On input to the authenticate user function, this identifies the current identity context. The authenticate user function can change this, at which point the queue manager adopts the new identity context. See [“MQZIC \(Identity context\) on IBM i” on page 1718](#) for more details on the MQZIC structure.

**CorrelationPtr (MQPTR) - output**

Correlation pointer.

Specifies the address of any correlation data. This pointer is then passed on to other OAM calls.

**ComponentData (MQBYTE x ComponentDataLength) - input/output**

Component data.

This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of this components functions is called. The length of this data area is passed by the queue manager in the **ComponentDataLength** parameter of the MQZ\_INIT\_AUTHORITY call.

**Continuation (MQLONG) - output**

Continuation flag.

The following values can be specified:

**MQZCI\_DEFAULT**

Continuation dependent on other components.

**MQZCI\_STOP**

Do not continue with next component.

**CompCode (MQLONG) - output**

Completion code.

It is one of the following:

**MQCC\_OK**

Successful completion.

**MQCC\_FAILED**

Call failed.

**Reason (MQLONG) - output**

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

**MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

### **MQRC\_SERVICE\_ERROR**

(2289, X'8F1') Unexpected error occurred accessing service.

For more information about these reason codes, see [Messages and reason codes](#).

## **C invocation**

```
MQZ_AUTHENTICATE_USER (QMgrName, SecurityParms, ApplicationContext,  
                      IdentityContext, &CorrelationPtr, ComponentData,  
                      &Continuation, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */  
MQCSP     SecurityParms;    /* Security parameters */  
MQZAC     ApplicationContext; /* Application context */  
MQZIC     IdentityContext;  /* Identity context */  
MQPTR     CorrelationPtr;   /* Correlation pointer */  
MQBYTE    ComponentData[n]; /* Component data */  
MQLONG    Continuation;     /* Continuation indicator set by  
                           component */  
MQLONG    CompCode;        /* Completion code */  
MQLONG    Reason;         /* Reason code qualifying CompCode */
```

## **MQZ\_CHECK\_AUTHORITY (Check authority) on IBM i**

This function is provided by a MQZAS\_VERSION\_1 authorization service component, and is invoked by the queue manager to check whether an entity has authority to perform a particular action, or actions, on a specified object.

The function identifier for this function (for MQZEP) is MQZID\_CHECK\_AUTHORITY.

### **Syntax**

**MQZ\_CHECK\_AUTHORITY** (*QMgrName*, *EntityName*, *EntityType*,  
*ObjectName*, *ObjectType*, *Authority*, *ComponentData*, *Continuation*, *CompCode*,  
*Reason*)

### **Parameters**

The MQZ\_CHECK\_AUTHORITY call has the following parameters.

#### **QMgrName (MQCHAR48) - input**

Queue manager name.

The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character. The queue manager name is passed to the component for information; the authorization service interface does not require the component to make use of it in any defined manner.

#### **EntityName (MQCHAR12) - input**

Entity name.

The name of the entity whose authorization to the object is to be checked. The maximum length of the string is 12 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

It is not essential for this entity to be known to the underlying security service. If it is not known, then the authorizations of the special **nobody** group (to which all entities are assumed to belong) are used for the check. An all-blank name is valid and can be used in this way.

**EntityType (MQLONG) - input**

Entity type.

The type of entity specified by *EntityName*. It is one of the following:

**MQZAET\_PRINCIPAL**

Principal.

**MQZAET\_GROUP**

Group.

**ObjectName (MQCHAR48) - input**

Object name.

The name of the object to which access is required. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

If *ObjectType* is MQOT\_Q\_MGR, this name is the same as *QMgrName*.

**ObjectType (MQLONG) - input**

Object type.

The type of entity specified by *ObjectName*. It is one of the following:

**MQOT\_AUTH\_INFO**

Authentication information.

**MQOT\_CHANNEL**

Channel.

**MQOT\_CLNTCONN\_CHANNEL**

Client connection channel.

**MQOT\_LISTENER**

Listener.

**MQOT\_NAMELIST**

Namelist.

**MQOT\_PROCESS**

Process definition.

**MQOT\_Q**

Queue.

**MQOT\_Q\_MGR**

Queue manager.

**MQOT\_SERVICE**

Service.

**Authority (MQLONG) - input**

Authority to be checked.

If one authorization is being checked, this field is equal to the appropriate authorization operation (MQZAO\_\* constant). If more than one authorization is being checked, it is the bitwise OR of the corresponding MQZAO\_\* constants.

The following authorizations apply to use of the MQI calls:

**MQZAO\_CONNECT**

Ability to use the MQCONN call.

**MQZAO\_BROWSE**

Ability to use the MQGET call with a browse option.

This allows the MQGMO\_BROWSE\_FIRST, MQGMO\_BROWSE\_MSG\_UNDER\_CURSOR, or MQGMO\_BROWSE\_NEXT option to be specified on the MQGET call.

**MQZAO\_INPUT**

Ability to use the MQGET call with an input option.

This allows the MQOO\_INPUT\_SHARED, MQOO\_INPUT\_EXCLUSIVE, or MQOO\_INPUT\_AS\_Q\_DEF option to be specified on the MQOPEN call.

**MQZAO\_OUTPUT**

Ability to use the MQPUT call.

This allows the MQOO\_OUTPUT option to be specified on the MQOPEN call.

**MQZAO\_INQUIRE**

Ability to use the MQINQ call.

This allows the MQOO\_INQUIRE option to be specified on the MQOPEN call.

**MQZAO\_SET**

Ability to use the MQSET call.

This allows the MQOO\_SET option to be specified on the MQOPEN call.

**MQZAO\_PASS\_IDENTITY\_CONTEXT**

Ability to pass identity context.

This allows the MQOO\_PASS\_IDENTITY\_CONTEXT option to be specified on the MQOPEN call, and the MQPMO\_PASS\_IDENTITY\_CONTEXT option to be specified on the MQPUT and MQPUT1 calls.

**MQZAO\_PASS\_ALL\_CONTEXT**

Ability to pass all context.

This allows the MQOO\_PASS\_ALL\_CONTEXT option to be specified on the MQOPEN call, and the MQPMO\_PASS\_ALL\_CONTEXT option to be specified on the MQPUT and MQPUT1 calls.

**MQZAO\_SET\_IDENTITY\_CONTEXT**

Ability to set identity context.

This allows the MQOO\_SET\_IDENTITY\_CONTEXT option to be specified on the MQOPEN call, and the MQPMO\_SET\_IDENTITY\_CONTEXT option to be specified on the MQPUT and MQPUT1 calls.

**MQZAO\_SET\_ALL\_CONTEXT**

Ability to set all context.

This allows the MQOO\_SET\_ALL\_CONTEXT option to be specified on the MQOPEN call, and the MQPMO\_SET\_ALL\_CONTEXT option to be specified on the MQPUT and MQPUT1 calls.

**MQZAO\_ALTERNATE\_USER\_AUTHORITY**

Ability to use alternate user authority.

This allows the MQOO\_ALTERNATE\_USER\_AUTHORITY option to be specified on the MQOPEN call, and the MQPMO\_ALTERNATE\_USER\_AUTHORITY option to be specified on the MQPUT1 call.

**MQZAO\_ALL\_MQI**

All of the MQI authorizations.

This enables all of the authorizations described previously.

The following authorizations apply to administration of a queue manager:

**MQZAO\_CREATE**

Ability to create objects of a specified type.

**MQZAO\_DELETE**

Ability to delete a specified object.

**MQZAO\_DISPLAY**

Ability to display the attributes of a specified object.

**MQZAO\_CHANGE**

Ability to change the attributes of a specified object.

**MQZAO\_CLEAR**

Ability to delete all messages from a specified queue.

**MQZAO\_AUTHORIZE**

Ability to authorize other users for a specified object.

**MQZAO\_CONTROL**

Ability to start, stop, or ping a non-client channel object.

**MQZAO\_CONTROL\_EXTENDED**

Ability to reset a sequence number, or resolve an indoubt message on a non-client channel object.

**MQZAO\_ALL\_ADMIN**

All of the administration authorizations, other than MQZAO\_CREATE.

The following authorizations apply to both use of the MQI and to administration of a queue manager:

**MQZAO\_ALL**

All authorizations, other than MQZAO\_CREATE.

**MQZAO\_NONE**

No authorizations.

**ComponentData (MQBYTE x ComponentDataLength) - input/output**

Component data.

This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of this component's functions is called.

The length of this data area is passed by the queue manager in the **ComponentDataLength** parameter of the MQZ\_INIT\_AUTHORITY call.

**Continuation (MQLONG) - output**

Continuation indicator set by component.

The following values can be specified:

**MQZCI\_DEFAULT**

Continuation dependent on queue manager.

For MQZ\_CHECK\_AUTHORITY this has the same effect as MQZCI\_STOP.

**MQZCI\_CONTINUE**

Continue with next component.

**MQZCI\_STOP**

Do not continue with next component.

**CompCode (MQLONG) - output**

Completion code.

It is one of the following:

**MQCC\_OK**

Successful completion.

**MQCC\_FAILED**

Call failed.

**Reason (MQLONG) - output**

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

**MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

**MQRC\_NOT\_AUTHORIZED**

(2035, X'7F3') Not authorized for access.

**MQRC\_SERVICE\_ERROR**

(2289, X'8F1') Unexpected error occurred accessing service.

**MQRC\_SERVICE\_NOT\_AVAILABLE**

(2285, X'8ED') Underlying service not available.

For more information about these reason codes, see [Messages and reason codes](#).

**C invocation**

```
MQZ_CHECK_AUTHORITY (QMgrName, EntityName, EntityType, ObjectName,
                    ObjectType, Authority, ComponentData,
                    &Continuation, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */
MQCHAR12  EntityName;       /* Entity name */
MQLONG    EntityType;       /* Entity type */
MQCHAR48  ObjectName;      /* Object name */
MQLONG    ObjectType;       /* Object type */
MQLONG    Authority;        /* Authority to be checked */
MQBYTE    ComponentData[n]; /* Component data */
MQLONG    Continuation;     /* Continuation indicator set by
                             component */
MQLONG    CompCode;         /* Completion code */
MQLONG    Reason;           /* Reason code qualifying CompCode */
```

**MQZ\_CHECK\_PRIVILEGED - Check if user is privileged**

This function is provided by an MQZAS\_VERSION\_6 authorization service component, and is invoked by the queue manager to determine whether a specified user is a privileged user.

The function identifier for this function (for MQZEP) is MQZID\_CHECK\_PRIVILEGED.

**Syntax**

```
MQZ_CHECK_PRIVILEGED( QMgrName , EntityData , EntityType , ComponentData ,
Continuation , CompCode , Reason )
```

**Parameters****QMgrName**

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

**EntityData**

Type: MQZED - input

Entity data. Data relating to the entity that is to be checked. For more information, see "[MQZED - Entity descriptor](#)" on page 1675.

**EntityType**

Type: MQLONG - input

Entity type. The type of entity specified by EntityData. It must be one of the following values:

**MQZAET\_PRINCIPAL**

Principal.

## **MQZAET\_GROUP**

Group.

### **ComponentData**

Type: MQBYTEExComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the **ComponentDataLength** parameter of the MQZ\_INIT\_AUTHORITY call.

### **Continuation**

Type: MQLONG - output

Continuation indicator set by component. The following values can be specified:

#### **MQZCI\_DEFAULT**

Continuation dependent on queue manager.

For MQZ\_CHECK\_AUTHORITY, this has the same effect as MQZCI\_STOP.

#### **MQZCI\_CONTINUE**

Continue with next component.

#### **MQZCI\_STOP**

Do not continue with next component.

If the call to a component fails (that is, *CompCode* returns MQCC\_FAILED), and the *Continuation* parameter is MQZCI\_DEFAULT or MQZCI\_CONTINUE, the queue manager continues to call other components if there are any.

If the call succeeds (that is, *CompCode* returns MQCC\_OK) no other components are called no matter what the setting of *Continuation* is.

If the call fails and the *Continuation* parameter is MQZCI\_STOP then no other components are called and the error is returned to the queue manager. Components have no knowledge of previous calls, so the *Continuation* parameter is always set to MQZCI\_DEFAULT before the call.

### **CompCode**

Type: MQLONG - output

Completion code. It must be one of the following values:

#### **MQCC\_OK**

Successful completion.

#### **MQCC\_FAILED**

Call failed.

### **Reason**

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

#### **MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

#### **MQRC\_NOT\_PRIVILEGED**

(2584, X'A18') This user is not a privileged user ID.

#### **MQRC\_UNKNOWN\_ENTITY**

(2292, X'8F4') Entity unknown to service.

#### **MQRC\_SERVICE\_ERROR**

(2289, X'8F1') Unexpected error occurred accessing service.

## **MQRC\_SERVICE\_NOT\_AVAILABLE**

(2285, X'8ED') Underlying service not available.

For more information about these reason codes, see [API completion and reason codes](#).

## **C invocation**

```
MQZ_CHECK_PRIVILEGED (QMgrName, &EntityData, EntityType,  
                     ComponentData, &Continuation,  
                     &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */  
MQZED     EntityData;        /* Entity name */  
MQLONG    EntityType;        /* Entity type */  
MQBYTE    ComponentData[n]; /* Component data */  
MQLONG    Continuation;      /* Continuation indicator set by  
                             component */  
MQLONG    CompCode;          /* Completion code */  
MQLONG    Reason;           /* Reason code qualifying CompCode */
```

## **MQZ\_COPY\_ALL\_AUTHORITY (Copy all authority) on IBM i**

This function is provided by an authorization service component. It is invoked by the queue manager to copy all of the authorizations that are currently in force for a reference object to another object.

The function identifier for this function (for MQZEP) is MQZID\_COPY\_ALL\_AUTHORITY.

### **Syntax**

**MQZ\_COPY\_ALL\_AUTHORITY** (*QMgrName*, *RefObjectName*, *ObjectName*,  
*ObjectType*, *ComponentData*, *Continuation*, *CompCode*, *Reason*)

### **Parameters**

The MQZ\_COPY\_ALL\_AUTHORITY call has the following parameters.

#### **QMgrName (MQCHAR48) - input**

Queue manager name.

The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to make use of it in any defined manner.

#### **RefObjectName (MQCHAR48) - input**

Reference object name.

The name of the reference object, the authorizations for which are to be copied. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

#### **ObjectName (MQCHAR48) - input**

Object name.

The name of the object for which accesses are to be set. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

#### **ObjectType (MQLONG) - input**

Object type.

The type of object specified by *RefObjectName* and *ObjectName*. It is one of the following:

**MQOT\_AUTH\_INFO**

Authentication information.

**MQOT\_CHANNEL**

Channel.

**MQOT\_CLNTCONN\_CHANNEL**

Client connection channel.

**MQOT\_LISTENER**

Listener.

**MQOT\_NAMELIST**

Namelist.

