the agent has capacity to run the transfers.

<retryCount>

The number of times that the transfer went into the recovery state and was retried by the agent. A transfer can go into a recovery state because the source and destination agents lose communication, either because of an IBM MQ network error or because they are not receiving data or acknowledgment messages for a period. This period is determined by the agent properties: transferAckTimeout and transferAckTimeoutRetries.

<numFileFailures>

The number of files in the transferSet that failed to transfer successfully.

<numFileWarnings>

The number of files in the transferSet that generated warnings while being transferred, but otherwise transferred successfully.

Examples

Examples of XML messages that conform to this schema are provided for each of the following types of transfer:

- [A transfer of a single file](#)
- [A transfer that contains multiple files](#)
- [A failed file transfer](#)
- [A transfer defined with a trigger](#)
- [A transfer started by a schedule](#)
- [A transfer that calls user exits](#)
- [A transfer through a Connect:Direct bridge node](#)

[“Single transfer log message examples” on page 2673](#)

When a transfer occurs, messages are published to the SYSTEM.FTE topic with a topic string of `Log/agent_name/transfer_id`. The XML examples show the log messages for a single file transfer being started, in progress, and completed.

[“Multiple file transfer log message examples” on page 2675](#)

Examples of the messages that are published to the SYSTEM.FTE topic with a topic string of `Log/agent_name/transfer_id` when a transfer that contains multiple files occurs.

[“Failed file transfer log message examples” on page 2677](#)

When a transfer occurs, messages are published to the SYSTEM.FTE topic with a topic string of `Log/agent_name/transfer_id`. The XML examples show the log messages for a file transfer that fails being started, in progress, and completed.

[“Triggered file transfer log message example” on page 2679](#)

When a transfer is in progress, messages are published to the SYSTEM.FTE topic with a topic string of `Log/agent_name/transfer_id`. The XML example shows the log message that is created when a file transfer containing a trigger condition is started.

[“MFT user exit log message examples” on page 2681](#)

When a transfer is in progress, messages are published to the SYSTEM.FTE topic with a topic string of `Log/agent_name/transfer_id`. The XML examples show the log messages that are created when a file transfer occurs that contains calls to user exits.

[“Connect:Direct bridge transfer log message examples” on page 2683](#)

The `destinationAgent` or `sourceAgent` element contains additional attributes when the destination agent or source agent is a Connect:Direct bridge agent. The Started log message contains only a subset of the information about the Connect:Direct transfer. The Progress and Completed log messages contain full information about the Connect:Direct transfer.

Single transfer log message examples

When a transfer occurs, messages are published to the SYSTEM.FTE topic with a topic string of `Log/agent_name/transfer_id`. The XML examples show the log messages for a single file transfer being started, in progress, and completed.

Related reference

[“Single transfer log message examples” on page 2673](#)

When a transfer occurs, messages are published to the SYSTEM.FTE topic with a topic string of `Log/agent_name/transfer_id`. The XML examples show the log messages for a single file transfer being started, in progress, and completed.

[“MFT user exit log message examples” on page 2681](#)

When a transfer is in progress, messages are published to the SYSTEM.FTE topic with a topic string of `Log/agent_name/transfer_id`. The XML examples show the log messages that are created when a file transfer occurs that contains calls to user exits.

[“File transfer log message formats” on page 2664](#)

File transfer log messages are published to the SYSTEM.FTE topic with a topic string of `Log/agent_name/transfer_id`. These messages conform to the schema `TransferLog.xsd`, which is located in the `MQ_INSTALLATION_PATH/mqft/samples/schema` directory of your Managed File Transfer installation.

Scheduled file transfer log message examples

When a transfer is in progress, messages are published to the SYSTEM.FTE topic with a topic string of `Log/agent_name/transfer_id`. The XML examples show the log messages that are created when a file transfer occurs as a result of a schedule.

Schedule transfer transaction messages

When the file transfer is started as a result of the schedule entry expiring, the file transfer follows the usual sequence of publishing transaction messages on the `SYSTEM.FTE/Log/agent_name` topic for:

- Action started (`TransferLog.xsd`)
- Action progress (`TransferLog.xsd`)
- Action completed (`TransferLog.xsd`)

Only the log transaction message with the action of started contains the ID of the scheduled transfer, in the ID attribute of the `<scheduleLog>` element. This allows the schedule ID to be tied to the transfer ID throughout the lifecycle of the entire transfer.

Started:

```
<?xml version="1.0" encoding="UTF-8"?>

Related reference

[“Single transfer log message examples” on page 2673](#)

When a transfer occurs, messages are published to the SYSTEM.FTE topic with a topic string of `Log/agent_name/transfer_id`. The XML examples show the log messages for a single file transfer being started, in progress, and completed.

[“Triggered file transfer log message example” on page 2679](#)

When a transfer is in progress, messages are published to the SYSTEM.FTE topic with a topic string of `Log/agent_name/transfer_id`. The XML example shows the log message that is created when a file transfer containing a trigger condition is started.

[“File transfer log message formats” on page 2664](#)

File transfer log messages are published to the SYSTEM.FTE topic with a topic string of `Log/agent_name/transfer_id`. These messages conform to the schema `TransferLog.xsd`, which is located in the `MQ_INSTALLATION_PATH/mqft/samples/schema` directory of your Managed File Transfer installation.

Connect:Direct bridge transfer log message examples

The `destinationAgent` or `sourceAgent` element contains additional attributes when the destination agent or source agent is a Connect:Direct bridge agent. The Started log message contains only a subset of the information about the Connect:Direct transfer. The Progress and Completed log messages contain full information about the Connect:Direct transfer.

Source agent is Connect:Direct bridge agent

Scheduled file transfer log message formats

Every time a request for a scheduled file transfer is processed by the agent, a schedule log message is published to the coordination queue manager (on its `SYSTEM.FTE/Log/agent name/schedule ID` topic). This message conforms to the `ScheduleLog.xsd` XML schema.

Schema

The following schema describes which elements are valid in a schedule log XML message.

```
<xsd:schema xmlns:xsd="https://www.w3.org/2001/XMLSchema">
  <xsd:include schemaLocation="fteutils.xsd"/>

  <xsd:element name="schedulelog">
    <xsd:complexType>
      <xsd:sequence>
        <xsd:element name="originator" type="hostUserIDType"
          maxOccurs="1" minOccurs="0"/>
        <xsd:element name="action" type="actionType"
          maxOccurs="1" minOccurs="1"/>
        <xsd:element name="schedule" type="scheduleType"
          maxOccurs="1" minOccurs="0"/>
        <xsd:element name="sourceAgent" type="agentType"
          maxOccurs="1" minOccurs="0"/>
        <xsd:element name="destinationAgent" type="agentClientType"
          maxOccurs="1" minOccurs="0"/>
        <xsd:element name="status" type="statusType"
          maxOccurs="1" minOccurs="0"/>
        <xsd:element name="transferSet" type="transferSetType"
          maxOccurs="1" minOccurs="0"/>
      </xsd:sequence>
    </xsd:complexType>
  </xsd:element>
</xsd:schema>
```

```

        <xsd:element name="job"
                    type="jobType"
                    maxOccurs="1"
                    minOccurs="0" />
    </xsd:sequence>
    <xsd:attribute name="version" type="versionType" use="required" />
    <xsd:attribute name="ID" type="xsd:string" use="required" />
</xsd:complexType>
</xsd:element>

<xsd:complexType name="actionType">
  <xsd:simpleContent>
    <xsd:extension base="actionEnumType">
      <xsd:attribute name="time" type="xsd:dateTime" use="required" />
    </xsd:extension>
  </xsd:simpleContent>
</xsd:complexType>

</xsd:schema>

```

Understanding the schedule log message

The elements and attributes used in the schedule log message are described:

<schedulelog>

Group element that describes a single submitted scheduled file transfer.

Attribute	Description
version	Specifies the version of this element as detailed by Managed File Transfer.
ID	The unique identifier for the submitted schedule file transfer.

<originator>

Group element that contains the elements specifying the originator of the request.

<hostName>

The host name of the system where the source file is located.

<userID>

The user ID that originated the file transfer.

<mqmdUserID>

The MQ user ID that was supplied in the message descriptor (MQMD)

<action>

Specifies the action to take with the scheduled transfer matching the ID attribute of <schedulelog> element. This element must be one of the following values:

- submit - new scheduled transfer
- delete - cancel schedule transfer
- expire - schedule transfer entry about to be processed
- skipped - a transfer that was scheduled cannot be started because the agent is offline. This message is logged when the agent becomes available to indicate the transfer was skipped.

Attribute	Description
time	Specifies the date and time the log entry was published (in date time format).

<sourceAgent>

Specifies the name of the agent on the system where the source file is located.

Attribute	Description
agent	Specifies the name of the agent.
QMgr	The name of the agent queue manager.

<destinationAgent>

Specifies the name of the agent on the system you want to transfer the file to.

Attribute	Description
agent	Specifies the name of the agent.
QMgr	The name of the agent queue manager.

<status>

The result code and supplement messages.

<transferSet>

Specifies a group of file transfers you want to perform together. During transmission <transferSet> is a group element containing <item> elements.

Attribute	Description
size	Specifies the number of transfer items.
priority	Priority level of the transfer. Priority is a value in the range 0-9, where 0 is the lowest priority. The default priority level is 0 and by default the transfer uses the priority level of the source agent.

<item>

Group element that contains elements specifying the source and destination file names and locations.

Attribute	Description
mode	Specifies the transfer mode as being either binary or text.
checksumMethod	Specifies the type of hash algorithm that generates the message digest to create the digital signature. Permitted values are MD5 or none

<source>

Group element that contains the <file> and <checksum> elements for the file on the source system.

Attribute	Description
recursive	Specifies that files are transferred recursively in subdirectories when the <source> element is a directory or contains wildcard characters.
disposition	Specifies the action that is taken on the <source> element when <source> has successfully been transferred to its destination. The valid options are as follows: <ul style="list-style-type: none"> • leave - the source files are left unchanged. • delete - the source files are deleted from the source system after the source file is successfully transferred.

<destination>

Group element that contains the <file> and <checksum> elements for the file on the destination system.

Attribute	Description
type	The type of file or directory at the destination. The valid options are as follows: <ul style="list-style-type: none"> • file - specifies a file as the destination • directory - specifies a directory as the destination •  z/OS dataset - specifies a z/OS data set as the destination •  z/OS PDS - specifies a z/OS partitioned data set as the destination
exist	Specifies the action that is taken if a destination file exists on the destination system. The valid options are as follows: <ul style="list-style-type: none"> • error - reports an error and the file is not transferred. • overwrite - overwrites the existing destination file.

<file>

Specifies the name of the file to transfer. Use the fully qualified path in the format consistent with your operating system, for example C : / from / here . txt. Do not use file URIs.

Attribute	Description
encoding	The encoding for a text file transfer.
EOL	Specifies the end of line marker. Permitted values are: <ul style="list-style-type: none"> • LF - line feed character only • CRLF - carriage return and line feed character sequence

<job>

Group element that contains an element specifying job details. <job> is a user-defined job name identifier that is added to the log message when the transfer has started. This <job> element is the same as the <job> element that is included in the transfer request message, which is described in the following topic: [“File transfer request message format” on page 2698.](#)

<name>

The value of name can be any string.

Examples

Examples of XML messages that conform to this schema are provided for each of the following scheduled transfer actions:

- [A scheduled transfer is created](#)

- [A scheduled transfer is canceled](#)
- [A schedule transfer expires](#)

Transfers that are started by a schedule are logged in the same way as a standard transfer. For examples of log messages for transfers started by a schedule, see [“Scheduled file transfer log message examples”](#) on page 2680.

Related reference

[“MFT agent status message format”](#) on page 2648

When a Managed File Transfer Agent is created or started, the agent publishes its details to the SYSTEM.FTE topic on its coordination queue manager (on the SYSTEM.FTE/Agents/*agent name* topic).

[“File transfer request message format”](#) on page 2698

File transfers are initiated by XML messages arriving at an agent command queue, typically as a result of a user issuing a file transfer command or by using the IBM MQ Explorer. The transfer request XML must conform to the FileTransfer.xsd schema and have the <request> element as the root element. The FileTransfer.xsd schema document is located in the MQ_INSTALLATION_PATH/mqft/samples/schema directory. The FileTransfer.xsd schema imports fteutils.xsd, which is in the same directory.

[“File transfer status message format”](#) on page 2660

Messages are published to the coordination queue manager to indicate transfer status of each file in the transfer set. Every time a request for file transfer is processed by the agent, a transaction message is published to the coordination queue manager (on its SYSTEM.FTE/Transfers/*agent_name/transfer ID* topic), which conforms to the TransferStatus.xsd XML schema. The TransferStatus.xsd file is located in the MQ_INSTALLATION_PATH/mqft/samples/schema directory of your WMQMFT installation.

[“File transfer log message formats”](#) on page 2664

File transfer log messages are published to the SYSTEM.FTE topic with a topic string of Log/*agent_name/transfer_id*. These messages conform to the schema TransferLog.xsd, which is located in the MQ_INSTALLATION_PATH/mqft/samples/schema directory of your Managed File Transfer installation.

[“MFT monitor request message formats”](#) on page 2715

Resource monitors are created when a suitable XML message arrives at an agent's command queue, typically as a result of a user issuing the **fteCreateMonitor** command or using the IBM MQ Explorer interface.

[“MFT message formats for security”](#) on page 2728

This topic describes the messages published to the Managed File Transfer coordination queue manager relevant to security.

Schedule file transfer log message examples

Examples of the messages that are published to the SYSTEM.FTE topic with a topic string of Log/*agent_name/schedule_id* when a scheduled transfer action occurs.

Scheduled transfer log message

Every time a request for a scheduled file transfer is processed by the agent, a schedule log message is published to the coordination queue manager (on its SYSTEM.FTE/Log/*agent_name/schedule ID* topic). This message conforms to the ScheduleLog.xsd XML schema. For example:

```
<?xml version="1.0" encoding="UTF-8"?>
<schedulelog version="1.00" ID="5"
  xmlns:xsi="https://www.w3.org/2001/XMLSchema-instance"
  xsi:noNamespaceSchemaLocation="ScheduleLog.xsd">
  <originator>
    <hostName>reportserver.com</hostName>
    <userID>USER1</userID>
  </originator>
  <action time="2008-11-23T21:32:01Z">submit</action>
  <schedule>
    <submit timebase="admin" timezone="Europe/London">2008-11-23T22:00</submit>
  </schedule>
</schedulelog>
```

```

<sourceAgent agent="FTEAGENT" QMgr="QM1" />
<destinationAgent agent="FTEAGENT" QMgr="QM1" />
<status resultCode="0" />
<transferSet size="1" priority="0">
  <item mode="binary" checksumMethod="MD5">
    <source recursive="false" disposition="leave">
      <file>c:\sourcefiles\source1.doc</file>
    </source>
    <destination type="file" exist="overwrite">
      <file>c:\destinationfiles\dest1.doc</file>
    </destination>
  </item>
</transferSet>
</schedulelog>

```

This message is a log of the following information:

- Who originated the request
- When the request was submitted
- When the scheduled transfer starts
- The source and destination agent details
- The transfer specification

The ID attribute of the <schedulelog> element is a unique ID for this scheduled transfer (in the source agent). This ID is used to correlate schedule entries with the actual file transfers.

The <action> element value of submit confirms the request has been received.

Scheduled transfer cancel log message

When a request to cancel a pending scheduled file transfer is received by the agent, the following message is published to the SYSTEM.FTE/Log/agent_name topic:

```

<?xml version="1.0" encoding="UTF-8"?>
<schedulelog version="1.00" ID="5"
  xmlns:xsi="https://www.w3.org/2001/XMLSchema-instance"
  xsi:noNamespaceSchemaLocation="ScheduleLog.xsd">
  <originator>
    <hostName>reportserver.com</hostName>
    <userID>USER1</userID>
  </originator>
  <action time="2008-11-23T21:56:27Z">delete</action>
  <status resultCode="0" />
</schedulelog>

```

The ID attribute value corresponds to the ID of the pending transfer request ID in the schedules message.

Scheduled transfer expire log message

When the current time matches the time of the earliest pending file transfer in the schedule list (as indicated by the value of the <next> element), a schedule log message is published to indicate that the scheduled transfer entry has expired:

```

<?xml version="1.0" encoding="UTF-8"?>
<schedulelog xmlns:xsi="https://www.w3.org/2001/XMLSchema-instance"
  version="4.00" ID="3"
  xsi:noNamespaceSchemaLocation="ScheduleLog.xsd">
  <originator>
    <hostName>example.com.</hostName>
    <userID>mqm</userID>
    <mqmdUserID>mqm</mqmdUserID>
  </originator>
  <action time="2011-01-26T13:03:26Z">expire</action>
  <sourceAgent agent="AGENT_JUPITER" QMgr="QM_JUPITER"/>
  <status resultCode="0"/>
</schedulelog>

```

The <action> element value of "expire" confirms the schedule entry has now been removed from the schedule list and is being processed. A schedule message for the agent is published with the expired entry no longer present.

Related reference

[“Scheduled file transfer log message formats” on page 2686](#)

Every time a request for a scheduled file transfer is processed by the agent, a schedule log message is published to the coordination queue manager (on its SYSTEM.FTE/Log/agent_name/schedule ID topic). This message conforms to the ScheduleLog.xsd XML schema.

[“Scheduled file transfer log message examples” on page 2680](#)

When a transfer is in progress, messages are published to the SYSTEM.FTE topic with a topic string of Log/agent_name/transfer_id. The XML examples show the log messages that are created when a file transfer occurs as a result of a schedule.

MFT monitor log message format

Monitor log messages are published to the SYSTEM.FTE topic with a topic string of Log/agent_name/Monitors/monitor_name/monitor_id.

If you want to collect data or view monitor actions, set up a subscription to a wildcard topic tailored to the monitors that you are interested in. For example:

```
Log/#
```

or,

```
Log/agent_name/#
```

This subscription can be durable or non-durable. Durable subscriptions continue to exist when a subscribing application's connection to the queue manager is closed. Non-durable subscriptions exist only as long as a subscribing application's connection to the queue manager remains open.

The MonitorLog.xsd schema document is located in the MQ_INSTALLATION_PATH/mqft/samples/schema directory. The MonitorLog.xsd schema imports fteutils.xsd, which is in the same directory.

Schema

The following schema describes which elements are valid in a monitor log XML message.

```
<xsd:schema xmlns:xsd="https://www.w3.org/2001/XMLSchema">
  <xsd:include schemaLocation="fteutils.xsd"/>
  <xsd:element name="monitorLog">
    <xsd:complexType>

```

Understanding the monitor log message

The elements and attributes used in the monitor log messages are described in the following list:

<monitorLog>

Group element containing the elements describe an action that has been performed by a monitor.

Attribute	Description
version	Required. The version of the monitor list message format.

Attribute	Description
monitorName	Required. The name of the monitor. Unique for the agent that the monitor is defined on.
referenceId	The ID of the monitor action.

<originator>

Group element that contains the elements specifying the originator of the request.

<hostName>

The host name of the system where the source file is located.

<userID>

The user ID that originated the file transfer.

<mqmdUserID>

Optional. The IBM MQ user ID that was supplied in the message descriptor (MQMD).

<references>

References to the IDs of other messages associated with this monitor action.

<createRequest>

The message ID of the XML request message that was used to create the monitor.

<taskRequest>

The message ID of the XML request message that the monitor submits as a result of this action.

<action>

The action that occurred, which this log message is associated with. The value inside the element can be one of the following: create, delete, start, stop, triggerSatisfied, triggerNotSatisfied, or triggerFail.

<monitorAgent>

The agent that is monitoring the resource.

Attribute	Description
agent	Required. The name of the agent.
QMgr	Optional. The name of the queue manager that the agent connects to.
bridgeURL	Optional. If the agent is a protocol bridge agent, the URL of the protocol server.

<status>

The status of the resource monitor action being logged.

Attribute	Description
resultCode	Required. The integer result code from the action.

<supplement>

Additional information about the status of the resource monitor action being logged.

<monitorMetaData>

Group element that contains the <originalMetaData> and <updatedMetaData> elements.

<originalMetaData>

Element that contains one or more <metadata> elements that describe the metadata of the monitor before the action occurs.

<updatedMetaData>

Element that contains one or more <metadata> elements that describe the metadata of the monitor after the action occurs.

<metadata>

Defines a metadata key-value pair. The key is an attribute of the element; the value is the content of the element.

Attribute	Description
key	The key of the metadata.

<monitorExits>

Group element containing one or more <exit> elements.

<exits>

Element describing an exit run by the resource monitor.

Attribute	Description
name	Required. The name of the resource monitor exit.

<status>

The status of the resource monitor exit that is being logged.

Attribute	Description
resultCode	Required. The integer result code from the exit.

<supplement>

Additional information about the status of the resource monitor exit that is being logged.

<jobDetails>

Element containing a single <name> element.

<name>

The name of the job..

<taskXMLRequest>

Group element that contains the <originalRequest> and <updatedRequest> elements.

Attribute	Description
taskId	The ID of the task request message.

<originalRequest>

Element that contains the escaped XML request message for the task that the monitor performs.

<updatedRequest>

Element that contains the updated escaped XML request message for the task that the monitor performs.

<monitorXMLRequest>

The monitor XML request.

Attribute	Description
type	Required. The format of the monitor XML request data inside of the <monitorXMLRequest> element. The only valid value is escapedXML.

Examples

Examples of XML messages that conform to this schema are provided for each of the following monitor actions:

- [A monitor is created](#)
- [The condition of a monitor is satisfied when the monitor polls the resource](#)
- [The condition of a monitor is not satisfied when the monitor polls the resource](#)
- [A monitor is deleted](#)

```

File transfer request message format

File transfers are initiated by XML messages arriving at an agent command queue, typically as a result of a user issuing a file transfer command or by using the IBM MQ Explorer. The transfer request XML must conform to the `FileTransfer.xsd` schema and have the `<request>` element as the root element. The `FileTransfer.xsd` schema document is located in the `MQ_INSTALLATION_PATH/mqft/samples/schema` directory. The `FileTransfer.xsd` schema imports `fteutils.xsd`, which is in the same directory.

File transfer messages can have one of following three root elements:

- `<request>` - for new file transfer requests, managed call requests, or deleting scheduled transfers that are pending
- `<cancel>` - for canceling file transfers in progress
- `<transferSpecifications>` - for specifying multiple transfer file groups, used by the **fteCreateTransfer** command

For information about specifying multiple transfer groups by using the **transferSpecifications** element, see [Using transfer definition files](#).

Schema

The following schema describes which elements are valid in a transfer request XML message.

```

<xsd:schema xmlns:xsd="https://www.w3.org/2001/XMLSchema">
  <xsd:include schemaLocation="fteutils.xsd"/>
  <!--
    Defines the request of a managed transfer and version number
  <request version="1.00" ...
    <managedTransfer>
      ...
    </managedTransfer>
  </request>
  -->
  <xsd:element name="request">
    <xsd:complexType>
      <xsd:choice>
        <xsd:element name="managedTransfer" type="managedTransferType"/>
        <xsd:element name="deleteScheduledTransfer" type="deleteScheduledTransferType" />
        <xsd:element name="managedCall" type="managedCallType"/>
      </xsd:choice>
    </xsd:complexType>
  </xsd:element>

```

```

        <xsd:attribute name="version" type="versionType" use="required" />
    </xsd:complexType>
</xsd:element>

<!--
    Defines the cancel request of a managed transfer and version number
    <cancel version="1.00"
        xmlns:xsi="https://www.w3.org/2001/XMLSchema-instance"
        xsi:noNamespaceSchemaLocation="FileTransfer.xsd">
        <originator>
            <hostName>myMachine</hostName>
            <userID>myUserId</userID>
        </originator>      - Delete a scheduled transfer.

        <transfer>
            Transfer ID to Cancel
        </transfer>
    </cancel>
-->
<xsd:element name="cancel">

```

Understanding the transfer request message

The elements and attributes used in transfer request messages are described in the following list:

Element descriptions

<request>

Group element containing all the elements required to specify a file transfer request.

Attribute	Description
version	Specifies the version of this element as supplied by Managed File Transfer.

<managedTransfer>

Group element that contains all the elements required for a single file transfer or single group of file transfers.

<deleteScheduledTransfer>

Group element that contains originator and ID information to cancel a schedule transfer.

<managedCall>

Group element that contains all the elements required for a single managed call of a program or executable.

<ID>

Unique identifier that specifies the transfer request to delete from the list of pending scheduled transfers.

<originator>

Group element that contains the elements specifying the originator of the request.

<hostName>

The host name of the system where the source file is located.

<userID>

The user ID that originated the file transfer.

<mqmdUserID>

Optional. The IBM MQ user ID that was supplied in the message descriptor (MQMD).

<schedule>

Group element describing the scheduled time for the file transfer, the repeat behavior, and when the next occurrence is due.

<submit>

Specifies the date and time that the scheduled transfer is due to start.

Attribute	Description
timebase	Specifies which time zone to use. This attribute can have one of the following values: <ul style="list-style-type: none"> • source - use the time zone of the source agent • admin - use the time zone of the administrator issuing the command • UTC - use Coordinated Universal Time
timezone	The time zone description according to the timebase value

<repeat>

Group element that contains details about how often a scheduled transfer repeats, how many times a scheduled transfer repeats, and when a scheduled transfer stops repeating.

<frequency>

The time period that must elapse before the transfer repeats.

Attribute	Description
interval	The interval units, which must be one of the following values: <ul style="list-style-type: none"> • minutes • hours • days • weeks • months • years

<expireTime>

Optional element that specifies the date and time that a repeating scheduled transfer stops. This element and the <expireCount> element are mutually exclusive.

<expireCount>

Optional element that specifies the number of times the scheduled file transfer occurs before stopping. This element and the <expireTime> element are mutually exclusive.

<sourceAgent>

Specifies the name of the agent on the system where the source file is located.

Attribute	Description
agent	Specifies the name of the agent.
QMgr	The name of the agent queue manager.

<destinationAgent>

Specifies the name of the agent on the system you want to transfer the file to.

Attribute	Description
agent	Specifies the name of the agent.
QMgr	The name of the agent queue manager.

Attribute	Description
hostName	The host name or IP address of the agent queue manager.
portNumber	The port number used for client connections to the destination agent queue manager.
channel	The channel name used to connect to the destination agent queue manager.

<trigger>

Optional element that specifies a condition that must be true for the file transfer to take place.

Attribute	Description
log	A flag indicating whether trigger failures are logged. The valid values are as follows: <ul style="list-style-type: none"> • yes - log entries are created for failed triggered transfers • no - log entries are not created for failed triggered transfers

<fileExist>

Specifies a comma-separated list of file names located on the same system as the source agent. If a file in this name list satisfies the condition of the trigger, the transfer occurs. This element and the <fileSize> element are mutually exclusive.

Attribute	Description
comparison	Indicates how to evaluate source file names against the name list. The valid values are as follows: <ul style="list-style-type: none"> • = at least one file name in the name list must match • != a minimum of one of the files in the name list does not exist
value	Indicates the comparison type: <ul style="list-style-type: none"> • exist: file must exist

<fileSize>

Specifies a comma-separated list of file names located on the same system as the source agent. If a file in this name list satisfies the condition of the trigger, the transfer occurs. This element and the <fileExist> element are mutually exclusive.

Attribute	Description
comparison	Indicates how to evaluate source file names against the name list. The valid value is as follows: <ul style="list-style-type: none"> • >= one of the file names in the name list exists and has a minimum size as specified in the value attribute
value	File size specified as an integer value with units specified as one of the following: <ul style="list-style-type: none"> • B - bytes • KB - kilobytes • MB - megabytes • GB - gigabytes (the units value is not case-sensitive)

<reply>

Specifies the name of the temporary reply queue generated for synchronous file transfers (specified with the **-w** parameter on the command line). The name of the queue is defined by the key

dynamicQueuePrefix in the `command.properties` configuration file or the default of `WMQFTE.*` if not specified.

Attribute	Description
detailed	<p>Whether detailed transfer result information is required in the reply message. Multiple reply messages for each transfer can be generated. The valid values are as follows:</p> <ul style="list-style-type: none"> • true - detailed reply information is required. The format of the information is the same as that published to the transfer log in the progress messages, that is, the <code><transferSet></code> element. For more information, see “File transfer log message formats” on page 2664. Detailed reply information is present only when the transfer source agent has the <code>enableDetailedReplyMessages</code> property set to true. • false - detailed reply information is not required. <p>The default value is false.</p>
QMGR	The name of the command queue manager on which the temporary dynamic queue is generated to receive replies.
persistent	<p>Whether the message written to the reply queue is persistent. The valid values are as follows:</p> <ul style="list-style-type: none"> • true - the message is persistent • false - the message is not persistent • qdef - the persistence of the message is defined by the properties of the reply queue <p>The default value is false.</p>

<transferSet>

Specifies a group of file transfers you want to perform together or a group of managed calls that you want to perform together. During transmission `<transferSet>` is a group element containing `<item>` elements.

Attribute	Description
priority	Priority level of the transfer. Priority is a value in the range 0-9, where 0 is the lowest priority. The default priority level is 0 and by default the transfer uses the priority level of the source agent.

<metaDataSet>

Optional group element containing one or more metadata items.

<metaData>

Specifies the user-defined metadata that is passed to the exit points called by the agent. The element contains the metadata value as a string.

Attribute	Description
key	Metadata name as a string

<call>

Group element that contains `<command>` elements specifying the program or executable to call.

<command>

Specifies the program or executable to call. The command must be located on the agent command path. For more information, see [Advanced agent properties](#). This element can contain optional `<argument>` elements.

Attribute	Description
name	The name of the command.

Attribute	Description
successRC	The successful return code that this command returns. Default is 0.
retryCount	The number of times that the command is to be retried if it fails.
retryWait	The time, in seconds, to wait between retries of the command.
type	The type of program to be called. The valid values are antscript, jcl, or executable.

<argument>

Specifies an argument to pass to the command.

<item>

Group element that contains elements specifying the source and destination file names and locations.

Attribute	Description
mode	Specifies the transfer mode as either binary or text.
checksumMethod	Specifies the type of hash algorithm that generates the message digest to create the digital signature. The valid values are MD5 or none.

<source>

Group element that specifies files on the source system and whether they are removed after the transfer completes

Attribute	Description
recursive	Specifies that files are transferred recursively in subdirectories when the <source> element is a directory or contains wildcard characters.
disposition	Specifies the action that is taken on the <source> element when <source> has successfully been transferred to its destination. The valid values are as follows: <ul style="list-style-type: none"> • leave - the source files are left unchanged. • delete - the source files are deleted from the source system after the source file is successfully transferred.

<file>

Specifies the transfer source.  For Multiplatforms, the transfer source can be a file or a directory name. For the z/OS platform, the transfer source can be a file, directory, data set, or PDS name. Use the fully qualified path in the format consistent with your operating system, for example C:/from/here.txt. Do not use file URIs.

Attribute	Description
alias	Specifies an alias for the source file. This alias is the name of the source file, excluding any directory path specified for the transfer.
EOL	Specifies the end of line marker for text transfers. Valid values are: <ul style="list-style-type: none"> • LF - line feed character only • CRLF - carriage return and line feed character sequence
encoding	The encoding of the source file for a text file transfer.
 delimiter	Specifies the delimiter that is included between records in record-oriented source files, for example, z/OS data sets. Specify the delimiter value as two hexadecimal digits in the range 00-FF, prefixed by x. For example, x12 or x03,x7F.

Attribute	Description
delimiterType	Specifies the type of delimiter that is included in the destination file after individual message data. The valid values is as follows: <ul style="list-style-type: none"> • binary - a hexadecimal delimiter This attribute is available only if you have enabled the V7.0.4.1 function.
delimiterPosition	Specifies the position to insert delimiters when writing record-oriented source file records to a normal file. The valid values are as follows: <ul style="list-style-type: none"> • prefix - the delimiter is inserted into the destination file before the data from each source record-oriented file record. • postfix - the delimiter is inserted into the destination file after the data from each source record-oriented file record.
includeDelimiterInFile	Specifies whether to include a delimiter between records in record-oriented source files.
 keepTrailingSpaces	Specifies whether trailing spaces are to be kept on source records read from a fixed-length-format data set as part of a text mode transfer. The default is that trailing spaces are stripped. The valid values are as follows: <ul style="list-style-type: none"> • true - trailing spaces are kept on source records read from a fixed-length-format data set • false - trailing spaces are stripped from source records read from a fixed-length-format data set

<queue>

When used with the <source> element, specifies the name of the queue to transfer from, which must be located on the source agent queue manager. Use the format *QUEUE*. Do not include the queue manager name, the queue must be present on the source agent queue manager. You cannot use the <queue> element inside the <source> element, if you have used it inside of the <destination> element.

Attribute	Description
useGroups	Specifies whether to transfer all of the messages on the source queue, or either a complete message group or an individual message not in a group. The valid values are as follows: <ul style="list-style-type: none"> • true - transfer only the first complete group of messages, or the first individual message not in a group. • false - transfer all messages on the source queue
groupId	Specifies the group identifier of a complete message group, or the message identifier for an individual message not in a group, to read from the source queue. This attribute is valid only when the value of the useGroups attribute is true.
messageInGroup	Specifies whether the identifier in the groupId attribute represents a message group, or an individual message not in a group. This attribute is valid only when the value of the useGroups attribute is true. The valid values are as follows: <ul style="list-style-type: none"> • true - the identifier in the groupId attribute represents a group identifier. • false - the identifier in the groupId attribute represents a message identifier.

Attribute	Description
delimiterType	Specifies the type of delimiter that is included in the destination file after individual message data. The valid values are as follows: <ul style="list-style-type: none"> • text - a text or Java literal delimiter • binary - a hexadecimal delimiter
delimiter	Specifies the delimiter that is included in the destination file between individual message data.
delimiterPosition	Specifies whether the delimiter is included in the destination file before or after individual message data. The valid values are as follows: <ul style="list-style-type: none"> • prefix - the delimiter is included before the data • postfix - the delimiter is included after the data
encoding	Specifies the source queue encoding.
waitTime	Specifies the time, in seconds, for the source agent to wait for either: <ul style="list-style-type: none"> • a message to appear on the source queue, if the queue is empty or has become empty • a complete group to appear on the source queue, if the useGroups attribute has been set to true <p>For information about setting the waitTime value, see “Guidance for specifying a wait time on a message-to-file transfer” on page 2586.</p>

<destination>

Group element that specifies the destination and the behavior if files exist at the destination agent.

You can specify only one of <file> and <queue> as a child element of destination.

Attribute	Description
type	The type of destination. The valid values are as follows: <ul style="list-style-type: none"> • file - specifies a file as the destination • directory - specifies a directory as the destination •  dataset - specifies a z/OS data set as the destination •  pds - specifies a z/OS partitioned data set as the destination • queue - specifies an IBM MQ queue as the destination • filespace - specifies a file space as the destination <p>The value queue is valid only when the <destination> element has a child element of <queue>.</p> <p>The value filespace is valid only when the <destination> element has a child element of <filespace>.</p> <p>The other values are valid only when the <destination> element has a child element of <file>.</p>
exist	Specifies the action that is taken if a destination file exists on the destination system. The valid values are as follows:

Attribute	Description
	<ul style="list-style-type: none"> error - reports an error and the file is not transferred. overwrite - overwrites the existing destination file. <p>This attribute is not valid if the <destination> element has a child element of <queue> or <filesystem>.</p>

<file>

Specifies additional settings for the previously-described **<destination>** element. Use the fully qualified path in the format consistent with your operating system, for example `C:/from/here.txt`. Do not use file URIs.

Attribute	Description
alias	Specifies an alias for the <destination> file. This alias is the name of the source file, excluding any directory path specified for the transfer.
encoding	The encoding of the <destination> file for a text file transfer.
EOL	Specifies the end of line marker for text transfers. Valid values are: <ul style="list-style-type: none"> LF - line feed character only CRLF - carriage return and line feed character sequence
truncateRecords	Optional. Specifies that <destination> records longer than the LRECL data set attribute are truncated. <ul style="list-style-type: none"> True - the records are truncated False - the records are wrapped <p>The default setting is false.</p>

<queue>

When used with the **<destination>** element, specifies the name of the queue to transfer to, which can be located on any queue manager that is connected to the destination agent queue manager. Use the format `QUEUE@QM` where `QUEUE` is the name of the queue to put the messages on and `QM` is the queue manager where the queue is located. You cannot use the **<queue>** element inside the **<destination>** element, if you have used it inside of the **<source>** element.