**MQOT\_PROCESS**

Process definition.

**MQOT\_Q**

Queue.

**MQOT\_Q\_MGR**

Queue manager.

**MQOT\_SERVICE**

Service.

**ComponentData (MQBYTE x ComponentDataLength) - input/output**

Component data.

This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of this component's functions is called.

The length of this data area is passed by the queue manager in the **ComponentDataLength** parameter of the MQZ\_INIT\_AUTHORITY call.

**Continuation (MQLONG) - output**

Continuation indicator set by component.

The following values can be specified:

**MQZCI\_DEFAULT**

Continuation dependent on queue manager.

For MQZ\_COPY\_ALL\_AUTHORITY this has the same effect as MQZCI\_STOP.

**MQZCI\_CONTINUE**

Continue with next component.

**MQZCI\_STOP**

Do not continue with next component.

**CompCode (MQLONG) - output**

Completion code.

It is one of the following:

**MQCC\_OK**

Successful completion.

**MQCC\_FAILED**

Call failed.

**Reason (MQLONG) - output**

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

**MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

**MQRC\_SERVICE\_ERROR**

(2289, X'8F1') Unexpected error occurred accessing service.

**MQRC\_SERVICE\_NOT\_AVAILABLE**

(2285, X'8ED') Underlying service not available.

**MQRC\_UNKNOWN\_REF\_OBJECT**

(2294, X'8F6') Reference object unknown.

For more information about these reason codes, see [Messages and reason codes](#).

**C invocation**

```
MQZ_COPY_ALL_AUTHORITY (QMgrName, RefObjectName, ObjectName, ObjectType,
                        ComponentData, &Continuation, &CompCode,
                        &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */
MQCHAR48  RefObjectName;     /* Reference object name */
MQCHAR48  ObjectName;       /* Object name */
MQLONG    ObjectType;        /* Object type */
MQBYTE    ComponentData[n]; /* Component data */
MQLONG    Continuation;      /* Continuation indicator set by
                             component */
MQLONG    CompCode;          /* Completion code */
MQLONG    Reason;            /* Reason code qualifying CompCode */
```

**MQZ\_DELETE\_AUTHORITY (Delete authority) on IBM i**

This function is provided by an authorization service component, and is invoked by the queue manager to delete all of the authorizations associated with the specified object.

The function identifier for this function (for MQZEP) is MQZID\_DELETE\_AUTHORITY.

**Syntax**

**MQZ\_DELETE\_AUTHORITY** (*QMgrName*, *ObjectName*, *ObjectType*,  
*ComponentData*, *Continuation*, *CompCode*, *Reason*)

**Parameters**

The MQZ\_DELETE\_AUTHORITY call has the following parameters.

**QMgrName (MQCHAR48) - input**

Queue manager name.

The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to make use of it in any defined manner.

**ObjectName (MQCHAR48) - input**

Object name.

The name of the object for which accesses are to be deleted. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

If *ObjectType* is MQOT\_Q\_MGR, this name is the same as *QMgrName*.

**ObjectType (MQLONG) - input**

Object type.

The type of entity specified by *ObjectName*. It is one of the following:

**MQOT\_AUTH\_INFO**

Authentication information.

**MQOT\_CHANNEL**

Channel.

**MQOT\_CLNTCONN\_CHANNEL**

Client connection channel.

**MQOT\_LISTENER**

Listener.

**MQOT\_NAMELIST**

Namelist.

**MQOT\_PROCESS**

Process definition.

**MQOT\_Q**

Queue.

**MQOT\_Q\_MGR**

Queue manager.

**MQOT\_SERVICE**

Service.

**ComponentData (MQBYTE x ComponentDataLength) - input/output**

Component data.

This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of this component's functions is called.

The length of this data area is passed by the queue manager in the **ComponentDataLength** parameter of the MQZ\_INIT\_AUTHORITY call.

**Continuation (MQLONG) - output**

Continuation indicator set by component.

The following values can be specified:

**MQZCI\_DEFAULT**

Continuation dependent on queue manager.

For MQZ\_DELETE\_AUTHORITY this has the same effect as MQZCI\_STOP.

**MQZCI\_CONTINUE**

Continue with next component.

**MQZCI\_STOP**

Do not continue with next component.

**CompCode (MQLONG) - output**

Completion code.

It is one of the following:

**MQCC\_OK**

Successful completion.

**MQCC\_FAILED**

Call failed.

### Reason (MQLONG) - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

#### **MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

#### **MQRC\_SERVICE\_ERROR**

(2289, X'8F1') Unexpected error occurred accessing service.

#### **MQRC\_SERVICE\_NOT\_AVAILABLE**

(2285, X'8ED') Underlying service not available.

For more information about these reason codes, see [Messages and reason codes](#).

## C invocation

```
MQZ_DELETE_AUTHORITY (QMgrName, ObjectName, ObjectType, ComponentData,  
&Continuation, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48 QMgrName;          /* Queue manager name */  
MQCHAR48 ObjectName;       /* Object name */  
MQLONG   ObjectType;       /* Object type */  
MQBYTE   ComponentData[n]; /* Component data */  
MQLONG   Continuation;     /* Continuation indicator set by  
                           component */  
MQLONG   CompCode;        /* Completion code */  
MQLONG   Reason;         /* Reason code qualifying CompCode */
```

## IBM i MQZ\_ENUMERATE\_AUTHORITY\_DATA (Enumerate authority data) on IBM i

This function is provided by an MQZAS\_VERSION\_4 authorization service component, and is invoked repeatedly by the queue manager to retrieve all of the authority data that matches the selection criteria specified on the first invocation.

The function identifier for this function (for MQZEP) is MQZID\_ENUMERATE\_AUTHORITY\_DATA.

### Syntax

```
MQZ_ENUMERATE_AUTHORITY_DATA (QMgrName, StartEnumeration,  
Filter, AuthorityBufferLength, AuthorityBuffer, AuthorityDataLength,  
ComponentData, Continuation, CompCode, Reason)
```

### Parameters

The MQZ\_ENUMERATE\_AUTHORITY\_DATA call has the following parameters.

#### **QMgrName (MQCHAR48) - input**

Queue manager name.

The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to make use of it in any defined manner.

#### **StartEnumeration (MQLONG) - input**

Flag indicating whether call should start enumeration.

This indicates whether the call should start the enumeration of authority data, or continue the enumeration of authority data started by a previous call to MQZ\_ENUMERATE\_AUTHORITY\_DATA. The value is one of the following:

#### **MQZSE\_START**

Start enumeration.

The call is invoked with this value to start the enumeration of authority data. The **Filter** parameter specifies the selection criteria to be used to select the authority data returned by this and successive calls.

#### **MQZSE\_CONTINUE**

Continue enumeration.

The call is invoked with this value to continue the enumeration of authority data. The **Filter** parameter is ignored in this case, and can be specified as the null pointer (the selection criteria are determined by the **Filter** parameter specified by the call that had *StartEnumeration* set to MQZSE\_START).

#### **Filter (MQZAD) - input**

Filter.

If *StartEnumeration* is MQZSE\_START, *Filter* specifies the selection criteria to be used to select the authority data to return. If *Filter* is the null pointer, no selection criteria are used, that is, all authority data is returned. See [“MQZAD \(Authority data\) on IBM i” on page 1714](#) for details of the selection criteria that can be used.

If *StartEnumeration* is MQZSE\_CONTINUE, *Filter* is ignored, and can be specified as the null pointer.

#### **AuthorityBufferLength (MQLONG) - input**

Length of *AuthorityBuffer*.

This is the length in bytes of the **AuthorityBuffer** parameter. The authority buffer must be big enough to accommodate the data to be returned.

#### **AuthorityBuffer (MQZAD) - output**

Authority data.

This is the buffer in which the authority data is returned. The buffer must be big enough to accommodate an MQZAD structure, an MQZED structure, plus the longest entity name and longest domain name defined.

**Note:** This parameter is defined as an MQZAD, as the MQZAD always occurs at the start of the buffer. However, if the buffer is actually declared as an MQZAD, the buffer will be too small - it needs to be bigger than an MQZAD so that it can accommodate the MQZAD, MQZED, plus entity and domain names.

#### **AuthorityDataLength (MQLONG) - output**

Length of data returned in *AuthorityBuffer*.

This is the length of the data returned in *AuthorityBuffer*. If the authority buffer is too small, *AuthorityDataLength* is set to the length of the buffer required, and the call returns completion code MQCC\_FAILED and reason code MQRC\_BUFFER\_LENGTH\_ERROR.

#### **ComponentData (MQBYTE x ComponentDataLength) - input/output**

Component data.

This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of this component's functions is called.

The length of this data area is passed by the queue manager in the **ComponentDataLength** parameter of the MQZ\_INIT\_AUTHORITY call.

#### **Continuation (MQLONG) - output**

Continuation indicator set by component.

The following values can be specified:

**MQZCI\_DEFAULT**

Continuation dependent on queue manager.

For MQZ\_ENUMERATE\_AUTHORITY\_DATA this has the same effect as MQZCI\_CONTINUE.

**MQZCI\_CONTINUE**

Continue with next component.

**MQZCI\_STOP**

Do not continue with next component.

**CompCode (MQLONG) - output**

Completion code.

It is one of the following:

**MQCC\_OK**

Successful completion.

**MQCC\_FAILED**

Call failed.

**Reason (MQLONG) - output**

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

**MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

**MQRC\_BUFFER\_LENGTH\_ERROR**

(2005, X'7D5') Buffer length parameter not valid.

**MQRC\_NO\_DATA\_AVAILABLE**

(2379, X'94B') No data available.

**MQRC\_SERVICE\_ERROR**

(2289, X'8F1') Unexpected error occurred accessing service.

For more information about these reason codes, see [Messages and reason codes](#).

## C invocation

```
MQZ_ENUMERATE_AUTHORITY_DATA (QMgrName, StartEnumeration, &Filter,  
                               AuthorityBufferLength,  
                               &AuthorityBuffer,  
                               &AuthorityDataLength, ComponentData,  
                               &Continuation, &CompCode,  
                               &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */  
MQLONG    StartEnumeration;   /* Flag indicating whether call should  
                               start enumeration */  
MQZAD     Filter;             /* Filter */  
MQLONG    AuthorityBufferLength; /* Length of AuthorityBuffer */  
MQZAD     AuthorityBuffer;    /* Authority data */  
MQLONG    AuthorityDataLength; /* Length of data returned in  
                               AuthorityBuffer */  
MQBYTE    ComponentData[n];   /* Component data */  
MQLONG    Continuation;       /* Continuation indicator set by  
                               component */  
MQLONG    CompCode;           /* Completion code */  
MQLONG    Reason;             /* Reason code qualifying CompCode */
```

## MQZ\_FREE\_USER - Free user

This function is provided by a MQZAS\_VERSION\_5 authorization service component, and is invoked by the queue manager to free associated allocated resource. It is invoked when an application has finished running under all user contexts, for example during an MQDISC MQI call.

The function identifier for this function (for MQZEP) is MQZID\_FREE\_USER.

## MQZ\_GET\_AUTHORITY (Get authority) on IBM i

This function is provided by a MQZAS\_VERSION\_1 authorization service component, and is invoked by the queue manager to retrieve the authority that an entity has to access the specified object.

The function identifier for this function (for MQZEP) is MQZID\_GET\_AUTHORITY.

### Syntax

**MQZ\_GET\_AUTHORITY** (*QMgrName, EntityName, EntityType, ObjectName, ObjectType, Authority, ComponentData, Continuation, CompCode, Reason*)

### Parameters

The MQZ\_GET\_AUTHORITY call has the following parameters.

#### **QMgrName (MQCHAR48) - input**

Queue manager name.

The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to make use of it in any defined manner.

#### **EntityName (MQCHAR12) - input**

Entity name.

The name of the entity whose access to the object is to be retrieved. The maximum length of the string is 12 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

#### **EntityType (MQLONG) - input**

Entity type.

The type of entity specified by *EntityName*. The following value can be specified:

##### **MQZAET\_PRINCIPAL**

Principal.

##### **MQZAET\_GROUP**

Group.

#### **ObjectName (MQCHAR48) - input**

Object name.

The name of the object for which the entity's authority is to be retrieved. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

If *ObjectType* is MQOT\_Q\_MGR, this name is the same as *QMgrName*.

#### **ObjectType (MQLONG) - input**

Object type.

The type of entity specified by *ObjectName*. It is one of the following:

##### **MQOT\_AUTH\_INFO**

Authentication information.

**MQOT\_CHANNEL**

Channel.

**MQOT\_CLNTCONN\_CHANNEL**

Client connection channel.

**MQOT\_LISTENER**

Listener.

**MQOT\_NAMELIST**

Namelist.

**MQOT\_PROCESS**

Process definition.

**MQOT\_Q**

Queue.

**MQOT\_Q\_MGR**

Queue manager.

**MQOT\_SERVICE**

Service.

**Authority (MQLONG) - output**

Authority of entity.

If the entity has one authority, this field is equal to the appropriate authorization operation (MQZAO\_\* constant). If it has more than one authority, this field is the bitwise OR of the corresponding MQZAO\_\* constants.

**ComponentData (MQBYTE x ComponentDataLength) - input/output**

Component data.

This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of this component's functions is called.

The length of this data area is passed by the queue manager in the **ComponentDataLength** parameter of the MQZ\_INIT\_AUTHORITY call.

**Continuation (MQLONG) - output**

Continuation indicator set by component.

The following values can be specified:

**MQZCI\_DEFAULT**

Continuation dependent on queue manager.

For MQZ\_GET\_AUTHORITY this has the same effect as MQZCI\_CONTINUE.

**MQZCI\_CONTINUE**

Continue with next component.

**MQZCI\_STOP**

Do not continue with next component.

**CompCode (MQLONG) - output**

Completion code.

It is one of the following:

**MQCC\_OK**

Successful completion.

**MQCC\_FAILED**

Call failed.

**Reason (MQLONG) - output**

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

**MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

**MQRC\_NOT\_AUTHORIZED**

(2035, X'7F3') Not authorized for access.

**MQRC\_SERVICE\_ERROR**

(2289, X'8F1') Unexpected error occurred accessing service.

**MQRC\_SERVICE\_NOT\_AVAILABLE**

(2285, X'8ED') Underlying service not available.

**MQRC\_UNKNOWN\_ENTITY**

(2292, X'8F4') Entity unknown to service.

For more information about these reason codes, see [Messages and reason codes](#).