Attribute	Description
delimiter	The delimiter to split the file into multiple messages.
delimiterType	Specifies the type of delimiter. The valid values are as follows: <ul style="list-style-type: none"> text - a Java regular expression binary - a sequence of hexadecimal bytes size - a number of bytes, kibibytes, or mebibytes. For example, 1 B, 1 K, or 1 M.
delimiterPosition	Specifies whether the delimiter is expected before or after the data to include in individual messages. The valid options are as follows: <ul style="list-style-type: none"> prefix - the delimiter is expected before the data postfix - the delimiter is expected after the data
includeDelimiterInMessage	A boolean specifying whether to include the delimiters that were used to split the file into multiple messages at the end of the messages.

Attribute	Description
encoding	Specifies the destination queue encoding.
persistent	Specifies whether the messages are persistent. The valid values are as follows: <ul style="list-style-type: none"> • true - the messages are persistent • false - the messages are not persistent • qdef - the persistence value of the messages is defined by the settings on the destination queue
setMqProps	A boolean specifying whether IBM MQ message properties are set on the first message in a file, and any messages written to the queue when an error occurs.
unrecognisedCodePage	Specifies whether a text mode transfer fails or conversion is performed, if the code page of the data is not recognized by the destination queue manager. The valid values are as follows: <ul style="list-style-type: none"> • fail - the transfer reports a failure • binary - the data is converted to the destination code page and the IBM MQ message header describing the format of the data is set to MQFMT_NONE. <p>The default behavior is fail.</p>

<filespace>

Group element specifying the name of the file space to transfer to.

<name>

When used with the <filespace> element, the value of this element specifies the name of the file space.

<preSourceCall>

Group element specifying a command to call at the source of the transfer, before the transfer starts.

<postSourceCall>

Group element specifying a command to call at the source of the transfer, after the transfer completes.

<preDestinationCall>

Group element specifying a command to call at the destination of the transfer, before the transfer starts.

<postDestinationCall>

Group element specifying a command to call at the destination of the transfer, after the transfer completes.

<command>

When used with the <preSourceCall>, <postSourceCall>, <preDestinationCall>, or <postDestinationCall> element, this element specifies the command to be called. The command must be located on the agent command path. For more information, see [Advanced agent properties](#).

Attribute	Description
name	The name of the command to run.
successRC	The return code that is expected if the command runs successfully.

<argument>

When used with the <command> element, this element specifies an argument to be passed in to the command. You can have any number of <argument> elements inside a <command> element.

<job>

Optional group element containing job information for the entire transfer specification. <job> is a user-defined job name identifier that is added to the log message when the transfer has started. This <job> element is the same as the <job> element that appears in the transfer log message, which is described in the following topic: [“File transfer log message formats” on page 2664.](#)

<name>

When used with the <job> element, the value of this element specifies the name of the job.

<transferSpecifications>

Group element that contains <item> elements for multiple transfer groups. See [Using transfer definition files](#) for further details about how to use this element.

<cancel>

Group element containing all the elements required to cancel a file transfer in progress.

Attribute	Description
version	Specifies the version of this element as supplied by Managed File Transfer.

<transfer>

When used with the <cancel> element, the value of this element specifies the transfer request ID to be canceled.

<job>

Group element containing job information.

<jobName>

Specifies logical job identifier.

File transfer cancel message format

A file transfer request returns a 48-character ID that identifies the transfer for a specific agent. This ID is used to cancel transfers.

Understanding the transfer cancel message

The elements and attributes used in transfer cancel messages are described:

<cancel>

Group element containing all the elements required to cancel a file transfer in progress.

Attribute	Description
version	Specifies the version of this element as supplied by Managed File Transfer.

<originator>

Group element that contains the elements specifying the originator of the request.

<hostName>

The host name of the system where the source file is located.

<userID>

The user ID that originated the file transfer.

<mqmdUserID>

Optional. The IBM MQ user ID that was supplied in the message descriptor (MQMD).

<transfer>

When used with the <cancel> element, the value of this element specifies the transfer request ID to be canceled.

<job>

Optional. Group element containing job information.

<jobName>

Specifies logical job identifier.

Examples

Examples of XML messages that conform to this schema are provided for each of the following requests:

- [Create a file transfer](#)
- [Create an asynchronous file transfer request](#)
- [Cancel a file transfer](#)
- [Create a scheduled transfer](#)
- [Delete a scheduled transfer](#)
- [Create a managed call](#)
- [Create a file transfer that includes managed calls](#)

Examples of the messages that you can put on the agent command queue to request that the agent creates a managed call or creates a transfer that calls programs.

[“MFT agent status message format” on page 2648](#)

When a Managed File Transfer Agent is created or started, the agent publishes its details to the SYSTEM.FTE topic on its coordination queue manager (on the SYSTEM.FTE/Agents/*agent name* topic).

[“File transfer status message format” on page 2660](#)

Messages are published to the coordination queue manager to indicate transfer status of each file in the transfer set. Every time a request for file transfer is processed by the agent, a transaction message is published to the coordination queue manager (on its SYSTEM.FTE/Transfers/*agent_name/transfer ID* topic), which conforms to the TransferStatus.xsd XML schema. The TransferStatus.xsd file is located in the *MQ_INSTALLATION_PATH/mqft/samples/schema* directory of your WMQMFT installation.

[“File transfer log message formats” on page 2664](#)

File transfer log messages are published to the SYSTEM.FTE topic with a topic string of Log/*agent_name/transfer_id*. These messages conform to the schema TransferLog.xsd, which is located in the *MQ_INSTALLATION_PATH/mqft/samples/schema* directory of your Managed File Transfer installation.

[“Scheduled file transfer log message formats” on page 2686](#)

Every time a request for a scheduled file transfer is processed by the agent, a schedule log message is published to the coordination queue manager (on its SYSTEM.FTE/Log/*agent_name/schedule ID* topic). This message conforms to the ScheduleLog.xsd XML schema.

[“MFT monitor request message formats” on page 2715](#)

Resource monitors are created when a suitable XML message arrives at an agent's command queue, typically as a result of a user issuing the **fteCreateMonitor** command or using the IBM MQ Explorer interface.

[“MFT message formats for security” on page 2728](#)

This topic describes the messages published to the Managed File Transfer coordination queue manager relevant to security.

File transfer request message examples

Examples of the messages that you can put on the agent command queue to request that the agent create or cancel a transfer.

Create transfer request

```
<?xml version="1.0" encoding="UTF-8"?>
<request xmlns:xsi="https://www.w3.org/2001/XMLSchema-instance"
version="4.00"
xsi:noNamespaceSchemaLocation="FileTransfer.xsd">
  <managedTransfer>
    <originator>
      <hostName>example.com.</hostName>
      <userID>mqm</userID>
    </originator>
    <sourceAgent QMgr="QM_JUPITER" agent="AGENT_JUPITER"/>
    <destinationAgent QMgr="QM_JUPITER" agent="AGENT_JUPITER"/>
    <transferSet>
      <item checksumMethod="MD5" mode="binary">
        <source disposition="leave" recursive="false">
          <file>/etc/passwd</file>
        </source>
        <destination exist="overwrite" type="directory">
          <file>/tmp</file>
        </destination>
      </item>
    </transferSet>
  </managedTransfer>
</request>
```

Create transfer request - synchronous

When a user requests a blocking synchronous request, that is, they wait for the transfer to complete and receive status messages, the message placed on the command queue contains a reply element that specifies the queue that a reply message is sent to. The following example shows the message placed on the command queue used by FTEAGENT:

```
<?xml version="1.0" encoding="UTF-8"?>
<request version="4.00"
  xmlns:xsi="https://www.w3.org/2001/XMLSchema-instance"
  xsi:noNamespaceSchemaLocation="FileTransfer.xsd">
  <managedTransfer>
    <originator>
      <hostName>reportserver.com</hostName>
      <userID>USER1</userID>
    </originator>
    <sourceAgent agent="FTEAGENT"
      QMgr="QM1"/>
    <destinationAgent agent="AGENT2"
      QMgr="QM2"/>
    <reply QMGR="QM1">WMQFTE.492D0D5502770020</reply>
    <transferSet>
      <item mode="binary" checksumMethod="MD5">
        <source recursive="false" disposition="leave">
          <file>c:\sourcefiles\source1.doc</file>
        </source>
        <destination type="file" exist="overwrite">
          <file>c:\destinationfiles\dest1.doc</file>
        </destination>
      </item>
    </transferSet>
  </managedTransfer>
</request>
```

The <reply> element is populated with the name of the command queue manager where a temporary dynamic queue has been created to receive reply about the successful (or otherwise) completion of the transfer. The name of the temporary dynamic queue is composed of two parts:

- The prefix as defined by the key **dynamicQueuePrefix** in the `command.properties` configuration file (it is `WMQFTE.` by default)
- The ID of the queue as generated by IBM MQ

Cancel transfer request

```
<?xml version="1.0" encoding="UTF-8"?>
<cancel xmlns:xsi="https://www.w3.org/2001/XMLSchema-instance"
  version="4.00"
  xsi:noNamespaceSchemaLocation="FileTransfer.xsd">
  <originator>
    <hostName>example.com.</hostName>
    <userID>mqm</userID>
  </originator>
  <transfer>414D51205553322E42494E444494E47538B0F404D032C0020</transfer>
  <reply QMGR="QM_JUPITER">WMQFTE.4D400F8B20002007</reply>
</cancel>
```

File transfers are initiated by XML messages arriving at an agent command queue, typically as a result of a user issuing a file transfer command or by using the IBM MQ Explorer. The transfer request XML must conform to the `FileTransfer.xsd` schema and have the `<request>` element as the root element. The `FileTransfer.xsd` schema document is located in the `MQ_INSTALLATION_PATH/mqft/samples/schema` directory. The `FileTransfer.xsd` schema imports `fteutils.xsd`, which is in the same directory.

Scheduled file transfer message examples

Examples of the messages that you can put on the agent command queue to request that the agent create or delete a schedule.

Create scheduled transfer

```
<?xml version="1.0" encoding="UTF-8"?>
<request xmlns:xsi="https://www.w3.org/2001/XMLSchema-instance"
  version="4.00"
  xsi:noNamespaceSchemaLocation="FileTransfer.xsd">
  <managedTransfer>
    <originator>
      <hostName>example.com.</hostName>
      <userID>mqm</userID>
    </originator>
    <schedule>
      <submit timebase="admin" timezone="Europe/London">2010-01-01T21:00</submit>
    </schedule>
    <sourceAgent QMgr="US2.BINDINGS" agent="US2.BINDINGS.FILE"/>
    <destinationAgent QMgr="US2.BINDINGS" agent="US2.BINDINGS.FILE"/>
    <transferSet>
      <item checksumMethod="MD5" mode="binary">
        <source disposition="leave" recursive="false">
          <file>/etc/passwd</file>
        </source>
        <destination exist="overwrite" type="directory">
          <file>/tmp</file>
        </destination>
      </item>
    </transferSet>
  </managedTransfer>
</request>
```

Delete scheduled transfer

```
<?xml version="1.0" encoding="UTF-8"?>
<request xmlns:xsi="https://www.w3.org/2001/XMLSchema-instance"
  version="4.00"
  xsi:noNamespaceSchemaLocation="FileTransfer.xsd">
```

```

<deleteScheduledTransfer>
  <originator>
    <delete>
      <hostName>example.com.</hostName>
      <userID>mqm</userID>
    </delete>
  </originator>
  <ID>1</ID>
  <reply QMGR="US2.BINDINGS">WMQFTE.4D400F8B20003902</reply>
</deleteScheduledTransfer>
</request>

```

MFT agent call request message examples

Examples of the messages that you can put on the agent command queue to request that the agent creates a managed call or creates a transfer that calls programs.

Managed call request example

```

<?xml version="1.0" encoding="UTF-8"?>
<request xmlns:xsi="https://www.w3.org/2001/XMLSchema-instance"
  version="1.00"
  xsi:noNamespaceSchemaLocation="FileTransfer.xsd">
  <managedCall>
    <originator>
      <hostName>example.com.</hostName>
      <userID>mqm</userID>
    </originator>
    <agent agent="DNWE" QMgr="QM1"/>
    <transferSet>
      <call>
        <command name="echo" successRC="0">
          <argument>call</argument>
          <argument>test</argument>
        </command>
      </call>
    </transferSet>
  </managedCall>
  <job>
    <name>managedCallCalls.xml</name>
  </job>
</request>

```

Managed transfer request example with calls

```

<?xml version="1.0" encoding="UTF-8"?>
<request xmlns:xsi="https://www.w3.org/2001/XMLSchema-instance"
  version="1.00"
  xsi:noNamespaceSchemaLocation="FileTransfer.xsd">
  <managedTransfer>
    <originator>
      <hostName>example.com.</hostName>
      <userID>mqm</userID>
    </originator>
    <sourceAgent agent="DNWE" QMgr="QM1"/>
    <destinationAgent agent="DNWE" QMgr="QM1"/>
    <transferSet>
      <preSourceCall>
        <command name="echo" successRC="0">
          <argument>preSourceCall</argument>
          <argument>test</argument>
        </command>
      </preSourceCall>
    </transferSet>
  </managedTransfer>

```

```

</preSourceCall>
<postSourceCall>
  <command name="echo" successRC="0">
    <argument>postSourceCall</argument>
    <argument>test</argument>
  </command>
</postSourceCall>
<preDestinationCall>
  <command name="echo" successRC="0">
    <argument>preDestinationCall</argument>
    <argument>test</argument>
  </command>
</preDestinationCall>
<postDestinationCall>
  <command name="echo" successRC="0">
    <argument>postDestinationCall</argument>
    <argument>test</argument>
  </command>
</postDestinationCall>
</transferSet>

“File transfer request message format” on page 2698

File transfers are initiated by XML messages arriving at an agent command queue, typically as a result of a user issuing a file transfer command or by using the IBM MQ Explorer. The transfer request XML must conform to the `FileTransfer.xsd` schema and have the `<request>` element as the root element. The `FileTransfer.xsd` schema document is located in the `MQ_INSTALLATION_PATH/mqft/samples/schema` directory. The `FileTransfer.xsd` schema imports `fteutils.xsd`, which is in the same directory.

MFT monitor request message formats

Resource monitors are created when a suitable XML message arrives at an agent's command queue, typically as a result of a user issuing the **fteCreateMonitor** command or using the IBM MQ Explorer interface.

The monitor XML must conform to the `Monitor.xsd` schema using the `<monitor>` element as the root element.

Monitor messages can have one of the following root elements:

- `<monitor>` - for creating and starting a new resource monitor
- `<deleteMonitor>` - for stopping and deleting an existing monitor

There is no command message for the **fteListMonitors** command because the command directly retrieves matching monitor definitions from the `SYSTEM.FTE` topic.

Schema

The following schema describes which elements are valid in a monitor request XML message.

```

<xsd:schema xmlns:xsd="https://www.w3.org/2001/XMLSchema"
  targetNamespace="https://www.ibm.com/xmlns/wmqfte/7.0.1/
  MonitorDefinition"
  xmlns="https://www.ibm.com/xmlns/wmqfte/7.0.1/MonitorDefinition">
  <xsd:include schemaLocation="FileTransfer.xsd" />
  <xsd:element name="monitor">
    <xsd:complexType>
      <xsd:sequence>
        <xsd:element name="name" type="monitorNameType"

```

```

        minOccurs="1"           maxOccurs="1" />
        <xsd:element name="description" type="xsd:string"

```

From IBM MQ 9.3.0, the `maxOccurs` attribute of the `directory` element is set to 1. This attribute was previously set to unbounded, which indicated that there could be multiple directory entries. However, this was incorrect because you can only specify one directory when creating a resource monitor that monitors a directory.

Create monitor message elements

The following elements and attributes are used in create monitor messages:

<monitor>

Group element containing all the elements required to cancel a file transfer in progress.

Attribute	Description
version	Specifies the version of this element as supplied by Managed File Transfer.

<name>

The name of the monitor, unique within the monitor's agent.

<description>

Description of the monitor (not currently used).

<pollInterval>

The time interval between each check of the resource against the trigger condition.

Attribute	Description
units	Specifies the time units for the poll interval. Valid values are: <ul style="list-style-type: none"> • seconds • minutes • hours • days • weeks • months • years

<agent>

Name of the agent the monitor is associated with.

<resources>

Group element that contains the elements specifying the resources to monitor.

<directory>

Fully qualified path specifying the directory on the monitor's agent machine to monitor.

Attribute	Description
recursionLevel	The number of subdirectories to monitor in addition to the specified directory.
id	Unique identifier for the resource.

<queue>

Queue name specifying the queue to monitor on the monitoring agent's queue manager.

<triggerMatch>

Group element that contains the elements specifying the trigger conditions to compare with the monitored resource.

<conditions>

Group element that contains the elements specifying the type of condition to compare with the monitored resource.

<allOf>

Predicate that specifies that all contained conditions must be satisfied.

<anyOf>

Predicate that specifies that any contained conditions must be satisfied.

<condition>

Defines a comparison condition that will contribute to the overall monitor trigger condition.

<name>

Name of the condition.

<resource>

Identifies the resource definition to compare the condition against.

Attribute	Description
id	Unique identifier for the resource.

If the resource that is being monitored is a directory, one of the following three elements must be specified in the condition:

- fileMatch
- fileNoMatch
- fileSize

If the resource that is being monitored is a queue, one of the following two elements must be specified in the condition:

- queueNotEmpty
- completeGroups

<fileMatch>

Group element for a file name match condition.

<pattern>

Specifies a file name match pattern. Files on the resource must match the pattern in order to satisfy the condition. The default pattern is * (any file will match).

<fileNoMatch>

Group element for an inverse file name match condition.

<pattern>

Specifies an inverse file name match pattern. If no files on the monitored resource match, the condition is satisfied. The default pattern is * (the absence of any file will match).

<fileSize>

Group element for a file size comparison.

<compare>

Specifies a file size comparison. The value must be a non-negative integer.

Attribute	Description
operator	Comparison operator to use. Only '>=' is supported.
units	Specifies file size units, which can be one of: <ul style="list-style-type: none"> • B - bytes • KB - kilobytes • MB - megabytes • GB - gigabytes The units value is case insensitive, so 'mb' works as well as 'MB'.

<pattern>

File name pattern to match. Default is * (any file will match).

<queueNotEmpty>

This can only be specified if the resource is a queue. Specifies that there must be a message on the queue for the monitor to be triggered.

<completeGroups>

This can only be specified if the resource is a queue. Specifies that there must be a complete group of messages present on the queue for the monitor to be triggered. A single transfer task is executed for each complete group on the queue.

<reply>

Optional element that is used to specify reply queue for asynchronous requests.

Attribute	Description
QMGR	Queue manager name.

<tasks>

Group element to contain elements which specify the tasks to invoke when the monitor trigger conditions are satisfied.

<task>

Group element which defines an individual task that the monitor will invoke when the trigger conditions are satisfied. Currently only one task can be specified.

<name>

Name of the task. Accepts any alphanumeric characters.

<description>

Description of the task. Any text value is allowed.

<transfer>

Group element that defines a transfer task.

<request>

Group element that defines the type of task. This must contain one of the following elements which are inherited from the `FileTransfer.xsd` schema definition:

- [managedTransfer](#)
- [managedCall](#)

Attribute	Description
version	Version of the request as provided by Managed File Transfer. This is in the form n.mm where n is the major release version and mm is the minor version. For example 1.00.

<originator>

Group element that contains the elements specifying the originator of the request.

<hostName>

The host name of the system where the source file is located.

<userID>

The user ID that originated the file transfer.

<mqmdUserID>

Optional. The IBM MQ user ID that was supplied in the message descriptor (MQMD).

<job>

Group element containing job information.

<jobName>

Specifies logical job identifier.

<defaultVariables>

Group element containing one or more variable elements. These variables are used in variable substitution when monitoring a queue. For more information about variable substitution, see [Customizing MFT tasks with variable substitution](#).

<variable>

Element containing the value associated with the key given by the key attribute.

Attribute	Description
key	The name of the default variable.

Delete monitor message elements

The following elements and attributes are used in delete monitor messages:

<deleteMonitor>

Group element containing all the elements required to stop and delete a monitor.

Attribute	Description
version	Specifies the version of this element as supplied by Managed File Transfer.

<name>

Name of monitor to delete.

<originator>

Group element that contains the elements specifying the originator of the request.

<hostName>

The host name of the system where the source file is located.

<userID>

The user ID that originated the file transfer.

<mqmdUserID>

Optional. The IBM MQ user ID that was supplied in the message descriptor (MQMD).

<reply>

Specifies the name of the temporary reply queue generated for the request. The name of the queue is as defined by the key `dynamicQueuePrefix` in the `command.properties` configuration file. If this is not specified, the queue name has a default value of `WMQFTE`.

Attribute	Description
QMGR	The name of the command queue manager on which the temporary dynamic queue is generated to receive replies.

Examples

Examples of XML messages that conform to this schema are provided for each of the following monitor requests:

- [Create a monitor](#)
- [Delete a monitor](#)

[Monitoring MFT resources](#)

Related reference

[“MFT monitor request message examples” on page 2724](#)

Examples of the messages that you can put on the agent command queue to request that the agent create or delete a monitor.

[“MFT agent status message format” on page 2648](#)

When a Managed File Transfer Agent is created or started, the agent publishes its details to the `SYSTEM.FTE` topic on its coordination queue manager (on the `SYSTEM.FTE/Agents/agent name` topic).

[“File transfer request message format” on page 2698](#)

File transfers are initiated by XML messages arriving at an agent command queue, typically as a result of a user issuing a file transfer command or by using the IBM MQ Explorer. The transfer request XML must conform to the `FileTransfer.xsd` schema and have the `<request>` element as the root element. The

FileTransfer.xsd schema document is located in the `MQ_INSTALLATION_PATH/mqft/samples/schema` directory. The FileTransfer.xsd schema imports fteutils.xsd, which is in the same directory.

[“File transfer status message format” on page 2660](#)

Messages are published to the coordination queue manager to indicate transfer status of each file in the transfer set. Every time a request for file transfer is processed by the agent, a transaction message is published to the coordination queue manager (on its `SYSTEM.FTE/Transfers/agent_name/transfer ID` topic), which conforms to the schema TransferStatus.xsd XML schema. The TransferStatus.xsd file is located in the `MQ_INSTALLATION_PATH/mqft/samples/schema` directory of your WMQMFT installation.

[“File transfer log message formats” on page 2664](#)

File transfer log messages are published to the `SYSTEM.FTE` topic with a topic string of `Log/agent_name/transfer_id`. These messages conform to the schema TransferLog.xsd, which is located in the `MQ_INSTALLATION_PATH/mqft/samples/schema` directory of your Managed File Transfer installation.

[“Scheduled file transfer log message formats” on page 2686](#)

Every time a request for a scheduled file transfer is processed by the agent, a schedule log message is published to the coordination queue manager (on its `SYSTEM.FTE/Log/agent name/schedule ID` topic). This message conforms to the ScheduleLog.xsd XML schema.

[“MFT message formats for security” on page 2728](#)

This topic describes the messages published to the Managed File Transfer coordination queue manager relevant to security.

Related reference

[“MFT monitor request message formats” on page 2715](#)

Resource monitors are created when a suitable XML message arrives at an agent's command queue, typically as a result of a user issuing the **fteCreateMonitor** command or using the IBM MQ Explorer interface.

Ping MFT agent request message format

You can ping an agent by issuing an **ftePingAgent** command or by putting an XML message on the agent command queue. The ping agent request XML must conform to the `PingAgent.xsd` schema. After you have installed Managed File Transfer, you can find the `PingAgent.xsd` schema file in the following directory: `MQ_INSTALLATION_PATH/mqft/samples/schema`. The `PingAgent.xsd` schema imports `fteutils.xsd`, which is in the same directory.

When the agent receives a ping agent request message on its command queue, if the agent is active, it returns an XML response message to the command or application that put the ping agent request message on the command queue. The response message from the agent is in the format defined by `Reply.xsd`. For more information about this format, see [“MFT agent reply message format” on page 2726](#).

Schema

The following schema describes which elements are valid in an ping agent request XML message.

```

<xsd:schema xmlns:xsd="https://www.w3.org/2001/XMLSchema"
  xmlns="https://www.ibm.com/xmlns/wmqfte/7.0.1/PingAgent"
  targetNamespace="https://www.ibm.com/xmlns/wmqfte/7.0.1/PingAgent">
  <xsd:include schemaLocation="fteutils.xsd"/>
  <xsd:element name="pingAgent">
    <xsd:complexType>
      <xsd:sequence>
        <xsd:element name="originator" type="origRequestType" maxOccurs="1" minOccurs="1"/>

```

```

        <xsd:element name="agent"          type="agentType"          maxOccurs="1" minOccurs="1"/>
        <xsd:element name="reply"        type="replyType"         maxOccurs="1" minOccurs="0" />
    </xsd:sequence>
    <xsd:attribute name="version" type="versionType" use="required" />
</xsd:complexType>
</xsd:element>
</xsd:schema>

```

Understanding the ping agent request message

The elements and attributes used in the ping agent request messages are described in the following list:

<pingAgent>

Group element containing all the elements required to specify a ping agent request.

<originator>

Group element containing all the elements required to specify the originator of the ping request.

<hostName>

The host name of the machine where the request originated.

<userID>

The user name of the originator of the request.

<mqmdUserID>

The MQMD user name of the originator of the request.

<agent>

The agent to ping.

Attribute	Description
agent	Required. The name of the agent.
QMGr	Optional. The queue manager that the agent connects to.

<reply>

The name of the queue for the agent to send the reply message to.

Attribute	Description
QMGR	Required. The name of the queue manager where the reply queue is located.

Example

This example shows a ping agent message sent to the agent AGENT_JUPITER. If AGENT_JUPITER is active and able to process agent requests, it sends a response message to the queue WMQFTE.4D400F8B20003708 on QM_JUPITER.

```

<?xml version="1.0" encoding="UTF-8"?>
<ping:pingAgent xmlns:xsi="https://www.w3.org/2001/XMLSchema-instance"
  xmlns:ping="https://www.ibm.com/xmlns/wmqfte/7.0.1/PingAgent"
  version="4.00">
  <originator>
    <hostName>example.com.</hostName>
    <userID>mqm</userID>
  </originator>
  <agent agent="AGENT_JUPITER" QMGr="QM_JUPITER"/>
  <reply QMGR="QM_JUPITER">WMQFTE.4D400F8B20003708</reply>
</ping:pingAgent>

```

MFT agent reply message format

When an agent receives an XML message on its agent command queue, if a response is required, the agent will send an XML reply message to the reply queue defined in the original message. The reply XML conforms to the Reply.xsd schema. The Reply.xsd schema document is located in

the `MQ_INSTALLATION_PATH/mqft/samples/schema` directory. The `Reply.xsd` schema imports `fteutils.xsd`, which is in the same directory.

Schema

The following schema describes which elements are valid in a reply XML message.

```
<xsd:schema xmlns:xsd="https://www.w3.org/2001/XMLSchema">
  <xsd:include schemaLocation="TransferLog.xsd"/>
  <xsd:element name="reply">
    <xsd:complexType>
      <xsd:sequence>
        <xsd:element name="transferSet" type="transferSetType" minOccurs="0"
maxOccurs="1" />
        <xsd:element name="status" type="statusType" minOccurs="1" maxOccurs="1" />
      </xsd:sequence>
      <xsd:attribute name="version" type="versionType" use="required"/>
      <xsd:attribute name="ID" type="IDType" use="required"/>
      <xsd:attribute name="detailedReplyMessagesDisabled" type="xsd:boolean"
use="optional"/>
    </xsd:complexType>
  </xsd:element>
</xsd:schema>
```

Understanding the reply message

The elements and attributes used in the reply messages are described in the following list:

<reply>

Element containing the elements that specify the reply information.

Attribute	Description
ID	The ID of the reply.
version	The version of the reply message format.
detailedReplyMessagesDisabled	A notification that the agent has disabled the detailed reply enableDetailedReplyMessages agent property is set to false).

<transferSet>

Specifies the transfer result information of the files requested for transfer. For more information, see [“File transfer log message formats”](#) on page 2664.

<status>

The status of the action that the agent was requested to perform.

Attribute	Description
resultCode	The result code returned from the action that the agent performed.

<supplement>

Additional response information about the action that the agent was requested to perform.

Example

In the following section is an example reply message:

```
<reply version="1.00"
  xmlns:xsi="https://www.w3.org/2001/XMLSchema-instance"
  xsi:noNamespaceSchemaLocation="Reply.xsd"
  ID="0102020300000000000000000000000000000000000000000000000000000000">
  <status resultCode="65">
    <supplement>Additional reply information</supplement>
```

```
</status>
</reply>
```

MFT message formats for security

This topic describes the messages published to the Managed File Transfer coordination queue manager relevant to security.

Not authorized log message

If user authority checking is enabled the agent can publish not authorized messages to the coordination queue manager. [Restricting user authorities on MFT agent actions](#) describes how to enable user authority checking.

Every time a user submits a request to perform a restricted action to the agent, either by using an Managed File Transfer command or by using the IBM MQ Explorer plugin, the agent checks that the user has the authority to perform the action. If the user fails that authority check, a not authorized log message is published to the coordination queue manager on its SYSTEM.FTE/Log/*agent_name*/NotAuthorized topic.

This message conforms to the TransferLog.xsd XML schema. For example:

```
<?xml version="1.0" encoding="UTF-8"?>
<notAuthorized version="3.00"
  ID="414d5120716d31202020202020202020202020204da5924a2010ce03"
  agentRole="sourceAgent"
  xmlns:xsi="https://www.w3.org/2001/XMLSchema-instance"
  xsi:noNamespaceSchemaLocation="TransferLog.xsd"
  xmlns="">
  <action time="2009-08-28T12:31:15.781Z">not_authorized</action>
  <originator>
    <mqmdUserID>test1</mqmdUserID>
  </originator>
  <authority>administration</authority>
  <status resultCode="53">
    <supplement>BFGCH0083E: The user (test1) does not have the authority (ADMINISTRATION) required
to shut down agent 'AGENT'.</supplement>
    <supplement>
      &lt;?xml version="1.0" encoding="UTF-8"?&gt;
      &lt;internal:request version="3.00" xmlns:xsi="https://www.w3.org/2001/XMLSchema-
instance"
        xmlns:internal="http://wmqfte.ibm.com/internal"&gt;
      &lt;internal:shutdown agent="SYSTEM.FTE.COMMAND.AGENT" hostname="qm1"
mode="controlled"/&gt;
      &lt;reply QMGR="qm1"&gt;WMQFTE.4A92A54D02CE1020&lt;/reply&gt;
      &lt;/internal:request&gt;
    </supplement>
  </status>
</notAuthorized>
```

This message is a log of the following information:

- Who originated the request
- The level of Managed File Transfer access authority required to perform the request
- The status of the request
- The request specification

Understanding the not authorized log message

The elements and attributes used in the not authorized message are described:

<notAuthorized>

Group element that describes a single failed user authorization check.

Attribute	Description
version	Specifies the version of this element as detailed by Managed File Transfer.

Attribute	Description
ID	The unique identifier for the request that was not authorized.

<originator>

Group element that contains the elements specifying the originator of the request.

<authority>

Specifies the level of Managed File Transfer access authority that the user required to perform the requested action.

<mqmdUserID>

The IBM MQ user ID that was supplied in the message descriptor (MQMD)

<action>

Specifies the authorization status of the request matching the ID attribute of <notAuthorized> element.

Attribute	Description
time	Specifies the date and time the log entry was published (in date time format).

<status>

The result code and supplement messages.

[“MFT agent status message format” on page 2648](#)

When a Managed File Transfer Agent is created or started, the agent publishes its details to the SYSTEM.FTE topic on its coordination queue manager (on the SYSTEM.FTE/Agents/*agent name* topic).

[“File transfer request message format” on page 2698](#)

File transfers are initiated by XML messages arriving at an agent command queue, typically as a result of a user issuing a file transfer command or by using the IBM MQ Explorer. The transfer request XML must conform to the FileTransfer.xsd schema and have the <request> element as the root element. The FileTransfer.xsd schema document is located in the MQ_INSTALLATION_PATH/mqft/samples/schema directory. The FileTransfer.xsd schema imports fteutils.xsd, which is in the same directory.

[“File transfer status message format” on page 2660](#)

Messages are published to the coordination queue manager to indicate transfer status of each file in the transfer set. Every time a request for file transfer is processed by the agent, a transaction message is published to the coordination queue manager (on its SYSTEM.FTE/Transfers/*agent_name/transfer ID* topic), which conforms to the TransferStatus.xsd XML schema. The TransferStatus.xsd file is located in the MQ_INSTALLATION_PATH/mqft/samples/schema directory of your WMQMFT installation.

[“File transfer log message formats” on page 2664](#)

File transfer log messages are published to the SYSTEM.FTE topic with a topic string of Log/*agent_name/transfer_id*. These messages conform to the schema TransferLog.xsd, which is located in the MQ_INSTALLATION_PATH/mqft/samples/schema directory of your Managed File Transfer installation.

[“Scheduled file transfer log message formats” on page 2686](#)

Every time a request for a scheduled file transfer is processed by the agent, a schedule log message is published to the coordination queue manager (on its SYSTEM.FTE/Log/*agent_name/schedule ID* topic). This message conforms to the ScheduleLog.xsd XML schema.

[“MFT monitor request message formats” on page 2715](#)

Resource monitors are created when a suitable XML message arrives at an agent's command queue, typically as a result of a user issuing the **fteCreateMonitor** command or using the IBM MQ Explorer interface.

MFT credentials file format

The `MQMFTCredentials.xml` file contains sensitive user ID and password information. The elements in the `MQMFTCredentials.xml` file must conform to the `MQMFTCredentials.xsd` schema. The security of credentials files is the responsibility of the user.

The **useMQCSPAAuthentication** parameter enables and disables MQCSP authentication for a Managed File Transfer agent. You can set this parameter in the `MQMFTCredentials.xml` file. For more information, see [Enabling connection authentication for MFT](#).

MQCSP authentication is enabled by default for the MFT agents and logger. If the **useMQCSPAAuthentication** parameter is not specified, it is by default set to `true`.

 The `MQMFTCredentials.xsd` file can also be a PDSE member on z/OS.

The `MQMFTCredentials.xml` file must conform to the `MQMFTCredentials.xsd` schema. The `MQMFTCredentials.xml` schema document is located in the `MQ_INSTALLATION_PATH/mqft/samples/schema` directory of the Managed File Transfer installation.

Schema

The following schema describes which elements are valid in the `MQMFTCredentials.xml` file.

```
<?xml version="1.0" encoding="UTF-8"?>

Understanding the MQMFTCredentials.xml file

The elements and attributes used in the MQMFTCredentials.xml file are described in the following list.

<mqmftCredentials>

The root element of the XML document.

<file>

The file in the transfer.

Attribute	Description
path	Path to the key or truststore file being accessed.
password	Password to access the file.

<logger>

The logger responsible for logging activity.

Attribute	Description
name	The name of the logger.
user	The user name the logger will use to connect to its database.

Attribute	Description
password	The password the logger will use to connect to its database.

<qmgr>

The IBM MQ queue manager connection.

Attribute	Description
name	The name of the associated IBM MQ queue manager.
user	Optional: The name of user requesting the connection.
mqUserId or mqUserIdCipher	The clear text user ID (mqUserId), or obfuscated text user ID (mqUserIdCipher) to supply to an IBM MQ queue manager.
mqPassword or mqPasswordCipher	The clear text password (mqPassword), or obfuscated text password (mqPasswordCipher) to supply to an IBM MQ queue manager.

Note: The `MQMFTCredentials.xml` file can contain sensitive information, so when it is created ensure that the file permissions are reviewed. When using a sandbox, set to it be excluded. For more information on sandboxes, see [Working with MFT agent sandboxes](#).

“[fteObfuscate \(encrypt sensitive data\)](#)” on page 2132

The **`fteObfuscate`** command encrypts sensitive data in credentials files. This stops the contents of credentials files being read by someone who gains access to the file.

Additional MFT agent configuration files

In addition to the `agent.properties` file, the Managed File Transfer agent can have a number of XML configuration files in its configuration directory.

Configuration files

The following XML configuration files can be used to specify additional information used by the agent:

ProtocolBridgeCredentials.xml

If your agent is a protocol bridge agent, you can use this file to specify the credentials to use to log in to the FTP or SFTP server that the agent connects to.

ProtocolBridgeProperties.xml

If your agent is a protocol bridge agent, you can use this file to define the properties of non-default protocol file servers that the agent connects to. The **`fteCreateBridgeAgent`** command creates a default protocol file server in this file for you.

ConnectDirectCredentials.xml

If your agent is a Connect:Direct bridge agent, you can use this file to specify the credentials to use to connect to the Connect:Direct nodes involved in a transfer.

ConnectDirectNodeProperties.xml

If your agent is a Connect:Direct bridge agent, you can use this file to specify the operating system information about the Connect:Direct nodes involved in a transfer.

ConnectDirectProcessDefinition.xml

If your agent is a Connect:Direct bridge agent, you can use this file to specify the user-defined Connect:Direct processes to call as part of a file transfer.

UserSandboxes.xml

You can use this file to specify which areas of the file system the agent can read from or write to.

Updating the configuration files

Unlike the `agent.properties` file, you can update the XML configuration files and have the agent pick up the changes without having to restart the agent.

When you submit a transfer, if it has been more than 10 second since the last time the agent checked the XML configuration file, the agent checks the last modified time of the XML configuration file. If the XML configuration file has been modified since the last time the agent read the file, the agent reads the file again. If the contents of the file are valid when compared to the XML schema, the agent updates its information. If the contents of the file are not valid, the agent uses the information from the previous version of the file and writes a message to the `output.log` file.

Related concepts

The `ProtocolBridgeProperties.xml` file in the agent configuration directory defines properties for protocol file servers.

[“Connect:Direct credentials file format” on page 2750](#)

The `ConnectDirectCredentials.xml` file in the Managed File Transfer Agent configuration directory defines the user names and credential information that the Connect:Direct agent uses to authorize itself with a Connect:Direct node.

[“Connect:Direct node properties file format” on page 2757](#)

The `ConnectDirectNodeProperties.xml` file in the Connect:Direct bridge agent configuration directory specifies information about remote Connect:Direct nodes that are involved in a file transfer.

[“Connect:Direct process definitions file format” on page 2753](#)

The `ConnectDirectProcessDefinitions.xml` file in the Connect:Direct bridge agent configuration directory specifies the user-defined Connect:Direct process to start as part of the file transfer.

Protocol bridge credentials file format

The `ProtocolBridgeCredentials.xml` file in the Managed File Transfer Agent configuration directory defines the user names and credential information that the protocol bridge agent uses to authorize itself with the protocol server.

The `ProtocolBridgeCredentials.xml` file must conform to the `ProtocolBridgeCredentials.xsd` schema. The `ProtocolBridgeCredentials.xsd` schema document is located in the `MQ_INSTALLATION_PATH/mqft/samples/schema` directory of the MQMFT installation. Users are responsible for manually creating the `ProtocolBridgeCredentials.xml` file, it is no longer created by the `fteCreateBridgeAgent` command. Sample files are available in the `MQ_INSTALLATION_PATH/mqft/samples` directory of the MQMFT installation.

V7.5 introduced a new `<agent>` element that contains the `<server>` or `<serverHost>` element for the named agent.

The `ProtocolBridgeCredentials.xml` file is periodically reloaded by the agent and any valid changes to the file will affect the behavior of the agent. The default reload interval is 30 seconds. This interval can be changed by specifying the agent property `xmlConfigReloadInterval` in the `agent.properties` file.

Schema - V7.5 or later

The following schema describes which elements are valid in the ProtocolBridgeCredentials.xml file for V8.

```
<schema targetNamespace="http://wmqfte.ibm.com/ProtocolBridgeCredentials" elementFormDefault="qualified"

Understanding the ProtocolBridgeCredentials.xml file

The elements and attributes used in the ProtocolBridgeCredentials.xml file are described in the following list.

<credentials>

Group element containing elements that describe the credentials used by a protocol bridge agent to connect to a protocol server.

<agent>

Element containing a <server> or <serverHost> definition for a named agent.

<server>

The protocol server that the protocol bridge connects to.

The <server> element is not supported for V7.0.4 or earlier.

Attribute	Description
name	The name of the protocol server.
pattern	If you have used wildcards or regular expressions to specify the pattern of a protocol server name, use either wildcard or regex.

Attribute	Description
trustStorePassword or trustStorePasswordCipher	Required when the <server> element refers to an FTPS server. The password used to access the truststore. If the fteObfuscate command has been used then the cipher version of the attribute must be used.
keyStorePassword or keyStorePasswordCipher	Optional. The password used to access the keystore. If the fteObfuscate command has been used then the cipher version of the attribute must be used.

<serverHost>

The host name of the protocol server that the protocol bridge connects to.

The ProtocolBridgeCredentials.xml file can either contain <serverHost> elements or <server> elements but you cannot use a mixture of the two different types. When you use <serverHost>, the name is matched against the protocol server's host name. When you use <server>, the name is matched against the protocol server's name (as defined in the ProtocolBridgeProperties.xml file).

Attribute	Description
name	The host name or IP address of the protocol server.
trustStorePassword or trustStorePasswordCipher	Required when the <serverHost> element refers to an FTPS server. The password used to access the truststore. If the fteObfuscate command has been used then the cipher version of the attribute must be used.
keyStorePassword or keyStorePasswordCipher	Optional. The password used to access the keystore. This property is optional unless you set the keyStore attribute, in which case it is required. If the fteObfuscate command has been used then the cipher version of the attribute must be used.

<user>

A user mapping from a Managed File Transfer user name to a protocol server user name.

Attribute	Description
name	A Java regular expression to match the MQMD user ID associated with the managed transfer request.
serverUserId or serverUserIdCipher	The user name that is used with the protocol server. If the fteObfuscate command has been used then the cipher version of the attribute must be used.
serverPassword or serverPasswordCipher	The password for the user name used on the protocol server. If the fteObfuscate command has been used then the cipher version of the attribute must be used.
hostKey	The server host SSH fingerprint.

<privateKey>

The private key of a user.

Attribute	Description
keyPassword or keyStorePasswordCipher	The password for the private key. If the fteObfuscate command has been used then the cipher version of the attribute must be used.

Attribute	Description
associationName	A name used for trace and logging.

Related tasks

Related reference

[The protocol bridge](#)

[Example: How to configure a bridge agent to use private key credentials with a UNIX SFTP server “fteObfuscate \(encrypt sensitive data\)” on page 2132](#)

The **fteObfuscate** command encrypts sensitive data in credentials files. This stops the contents of credentials files being read by someone who gains access to the file.

Protocol bridge properties file format

The ProtocolBridgeProperties.xml file in the agent configuration directory defines properties for protocol file servers.

The ProtocolBridgeProperties.xml file must conform to the ProtocolBridgeProperties.xsd schema. The ProtocolBridgeProperties.xsd schema document is located in the `MQ_INSTALLATION_PATH/mqft/samples/schema` directory of the Managed File Transfer installation. A template file, ProtocolBridgeProperties.xml, is created by the **fteCreateBridgeAgent** command in the agent configuration directory.

The ProtocolBridgeProperties.xml file is periodically reloaded by the agent and any valid changes to the file will affect the behavior of the agent. The default reload interval is 30 seconds. This interval can be changed by specifying the agent property **xmlConfigReloadInterval** in the agent.properties file.

Schema

The following schema describes the ProtocolBridgeProperties.xml file.

If you do not use the attributes of:

- maxActiveDestinationTransfers (global property)
- maxActiveDestinationTransfers (individual server property)
- failTransferWhenCapacityReached

managed file transfer processing continues in its current form, and the following schema does not change.

Attention: Both the source and destination protocol bridge agents must be at IBM MQ 9.2.1 or later, to use the additional attributes.

See [“Changes to the sequence group” on page 2741](#), [“Changes to the limits group” on page 2741](#) for changes these attributes make to the schema, and [Scenarios and examples for limiting the number of file transfers to individual file servers](#) for information on how the changes affect the working of the protocol bridge agent.

Changes to the sequence group

Following the additions of the **maxActiveDestinationTransfers** (global) and **failTransferWhenCapacityReached** attributes, the sequence group under ComplexType is as follows, with the changes shown in bold text:

```
<!--
  A container for all protocol bridge server properties
-->
<complexType name="serverPropertiesType">
<sequence>
  <element name="credentialsFile" type="tns:credentialsFileName" minOccurs="0" maxOccurs="1" />
  <element name="credentialsKeyFile" type="tns:credentialsKeyFileName" minOccurs="0" maxOccurs="1" />
  <element name="maxActiveDestinationTransfers"
    type="tns:maxActiveDestinationTransfersValue" minOccurs="0"
    maxOccurs="1" />
  <element name="failTransferWhenCapacityReached"
    type="tns:failTransferWhenCapacityReachedValue" minOccurs="0"
    maxOccurs="1" />
  <element name="defaultServer" type="tns:serverName" minOccurs="0" maxOccurs="1" />
  <choice minOccurs="0" maxOccurs="unbounded">
    <element name="ftpServer" type="tns:ftpServerType" />
    <element name="sftpServer" type="tns:sftpServerType" />
    <element name="ftpsServer" type="tns:ftpsServerType" />
    <element name="ftpsfgServer" type="tns:ftpsfgServerType" />
    <element name="ftpsfigServer" type="tns:ftpsfigServerType" />
  </choice>
</sequence>
</complexType>

<!--
  A container for default value for maxActiveDestinationTransfers
-->
<complexType name="maxActiveDestinationTransfersValue">
  <attribute name="value" type="positiveInteger" use="required" />
</complexType>

<!--
  A container for a boolean value to decide to fail a transfer if max capacity is reached
-->
<complexType name="failTransferWhenCapacityReachedValue">
  <attribute name="value" type="boolean" use="required" />
</complexType>
```

Changes to the limits group

Following the addition of the **maxActiveDestinationTransfers** (individual server) attribute, the limits group is as follows, with the changes shown in bold text:

```
<!--
Attributes for limits common to all server types
-->
<attributeGroup name="generalLimitAttributes">
  <attribute name="maxListFileNames" type="positiveInteger"
    use="optional" />
  <attribute name="maxListDirectoryLevels" type="nonNegativeInteger"
    use="optional" />
  <attribute name="maxReconnectRetry" type="nonNegativeInteger"
    use="optional" />
  <attribute name="reconnectWaitPeriod" type="nonNegativeInteger"
    use="optional" />
  <attribute name="maxSessions" type="positiveInteger" use="optional" />
  <attribute name="socketTimeout" type="nonNegativeInteger" use="optional"
    />
  <attribute name="connectionTimeout" type="nonNegativeInteger"
    use="optional" />
  <attribute name="maxActiveDestinationTransfers" type="nonNegativeInteger"
    use="optional" />
</attributeGroup>
```

Example XML file

```
<tns:serverProperties
  xmlns:tns="http://wmqfte.ibm.com/ProtocolBridgeProperties"
  xmlns:xsi="https://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://wmqfte.ibm.com/ProtocolBridgeProperties
  ProtocolBridgeProperties.xsd">

  <tns:maxActiveDestinationTransfers value="5" />
  <tns:failTransferWhenCapacityReached value="true"/>
  <tns:defaultServer name="guestServer" />

  <tns:sftpServer name="guestServer" host="9.202.177.44" port="22"
  platform="unix" fileEncoding="UTF-8" limitedWrite="false">

  <tns:limits connectionTimeout="60"
  maxActiveDestinationTransfers="2"/>
  </tns:sftpServer>

  </tns:sftpServer>

  <tns:sftpServer name="mySFTPserver" host="Harrison.hursley.ibm.com"
  port="22" platform="unix" fileEncoding="UTF-8" limitedWrite="false"
  >

  <tns:limits connectionTimeout="60" />
  </tns:sftpServer>

</tns:serverProperties>
```

Understanding the ProtocolBridgeProperties.xml file

The elements and attributes that are used in the ProtocolBridgeProperties.xml file are described in the following list:

<serverProperties>

Root element of the XML document

<credentialsFile>

Path to the file containing credentials. The value of this property can contain environment variables. For more information, see [Environment variables in MFT properties](#)

<defaultServer>

The protocol file server that acts as the default server for file transfers

<ftpServer>

An FTP file server

<sftpServer>

An SFTP file server

<ftpsServer>

An FTPS file server

<limits>

Container element for attributes that are common to all types of server and for attributes that are specific to a type of server:

General server attributes that apply to all types of protocol file server:

Attribute	Description
name	Required. The name of the protocol file server. Protocol server names must be at least two characters in length, are not case-sensitive, and are limited to alphanumeric characters and the following characters:

Attribute	Description
	<ul style="list-style-type: none"> • period (.) • underscore (_) • forward slash (/) • percent sign (%)
host	Required. The host name or IP address of the protocol file server that you want to send files to or receive files from.
port	Optional. The port number of the protocol file server that you want to send files to or receive files from.
platform	Required. The platform of the protocol file server that you want to send files to or receive files from. Specify either UNIX or WINDOWS. Set this property according to how you enter paths on your FTP, FTPS, or SFTP server. For example, if you are running an FTP server on Windows but when you log in to the server, you must enter UNIX-style paths (that is, with forward slashes), set this value to UNIX and not WINDOWS. Servers running on Windows often present a UNIX-style file system.
fileEncoding	Required. Defines the character encoding that is used by the file server. This property is used when you transfer files in text mode so that the correct encoding sequences are changed when the files are moved between platforms. For example, UTF-8.
limitedWrite	Optional. The default mode when writing to a file server is to create a temporary file and then rename that file when the transfer has completed. For a file server that is configured as write only, the file is created directly with its final name. The value of this property can be true or false. The default is false.
controlEncoding	Optional. The control encoding value for control messages being sent to the protocol file server. This property affects the encoding of the file name that is used and must be compatible with the control encoding of the protocol file server. The default is UTF-8.

General attributes that apply to FTP and FTPS servers only:

Attribute	Description
timeZone	Required. The time zone of the protocol file server that you want to send files to or receive files from. For example: America/New_York or Asia/Tokyo.
locale	Required. The language that is used on the protocol file server that you want to send files to or receive files from. For example: en_US or ja_JP
listFormat	Optional. The listing format that defines the format of the file-listed information that is returned from the protocol file server. Use either Windows or UNIX. The default is UNIX.
listFileRecentDateFormat	Optional. The recent date format (less than a year) for FTP client directory listing on an FTP server. This attribute and the listFileOldDateFormat attribute allow you to redefine the expected date formats that are returned by the protocol file server. The default is as defined by the protocol file server.
listFileOldDateFormat	Optional. The old date format (more than a year) for FTP client directory listing on an FTP server. This attribute and the listFileRecentDateFormat attribute allow you to redefine the

Attribute	Description
	expected date formats that are returned by the protocol file server. The default is as defined by the protocol file server.
monthShortNames	Optional. A replacement list of month names that are used to decode date information returned from the protocol file server. This property consists of a list of 12 comma-separated names to override the default locale month values. The default is as defined by the protocol file server.

General attributes that apply to FTP servers only:

Attribute	Description
passiveMode	Optional. Controls whether the connection to the FTP server is passive or active. If you set the value of this property to <code>false</code> , the connection is active. If you set the value to <code>true</code> , the connection is passive. The default is <code>false</code> .

General attributes that apply to FTPS servers only:

Attribute	Description
ftpsType	Optional. Specifies whether the explicit or implicit form of the FTPS protocol is used. The default is <code>explicit</code> .
trustStore	Required. The location of the truststore that is used to determine whether the certificate presented by the FTPS server is trusted.
trustStoreType	Optional. The format of the truststore file. The default is <code>JKS</code> .
keyStore	Optional. The location of the keystore that is used to provide certificate information if challenged by the FTPS server. The default is for the protocol bridge to not be able to connect to FTPS servers that are configured to require the authentication of clients.
keyStoreType	Optional. The format of the keystore file. The default is <code>JKS</code> .
ccc	Optional. Selects whether a clear (unencrypted) command channel is used when authentication has completed. The default value is <code>false</code> , which means that the command channel remains encrypted for the entire duration of the FTPS session. This attribute is applicable only when the <code>ftpsType</code> is set to <code>explicit</code> .
protFirst	Optional. Specifies whether the USER/PASS commands are issued to the FTPS server before or after the PBSZ/PROT commands. The default value is <code>false</code> , which means USER/PASS commands are sent first followed by PBSZ/PROT commands. This attribute is applicable only when the <code>ftpsType</code> is set to <code>explicit</code> .
auth	Optional. Specifies the protocol that is specified as part of the AUTH command. A specified protocol will be tried first, then the default is to try <code>TLS</code> , <code>SSL</code> , <code>TLS-C</code> , or <code>TLS-P</code> until the FTPS server does not reject with a 504 reply code. This attribute is applicable only when the <code>ftpsType</code> is set to <code>explicit</code> .

General attributes that apply to SFTP servers only:

V 9.4.0

Important: The default values for the `cipherList` and the SFTP server specific attributes have changed from the IBM MQ 9.4.0 release.

You are likely to see the following error message after migration to IBM MQ 9.4.0:

```
BFGBR0127E: Bridge agent has rejected connection with {0} as its supplied host key does not match the expected value. Host key returned was {1}.
```

You can take one of the following actions to resolve the error:

1. Change the value of the **hostKey** attribute of the **tns:server** element in the `ProtocolBridgeCredentials.xml` file to the value {1}, provided in error message BFGBR0127E.
2. Specify the values for **cipherList**, **hostKeyCipherList**, **keyExchangeCipherList**, **MACCipherList**, and **fingerprintHash** attributes for your SFTP server in the `ProtocolBridgeProperties.xml` file to pre-IBM MQ 9.4.0 release. The following example sets the values for these attributes to pre-IBM MQ 9.4.0 release:

```
<tns:sftpServer name='yoursftpserver' fileEncoding='UTF-8' host='yoursftpserver.ibm.com' platform='unix'
limitedWrite='false'
  cipherList='aes128-ctr,aes128-cbc,3des-ctr,3des-cbc,blowfish-cbc,aes192-ctr,aes192-cbc,aes256-
ctr,aes256-cbc'
  hostKeyCipherList='ssh-rsa,ssh-dss,ecdsa-sha2-nistp256,ecdsa-sha2-nistp384,ecdsa-sha2-nistp521'
  keyExchangeCipherList='ecdh-sha2-nistp256,ecdh-sha2-nistp384,ecdh-sha2-nistp521,diffie-hellman-group14-
sha1,diffie-hellman-group-exchange-sha256,diffie-hellman-group-exchange-sha1,diffie-hellman-group1-sha1'
  MACCipherList='hmac-md5,hmac-sha1,hmac-sha2-256,hmac-sha1-96,hmac-md5-96'
  fingerprintHash='md5'>
  <tns:limits/>
</tns:sftpServer>
```

Attribute	Description
connectionTimeout	Optional. The time, in seconds, to wait for a response from the protocol file server to a connection request. A timeout indicates that the protocol file server is not available. The default value is 30 seconds.
cipherList	<p>Optional. Specifies a comma-separated list of ciphers that are used to communicate between the protocol bridge agent and the SFTP server. The ciphers are called in the order that they are specified in this list. The cipher must be available on the server and the client before it can be used.</p> <p>Note that the order of cipher names in the attribute value matters when bridge agent and SFTP Server negotiate a cipher to use for communication.</p> <p>The ciphers that the protocol bridge agent supports are as follows:</p> <ul style="list-style-type: none"> • aes128-ctr • aes192-ctr • aes256-ctr •  aes128-gcm •  aes256-gcm • aes128-cbc • 3des-ctr • 3des-cbc • blowfish-cbc • aes192-cbc • aes256-cbc <p>By default, the list of ciphers used by protocol bridge agents is aes128-ctr, aes192-ctr, aes256-ctr, aes128-gcm@openssh.com, aes256-gcm@openssh.com.</p>
 keyExchangeCipherList	Optional. Specifies a comma separated list of cipher names for key exchange. The cipher must be available on the server and the client before it can be used.

Attribute	Description
	<p>SSH key exchange (KEX for short) is used by the client (Bridge agent in this case) and SFTP server to exchange information in public that leads to the generation of a secret key shared by the client and server that an observer can't discover or derive from public information.</p> <p>Note that the order of cipher names in the attribute value matters when bridge agent and SFTP Server negotiate which cipher to use.</p> <p>Supported ciphers:</p> <ul style="list-style-type: none"> • curve25519-sha256 • ecdh-sha2-nistp256 • ecdh-sha2-nistp384 • ecdh-sha2-nistp521 • diffie-hellman-group-exchange-sha256 • diffie-hellman-group16-sha512 • diffie-hellman-group18-sha512 • diffie-hellman-group14-sha256 • diffie-hellman-group14-sha1 • diffie-hellman-group-exchange-sha1 • diffie-hellman-group1-sha1 <p>Default values:curve25519-sha256, curve25519-sha256@libssh.org, ecdh-sha2-nistp256, ecdh-sha2-nistp384, ecdh-sha2-nistp521, diffie-hellman-group-exchange-sha256, diffie-hellman-group16-sha512, diffie-hellman-group18-sha512, diffie-hellman-group14-sha256</p>
<p>V 9.4.0 hostKeyCipherList</p>	<p>Optional. Specifies a comma separated list of cipher names. The cipher must be available on the server and the client before it can be used.</p> <p>A host key (or public key of the server) uniquely identifies a SFTP server. The host key is specified in ProtocolBridgeCredentials.xml file. During negotiations, the SFTP server sends its host key to bridge agent. The bridge agent then compares the received host key with the one from ProtocolBridgeCredentials.xml file to ensure the bridge agent has connected to right SFTP server.</p> <p>If the keys are different, the connection is ended. A SFTP server can support multiple unique host keys generated using different ciphers. The ciphers list of this attribute determines what algorithm is used for host key generation.</p> <p>Note that the order of cipher names in the attribute value matters when bridge agent and SFTP Server negotiate which cipher to use.</p> <p>Supported ciphers:</p> <ul style="list-style-type: none"> • ssh-ed25519 • ecdsa-sha2-nistp256 • ecdsa-sha2-nistp384 • ecdsa-sha2-nistp521 • rsa-sha2-512

Attribute	Description
	<ul style="list-style-type: none"> • rsa-sha2-256 • ssh-rsa • ssh-dss <p>Default values:ssh-ed25519,ecdsa-sha2-nistp256,ecdsa-sha2-nistp384,ecdsa-sha2-nistp521,rsa-sha2-512,rsa-sha2-256</p>
<p>V 9.4.0 MACCipherList</p>	<p>Optional. Specifies a comma separated list of cipher names. The cipher must be available on the server and the client before it can be used.</p> <p>Message Authentication Code (MAC) is used to confirm data integrity and authenticity of message data. It is used to ensure no attacker has altered the message data in middle. The value defines the list of ciphers used for MAC.</p> <p>Note that the order of cipher names in the attribute value matters when bridge agent and SFTP Server negotiate which cipher to use.</p> <p>Supported ciphers:</p> <ul style="list-style-type: none"> • hmac-sha2-256-etm • hmac-sha2-512-etm • hmac-sha1-etm • hmac-sha2-256 • hmac-sha2-512 • hmac-sha1 • hmac-md5 • hmac-sha1-96 • hmac-md5-96 <p>Default values:hmac-sha2-256-etm,hmac-sha2-512-etm,hmac-sha1-etm,hmac-sha2-256,hmac-sha2-512,hmac-sha1</p>
<p>V 9.4.0 fingerprintHash</p>	<p>Optional. Specifies the name of the hashing algorithm used for hostKey.</p> <p>Depending on the algorithm used, the value of host key differs. An SFTP server can support all three hashing algorithms and the client can choose a suitable one; preferably a stronger algorithm.</p> <p>Supported values:</p> <ul style="list-style-type: none"> • md5 • sha1 • sha256. <p>Default value:sha256</p>

V 9.4.0 Example of the revised output:

```
<tns:sftpServer name='elbow' fileEncoding='UTF-8' host='elbow.v6.hursley.ibm.com' platform='unix'
limitedWrite='false'
cipherList= 'aes128-ctr,aes192-ctr,aes256-ctr,aes128-gcm,aes256-gcm'
hostKeyCipherList='ssh-ed25519,ecdsa-sha2-nistp256,ecdsa-sha2-nistp384,ecdsa-sha2-nistp521,rsa-
sha2-512,rsa-sha2-256'
keyExchangeCipherList= 'curve25519-sha256,curve25519-sha256,ecdh-sha2-nistp256,ecdh-sha2-nistp384,ecdh-
sha2-nistp521,
diffie-hellman-group-exchange-sha256,diffie-hellman-group16-sha512,diffie-
hellman-group18-sha512,
```

```

diffie-hellman-group14-sha256'
MACCipherList='hmac-sha2-256-etm,hmac-sha2-512-etm,hmac-sha1-etm,hmac-sha2-256,hmac-sha2-512,hmac-sha1'
fingerprintHash='sha256'>
<tns:limits/>
</tns:sftpServer>

```

General limit attributes that apply to all types of protocol file server:

Attribute	Description
maxListFileNames	Optional. The maximum number of names that are collected when scanning a directory on the protocol file server for file names. The default is 999999999.
maxListDirectoryLevels	Optional. The maximum number of directory levels on the protocol server to recursively scan for file names. The default is 1000.
 maxReconnectRetry	Optional. The maximum number of times a protocol server tries to reconnect before the protocol bridge agent stops trying. The default is 2.
 reconnectWaitPeriod	Optional. The time period, in seconds, to wait to before attempting to reconnect. The default is 10 seconds.
maxSessions	Optional. The maximum number of sessions for the protocol server. This number must be greater than or equal to the sum of the maximum number of source and destination transfers for the protocol bridge agent. The default is the sum of the values for the agent properties maxSourceTransfers, maxDestinationTransfers, and maxCommandHandlerThreads, plus 1. If these three properties are using their default values of 25, 25, and 5, the maxSessions default is then 56.
socketTimeout	Optional. The socket timeout in seconds. The value of this attribute is used during file streaming. The default is 30 seconds.
maxActiveDestinationTransfers (global property)	Optional. Used to specify the global value, to limit the number of active transfers for each destination *ftp* endpoint. This is a non-zero positive integer with a minimum value of 0 and a maximum value of 1. maxActiveDestinationTransfers requires the use of an AttributeName.
maxActiveDestinationTransfers (individual server level)	Optional. Used to specify the limit of the number of active transfers for each destination *ftp* endpoint. This is a non-negative integer. This property can be utilized by any of the three servers, and if specified, this value overrides the global value of maxActiveDestinationTransfers for that endpoint server. The value of this property cannot exceed the value of maxDestinationTransfers. If you exceed this value, the protocol bridge agent assumes that this value is not set and processes the managed transfers in the standard existing flow. Message BFGSS0088W is logged in the output0.log file.  Attention: It is possible to over commit the new maxActiveDestinationTransfers properties. That is, you can have the sum of maxActiveDestinationTransfers for all the endpoints greater than the value of

Attribute	Description
	<p>maxDestinationTransfers. You must consider whether this feature is appropriate for your enterprise.</p>
<p>failTransferWhenCapacityReached (global property)</p>	<p>Optional. This is a non-zero positive integer with a minimum value of 0 and a maximum value of 1.</p> <p>failTransferWhenCapacityReached requires the use of an <code>AttributeName</code>.</p> <p>Applies to both <code>maxDestinationTransfers</code> and <code>maxActiveDestinationTransfers</code> and can be used to specify whether to fail a protocol bridge agent transfer in the following cases:</p> <ul style="list-style-type: none"> When the total number of active transfers for an endpoint server exceeds the <code>maxDestinationTransfers</code> count, the two possible conditions are: <ul style="list-style-type: none"> failTransferWhenCapacityReached = false Takes the standard existing route of handling the managed transfers. failTransferWhenCapacityReached = true Fails the transfer if the total number of active transfers is greater than <code>maxActiveTransfers</code> When the total number of active transfers for an endpoint server exceeds the <code>maxActiveDestinationTransfers</code> count, the two possible values are: <ul style="list-style-type: none"> failTransferWhenCapacityReached = false The default value which applies if <code>maxActiveDestinationTransfers</code> is not set. Once the number of active transfers for an endpoint server exceeds the <code>maxActiveDestinationTransfers</code> value, the next managed transfer to that particular endpoint server is rejected and moved to a new state called <code>WaitingForDestinationFileServerCapacity</code> by the protocol bridge agent. Source agents then handle this state in the same way as they currently do for managed transfers that go into a <code>WaitingForDestinationCapacity</code> state; that is, wait for a period of time before contacting the destination agent again. failTransferWhenCapacityReached = true Once the number of active transfers for an endpoint server exceeds <code>maxActiveDestinationTransfers</code> value, the next managed transfer to that particular endpoint server is rejected and marked as failed by the protocol bridge agent.

Connect:Direct credentials file format

The `ConnectDirectCredentials.xml` file in the Managed File Transfer Agent configuration directory defines the user names and credential information that the Connect:Direct agent uses to authorize itself with a Connect:Direct node.

The `ConnectDirectCredentials.xml` file must conform to the `ConnectDirectCredentials.xsd` schema. The `ConnectDirectCredentials.xsd` schema document is located in the `MQ_INSTALLATION_PATH/mqft/samples/schema` directory of the MQMFT installation. A sample `ConnectDirectCredentials.xml` file is located in the `MQ_INSTALLATION_PATH/mqft/samples/credentials` directory of the MQMFT installation.

The file `ConnectDirectCredentials.xml` is periodically reloaded by the agent and any valid changes to the file will affect the behavior of the agent. The default reload interval is 30 seconds. This interval can be changed by specifying the agent property `xmlConfigReloadInterval` in the `agent.properties` file.

```

Understanding the ConnectDirectCredentials.xml file

The elements and attributes used in the ConnectDirectCredentials.xml file are described in the following list.

<credentials>

Group element containing elements that describe the credentials used by a Connect:Direct bridge agent to connect to a Connect:Direct node.

<agent>

Group element containing elements for <pnode> definitions for a named agent.

<pnode>

The primary node (PNODE) in the Connect:Direct transfer. This node initiates the connection to the secondary node (SNODE).

Attribute	Description
name	The name of the Connect:Direct node. The value of this attribute can be a pattern that matches many node names.
pattern	Specifies the type of pattern that is used for the value of the name attribute. Valid values for the pattern attribute are <ul style="list-style-type: none"> wildcard - wildcards are used regex - Java regular expressions are used

<user>

The IBM MQ user that submits the transfer request.

Attribute	Description
name	The user name that is used with Managed File Transfer. The value of this attribute can be a pattern that matches many user names.
ignorecase	Specifies whether the case of the name is ignored. Valid values for the ignorecase attribute are <ul style="list-style-type: none"> • true - the name is not case sensitive • false - the name is case sensitive
pattern	Specifies the type of pattern that is used for the value of the name attribute. Valid values for the pattern attribute are <ul style="list-style-type: none"> • wildcard - wildcards are used • regex - Java regular expressions are used
cdUserId or cdUserIdCipher	The user name that is used by the Connect:Direct bridge to connect to its associated Connect:Direct node. If the fteObfuscate command has been used then the cipher version of the attribute must be used.
cdPassword or cdPasswordCipher	The password associated with the user name specified by the cdUserId attribute. If the fteObfuscate command has been used then the cipher version of the attribute must be used.
pnodeUserId or pnodeUserIdCipher	The user name that is used by the Connect:Direct primary node. If the fteObfuscate command has been used then the cipher version of the attribute must be used.
pnodePassword or pnodePasswordCipher	The password associated with the user name specified by the pnodeUserId attribute. If the fteObfuscate command has been used then the cipher version of the attribute must be used.

<snode>

The Connect:Direct node that performs the role of secondary node (SNODE) during the Connect:Direct file transfer.

Attribute	Description
name	The name of the Connect:Direct node. The value of this attribute can be a pattern that matches many node names.
pattern	Specifies the type of pattern that is used for the value of the name attribute. Valid values for the pattern attribute are <ul style="list-style-type: none"> • wildcard - wildcards are used • regex - Java regular expressions are used
userId or userIdCipher	The user name used to connect to this node during a file transfer. If the fteObfuscate command has been used then the cipher version of the attribute must be used.
password or passwordCipher	The password associated with the user name specified by the userId attribute. If the fteObfuscate command has been used then the cipher version of the attribute must be used.

Example

In this example, the Connect:Direct bridge agent connects to the Connect:Direct node pnode1. When an IBM MQ user with the user name beginning with the prefix fteuser followed by a single character, for example fteuser2, requests a transfer involving the Connect:Direct bridge, the Connect:Direct bridge agent will use the user name cduser and the password passw0rd to connect to the Connect:Direct node pnode1. When the Connect:Direct node pnode1 performs its part of the transfer it uses the user name pnodeuser and the password passw0rd1.

If the secondary node in the Connect:Direct transfer has a name that begins with the prefix FISH, the node pnode1 uses the user name fishuser and the password passw0rd2 to connect to the secondary node. If the secondary node in the Connect:Direct transfer has a name that begins with the prefix CHIPS, the node pnode1 uses the user name chipsuser and the password passw0rd3 to connect to the secondary node.

```
<?xml version="1.0" encoding="UTF-8"?>
<tns:credentials xmlns:tns="http://wmqfte.ibm.com/ConnectDirectCredentials"
  xmlns:xsi="https://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://wmqfte.ibm.com/ConnectDirectCredentials
ConnectDirectCredentials.xsd">
  <tns:agent name="CDAGENT01">
    <tns:pnode name="pnode1" pattern="wildcard">
      <tns:user name="fteuser?" pattern="wildcard" ignorecase="true"
        cdUserId="cduser" cdPassword="passw0rd"
        pnodeUserId="pnodeuser" pnodePassword="passw0rd1">
      <tns:snode name="FISH*" pattern="wildcard"
        userId="fishuser" password="passw0rd2"/>
      <tns:snode name="CHIPS*" pattern="wildcard"
        userId="chipsuser" password="passw0rd3"/>
    </tns:user>
  </tns:pnode>
</tns:agent>
</tns:credentials>
```

Related reference

[“fteCreateCDAgent \(create a Connect:Direct bridge agent\)” on page 2043](#)

The fteCreateCDAgent command creates a Managed File Transfer Agent and its associated configuration for use with the Connect:Direct bridge.

[The Connect:Direct bridge](#)

[“Regular expressions used by MFT” on page 2556](#)

Managed File Transfer uses regular expressions in a number of scenarios. For example, regular expressions are used to match user IDs for Connect:Direct security credentials, or to split a file into multiple messages by creating a new message each time a regular expression is matched. The regular expression syntax used by Managed File Transfer is the syntax supported by the `java.util.regex` API. This regular expression syntax is similar to, but not the same as, the regular expression syntax used by the Perl language.

Connect:Direct process definitions file format

The `ConnectDirectProcessDefinitions.xml` file in the Connect:Direct bridge agent configuration directory specifies the user-defined Connect:Direct process to start as part of the file transfer.

The `ConnectDirectProcessDefinitions.xml` file must conform to the `ConnectDirectProcessDefinitions.xsd` schema. The `ConnectDirectProcessDefinitions.xsd` schema document is located in the `MQ_INSTALLATION_PATH/mqft/samples/schema` directory of the MFT installation. A template `ConnectDirectProcessDefinitions.xml` file is created by the **fteCreateCDAgent** command in the agent configuration directory.

The file `ConnectDirectProcessDefinitions.xml` is periodically reloaded by the agent and any valid changes to the file will affect the behavior of the agent. The default reload interval is 30 seconds. This interval can be changed by specifying the agent property `xmlConfigReloadInterval` in the `agent.properties` file.

Schema

The following schema describes which elements are valid in the ConnectDirectProcessDefinitions.xml file.

```
<schema targetNamespace="http://wmqfte.ibm.com/ConnectDirectProcessDefinitions"
  elementFormDefault="qualified"
  xmlns="https://www.w3.org/2001/XMLSchema"

      <enumeration value="wildcard" />
    </restriction>
  </simpleType>

</schema>
```

Understanding the ConnectDirectProcessDefinitions.xml file

The elements and attributes used in the ConnectDirectProcessDefinitions.xml file are described in the following list.

cdProcess

The root element of the XML document.

processSet

Group element containing all the information about a set of user-defined processes.

condition

Group element containing the conditions that a transfer is tested against to determine whether the set of processes contained in the processSet element are used.

match

A condition that tests whether a the value of a variable matches a given value.