## C invocation

```
MQZ_GET_AUTHORITY (QMgrName, EntityName, EntityType, ObjectName,  
                  ObjectType, &Authority, ComponentData,  
                  &Continuation, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48 QMgrName;          /* Queue manager name */  
MQCHAR12 EntityName;       /* Entity name */  
MQLONG   EntityType;       /* Entity type */  
MQCHAR48 ObjectName;       /* Object name */  
MQLONG   ObjectType;       /* Object type */  
MQLONG   Authority;        /* Authority of entity */  
MQBYTE   ComponentData[n]; /* Component data */  
MQLONG   Continuation;     /* Continuation indicator set by  
                           component */  
MQLONG   CompCode;         /* Completion code */  
MQLONG   Reason;          /* Reason code qualifying CompCode */
```

## IBM i MQZ\_GET\_EXPLICIT\_AUTHORITY (Get explicit authority) on IBM i

This function is provided by a MQZAS\_VERSION\_1 authorization service component, and is invoked by the queue manager to retrieve the authority that a named group has to access a specified object (but without the additional authority of the **nobody** group), or the authority that the primary group of the named principal has to access a specified object.

The function identifier for this function (for MQZEP) is MQZID\_GET\_EXPLICIT\_AUTHORITY.

### Syntax

**MQZ\_GET\_EXPLICIT\_AUTHORITY** (*QMgrName*, *EntityName*, *EntityType*,  
*ObjectName*, *ObjectType*, *Authority*, *ComponentData*, *Continuation*, *CompCode*,  
*Reason*)

### Parameters

The MQZ\_GET\_EXPLICIT\_AUTHORITY call has the following parameters.

**QMgrName (MQCHAR48) - input**

Queue manager name.

The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to make use of it in any defined manner.

**EntityName (MQCHAR12) - input**

Entity name.

The name of the entity from which access to the object is to be retrieved. The maximum length of the string is 12 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

**EntityType (MQLONG) - input**

Entity type.

The type of entity specified by *EntityName*. The following value can be specified:

**MQZAET\_PRINCIPAL**

Principal.

**MQZAET\_GROUP**

Group.

**ObjectName (MQCHAR48) - input**

Object name.

The name of the object for which the entity's authority is to be retrieved. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

If *ObjectType* is MQOT\_Q\_MGR, this name is the same as *QMgrName*.

**ObjectType (MQLONG) - input**

Object type.

The type of entity specified by *ObjectName*. It is one of the following:

**MQOT\_AUTH\_INFO**

Authentication information.

**MQOT\_CHANNEL**

Channel.

**MQOT\_CLNTCONN\_CHANNEL**

Client connection channel.

**MQOT\_LISTENER**

Listener.

**MQOT\_NAMELIST**

Namelist.

**MQOT\_PROCESS**

Process definition.

**MQOT\_Q**

Queue.

**MQOT\_Q\_MGR**

Queue manager.

**MQOT\_SERVICE**

Service.

**Authority (MQLONG) - output**

Authority of entity.

If the entity has one authority, this field is equal to the appropriate authorization operation (MQZAO\_\* constant). If it has more than one authority, this field is the bitwise OR of the corresponding MQZAO\_\* constants.

**ComponentData (MQBYTE x ComponentDataLength) - input/output**

Component data.

This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of this component's functions is called.

The length of this data area is passed by the queue manager in the **ComponentDataLength** parameter of the MQZ\_INIT\_AUTHORITY call.

#### **Continuation (MQLONG) - output**

Continuation indicator set by component.

The following values can be specified:

##### **MQZCI\_DEFAULT**

Continuation dependent on queue manager.

For MQZ\_GET\_EXPLICIT\_AUTHORITY this has the same effect as MQZCI\_CONTINUE.

##### **MQZCI\_CONTINUE**

Continue with next component.

##### **MQZCI\_STOP**

Do not continue with next component.

#### **CompCode (MQLONG) - output**

Completion code.

It is one of the following:

##### **MQCC\_OK**

Successful completion.

##### **MQCC\_FAILED**

Call failed.

#### **Reason (MQLONG) - output**

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

##### **MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

##### **MQRC\_NOT\_AUTHORIZED**

(2035, X'7F3') Not authorized for access.

##### **MQRC\_SERVICE\_ERROR**

(2289, X'8F1') Unexpected error occurred accessing service.

##### **MQRC\_SERVICE\_NOT\_AVAILABLE**

(2285, X'8ED') Underlying service not available.

##### **MQRC\_UNKNOWN\_ENTITY**

(2292, X'8F4') Entity unknown to service.

For more information about these reason codes, see [Messages and reason codes](#).

## **C invocation**

```
MQZ_GET_EXPLICIT_AUTHORITY (QMgrName, EntityName, EntityType,  
                             ObjectName, ObjectType, &Authority,  
                             ComponentData, &Continuation,  
                             &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48 QMgrName;          /* Queue manager name */  
MQCHAR12 EntityName;       /* Entity name */
```

```

MQLONG  EntityType;          /* Entity type */
MQCHAR48 ObjectName;        /* Object name */
MQLONG  ObjectType;         /* Object type */
MQLONG  Authority;         /* Authority of entity */
MQBYTE  ComponentData[n];  /* Component data */
MQLONG  Continuation;      /* Continuation indicator set by
                           component */
MQLONG  CompCode;          /* Completion code */
MQLONG  Reason;            /* Reason code qualifying CompCode */

```

## MQZ\_INIT\_AUTHORITY (Initialize authorization service) on IBM i

This function is provided by an authorization service component, and is invoked by the queue manager during configuration of the component. It is expected to call MQZEP in order to provide information to the queue manager.

The function identifier for this function (for MQZEP) is MQZID\_INIT\_AUTHORITY.

### Syntax

**MQZ\_INIT\_AUTHORITY** (*Hconfig, Options, QMgrName, ComponentDataLength, ComponentData, Version, CompCode, Reason*)

### Parameters

The MQZ\_INIT\_AUTHORITY call has the following parameters.

#### **Hconfig (MQHCONFIG) - input**

Configuration handle.

This handle represents the particular component being initialized. It is to be used by the component when calling the queue manager with the MQZEP function.

#### **Options (MQLONG) - input**

Initialization options.

It is one of the following:

##### **MQZIO\_PRIMARY**

Primary initialization.

##### **MQZIO\_SECONDARY**

Secondary initialization.

#### **QMgrName (MQCHAR48) - input**

Queue manager name.

The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to make use of it in any defined manner.

#### **ComponentDataLength (MQLONG) - input**

Length of component data.

Length in bytes of the *ComponentData* area. This length is defined in the component configuration data.

#### **ComponentData (MQBYTE x ComponentDataLength) - input/output**

Component data.

This is initialized to all zeros before calling the component's primary initialization function. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions (including the initialization function) provided by this component are preserved, and presented the next time one of this component's functions is called.

### Version (MQLONG) - input/output

Version number.

On input to the initialization function, this identifies the *highest* version number that the queue manager supports. The initialization function must change this, if necessary, to the version of the interface which *it* supports. If on return the queue manager does not support the version returned by the component, it calls the component's MQZ\_TERM\_AUTHORITY function and makes no further use of this component.

The following values are supported:

#### **MQZAS\_VERSION\_1**

Version 1.

#### **MQZAS\_VERSION\_2**

Version 2.

#### **MQZAS\_VERSION\_3**

Version 3.

#### **MQZAS\_VERSION\_4**

Version 4.

#### **MQZAS\_VERSION\_5**

Version 5.

#### **MQZAS\_VERSION\_6**

IBM WebSphere MQ 6.

### CompCode (MQLONG) - output

Completion code.

It is one of the following:

#### **MQCC\_OK**

Successful completion.

#### **MQCC\_FAILED**

Call failed.

### Reason (MQLONG) - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

#### **MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

#### **MQRC\_INITIALIZATION\_FAILED**

(2286, X'8EE') Initialization failed for an undefined reason.

#### **MQRC\_SERVICE\_NOT\_AVAILABLE**

(2285, X'8ED') Underlying service not available.

For more information about these reason codes, see [Messages and reason codes](#).

## C invocation

```
MQZ_INIT_AUTHORITY (Hconfig, Options, QMgrName, ComponentDataLength,  
                    ComponentData, &Version, &CompCode,  
                    &Reason);
```

The parameters passed to the service are declared as follows:

```
MQHCONFIG  Hconfig;          /* Configuration handle */  
MQLONG     Options;         /* Initialization options */
```

```

MQCHAR48  QMgrName;           /* Queue manager name */
MQLONG    ComponentDataLength; /* Length of component data */
MQBYTE    ComponentData[n];  /* Component data */
MQLONG    Version;          /* Version number */
MQLONG    CompCode;         /* Completion code */
MQLONG    Reason;           /* Reason code qualifying CompCode */

```

## IBM i MQZ\_INQUIRE (Inquire authorization service) on IBM i

This function is provided by a MQZAS\_VERSION\_5 authorization service component, and is invoked by the queue manager to query the supported functionality. Where multiple service components are used, service components are called in reverse order to the order they were installed in.

The function identifier for this function (for MQZEP) is MQZID\_INQUIRE.

### Syntax

#### MQZ\_INQUIRE

*(QMgrName, SelectorCount, Selectors, IntAttrCount, IntAttrs, CharAttrLength, CharAttrs, SelectorReturned, ComponentData, Continuation, CompCode, Reason)*

### Parameters

The MQZ\_INQUIRE call has the following parameters.

#### QMgrName (MQCHAR48) - input

Queue manager name.

The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to make use of it in any defined manner.

#### SelectorCount (MQLONG) - input

Number of selectors.

The number of selectors supplied in the Selectors parameter.

The value must be between zero and 256.

#### Selectors (MQLONG x SelectorCount) - input

Selectors.

Array of selectors. Each selector identifies a required attribute and must be of one of the following types:

- MQIACF\_\* (integer)
- MQCACF\_\* (character)

Selectors can be specified in any order. The number of selectors in the array is indicated by the SelectorCount parameter.

Integer attributes identified by selectors are returned in the IntAttrs parameter in the same order as they appear in Selectors.

Character attributes identified by selectors are returned in the CharAttrs parameter in the same order as they appear in Selectors.

#### IntAttrCount (MQLONG) - input

Number of integer attributes.

The number of integer attributes supplied in the IntAttrs parameter.

The value must be in the range 0 through 256.

**IntAttrs (MQLONG x IntAttrCount) - output**

Integer attributes.

Array of integer attributes. The integer attributes are returned in the same order as the corresponding integer selectors in the Selectors array.

**CharAttrCount (MQLONG) - input**

Length of the character attributes buffer.

The length in bytes of the CharAttrs parameter.

The value must at least sum of the lengths of the requested character attributes. If no character attributes are requested, zero is a valid value.

**CharAttrs (MQLONG x CharAttrCount) - output**

Character attributes buffer.

Buffer containing character attributes, concatenated together. The character attributes are returned in the same order as the corresponding character selectors in the Selectors array.

The length of the buffer is given by the CharAttrCount parameter.

**SelectorReturned (MQLONGxSelectorCount) - input**

Selector returned.

Array of values identifying which attributes have been returned from the set requested for by the selectors in the Selectors parameter. The number of values in this array is indicated by the SelectorCount parameter. Each value in the array relates to the selector from the corresponding position in the Selectors array. Each value is one of the following:

**MQZSL\_RETURNED**

The attribute requested by the corresponding selector in the Selectors parameter has been returned.

**MQZSL\_NOT\_RETURNED**

The attribute requested by the corresponding selector in the Selectors parameter has not been returned.

The array is initialized with all values as *MQZSL\_NOT\_RETURNED*. When an authorization service component returns an attribute, it sets the appropriate value in the array to *MQZSL\_RETURNED*. This allows any other authorization service components, to which the inquire call is made, to identify which attributes have already been returned.

**ComponentData (MQBYTE x ComponentDataLength) - input/output**

Component data.

This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of this component's functions is called.

The length of this data area is passed by the queue manager in the **ComponentDataLength** parameter of the MQZ\_INIT\_AUTHORITY call.

**Continuation (MQLONG) - output**

Continuation flag.

The following values can be specified:

**MQZCI\_DEFAULT**

Continuation dependent on other components.

**MQZCI\_STOP**

Do not continue with next component.

**CompCode (MQLONG) - output**

Completion code.

It is one of the following:

**MQCC\_OK**

Successful completion.

**MQCC\_WARNING**

Partial completion.

**MQCC\_FAILED**

Call failed.

**Reason (MQLONG) - output**

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

**MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_WARNING:

**MQRC\_CHAR\_ATTRS\_TOO\_SHORT**

Not enough space for character attributes.

**MQRC\_INT\_COUNT\_TOO\_SMALL**

Not enough space for integer attributes.

If *CompCode* is MQCC\_FAILED:

**MQRC\_SELECTOR\_COUNT\_ERROR**

Number of selectors is not valid.

**MQRC\_SELECTOR\_ERROR**

Attribute selector not valid.

**MQRC\_SELECTOR\_LIMIT\_EXCEEDED**

Too many selectors specified.

**MQRC\_INT\_ATTR\_COUNT\_ERROR**

Number of integer attributes is not valid.

**MQRC\_INT\_ATTRS\_ARRAY\_ERROR**

Integer attributes array not valid.

**MQRC\_CHAR\_ATTR\_LENGTH\_ERROR**

Number of character attributes is not valid.

**MQRC\_CHAR\_ATTRS\_ERROR**

Character attributes string is not valid.

**MQRC\_SERVICE\_ERROR**

(2289, X'8F1') Unexpected error occurred accessing service.

**C invocation**

```
MQZ_INQUIRE (QMgrName, SelectorCount, Selectors, IntAttrCount,
              &IntAttrs, CharAttrLength, &CharAttrs,
              SelectorReturned, ComponentData, &Continuation,
              &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */
MQLONG    SelectorCount;     /* Selector count */
MQLONG    Selectors[n];      /* Selectors */
MQLONG    IntAttrCount;     /* IntAttrs count */
MQLONG    IntAttrs[n];      /* Integer attributes */
MQLONG    CharAttrCount;    /* CharAttrs count */
MQLONG    CharAttrs[n];     /* Character attributes */
MQLONG    SelectorReturned[n]; /* Selector returned */
MQBYTE    ComponentData[n]; /* Component data */
MQLONG    Continuation;     /* Continuation indicator set by
```

```

MQLONG      Component;          component */
MQLONG      Reason;            /* Completion code */
                                     /* Reason code qualifying CompCode */

```

## IBM i MQZ\_REFRESH\_CACHE (Refresh all authorizations) on IBM i

This function is provided by an MQZAS\_VERSION\_3 authorization service component. It is invoked by the queue manager to refresh the list of authorizations held internally by the component.

The function identifier for this function (for MQZEP) is MQZID\_REFRESH\_CACHE (8L).

### Syntax

#### MQZ\_REFRESH\_CACHE

(*QMgrName, ComponentData, Continuation, CompCode, Reason*)

### Parameters

#### QMgrName (MQCHAR48) - input

Queue manager name.

The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

#### ComponentData (MQBYTE x ComponentDataLength) - input/output

Component data.

This data is kept by the queue manager on behalf of this particular component. Any changes made to it by any of the functions provided by this component are preserved, and presented the next time a function of the component is called.