Attribute	Description
variable	Specifies a variable. The value of this variable is compared with the value of the value attribute. The variable is an intrinsic symbol. For more information, see “Substitution variables for use with user-defined Connect:Direct processes” on page 2556.
value	Specifies a pattern to match against the value of the variable specified by the variable attribute.
pattern	Specifies the type of pattern that is used for the value of the value attribute. Valid values for the pattern attribute are <ul style="list-style-type: none"> • <code>wildcard</code> - wildcards are used • <code>regex</code> - Java regular expressions are used This attribute is optional and the default is <code>wildcard</code> .

defined

A condition that tests whether a variable has been defined.

Attribute	Description
variable	Specifies a variable. If this variable exists, the match condition is satisfied. The variable is an intrinsic symbol. For more information, see “Substitution variables for use with user-defined Connect:Direct processes” on page 2556.

process

Group element containing the information about where to locate the Connect:Direct processes to call when a match is found.

transfer

The Connect:Direct process to call during a transfer request.

Attribute	Description
process	Optional. Specifies the name of a file that contains a Connect:Direct process to call during a transfer request. The file path is relative to the Connect:Direct bridge agent configuration directory. This attribute is optional, the default is to use a process generated by MFT. For IBM WebSphere MQ 7.5 or later, the value of this property can contain environment variables. For more information, see Environment variables in MFT properties

Example

In this example, there are three processSet elements.

The first processSet element specifies that if a transfer request has a **%FTESNODE** variable with a value that matches the pattern `Client*` and a **%FTESUSER** variable with a value of `Admin`, the Connect:Direct bridge agent submits the Connect:Direct process located in the `agent_configuration_directory/AdminClient.cdp` as part of the transfer.

The second processSet element specifies that if a transfer request has a **%FTESNODE** variable with a value that matches the pattern `Client*`, the Connect:Direct bridge agent submits the Connect:Direct process located in the `agent_configuration_directory/Client.cdp` as part of the transfer. The Connect:Direct bridge agent reads the processSet elements in the order that they are defined, and if it finds a match, it uses the first match and does not look for another match. For transfer requests that match the conditions of both the first and second processSet, the Connect:Direct bridge agent calls only the processes specified by the first processSet.

The third processSet element has no conditions and matches all transfers. If the transfer request does not match the conditions of the first or second processSet, the Connect:Direct bridge agent submits the Connect:Direct process specified by the third condition. This process is located in the `agent_configuration_directory/Default.cdp` as part of the transfer.

```
<?xml version="1.0" encoding="UTF-8"?>
<tns:cdprocess xmlns:tns="http://wmqfte.ibm.com/ConnectDirectProcessDefinitions"
  xmlns:xsi="https://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://wmqfte.ibm.com/ConnectDirectProcessDefinitions
ConnectDirectProcessDefinitions.xsd">

  <tns:processSet>
    <tns:condition>
      <tns:match variable="%FTESNODE" value="Client*" pattern="wildcard" />
      <tns:match variable="%FTESUSER" value="Admin" pattern="wildcard" />
    </tns:condition>
    <tns:process>
      <tns:transfer process="AdminClient.cdp" />
    </tns:process>
  </tns:processSet>

  <tns:processSet>
    <tns:condition>
      <tns:match variable="%FTESNODE" value="Client*" pattern="wildcard" />
    </tns:condition>
    <tns:process>
      <tns:transfer process="Client.cdp" />
    </tns:process>
  </tns:processSet>

  <tns:processSet>
    <tns:process>
      <tns:transfer process="Default.cdp" />
    </tns:process>
  </tns:processSet>

</tns:cdprocess>
```

Connect:Direct node properties file format

The ConnectDirectNodeProperties.xml file in the Connect:Direct bridge agent configuration directory specifies information about remote Connect:Direct nodes that are involved in a file transfer.

The ConnectDirectNodeProperties.xml file must conform to the ConnectDirectNodeProperties.xsd schema. The ConnectDirectNodeProperties.xsd schema document is located in the `MQ_INSTALLATION_PATH/mqft/samples/schema` directory of the MFT installation. A template ConnectDirectNodeProperties.xml file is created by the **fteCreateCDAgent** command in the agent configuration directory.

The file ConnectDirectNodeProperties.xml is periodically reloaded by the agent and any valid changes to the file will affect the behavior of the agent. The default reload interval is 30 seconds. This interval can be changed by specifying the agent property `xmlConfigReloadInterval` in the agent.properties file.

Schema

The following schema describes which elements are valid in the ConnectDirectNodeProperties.xml file.

```
<?xml version="1.0" encoding="UTF-8"?>
<schema targetNamespace="http://wmqfte.ibm.com/ConnectDirectNodeProperties"
  elementFormDefault="qualified"
  xmlns="https://www.w3.org/2001/XMLSchema"
  xmlns:tns="http://wmqfte.ibm.com/ConnectDirectNodeProperties">
  <element name="nodeProperties" type="tns:nodePropertiesType"></element>
  <complexType name="nodePropertiesType">

      <enumeration value="regex" />
      <enumeration value="wildcard" />
    </restriction>
  </simpleType>
</schema>
```

Understanding the ConnectDirectNodeProperties.xml file

The elements and attributes used in the ConnectDirectNodeProperties.xml file are described in the following list.

nodeProperties

Root element of the XML document.

credentialsFile

Path to the credentials file where sensitive information is stored. For IBM WebSphere MQ 7.5 or later, the value of this property can contain environment variables. For more information, see [Environment variables in MFT properties](#)

node

Specifies one or more Connect:Direct nodes.

Attribute	Description
name	A pattern that identifies the names of Connect:Direct nodes that use the definitions specified by the node element. Pattern matching is not case sensitive.
pattern	Specifies the type of pattern that is used for the value of the name attribute. Valid values for the pattern attribute are: <ul style="list-style-type: none"> wildcard - wildcards are used regex - Java regular expressions are used For information about the types of regular expressions used by MFT, see “Regular expressions used by MFT” on page 2556.
type	Specifies the operating system type of the Connect:Direct node or nodes that match the pattern given by the name attribute. Valid values for the type attribute are: <ul style="list-style-type: none"> Windows - the node runs on Windows UNIX - the node runs on AIX and Linux  z/OS, zos, os/390, or os390 - the node runs on z/OS The value of this attribute is not case sensitive.

Example

In this example, the Connect:Direct credentials filename is specified as `ConnectDirectCredentials.xml`. The example code specifies the following platform connections:

- All Connect:Direct nodes that have a name that begins with "cdnodew" run on the Windows platform.
- All Connect:Direct nodes that have a name that begins with "cdnodeu" run on the AIX and Linux platforms.
- All Connect:Direct nodes that have a name that begins with "cdnodez" run on the z/OS platform.
- All other Connect:Direct nodes run on the AIX and Linux platforms.

The Connect:Direct bridge agent searches for matches from the start of the file to the end, and uses the first match that it finds.

```
<?xml version="1.0" encoding="UTF-8"?>
<tns:nodeProperties xmlns:tns="http://wmqfte.ibm.com/ConnectDirectNodeProperties"
  xmlns:xsi="https://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://wmqfte.ibm.com/ConnectDirectNodeProperties
    ConnectDirectNodeProperties.xsd">

  <tns:credentialsFile path="ConnectDirectCredentials.xml" />
  <tns:node name="cdnodew*" pattern="wildcard" type="windows" />
  <tns:node name="cdnodeu.*" pattern="regex" type="unix" />
  <tns:node name="cdnodez*" pattern="wildcard" type="zos" />
  <tns:node name="*" pattern="wildcard" type="unix" />

</tns:nodeProperties>
```

Table 385. The remaining IBM MQ utilities

Name	Purpose	See topic
CSQJU004 (Print log map utility)	List information about the log.	“The print log map utility (CSQJU004) on z/OS” on page 2817
CSQ1LOGP (Log print utility)	Print the log. Extract log records into sequential files.	“The log print utility (CSQ1LOGP) on z/OS” on page 2818
CSQ5PQSG (IBM MQ table update utility)	Add and remove queue sharing group and queue manager entries in the IBM MQ tables held in the shared Db2 data-sharing group.	“The queue sharing group utility (CSQ5PQSG) on z/OS” on page 2830
CSQJUFMT (Active log preformat utility)	Preformat log data sets Preformat Shared Message Data Sets (SMDS)	“The active log preformat utility (CSQJUFMT) on z/OS” on page 2833
CSQUDLQH (Dead-letter queue handler utility)	Process messages on the dead-letter queue.	“The dead-letter queue handler utility (CSQUDLQH) on z/OS” on page 2834
CSQUCVX (Data conversion exit utility)	Generate data conversion exit routines.	Writing a data-conversion exit program for IBM MQ for z/OS
CSQUDSPM (Display queue manager utility)	Display information about queue managers. The equivalent function on Multiplatforms is dspmq .	“Display queue manager information utility (CSQUDSPM)” on page 2847

These utilities are located in the `hlq1.SCSQAUTH` or `hlq1.SCSQLOAD` IBM MQ load libraries. Concatenate the appropriate IBM MQ language load library `hlq1.SCSQANLx` (where x is the language letter) in the STEPLIB with the `hlq1.SCSQAUTH` and `hlq1.SCSQLOAD`.

Note: Failing to do so leads to unpredictable results (including issues with queue manager initialization).

Depending upon the utility work that your enterprise undertakes, you should use versions of the libraries at the same level as your queue managers where possible.

The utility control statements are available only in U.S. English. In some cases, the Db2 library `db2qua1.SDSNLOAD` is also needed.

IBM MQ utility program (CSQUTIL) on z/OS

The CSQUTIL utility program is provided with IBM MQ to help you to perform backup, restoration, and reorganization tasks, and to issue IBM MQ commands.

Through this utility program, you can invoke functions in these groups:

Page set management

These functions enable you to manage IBM MQ page sets. You can format data sets as page sets, change the recovery processing performed against page sets, extract page set information, increase the size of page sets and reset the log information contained in a page set. The page set must not belong to a queue manager that is currently running.

Command management

These functions enable you to:

- Issue commands to IBM MQ
- Produce a list of DEFINE, ALTER, or DELETE commands for your IBM MQ objects

Queue management

These functions enable you to back up and restore queues and page sets, copy queues and page sets to another queue manager, reset your queue manager, or to migrate from one queue manager to another.

Specifically, you can:

- Copy messages from a queue to a data set
- Delete messages from a queue
- Restore previously copied messages to their appropriate queues

The scope of these functions can be either:

- A *queue*, in which case the function operates on all messages in the specified queue.
- A *page set*, in which case the function operates on all the messages, in all the queues, on the specified page set.

Use these functions only for your own queues; do not use them for system queues (those with names beginning SYSTEM).

All the page set management functions, and some of the other functions, operate while the queue manager is not running, so you do not need any special authorization other than the appropriate access to the page set data sets. For the functions that operate while the queue manager is running, CSQUTIL runs as an ordinary z/OS batch IBM MQ program, issuing commands through the command server, and using the IBM MQ API to access queues.

You need the necessary authority to use the command server queues (SYSTEM.COMMAND.INPUT, SYSTEM.COMMAND.REPLY.MODEL, and SYSTEM.CSQUTIL.*), to use the IBM MQ DISPLAY commands, and to use the IBM MQ API to access any queues that you want to manage. See the usage notes for each function for more information.

Attention: If you use CSQUTIL to define a channel, and the connection name contains two parts (the host name and port number) you must enclose the host name and port number within single quotation marks to maintain the limit on the number of permissible parameters. Similarly, if your connection name consists of an IP address and port number, you must enclose these parameters within single quotation marks.

Invoking the IBM MQ utility program on z/OS

Use this topic to understand how to invoke CSQUTIL, the format of its parameters, and its return codes.

The CSQUTIL utility program runs as a z/OS batch program, below the 16 MB storage line. Specify the resources that the utility is to work with in the PARM parameter of the EXEC statement of the JCL.

```
// EXEC PGM=CSQUTIL,PARM=
```

Figure 11. How to invoke the CSQUTIL utility program

where PARM= expands to:

- [PARM parameters](#)
- [Return codes](#)

PARM parameters

QMGRname

Specifies the 1- to 4-character name of the queue manager or queue sharing group to which CSQUTIL is to connect.

If you specify the name of a queue sharing group, CSQUTIL connects to any queue manager in that group

QSGname

Specifies the 1- to 4-character name of the queue sharing group from which CSQUTIL is to extract definitions.

DSGname

Specifies the 8-character name of the Db2 data-sharing group from which CSQUTIL is to extract definitions.

db2ssid

Specifies the 4-character name, or group attach name, of the Db2 database subsystem to which CSQUTIL is to attach for stand-alone functions.

Which PARM parameters do you need?

Figure 11 on page 2775 shows that you can specify one of four options on the PARM statement. The option you specify depends on the function you need to implement, as follows:

- Use PARM= (or omit it all together) if you are using only offline functions, and not QSGDISP(GROUP) or QSGDISP(SHARED).
- Use PARM= ' QMGRname ' only if you intend to use functions that require the queue manager to be running, such as COPY and COMMAND.
- Use PARM= ' QSGname , DSGname , db2ssid ' if you intend to use the SDEFS function with either QSGDISP(GROUP) or QSGDISP(SHARED) specified. This is because CSQUTIL requires access to Db2 to perform the SDEFS function in this situation.
- Use PARM= ' QMGRname , QSGname , DSGname , db2ssid ' if you intend to combine the previous two functions in one CSQUTIL job.

If you specify a queue manager name as blanks, CSQUTIL uses the name of the default queue manager specified for z/OS batch programs in CSQBDEFV. The utility then uses this queue manager for the whole job step. When the utility connects to the queue manager, the authorization of the "signed-on user name" is checked to see which functions the invocation is allowed to use.

You specify the functions required by statements in the SYSIN data set according to these rules:

- The data set must have a record length of 80.
- Only columns 1 through 72 are significant. Columns 73 through 80 are ignored.
- Records with an asterisk (*) in column 1 are interpreted as comments and are ignored.
- Blank records are ignored.
- Each statement must start on a new line.

- A trailing - means continue from column 1 of the next record.
- A trailing + means continue from the first non-blank column of the next record.
- The keywords of statements are not case-sensitive. However, some arguments, such as queue name, are case sensitive.

The utility statements refer to the default or explicitly named DDnames for input and output. Your job can use the COPY and LOAD functions repeatedly and process different page sets or queues during a single run of the utility.

All output messages are sent to the SYSPRINT data set, which must have a record format of VBA and a record length of 125.

While running, CSQUTIL uses temporary dynamic queues with names of the form SYSTEM.CSQUTIL.*

Return codes

When you are using the COMMAND verb to issue MQSC commands, you must use FAILURE(CONTINUE) so any failure in the commands that are issued give a non-zero return code. The default is FAILURE(IGNORE) and the return code from the command is always zero.

When CSQUTIL returns to the operating system, the return code can be:

0

All functions completed successfully.

4

Some functions completed successfully, some did not, or forced a sync point.

8

All the attempted functions failed.

12

No functions attempted; there was a syntax error in the statements or the expected data sets were missing.

In most cases, if a function fails or is forced to take a sync point, no further functions are attempted. In this case, the message CSQU147I replaces the normal completion message CSQU148I.

See the usage notes for each function for more information about success or failure.

Syncpoints

The queue management functions used when the queue manager is running operate within a syncpoint so that, if a function fails, its effects can be backed out. The queue manager attribute, MAXUMSGS, specifies the maximum number of messages that a task can get or put within a single unit of recovery.

The utility issues an MQCMIT call when the MAXUMSGS limit is reached and issues the warning message CSQU087I. If the utility later fails, the changes already committed are not backed out.

Do not just rerun the utility to correct the problem or you might get duplicate messages on your queues.

Instead, use the current depth of the queue to work out, from the utility output, which messages have not been backed out. Then determine the most appropriate course of action. For example, if the function is LOAD, you can empty the queue and start again, or you can choose to accept duplicate messages on the queues.

To avoid such difficulties if the function fails, there are two options:

1. Temporarily increase the value of MAXUMSGS to be greater than the number of messages in the:
 - Queue, if you are working with a single queue.
 - Longest queue in the page set, if you are working with an entire page set.

Use the `DISPLAY QSTATUS` command to find out the value of the `CURDEPTH` attribute, which is the current depth of the queue.

To find out the value of `MAXUMSGS`, use the `DISPLAY QMGR MAXUMSGS` command.

Then rerun the command, and after the utility has successfully run change `MAXUMSGS` back to what it was before.

Note: This approach is simpler but having a large number of messages in a single unit of work can incur a high CPU cost.

2. Use the utility to `LOAD` the messages to a temporary queue.

Note that you can delete the temporary queue in the event of failure and the job rerun.

Then use the `MQSC MOVE` command to move the messages from the temporary queue to the target queue. For example:

```
MOVE QL(tempq) TOQLLOCAL(targetq) TYPE(ADD)
```

Once the command has completed successfully, you can delete the temporary queue.

This approach takes longer, but moves the messages in a number of small units of work so is more efficient in terms of CPU cost.

Monitoring the progress of the IBM MQ utility program on z/OS

You can monitor the progress of the `CSQUTIL` program by monitoring statements output to `SYSPRINT`.

To record the progress of `CSQUTIL`, every `SYSIN` statement is echoed to `SYSPRINT`.

The utility first checks the syntax of the statements in the `SYSIN`. The requested functions are started only if all the statements are syntactically correct.

Messages giving a commentary on the progress of each function are sent to `SYSPRINT`. When the processing of the utility is complete, statistics are printed with an indication of how the functions completed.

Formatting page sets (FORMAT) on z/OS

You can use the `CSQUTIL` program to format page sets.

Use the `FORMAT` function to format page sets on all data sets specified by `DDnames` `CSQP0000` through `CSQP0099`. In this way, you can format up to 100 page sets in a single invocation of the utility program. Use the `FORCE` keyword to reuse existing data sets.

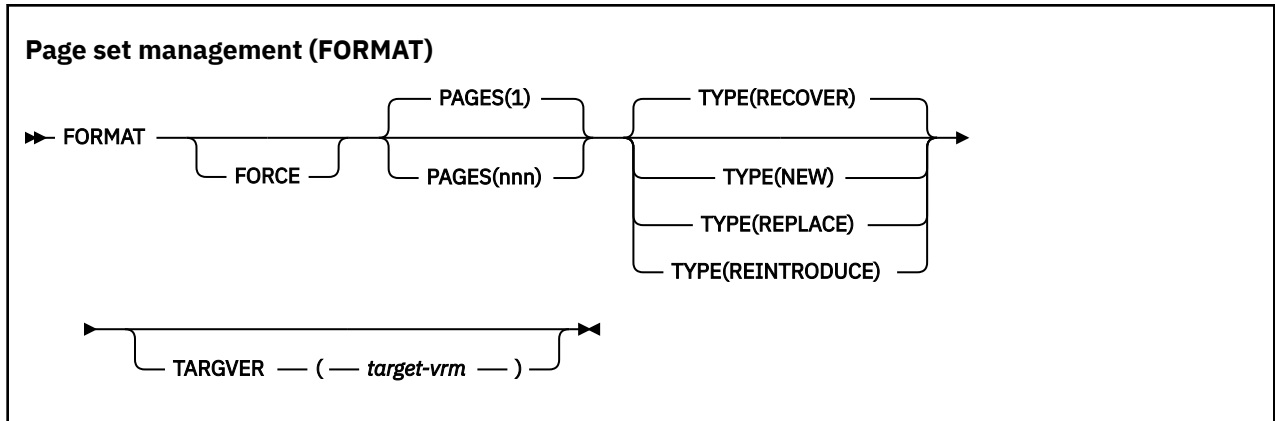

You can also use the `FORMAT` function to change the recovery processing that is performed against page sets when the queue manager starts, using the `TYPE` keyword. This can assist in changing or recovering page sets, or reintroducing page sets that have been offline or suspended.

In summary, to:

- Reinststate a page set with no data, use `FORMAT` with the `TYPE(NEW)` option
- Reinststate a page set with old data, use `FORMAT` with the `TYPE(REPLACE)` option
- Reinststate a page set with old data made up-to-date, do not use `FORMAT` but start the queue manager with a backed-up copy of the page set
- Reintroduce a page set that was offline when the queue manager was backwards migrated using the `START QMGR BACKMIG` command, use `FORMAT` with the `TYPE(REINTRODUCE)` option.

Page sets have identifiers (`PSIDs`, in the range 00 through 99) which are established by the `DDnames` used for the data sets in the queue manager started task procedure; `DDname` `CSQP00nn` specifies the page set with identifier `nn`. The `DDnames` you use for the `FORMAT` function do not have to correspond

to those used in the queue manager started task procedure, and do not therefore have any significance regarding page set identifiers.

- [Keywords and parameters](#)
- [Example](#)
- [Usage notes](#)

Keywords and parameters

FORCE

Specifies that existing data sets are to be reused without having to delete and redefine them first. You must define any page sets you want to reuse with the REUSE attribute in the AMS DEFINE CLUSTER statement.

See the [Optional Parameters](#) section of the z/OS DEFINE CLUSTER command for more information on REUSE.

The following code is an example on how you set REUSE:

```
//IDCAMS EXEC PGM=IDCAMS,REGION=0M
//SYSPRINT DD SYSOUT=*
//SYSIN DD *
ALTER VICY.MQOM.PSID04 REUSE
/*
```

To undo the REUSE option, use the ALTER attribute to change the REUSE parameter to NOREUSE.

The FORCE keyword is not valid if TYPE(REPLACE) is specified.

PAGES (nnn)

Specifies the minimum number of pages to format in each page set. This enables a data set that spans more than one volume to be formatted.

Formatting of the data set is always done in whole space allocations, as specified as primary or secondary quantities when the data set is defined. The number of space allocations formatted is the minimum necessary to provide the requested number of pages; if there is insufficient data set space available, as many extents as can be obtained are formatted. If an existing page set is being reused (with the FORCE keyword), the whole page set is formatted, if that is larger.

The number of pages must be in the range 1 through 16 777 213 (because the maximum page set size is 64 GB (gigabytes)). The default is 1.

The PAGES keyword is not valid if TYPE(REPLACE) is specified.

TYPE

Specifies the type of recovery processing that is performed against queue manager page sets. Values are:

RECOVER

Use RECOVER for a data set that is to be a new page set for a queue manager (that is, to have a PSID which was never been used before).

This is the default.

The data set is formatted, and any messages or other data are erased. If a DDname is added to the queue manager's started task procedure for the new PSID that specifies this data set, it will be recognized as a new page set when the queue manager is restarted.

If such a data set was used as a page set with a PSID that has been used before, on restart the queue manager attempts to recover all queues and their messages that use storage classes that reference the page set from the time the page set was first used. This may make restart a lengthy process, and is unlikely to be what is wanted.

NEW

Use NEW for a data set that is to be a page set with a PSID that has been used before for a queue manager and with data that can be discarded, to restart a failed queue manager quickly or to reintroduce the page set after it has been offline or suspended.

The data set is formatted, and any messages or other data are erased. When the queue manager is restarted, with a DDname for the old PSID that specifies this data set, it does not recover the page set but treats it as if it has been newly added to the queue manager, and any historical information about it is discarded. All queues that use storage classes referencing this page set are cleared of all messages, in a similar fashion to the way that nonpersistent messages are cleared during restart processing. This means that there will be no effect on restart time.

REPLACE

Use REPLACE for a data set with a PSID that has been used before for a queue manager and with data that is known to be consistent and up to date, to reintroduce the page set after being offline or suspended.

The data set is not formatted, and any messages or other data are preserved. When the queue manager is restarted with a DDname for the PSID that specifies this data set, it does not recover the page set but treats it as if it has never been offline, or suspended, and any historical information about it is retained. All queues that use storage classes that reference the page set keep their messages. This means that there will be no effect on restart time.

This option will only be successful if the page set is in a consistent state; that is, on its last use the queue manager was terminated normally by a STOP QMGR MODE(FORCE) or MODE(QUIESCE) command.

REINTRODUCE

Use REINTRODUCE for a data set that was offline when the queue manager was backward migrated using the START QMGR BACKMIG command, and you want to reintroduce the page set with old data made up-to-date, or if you want to reintroduce the data set with old data.

If you want to reintroduce the data set with old data, you also need to subsequently run FORMAT TYPE(REPLACE) CSQUTIL against the data set.

The data set is migrated to the version specified by the TARGVER keyword, and the data is not changed.

TYPE(REINTRODUCE) is not valid for page set zero.

The version of CSQUTIL must match the version of queue manager that last used the IBM MQ page set when TYPE(REINTRODUCE) is used. The command fails if migration is not allowed to the version specified by the TARGVER keyword.

You can also use TYPE(NEW) or TYPE(RECOVER) with CSQUTIL, at the migration target version to reintroduce the page set at that version.

TARGVER

Specifies the target version for the formatted page set

target-*vr*m

The version, release and modification number for the target version for TYPE(REINTRODUCE), for example 910.

This must be an LTS release, otherwise a [CSQU104E](#) message is output, and the utility exits with a return code of 12.

Attention: TARGVER is not valid if you do not also specify TYPE(REINTRODUCE).

Example

Figure 12 on page 2781 illustrates how the FORMAT command is invoked from CSQUTIL. In this example, two page sets, referenced by CSQP0000 and CSQP0003, are formatted by CSQUTIL.

```
//FORMAT EXEC PGM=CSQUTIL
//STEPLIB DD DISP=SHR,DSN=thlqual.SCSQANLE
// DD DISP=SHR,DSN=thlqual.SCSQAUTH
//CSQP0000 DD DISP=OLD,DSN=pageset.dsname0
//CSQP0003 DD DISP=OLD,DSN=pageset.dsname3
//SYSPRINT DD SYSOUT=*
//SYSIN DD *
FORMAT
/*
```

Figure 12. Sample JCL for the FORMAT function of CSQUTIL

Figure 13 on page 2781 illustrates how the FORMAT command with the TYPE option is invoked from CSQUTIL. In this example, the page set referenced by CSQP0003 is formatted by CSQUTIL.

```
//FORMAT EXEC PGM=CSQUTIL
//STEPLIB DD DISP=SHR,DSN=thlqual.SCSQANLE
// DD DISP=SHR,DSN=thlqual.SCSQAUTH
//CSQP0003 DD DISP=OLD,DSN=page set.dsname3
//SYSPRINT DD SYSOUT=*
//SYSIN DD *
FORMAT TYPE(RECOVER)
/*
```

Figure 13. Sample JCL for the FORMAT function of CSQUTIL with the TYPE option

Usage notes

1. You cannot format page sets that belong to a queue manager that is still running.
2. When you use FORMAT, it is not necessary to specify a queue manager name.
3. If you use TYPE(REPLACE), recovery logs starting from when the page set was first used with the queue manager, or from when the page set was last formatted, must be available.
4. If you use data set names in which the queue manager name is a high-level qualifier, you can more easily identify which page sets are used by which queue manager, if more than one queue manager is defined.
5. Any update to a resource due to the resolution of an incomplete unit of work, where the update relates to a page on a page set that has been formatted with TYPE(REPLACE) or TYPE(NEW), is not honored. The update to the resource is lost.
6. If there is an error when formatting a page set, it does not prevent other page sets from being formatted, although the FORMAT function is considered to have failed.
7. Failure of this function does not prevent other CSQUTIL functions being attempted.

Page set information (PAGEINFO) on z/OS

Use the PAGEINFO function to extract page set information from one or more page sets, specified by DDnames in the range CSQP0000 through CSQP0099, for the source data sets from which page set information is required.

Page set management (PAGEINFO)

▶▶ PAGEINFO ◀◀

Keywords and parameters

There are no keywords or parameters.

Example

In Figure 14 on page 2782, page set information is required from two existing page sets.

```
//PAGEINFO EXEC PGM=CSQUTIL
//STEPLIB DD DISP=SHR,DSN=thlqual.SCSQANLE
// DD DISP=SHR,DSN=thlqual.SCSQAUTH
//CSQP0001 DD DISP=OLD,DSN=page set.existing.name1
//CSQP0006 DD DISP=OLD,DSN=page set.existing.name6
//SYSPRINT DD SYSOUT=*
//SYSIN DD
* Extract page set information for 2 existing page sets (CSQS0001 and CSQS0006)
PAGEINFO
/*
```

Figure 14. Sample JCL showing the use of the PAGEINFO function

where:

CSQP0001, CSQP0006

Are the DDnames of the source data sets from which you want to extract page set information.

Information returned from PAGEINFO might include:

- Page set number
- Number of pages in a page set
- Queue manager associated with a page set
- Utility status information
- Page set recovery RBA for each page set
- System recovery RBA for all the page sets reported on by the PAGEINFO function

Usage notes

1. You cannot use PAGEINFO on the page sets of a queue manager that is running.
2. Failure of this function does not prevent other CSQUTIL functions from being attempted.
3. If you attempt to use the PAGEINFO function after the queue manager has terminated abnormally, the page sets might not have been closed properly. If a page set has not been closed properly, you cannot successfully run the PAGEINFO function against it. To avoid this problem, run the AMS VERIFY command before using the PAGEINFO function. The AMS VERIFY command might produce error messages. However, it does close the page sets properly so that the PAGEINFO function can complete successfully.

For more information about the AMS [VERIFY](#) command, see the *z/OS DFSMS Access Method Services for VSAM* manual.

4. The system recovery RBA relates only to those page sets processed; it does not relate to the whole queue manager unless all the page sets for the queue manager are included. If the page sets are from more than one queue manager, no system recovery RBA can be determined.

Expanding a page set (COPYPAGE) on z/OS

Use the COPYPAGE function to copy one or more page sets to a larger page set.

Note: The COPYPAGE function is only used for *expanding* page sets. It is not used for making backup copies of page sets. If you want to do this, use AMS REPRO as described in [How to back up and recover page sets](#). When you have used the COPYPAGE function, the page sets cannot be used by a queue manager with a different name, so do not rename your queue manager.

Use the COPYPAGE function to copy one or more page sets to a larger page set. All queues and messages on the page set are copied. If you copy page set zero, all the IBM MQ object definitions are also copied. Each page set is copied to a destination data set that must be formatted as a page set. Copying to a smaller page set is not supported.

If you use this function, you must modify the page set definition in the started task procedure to reflect the change of the name of the data set on which the new page set resides.

To use the COPYPAGE function, define DDnames in the range CSQS0000 through CSQS0099 for the source data sets, and define DDnames for the target data sets from CSQT0000 through CSQT0099.

For more information, see [Managing page sets](#).

Page set management (COPYPAGE)

►► COPYPAGE ◄◄

Keywords and parameters

There are no keywords or parameters.

Example

In [Sample JCL showing the use of the COPYPAGE function](#), two existing page sets are copied onto two new page sets. The procedure for this is:

1. Set up the required DDnames, where:

CSQP0005, CSQP0006

Identify the destination data sets. These DDnames are used by the FORMAT function.

CSQS0005, CSQS0006

Identify the source data sets containing the two page sets you want to copy.

CSQT0005, CSQT0006

Identify the destination data sets (page sets), but this time for the COPYPAGE function.

2. Format the destination data sets, referenced by DDnames CSQP0005 and CSQP0006, as page sets using the FORMAT function.
3. Copy the two existing page sets onto the new page sets using the COPYPAGE function.

```

//JOB LIB DD DISP=SHR,DSN=ANTZ.MQ.&VER..&LVL..OUT.SCSQANLE
// DD DISP=SHR,DSN=ANTZ.MQ.&VER..&LVL..OUT.SCSQAUTH
//*
//S1 EXEC PGM=IDCAMS
//* Delete any prior attempt, then allocate a new larger page set
//SYSPRINT DD SYSOUT=*
//SYSIN DD *
DELETE 'VICY.MQ38.PAGE01.NEW' CLUSTER
DEFINE CLUSTER (NAME('VICY.MQ38.PAGE01.NEW') +
MODEL('VICY.MQ38.PAGE01') +
DATA CLAS(EXTENDED) +
LINEAR CYLINDERS(100,50))
//*
//MQMUTIL EXEC PGM=CSQUTIL,PARM='',REGION=4M
//* CSQUTIL
//* FORMAT acts on DDNAME like CSQPnnnn
//* optional, FORMAT PAGES(nnn) to force allocation and format of
//* secondary extents.
//* COPYPAGE copies from source, CSQSnnnn
//* to target, CSQTnnnn
//SYSPRINT DD SYSOUT=*
//CSQP0001 DD DISP=SHR,DSN=VICY.MQ38.PAGE01.NEW
//CSQS0001 DD DISP=SHR,DSN=VICY.MQ38.PAGE01
//CSQT0001 DD DISP=SHR,DSN=VICY.MQ38.PAGE01.NEW
//SYSIN DD *
FORMAT
COPYPAGE
//*
//RENAME EXEC PGM=IDCAMS
//* the cluster and data components must be renamed independently
//SYSPRINT DD SYSOUT=*
//SYSIN DD *
ALTER 'VICY.MQ38.PAGE01' NEWNAME('VICY.MQ38.PAGE01.OLD')
ALTER 'VICY.MQ38.PAGE01.DATA' +
NEWNAME('VICY.MQ38.PAGE01.OLD.DATA')
ALTER 'VICY.MQ38.PAGE01.NEW' +
NEWNAME('VICY.MQ38.PAGE01')
ALTER 'VICY.MQ38.PAGE01.NEW.DATA' +
NEWNAME('VICY.MQ38.PAGE01.DATA')
//*

```

Figure 15. Sample JCL showing the use of the COPYPAGE function

Usage notes

1. You cannot use COPYPAGE on page sets of a queue manager that is running.
2. Using COPYPAGE involves stopping the queue manager. This results in the loss of nonpersistent messages.
3. Before you use COPYPAGE, the new data sets must be preformatted as page sets. To do this, use the FORMAT function, as shown in [Figure 15 on page 2784](#).
4. Ensure that the new (destination) data sets are larger than the old (source) data sets.
5. You cannot change the page set identifier (PSID) associated with a page set. For example, you cannot 'make' page set 03 become page set 05.
6. Failure of this function does not prevent other CSQUTIL functions from being attempted.
7. If you attempt to use the COPYPAGE function after the queue manager has terminated abnormally, the page sets might not have been closed properly. If a page set has not been closed properly, you cannot successfully run the COPYPAGE function against it.

To avoid this problem, run the AMS VERIFY command before using the COPYPAGE function. The AMS VERIFY command might produce error messages. However, it does close the page sets properly, so that the COPYPAGE function can complete successfully.

For more information about the AMS [VERIFY](#) command, see the *z/OS DFSMS Access Method Services Commands* manual.

8. See [Defining a page set to be larger than 4 GB](#) for information on using the EXTENDED attribute on the DATA CLAS parameter.

Copying a page set and resetting the log (RESETPAGE) on z/OS

The RESETPAGE function is like the COPYPAGE function except that it also resets the log information in the new page sets.

RESETPAGE lets you restart the queue manager from a known, valid set of page sets, even if the corresponding log data sets have been corrupted.

The source page sets for RESETPAGE must be in a consistent state. They must be either:

- Page sets that have been through a successful queue manager shutdown using the IBM MQ command STOP QMGR.
- Copies of page sets that have been through a successful stop.

The RESETPAGE function must not be run against copies of page sets made using fuzzy backup (see [Method 2: Fuzzy backup](#)), or against page sets that are from a queue manager that has terminated abnormally.

RESETPAGE either:

- Copies page sets on all data sets referenced by DDnames CSQS0000 through CSQS0099 to new data sets referenced by DDnames CSQT0000 through CSQT0099. If you use this function, modify the page set definition in the started task procedure to reflect the change of the name of the data set on which the new page set resides.
- Resets the log information in the page set referenced by DDnames CSQP0000 through CSQP0099.

For more information, see [Managing page sets](#).

Using the RESETPAGE function

You can use the RESETPAGE function to update a set of consistent page sets so that they can be used with a set of new (clean) BSDS and log data sets to start the queue manager. You only have to use the RESETPAGE function if both copies of the log have been lost or damaged; you can restart from backup copies of page sets (and accept the resulting loss of data from the time the copies were made), or from your existing page sets.

In this situation, use the RESETPAGE function on **all** the page sets of the affected queue manager. You must also create new BSDS and log data sets.

Note: Do not use the RESETPAGE function on a subset of the page sets known to IBM MQ.