The length of this data area is passed by the queue manager in the *ComponentDataLength* parameter of the MQZ\_INIT\_AUTHORITY call.

#### Continuation (MQLONG) - output

Continuation indicator set by component.

The following values can be specified:

##### MQZCI\_DEFAULT

Continuation dependent on queue manager.

For MQZ\_REFRESH\_CACHE, this has the same effect as MQZCI\_CONTINUE.

##### MQZCI\_CONTINUE

Continue with next component.

##### MQZCI\_STOP

Do not continue with next component.

#### CompCode (MQLONG) - output

Completion code.

It is one of the following:

##### MQCC\_OK

Successful completion.

##### MQCC\_FAILED

Call failed.

#### Reason (MQLONG) - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

## **MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

## **MQRC\_SERVICE\_ERROR**

(2289, X'8F1') Unexpected error occurred accessing service.

## **C invocation**

```
MQZ_REFRESH_CACHE (QMgrName, ComponentData,  
                  &Continuation, &CompCode, &Reason);
```

Declare the parameters as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */  
MQBYTE    ComponentData[n];  /* Component data */  
MQLONG    Continuation;      /* Continuation indicator set by  
                             component */  
MQLONG    CompCode;          /* Completion code */  
MQLONG    Reason;            /* Reason code qualifying CompCode */
```

## **MQZ\_SET\_AUTHORITY (Set authority) on IBM i**

This function is provided by a MQZAS\_VERSION\_1 authorization service component, and is invoked by the queue manager to set the authority that an entity has to access the specified object.

The function identifier for this function (for MQZEP) is MQZID\_SET\_AUTHORITY.

**Note:** This function overrides any existing authorities. To preserve any existing authorities you must set them again with this function.

## **Syntax**

**MQZ\_SET\_AUTHORITY (QMgrName, EntityName, EntityType, ObjectName, ObjectType, Authority, ComponentData, Continuation, CompCode, Reason)**

## **Parameters**

The MQZ\_SET\_AUTHORITY call has the following parameters.

### **QMgrName (MQCHAR48) - input**

Queue manager name.

The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to make use of it in any defined manner.

### **EntityName (MQCHAR12) - input**

Entity name.

The name of the entity for which access to the object is to be set. The maximum length of the string is 12 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

### **EntityType (MQLONG) - input**

Entity type.

The type of entity specified by *EntityName*. The following value can be specified:

#### **MQZAET\_PRINCIPAL**

Principal.

**MQZAET\_GROUP**

Group.

**ObjectName (MQCHAR48) - input**

Object name.

The name of the object to which access is required. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

If *ObjectType* is MQOT\_Q\_MGR, this name is the same as *QMgrName*.

**ObjectType (MQLONG) - input**

Object type.

The type of entity specified by *ObjectName*. It is one of the following:

**MQOT\_AUTH\_INFO**

Authentication information.

**MQOT\_CHANNEL**

Channel.

**MQOT\_CLNTCONN\_CHANNEL**

Client connection channel.

**MQOT\_LISTENER**

Listener.

**MQOT\_NAMELIST**

Namelist.

**MQOT\_PROCESS**

Process definition.

**MQOT\_Q**

Queue.

**MQOT\_Q\_MGR**

Queue manager.

**MQOT\_SERVICE**

Service.

**Authority (MQLONG) - input**

Authority to be checked.

If one authorization is being set, this field is equal to the appropriate authorization operation (MQZAO\_\* constant). If more than one authorization is being set, it is the bitwise OR of the corresponding MQZAO\_\* constants.

**ComponentData (MQBYTE x ComponentDataLength) - input/output**

Component data.

This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of this component's functions is called.

The length of this data area is passed by the queue manager in the **ComponentDataLength** parameter of the MQZ\_INIT\_AUTHORITY call.

**Continuation (MQLONG) - output**

Continuation indicator set by component.

The following values can be specified:

**MQZCI\_DEFAULT**

Continuation dependent on queue manager.

For MQZ\_SET\_AUTHORITY this has the same effect as MQZCI\_STOP.

**MQZCI\_CONTINUE**

Continue with next component.

**MQZCI\_STOP**

Do not continue with next component.

**CompCode (MQLONG) - output**

Completion code.

It is one of the following:

**MQCC\_OK**

Successful completion.

**MQCC\_FAILED**

Call failed.

**Reason (MQLONG) - output**

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

**MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

**MQRC\_NOT\_AUTHORIZED**

(2035, X'7F3') Not authorized for access.

**MQRC\_SERVICE\_ERROR**

(2289, X'8F1') Unexpected error occurred accessing service.

**MQRC\_SERVICE\_NOT\_AVAILABLE**

(2285, X'8ED') Underlying service not available.

**MQRC\_UNKNOWN\_ENTITY**

(2292, X'8F4') Entity unknown to service.

**C invocation**

```
MQZ_SET_AUTHORITY (QMgrName, EntityName, EntityType, ObjectName,
                  ObjectType, Authority, ComponentData,
                  &Continuation, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */
MQCHAR12  EntityName;        /* Entity name */
MQLONG    EntityType;        /* Entity type */
MQCHAR48  ObjectName;       /* Object name */
MQLONG    ObjectType;        /* Object type */
MQLONG    Authority;         /* Authority to be checked */
MQBYTE    ComponentData[n]; /* Component data */
MQLONG    Continuation;     /* Continuation indicator set by
                             component */
MQLONG    CompCode;         /* Completion code */
MQLONG    Reason;          /* Reason code qualifying CompCode */
```

**MQZ\_TERM\_AUTHORITY - Terminate authorization service**

This function is provided by an authorization service component, and is invoked by the queue manager when it no longer requires the services of this component. The function must perform any cleanup required by the component.

The function identifier for this function (for MQZEP) is MQZID\_TERM\_AUTHORITY.

## Syntax

**MQZ\_TERM\_AUTHORITY** (*Hconfig*, *Options*, *QMgrName*, *ComponentData*,  
*CompCode*, *Reason*)

## Parameters

The MQZ\_TERM\_AUTHORITY call has the following parameters.

### **Hconfig (MQHCONFIG) - input**

Configuration handle.

This handle represents the particular component being terminated.

### **Options (MQLONG) - input**

Termination options.

It is one of the following:

#### **MQZTO\_PRIMARY**

Primary termination.

#### **MQZTO\_SECONDARY**

Secondary termination.

### **QMgrName (MQCHAR48) - input**

Queue manager name.

The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to make use of it in any defined manner.

### **ComponentData (MQBYTE x ComponentDataLength) - input/output**

Component data.

This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of this component's functions is called.

The length of this data area is passed by the queue manager in the **ComponentDataLength** parameter on the MQZ\_INIT\_AUTHORITY call.

When the MQZ\_TERM\_AUTHORITY call has completed, the queue manager discards this data.

### **CompCode (MQLONG) - output**

Completion code.

It is one of the following:

#### **MQCC\_OK**

Successful completion.

#### **MQCC\_FAILED**

Call failed.

### **Reason (MQLONG) - output**

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

#### **MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

#### **MQRC\_SERVICE\_NOT\_AVAILABLE**

(2285, X'8ED') Underlying service not available.

## **MQRC\_TERMINATION\_FAILED**

(2287, X'8FF') Termination failed for an undefined reason.

For more information about these reason codes, see [Messages and reason codes](#).

## **C invocation**

```
MQZ_TERM_AUTHORITY (Hconfig, Options, QMgrName, ComponentData,  
                    &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQHCONFIG  Hconfig;           /* Configuration handle */  
MQLONG     Options;          /* Termination options */  
MQCHAR48   QMgrName;        /* Queue manager name */  
MQBYTE     ComponentData[n]; /* Component data */  
MQLONG     CompCode;         /* Completion code */  
MQLONG     Reason;          /* Reason code qualifying CompCode */
```

## **MQZAC (Application context) on IBM i**

This parameter specifies data related to the calling application.

The MQZAC structure is used on the MQZ\_AUTHENTICATE\_USER call for the **ApplicationContext** parameter.

### **Fields**

#### **StrucId (MQCHAR4)**

Structure identifier.

The value is:

#### **MQZAC\_STRUC\_ID**

Identifier for application context structure.

For the C programming language, the constant MQZAC\_STRUC\_ID\_ARRAY is also defined; this has the same value as MQZAC\_STRUC\_ID, but is an array of characters instead of a string.

This is an input field to the service.

#### **Version (MQLONG)**

Structure version number.

The value is:

#### **MQZAC\_VERSION\_1**

Version-1 application context structure.

The following constant specifies the version number of the current version:

#### **MQZAC\_CURRENT\_VERSION**

Current version of application context structure.

This is an input field to the service.

#### **ProcessId (MQPID)**

Process identifier.

The process identifier of the application.

#### **ThreadId (MQTID)**

Thread identifier.

The thread identifier of the application.

**ApplName (MQCHAR28)**

Application name.

The application name.

**UserID (MQCHAR12)**

User identifier.

For IBM i systems the user profile that the application job was created under. (On IBM i, when a profile swap is done with the QWTSETP API in the application job, the current user profile is returned).

**EffectiveUserID (MQCHAR12)**

Effective user identifier.

For IBM i systems the application job's current user profile.

**Environment (MQLONG)**

Environment.

This field specifies the environment from which the call was made.

This can have one of the following values:

**MQXE\_COMMAND\_SERVER**

Command server.

**MQXE\_MQSC**

runmqsc command interpreter.

**MQXE\_MCA**

Message channel agent

**MQXE\_OTHER**

Undefined environment

**CallerType (MQLONG)**

Caller Type.

This field specifies the type of program that made the call.

This can have one of the following values:

**MQXACT\_EXTERNAL**

The call is external to the queue manager.

**MQXACT\_INTERNAL**

The call is internal to the queue manager.

**AuthenticationType (MQLONG)**

Authentication Type.

This field specifies the type of authentication being performed.

This can have one of the following values:

**MQZAT\_INITIAL\_CONTEXT**

The authentication call is due to user context being initialized. This value is used during an MQCONN or MQCONNX call.

**MQZAT\_CHANGE\_CONTEXT**

The authentication call is due to the user context being changed. This value is used when the MCA changes the user context.

v

**BindType (MQLONG)**

Bind Type.

This field specifies the type of binding in use.

This can have one of the following values:

## **MQCNO\_FASTPATH\_BINDING**

Fastpath binding.

## **MQCNO\_SHARED\_BINDING**

Shared binding.

## **MQCNO\_ISOLATED\_BINDING**

Isolated binding.

## **C declaration**

```
typedef struct tagMQZAC MQZAC;
struct tagMQZAC {
    MQCHAR4    StrucId;           /* Structure identifier */
    MQLONG     Version;          /* Structure version number */
    MQPID      ProcessId;        /* Process identifier */
    MQTID      ThreadId;         /* Thread identifier */
    MQCHAR28   ApplName;         /* Application name */
    MQCHAR12   UserID;           /* User identifier */
    MQCHAR12   EffectiveUserID;  /* Effective user identifier */
    MQLONG     Environment;      /* Environment */
    MQLONG     CallerType;        /* Caller type */
    MQLONG     AuthenticationType; /* Authentication type */
    MQLONG     BindType;         /* Bind type */
};
```

## **MQZAD (Authority data) on IBM i**

The MQZAD structure is used on the MQZ\_ENUMERATE\_AUTHORITY\_DATA call for two parameters.

See “MQZ\_ENUMERATE\_AUTHORITY\_DATA (Enumerate authority data) on IBM i” on page 1694 for further information on the **Filter** and **AuthorityBuffer** parameters:

- MQZAD is used for the **Filter** parameter which is input to the call. This parameter specifies the selection criteria that are to be used to select the authority data returned by the call.
- MQZAD is also used for the **AuthorityBuffer** parameter which is output from the call. This parameter specifies the authorizations for one combination of profile name, object type, and entity.

## **Fields**

### **StrucId (MQCHAR4)**

Structure identifier.

The value is:

### **MQZAD\_STRUC\_ID**

Identifier for authority data structure.

For the C programming language, the constant MQZAD\_STRUC\_ID\_ARRAY is also defined; this has the same value as MQZAD\_STRUC\_ID, but is an array of characters instead of a string.

This is an input field to the service.

### **Version (MQLONG)**

Structure version number.

The value is:

### **MQZAD\_VERSION\_1**

Version-1 authority data structure.

The following constant specifies the version number of the current version:

### **MQZAD\_CURRENT\_VERSION**

Current version of authority data structure.

This is an input field to the service.

**ProfileName (MQCHAR48)**

Profile name.

For the **Filter** parameter, this field is the profile name from which authority data is required. If the name is entirely blank up to the end of the field or the first null character, authority data for all profile names is returned.

For the **AuthorityBuffer** parameter, this field is the name of a profile that matches the specified selection criteria.

**ObjectType (MQLONG)**

Object type.

For the **Filter** parameter, this field is the object type for which authority data is required. If the value is MQOT\_ALL, authority data for all object types is returned.

For the **AuthorityBuffer** parameter, this field is the object type to which the profile identified by **ProfileName** applies.

The value is one of the following; for the **Filter** parameter, the value MQOT\_ALL is also valid:

**MQOT\_AUTH\_INFO**

Authentication information.

**MQOT\_CHANNEL**

Channel.

**MQOT\_CLNTCONN\_CHANNEL**

Client connection channel.

**MQOT\_LISTENER**

Listener.

**MQOT\_NAMELIST**

Namelist.

**MQOT\_PROCESS**

Process definition.

**MQOT\_Q**

Queue.

**MQOT\_Q\_MGR**

Queue manager.

**MQOT\_SERVICE**

Service.

**Authority (MQLONG)**

Authority.

For the **Filter** parameter, this field is ignored.

For the **AuthorityBuffer** parameter, this field represents the authorizations that the entity has to the objects identified by **ProfileName** and **ObjectType**. If the entity has only one authority, the field is equal to the appropriate authorization value (MQZAO\_\* constant). If the entity has more than one authority, the field is the bitwise OR of the corresponding MQZAO\_\* constants.

**EntityDataPtr (PMQZED)**

Address of MQZED structure identifying an entity.

For the **Filter** parameter, this field points to an MQZED structure that identifies the entity from which authority data is required. If **EntityDataPtr** is the null pointer, authority data for all entities is returned.

For the **AuthorityBuffer** parameter, this field points to an MQZED structure that identifies the entity that the returned authority data came from.

**EntityType (MQLONG)**

Entity type.

For the **Filter** parameter, this field specifies the entity type for which authority data is required. If the value is MQZAET\_NONE, authority data for all entity types is returned.

For the **AuthorityBuffer** parameter, this field specifies the type of the entity identified by the MQZED structure pointed to by **EntityDataPtr**.

The value is one of the following; for the **Filter** parameter, the value MQZAET\_NONE is also valid:

**MQZAET\_PRINCIPAL**

Principal.

**MQZAET\_GROUP**

Group.

**Options (MQAUTHOPT)**

Options.

This field specifies options that give control over the profiles that are displayed.

One of the following must be specified:

**MQAUTHOPT\_NAME\_ALL\_MATCHING**

Displays all profiles

**MQAUTHOPT\_NAME\_EXPLICIT**

Displays profiles that have exactly the same name as specified in the **ProfileName** field.

In addition, one of the following must also be specified:

**MQAUTHOPT\_ENTITY\_SET**

Display all profiles used to calculate the cumulative authority that the entity has to the object specified by **ProfileName**. The **ProfileName** field must not contain any wildcard characters.

- If the specified entity is a principal, for each member of the set {entity, groups} the most applicable profile that applies to the object is displayed.
- If the specified entity is a group, the most applicable profile from the group that applies to the object is displayed.
- If this value is specified, then the values of **ProfileName**, **ObjectType**, **EntityType**, and the entity name specified in the **EntityDataPtr** MQZED structure, must all be non-blank.

If you have specified *MQAUTHOPT\_NAME\_ALL\_MATCHING*, you can also specify the following:

**MQAUTHOPT\_ENTITY\_EXPLICIT**

Displays profiles that have exactly the same entity name as the entity name specified in the **EntityDataPtr** MQZED structure.

## C declaration

```
typedef struct tagMQZAD MQZAD;
struct tagMQZAD {
    MQCHAR4    StructId;           /* Structure identifier */
    MQLONG     Version;           /* Structure version number */
    MQCHAR48   ProfileName;       /* Profile name */
    MQLONG     ObjectType;        /* Object type */
    MQLONG     Authority;         /* Authority */
    PMQZED     EntityDataPtr;     /* Address of MQZED structure identifying an
                                   entity */
    MQLONG     EntityType;        /* Entity type */
    MQAUTHOPT  Options;          /* Options */
};
```

The MQZED structure is used in a number of authorization service calls to specify the entity for which authorization is to be checked.

## Fields

### StrucId (MQCHAR4)

Structure identifier.

The value is:

#### MQZED\_STRUC\_ID

Identifier for entity descriptor structure.

For the C programming language, the constant MQZED\_STRUC\_ID\_ARRAY is also defined; this has the same value as MQZED\_STRUC\_ID, but is an array of characters instead of a string.

This is an input field to the service.

### Version (MQLONG)

Structure version number.

The value is:

#### MQZED\_VERSION\_1

Version-1 entity descriptor structure.

The following constant specifies the version number of the current version:

#### MQZED\_CURRENT\_VERSION

Current version of entity descriptor structure.

This is an input field to the service.

### EntityNamePtr (PMQCHAR)

Address of entity name.

This is a pointer to the name of the entity whose authorization is to be checked.

### EntityDomainPtr (PMQCHAR)

Address of entity domain name.

This is a pointer to the name of the domain containing the definition of the entity whose authorization is to be checked.

### SecurityId (MQBYTE40)

Security identifier.

This is the security identifier whose authorization is to be checked.

### CorrelationPtr (MQPTR)

Correlation pointer.

This facilitates the passing of correlational data between the authenticate user function and other appropriate OAM functions.

## C declaration

```
typedef struct tagMQZED MQZED;
struct tagMQZED {
    MQCHAR4    StrucId;           /* Structure identifier */
    MQLONG     Version;          /* Structure version number */
    PMQCHAR    EntityNamePtr;    /* Address of entity name */
    PMQCHAR    EntityDomainPtr; /* Address of entity domain name */
    MQBYTE40   SecurityId;       /* Security identifier */
    MQPTR      CorrelationPtr;   /* Address of correlation data */
}
```

## IBM i MQZFP (Free parameters) on IBM i

This parameter specifies data related to resource to be freed.

The MQZFP structure is used on the MQZ\_FREE\_USER call for the **FreeParms** parameter.

### Fields

#### StrucId (MQCHAR4)

Structure identifier.

The value is:

#### MQZFP\_STRUC\_ID

Identifier for free parameters structure.

For the C programming language, the constant MQZFP\_STRUC\_ID\_ARRAY is also defined; this has the same value as MQZFP\_STRUC\_ID, but is an array of characters instead of a string.

This is an input field to the service.

#### Version (MQLONG)

Structure version number.

The value is:

#### MQZFP\_VERSION\_1

Version-1 free parameters structure.

The following constant specifies the version number of the current version:

#### MQZFP\_CURRENT\_VERSION

Current version of free parameters structure.

This is an input field to the service.

#### Reserved (MQBYTE8)

Reserved field.

The initial value is null.

#### CorrelationPtr (MQPTR)

Correlation pointer.

Address of correlation data relating to the resource to be freed.

### C declaration

```
typedef struct tagMQZFP MQZFP;
struct tagMQZFP {
    MQCHAR4   StrucId;           /* Structure identifier */
    MQLONG    Version;          /* Structure version number */
    MQBYTE8   Reserved;        /* Reserved field */
    MQPTR     CorrelationPtr;   /* Address of correlation data */
};
```

## IBM i MQZIC (Identity context) on IBM i

The MQZIC structure is used on the MQZ\_AUTHENTICATE\_USER call for the **IdentityContext** parameter.

The MQZIC structure contains identity context information, that identifies the user of the application that first put the message on a queue:

- The queue manager fills the UserIdentifier field with a name that identifies the user, the way that the queue manager can do this depends on the environment in which the application is running.

- The queue manager fills the `AccountingToken` field with a token or number that it determined from the application that put the message.
- Applications can use the `ApplIdentityData` field for any extra information that they want to include about the user (for example, an encrypted password).

Suitably authorized applications may set the identity context using the `MQZ_AUTHENTICATE_USER` function.

A Windows systems security identifier (SID) is stored in the `AccountingToken` field when a message is created under IBM MQ for Windows. The SID can be used to supplement the `UserIdentifier` field and to establish the credentials of a user.

## Fields

### **StrucId (MQCHAR4)**

Structure identifier.

The value is:

#### **MQZIC\_STRUC\_ID**

Identifier for identity context structure.

For the C programming language, the constant `MQZIC_STRUC_ID_ARRAY` is also defined; this has the same value as `MQZIC_STRUC_ID`, but is an array of characters instead of a string.

This is an input field to the service.

### **Version (MQLONG)**

Structure version number.

The value is:

#### **MQZIC\_VERSION\_1**

Version-1 identity context structure.

The following constant specifies the version number of the current version:

#### **MQZIC\_CURRENT\_VERSION**

Current version of identity context structure.

This is an input field to the service.

### **UserIdentifier (MQCHAR12)**

User identifier.

This is part of the **identity context** of the message.

*UserIdentifier* specifies the user identifier of the application that originated the message. The queue manager treats this information as character data, but does not define the format of it. For more information on the *UserIdentifier* field, see [“UserIdentifier \(MQCHAR12\) for MQMD” on page 459](#).

### **AccountingToken (MQBYTE32)**

Accounting token.

This is part of the **identity context** of the message.

*AccountingToken* allows an application to cause work done as a result of the message to be appropriately charged. The queue manager treats this information as a string of bits and does not check its content. For more information on the *AccountingToken* field, see [“AccountingToken \(MQBYTE32\) for MQMD” on page 460](#).

### **ApplIdentityData (MQCHAR32)**

Application data relating to identity.

This is part of the **identity context** of the message.

*ApplIdentityData* is information that is defined by the application suite that can be used to provide additional information about the origin of the message. For example, it could be set by applications running with suitable user authority to indicate whether the identity data is trusted. For more information on the *ApplIdentityData* field, see [“ApplIdentityData \(MQCHAR32\) for MQMD”](#) on page 462.

## C declaration

```
typedef struct tagMQZED MQZED;
struct tagMQZED {
    MQCHAR4   StrucId;           /* Structure identifier */
    MQLONG    Version;          /* Structure version number */
    MQCHAR12  UserIdentifier;    /* User identifier */
    MQBYTE32  AccountingToken;  /* Accounting token */
    MQCHAR32  ApplIdentityData; /* Application data relating to identity */
};
```

## The IBM MQ .NET classes and interfaces

IBM MQ .NET classes and interfaces are listed alphabetically. The properties, methods and constructors are described.

### MQAsyncStatus.NET class

Use *MQAsyncStatus* to inquire on the status of previous MQI activity; for example inquiring on the success of previous asynchronous put operations. *MQAsyncStatus* encapsulates features of the MQSTS data structure.

#### Class

```
System.Object
├── IBM.WMQ.MQBase
│   └── IBM.WMQ.MQBaseObject
│       └── IBM.WMQ.MQAsyncStatus
```

```
public class IBM.WMQ.MQAsyncStatus extends IBM.WMQ.MQBaseObject;
```

- [“Properties” on page 1720](#)
- [“Constructors” on page 1721](#)

#### Properties

Test for *MQException* being thrown when getting properties.

```
public static int CompCode {get;}
```

The completion code from the first error or warning.

```
public static int Reason {get;}
```

The reason code from the first error or warning.

```
public static int PutSuccessCount {get;}
```

The number of successful asynchronous MQI put calls.

```
public static int PutWarningCount {get;}
```

The number of asynchronous MQI put calls that succeeded with a warning.

```
public static int PutFailureCount {get;}
```

The number of failed asynchronous MQI put calls.

```
public static int ObjectType {get;}
```

The object type for the first error. The following values are possible:

- MQC.MQOT\_ALIAS\_Q
- MQC.MQOT\_LOCAL\_Q
- MQC.MQOT\_MODEL\_Q
- MQC.MQOT\_Q
- MQC.MQOT\_REMOTE\_Q
- MQC.MQOT\_TOPIC
- 0, meaning that no object is returned

```
public static string ObjectName {get;}
```

The object name.

```
public static string ObjectQMgrName {get;}
```

The object queue manager name.

```
public static string ResolvedObjectName {get;}
```

The resolved object name.

```
public static string ResolvedObjectQMgrName {get;}
```

The resolved object queue manager name.

## Constructors

```
public MQAsyncStatus() throws MQException;
```

Constructor method, constructs an object with fields initialized to zero or blank as appropriate.

## MQAuthenticationInformationRecord.NET class

Use `MQAuthenticationInformationRecord` to specify information about an authenticator that is to be used in an IBM MQ TLS client connection. `MQAuthenticationInformationRecord` encapsulates an authentication information record, MQAIR.

### Class

```
System.Object
└─ IBM.WMQ.MQAuthenticationInformationRecord
```

```
public class IBM.WMQ.MQAuthenticationInformationRecord extends System.Object;
```

- [“Properties” on page 1721](#)
- [“Constructors” on page 1722](#)

### Properties

Test for `MQException` being thrown when getting properties.

```
public long Version {get; set;}
```

Structure version number.

**public long AuthInfoType {get; set;}**

The type of authentication information. This attribute must be set to one of the following values:

- OCSP - Certificate revocation status checking is done using OCSP.
- CRLLDAP - Certificate revocation status checking is done using Certificate Revocation Lists on LDAP servers.

**public string AuthInfoConnName {get; set;}**

The DNS name or IP address of the host on which the LDAP server is running, with an optional port number. This keyword is required.

**public string LDAPPASSWORD {get; set;}**

The password associated with the distinguished name of the user who is accessing the LDAP server. This property applies only when **AuthInfoType** is set to CRLLDAP.

**public string LDAPUserName {get; set;}**

The distinguished name of the user who is accessing the LDAP server. When you set this property, **LDAPUserNameLength** and **LDAPUserNamePtr** are automatically set correctly. This property applies only when **AuthInfoType** is set to CRLLDAP.

**public string OCSPResponderURL {get; set;}**

The URL at which the OCSP responder can be contacted. This property applies only when **AuthInfoType** is set to OCSP

This field is case sensitive. It must start with the string `http://` in lowercase. The rest of the URL might be case sensitive, depending on the OCSP server implementation.

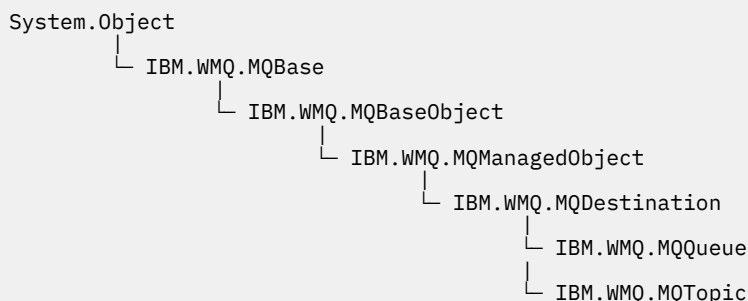

## Constructors

**MQAuthenticationInformationRecord();**

## MQDestination.NET class

Use **MQDestination** to access methods that are common to **MQQueue** and **MQTopic**. **MQDestination** is an abstract base class and cannot be instantiated.

## Class

**public class IBM.WMQ.MQDestination extends IBM.WMQ.MQManagedObject;**

- [“Properties” on page 1723](#)
- [“Methods” on page 1723](#)
- [“Constructors” on page 1724](#)

## Properties

Test for MQException being thrown when getting properties.

### **public DateTime CreationDateTime {get;}**

The date and time that the queue or topic was created. Originally contained within MQQueue, this property has been moved into the base MQDestination class.

There is no default value.

### **public int DestinationType {get;}**

Integer value describing the type of destination being used. Initialized from the sub classes constructor, MQQueue or MQTopic, this value can take one of these values:

- MQOT\_Q
- MQOT\_TOPIC

There is no default value.

## Methods

### **public void Get(MQMessage message);**

### **public void Get(MQMessage message, MQGetMessageOptions getMessageOptions);**

### **public void Get(MQMessage message, MQGetMessageOptions getMessageOptions, int MaxMsgSize);**

Throws MQException.

Gets a message from a queue if the destination is an MQQueue object or from a topic if the destination is an MQTopic object, using a default instance of MQGetMessageOptions to do the get.

If the get fails, the MQMessage object is unchanged. If it succeeds, the message descriptor and message data portions of the MQMessage are replaced with the message descriptor and message data from the incoming message.

All calls to IBM MQ from a particular MQQueueManager are synchronous. Therefore, if you perform a get with wait, all other threads using the same MQQueueManager are blocked from making further IBM MQ calls until the Get call is accomplished. If you need multiple threads to access IBM MQ simultaneously, each thread must create its own MQQueueManager object.

#### **message**

Contains the message descriptor and the returned message data. Some of the fields in the message descriptor are input parameters. It is important to ensure that the MessageId and CorrelationId input parameters are set as required.

A reconnectable client returns the reason code MQRC\_BACKED\_OUT after successful reconnection, for messages received under MQGM\_SYNCPOINT.

#### **getMessageOptions**

Options controlling the action of the get.

Using option MQC.MQGMO\_CONVERT might result in an exception with reason code MQC.MQRC\_CONVERTED\_STRING\_TOO\_BIG when converting from single-byte character codes to double byte codes. In this case, the message is copied into the buffer without conversion.

If *getMessageOptions* is not specified, the message option used is MQGMO\_NOWAIT.

If you use the MQGMO\_LOGICAL\_ORDER option in a reconnectable client, the MQRC\_RECONNECT\_INCOMPATIBLE reason code is returned.

#### **MaxMsgSize**

The largest message this message object is to receive. If the message on the queue is larger than this size, one of two things occurs:

- If the MQGMO\_ACCEPT\_TRUNCATED\_MSG flag is set in the MQGetMessageOptions object, the message is filled with as much of the message data as possible. An exception is thrown with the MQCC\_WARNING completion code and MQRC\_TRUNCATED\_MSG\_ACCEPTED reason code.
- If the MQGMO\_ACCEPT\_TRUNCATED\_MSG flag is not set, the message remains on the queue. An exception is thrown with the MQCC\_WARNING completion code and MQRC\_TRUNCATED\_MSG\_FAILED reason code.

If *MaxMsgSize* is not specified, the whole message is retrieved.