If you run the RESETPAGE function against any page sets, but do not provide clean BSDS and log data sets for the queue manager, IBM MQ attempts to recover the logs from RBA zero, and treats the page sets as empty. For example, the following messages are produced if you attempt to use the RESETPAGE function to generate page sets zero, 1, 2, and 3 without providing a clean set of BSDS and log data sets:

```
CSQI021I +CSQ1 CSQIECUR PAGE SET 0 IS EMPTY. MEDIA RECOVERY STARTED
CSQI021I +CSQ1 CSQIECUR PAGE SET 1 IS EMPTY. MEDIA RECOVERY STARTED
CSQI021I +CSQ1 CSQIECUR PAGE SET 2 IS EMPTY. MEDIA RECOVERY STARTED
CSQI021I +CSQ1 CSQIECUR PAGE SET 3 IS EMPTY. MEDIA RECOVERY STARTED
```

Page set management (RESETPAGE)

Keywords and parameters

FORCE

Specifies that the page sets specified by DDnames CSQP0000 through CSQP00nn are to be reset in place.

If FORCE is not specified, the page sets specified by DDnames CSQS0000 through CSQS00nn are copied to new page sets specified by DDnames CSQT0000 through CSQT00nn. This is the default.

You should take a copy of the page sets first. See [backing up page sets](#) for sample JCL to perform this operation.

Example

An existing page set, referenced by DDname CSQS0007, is copied to a new data set referenced by DDname CSQT0007. The new data set, which is also referenced by DDname CSQP0007, is already formatted as a page set before the RESETPAGE function is called.

```
//RETPAGE EXEC PGM=CSQUTIL
//STEPLIB DD DISP=SHR,DSN=thlqua1.SCSQANLE
// DD DISP=SHR,DSN=thlqua1.SCSQAUTH
//CSQP0007 DD DISP=OLD,DSN=pageset.newname7
//CSQS0007 DD DISP=OLD,DSN=pageset.oldname7
//CSQT0007 DD DISP=OLD,DSN=pageset.newname7
//SYSPRINT DD SYSOUT=*
//SYSIN DD *
* Format new data set, CSQP0007, as page set
  FORMAT
* Copy page set CSQS0007 to CSQT0007 and reset it
  RESETPAGE
/*
```

Figure 16. Sample JCL showing the use of the RESETPAGE function

Usage notes

1. Do not use the RESETPAGE function against page sets after the queue manager has terminated abnormally. Page sets from a queue manager that terminated abnormally will probably contain inconsistent data; using RESETPAGE on page sets in this state leads to data integrity problems.
2. You cannot use RESETPAGE on page sets belonging to a queue manager that is running.
3. Before you use RESETPAGE, the new data sets must be pre-formatted as page sets. To do this, use the FORMAT function, as shown in [Figure 16 on page 2786](#).
4. Ensure that the new (destination) data sets are larger than the old (source) data sets.
5. You cannot change the page set identifier (PSID) associated with a page set. For example, you cannot 'make' page set 03 become page set 05.
6. Failure of this function does not prevent other CSQUTIL functions from being attempted.

Using the COMMAND function of CSQUTIL on z/OS

You can use the COMMAND function of CSQUTIL to direct commands to the queue manager.

Use the COMMAND function to:

1. Pass commands from an input data set to the queue manager.
2. Produce a list of DEFINE commands that describe the objects in a queue manager. The commands can be used to keep a record of the object definitions or to regenerate all or part of a queue manager's objects as part of a migration from one queue manager to another.
3. Produce a list of commands to change or delete a set of objects in a queue manager.
4. Make a client channel definition file.

The queue manager specified in the PARM parameter of the EXEC statement must be running.

- [Keywords and parameters](#)
- [Examples](#)
- [Usage notes for CSQUTIL COMMAND](#)

If you use **FAILURE (IGNORE)** the job step always obtains return code 0.

If you use **FAILURE (STOP)** or **FAILURE (CONTINUE)** the job step obtains return code 8 if there were any non zero return codes from the statements.

You should use **FAILURE (STOP)** or **FAILURE (CONTINUE)** to report any errors in the definitions.

Keywords and parameters

DDNAME(*ddname1*)

Specifies that the commands are to be read from a named input data set. If this keyword is omitted, the default DDname, CSQUCMD, is used.

ddname1 specifies the DDname that identifies the input data set from which commands are to be read.

MAKEDEF(*ddname2*), MAKEDEL(*ddname2*), MAKEREP(*ddname2*), MAKEALT(*ddname2*)

Specify that commands are to be generated from any DISPLAY object commands in the input data set.

The commands that are generated are:

MAKEDEF

DEFINE NOREPLACE, with all the attributes and values returned by the DISPLAY commands. For the queue manager object, an ALTER command is generated with all the attributes and values. For channel authentication records, a SET command is generated.

Both CSQUTIL SDEFS and the CSQUTIL COMMAND with the MAKEDEF option can be used to produce a set of MQSC commands to re-create the objects currently defined in the queue manager.

The difference between the two is that CSQUTIL COMMAND must be run against an active queue manager and is most appropriate for regular backup of object definitions, whereas CSQUTIL SDEFS can be used to re-create definitions for a queue manager that is not currently running. This makes the CSQUTIL SDEFS option more appropriate for recovery scenarios.

MAKEDEL

DELETE. For local queues, NOPURGE is used. For channel authentication records, a SET command with ACTION(REMOVE) is used

MAKEREP

DEFINE REPLACE, with any keywords and values from the data set specified by the DATA keyword. For channel authentication records, a SET command with ACTION(REPLACE) is used.

MAKEALT

ALTER, with any keywords and values from the data set specified by the DATA keyword. For channel authentication records, a SET command with ACTION(REPLACE) is used.

Only one of these keywords may be specified. If these keywords are omitted, no commands are generated.

ddname2 specifies the DDname that identifies the output data set in which the DEFINE, DELETE or ALTER commands are to be stored. The data set should be RECFM=FB, LRECL=80. This data set can then be used as input for a later invocation of the COMMAND function or it can be incorporated into the initialization data sets CSQINP1 and CSQINP2.

DATA(*ddname4*)

ddname4 specifies a data set from which command keywords and values are to be read, and appended to each command generated for MAKEREP or MAKEALT.

TGTQMGR(*qmgrname*)

Specifies the name of the z/OS queue manager where you want the commands to be performed. This option is not supported for use with queue managers on distributed platforms. You can specify a target queue manager that is not the one you connect to. In this case, you would normally specify the name of a remote queue manager object that provides a queue manager alias definition (the name is used as the *ObjectQMgrName* when opening the command input queue). To do this, you must have suitable queues and channels set up to access the remote queue manager.

The default is that commands are performed on the queue manager to which you are connected, as specified in the PARM field of the EXEC statement.

RESPTIME(*nnn*)

Specifies the time in seconds to wait for a response to each command, in the range 5 through 999.

The default is 30 seconds.

MAKECLNT(*ddname3*)

Specifies that a client channel definition file is generated from any DISPLAY CHANNEL commands in the input data set that return information about client-connection channels, and any DISPLAY AUTHINFO commands that return information about authentication information objects for which the LDAPUSER and LDAPPWD attributes are not set.

If this keyword is omitted, no file is generated.

Important:  From IBM MQ 9.1, the MAKECLNT attribute is deprecated.

ddname3 specifies the DDname that identifies the output data set in which the generated file is to be stored; the data set should be RECFM=U, LRECL=6144. The file can then be downloaded as binary data to the client machine by a suitable file transfer program.

CCSID(*ccsid*)

Specifies the coded character set identifier (CCSID) that is to be used for the data in a client channel definition file. The value must be in the range 1 through 65535; the default is 437. You can only specify CCSID if you also specify MAKECLNT.

Note: IBM MQ assumes that the data is to be in ASCII, and that the encoding for numeric data is to be MQENC_INTEGER_REVERSED.

FAILURE

Specifies what action to take if an IBM MQ command that is issued fails to execute successfully. Values are:

IGNORE

Ignore the failure; continue reading and issuing commands, and treat the COMMAND function as being successful. This is the default.

CONTINUE

Read and issue any remaining commands in the input data set, but treat the COMMAND function as being unsuccessful.

STOP

Do not read or issue any more commands, and treat the COMMAND function as being unsuccessful.

Examples

This section gives examples of using the COMMAND function for the following:

- [“Issuing commands” on page 2789](#)
- [“Making a list of DEFINE commands” on page 2789](#)
- [“Making a list of ALTER commands” on page 2790](#)
- [“Making a client channel definition file” on page 2791](#)

Issuing commands

In [Figure 17 on page 2789](#), the data sets referenced by DDnames CSQUCMD and OTHER contain sets of commands. The first COMMAND statement takes commands from the default input data set MY.COMMANDS(COMMAND1) and passes them to the queue manager. The second COMMAND statement takes commands from the input data set MY.COMMANDS(OTHER1), which is referenced by DDname OTHER, and passes them to the queue manager.

```
//COMMAND EXEC PGM=CSQUTIL,PARM='CSQ1'  
//STEPLIB DD DISP=SHR,DSN=thlqua1.SCSQANLE  
// DD DISP=SHR,DSN=thlqua1.SCSQAUTH  
//CSQUCMD DD DSN=MY.COMMANDS(COMMAND1),DISP=SHR  
//OTHER DD DSN=MY.COMMANDS(OTHER1),DISP=SHR  
//SYSPRINT DD SYSOUT=*  
//SYSIN DD *  
* THE NEXT STATEMENT CAUSES COMMANDS TO BE READ FROM CSQUCMD DDNAME  
COMMAND  
* THE NEXT SET OF COMMANDS WILL COME FROM 'OTHER' DDNAME  
COMMAND DDNAME(OTHER)  
* THE NEXT STATEMENT CAUSES COMMANDS TO BE READ FROM CSQUCMD  
* DDNAME AND ISSUED ON QUEUE MANAGER CSQ2 WITH A RESPONSE TIME  
* OF 10 SECONDS  
COMMAND TGTQMR(CSQ2) RESPTIME(10)  
/*
```

Figure 17. Sample JCL for issuing IBM MQ commands using CSQUTIL

Making a list of DEFINE commands

In [Figure 18 on page 2790](#), the data set referenced by DDname CMDINP contains a set of DISPLAY commands. These DISPLAY commands specify generic names for each object type (except the queue manager itself). If you run these commands, a list is produced containing all the IBM MQ objects. In these DISPLAY commands, the ALL keyword is specified to ensure that all the attributes of all the objects are included in the list, and that all queue sharing group dispositions are included.

Note: Failing to issue DISPLAY STGCLASS as the first command can result in a set of definitions that will not be successfully processed by the queue manager, as STGCLASS definitions must be defined

before the associated queue objects are defined. MAKEDEFS generate output based on the order of the input DISPLAY commands.

The MAKEDEF keyword causes this list to be converted into a corresponding set of DEFINE NOREPLACE commands (ALTER for the queue manager). These commands are put into a data set referenced by the **ddname2** parameter of the MAKEDEF keyword, that is, OUTPUT1. If you run this set of commands, IBM MQ regenerates all the object definitions in the queue manager.

```
//QDEFS EXEC PGM=CSQUTIL,PARM='CSQ1'
//STEPLIB DD DISP=SHR,DSN=thlqua1.SCSQANLE
// DD DISP=SHR,DSN=thlqua1.SCSQAUTH
//OUTPUT1 DD DISP=OLD,DSN=MY.COMMANDS(DEFS)
//SYSPRINT DD SYSOUT=*
//SYSIN DD *
COMMAND DDNAME(CMDINP) MAKEDEF(OUTPUT1)
/*
//CMDINP DD *

DISPLAY CHLAUTH('*') ALL
DIS SUB(*) SUBTYPE(ADMIN) ALL DISTYPE(DEFINED)

DISPLAY QMGR ALL

/*
```

Figure 18. Sample JCL for using the MAKEDEF option of the COMMAND function

Making a list of ALTER commands

In Figure 19 on page 2791, the data set referenced by DDname CMDINP contains a DISPLAY command that will produce a list of all local queues with names beginning "ABC".

The MAKEALT keyword causes this list to be converted into a corresponding set of ALTER commands, each of which includes the data from the data set referenced by DDname CMDALT. These commands are put into a data set referenced by the ddname2 parameter of the MAKEALT keyword, that is, OUTPUTA. If you run this set of commands, all the local queues with names beginning "ABC" will be disabled for PUT and GET.

```

//QALTS EXEC PGM=CSQUTIL,PARM='CSQ1 '
//STEPLIB DD DISP=SHR,DSN=thlqua1.SCSQANLE
// DD DISP=SHR,DSN=thlqua1.SCSQAUTH
//OUTPUTA DD DISP=OLD,DSN=MY.COMMANDS(ALTS)
//SYSPRINT DD SYSOUT=*
//SYSIN DD *
COMMAND DDNAME(CMDINP) MAKEALT(OUTPUTA) DATA(CMDALT)
/*
//CMDINP DD *
DISPLAY QLOCAL(ABC*)
/*
//CMDALT DD *
PUT(DISABLED) +
GET(DISABLED)
/*

```

Figure 19. Sample JCL for using the MAKEALT option of the COMMAND function

Making a client channel definition file

In Figure 20 on page 2791, the data set referenced by DDname CMDCHL contains a DISPLAY CHANNEL command and a DISPLAY AUTHINFO command. The DISPLAY commands specify a generic name and the ALL keyword is specified to ensure that all the attributes are included.

The MAKECLNT keyword converts these attributes into a corresponding set of client channel definitions. These are put into a data set referenced by the *ddname3* parameter of the MAKECLNT keyword, that is, OUTCLNT, which is ready to be downloaded to the client machine.

```

//CLIENT EXEC PGM=CSQUTIL,PARM='CSQ1'
//STEPLIB DD DISP=SHR,DSN=thlqua1.SCSQANLE
// DD DISP=SHR,DSN=thlqua1.SCSQAUTH
//OUTCLNT DD DISP=OLD,DSN=MY.CLIENTS
//SYSPRINT DD SYSOUT=*
//SYSIN DD *
COMMAND DDNAME(CMDCHL) MAKECLNT(OUTCLNT)
/*
//CMDCHL DD *
DISPLAY CHANNEL(*) ALL TYPE(CLNTCONN)
DISPLAY AUTHINFO(*) ALL
/*

```

Figure 20. Sample JCL for using the MAKECLNT option of the COMMAND function

Usage notes for CSQUTIL COMMAND

1. The rules for specifying commands in the input data set are the same as for the initialization data sets:

- The data set must have a record length of 80.
- Only columns 1 through 72 are significant. Columns 73 through 80 are ignored.
- Records with an asterisk (*) in column 1 are interpreted as comments and are ignored.
- Blank records are ignored.
- Each command must start on a new record.
- A trailing - means continue from column 1 of the next record.
- A trailing + means continue from the first non-blank column of the next record.
- The maximum number of characters permitted in a command is 32 762.

With the additional rule:

- A semicolon (;) can be used to terminate a command; the remaining data in the record is ignored.

See [Running MQSC commands from text files](#) for more information about the rules for building IBM MQ commands.

2. The output from a [“DISPLAY QMGR \(display queue manager settings\)”](#) on page 792 command contains all the queue manager attributes. Using the **DISPLAY QMGR** command as part of MAKEDEF might generate an ALTER command that cannot be issued before the channel initiator is active.

Since setting PSCLUS(DISABLED) can only be done if the channel initiator is active, it might be necessary to modify the resulting ALTER command so that it does not attempt to set PSCLUS(DISABLED) until the channel initiator is active.

3. If you specify the MAKEDEF keyword:

- In the input data set, the DISPLAY commands for objects must contain the ALL parameter so that the complete definition of each object is produced. See [Figure 18 on page 2790](#).
- To obtain a complete definition, you must DISPLAY the following:
 - queues
 - topic
 - namelists
 - process definitions
 - channels
 - storage classes
 - authentication information objects
 - CF structures
 - channel authentication records
 - queue manager

Note: DEFINE commands are not generated for any local queues that can be identified as dynamic, or for channels that were defined automatically.

- Do not specify the same MAKEDEF data set for more than one COMMAND function, unless its DD statement specifies a sequential data set with DISP=MOD.

4. If you specify the MAKEREP, MAKEALT, or MAKEDEL keywords:

- In the input data set, include DISPLAY commands that select the set of objects for which you want to generate commands.
- For MAKEREP and MAKEALT, the data (if any) from the data set specified by the DATA keyword is appended to each generated command, exactly as entered. The format of the data set and the rules for specifying command data are the same as for the command input data set. Because the same data is appended to each command, if you want to process several sets of objects, you will need to use several separate COMMAND functions, each with a different DATA data set.
- Commands are not generated for channels that were defined automatically.

5. If you specify the MAKEDEF, MAKEREP, MAKEALT, or MAKEDEL keywords, commands are generated only for objects reported by the target queue manager (as specified by the TGTQMGR keyword or defaulted), even if CMDSCOPE is used in the DISPLAY commands. To generate commands for several queue managers in a queue sharing group, use a separate COMMAND function for each.

In a queue sharing group, queues, processes, channels, storage classes and authentication information objects should each have two DISPLAY commands, one with QSGDISP(QMGR) and one with QSGDISP(GROUP). Queues should have a third with QSGDISP(SHARED). It is not necessary to specify QSGDISP(COPY) because the required commands will be generated automatically when the commands for objects with QSGDISP(GROUP) are issued.

6. Do not specify the same MAKEDEF, MAKEREP, MAKEALT, or MAKEDEL data set for more than one COMMAND function, unless its DD statement specifies a sequential data set with DISP=MOD.

7. If you specify the MAKECLNT keyword:

- In the input data set, the display commands for channels and authentication information objects must contain the ALL parameter so that the complete definition of each channel and authentication information object is produced.
 - If the DISPLAY commands return information for a particular channel more than once, only the last set of information is used.
 - Do not specify the same client definition file data set for more than one COMMAND function, unless its DD statement specifies a sequential data set with DISP=MOD.
8. The results of DISPLAY commands used in conjunction with MAKEDEF, MAKEREP, MAKEALT, MAKEDEL or MAKECLNT are also sent to SYSPRINT.
 9. If you specify the FAILURE keyword, a command is determined to be a success or failure according to the codes returned in message CSQN205I. If the return code is 00000000 and the reason code is 00000000 or 00000004, it is a success; for all other values it is a failure.
 10. The COMMAND function is determined to be a success only if both:
 - All the commands in the input data set are read and issued and get a response from IBM MQ, regardless of whether the response indicates successful execution of the command or not.
 - Every command issued executes successfully, if FAILURE(CONTINUE) or FAILURE(STOP) is specified.

If COMMAND fails, no further CSQUTIL functions are attempted.
 11. You need the necessary authority to use command server queues (SYSTEM.COMMAND.INPUT, SYSTEM.COMMAND.REPLY.MODEL, and SYSTEM.CSQUTIL.*) and to use the IBM MQ commands that you want to issue.

Producing a list of IBM MQ define commands (SDEFS) on z/OS

You can use the SDEFS function of CSQUTIL to produce a list of DEFINE commands describing the objects in your queue manager or queue sharing group.

Both CSQUTIL SDEFS and the CSQUTIL COMMAND with the MAKEDEF option can be used to produce a set of MQSC commands to re-create the objects currently defined in the queue manager.

The difference between the two is that CSQUTIL COMMAND must be run against an active queue manager and is most appropriate for regular backup of object definitions, whereas CSQUTIL SDEFS can be used to re-create definitions for a queue manager that is not currently running. This makes the CSQUTIL SDEFS option more appropriate for recovery scenarios.

- [Keywords and parameters](#)
- [Examples](#)
- [Usage notes](#)

Keywords and parameters

OBJECT

Specifies the type of object to be listed.

A value of QUEUE lists queues of all types, as if you had specified QALIAS, QLOCAL, QMODEL and QREMOTE.

QSGDISP

Specifies from where the object definition information is obtained. Depending on how the object has been defined, this information is either:

- On the page set zero referred to by the CSQP0000 DD statement, or
- In a Db2 shared repository.

Permitted values are shown in [Table 386 on page 2794](#).

<i>Table 386. SDEFS QSGDISP parameters and their actions</i>	
QSGDISP parameter	What the SDEFS utility does
QMGR	Creates DEFINE statements for the specified object type from definitions held on the page set zero referred to by the CSQP0000 DD statement. (1) Only objects defined with QSGDISP(QMGR) are included.
COPY	Creates DEFINE statements for the specified object type from definitions held on the page set zero referred to by the CSQP0000 DD statement. (1) Only objects defined with QSGDISP(COPY) are included.

<i>Table 386. SDEFS QSGDISP parameters and their actions (continued)</i>	
QSGDISP parameter	What the SDEFS utility does
PRIVATE	Creates DEFINE statements for the specified object type from definitions held on the page set zero referred to by the CSQP0000 DD statement. (1) Both QSGDISP(QMGR) and QSGDISP(COPY) objects are included.
GROUP	Creates DEFINE statements for the specified object type from definitions held on Db2 resource definition tables for the specified queue sharing group. Only objects defined with QSGDISP(GROUP) are included. No CSQP0000 DD statement is required; the Db2 subsystem specified at object definition is accessed. The Db2 library db2qual.SDSNLOAD is required.
SHARED	Creates DEFINE statements for all local queues defined with QSGDISP(SHARED) by accessing the Db2 resource definition table for the specified queue sharing group. This parameter is permitted only with OBJECT(QLOCAL) or OBJECT(Queue). No CSQP0000 DD statement is required; the Db2 subsystem specified at object definition is accessed. The Db2 library db2qual.SDSNLOAD is required.

Notes:

1. Because only page set zero is accessed, you must ensure that the queue manager is not running.

MAKEDEF(ddname2)

Specifies that define commands generated for the object are to be placed in the output data set identified by the DDname. The data set should be RECFM=FB, LRECL=80. This data set can then be used as input for a later invocation of the COMMAND function or it can be incorporated into the initialization data sets CSQINP1 and CSQINP2.

The commands generated are DEFINE NOREPLACE, with all the attributes and values for the object.

Note: DEFINE commands are not generated for any local queues that can be identified as dynamic, or for channels that were defined automatically.

Examples

```
//SDEFS EXEC PGM=CSQUTIL
//STEPLIB DD DISP=SHR,DSN=th1qual.SCSQANLE
// DD DISP=SHR,DSN=th1qual.SCSQAUTH
//CSQP0000 DD DISP=OLD,DSN=pageset.dsname0

/*

```

Figure 23. Sample JCL for the SDEFS function of CSQUTIL, when recovering all objects from a valid page set zero

Usage notes

1. For local definitions, do not use SDEFS for a queue manager that is running because results will be unpredictable. You can avoid doing this accidentally by using DISP=OLD in the CSQP0000 DD statement. For shared or group queue definitions, this does not matter because the information is derived from Db2.
2. When you use SDEFS for local queues you do not need to specify a queue manager name. However, for shared and group queue definitions, a queue manager name is required to access Db2.
3. To use the SDEFS function more than once in a job, specify different DDnames and data sets for each invocation of the function, or specify a sequential data set and DISP=MOD in the DD statements.
4. If the SDEFS function fails, no further CSQUTIL functions are attempted.
5. The SDEFS function does not support the CHLAUTH, SUB, CFSTRUCT or QMGR objects. To back these objects up, use the [CSQUTIL COMMAND](#) function.

Related concepts

[“IBM MQ utility program \(CSQUTIL\) on z/OS” on page 2774](#)

The CSQUTIL utility program is provided with IBM MQ to help you to perform backup, restoration, and reorganization tasks, and to issue IBM MQ commands.

z/OS Copying queues into a data set while the queue manager is running (COPY) on z/OS

You can use the COPY function of CSQUTIL to copy queued messages to a sequential data set while the queue manager is running, without destroying any messages in the original queues.

The scope of the COPY function is determined by the keyword that you specify in the first parameter. You can either copy all the messages from a named queue, or all the messages from all the queues on a named page set.

Use the complementary function, LOAD, to restore the messages to their appropriate queues.

Note:

1. If you want to copy the object definitions from the named page set, use COPYPAGE.
2. If you want to copy messages to a data set when the queue manager is stopped, use SCOPY.
3. For information about how to avoid problems with duplicate messages if this function fails, see [Syncpoints in IBM MQ for z/OS applications](#).
4. An alternative approach to the COPY function is to use the [“dmpmqmsg \(queue load and unload\)” on page 65](#) utility which is more flexible in many cases.

- [Keywords and parameters](#)
- [Example](#)
- [Usage notes](#)

Keywords and parameters

QUEUE(*q-name*)

Specifies that messages in the named queue are to be copied. The keyword QUEUE can be abbreviated to Q.

q-name specifies the name of the queue to be copied. This name is case-sensitive.

PSID(*psid-number*)

Specifies that all the messages in all the queues in the specified page set are to be copied.

psid-number is the page set identifier, which specifies the page set to be used. This identifier is a two-digit integer (whole number) representing a single page set.

DEFTYPE

Specifies whether to copy dynamic queues:

ALL

Copy all queues; this is the default.

PREDEFINED

Do not include dynamic queues; this is the same set of queues that are selected by the COMMAND and SDEFS functions with the MAKEDEF parameter.

DDNAME(ddname)

Specifies that the messages are to be copied to a named data set. If this keyword is omitted, the default DDname, CSQUOUT, is used. The keyword DDname can be abbreviated to DD.

ddname specifies the DDname of the destination data set, which is used to store the messages. The record format of this data set must be variable block spanned (VBS).

Example

```
//COPY EXEC PGM=CSQUTIL,PARM='CSQ1',REGION=0M
//STEPLIB DD DISP=SHR,DSN=thlqua1.SCSQANLE
// DD DISP=SHR,DSN=thlqua1.SCSQAUTH
//OUTPUTA DD DSN=SAMPLE.UTILITY.COPYA,DISP=(NEW,CATLG),
// SPACE=(CYL,(5,1),RLSE),UNIT=SYSDA,
// DCB=(RECFM=VBS,BLKSIZE=23200)
//CSQUOUT DD DSN=SAMPLE.UTILITY.COPY3,DISP=(NEW,CATLG),
// SPACE=(CYL,(5,1),RLSE),UNIT=SYSDA,
// DCB=(RECFM=VBS,BLKSIZE=23200)
//SYSPRINT DD SYSOUT=*
//SYSIN DD *
* COPY WHOLE PAGE SET TO 'CSQUOUT'
COPY PSID(03)
* COPY ONE QUEUE TO 'OUTPUT'
COPY QUEUE(ABC123A) DDNAME(OUTPUTA)
/*
```

Figure 24. Sample JCL for the CSQUTIL COPY functions

Usage notes

1. The queues involved must not be in use when the function is started.
2. If you want to operate on a range of page sets, repeat the COPY function for each page set.
3. The function operates only on local queues.
4. A COPY PSID function is considered successful only if it successfully copies all the queues on the page set.
5. If you try to copy an empty queue (either explicitly by COPY QUEUE or because there are one or more empty queues on a page set that you are copying), data indicating this is written to the sequential data set, and the copy is considered to be a success. However, if you attempt to copy a nonexistent queue, or a page set containing no queues, the COPY function fails, and no data is written to the data set.
6. If COPY fails, no further CSQUTIL functions are attempted.
7. To use the COPY function more than once in the job, specify different DDnames and data sets for each invocation of the function, or specify a sequential data set and DISP=MOD in the DD statements.
8. You need the necessary authority to use the command server queues (SYSTEM.COMMAND.INPUT, SYSTEM.COMMAND.REPLY.MODEL, and SYSTEM.CSQUTIL.*), to use the DISPLAY QUEUE and DISPLAY STGCLASS MQSC commands, and to open the queues that you want to copy with the MQOO_INPUT_EXCLUSIVE and MQOO_BROWSE options.
9. For the **REGION** parameter, a value of 0M means that the job is allowed to have the amount of storage it needs. However, if a job tries to acquire too much storage, it might impact other jobs in the system.

You must ideally look to limit the REGION size and specify an absolute maximum value that the job is allowed to acquire.

z/OS Copying queues into a data set while the queue manager is not running (SCOPY) on z/OS

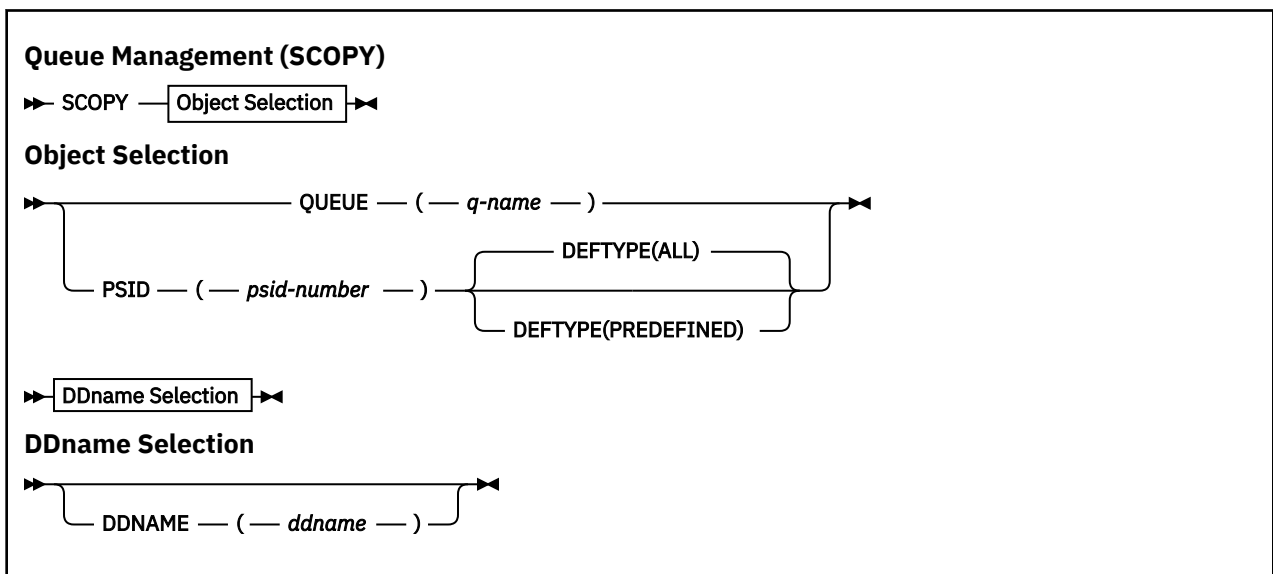

You can use the SCOPY function of CSQUTIL to copy queued messages to a sequential data set when the queue manager is not running, without destroying any messages in the original queues.

The scope of the SCOPY function is determined by the keyword that you specify in the first parameter. You can either copy all the messages from a named queue, or all the messages from all the queues on a named page set.

Use the complementary function, LOAD, to restore the messages to their queues.

To use the SCOPY function, DDname CSQP0000 must specify the data set with page set zero for the subsystem required.

Note: The SCOPY function does not operate on shared queues.

- [Keywords and parameters](#)
- [Example](#)
- [Usage notes](#)

Keywords and parameters

QUEUE(*q-name*)

Specifies that messages in the named queue are to be copied. The keyword QUEUE can be abbreviated to Q.

q-name specifies the name of the queue to be copied. This name is case-sensitive.

DDname CSQP00 *nn* must specify the data set with page set *nn* for the subsystem required, where *nn* is the number of the page set where the queue resides.

PSID(*psid-number*)

Specifies that all the messages in all the queues in the specified page set are to be copied.

psid-number is the page set identifier, which specifies the page set to be used. This identifier is a two-digit integer (whole number) representing a single page set.

DDname CSQP00 *psid-number* must specify the data set with the required page set for the subsystem required.

DEFTYPE

Specifies whether to copy dynamic queues:

ALL

Copy all queues; this is the default.

PREDEFINED

Do not include dynamic queues; this is the same set of queues that are selected by the COMMAND and SDEFS functions with the MAKEDEF parameter.

This parameter is only valid if you specify PSID.

DDNAME(ddname)

Specifies that the messages are to be copied to a named data set. If this keyword is omitted, the default DDname, CSQUOUT, is used. The keyword DDname can be abbreviated to DD.

ddname specifies the DDname of the destination data set, which is used to store the messages. The record format of this data set must be variable block spanned (VBS).

Do not specify the same DDname on more than one SCOPY statement, unless its DD statement specifies a sequential data set with DISP=MOD.

Example

```
//SCOPY EXEC PGM=CSQUTIL,REGION=0M
//STEPLIB DD DISP=SHR,DSN=thlqua1.SCSQANLE
// DD DISP=SHR,DSN=thlqua1.SCSQAUTH
//OUTPUTA DD DSN=SAMPLE.UTILITY.COPYA,DISP=(NEW,CATLG),
// SPACE=(CYL,(5,1),RLSE),UNIT=SYSDA,
// DCB=(RECFM=VBS,BLKSIZE=23200)
//CSQUOUT DD DSN=SAMPLE.UTILITY.COPY3,DISP=(NEW,CATLG),
// SPACE=(CYL,(5,1),RLSE),UNIT=SYSDA,
// DCB=(RECFM=VBS,BLKSIZE=23200)
//CSQP0000 DD DISP=OLD,DSN=pageset.dsname0
//CSQP0003 DD DISP=OLD,DSN=pageset.dsname3
//CSQP0006 DD DISP=OLD,DSN=pageset.dsname6
//SYSPRINT DD SYSOUT=*
//SYSIN DD *
* COPY WHOLE PAGE SET TO 'CSQUOUT'
SCOPY PSID(03)
* COPY ONE QUEUE TO 'OUTPUT' - QUEUE IS ON PAGE SET 6
SCOPY QUEUE(ABC123A) DDNAME(OUTPUTA)
/*
```

Figure 25. Sample JCL for the CSQUTIL SCOPY functions

Usage notes

1. Do not use SCOPY for a queue manager that is running because results are unpredictable. You can avoid doing this accidentally by using DISP=OLD in the page set DD statement.
2. When you use SCOPY, you do not need to specify a queue manager name.
3. If you want to operate on a range of page sets, repeat the SCOPY function for each page set.
4. The function operates only on local queues and only for persistent messages.
5. An SCOPY PSID function is considered successful only if it successfully copies all the queues on the page set. If an empty queue is processed, data indicating this is written to the sequential data set. If the page set has no queues, the SCOPY function fails, and no data is written to the data set.
6. If you try to copy an empty queue explicitly by SCOPY QUEUE, data indicating this is written to the sequential data set, and the copy is considered to be a success. However, if you attempt to copy a nonexistent queue, the SCOPY function fails, and no data is written to the data set.
7. If the SCOPY function fails, no further CSQUTIL functions are attempted.

8. To use the SCOPY function more than once in the job, specify different DDnames and data sets for each invocation of the function, or specify a sequential data set and DISP=MOD in the DD statements.
9. For the **REGION** parameter, a value of 0M means that the job is allowed to have the amount of storage it needs. However, if a job tries to acquire too much storage, it might impact other jobs in the system. You must ideally look to limit the REGION size and specify an absolute maximum value that the job is allowed to acquire.

Analyzing the queue data copied to a data set by COPY or SCOPY using ANALYZE on z/OS

Use this topic to understand analyzing the queue data copied to a data set by COPY or SCOPY.

This function reads and analyzes a data set (created using COPY or SCOPY), and for each queue, displays:

- queue name
- number of messages for the queue
- total length of the messages

- [“Keywords and parameters” on page 2801](#)
- [“Example” on page 2801](#)
- [“Usage notes” on page 2801](#)

Keywords and parameters

DDNAME(*ddname*)

Specifies the data set to be processed. This keyword can be abbreviated to DD.

ddname specifies the DDname that identifies the destination data set of a prior COPY or SCOPY operation. This name is not case sensitive, and can be up to eight characters long.

Example

```
//LOAD EXEC PGM=CSQUTIL
//STEPLIB DD DISP=SHR,DSN=thlqua1.SCSQANLE
// DD DISP=SHR,DSN=thlqua1.SCSQAUTH
//OUTPUTA DD DSN=MY.UTILITY.OUTPUTA,DISP=SHR
//SYSPRINT DD SYSOUT=*
//SYSIN DD *
ANALYZE DDNAME(OUTPUTA)
```

Figure 26. Sample JCL for the CSQUTIL ANALYZE function

Usage notes

1. If you omit DDname(*ddname*) the default DDname, CSQUINP, is used.

Emptying a queue of all messages (EMPTY) on z/OS

You can use the EMPTY function of CSQUTIL to delete all messages from a named queue or all the queues on a page set.

The queue manager must be running. The scope of the function is determined by the keyword that you specify in the first parameter.

Use this function with care. Only delete messages of which copies have already been made.

Note: See “Syncpoints” on page 2777 for information about how to avoid problems with duplicate messages if this function fails.