```
public void Put(MQMessage message);  
public void Put(MQMessage message, MQPutMessageOptions putMessageOptions);
```

Throws MQException.

Puts a message to a queue if the destination is an MQQueue object or publishes a message to a topic if the destination is an MQTopic object.

Modifications to the MQMessage object after the Put call has been accomplished do not affect the actual message on the IBM MQ queue or publication topic.

Put updates the MessageId and CorrelationId properties of the MQMessage object and does not clear message data. Further Put or Get calls refer to the updated information in the MQMessage object. For example, in the following code snippet, the first message contains a and the second ab.

```
msg.WriteString("a");  
q.Put(msg, pmo);  
msg.WriteString("b");  
q.Put(msg, pmo);
```

### message

An MQMessage object containing the message descriptor data, and message to be sent. The message descriptor can be altered as a consequence of this method. The values in the message descriptor immediately after the completion of this method are the values that were put to the queue or published to the topic.

The following reason codes are returned to a reconnectable client:

- MQRC\_CALL\_INTERRUPTED if the connection is broken while running a Put call on a persistent message and the reconnection is successful.
- MQRC\_NONE if the connection is successful while running a Put call on a non-persistent message (see [Application Recovery](#)).

### putMessageOptions

Options controlling the action of the put.

If *putMessageOptions* is not specified the default instance of MQPutMessageOptions is used.

If you use the MQPMO\_LOGICAL\_ORDER option in a reconnectable client, the MQRC\_RECONNECT\_INCOMPATIBLE reason code is returned.

**Note:** For simplicity and performance, if you want to put a single message to a queue, use MQQueueManager.Put object. You should have an MQQueue object for this.

## Constructors

MQDestination is an abstract base class and cannot be instantiated. Access destinations using MQQueue and MQTopic constructors, or using MQQueueManager.AccessQueue and MQQueueManager.AccessTopic methods.

## MQEnvironment.NET class

Use `MQEnvironment` to control how the `MQueueManager` constructor is called and to select an IBM MQ MQI client connection. The `MQEnvironment` class contains properties that control the behavior of the IBM MQ.

### Class

```
System.Object
└─ IBM.WMQ.MQEnvironment
```

```
public class IBM.WMQ.MQEnvironment extends System.Object;
```

- [“Properties - client only” on page 1725](#)
- [“Properties” on page 1726](#)
- [“Constructors” on page 1727](#)

### Properties - client only

Test for `MQException` being thrown when getting properties.

```
public static int CertificateValPolicy {get; set;}
```

Set which TLS certificate validation policy is used to validate digital certificates received from remote partner systems. Valid values are:

- `MQC.CERTIFICATE_VALIDATION_POLICY_ANY`
- `MQC.CERTIFICATE_VALIDATION_POLICY_RFC5280`

```
public static ArrayList EncryptionPolicySuiteB {get; set;}
```

Set the level of Suite B compliant cryptography. Valid values are:

- `MQC.MQ_SUITE_B_NONE` - This is the default value.
- `MQC.MQ_SUITE_B_128_BIT`
- `MQC.MQ_SUITE_B_192_BIT`

```
public static string Channel {get; set;}
```

The name of the channel to connect to the target queue manager. You must set the channel property before instantiating an `MQueueManager` instance in client mode.

```
public static int FipsRequired {get; set;}
```

Specify `MQC.MQSSL_FIPS_YES` to use only FIPS-certified algorithms if cryptography is carried out in IBM MQ. The default is `MQC.MQSSL_FIPS_NO`.

If cryptographic hardware is configured, the cryptographic modules used are those provided by the hardware product. Depending on the hardware in use, these might not be FIPS-certified to a particular level.

```
public static string Hostname {get; set;}
```

The TCP/IP host name of the computer on which the IBM MQ server resides. If the host name is not set, and no overriding properties are set, server bindings mode is used to connect to the local queue manager.

```
public static int Port {get; set;}
```

The port to connect to. This is the port on which the IBM MQ server is listening for incoming connection requests. The default value is 1414.

**public static string SSLCipherSpec {get; set;}**

Set SSLCipherSpec to the value of the CipherSpec set on the SVRCONN channel to enable TLS for the connection. The default is Null, and TLS is not enabled for the connection.

**public static string sslPeerName {get; set;}**

A distinguished name pattern. If sslCipherSpec is set, this variable can be used to ensure that the correct queue manager is used. If set to null (default), the DN of the queue manager is not performed. sslPeerName is ignored if sslCipherSpec is null.

**public static string SSLKeyRepository {get; set;}**

The plain text or encrypted passphrase to access the key repository. Key repository passphrases are encrypted for use by client applications using the **runmqicred** utility.

If SSLKeyRepositoryPassword is set to null (default), the value of the *MQKEYRPWD* environment variable, or the **SSLKeyRepositoryPassword** attribute in the client configuration file, is used.

**public static string InitialKey {get; set;}**

The initial key that was used to encrypt the key repository passphrase specified in SSLKeyRepositoryPassword.

The initial key must be specified if an initial key file was specified when the key repository passphrase was encrypted using the **runmqicred** utility.

## Properties

Test for MQException being thrown when getting properties.

**public static ArrayList HdrCompList {get; set;}**

Header Data Compression List

**public static int KeyResetCount {get; set;}**

Indicates the number of unencrypted bytes sent and received within an TLS conversation before the secret key is renegotiated.

**public static ArrayList MQAIRArray {get; set;}**

An array of MQAuthenticationInformationRecord objects.

**public static ArrayList MsgCompList {get; set;}**

Message Data Compression List

**public static string Password {get; set;}**

The password to be authenticated. The password referenced from the MQCSP structure gets populated by setting this Password property.

**public static string ReceiveExit {get; set;}**

A receive exit allows you to examine and alter data received from a queue manager. It is normally used with a corresponding send exit at the queue manager. If ReceiveExit is set to null, no receive exit is called.

**public static string ReceiveUserData {get; set;}**

The user data associated with a receive exit. Limited to 32 characters.

**public static string SecurityExit {get; set;}**

A security exit allows you to customize the security flows that occur when an attempt is made to connect to a queue manager. If SecurityExit is set to null, no security exit is called.

**public static string SecurityUserData {get; set;}**

The user data associated with a security exit. Limited to 32 characters.

**public static string SendExit {get; set;}**

A send exit allows you to examine or alter the data sent to a queue manager. It is normally used with a corresponding receive exit at the queue manager. If SendExit is set to null, no send exit is called.

**public static string SendUserData {get; set;}**

The user data associated with a send exit. Limited to 32 characters.

**public static string SharingConversations {get; set;}**

The SharingConversations field is used on connections from .NET applications, when these applications are not using a client channel definition table (CCDT).

SharingConversations determines the maximum number of conversations that can be shared on a socket associated with this connection.

A value of 0 means that the channel operates as it did before IBM WebSphere MQ 7.0, with regard to conversation sharing, read ahead, and heartbeat.

The field is passed in the hash table of properties as a SHARING\_CONVERSATIONS\_PROPERTY, when instantiating an IBM MQ queue manager.

If you do not specify SharingConversations, a default value of 10 is used.

**public static string SSLCryptoHardware {get; set;}**

Sets the name of the parameter string required to configure the cryptographic hardware present on the system. SSLCryptoHardware is ignored if sslCipherSpec is null.

**public static string SSLKeyRepository {get; set;}**

Set the fully qualified file name of the key repository.

If the file extension is not supplied, it is assumed to be .kdb

If SSLKeyRepository is set to null (default), the certificate MQSSLKEYR environment variable is used to locate the key repository.

**public static string UserId {get; set;}**

The user ID to be authenticated. The user ID referenced from the MQCSP structure gets populated by setting UserId. Authenticate UserId using an API or Security exit.

## Constructors

**public MQEnvironment()**

## MQException.NET class

Use MQException to find out the completion and reason code of a failed IBM MQ function. An MQException is thrown whenever an IBM MQ error occurs.

### Class

```
public class IBM.WMQ.MQException extends System.ApplicationException;
```

- [“Properties” on page 1727](#)
- [“Constructors” on page 1728](#)

## Properties

**public int CompletionCode {get; set;}**

The IBM MQ completion code associated with the error. The possible values are:

- MQException.MQCC\_OK

- MQException.MQCC\_WARNING
- MQException.MQCC\_FAILED

**public int ReasonCode {get; set;}**  
IBM MQ reason code describing the error.

## Constructors

**public MQException(int completionCode, int reasonCode)**

**completionCode**  
The IBM MQ completion code.

**reasonCode**  
The IBM MQ completion code.

## MQGetMessageOptions.NET class

Use MQGetMessageOptions to specify how messages are retrieved. It modifies the behavior of MQDestination.Get.

### Class

**public class IBM.WMQ.MQGetMessageOptions extends IBM.WMQ.MQBaseObject;**

- [“Properties” on page 1728](#)
- [“Constructors” on page 1731](#)

### Properties

**Note:** The behavior of some of the options available in this class depends on the environment in which they are used. These elements are marked with an asterisk \*.

Test for MQException being thrown when getting properties.

**public int GroupStatus {get;}\***

GroupStatus indicates whether the retrieved message is in a group and if it is the last in the group. Possible values are:

**MQC.MQGS\_LAST\_MSG\_IN\_GROUP**  
Message is the last or only message in the group.

**MQC.MQGS\_MSG\_IN\_GROUP**  
Message is in a group, but is not the last in the group.

**MQC.MQGS\_NOT\_IN\_GROUP**  
Message is not in a group.

**public int MatchOptions {get; set;}\***

MatchOptions determines how a message is selected. The following match options can be set:

**MQC.MQMO\_MATCH\_CORREL\_ID**  
Correlation ID to be matched.

**MQC.MQMO\_MATCH\_GROUP\_ID**  
Group ID to be matched.

**MQC.MQMO\_MATCH\_MSG\_ID**

Message ID to be matched.

**MQC.MQMO\_MATCH\_MSG\_SEQ\_NUMBER**

Match message sequence number.

**MQC.MQMO\_NONE**

No matching required.

**public int Options {get; set;}**

Options control the action of `MQQueue.get`. Any of the following values can be specified. If more than one option is required, the values can be added, or combined using the bitwise OR operator.

**MQC.MQGMO\_ACCEPT\_TRUNCATED\_MSG**

Allow truncation of message data.

**MQC.MQGMO\_ALL\_MSGS\_AVAILABLE\***

Retrieve messages from a group only when all the messages in the group are available.

**MQC.MQGMO\_ALL\_SEGMENTS\_AVAILABLE\***

Retrieve the segments of a logical message only when all the segments in the group are available.

**MQC.MQGMO\_BROWSE\_FIRST**

Browse from start of queue.

**MQC.MQGMO\_BROWSE\_MSG\_UNDER\_CURSOR\***

Browse message under browse cursor.

**MQC.MQGMO\_BROWSE\_NEXT**

Browse from the current position in the queue.

**MQC.MQGMO\_COMPLETE\_MSG\***

Retrieve only complete logical messages.

**MQC.MQGMO\_CONVERT**

Request the application data to be converted, to conform to the `CharacterSet` and `Encoding` attributes of the `MQMessage`, before the data is copied into the message buffer. Because data conversion is also applied when the data is retrieved from the message buffer, applications do not set this option.

Using this option can cause problems when converting from single-byte character sets to double-byte character sets. Instead, do the conversion using the `readString`, `readLine`, and `writeString` methods after the message has been delivered.

**MQC.MQGMO\_FAIL\_IF QUIESCING**

Fail if the queue manager is quiescing.

**MQC.MQGMO\_LOCK\***

Lock the message that is browsed.

**MQC.MQGMO\_LOGICAL\_ORDER\***

Return messages in groups, and segments of logical messages, in logical order.

If you use the `MQGMO_LOGICAL_ORDER` option in a reconnectable client, the `MQRC_RECONNECT_INCOMPATIBLE` reason code is returned to the application.

**MQC.MQGMO\_MARK\_SKIP\_BACKOUT\***

Allow a unit of work to be backed out without reinstating the message on the queue.

**MQC.MQGMO\_MSG\_UNDER\_CURSOR**

Get message under browse cursor.

**MQC.MQGMO\_NONE**

No other options have been specified; all options assume their default values.

**MQC.MQGMO\_NO\_PROPERTIES**

No properties of the message, except properties contained in the message descriptor (or extension) are retrieved.

**MQC.MQGMO\_NO\_SYNCPOINT**

Get message without sync point control.

**MQC.MQGMO\_NO\_WAIT**

Return immediately if there is no suitable message.

**MQC.MQGMO\_PROPERTIES\_AS\_Q\_DEF**

Retrieve message properties as defined by the `PropertyControl` attribute of `MQQueue`. Access to the message properties in the message descriptor, or extension, are not affected by the `PropertyControl` attribute.

**MQC.MQGMO\_PROPERTIES\_COMPATIBILITY**

Retrieve message properties with a prefix of `mcd`, `jms`, `usr`, or `mqext`, in `MQRFH2` headers. Other properties of the message, except properties contained in the message descriptor, or extension, are discarded.

**MQC.MQGMO\_PROPERTIES\_FORCE\_MQRFH2**

Retrieve message properties, except properties contained in the message descriptor, or extension, in `MQRFH2` headers. Use `MQC.MQGMO_PROPERTIES_FORCE_MQRFH2` in applications that are expecting to retrieve properties but cannot be changed to use message handles.

**MQC.MQGMO\_PROPERTIES\_IN\_HANDLE**

Retrieve message properties using a `MsgHandle`.

**MQC.MQGMO\_SYNCPOINT**

Get the message under sync point control. The message is marked as being unavailable to other applications, but it is deleted from the queue only when the unit of work is committed. The message is made available again if the unit of work is backed out.

**MQC.MQGMO\_SYNCPOINT\_IF\_PERSISTENT\***

Get message with sync point control if message is persistent.

**MQC.MQGMO\_UNLOCK\***

Unlock a previously locked message.

**MQC.MQGMO\_WAIT**

Wait for a message to arrive.

**public string ResolvedQueueName {get;}**

The queue manager sets `ResolvedQueueName` to the local name of the queue from which the message was retrieved. `ResolvedQueueName` is different from the name used to open the queue if an alias queue or model queue was opened.

**public char Segmentation {get;}\***

`Segmentation` indicates whether you can allow segmentation for the retrieved message. Possible values are:

**MQC.MQSEG\_INHIBITED**

Do not allow segmentation.

**MQC.MQSEG\_ALLOWED**

Allow segmentation

**public byte SegmentStatus {get;}\***

`SegmentStatus` is an output field that indicates whether the retrieved message is a segment of a logical message. If the message is a segment, the flag indicates whether it is the last segment. Possible values are:

**MQC.MQSS\_LAST\_SEGMENT**

Message is the last or only segment of the logical message.

**MQC.MQSS\_NOT\_A\_SEGMENT**

Message is not a segment.

**MQC.MQSS\_SEGMENT**

Message is a segment, but is not the last segment of the logical message.

**public int WaitInterval {get; set;}**

`WaitInterval` is the maximum time in milliseconds that an `MQQueue.get` call waits for a suitable message to arrive. Use `WaitInterval` with `MQC.MQGMO_WAIT`. Set a value of `MQC.MQWI_UNLIMITED` to wait an unlimited time for a message.

## Constructors

### **public MQGetMessageOptions()**

Construct a new MQGetMessageOptions object with Options set to MQC.MQGMO\_NO\_WAIT, WaitInterval set to zero, and ResolvedQueueName set to blank.

## MQManagedObject.NET class

Use MQManagedObject to inquire and set attributes of MQDestination, MQProcess, MQQueueManager, and MQSubscription. MQManagedObject is a superclass of these classes.

## Classes