- [Keywords and parameters](#)
- [Example](#)
- [Usage notes](#)

Keywords and parameters

You must specify the scope of the EMPTY function. Choose one of these:

QUEUE(*q-name*)

Specifies that messages are to be deleted from a named queue. This keyword can be abbreviated to Q.

q-name specifies the name of the queue from which messages are to be deleted. This name is case sensitive.

PSID(*psid-number*)

Specifies that all the messages are to be deleted from all queues in the named page set.

psid-number specifies the page-set identifier. This identifier is a two-digit integer (whole number) representing a single page set.

Example

```
//EMPTY EXEC PGM=CSQUTIL,PARM=('CSQ1')
//STEPLIB DD DISP=SHR,DSN=thlqua1.SCSQANLE
// DD DISP=SHR,DSN=thlqua1.SCSQAUTH
//SYSPRINT DD SYSOUT=*
//SYSIN DD *
EMPTY QUEUE (SPARE)
EMPTY PSID(66)
/*
```

Figure 27. Sample JCL for the CSQUTIL EMPTY function

Usage notes

1. The queues involved must not be in use when the function is invoked.

2. This function operates only on local queues.
3. If you want to operate on a range of page sets, repeat the EMPTY function for each page set.
4. You cannot empty the system-command input queue (SYSTEM.COMMAND.INPUT).
5. An EMPTY PSID function is considered successful only if it successfully empties all the queues on the page set.
6. If you empty a queue that is already empty (either explicitly by EMPTY QUEUE or because there are one or more empty queues on a page set that you are emptying), the EMPTY function is considered to be a success. However, if you attempt to empty a nonexistent queue, or a page set containing no queues, the EMPTY function fails.
7. If EMPTY fails or is forced to take a syncpoint, no further CSQUTIL functions are attempted.
8. You need the necessary authority to use the command server queues (SYSTEM.COMMAND.INPUT, SYSTEM.COMMAND.REPLY.MODEL, and SYSTEM.CSQUTIL.*), to use the DISPLAY QUEUE and DISPLAY STGCLASS MQSC commands, and to use the IBM MQ API to get messages from the queues that you want to empty.

Related concepts

[“Invoking the IBM MQ utility program on z/OS” on page 2775](#)

Use this topic to understand how to invoke CSQUTIL, the format of its parameters, and its return codes.

Restoring messages from a data set to a queue (LOAD) on z/OS

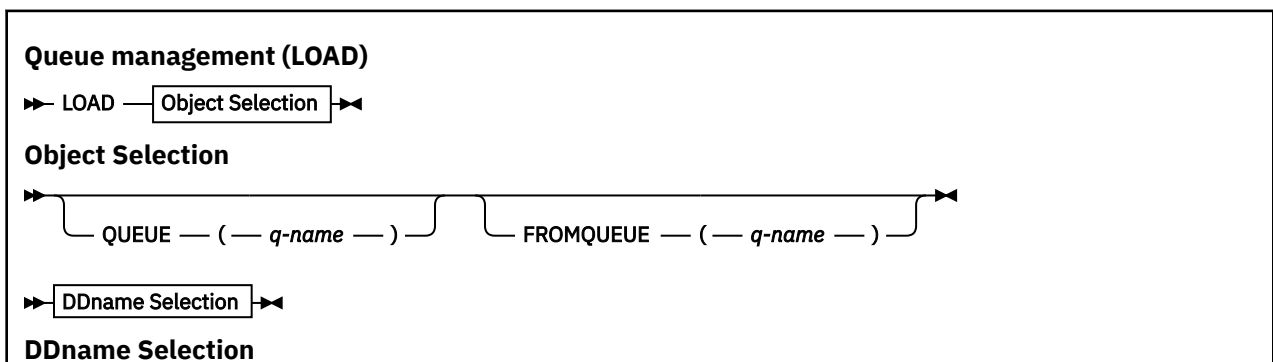

The LOAD function of CSQUTIL is complementary to the COPY or SCOPY function. LOAD restores messages from the destination data set of an earlier COPY or SCOPY operation. The queue manager must be running.

The data set can contain messages from one queue only if it was created by COPY or SCOPY QUEUE, or from a number of queues if it was created by COPY PSID or several successive COPY or SCOPY QUEUE operations. Messages are restored to queues with the same name as those from which they were copied. You can specify that the first or only queue is loaded to a queue with a different name. (This would normally be used with a data set created with a single COPY queue operation to restore the messages to a queue with a different name.)

Notes:

1. See [“Syncpoints” on page 2777](#) for information about how to avoid problems with duplicate messages if this function fails.
2. An alternative approach to the LOAD function is to use the [“dmpmqmsg \(queue load and unload\)” on page 65](#) utility which is more flexible in many cases.

Messages are restored to queues with the same name as those from which they were copied. You can specify that the first or only queue is loaded to a queue with a different name using the **QUEUE** parameter. (This would normally be used with a data set created with a single COPY queue operation to restore the messages to a queue with a different name.) For a data set containing multiple queues, the first queue to be processed can be specified using the **FROMQUEUE** parameter. Messages are restored to this queue and all subsequent queues in the data set.

- [Keywords and parameters](#)
- [Example](#)
- [Usage notes](#)

Keywords and parameters

QUEUE(*q-name*)

This parameter specifies that the messages from the first or only queue on the destination data set of a prior COPY or SCOPY operation are loaded to a named queue. Messages from any subsequent queues are loaded to queues with the same names as those they came from. The keyword QUEUE can be abbreviated to Q.

q-name specifies the name of the queue to which the messages are to be loaded. This name is case sensitive. It must not be a model queue.

FROMQUEUE(*q_name*)

Specifies the name of the first queue to process on the destination data set of a prior COPY or SCOPY operation. Messages from this queue and any subsequent queues on the data set are loaded to queues with the same names as those that they came from. If this parameter is removed, the LOAD function starts with the first queue on the data set and processes all queues. The keyword FROMQUEUE can be abbreviated to FROMQ.

DDNAME(*ddname*)

Specifies that messages are loaded from a named data set. This keyword can be abbreviated to DD.

ddname specifies the **DDNAME** that identifies the destination data set of a prior COPY or SCOPY operation, from which the messages are to be loaded. This name is not case sensitive, and can be up to 8 characters long.

If you omit **DDNAME** (*ddname*) the default **DDNAME**, CSQUINP, is used.

SKIPMSGS(*n*)

Specifies that the first *n* messages in the sequential data set are to be skipped before commencing the load of the queue.

If you omit SKIPMSGS(*n*) no messages are skipped; the load starts at the first message.

MSGCOUNT(*m*)

Specifies that only *m* messages are read from the data set and loaded to the queue.

If you omit MSGCOUNT(*m*) the number of messages read is unlimited.

Example

```
//LOAD EXEC PGM=CSQUTIL,PARM=('CSQ1'),REGION=0M
//STEPLIB DD DISP=SHR,DSN=thlqua1.SCSQANLE
// DD DISP=SHR,DSN=thlqua1.SCSQAUTH
//OUTPUTA DD DSN=MY.UTILITY.OUTPUTA,DISP=SHR
//CSQUINP DD DSN=MY.UTILITY.COPYA,DISP=SHR
//SYSPRINT DD SYSOUT=*
//SYSIN DD *
LOAD QUEUE(ABC123) DDNAME(OUTPUTA)
LOAD QUEUE(TOQ) FROMQUEUE(QUEUEA) SKIPMSGS(55)
/*
```

Figure 28. Sample JCL for the CSQUTIL LOAD function

Note:

REGION - A value of 0M means that the job is allowed to have the amount of storage it needs. However, if a job tries to acquire too much storage, it might impact other jobs in the system. You must ideally look to limit the REGION size and specify an absolute maximum value that the job is allowed to acquire.

LOAD QUEUE(ABC123) DDNAME(OUTPUTA) - Reloads all queues from the input data set MY.UTILITY.OUTPUTA. The names of the queues loaded are the same as the queue names from which the data was copied, apart from the first queue on the data set which is reloaded to queue ABC123.

LOAD QUEUE(TOQ) FROMQUEUE(QUEUEA) SKIPMSGS(55) - Reloads all queues from the input data set MY.UTILITY.COPYA, starting from queue QUEUEA. The names of the queues loaded are the same as the queue names from which the data was copied, apart from the first queue QUEUEA, which is reloaded to queue TOQ. In processing the messages in QUEUEA, the first 55 messages are ignored, and loading starts from the 56th message.

Usage notes

1. To use the LOAD function, the queues or page sets involved must not be in use when the function is invoked.
2. If the data set contains multiple queues, the LOAD function is considered successful only if it successfully loads all the queues on the data set. (or all those following the starting queue specified with FROMQUEUE, if this is set).
3. If LOAD fails, or is forced to take a syncpoint, no further CSQUTIL functions are attempted.
4. CSQUTIL uses MQPMO_SET_ALL_CONTEXT to ensure that the message descriptor fields remain the same as the original copy. It therefore needs an access of CONTROL in the CONTEXT profile of the queue. For full details, see [Profiles for context security](#).

Restoring messages from a data set to a queue (SLOAD) on z/OS

The SLOAD function of CSQUTIL is complementary to the COPY or SCOPY function. SLOAD restores messages from the destination data set of an earlier COPY or SCOPY operation. SLOAD processes a single queue.

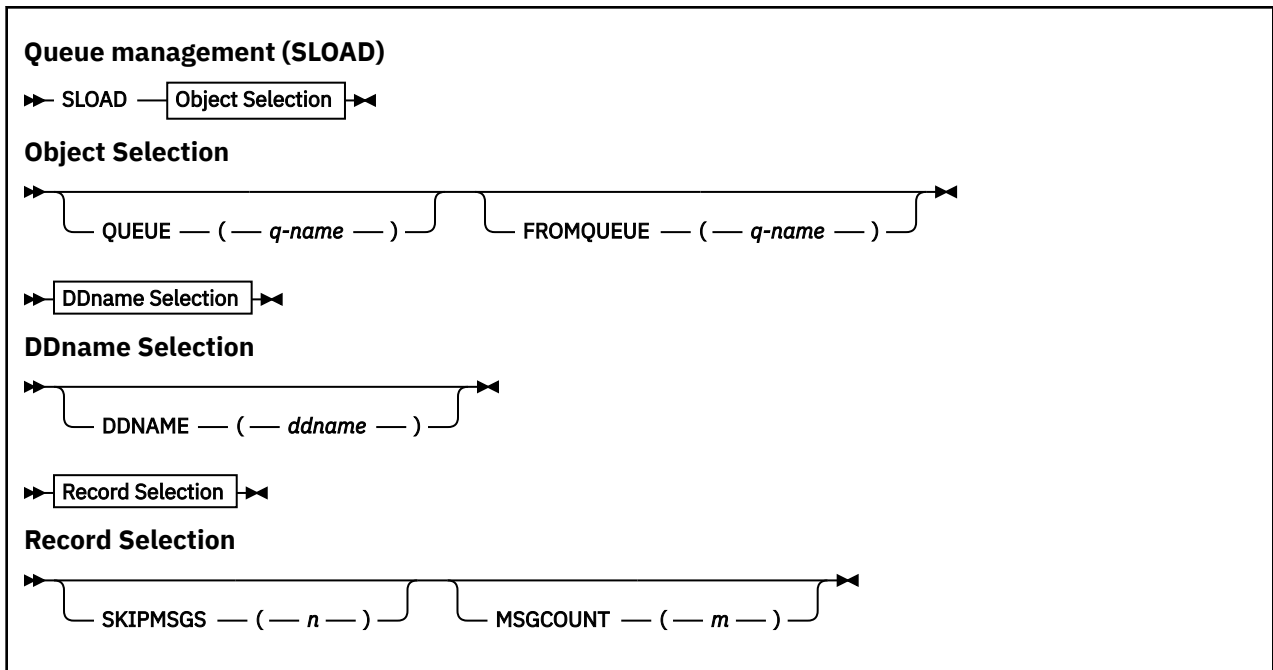

To use SLOAD the queue manager must be running.

If the data set was created by COPY or SCOPY QUEUE it contains messages from one queue only. If the data set was created by COPY PSID or several successive COPY or SCOPY QUEUE operations, it might contain messages from a number of queues.

By default, SLOAD processes the first queue on the data set. You can specify a particular queue to process using the **FROMQUEUE** parameter.

By default, messages are restored to a queue with the same name as the one from which it was copied. You can specify that the queue is loaded to a queue with a different name using the **QUEUE** parameter.

Note: See “Syncpoints” on page 2777 for information about how to avoid problems with duplicate messages if this function fails.

- “Keywords and parameters” on page 2806
- “Example” on page 2807
- “Usage notes” on page 2807

Keywords and parameters

QUEUE(*q-name*)

This parameter specifies that the messages from the first or only queue on the destination data set of a prior COPY or SCOPY operation are to be loaded to a named queue. The keyword QUEUE can be abbreviated to Q.

q-name specifies the name of the queue to which the messages are to be loaded. This name is case sensitive. It must not be a model queue.

FROMQUEUE(*q-name*)

Specifies the name of the queue to process. If this parameter is omitted, the first queue is processed. The keyword FROMQUEUE can be abbreviated to FROMQ.

q-name specifies the name of the queue to be processed. This name is case sensitive.

DDNAME(*ddname*)

Specifies that messages are to be loaded from a named data set. This keyword can be abbreviated to DD.

ddname specifies the **DDNAME** that identifies the destination data set of a prior COPY or SCOPY operation, from which the messages are to be loaded. This name is not case sensitive, and can be up to 8 characters long.

If you omit **DDNAME** (*ddname*) the default **DDNAME**, CSQUINP, is used.

SKIPMSGS(*n*)

Specifies that the first *n* messages in the sequential data set are to be skipped before commencing the load of the queue.

If you omit SKIPMSGS(*n*) no messages are skipped; the load starts at the first message.

- [Keywords and parameters](#)
- [Example](#)
- [Usage notes](#)

Keywords and parameters

CHANNEL (*channel name*)

Specifies the name of a cluster-sender channel, or a generic channel name.

If a generic channel name is specified each cluster-sender channel that matches the generic name is processed.

If a single asterisk is specified all cluster-sender channels are processed.

MOVEMSGS

Specifies whether messages queued for the channel should be moved from the old transmission queue to the new transmission queue during the switching process. Values are:

YES

Messages are moved from the old transmission queue to the new transmission queue. This is the default.

NO

Messages are not moved from the old transmission queue to the new transmission queue. If this option is selected it is the responsibility of the system programmer to resolve any messages for the channel on the old transmission queue after the switch has completed.

STATUS

Display the switching status for matching cluster-sender channels. If this keyword is not specified the command switches the transmission queue for stopped or inactive cluster-sender channels that require switching.

Examples

Figure 1 illustrates how the SWITCH function can be used to query the switching status of all cluster-sender channels whose names match the generic name CLUSTER.*.

```
//SWITCH EXEC PGM=CSQUTIL,PARM=('CSQ1')
//STEPLIB DD DISP=SHR,DSN=thlqua1.SCSQANLE
// DD DISP=SHR,DSN=thlqua1.SCSQAUTH
//SYSPRINT DD SYSOUT=*
//SYSIN DD *
SWITCH CHANNEL(CLUSTER.*) STATUS
/*
```

Figure 30. Sample JCL for querying the switching status of cluster-sender channels using the CSQUTIL SWITCH function

Figure 2 illustrates how the SWITCH function can be used to switch the transmission queue for the cluster-sender channel CLUSTER.TO.QM1.

```
//SWITCH EXEC PGM=CSQUTIL,PARM=('CSQ1')
//STEPLIB DD DISP=SHR,DSN=thlqua1.SCSQANLE
// DD DISP=SHR,DSN=thlqua1.SCSQAUTH
//SYSPRINT DD SYSOUT=*
//SYSIN DD *
SWITCH CHANNEL(CLUSTER.TO.QM1)
/*
```

Figure 31. Sample JCL for switching the transmission queue associated with a cluster-sender channel using the CSQUTIL SWITCH function

Usage notes

1. The channel initiator must be running to initiate a switch of transmission queue for cluster-sender channels.
2. The transmission queue associated with a cluster-sender channel can only be switched if the channel is STOPPED or INACTIVE.
3. You need the necessary authority to use the command server queues (SYSTEM.COMMAND.INPUT, SYSTEM.COMMAND.REPLY.MODEL, and SYSTEM.CSQUTIL.*)
4. You need the necessary authority to issue the START CHANNEL command.
5. To initiate a switch of transmission queue for a cluster-sender channel, you also need command resource authority for the channel.

Related tasks

Clustering: [Switching cluster transmission queues](#)

z/OS

The change log inventory utility (CSQJU003) on z/OS

The IBM MQ change log inventory utility runs as a z/OS batch job to change the bootstrap data set (BSDS).

Through this utility, you can invoke these functions:

NEWLOG

Add active or archive log data sets.

DELETE

Delete active or archive log data sets.

ARCHIVE

Supply passwords for archive logs.

CRESTART

Control the next restart of IBM MQ.

CHECKPT

Set checkpoint records.

HIGHRBA

Update the highest written log RBA.

Only run this utility when IBM MQ is stopped. This is because the active log data sets named in the BSDS are dynamically added for exclusive use to IBM MQ and remain allocated exclusively to IBM MQ until it terminates. You can add new active log data sets to an active queue manager with the [“DEFINE LOG \(define a new active log\) on z/OS”](#) on page 561 command.

The DEFINE LOG command can be used to update a BSDS of any version. However, you must use the CSQJUCNV utility to convert the BSDS from version 1 to version 2. A version 1 BSDS has space for up to 31 active log data sets in each log copy ring, whereas a version 2, or higher, BSDS has space for up to 310 active log data sets in each log copy ring.

Invoking the CSQJU003 utility on z/OS

Use this topic to understand how to invoke the CSQJU003 utility.

The utility runs as a z/OS batch program. [Figure 32 on page 2810](#) gives an example of the JCL required.

```
//JU003 EXEC PGM=CSQJU003
//STEPLIB DD DISP=SHR,DSN=th1qua1.SCSQANLE
// DD DISP=SHR,DSN=th1qua1.SCSQAUTH
//SYSPRINT DD SYSOUT=*,DCB=BLKSIZE=629
//SYSUT1 DD DISP=SHR,DSN=bsds.dsname
//SYSIN DD *
NEWLOG DSN=CSQREPAL.A0001187,COPY1VOL=CSQV04,UNIT=SYSDA,
STARTRBA=3A190000,ENDRBA=3A1F0FFF,CATALOG=YES,PASSWORD=PASSWRD
/*
```

Figure 32. Sample JCL to invoke the CSQJU003 utility

Data definition (DD) statements

CSQJU003 requires DD statements with these DDnames:

SYSUT1

This statement is required; it names the BSDS.

SYSUT2

This statement is required if you use dual BSDSs; it names the second copy of the BSDS.

Dual BSDSs and CSQJU003

Each time you run the CSQJU003 utility, the BSDS time stamp field is updated with the current system time. If you run CSQJU003 separately for each copy of a dual copy BSDS, the time stamp fields are not synchronized, so the queue manager fails at startup, issuing error message CSQJ120E. Therefore, if CSQJU003 is used to update dual copy BSDSs, both BSDSs must be updated within a single run of CSQJU003.

SYSPRINT

This statement is required; it names a data set for print output. The logical record length (LRECL) is 125. The block size (BLKSIZE) must be 629.

SYSIN

This statement is required; it names the input data set for statements that specify what the utility is to do. The logical record length (LRECL) is 80.

You can use more than one statement of each type. In each statement, separate the operation name (NEWLOG, DELETE, ARCHIVE, CRESTART) from the first parameter by one or more blanks. You can use parameters in any order; separate them by commas with no blanks. Do not split a parameter description across two SYSIN records.

A statement containing an asterisk (*) in column 1 is considered to be a comment, and is ignored. However, it appears in the output listing. To include a comment or sequence number in a SYSIN record, separate it from the last comma by a blank. When a blank follows a comma, the rest of the record is ignored.

Multiple statement operation

When running CSQJU003, a significant error in any statement causes the control statements for the statement in error and all following statements to be skipped. Therefore, BSDS updates cannot occur for any operation specified in the statement in error, or any following statements. However, all the remaining statements are checked for syntax errors.

z/OS Adding information about a data set to the BSDS (NEWLOG) on z/OS

You can use the NEWLOG function of CSQJU003 to add information about a data set to BSDS.

The NEWLOG function declares one of the following data sets:

- A VSAM data set that is available for use as an active log data set.

Use the keywords DSNAME, COPY1, COPY2, and PASSWORD.

- An active log data set that is replacing one that encountered an I/O error.

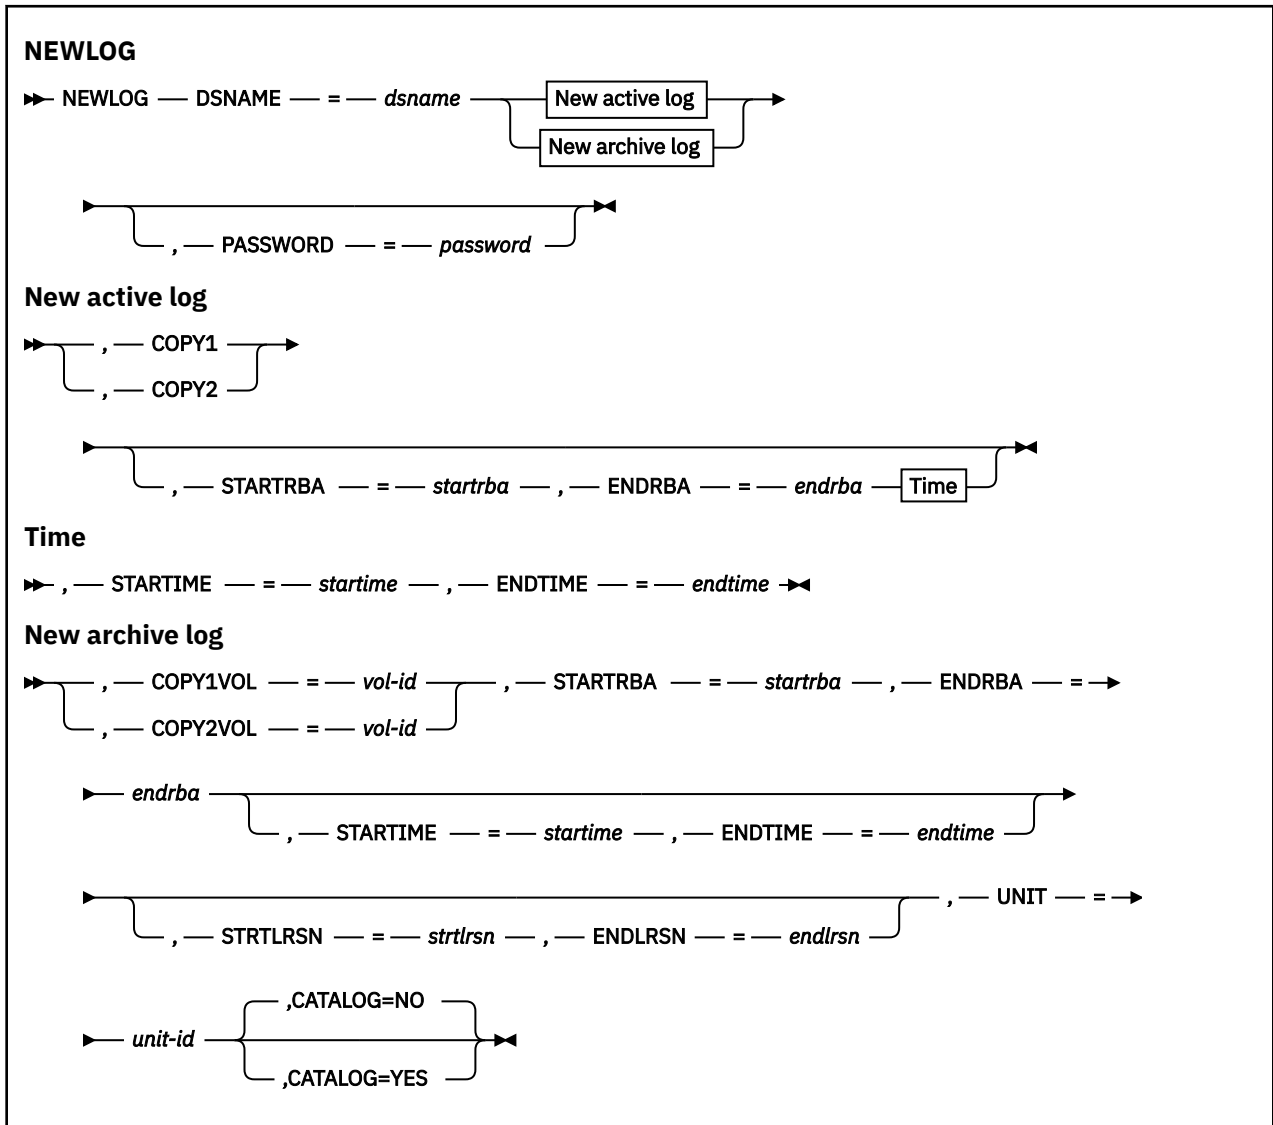

Use the keywords DSNAME, COPY1, COPY2, STARTRBA, ENDRBA, and PASSWORD.

- An archive log data set volume.

Use the keywords DSNAME, COPY1VOL, COPY2VOL, STARTRBA, ENDRBA, STRTLRSN, ENDLRSN, UNIT, CATALOG, and PASSWORD.

In a queue sharing group environment, you should always supply LRSN information. Run the print log map utility ([“The print log map utility \(CSQJU004\) on z/OS” on page 2817](#)) to find RBAs and LRSNs to use for archive log data sets.

A maximum of 310 data sets can be defined for each log copy, either by this NEWLOG function or the MQSC DEFINE LOG command.

Keywords and parameters

DSNAME= *dsname*

Names a log data set.

dsname can be up to 44 characters long.

PASSWORD= *password*

Assigns a password to the data set. It is stored in the BSDS and later used in any access to the active or archive log data sets.

The password is a data set password, and should follow standard VSAM convention: 1 through 8 alphanumeric characters (A through Z, 0 through 9) or special characters (& * + - . ; ' /).

You should use an ESM such as RACF to provide your data set security requirements.

COPY1

Makes the data set an active log copy-1 data set.

COPY2

Makes the data set an active log copy-2 data set.

STARTRBA= *startrba*

Gives the log RBA (relative byte address within the log) of the beginning of the replacement active log data set or the archive log data set volume specified by DSNAME.

startrba is a hexadecimal number of up to 16 characters. The value must end with 000. If you use fewer than 16 characters, leading zeros are added. The RBA can be obtained from messages or by printing the log map.

The value of STARTRBA must be a multiple of 4096. (The hexadecimal value must end in 000.)

A value higher than FFFFFFFF000 cannot be specified for a version 1 format BSDS.

ENDRBA= *endrba*

Gives the log RBA (relative byte address within the log) of the end of the replacement active log data set or the archive log data set volume specified by DSNAME.

endrba is a hexadecimal number of up to 16 characters. The value must end with FFF. If you use fewer than 16 characters, leading zeros are added.

A value higher than FFFFFFFFFF cannot be specified for a version 1 format BSDS.

STARTIME= *starttime*

Start time of the RBA in the BSDS. This is an optional field. The time stamp format (with valid values in parentheses) is yyyydddhhmssst, where:

yyyy

Indicates the year (1993 through 2099)

ddd

Indicates the day of the year (1 through 365; 366 in leap years)

hh

Indicates the hour (zero through 23)

mm

Indicates the minutes (zero through 59)

ss

Indicates the seconds (zero through 59)

t

Indicates tenths of a second

If fewer than 14 digits are specified for the STARTIME and ENDTIME parameter, trailing zeros are added.

STARTRBA is required when STARTIME is specified.

ENDTIME= *endtime*

End time of the RBA in the BSDS. This is an optional field. For time stamp format, see the STARTIME option. The ENDTIME value must be greater than or equal to the value of STARTIME.

STRTLRSN= *strtlrsn*

Gives the LRSN (logical record sequence number) of the first complete log record on the new archive data set.

strtlrsn is a hexadecimal number of up to 12 characters. If you use fewer than 12 characters, leading zeros are added.

ENDLRSN= *endlrsn*

Gives the LRSN (logical record sequence number) of the last log record on the new archive data set.

endlrsn is a hexadecimal number of up to 12 characters. If you use fewer than 12 characters, leading zeros are added.

COPY1VOL= *vol-id*

The volume serial of the copy-1 archive log data set named after DSNAME.

COPY2VOL= *vol-id*

The volume serial of the copy-2 archive log data set named after DSNAME.

UNIT= *unit-id*

The device type of the archive log data set named after DSNAME.

CATALOG

Specifies whether the archive log data set is cataloged:

NO

The archive log data set is not cataloged. All subsequent allocations of the data set are made using the unit and volume information specified on the function. This is the default.

YES

The archive log data set is cataloged. A flag is set in the BSDS indicating this, and all subsequent allocations of the data set are made using the catalog.

IBM MQ requires that all archive log data sets on DASD be cataloged. Select CATALOG=YES if the archive log data set is on DASD.

Deleting information about a data set from the BSDS (DELETE) on z/OS

You can use the DELETE function of CSQJU003 to delete all information about a specified log data set or data set volume from the bootstrap data sets.

For example, you can use this function to delete outdated archive log data sets.

**Keywords and parameters****DSNAME= *dsname***

Specifies the name of the log data set.

dsname can be up to 44 characters long.

COPY1VOL= *vol-id*

The volume serial number of the copy-1 archive log data set named after DSNAME.

COPY2VOL= vol-id

The volume serial number of the copy-2 archive log data set named after DSNAME.

z/OS Supplying a password for archive log data sets (ARCHIVE) on z/OS

You can use the ARCHIVE function of CSQJU003 to assign a password to all archive data sets created after this operation.

This password is added to the z/OS password data set each time a new archive log data set is created.

Use the NOPASSWD keyword to remove the password protection for all archives created after the archive operation.

Note: Typically, use an external security manager (ESM), such as RACF, if you want to implement security on any IBM MQ data sets.

Keywords and parameters

PASSWORD= password

Specifies that a password is to be assigned to the archive log data sets.

password specifies the password, which is a data set password and it must follow the standard VSAM convention; that is, 1 through 8 alphanumeric characters (A through Z, 0 through 9) or special characters (& * + - . ; ' /).

NOPASSWD

Specifies that archive password protection is not to be active for all archives created after this operation. No other keyword can be used with NOPASSWD.

z/OS Controlling the next restart (CRESTART) on z/OS

You can use the CRESTART function of CSQJU003 to control the next restart of the queue manager, either by creating a new conditional restart control record or by canceling the one currently active.

These records limit the scope of the log data used during restart (truncating the log, in effect) . Any existing conditional restart control record governs every restart until one of these events occurs:

- A restart operation completes
- A CRESTART CANCEL is issued
- A new conditional restart control record is created

Attention: This can override IBM MQ efforts to maintain data in a consistent state. Only use this function when implementing the disaster recovery process described in [Recovering a single queue manager at an alternative site](#) and [Recovering a queue sharing group at the alternative site](#), or under the guidance of IBM service.

Keywords and parameters

CREATE

Creates a new conditional restart control record. When the new record is created, the previous control record becomes inactive.

CANCEL

Makes the currently active conditional restart control record inactive. The record remains in the BSDS as historical information.

No other keyword can be used with CANCEL.

ENDRBA= *endrba*

Gives the last RBA of the log to be used during restart (the point at which the log is to be truncated), and the starting RBA of the next active log to be written after restart. Any log information in the bootstrap data set and the active logs, with an RBA greater than *endrba*, is discarded.

endrba is a hexadecimal number of up to 16 digits. If you use fewer than 16 digits, leading zeros are added.

The value of ENDRBA must be a multiple of 4096. (The hexadecimal value must end in 000.)

A value higher than FFFFFFFF000 cannot be specified for a version 1 format BSDS.

ENDLRSN= *endlrsn*

Gives the LRSN of the last log record to be used during restart (the point at which the log is to be truncated). Any log information in the bootstrap data set and the active logs with an LRSN greater than *endlrsn* is discarded.

z/OS Setting checkpoint records (CHECKPT) on z/OS

You can use the CHECKPT function of CSQJU003 to add or delete a record in the BSDS checkpoint queue.

Use the STARTRBA and ENDRBA keywords to add a record, or the STARTRBA and CANCEL keywords to delete a record.

Attention: This can override IBM MQ efforts to maintain data in a consistent state. Only use this function when implementing the disaster recovery process described in [Recovering a single queue manager at an alternative site](#) and [Recovering a queue sharing group at the alternative site](#), or under the guidance of IBM service.

CHECKPT

```
▶▶ CHECKPT — STARTRBA — = — startrba —▶  
  
▶ — ENDRBA — = — offlrba — , — TIME — = — time —▶  
    , — CANCEL —▶
```

Keywords and parameters

STARTRBA= *startrba*

Indicates the start checkpoint log record.

startrba is a hexadecimal number of up to 16 digits. If you use fewer than 16 digits, leading zeros are added. The RBA can be obtained from messages or by printing the log map.

A value higher than FFFFFFFFFF cannot be specified for a version 1 format BSDS.

ENDRBA= *endrba*

Indicates the end checkpoint log record corresponding to the start checkpoint record.

endrba is a hexadecimal number of up to 16 digits. If you use fewer than 16 digits, leading zeros are added. The RBA can be obtained from messages or by printing the log map.

A value higher than FFFFFFFFFF cannot be specified for a version 1 format BSDS.

TIME= *time*

Gives the time the start checkpoint record was written. The time stamp format (with valid values in parentheses) is *yyydddhhmmsst*, where:

yyyy

Indicates the year (1993 through 2099)

ddd

Indicates the day of the year (1 through 365; 366 in leap years)

hh

Indicates the hour (zero through 23)

mm

Indicates the minutes (zero through 59)

ss

Indicates the seconds (zero through 59)

t

Indicates tenths of a second

If fewer than 14 digits are specified for the TIME parameter, trailing zeros are added.

CANCEL

Deletes the checkpoint queue record containing a starting RBA that matches the RBA specified by STARTRBA.

z/OS Updating the highest written log RBA (HIGHRBA) on z/OS

You can use the HIGHRBA function of CSQJU003 to update the highest written log RBA recorded in the BSDS for either the active or archive log data sets.

Use the STARTRBA keyword to update the active log, and the OFFLRBA keyword to update the archive log.

Attention: This can override IBM MQ efforts to maintain data in a consistent state. Only use this function when implementing the disaster recovery process described in [Recovering a single queue manager at an alternative site](#), or under the guidance of IBM service personnel.

Keywords and parameters

STARTRBA= *startrba*

Indicates the log RBA of the highest written log record in the active log data set.

startrba is a hexadecimal number of up to 16 digits. If you use fewer than 16 digits, leading zeros are added. The RBA can be obtained from messages or by printing the log map.

A value higher than FFFFFFFFFF cannot be specified for a version 1 format BSDS.

TIME= *time*

Specifies when the log record with the highest RBA was written to the log. The time stamp format (with valid values in parentheses) is *yyydddhhmmsst*, where:

yyyy

Indicates the year (1993 through 2099)

ddd

Indicates the day of the year (1 through 365; 366 in leap years)

hh

Indicates the hour (zero through 23)

mm

Indicates the minutes (zero through 59)

ss

Indicates the seconds (zero through 59)

t

Indicates tenths of a second

If fewer than 14 digits are specified for the TIME parameter, trailing zeros are added.

OFFLRBA= *offlrba*

Specifies the highest offloaded RBA in the archive log.

offlrba is a hexadecimal number of up to 16 digits. If you use fewer than 16 digits, leading zeros are added. The value must end with hexadecimal 'FFF'.

A value higher than FFFFFFFFFFFFFFFF cannot be specified for a version 1 format BSDS.

 z/OS**The print log map utility (CSQJU004) on z/OS**

CSQJU004 is the batch utility program used to print log data information from the BSDS.

The IBM MQ print log map utility runs as a z/OS batch program to list the following information:

- The BSDS version
- Log data set name and log RBA association for both copies of all active and archive log data sets
- Active log data sets available for new log data
- Contents of the queue of checkpoint records in the bootstrap data set (BSDS)
- Contents of the quiesce history record
- System and utility time stamps
- Passwords for the active and archive log data sets, if provided

You can run the CSQJU004 program regardless of whether the queue manager is running. However, if the queue manager is running, consistent results from the utility can be ensured only if both the utility and the queue manager are running under control of the same z/OS system.

For further information, see

- [Invoking the CSQJU004 utility](#)
- [Data definition statements required for the CSQJU004 utility](#)

To use this utility, the user ID of the job must have the requisite security authorization, or, if the BSDS is password protected, the appropriate VSAM password for the data set.

Invoking the CSQJU004 utility

The following example shows the JCL used to invoke the CSQJU004 utility:

```
//JU004 EXEC PGM=CSQJU004
//STEPLIB DD DISP=SHR,DSN=thlqua1.SCSQANLE
// DD DISP=SHR,DSN=thlqua1.SCSQAUTH
//SYSPRINT DD SYSOUT=*
//SYSUT1 DD DISP=SHR,DSN=bsds.dsname
```

Figure 33. Sample JCL to invoke the CSQJU004 utility

The EXEC statement can use an optional parameter TIME(RAW) which changes the way timestamps are formatted.

```
//JU004 EXEC PGM=CSQJU004,PARM='TIME(RAW)'
```

This parameter causes timestamps to be formatted without applying timezone or leap second offsets for the formatting system. You can use this mode of operation when formatting a BSDS created at a remote site, or before a daylight saving time change, for example. The default, no parameter specified, is to format timestamps using the current formatting system's timezone and leap second corrections.

Formatted times affected by this parameter are:

- highest RBA written
- archive log command times
- checkpoint times
- conditional restart record times

Data definition statements

The CSQJU004 utility requires DD statements with the following DDnames:

SYSUT1

This statement is required to specify and allocate the bootstrap data set. If the BSDS must be shared with a concurrently running queue manager subsystem, use DISP=SHR on the DD statement.

SYSPRINT

This statement is required to specify a data set or print spool class for print output. The logical record length (LRECL) is 125 and the record format (RECFM) is VBA.

[Finding out what the BSDS contains](#) describes the output.

z/OS

The log print utility (CSQ1LOGP) on z/OS

Use this utility to print information, including messages, contained in the IBM MQ active or archive log data sets.

- [“Typical uses of CSQ1LOGP” on page 2819](#)
- [“Data definition statements” on page 2819](#)
- [Input control parameters](#)
- [Exec parameters](#)
- [Usage notes](#)
- [CSQ1LOGP output](#)
 - [Detail report](#)
 - [Record layouts for the output data sets](#)
- [“CSQ1LOGP errors and messages” on page 2827](#)
- [“Examples that do not use the EXTRACT parameter” on page 2827](#)

- The EXTRACT parameter
 - Example of using the EXTRACT parameter

Typical uses of CSQ1LOGP

You can use CSQ1LOGP for the following purposes. Data sets can be either active logs, archive logs, or both:

- Displaying every log record in one or more data sets.
- Displaying a specific range of log records from one or more data sets. The range can either be defined by relative byte address (RBA) using the RBASTART and RBAEND parameters, or log record sequence number (LRSN), using the LRSNSTART and LRSNEND parameters.
- Displaying log records for one or more specific unit of recovery identifiers (URIDs) using the URID parameter.
- Displaying log records containing specific data using the DATA parameter.
- Displaying log records relating to specific page sets using the PAGESET parameter.
- Displaying log records relating to specific IBM MQ resource managers using the RM parameter.
- Writing logged messages that meet a set of criteria to a data set for subsequent processing, which could include sending those messages to a queue; see [“Using CSQ4LOGS to process output from CSQ1LOGP EXTRACT” on page 2829](#). This might be useful if an application processes persistent messages incorrectly, as those messages can be retrieved from the logs and sent back to the original queue for the corrected application to process again.
- Writing altered objects that meet a set of criteria to a data set for subsequent processing.

Note: Users of CSQ1LOGP can directly specify a set of active and /or archive logs to process, or use information in the bootstrap data sets (BSDS) to locate the required logs.

Data definition statements

CSQ1LOGP takes several different DD statements depending on how it is being used.

Required DD statements

SYSPRINT

All error messages, exception conditions, and the detail report are written to this data set. The logical record length (LRECL) is 131.

Optional DD statements

You must specify at least one of the BSDS, ACTIVE n , or ARCHIVE DD statements.

You can use the BSDS and ACTIVE n options even if the queue manager is running, provided that the BSDS and relevant active log data sets are defined with at least SHAREOPTIONS(2 3).

ACTIVE n

Name of an active log data set you want to print (n =number), for example, ACTIVE1.

ARCHIVE

A concatenation of one or more archive logs that you want to print. If multiple archive logs are specified they should represent a continuous range of logs without gaps.

BSDS

Name of the bootstrap data set (BSDS) to locate active or archive log data sets from. Note that you must specify RBASTART or LRSNSTART.

SYSIN

Input selection criteria can be specified in this data set. See [“Input control parameters” on page 2820](#) for more information. If no selection criteria are specified, then all log records are printed.

The logical record length (LRECL) must be 80, but only columns 1 through 72 are significant; columns 73 through 80 are ignored. At most 50 records can be used. Records with an asterisk (*) in column 1 are interpreted as comments and are ignored.

SYSSUMRY

If a summary report is requested, by specifying the parameter **SUMMARY (YES)** or **SUMMARY (ONLY)**, the output is written to this data set. The logical record length (LRECL) is 131.

If you specify the keyword **EXTRACT (YES)**, provide one or more of the following DD statements, depending on what types of data you want to extract. Do not specify an LRECL, as it is set internally by the utility. For each of these DD statements, the record format (RECFM) is VB, the logical record length (LRECL) is 32756, and the block size (BLKSIZE) must be 32760.

CSQBACK

This data set contains persistent messages written to the log by units of work that were rolled back during the log range specified.

CSQCMT

This data set contains persistent messages written to the log by units of work that were committed during the log range specified.

CSQBOTH

This data set contains persistent messages written to the log by units of work that were either committed or rolled back during the log range specified.

CSQINFLT

This data set contains persistent messages written to the log by units of work that remained in flight during the log range specified.

CSQOBS

This data set contains information about object alterations that occurred during the log range specified.

Input control parameters

These parameters must be in the SYSIN data set and specify various selection criteria to limit the log records that are processed. These are:

LRSNSTART (hexadecimal-constant)

Specifies the logical record sequence number (LRSN) from which to begin processing. You cannot use this keyword together with RBASTART. Use this keyword only if your queue manager is in a queue sharing group.

LRSN values are always greater than A00000000000; this value is used as the start value if a lower value is specified.

You can also use the forms STARTLRSN or STRTLRSN or LRSNSTRT. Specify this keyword only once.

LRSNEND (hexadecimal-constant)

Specifies the logical record sequence number (LRSN) of the last record to be scanned. The default is FFFFFFFFFF (the end of the data sets). You can use this keyword only with LRSNSTART.

You can also use the form ENDLRSN.

Specify this keyword only once.

RBASTART (hexadecimal-constant)

Specifies the log RBA from which to begin processing. You cannot use this keyword together with LRSNSTART.

You can also use the forms STARTRBA or ST. Specify this keyword only once.

RBAEND (hexadecimal-constant)

Specifies the last valid log RBA that is to be processed. If this keyword is omitted, processing continues to the end of the log (FFFFFFFFFFFF if 6 byte RBAs are in use, or FFFFFFFFFFFFFFFF if 8 byte RBAs are in use). You can use this keyword only with RBASTART.

You can also use the forms ENDRBA or EN. Specify this keyword only once.

PAGESET (decimal-integer)

Specifies a page set identifier. The number must be in the range 00 through 99. You can specify a maximum of 10 PAGESET keywords. If PAGESET keywords are specified, only log records associated with the page sets you specify are processed.

URID (hexadecimal-constant)

Specifies a hexadecimal unit of recovery identifier. Changes to data occur in the context of an IBM MQ unit of recovery. A unit of recovery is identified on the log by a BEGIN UR record. The log RBA of that BEGIN UR record is the URID value you must use. If you know the URID for a particular UR that you are interested in, you can limit the extraction of information from the log to that URID.

The hexadecimal constant can consist of 1 through 16 characters (8 bytes), and leading zeros are not required.

You can specify a maximum of 10 URID keywords.

DATA (hexadecimal-string)

Specifies a data string in hexadecimal.

The string can consist of 2 through 48 characters (24 bytes), and must have an even number of characters.

You can specify a maximum of 10 DATA keywords.

If multiple DATA keywords are specified, only log records that contain at least one of the strings are processed.

Note: Though you can use the DATA and EXTRACT parameters together, it is difficult to reliably derive meaning from the output, unless you have a good understanding of the internal implementation of IBM MQ. This is because only the low level individual log records that contain the requested DATA are processed so you do not extract the full output that is logically associated with the data, only the records where that DATA sequence actually appears. For example you might get only records associated with putting messages and not with getting messages, or you might get only the first part of the data for long messages because the rest of the data is in other log records that do not contain the requested DATA string.

RM (resource_manager)

Specifies a particular resource manager. Only records associated with this resource manager are processed. Valid values for this keyword are:

RECOVERY

Recovery log manager

DATA

Data manager

BUFFER

Buffer manager

IMSBRIDGE

IMS bridge

SUMMARY (YES|NO|ONLY)

Specifies whether a summary report is to be produced or not:

YES

Produce a summary report in addition to the detail report.

NO

Do not produce a summary report.

ONLY

Produce only a summary report (no detail report).

The default is NO.

EXTRACT (YES|NO)

Specifying EXTRACT(YES) causes each log record that meets the input selection criteria to be written to the appropriate output file, as explained on page [“The EXTRACT parameter” on page 2827](#). The default is NO.

Note: Though you can use the DATA and EXTRACT parameters together, it is difficult to reliably derive meaning from the output, unless you have a good understanding of the internal implementation of IBM MQ. This is because only the low level individual log records that contain the requested DATA are processed so you do not extract the full output that is logically associated with the data, only the records where that DATA sequence actually appears. For example you might get only records associated with putting messages and not with getting messages, or you might get only the first part of the data for long messages because the rest of the data is in other log records that do not contain the requested DATA string.

V 9.4.0 QMCCSID (decimal-integer)

Specifies the Coded Character Set Identifier to use as the queue manager CCSID. This should match the CCSID of the queue manager to which the logs belong.

It is ignored unless EXTRACT(YES) is also used, and is used with EXTRACT(YES) to process messages with message properties. The default is 500.

V 9.4.0 EXV6COMPAT (YES|NO)

Specifying EXV6COMPAT(YES) causes extracted messages that were put under PROPCTL(V6COMPAT) and that have had additional message properties added to be written to the appropriate output file with `csveib` of MQPUTV6C. See [“The EXTRACT parameter” on page 2827](#) for more information.

It is ignored unless EXTRACT(YES) is also used. The default is NO.

DECOMPRESS (YES|NO)

Specifies whether any compressed log records will be expanded:

YES

Any compressed log records will be expanded before a Search, Print or Extract function is performed.

NO

Any compressed log records will not be expanded before a Search or Print function is performed. Do not use DECOMPRESS(NO) with the Extract function.

The default is YES.

Exec parameters

The EXEC statement can use an optional parameter TIME(RAW) which changes the way timestamps are formatted.

```
//PRTLOG EXEC PGM=CSQ1LOGP,PARM='TIME(RAW)'
```

This causes timestamps to be formatted without applying time zone or leap second offsets for the formatting system. You can use this mode of operation when formatting log data created at a remote site, or before a daylight saving time change, for example.

If no parameter is specified, the default behavior is to format timestamps using the time zone and leap second corrections of the system doing the formatting.

Formatted times affected by this parameter are those associated with:

- Checkpoint time
- Restart time
- UR start time

Usage notes

1. If your queue manager is in a queue sharing group, you can specify the log range required by either LRSNSTART (optionally with LRSNEND) or RBASTART (optionally with RBAEND). You cannot mix LRSN and RBA specifications.

If you need to coordinate the log information from the different queue managers in the queue sharing group, use LRSN specifications. Note that processing logs simultaneously from different queue managers in a queue sharing group is not supported.
2. If your queue manager is not in a queue sharing group, you cannot use LRSN specifications; you must use RBA specifications.
3. CSQ1LOGP starts its processing on the first record containing an LRSN or RBA value greater than or equal to the value specified on LRSNSTART or RBASTART.
4. Normally you are only interested in the most recent additions to the log. Take care to choose a suitable value for the start of the log range, and do not use the defaults. Otherwise, you create an enormous amount of data, most of which is of no interest to you.

CSQ1LOGP output

Detail report

The detail report begins by echoing the input selection criteria specified by SYSIN, and then prints each valid log record encountered. Definitions of keywords in the detail report are as follows:

RM

Resource manager that wrote the log record.

TYPE

Type of log record.

URID

BEGIN UR for this unit of recovery, see the previous description.

LRID

Logical record identifier in the form: AAAAAAAA .BBBBBBCC where:

AAAAAAA

Is the page set number.

BBBBBB

Is the relative page number in the page set.

CC

Is the relative record number on the page.

LRSN

Logical record sequence number (LRSN) of the log record scanned.

SUBTYPE

Subtype of the log record type.

CHANGE LENGTH

Length of the logged change.

CHANGE OFFSET

Start position of the change.

BACKWARD CHAIN

Pointer to the previous page.

FORWARD CHAIN

Pointer to the next page.

RECORD LENGTH

Length of the inserted record.

Record layouts for the output data sets

The data sets produced when the EXTRACT keyword is specified contains information about persistent messages. Messages are identified by their queue name and an eight character key. Once a message has been got, the key can be reused by another message, so it is important to ensure that time sequence is maintained. In the records are times. A time stamp can be extracted only from a Begin-UR record or from an MQPUT request. Thus if there is only a long running transaction which is getting messages, the times when the gets occurred are the time the transaction started (the Begin-UR record). If there are many short units of work, or many messages being put, the time is reasonably accurate (within milliseconds). Otherwise the times become less and less accurate.

Note: There is a 4 byte Record Descriptor Word at the front of each record because the files are Variable Blocked format. The first data byte of a variable-length record has relative position 5 and the first 4 bytes contain the record descriptor word. The field names correspond to those in the C header file CSQ4LOGD in thlqual.SCSQC370.

The information in the data sets has the following layout:

Offset (Dec)	Offset (Hex)	Type	Length	Name	Description
0	0	Character	21	csrecord date	The approximate time the log was written, in the format yyyy.ddd hh:mm:ss.thm
21	15	Character	7	cstimedelta	Approximate time difference in milliseconds from the start of the unit of work. Right-aligned and padded with blanks.
28	1C	64-bit integer	8	dtodout	Estimated time that the log record was created, in STCK format.
36	24	Character	8	csurid	Queue manager-specific unique identifier of the unit of work that created the log record.
44	2C	Character	12	cscorrelator	Thread correlation identifier
56	38	Character	8	csauth	Authorization identifier (Userid associated with unit of work)
64	40	64-bit integer	8	dtime	Time that the unit of work was started, in STCK format
72	48	Character	8	csresource	Resource name
80	50	Character	8	cscnty	Connection type: one of BATCH, RRSBATCH, IMS, CICS, CHIN, or nulls for an internal task
88	58	Character	8	cscnid	Connection ID of thread that created this unit of work
96	60	Character	3	csstatus	Unit of work type: BUR for begin or CP for checkpoint information
99	63	Integer	4	ldatalen	Length of the message data (if any)
103	67	Character	4	csqmgrname	Name of queue manager

Table 387. Record layout for the output data set (continued)

Offset (Dec)	Offset (Hex)	Type	Length	Name	Description
107	6B	Character	48	csqueue name	Name of queue, for get, put, or expired messages. This field can be question marks. Question marks appear when it is not possible to determine the user ID associated with the entry. This typically happens when the begin_ur record or the checkpoint record from which you might get the URID is not in the log range specified in the job, nor on the log data sets used.
155	9B	Character	12	cssqdmcp	Shared queue message key. Blank if not a shared queue
167	A7	Character	8	csdmcp	Non-shared queue message key. Blank if a shared queue.
175	AF	Character	8	csverb	Activity: ALTER the object was changed DEFINE the object was created MQGET the message was got MQPUT the message was put V 9.4.0 MQPUTPRP the message was put with properties. See Note “1” on page 2826. V 9.4.0 MQPUTV6C the message was put with PROPCTL(V6COMPAT) and additional properties were added, and the EXV6COMPAT(YES) option was specified. See Note “2” on page 2826. EXPIRE the message expired ABORT2 the message was backed out PHASE1 the first phase of two-phase commit PHASE2 the second phase of two-phase commit, or the only phase of one phase commit
183	B7	Character	1	cscmitstatus	Status of unit of work: B backed out C committed I inflight

Table 387. Record layout for the output data set (continued)					
Offset (Dec)	Offset (Hex)	Type	Length	Name	Description
184	B8	Character	1	csshunt	Shunted indicator: S shunted record N not shunted
185	B9	Character	8	cslogrba	RBA of log record
193	C1	Character	8	csshuntrba	RBA of shunted log record
201	C9	Character	1	csuowscope	UOW scope in hexadecimal: 01 local 02 shared
202	CA	Integer	4	lsegment	The segment number of the data, starting from 1.
206	CE		Variable		Data part
206	CE	Character	1	csbora	If csverb is ALTER, indicates whether the data is the 'before' or 'after' copy of the object. B before A after
207	CF	Character	Variable	csvardata	Message or object data. Length as given in ldatalen. Message data is the MQMD followed by the body of the message. V9.4.0 If the message has message properties, these are represented as an MQRFH2 header chained into the body of the message following the MQMD, and any MQMDE, MQXQH, and MQDLH header. See Note “1” on page 2826.

Notes: **V9.4.0**

1. MQPUTPRP was used by versions prior to IBM MQ 9.3.4 for put of a message with message properties. The properties were in the message data in an internal format that made replay challenging.
2. Message replay needs to remove the MQRFH2 header added by log extract, and convert it to a message handle before putting the message, to preserve the PROPCTL(V6COMPAT) behavior. The CSQ4LOGS replay sample does this.

CSQ1LOGP errors and messages

Messages for CSQ1LOGP are described here - [Service facilities messages](#).

Reason codes for CSQ1LOGP are described here - [Recovery log manager codes](#).

Examples that do not use the EXTRACT parameter

```
V9.4.0
//PRTLOG EXEC PGM=CSQ1LOGP
//STEPLIB DD DISP=SHR,DSN=thlqual.SCSQANLE
// DD DISP=SHR,DSN=thlqual.SCSQLOAD
//BSDS DD DSN=qmgr.bsds.dsname,DISP=SHR
//SYSPRINT DD SYSOUT=*
//SYSSUMRY DD SYSOUT=*
//SYSIN DD *
* select records for page set 3. Produce both summary and detail reports
PAGESET(3)
RBASTART(rba)
SUMMARY(YES)
/*
```

Figure 34. Sample JCL to invoke the CSQ1LOGP utility using a BSDS

```

//SYSSUMRY DD SYSOUT=*
//SYSIN DD *
* insert your input control statements here
/*
```

Figure 36. Sample JCL to invoke the CSQ1LOGP utility using archive log data sets

The EXTRACT parameter

Typical uses of the EXTRACT parameter are to:

- Review which persistent messages were put to or got from a queue and whether the request was committed. This allows messages to be replayed.
- Review persistent messages that were put or got, but the request was backed out.

- Display which applications backed out rather than committed.
- Discover the volume of persistent data processed by queues, to identify the high use queues.
- Identify which applications set object attributes.
- Re-create object definitions for recovery purposes after a major failure, for private queues only.

When CSQ1LOGP with the EXTRACT parameter set is run against a log data set it processes all records in the data set, or all those within a specified range. Processing is as follows:

1. When a commit request is found, if the CSQCMT ddname is present then the data is written to this data set. If the CSQBOTH ddname is present the data is also written to this data set.
2. When a backout request is found, if the CSQBACK ddname is present then the data is written to this data set. If the CSQBOTH ddname is present the data is also written to this data set.
3. When changes to objects are detected, the information is written to the data set identified by the CSQOBS ddname.
4. When the last record has been processed, information about remaining units of work is written to the data set identified by the CSQINFLT ddname.

If you do not want to collect one or more of these classes of information, then omit the appropriate DD statements.

Examples of using the EXTRACT parameter

```
//PRTLOG EXEC PGM=CSQ1LOGP
//STEPLIB DD DISP=SHR,DSN=thlqual.SCSQANLE
//        DD DISP=SHR,DSN=thlqual.SCSQLOAD
//        DD DISP=SHR,DSN=thlqual.SCSQAUTH
//ARCHIVE DD DSN=qmgr.archive1.ds01,DISP=SHR
//        DD DSN=qmgr.archive1.ds02,DISP=SHR
//        DD DSN=qmgr.archive1.ds03,DISP=SHR
//CSQBACK DD DSN=backout.dataset,DISP=(NEW,CATLG)
//CSQCMT  DD DSN=commit.dataset,DISP=(NEW,CATLG)
//SYSIN   DD *
          RBASTART(startriba)
          RBAEND(endriba)
/*
```

Figure 37. Sample JCL for using the EXTRACT parameter to extract committed and backed out messages from archive logs in a specific RBA range.

Note: V9.4.0 thlqual.SCSQAUTH DD is required in STEPLIB for EXTRACT.

The following job uses DFSORT facilities to process output from CSQCMT to add up the number of bytes put to each queue.

```

//TOOLRUN EXEC PGM=ICETOOL,REGION=1024K
//TOOLMSG DD SYSOUT=*
//DFSMSG DD SYSOUT=*
//TOOLIN DD *
SORT FROM(IN) TO(TEMP1) USING(CTL1)
DISPLAY FROM(TEMP1) LIST(OUT1) ON(5,48,CH) ON(53,4,BI)
/*
//CTL1 DD *
* SELECT THE RECORDS WHICH WERE PUT
  INCLUDE COND=(180,5,CH,EQ,C'MQPUT')
* SORT BY QUEUE NAME
  SORT FIELDS=(112,48,CH,A)
* ONLY COPY THE QUEUE NAME AND SIZE OF USER DATA TO OUTPUT REC
  OUTREC FIELDS=(1,4,112,48,104,4)
* ADD UP THE NUMBER OF BYTES PROCESSED
* SUM FIELDS=(104,4,FI)
/*
//IN DD DISP=SHR,DSN=commit.dataset
//TEMP1 DD DISP=(NEW,DELETE),DSN=&TEMP1,SPACE=(CYL,(10,10))
//OUT1 DD SYSOUT=*

```

Figure 38. Accumulating bytes put to each queue

See “Using CSQ4LOGS to process output from CSQ1LOGP EXTRACT” on page 2829 for how to replay messages from EXTRACT output, using the CSQ4LOGS sample.

Using CSQ4LOGS to process output from CSQ1LOGP EXTRACT

The CSQ4LOGS sample can process the output from CSQ1LOGP EXTRACT. The sample reports on unit of work activity, and on activity that defines and alters objects.

CSQ4LOGS can also optionally replay messages, which is useful in scenarios where an application does not process a persistent message correctly.

CSQ4LOGS is a C sample, with source code in th1qua1.SCSQC37S (CSQ4LOGS). Compiled output is in th1qua1.SCSQLOAD (CSQ4LOGS), which can be run using sample JCL from th1qua1.SCSQPROC (CSQ4LOGJ).

CSQ4LOGS makes use of a header file th1qua1.SCSQC370 (CSQ4LOGD), which maps the output from CSQ1LOGP EXTRACT. That header file can be used for your own programs, based off CSQ4LOGS.

Important: You should not run the CSQ4LOGS program from an APF authorized library. In some circumstances you receive an abend code if you do so.

CSQ4LOGS parameters

CSQ4LOGS takes two parameters:

- The queue manager name to which the sample connects
- An action:

REPLAY

Summarize unit of recovery activity and send messages back to the queue they were originally put on.

REPLAY_ORIGINAL

Summarize unit of recovery activity and send messages back to the non-system queue they were originally put on, using their original message descriptor context.

SUMMARY

Summarize unit of recovery activity.

Warning: Before making use of REPLAY or REPLAY_ORIGINAL, ensure that you want all messages passed into CSQ4LOGS to be sent back to their original queue.

The following sample JCL shows how CSQ1LOGP can be used to extract committed messages from the IBM MQ log to the xxx.MSGS.COMMIT data set and replay them to queue manager MQST using CSQ4LOGS.

```
//STEP1 EXEC PGM=CSQ1LOGP,REGION=0M
//STEPLIB DD DISP=SHR,DSN=thlqual.SCSQANLE
//          DD DISP=SHR,DSN=thlqual.SCSQAUTH
//          DD DISP=SHR,DSN=thlqual.SCSQLOAD
//ARCHIVE DD DISP=SHR,DSN=xxx.yyy.A0030620
//          DD DISP=SHR,DSN=xxx.yyy.A0030621
//SYSPRINT DD SYSOUT=*
//SYSSUMRY DD SYSOUT=*
//CSQCMT DD DSN=xxx.MSGS.COMMIT,
//          DISP=(NEW,CATLG),SPACE=(CYL,(1,10),RLSE),UNIT=SYSDA
//SYSIN DD *
EXTRACT(YES) SUMMARY(NO)
URID(xxxxxxxxxxxx)
/*
//STEP2 EXEC PGM=CSQ4LOGS,PARM=('MQST REPLAY'),REGION=0M
//STEPLIB DD DSN=thlqual.SCSQANLE,DISP=SHR
//          DD DSN=thlqual.SCSQAUTH,DISP=SHR
//          DD DSN=thlqual.SCSQLOAD,DISP=SHR
//FILEIN DD DSN=xxx.MSGS.COMMIT,DISP=SHR
//SYSDBOUT DD SYSOUT=*
//SYSABOUT DD SYSOUT=*
//SYSPRINT DD SYSOUT=*
//SYSOUT DD SYSOUT=*
/*
```

Figure 39. Sample JCL for using CSQ1LOGP and CSQ4LOGS together

z/OS

The queue sharing group utility (CSQ5PQSG) on z/OS

You can use the CSQ5PQSG utility program to add queue sharing group and queue manager definitions to the IBM MQ Db2 tables, and to remove them.

The CSQ5PQSG utility can also be used to verify the consistency of Db2 object definitions for queue manager, CF structure, and shared queue objects, within a queue sharing group.

- [Invoking the queue sharing group utility](#)
- [Syntax, keywords, and parameters](#)
- [Example](#)

Invoking the queue sharing group utility

Figure 40 on page 2830 shows an example of the JCL used to invoke the CSQ5PQSG utility.

```
//S001 EXEC PGM=CSQ5PQSG,REGION=4M,
//          PARM='function,function parameters'
//STEPLIB DD DSN=thlqual.SCSQANLE,DISP=SHR
//          DD DSN=thlqual.SCSQAUTH,DISP=SHR
//          DD DSN=db2qual.SDSNLOAD,DISP=SHR
//SYSPRINT DD SYSOUT=*
```

Figure 40. Sample JCL to invoke the CSQ5PQSG utility

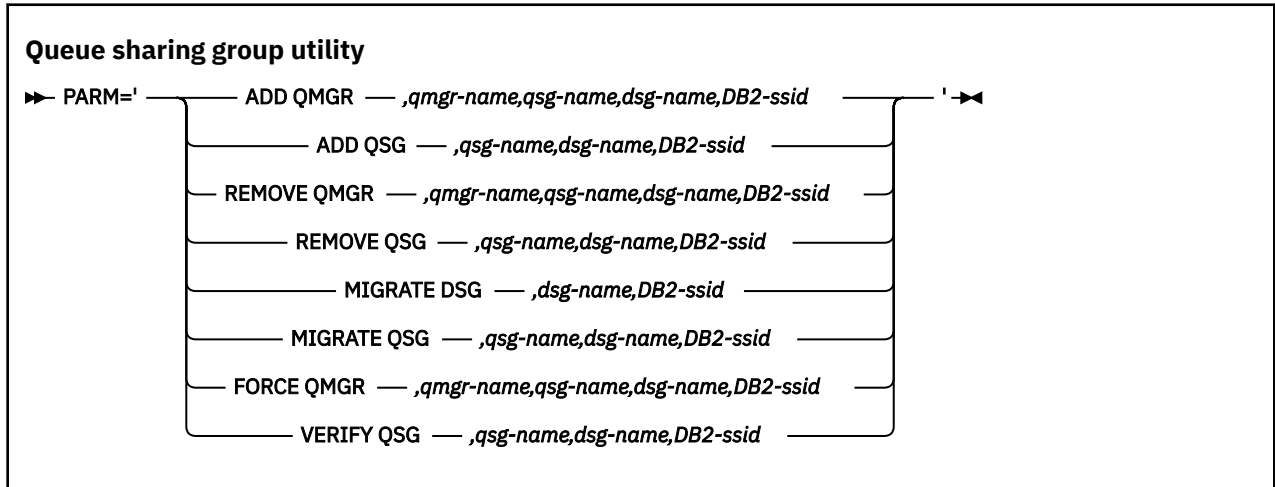

Data definition statements

The CSQ5PQSG utility requires data definition statements with the following DDname:

SYSPRINT

This statement is required; it names the data set for print output. The logical record length (LRECL) is 125.

Syntax, keywords, and parameters

A queue sharing group name (*qsg-name*) can have up to 4 characters, comprising uppercase A-Z, 0-9, \$, #, @. It must not start with a numeric. For implementation reasons, names of less than 4 characters are padded internally with @ symbols, so do not use names ending in @.

The queue sharing group name must be different from any of the queue manager names within the queue sharing group.

PARM

This field contains the function request followed by the function-specific parameters. These are described in the following text:

ADD QMGR

Add a queue manager record into the CSQ.ADMIN_B_QMGR table. This operation completes successfully only if all the following conditions are met:

- A corresponding queue sharing group record exists in the CSQ.ADMIN_B_QSG table.
- The queue manager entry does not exist in the CSQ.ADMIN_B_QMGR table as the member of a different queue sharing group.
- There is no member entry in the XCF group with a different QMGR number value than the one created by the utility when you add a record to the CSQ.ADMIN_B_QMGR table.

Note that it does not matter whether the queue manager being added is active or inactive when the ADD QMGR function is being performed.

If there are members in the XCF group without the corresponding entries in the Db2 table, you can use the utility to add them. Add queue managers in the order that is indicated by the CSQ524I messages that are issued by the queue sharing group utility (CSQ5PQSG) when it is run with the **VERIFY QSG** parameter.

If a queue manager exists in Db2 table CSQ.ADMIN_B_QMGR, but is missing from MVS XCF group, you can run this utility to restore the appropriate XCF group entry, as indicated by CSQ5010E message.

qmgr-name

The queue manager name

qsg-name

The queue sharing group name

dsg-name

The Db2 data-sharing group name

DB2-ssid

The Db2 subsystem ID

ADD QSG

Add a queue sharing group record into the CSQ.ADMIN_B_QSG table.

qsg-name

The queue sharing group name

dsg-name

The Db2 data-sharing group name

DB2-ssid

The Db2 subsystem ID

REMOVE QMGR

Remove a queue manager record from the CSQ.ADMIN_B_QMGR table. This only completes successfully if the queue manager has either never been started, or terminated normally from its last execution.

qmgr-name

The queue manager name

qsg-name

The queue sharing group name

dsg-name

The Db2 data-sharing group name

DB2-ssid

The Db2 subsystem ID

REMOVE QSG

Remove a queue sharing group record from the CSQ.ADMIN_B_QSG table. This only completes successfully if no queue managers are defined to the queue sharing group.

qsg-name

The queue sharing group name

dsg-name

The Db2 data-sharing group name

DB2-ssid

The Db2 subsystem ID

MIGRATE DSG

Verify that all the queue managers in the data-sharing group are at a version that is compatible with IBM MQ 9.4.

dsg-name

The Db2 data-sharing group name

DB2-ssid

The Db2 subsystem ID

This function does not do the migration, which involves several steps.

MIGRATE QSG

Verify that all the queue managers in the data-sharing group are at a version that is compatible with IBM MQ 9.4.

The MIGRATE QSG and MIGRATE DSG functions perform the same function. The only difference is in the scope of the processing. MIGRATE QSG works on a single queue sharing group only, MIGRATE DSG works on all queue sharing groups that are defined within the data-sharing group.

qsg-name

The queue sharing group name

dsg-name

The Db2 data-sharing group name

DB2-ssid

The Db2 subsystem ID

This function does not do the migration, which involves several steps.

FORCE QMGR

Remove a queue manager record from the CSQ.ADMIN_B_QMGR table, even if the queue manager has terminated abnormally.

Use the **FORCE** option, rather than **REMOVE**, to remove the last queue manager in a queue sharing group.

Attention: This can override IBM MQ efforts to maintain data in a consistent state. Only use this function when you cannot carry out the procedure for removing a queue manager from a queue sharing group on page [Removing a queue manager from a queue sharing group](#).

qmgr-name

The queue manager name

qsg-name

The queue sharing group name

dsg-name

The Db2 data-sharing group name

DB2-ssid

The Db2 subsystem ID

VERIFY QSG

Validate the consistency of the Db2 object definitions for queue manager, CF structure, and shared queue objects, within the queue sharing group.

qsg-name

The queue sharing group name

dsg-name

The Db2 data-sharing group name

DB2-ssid

The Db2 subsystem ID

Example

The following sample JCL adds an entry for queue manager QM01 into queue sharing group QSG1. It specifies a connection to Db2 subsystem DB2A, which is a member of Db2 data-sharing group DSN510PG.

```
//S001 EXEC PGM=CSQ5PQSG,REGION=4M,
//      PARM='ADD QMGR,QM01,QSG1,DSN510PG,DB2A'
//STEPLIB DD DSN=th1qua1.SCSQANLE,DISP=SHR
//          DD DSN=th1qua1.SCSQAUTH,DISP=SHR
//          DD DSN=db2qua1.SDSNLOAD,DISP=SHR
//SYSPRINT DD SYSOUT=*
```

Figure 41. Using the queue sharing group utility to add a queue manager into a queue sharing group

You can use the CSQJUFMT utility to format active log data sets before they are used by a queue manager.

If the active log data sets are preformatted by the utility, log write performance is improved on the queue manager's first pass through the active logs. If the utility is not used, the queue manager must format

each log control interval at log write time before it is used. On the second and subsequent passes through the active log data sets, the log control intervals already contain data, so need no further formatting, and no performance benefit accrues.

Invoking the CSQJUFMT utility

You can only run the CSQJUFMT program before starting the queue manager that use the logs.

Note: Do not use this utility to format a log data set after the queue manager has started, or data will be lost.

```
EXEC PGM=CSQJUFMT
```

Each step running the CQJUFMT utility formats a single active log data set. Add additional CSQJUFMT steps for each active log being created.

Attention: JCL limits the number of steps in a single job to 255. If you are formatting more than 255 active log data sets, you will need to run multiple jobs.

These DD statements should be provided:

SYSPRINT

This statement is required to specify a data set or print spool class for print output.

SYSUT1

This statement identifies the log data set to be preformatted.

```
//JOB LIB DD DISP=SHR,DSN=thlqual.SCSQANLE
// DD DISP=SHR,DSN=thlqual.SCSQAUT
// *
//JUFMT11 EXEC PGM=CSQJUFMT
//SYSPRINT DD SYSOUT=*
//SYSUT1 DD DISP=OLD,DSN=h1q.LOGCOPY1.DS01
// *
//JUFMT21 EXEC PGM=CSQJUFMT
//SYSPRINT DD SYSOUT=*
//SYSUT1 DD DISP=OLD,DSN=h1q.LOGCOPY2.DS01
```

Figure 42. Example of the JCL used to invoke the CSQJUFMT utility

Sample JCL is supplied in thlqual.SCSQPROC (CSQ4LFMT) for preformatting a newly defined dual log data set. It contains two steps, one step to format each of the copies of the log data set.

z/OS

The dead-letter queue handler utility (CSQUDLQH) on z/OS

You can use the default dead-letter utility (CSQUDLQH) to handle message written to the dead-letter queue.

A *dead-letter queue* (DLQ) is a holding queue for messages that cannot be delivered to their destination queues. Every queue manager in a network can have an associated DLQ.

Queue managers, message channel agents, and applications can put messages on the DLQ. All messages on the DLQ can be prefixed with a *dead-letter header* structure, MQDLH. Messages put on the DLQ by a queue manager or by a message channel agent always have a dead-letter header; ensure that applications putting messages on the DLQ also supply a dead-letter header structure. The *Reason* field of the MQDLH structure contains a reason code that identifies why the message is on the DLQ.

Implement a routine that runs regularly to process messages on the DLQ. Such a routine is called a *dead-letter queue handler*. IBM MQ supplies a default *dead-letter queue handler* (DLQ handler) called CSQUDLQH. A user-written *rules table* supplies instructions to the DLQ handler, for processing messages on the DLQ. That is, the DLQ handler matches messages on the DLQ against entries in the rules table.

When a DLQ message matches an entry in the rules table, the DLQ handler performs the action associated with that entry.

Invoking the DLQ handler on z/OS

Use this topic to understand how to invoke the CSQUDLQH utility program, and its data definition statements.

The CSQUDLQH utility program runs as a z/OS batch program. Specify the name of the dead-letter queue that you want to process and the queue manager on which it resides. You can do this in one of the following two ways (in these examples, the dead-letter queue is called CSQ1.DEAD.QUEUE and the queue manager is called CSQ1):

1. The names can be specified as positional parameters in the PARM parameter of the EXEC statement within the submitted JCL, for example:

```
//READQ EXEC PGM=CSQUDLQH,  
// PARM='CSQ1.DEAD.QUEUE CSQ1'
```

Figure 43. Specifying the queue manager and dead-letter queue names for the dead-letter queue handler in the JCL

2. The names can be specified in the rules table, for example:

```
INPUTQ(CSQ1.DEAD.QUEUE) INPUTQM(CSQ1)
```

Figure 44. Specifying the queue manager and dead-letter queue names for the dead-letter queue handler in the rules table

Any parameters that you specify in the PARM parameter override those in the rules table. If you specify only one parameter in the PARM statement, it is used as the name of the dead-letter queue. The rules table is taken from the SYSIN data set.

For further information on the keywords you can specify, to match and process pattern and action keywords, see [“Rules \(patterns and actions\) on z/OS” on page 2837](#).

Stopping the DLQ handler

The CSQUDLQH utility is stopped when any of the following conditions is true:

- The dead letter queue is empty for a specified amount of time as configured by the WAIT control data keyword.
- The dead letter queue is set to GET(DISABLED).
- The queue manager is quiesced.
- The CSQUDLQH job is cancelled.

Messages generated during the handling of the queue are written to the standard output when the CSQUDLQH utility ends in a controlled manner. If the handler is cancelled, it does not generate these messages.

Data definition statements

CSQUDLQH requires DD statements with these DDnames:

SYSOUT

This statement is required; it names the data set for print output. You can specify the logical record length (LRECL) and block size (BLKSIZE) for this output data set.

SYSIN

This statement is required; it names the input data set containing the rules table that specifies what the utility is to do. The logical record length (LRECL) is 80.

Sample JCL

```
//READQ EXEC PGM=CSQUDLQH,  
//      PARM='CSQ1.DEAD.QUEUE CSQ1'  
//STEPLIB DD DSN=thlqual.SCSQAUTH,DISP=SHR  
//      DD DSN=thlqual.SCSQLOAD,DISP=SHR  
//      DD DSN=thlqual.SCSQANLE,DISP=SHR  
//SYSOUT DD SYSOUT=*  
//SYSIN DD *  
INPUTQM(CSQ2) INPUTQ('CSQ2.DEAD.QUEUE')  
ACTION(RETRY)  
/*
```

Figure 45. Sample JCL to invoke the CSQUDLQH utility

The DLQ handler rules table on z/OS

The DLQ handler rules table defines how the DLQ handler is to process messages that arrive on the DLQ.

There are two types of entry in a rules table:

- The first entry in the table, which is optional, contains “Control data” on page 2836.
- All other entries in the table are *rules* for the DLQ handler to follow. Each rule consists of a *pattern* (a set of message characteristics) that a message is matched against, and an *action* to be taken when a message on the DLQ matches the specified pattern. There must be at least one rule in a rules table.

Each entry in the rules table comprises one or more keywords.

See “Rules table conventions on z/OS” on page 2840 for information about the syntax of the rules table.

See [Rules \(patterns and actions\)](#) for information about how the pattern-matching, and action keywords control the CSQUDLQH utility

Control data

This section describes the keywords that you can include in a control-data entry in a DLQ handler rules table.

- All keywords are optional.
- If a control-data entry is included in the rules table, it must be the first entry in the table.
- The default value for a keyword, if any, is underlined>.
- The vertical line (|) separates alternatives. You can specify only one of these.

INPUTQ (QueueName|' ' (default))

Specifies the name of the DLQ that you want to process:

1. If you specify a queue name in the PARM parameter of the EXEC statement, this overrides any INPUTQ value in the rules table.
2. If you do not specify a queue name in the PARM parameter of the EXEC statement, the INPUTQ value in the rules table is used.
3. If you do not specify a queue name in the PARM parameter of the EXEC statement or the rules table, the dead-letter queue named *qmgr-name.DEAD.QUEUE* is used if it has been defined. If this queue does not exist, the program fails and returns error message CSQU224E, giving the reason code for the error.

INPUTQM (QueueManagerName|' ' (default))

Specifies the name of the queue manager that owns the DLQ named on the INPUTQ keyword.

1. If you specify a queue manager name in the PARM parameter of the EXEC statement, this overrides any INPUTQM value in the rules table.
2. If you do not specify a queue manager name in the PARM parameter of the EXEC statement, the INPUTQM value in the rules table is used.
3. If you do not specify a queue manager name in the PARM parameter of the EXEC statement or the rules table, the default queue manager is used (if one has been defined using CSQBDEFV). If not, the program fails and returns error message CSQU220E, giving the reason code for the error.

RETRYINT (Interval|60 (default))

Specifies the interval, in seconds, at which the DLQ handler should attempt to reprocess messages on the DLQ that could not be processed at the first attempt, and for which repeated attempts have been requested. The DLQ handler reprocesses messages after it has first browsed to the end of the queue.

The default is 60 seconds.

WAIT (YES (default) |NO|nnn)

Specifies whether the DLQ handler should wait for further messages to arrive on the DLQ when it detects that there are no further messages that it can process.

YES

The DLQ handler waits indefinitely.

NO

The DLQ handler terminates when it detects that the DLQ is either empty or contains no messages that it can process.

nnn

The DLQ handler waits for *nnn* seconds for new work to arrive after it detects that the queue is either empty or contains no messages that it can process, before terminating.

Specify a value in the range 1 through 999 999.

Specify WAIT (YES) for busy DLQs, and WAIT (NO) or WAIT (*nnn*) for DLQs that have a low level of activity. If the DLQ handler is allowed to terminate, you can use triggering to invoke it when needed.

Rules (patterns and actions) on z/OS

The DLQ handler is controlled with a series of pattern-matching and action keywords described here.

Figure 46 on page 2837 shows an example rule from a DLQ handler rules table.

```
PERSIST(MQPER_PERSISTENT) REASON (MQRC_PUT_INHIBITED) +
ACTION (RETRY) RETRY (3)
```

Figure 46. An example rule from a DLQ handler rules table

This section describes the keywords that you can include in a rules table. It begins with a description of the pattern-matching keywords (those keywords against which messages on the DLQ are matched). It then describes the action keywords (those keywords that determine how the DLQ handler is to process a matching message).

- All keywords except ACTION are optional.
- The default value for a keyword, if any, is underlined>. For most keywords, the default value is asterisk (*), which matches any value.
- The vertical line (|) separates alternatives. You can specify only one of these keywords.

The keywords can be grouped as follows:

- [The pattern-matching keywords](#)
- [The action keywords](#)

The pattern-matching keywords

The pattern-matching keywords, are described in the following table. You use these keywords to specify values against which messages on the DLQ are matched. All pattern-matching keywords are optional.

APPLIDAT (*ApplIdentityData*|* (default))

The *ApplIdentityData* value of the message on the DLQ, specified in the message descriptor, MQMD.

APPLNAME (*PutAppName*|* (default))

The name of the application that issued the MQPUT or MQPUT1 call, as specified in the *PutAppName* field of the message descriptor, MQMD, of the message on the DLQ.

APPLTYPE (*PutApplType*|* (default))

The *PutApplType* value specified in the message descriptor, MQMD, of the message on the DLQ.

DESTQ (*QueueName*|* (default))

The name of the message queue for which the message is destined.

DESTQM (*QueueManagerName*|* (default))

The queue manager name for the message queue for which the message is destined.

FEEDBACK (*Feedback*|* (default))

Describes the nature of the report when the *MsgType* value is MQMT_REPORT.

You can use symbolic names. For example, you can use the symbolic name MQFB_COA to identify those messages on the DLQ that require confirmation of their arrival on their destination queues. A few symbolic names are not accepted by the utility and lead to a syntax error. In these cases, you can use the corresponding numeric value.

FORMAT (*Format*|* (default))

The name that the sender of the message uses to describe the format of the message data.

MSGTYPE (*MsgType*|* (default))

The message type of the message on the DLQ.

You can use symbolic names. For example, you can use the symbolic name MQMT_REQUEST to identify those messages on the DLQ that require replies.

PERSIST (*Persistence*|* (default))

The persistence value of the message. (The persistence of a message determines whether it survives restarts of the queue manager.)

You can use symbolic names. For example, you can use the symbolic name MQPER_PERSISTENT to identify those messages on the DLQ that are persistent.

REASON (*ReasonCode*|* (default))

The reason code that describes why the message was put to the DLQ.

You can use symbolic names. For example, you can use the symbolic name MQRC_Q_FULL to identify those messages placed on the DLQ because their destination queues were full. A few symbolic names are not accepted by the utility and lead to a syntax error. In these cases, you can use the corresponding numeric value.

REPLYQ (*QueueName*|* (default))

The reply-to queue name specified in the message descriptor, MQMD, of the message on the DLQ.

REPLYQM (*QueueManagerName*|* (default))

The queue manager name of the reply-to queue specified in the REPLYQ keyword.

USERID (*UserIdentifier*|* (default))

The user ID of the user who originated the message on the DLQ, as specified in the message descriptor, MQMD.

The action keywords

The action keywords are described in the following table. You use these keywords to describe how a matching message is processed.

ACTION (DISCARD | IGNORE | RETRY | FWD)

The action taken for any message on the DLQ that matches the pattern defined in this rule.

DISCARD

Causes the message to be deleted from the DLQ.

IGNORE

Causes the message to be left on the DLQ.

RETRY

Causes the DLQ handler to try again to put the message on its destination queue.

FWD

Causes the DLQ handler to forward the message to the queue named on the FWDQ keyword.

You must specify the ACTION keyword. The number of attempts made to implement an action is governed by the RETRY keyword. The RETRYINT keyword of the control data controls the interval between attempts.

CONVERT (YES (default) |NO)

By default, this keyword is set to CONVERT(YES). When forwarding or retrying a message, the DLQ handler performs an MQGET with MQGMO_CONVERT; that is, it converts the message data to the CCSID and encoding of the queue manager.

However, setting CONVERT(NO) forwards or retries the message without converting the message contents.

FWDQ (QueueName | &DESTQ | &REPLYQ)

The name of the message queue to which the message is forwarded when you select the ACTION keyword.

QueueName

This parameter is the name of a message queue. FWDQ(' ') is not valid.

&DESTQ

Takes the queue name from the *DestQName* field in the MQDLH structure.

&REPLYQ

Takes the name from the *ReplyToQ* field in the message descriptor, MQMD. You can specify REPLYQ (?*) in the message pattern to avoid error messages, when a rule specifying FWDQ (&REPLYQ), matches a message with a blank *ReplyToQ* field.

FWDQM (QueueManagerName|&DESTQM|&REPLYQM| ' ' (default))

The queue manager of the queue to which a message is forwarded.

QueueManagerName

This parameter defines the queue manager name for the queue to which the message is forwarded when you select the ACTION (FWD) keyword.

&DESTQM

Takes the queue manager name from the *DestQMGrName* field in the MQDLH structure.

&REPLYQM

Takes the name from the *ReplyToQMGr* field in the message descriptor, MQMD.

..

The local queue manager.

HEADER (YES (default) |NO)

Whether the MQDLH should remain on a message for which ACTION (FWD) is requested. By default, the MQDLH remains on the message. The HEADER keyword is not valid for actions other than FWD.

PUTAUT (DEF (default) |CTX)

The authority with which messages should be put by the DLQ handler:

DEF

Puts messages with the authority of the DLQ handler itself.

CTX

Causes the messages to be put with the authority of the user ID in the message context. You must be authorized to assume the identity of other users, if you specify PUTAUT (CTX).

RETRY (RetryCount|1 (default))

The number of times that an action should be attempted (at the interval specified on the RETRYINT keyword of the control data). Specify a value in the range 1 through 999 999 999.

Note: The count of attempts made by the DLQ handler to implement any particular rule is specific to the current instance of the DLQ handler; the count does not persist across restarts. If you restart the DLQ handler, the count of attempts made to apply a rule is reset to zero.

Rules table conventions on z/OS

Use this topic to understand the conventions used in the CSQUDLQH rule table.

The rules table must adhere to the following conventions regarding its syntax, structure, and contents:

- A rules table must contain at least one rule.
- Keywords can occur in any order.
- A keyword can be included once only in any rule.
- Keywords are not case-sensitive.
- A keyword and its parameter value can be separated from other keywords by at least one blank or comma.
- Any number of blanks can occur at the beginning or end of a rule, and between keywords, punctuation, and values.
- Each rule must begin on a new line.
- For reasons of portability, the significant length of a line should not be greater than 72 characters.
- Use the plus sign (+) as the last non-blank character on a line to indicate that the rule continues from the first non-blank character in the next line. Use the minus sign (-) as the last non-blank character on a line to indicate that the rule continues from the start of the next line. Continuation characters can occur within keywords and parameters.

For example:

```
APPLNAME('ABC+
D')
```

results in 'ABCD'.

```
APPLNAME('ABC-
D')
```

results in 'ABC D'.

- Comment lines, which begin with an asterisk (*), can occur anywhere in the rules table.
- Blank lines are ignored.

Each entry in the DLQ handler rules table comprises one or more keywords and their associated parameters. The parameters must follow these syntax rules:

- Each parameter value must include at least one significant character. The delimiting quotation marks in following examples are not considered significant. For example, these parameters are valid:

FORMAT('ABC')

3 significant characters

FORMAT(ABC)

3 significant characters

FORMAT('A')

1 significant character

FORMAT(A)

1 significant character

FORMAT('')

1 significant character

These parameters are not valid because they contain no significant characters:

– FORMAT('')

– FORMAT()

– FORMAT()

– FORMAT

- Wildcard characters are supported. You can use the question mark (?) instead of any single character, except a trailing blank. You can use the asterisk (*) instead of zero or more adjacent characters. The asterisk (*) and the question mark (?) are **always** interpreted as wildcard characters in parameter values.
- You cannot include wildcard characters in the parameters of these keywords: ACTION, HEADER, RETRY, FWDQ, FWDQM, and PUTAUT.
- Trailing blanks in parameter values, and in the corresponding fields in the message on the DLQ, are not significant when performing wildcard matches. However, leading and embedded blanks within strings in quotation marks are significant to wildcard matches.
- Numeric parameters cannot include the question mark (?) wildcard character. You can include the asterisk (*) instead of an entire numeric parameter, but the asterisk cannot be included as part of a numeric parameter. For example, these are valid numeric parameters:

MSGTYPE(2)

Only reply messages are eligible

MSGTYPE(*)

Any message type is eligible

MSGTYPE('*')

Any message type is eligible

However, MSGTYPE('2*') is not valid, because it includes an asterisk (*) as part of a numeric parameter.

- Numeric parameters must be in the range zero through 999 999 999 unless otherwise stated. If the parameter value is in this range, it is accepted, even if it is not currently valid in the field to which the keyword relates. You can use symbolic names for numeric parameters.
- If a string value is shorter than the field in the MQDLH or MQMD to which the keyword relates, the value is padded with blanks to the length of the field. If the value, excluding asterisks, is longer than the field, an error is diagnosed. For example, these are all valid string values for an eight character field:

'ABCDEFGH'

8 characters

'A*C*E*G*I'

5 characters excluding asterisks

'*A*C*E*G*I*K*M*O*'

8 characters excluding asterisks

- Strings that contain blanks, lowercase characters, or special characters other than period (.), forward slash (/), underscore (_), and percent sign (%) must be enclosed in single quotation marks. Lowercase characters not enclosed in quotation marks are folded to uppercase. If the string includes a quotation, two single quotation marks must be used to denote both the beginning and the end of the quotation.

When the length of the string is calculated, each occurrence of double quotation marks is counted as a single character.

Processing the rules table on z/OS

Use this topic to understand how the CSQUDLQH utility processes the rules table.

The DLQ handler searches the rules table for a rule with a pattern that matches a message on the DLQ. The search begins with the first rule in the table, and continues sequentially through the table. When a rule with a matching pattern is found, the rules table attempts the action from that rule. The DLQ handler increments the retry count for a rule by 1 whenever it attempts to apply that rule. If the first attempt fails, the attempt is repeated until the count of attempts made matches the number specified on the RETRY keyword. If all attempts fail, the DLQ handler searches for the next matching rule in the table.

This process is repeated for subsequent matching rules until an action is successful. When each matching rule has been attempted the number of times specified on its RETRY keyword, and all attempts have failed, ACTION (IGNORE) is assumed. ACTION (IGNORE) is also assumed if no matching rule is found.

For further information, see [Ensuring that all DLQ messages are processed](#).

Note:

1. Matching rule patterns are sought only for messages on the DLQ that begin with an MQDLH. If the dead-letter queue handler encounters one or more messages that are not prefixed by an MQDLH, it issues an information message to report this. Messages that do not contain an MQDLH are not processed by the DLQ handler and remain on the dead-letter queue until dealt with by another method.
2. All pattern keywords can default, so that a rule can consist of an action only. Note, however, that action-only rules are applied to all messages on the queue that have MQDLHs and that have not already been processed in accordance with other rules in the table.
3. The rules table is validated when the DLQ handler starts, and errors flagged at that time. You can change the rules table at any time, but those changes do not come into effect until the DLQ handler is restarted.
4. The DLQ handler does not alter the content of messages, of the MQDLH, or of the message descriptor. The DLQ handler always puts messages to other queues with the message option MQPMO_PASS_ALL_CONTEXT.
5. Consecutive syntax errors in the rules table might not be recognized because the validation of the rules table is designed to eliminate the generation of repetitive errors.
6. The DLQ handler opens the DLQ with the MQOO_INPUT_AS_Q_DEF option.
7. Do not run applications that perform MQGET calls against the queue at the same time as the DLQ handler. This includes multiple instances of the DLQ handler. There is typically a one-to-one relationship between the dead-letter queue and the DLQ handler.

Ensuring that all DLQ messages are processed

The DLQ handler keeps a record of all messages on the DLQ that have been seen but not removed. If you use the DLQ handler as a filter to extract a small subset of the messages from the DLQ, the DLQ handler still keeps a record of those messages on the DLQ that it did not process. Also, the DLQ handler cannot guarantee that new messages arriving on the DLQ will be seen, even if the DLQ is defined as first-in first-out (FIFO). Therefore, if the queue is not empty, the DLQ is periodically rescanned to check all messages. For these reasons, ensure that the DLQ contains as few messages as possible. If messages that cannot be discarded or forwarded to other queues (for whatever reason) are allowed to accumulate on the queue, the workload of the DLQ handler increases and the DLQ itself is in danger of filling up.

You can take specific measures to enable the DLQ handler to empty the DLQ. For example, do not use ACTION (IGNORE), which leaves messages on the DLQ. (Remember that ACTION (IGNORE) is assumed

for messages that are not explicitly addressed by other rules in the table.) Instead, for those messages that you would otherwise ignore, use an action that moves the messages to another queue. For example:

```
ACTION (FWD) FWDQ (IGNORED.DEAD.QUEUE) HEADER (YES)
```

Similarly, the final rule in the table should be a catchall to process messages that have not been addressed by earlier rules in the table. For example, the final rule in the table could be something like this:

```
ACTION (FWD) FWDQ (REALLY.DEAD.QUEUE) HEADER (YES)
```

This forwards messages that fall through to the final rule in the table to the queue `REALLY.DEAD.QUEUE`, where they can be processed manually. If you do not have such a rule, messages are likely to remain on the DLQ indefinitely.

An example DLQ handler rules table on z/OS

Use this topic as an example of the DLQ handler rules table.

Here is an example rules table that contains a single control-data entry and several rules:

```
*****
*           An example rules table for the CSQUDLQH utility           *
*****
* Control data entry
* -----
* If no queue manager name is supplied as an explicit parameter to CSQUDLQH,
* use the default queue manager.
* If no queue name is supplied as an explicit parameter to CSQUDLQH, use the
* DLQ defined for the queue manager.
*
inputqm(' ') inputq(' ')

* Rules
* -----

* The first check deals with attempted security violations.
* If a message was placed on the DLQ because the putter did not have the
* appropriate authority for the target queue, forward the message to a queue
* for manual inspection.

REASON(MQRC_NOT_AUTHORIZED) ACTION(FWD) +
FWDQ(DEADQ.MANUAL.SECURITY)

* The next set of rules with ACTION (RETRY) try to deliver the message to the
* intended destination.

* If a message is placed on the DLQ because its destination queue is full,
* attempt to forward the message to its destination queue. Make 5 attempts at
* approximately 60-second intervals (the default value for RETRYINT).

REASON(MQRC_Q_FULL) ACTION(RETRY) RETRY(5)

* If a message is placed on the DLQ because there has been a problem starting the
* application by triggering, forward the message to another queue for manual
* inspection.

REASON(MQFB_APPL_CANNOT_BE_STARTED) ACTION(FWD) +
FWDQ(DEADQ.MANUAL.TRIGGER)

* If a message is placed on the DLQ because of a put inhibited condition, attempt
* to forward the message to its destination queue. Make 5 attempts at
* approximately 60-second intervals (the default value for RETRYINT).

REASON(MQRC_PUT_INHIBITED) ACTION(RETRY) RETRY(5)

* The AAAA corporation often send messages with incorrect addresses. When we find
* a request from the AAAA corporation, we return it to the DLQ (DEADQ) of the
* reply-to queue manager (&REPLYQM). The AAAA DLQ handler attempts to
* redirect the message.

MSGTYPE(MQMT_REQUEST) REPLYQM(AAAA.*) +
ACTION(FWD) FWDQ(DEADQ) FWDQM(&REPLYQM)
```

- * The BBBB corporation requests that we try sending messages to queue manager
- * BBB2 if queue manager BBB1 is unavailable.

```
DESTQM(BBB1) +
  ACTION(FWD) FWDQ(&DESTQ) FWDQM(BBB2) HEADER(NO)
```

- * The CCCC corporation is very security conscious, and believes that none of its messages will ever end up on one of our DLQs. If we do see a message from a
- * CCCC queue manager on our DLQ, we send it to a special destination in the CCCC
- * organization where the problem is investigated.

```
REPLYQM(CCCC.*) +
  ACTION(FWD) FWDQ(ALARM) FWDQM(CCCC.SYSTEM)
```

- * Messages that are not persistent risk being lost when a queue manager terminates.
- * If an application is sending nonpersistent messages, it will be able to cope with
- * the message being lost, so we can afford to discard the message.

```
PERSIST(MQPER_NOT_PERSISTENT) ACTION(DISCARD)
```

- * For performance and efficiency reasons, we like to keep the number of messages on
- * the DLQ small. If we receive a message that has not been processed by an earlier
- * rule in the table, we assume that it requires manual intervention to resolve the
- * problem.

- * Some problems are best solved at the node where the problem was detected, and
- * others are best solved where the message originated. We do not have the message
- * origin, but we can use the REPLYQM to identify a node that has some interest
- * in this message. Attempt to put the message onto a manual intervention queue
- * at the appropriate node. If this fails, put the message on the manual
- * intervention queue at this node.

```
REPLYQM('?*') +
  ACTION(FWD) FWDQ(DEADQ.MANUAL.INTERVENTION) FWDQM(&REPLYQM)
```

```
ACTION(FWD) FWDQ(DEADQ.MANUAL.INTERVENTION)
```

The BSDS conversion utility (CSQJUCNV) on z/OS

You can use the CSQJUCNV BSDS conversion utility to convert a version 1 bootstrap data set (BSDS) to version 2. CSQJUCNV runs as a batch job.

A version 1 BSDS supports 6 byte log RBA (Relative Byte Address) values. A version 2 BSDS can be used by queue managers running IBM MQ 8.0.0, or later, and supports 8 byte log RBA values. For more information about the change from 6 byte to 8 byte log RBA, see [Larger log Relative Byte Address](#).

From IBM MQ for z/OS 9.3, there is no Db2 interaction.

From IBM MQ for z/OS 9.2.5, queue managers are automatically created with a version 2 BSDS. However, the CSQJUCNV utility is still provided so that migrated queue managers with a version 1 BSDS can be converted to version 2 if required.

The converted BSDSs are written to new data sets. These new data sets must be allocated with similar attributes to the current BSDS before the utility is run, and must be empty. A version 2 BSDS contains more data than a version 1 BSDS, therefore, you must ensure that the new data sets are allocated with sufficient available space. The sample JCL in `thlqual.SCSQPROC(CSQ4BSDS)` contains the recommended values when defining a new BSDS.

The current BSDSs are not modified and can be used to start the queue manager, should the attempt to convert the BSDSs and restart the queue manager with the new BSDS be unsuccessful.

Important:

1. Only run this utility when the queue manager that owns the BSDS is stopped.
2. Do not attempt to start the queue manager with the new BSDS until the utility has completed successfully. If a queue manager is started with a BSDS that is the output of an unsuccessful or incomplete conversion, it terminates with reason code `00D10121`.
3. To use this utility, your user ID of the job must have read and write access to both the old and new BSDSs.

- [“Invoking the CSQJUCNV utility” on page 2845](#)
- [“Data definition \(DD\) statements” on page 2845](#)

Invoking the CSQJUCNV utility

The utility runs as a z/OS batch program. Figure 1 shows an example of the JCL used to invoke the CSQJUCNV utility for a queue manager that is a member of a queue sharing group.

```
//CONVERT EXEC PGM=CSQJUCNV,REGION=32M
//STEPLIB DD DSN=thlqual.SCSQAUTH,DISP=SHR
//        DD DSN=thlqual.SCSQANLE,DISP=SHR
//        DD DSN=db2qual.SDSNLOAD,DISP=SHR
//SYSPRINT DD SYSOUT=*
//SYSUT1 DD DSN=h1q.BSDS01,DISP=SHR
//SYSUT2 DD DSN=h1q.BSDS02,DISP=SHR
//SYSUT3 DD DSN=newh1q.BSDS01,DISP=OLD
//SYSUT4 DD DSN=newh1q.BSDS02,DISP=OLD
```

Figure 47. Sample JCL to invoke the CSQJUCNV utility

Sample JCL to run the utility is also provided in thlqual.SCSQPROC (CSQ4BCNV).

From IBM MQ for z/OS 9.2.5 CSQJUCNV takes no parameters.

Data definition (DD) statements

CSQJUCNV recognizes DD statements with the following DD names:

SYSUT1

Specifies the old BSDS that is to be converted. This statement is required.

SYSUT2

Specifies the second copy of the old BSDS that is to be converted. If you are using dual BSDS, you should specify this.

SYSUT3

Specifies the new, converted BSDS. This statement is required.

SYSUT4

Specifies the second copy of the converted BSDS. This statement is required if the installation uses dual BSDS; otherwise, it is optional.

SYSPRINT

Contains the output messages from the conversion utility. This statement is required.

z/OS

The message security policy utility (CSQOUTIL)

The Advanced Message Security policy utility is provided to manage security policies that specify the cryptographic encryption and signature algorithms for encrypting and authenticating messages that flow through queues.

Using this utility program, you can display, define, alter, delete and export security policies.

The CSQOUTIL utility program runs as a z/OS batch utility that accepts **SYSIN** command input. Sample JCL to run the utility is provided in member CSQ40CFG of thlqual.SCSQPROC.

```
-----
//CSQ40CFG JOB 1,CSQ0,CLASS=A,MSGCLASS=X
//CSQ40CFG EXEC PGM=CSQ0UTIL,
//        PARM='ENVAR(" _CEE_ENVFILE_S=DD:ENVAR") /'
//STEPLIB DD DSN=thlqual.SCSQANLE,DISP=SHR
//        DD DSN=thlqual.SCSQAUTH,DISP=SHR
//ENVAR DD DSN=thlqual.SCSQPROC(CSQ40ENV),DISP=SHR
//SYSPRINT DD SYSOUT=*
//SYSIN DD *
```

```
dspmqspl -m qmgr
/*
```

The utility accepts the following commands:

dspmqspl

Display or export information about one or more security policies.

setmqspl

Define, alter or remove a security policy

For information on how to use these commands to manage security policies see [Managing security policies](#).

General usage notes

When specifying distinguished names (DNs) that have embedded blanks, you must enclose the entire DN in double quotes ("). For example:

```
-a "CN=John Smith,O=IBM,C=US"
-r "CN=JSmith,O=IBM Australia,C=AU"
```

Arguments that would exceed column 80 of a SYSIN input record can be continued on subsequent SYSIN records provided those arguments are enclosed in double quotes ("), and relevant continuations resume in column 1 of subsequent SYSIN records.

When exporting policy information using **dspmqspl** with the `-export` parameter the output is written to an additional DD named EXPORT. The EXPORT DD can be `SYSOUT=*`, a sequential data set, or the member of a partitioned data set. The record format is fixed block and the logical record length is 80. The output is in the form of one or more **setmqspl** commands that can subsequently be used as input to CSQOUTIL.

Specific security information

To use this utility you need authority to connect to the queue manager as a batch application. This authority is granted by giving READ access to the hlq.BATCH profile in the MQCONN class.

You also need authority to put messages to the queue SYSTEM.PROTECTION.POLICY.QUEUE. This authority is granted by giving UPDATE access to the hlq.SYSTEM.PROTECTION.POLICY.QUEUE profile in the MQQUEUE class.

If command events have been enabled for the queue manager you also need put authority to the queue SYSTEM.ADMIN.COMMAND.EVENT. If configuration events have been enabled for the queue manager you need put authority to the queue SYSTEM.ADMIN.CONFIG.EVENT.

Related concepts

[Security policies](#)

Related reference

[“dspmqspl \(display security policy\)” on page 99](#)

Use the **dspmqspl** command to display a list of all policies and details of a named policy.  On z/OS you use the command with the CSQOUTIL utility.

[“setmqspl \(set security policy\)” on page 245](#)

Use the **setmqsp1** command to define a new security policy, replace an already existing one, or remove an existing policy.  On z/OS you use the command with the CSQOUTIL utility.

Display queue manager information utility (CSQUDSPM)

CSQUDSPM displays information about queue managers and provides the equivalent function to **dspmq** on Multiplatforms.

Purpose

You use the CSQUDSPM utility to list all IBM MQ subsystems on the LPAR, regardless of what version of IBM MQ they are associated with.

Sample JCL, CSQ4DSPM, is provided for this purpose. The JCL is in the SCSQPROC data set.

Packaging

The CSQUDSPM load module is provided in the SCSQAUTH data set with an alias called DSPMQ.

If you need to run CSQUDSPM from z/OS UNIX System Services (z/OS UNIX), you can follow this procedure:

1. Create an empty file in z/OS UNIX with the name `csqudspm` or `dspmq`. For example, issue the following command:

```
touch dspmq
```

2. Set the file permissions so that it is executable:

```
chmod 755 dspmq
```

3. Enable the sticky bit:

```
chmod +t dspmq
```

4. Set the APF authorized attribute:

```
extattr +a dspmq
```

To be authorized to issue the **extattr** command with the `+a` option, you must have at least read access to the BPX.FILEATTR.APF resource in the FACILITY class profile.

5. Ensure that the SCSQAUTH library is in the STEPLIB environment variable, and that all libraries in the STEPLIB concatenation are APF authorized. For example, to set the STEPLIB concatenation to contain the SCSQANLE and SCSQAUTH libraries, issue the following command:

```
export STEPLIB=thqual.SCSQANLE:thqual.SCSQAUTH
```

You can now execute the file you created to run CSQUDSPM from z/OS UNIX.

Syntax

From IBM MQ for z/OS 9.2.4, all the parameters for this utility are case insensitive. For example:

```
dspmq -o status
```

is the same as

```
dspmq -O STATUS
```

Required parameters

None

Optional parameters

-a

Displays information about running queue managers only.

-m QMgrName

The queue manager for which to display details. If you do not specify a name, all queue managers on the LPAR are displayed.

-s

The operational status of the queue managers is displayed. This parameter is the default status setting.

The parameter **-o status** is equivalent to **-s**.

-o all

All details about the queue manager, or queue managers, are displayed.

-o status

The operational status of the queue managers is displayed.

-su

Suppress information about queue managers whose version is unknown.

An unknown version displays an INSTVER V . R . M of 0 . 0 . 0.

Command output

Output name	Details
QMNAME	The name of the queue manager consisting of up to four characters. If the queue manager name is less than four characters the string is not padded. This parameter is always output. Examples: QMNAME(MQ21), QMNAME(MQ1)
STATUS	The status of the queue manager. Either Running or Stopped. This parameter is always output. Examples: STATUS(Running), STATUS(Stopped)

Output name	Details
INSTVER	<p>The version that the queue manager was last started up with, in the format V . R . M.</p> <p>Note: In the case of a queue manager that has not been started since the last IPL of the LPAR, the version of that queue manager cannot be obtained. In that situation, the INSTVER attribute displays a V . R . M of 0 . 0 . 0.</p> <p>Examples: INSTVER(8.0.0), INSTVER(9.0.1)</p>
ERLYVER	<p>The version of early code associated with the queue manager, in the format V . R . M. This is usually the same for all queue managers in the LPAR, as a single set of early code modules is loaded into the Link Pack Area (LPA) and should be used by all queue managers.</p> <p>Examples: ERLYVER(9.0.1)</p>
CMDPFX	<p>The command prefix for the queue manager subsystem. This can be from one to eight characters long, and is not padded.</p> <p>Examples: CMDPFX(!MQ21), CMDPFX(MQ90ATST)</p>
QSGNAME	<p>The name of the queue sharing group, that the queue manager is a member of, consisting of up to four characters. If the queue manager name is less than four characters the string is not padded. This parameter is always output.</p> <p>If the queue manager is not a member of a queue sharing group then QSGNAME() is displayed.</p> <p>QSGNAME information can only be obtained when the queue manager is running, that is, STATUS(Running). If the queue manager is stopped QSGNAME(Unknown) is displayed.</p> <p>Example: QSGNAME(QSG1)</p>
RELTYPE	<p>The release type. The queue manager is running against a CD release if the value is <i>CDR</i> or against an LTS release if the value is <i>LTSR</i>.</p> <p>In the case of a queue manager that has not been started since the last IPL of the LPAR, the release type of that queue manager cannot be obtained. In that situation, the RELTYPE attribute displays <i>Unknown</i>.</p>

Examples

1. Input:

```
dspmq
```

Output:

```
QMNAME(QM01) STATUS(Stopped)
QMNAME(QM02) STATUS(Running)
QMNAME(QM03) STATUS(Stopped)
QMNAME(QM04) STATUS(Running)
```

2. Input:

```
dspmqr -o all
```

Output:

```
QMNAME(QM01) STATUS(Stopped) INSTVER(0.0.0) ERLYVER(9.2.0) CMDPFX(!QM01) QSGNAME(Unknown)
RELTYPE(Unknown)
QMNAME(QM02) STATUS(Running) INSTVER(9.2.0) ERLYVER(9.2.0) CMDPFX(!QM02) QSGNAME(QSG1) RELTYPE(LTSR)
QMNAME(QM03) STATUS(Stopped) INSTVER(9.2.0) ERLYVER(9.2.0) CMDPFX(!QM03) QSGNAME(Unknown) RELTYPE(CDR)
QMNAME(QM04) STATUS(Running) INSTVER(9.1.0) ERLYVER(9.2.0) CMDPFX(!QM04) QSGNAME() RELTYPE(LTSR)
```

3. Input:

```
dspmqr -o all -su
```

Output:

```
QMNAME(QM02) STATUS(Running) INSTVER(9.2.0) ERLYVER(9.2.0) CMDPFX(!QM02) QSGNAME(QSG1) RELTYPE(LTSR)
QMNAME(QM03) STATUS(Stopped) INSTVER(9.2.0) ERLYVER(9.2.0) CMDPFX(!QM03) QSGNAME(Unknown) RELTYPE(CDR)
QMNAME(QM04) STATUS(Running) INSTVER(9.1.0) ERLYVER(9.2.0) CMDPFX(!QM04) QSGNAME() RELTYPE(LTSR)
```