```
public class IBM.WMQ.MQManagedObject extends IBM.WMQ.MQBaseObject;
```

- [“Properties” on page 1731](#)
- [“Methods” on page 1732](#)
- [“Constructors” on page 1733](#)

## Properties

Test for MQException being thrown when getting properties.

### **public string AlternateUserId {get; set;}**

The alternate user ID, if any, set when the resource was opened. AlternateUserID.set is ignored when issued for an object that is opened. AlternateUserId is not valid for subscriptions.

### **public int CloseOptions {get; set;}**

Set this attribute to control the way the resource is closed. The default value is MQC.MQCO\_NONE. MQC.MQCO\_NONE is the only permissible value for all resources other than permanent dynamic queues, temporary dynamic queues, subscriptions, and topics that are being accessed by the objects that created them.

For queues and topics, the following additional values are permissible:

#### **MQC.MQCO\_DELETE**

Delete the queue if there are no messages.

#### **MQC.MQCO\_DELETE\_PURGE**

Delete the queue, purging any messages on it.

#### **MQC.MQCO\_QUIESCE**

Request the queue be closed, receiving a warning if any messages remain (allowing them to be retrieved before final closing).

For subscriptions, the following additional values are permissible:

**MQC.MQCO\_KEEP\_SUB**

The subscription is not deleted. This option is valid only if the original subscription is durable. MQC.MQCO\_KEEP\_SUB is the default value for a durable topic.

**MQC.MQCO\_REMOVE\_SUB**

The subscription is deleted. MQC.MQCO\_REMOVE\_SUB is the default value for a non-durable, unmanaged topic.

**MQC.MQCO\_PURGE\_SUB**

The subscription is deleted. MQC.MQCO\_PURGE\_SUB is the default value for a non-durable, managed topic.

**public MQQueueManager ConnectionReference {get;}**

The queue manager to which this resource belongs.

**public string MQDescription {get;}**

The description of the resource as held by the queue manager. MQDescription returns an empty string for subscriptions and topics.

**public boolean IsOpen {get;}**

Indicates whether the resource is currently open.

**public string Name {get;}**

The name of the resource. The name is either the supplied on the access method, or the allocated by the queue manager for a dynamic queue.

**public int OpenOptions {get; set;}**

OpenOptions are set when an IBM MQ object is opened. The OpenOptions.set method is ignored and does not cause an error. Subscriptions have no OpenOptions.

**Methods****public virtual void Close();**

Throws MQException.

Closes the object. No further operations against this resource are permitted after calling Close. To change the behavior of the Close method, set the closeOptions attribute.

**public string GetAttributeString(int selector, int length);**

Throws MQException.

Gets an attribute string.

**selector**

Integer indicating which attribute is being queried.

**length**

Integer indicating the length of the string required.

**public void Inquire(int[] selectors, int[] intAttrs, byte[] charAttrs);**

Throws MQException.

Returns an array of integers and a set of character strings containing the attributes of a queue, process, or queue manager. The attributes to be queried are specified in the selectors array.

**Note:** Many of the more common attributes can be queried using the Get methods defined in MQManagedObject, MQQueue and MQQueueManager.

**selectors**

Integer array identifying the attributes with values to be inquired on.

**intAttrs**

The array in which the integer attribute values are returned. Integer attribute values are returned in the same order as the integer attribute selectors in the selectors array.

**charAttrs**

The buffer in which the character attributes are returned, concatenated. Character attributes are returned in the same order as the character attribute selectors in the selectors array. The length of each attribute string is fixed for each attribute.

**public void Set(int[] selectors, int[] intAttrs, byte[] charAttrs);**

Throws MQException.

Sets the attributes defined in the vector of selectors. The attributes to be set are specified in the selectors array.

**selectors**

Integer array identifying the attributes with values to be set.

**intAttrs**

The array of integer attribute values to be set. These values must be in the same order as the integer attribute selectors in the selectors array.

**charAttrs**

The buffer in which the character attributes to be set are concatenated. These values must be in the same order as the character attribute selectors in the selectors array. The length of each character attribute is fixed.

**public void SetAttributeString(int selector, string value, int length);**

Throws MQException.

Sets an attribute string.

**selector**

Integer indicating which attribute is being set.

**value**

The string to set as the attribute value.

**length**

Integer indicating the length of the string required.

## Constructors

**protected MQManagedObject()**

Constructor method. This object is an abstract base class which cannot be instantiated by itself.

## MQMessage.NET class

Use MQMessage to access the message descriptor and data for an IBM MQ message. MQMessage encapsulates an IBM MQ message.

### Class

**public class IBM.WMQ.MQMessage extends IBM.WMQ.MQBaseObject;**

Create an MQMessage object and then use the Read and Write methods to transfer data between the message and other objects in your application. Send and receive MQMessage objects using the Put and Get methods of the MQDestination, MQQueue and MQTopic classes.

Get and set the properties of the message descriptor using the properties of MQMessage. Set and Get extended message properties using the SetProperty and GetProperty methods.

- [“Properties” on page 1734](#)
- [“Read and Write message methods” on page 1739](#)
- [“Buffer methods” on page 1742](#)

- [“Property methods” on page 1743](#)
- [“Constructors” on page 1745](#)

## Properties

Test for `MQException` being thrown when getting properties.

**public string AccountingToken {get; set;}**

Part of the identity context of the message; it helps an application to charge for work done as a result of the message. The default value is `MQC.MQACT_NONE`.

**public string ApplicationIdData {get; set;}**

Part of the identity context of the message. `ApplicationIdData` is information that is defined by the application suite, and can be used to provide additional information about the message or its originator. The default value is "".

**public string ApplicationOriginData {get; set;}**

Information defined by the application that can be used to provide additional information about the origin of the message. The default value is "".

**public int BackoutCount {get;}**

A count of the number of times the message has previously been returned and backed out by an `MQQueue`. `Get` call as part of a unit of work. The default value is zero.

**public int CharacterSet {get; set;}**

The coded character set identifier of character data in the message.

Set `CharacterSet` to identify the character set of character data in the message. Get `CharacterSet` to find out in what character set has been used to encode character data in the message.

.NET applications always run in Unicode, whereas in other environments applications run in the same character set as the queue manager is running under.

The `ReadString` and `ReadLine` methods convert the character data in the message to Unicode for you.

The `WriteString` method converts from Unicode to the character set encoded in `CharacterSet`. If `CharacterSet` is set to its default value, `MQC.MQCCSI_Q_MGR`, which is 0, no conversion takes place and `CharacterSet` is set to 1200. If you set `CharacterSet` to some other value, `WriteString` converts from Unicode to the alternate value.

**Note:** Other read and write methods do not use `CharacterSet`.

- `ReadChar` and `WriteChar` read and write a Unicode character to and from the message buffer without conversion.
- `ReadUTF` and `WriteUTF` convert between a Unicode string in the application, and a UTF-8 string, prefixed by a 2-byte length field, in the message buffer.
- Byte methods transfer bytes between the application and the message buffer without alteration.

**public byte[] CorrelationId {get; set;}**

- For an `MQQueue`.`Get` call, the correlation identifier of the message to be retrieved. The queue manager returns the first message with a message identifier and a correlation identifier that match the message descriptor fields. The default value, `MQC.MQCI_NONE`, helps any correlation identifier to match.
- For an `MQQueue`.`Put` call, the correlation identifier to set.

**public int DataLength {get;}**

The number of bytes of message data remaining to be read.

**public int DataOffset {get; set;}**

The current cursor position within the message data. Reads and writes take effect at the current position.

**public int Encoding {get; set;}**

The representation used for numeric values in the application message data. Encoding applies to binary, packed decimal, and floating point data. The behavior of the read and write methods for these numeric formats is altered accordingly. Construct a value for the encoding field by adding one value from each of these three sections. Alternatively, construct the value combining the values from each of the three sections using the bitwise OR operator.

## 1. Binary integer

**MQC.MQENC\_INTEGER\_NORMAL**

Big-endian integers.

**MQC.MQENC\_INTEGER\_REVERSED**

Little-endian integers, as used in Intel architecture.

## 2. Packed-decimal

**MQC.MQENC\_DECIMAL\_NORMAL**

Big-endian packed-decimal, as used by z/OS.

**MQC.MQENC\_DECIMAL\_REVERSED**

Little-endian packed-decimal.

## 3. Floating-point

**MQC.MQENC\_FLOAT\_IEEE\_NORMAL**

Big-endian IEEE floats.

**MQC.MQENC\_FLOAT\_IEEE\_REVERSED**

Little-endian IEEE floats, as used Intel architecture.

**MQC.MQENC\_FLOAT\_S390**

z/OS format floating points.

The default value is:

```
MQC.MQENC_INTEGER_REVERSED |  
MQC.MQENC_DECIMAL_REVERSED |  
MQC.MQENC_FLOAT_IEEE_REVERSED
```

The default setting causes `WriteInt` to write a little-endian integer, and `ReadInt` to read a little-endian integer. If you set the flag `MQC.MQENC_INTEGER_NORMAL` flag instead, `WriteInt` writes a big-endian integer, and `ReadInt` reads a big-endian integer.

**Note:** A loss in precision can occur when converting from IEEE format floating points to zSeries format floating points.

**public int Expiry {get; set;}**

An expiry time expressed in tenths of a second, set by the application that puts the message. After the expiry time of a message has elapsed, it is eligible to be discarded by the queue manager. If the message specified one of the `MQC.MQRO_EXPIRATION` flags, a report is generated when the message is discarded. The default value is `MQC.MQEI_UNLIMITED`, meaning that the message never expires.

**public int Feedback {get; set;}**

Use `Feedback` with a message of type `MQC.MQMT_REPORT` to indicate the nature of the report. The following feedback codes are defined by the system:

- `MQC.MQFB_EXPIRATION`
- `MQC.MQFB_COA`
- `MQC.MQFB_COD`
- `MQC.MQFB_QUIT`
- `MQC.MQFB_PAN`
- `MQC.MQFB_NAN`
- `MQC.MQFB_DATA_LENGTH_ZERO`

- MQC.MQFB\_DATA\_LENGTH\_NEGATIVE
- MQC.MQFB\_DATA\_LENGTH\_TOO\_BIG
- MQC.MQFB\_BUFFER\_OVERFLOW
- MQC.MQFB\_LENGTH\_OFF\_BY\_ONE
- MQC.MQFB\_IIH\_ERROR

Application-defined feedback values in the range MQC.MQFB\_APPL\_FIRST to MQC.MQFB\_APPL\_LAST can also be used. The default value of this field is MQC.MQFB\_NONE, indicating that no feedback is provided.

**public string Format {get; set;}**

A format name used by the sender of the message to indicate the nature of the data in the message to the receiver. You can use your own format names, but names beginning with the letters MQ have meanings that are defined by the queue manager. The queue manager built-in formats are:

**MQC.MQFMT\_ADMIN**

Command server request/reply message.

**MQC.MQFMT\_COMMAND\_1**

Type 1 command reply message.

**MQC.MQFMT\_COMMAND\_2**

Type 2 command reply message.

**MQC.MQFMT\_DEAD\_LETTER\_HEADER**

Dead-letter header.

**MQC.MQFMT\_EVENT**

Event message.

**MQC.MQFMT\_NONE**

No format name.

**MQC.MQFMT\_PCF**

User-defined message in programmable command format.

**MQC.MQFMT\_STRING**

Message consisting entirely of characters.

**MQC.MQFMT\_TRIGGER**

Trigger message

**MQC.MQFMT\_XMIT\_Q\_HEADER**

Transmission queue header.

The default value is MQC.MQFMT\_NONE.

**public byte[] GroupId {get; set;}**

A byte string that identifies the message group to which the physical message belongs. The default value is MQC.MQGI\_NONE.

**public int MessageFlags {get; set;}**

Flags controlling the segmentation and status of a message.

**public byte[] MessageId {get; set;}**

For an MQQueue .Get call, this field specifies the message identifier of the message to be retrieved. Normally, the queue manager returns the first message with a message identifier and correlation identifier that match the message descriptor fields. Allow any message identifier to match using the special value MQC.MQMI\_NONE.

For an MQQueue .Put call, this field specifies the message identifier to use. If MQC.MQMI\_NONE s specified, the queue manager generates a unique message identifier when the message is put. The value of this member variable is updated after the put, to indicate the message identifier that was used. The default value is MQC.MQMI\_NONE.

**public int MessageLength {get;}**

The number of bytes of message data in the MQMessage object.

**public int MessageSequenceNumber {get; set;}**

The sequence number of a logical message within a group.

**public int MessageType {get; set;}**

Indicates the type of the message. The following values are currently defined by the system:

- MQC.MQMT\_DATAGRAM
- MQC.MQMT\_REPLY
- MQC.MQMT\_REPORT
- MQC.MQMT\_REQUEST

Application-defined values can also be used, in the range MQC.MQMT\_APPL\_FIRST to MQC.MQMT\_APPL\_LAST. The default value of this field is MQC.MQMT\_DATAGRAM.

**public int Offset {get; set;}**

In a segmented message, the offset of data in a physical message from the start of a logical message.

**public int OriginalLength {get; set;}**

The original length of a segmented message.

**public int Persistence {get; set;}**

Message persistence. The following values are defined:

- MQC.MQPER\_NOT\_PERSISTENT

If you set this option in a reconnectable client, the MQRC\_NONE reason code is returned to the application when the connection is successful.

- MQC.MQPER\_PERSISTENT

If you set this option in a reconnectable client, the MQRC\_CALL\_INTERRUPTED reason code is returned to the application after the connection is successful.

- MQC.MQPER\_PERSISTENCE\_AS\_Q\_DEF

The default value is MQC.MQPER\_PERSISTENCE\_AS\_Q\_DEF, which takes the persistence for the message from the default persistence attribute of the destination queue.

**public int Priority {get; set;}**

The message priority. The special value MQC.MQPRI\_PRIORITY\_AS\_Q\_DEF can also be set in outbound message. The priority for the message is then taken from the default priority attribute of the destination queue. The default value is MQC.MQPRI\_PRIORITY\_AS\_Q\_DEF.

**public int PropertyValidation {get; set;}**

Specifies whether validation of properties takes place when a property of the message is set. Possible values are:

- MQCMHO\_DEFAULT\_VALIDATION
- MQCMHO\_VALIDATE
- MQCMHO\_NO\_VALIDATION

The default value is MQCMHO\_DEFAULT\_VALIDATION.

**public string PutApplicationName {get; set;}**

The name of the application that put the message. The default value is "".

**public int PutApplicationType {get; set;}**

The type of application that put the message. PutApplicationType can be a system-defined or user-defined value. The following values are defined by the system:

- MQC.MQAT\_AIX
- MQC.MQAT\_CICS
- MQC.MQAT\_DOS
- MQC.MQAT\_IMS
- MQC.MQAT\_MVS

- MQC.MQAT\_OS2
- MQC.MQAT\_OS400
- MQC.MQAT\_QMGR
- MQC.MQAT\_UNIX
- MQC.MQAT\_WINDOWS
- MQC.MQAT\_JAVA

The default value is MQC.MQAT\_NO\_CONTEXT, which indicates that no context information is present in the message.

**public DateTime PutDateTime {get; set;}**

The time and date that the message was put.

**public string ReplyToQueueManagerName {get; set;}**

The name of the queue manager to send reply or report messages. The default value is "", and the queue manager provides the ReplyToQueueManagerName.

**public string ReplyToQueueName {get; set;}**

The name of the message queue to which the application that issued the get request for the message sends MQC.MQMT\_REPLY and MQC.MQMT\_REPORT messages. The default ReplyToQueueName is "".

**public int Report {get; set;}**

Use Report to specify options about report and reply messages:

- Whether reports are required.
- Whether the application message data is to be included in the reports.
- How to set the message and correlation identifiers in the report or reply.

Any combination of the four report types can be requested:

- Specify any combination of the four report types. Selecting any of the three options for each report type, depending on whether the application message data is to be included in the report message.

1. Confirm on arrival

- MQC.MQRO\_COA
- MQC.MQRO\_COA\_WITH\_DATA
- MQC.MQRO\_COA\_WITH\_FULL\_DATA \*\*

2. Confirm on delivery

- MQC.MQRO\_COD
- MQC.MQRO\_COD\_WITH\_DATA
- MQC.MQRO\_COD\_WITH\_FULL\_DATA \*\*

3. Exception

- MQC.MQRO\_EXCEPTION
- MQC.MQRO\_EXCEPTION\_WITH\_DATA
- MQC.MQRO\_EXCEPTION\_WITH\_FULL\_DATA \*\*

4. Expiration

- MQC.MQRO\_EXPIRATION
- MQC.MQRO\_EXPIRATION\_WITH\_DATA
- MQC.MQRO\_EXPIRATION\_WITH\_FULL\_DATA \*\*

**Note:** Values marked with \*\* in the list are not supported by z/OS queue managers. Do not use them if your application is likely to access a z/OS queue manager, regardless of the platform on which the application is running.

- Specify one of the following to control how the message ID is generated for the report or reply message:

- MQC.MQRO\_NEW\_MSG\_ID
- MQC.MQRO\_PASS\_MSG\_ID
- Specify one of the following to control how the correlation ID of the report or reply message is to be set:
  - MQC.MQRO\_COPY\_MSG\_ID\_TO\_CORREL\_ID
  - MQC.MQRO\_PASS\_CORREL\_ID
- Specify one of the following to control the disposition of the original message when it cannot be delivered to the destination queue:
  - MQC.MQRO\_DEAD\_LETTER\_Q
  - MQC.MQRO\_DISCARD\_MSG \*\*
- If no report options are specified, the default is:

```
MQC.MQRO_NEW_MSG_ID |
MQC.MQRO_COPY_MSG_ID_TO_CORREL_ID |
MQC.MQRO_DEAD_LETTER_Q
```

- You can specify one or both of the following to request that the receiving application sends a positive action or negative action report message.
  - MQC.MQRO\_PAN
  - MQC.MQRO\_NAN

#### **public int TotalMessageLength {get;}**

The total number of bytes in the message as stored on the message queue from which this message was received.

#### **public string UserId {get; set;}**

UserId is part of the identity context of the message. The queue manager generally provides the value. You can override the value if you have authority to set the identity context.

#### **public int Version {get; set;}**

The version of the MQMD structure in use.

## **Read and Write message methods**

The Read and Write methods perform the same functions as the members of the `BinaryReader` and `BinaryWriter` classes in the `.NET System.IO` namespace. See MSDN for the full language syntax and usage examples. The methods read or write from the current position in the message buffer. They move the current position forward by the number of bytes read or written.

**Note:** If the message data contains an MQRFH or MQRFH2 header, you must use the `ReadBytes` method to read the data.

- All the methods throw `IOException`.
- The `ReadFully` methods automatically resize the target byte or sbyte array to fit the message exactly. A null array is also resized.
- Read methods throw `EndOfStreamException`.
- `WriteDecimal` methods throw `MQException`.
- `ReadString`, `ReadLine` and `WriteString` methods convert between Unicode and the character set of the message; see [CharacterSet](#).
- The `Decimal` methods read and write packed decimal numbers encoded either in big-endian, `MQC.MQENC_DECIMAL_NORMAL`, or little-endian `MQC.MQENC_DECIMAL_REVERSE` format, according to the value of `Encoding`. Decimal ranges and corresponding `.NET` types are as follows:

**Decimal2/short**  
-999 to 999

**Decimal4/int**

-9999999 to 9999999

**Decimal18/long**

-9999999999999999 to 9999999999999999

- The `Double` and `Float` methods read and write floating values encoded in IEEE big-endian and little-endian formats, `MQC.MQENC_FLOAT_IEEE_NORMAL` and `MQC.MQENC_FLOAT_IEEE_REVERSED`, or in S/390 format, `MQC.MQENC_FLOAT_S390`, according to the value of `Encoding`.
- The `Int` methods read and write integer values encoded in big-endian, `MQC.MQENC_INTEGER_NORMAL`, or little-endian, `MQC.MQENC_INTEGER_REVERSED`, format, according to the value of `Encoding`. The integers are all signed, except for the addition of an unsigned 2-byte integer type. The integer sizes, and .NET and IBM MQ types are as follows:

**2 byte**

short, Int2, ushort, UInt2

**4 byte**

int, Int4

**8 byte**

long, Int8

- `WriteObject` transfers the class of an object, the values of its non-transient and non-static fields, and the fields of its supertypes, to the message buffer.
- `ReadObject` creates an object from the class of the object, the signature of the class, and the values of its non-transient and non-static fields, and the fields of its supertypes.

Table 843. Read and Write message methods

Target type	Method signatures
<b>Boolean</b>	<pre>public bool ReadBoolean();  public void WriteBoolean(bool value);</pre>
<b>Byte</b>	<pre>public byte ReadByte() public byte ReadUnsignedByte()  public void Write(int value) public void WriteByte(int value) public void WriteByte(byte value) public void WriteByte(sbyte value)</pre>
<b>Bytes</b>	<pre>public byte[] ReadBytes(int count) public void ReadFully(ref byte[] value) public void ReadFully(ref sbyte[] value) public void ReadFully(ref byte[] value, int offset, int length) public void ReadFully(ref sbyte[] value, int offset, int length)  public void Write(byte[] value) public void Write(sbyte[] value) public void Write(byte[] value, int offset, int length) public void Write(sbyte[] value, int offset, int length) public void WriteBytes(string value)</pre>

Table 843. Read and Write message methods (continued)

Target type	Method signatures
<b>Decimal2</b>	<pre>public void WriteDecimal2(short value)</pre>
<b>Decimal4</b>	<pre>public void WriteDecimal4(short value)</pre>
<b>Decimal8</b>	<pre>public void WriteDecimal8(short value)</pre>
<b>Double</b>	<pre>public double ReadDouble()  public void WriteDouble(double value)</pre>
<b>Float</b>	<pre>public float ReadFloat()  public void WriteFloat(float value)</pre>
<b>Int2</b>	<pre>public void WriteInt2(int value)</pre>
<b>Int4</b>	<pre>public int readDecimal4() public int ReadInt() public int ReadInt4()  public void WriteInt(int value) public void WriteInt4(int value)</pre>
<b>Int8</b>	<pre>public void WriteInt8(long value)</pre>
<b>Long</b>	<pre>public long ReadDecimal8() public long ReadLong() public long ReadInt8()  public void WriteLong(long value)</pre>
<b>Object</b>	<pre>public Object ReadObject()  public void WriteObject(Object object)</pre>

Table 843. Read and Write message methods (continued)

Target type	Method signatures
<b>Short</b>	<pre>public short ReadShort() public short ReadDecimal2() public short ReadInt2()  public void WriteShort(int value)</pre>
<b>string</b>	<pre>public string ReadString(int length)  public void WriteString(string string)</pre>
<b>Unsigned Short</b>	<pre>public ushort ReadUnsignedShort() public ushort ReadUInt2()</pre>
<b>Unicode</b>	<pre>public string ReadLine() public char ReadChar()  public void WriteChar(int value) public void WriteChars(string string)</pre>
<b>UTF</b>	<pre>public string ReadUTF()  public void WriteUTF(string string)</pre>

## Buffer methods

### **public void ClearMessage();**

Throws IOException.

Discards any data in the message buffer and sets the data offset back to zero.

### **public void ResizeBuffer(int size)**

Throws IOException.

A hint to the MQMessage object about the size of buffer that might be required for subsequent get operations. If the message currently contains message data, and the new size is less than the current size, the message data is truncated.

### **public void Seek(int pos)**

Throws IOException, ArgumentOutOfRangeException, ArgumentException.

Moves the cursor to the absolute position in the message buffer given by *pos*. Subsequent reads and writes act at this position in the buffer.

### **public int SkipBytes(int i)**

Throws IOException, EndOfStreamException.

Moves forward *n* bytes in the message buffer and returns *n*, the number of bytes skipped.

SkipBytes method blocks until one of the following events occurs:

- All the bytes are skipped
- The end of message buffer is detected
- An exception is thrown

## Property methods

**public void DeleteProperty(string name);**

Throws MQException.

Deletes a property with the specified name from the message.

**name**

The name of the property to delete.

**public System.Collections.IEnumerator GetPropertyNames(string name)**

Throws MQException.

Returns an `IEnumerator` of all the property names matching the specified name. The percent sign '%' can be used at the end of the name as a wildcard character to filter the properties of the message, matching on zero, or more characters, including the period.

**name**

The name of the property to match on.

## SetProperty and GetProperty methods

All the SetProperty and GetProperty methods throw MQException.

The SetProperty method of `MQMessage` .NET class adds a new property if a property does not exist already. However, if the property already exists, then the supplied property value is added to the end of the list. When multiple values are set to a property name using SetProperty, calling GetProperty for that name returns those values sequentially in the order that those values were set.

The behavior is same for all the Set\*Property and Get\*Property typed methods such as GetLongProperty, SetLongProperty, GetBooleanProperty, SetBooleanProperty, GetStringProperty, and SetStringProperty.

Type	Method signatures
<b>Boolean</b>	<pre>public boolean GetBooleanProperty(string name); public boolean GetBooleanProperty(string name, MQPropertyDescriptor pd);  public void SetBooleanProperty(string name, boolean value); public void SetBooleanProperty(string name, MQPropertyDescriptor pd, boolean value);</pre>
<b>Byte</b>	<pre>public sbyte GetByteProperty(string name); public sbyte GetByteProperty(string name, MQPropertyDescriptor pd);  public void SetByteProperty(string name, sbyte value); public void SetByteProperty(string name, MQPropertyDescriptor pd, sbyte value);</pre>

Table 844. SetProperty and GetProperty methods (continued)

Type	Method signatures
<b>Bytes</b>	<pre> public sbyte[] GetBytesProperty(string name); public sbyte[] GetBytesProperty(string name, MQPropertyDescriptor pd);  public void SetBytesProperty(string name, sbyte[] value); public void SetBytesProperty(string name, MQPropertyDescriptor pd, sbyte[] value); </pre>
<b>Double</b>	<pre> public double GetDoubleProperty(string name); public double GetDoubleProperty(string name, MQPropertyDescriptor pd);  public void SetDoubleProperty(string name, double value); public void SetDoubleProperty(string name, MQPropertyDescriptor pd, double value); </pre>
<b>Float</b>	<pre> public float GetFloatProperty(string name); public float GetFloatProperty(string name, MQPropertyDescriptor pd);  public void SetFloatProperty(string name, float value); public void SetFloatProperty(string name, MQPropertyDescriptor pd, float value); </pre>
<b>Int2</b>	<pre> public short GetInt2Property(string name); public short GetInt2Property(string name, MQPropertyDescriptor pd);  public void SetInt2Property(string name, short value); public void SetInt2Property(string name, MQPropertyDescriptor pd, short value); </pre>
<b>Int4</b>	<pre> public int GetInt4Property(string name); public int GetInt4Property(string name, MQPropertyDescriptor pd);  public void SetInt4Property(string name, int value); public void SetInt4Property(string name, MQPropertyDescriptor pd, int value); </pre>
<b>Int8</b>	<pre> public long GetInt8Property(string name); public long GetInt8Property(string name, MQPropertyDescriptor pd);  public void SetInt8Property(string name, long value); public void SetInt8Property(string name, MQPropertyDescriptor pd, long value); </pre>
<b>Long</b>	<pre> public long GetLongProperty(string name); public long GetLongProperty(string name, MQPropertyDescriptor pd);  public void SetLongProperty(string name, long value); public void SetLongProperty(string name, MQPropertyDescriptor pd, long value); </pre>

Table 844. SetProperty and GetProperty methods (continued)

Type	Method signatures
<b>Object</b>	<pre>public Object GetObjectProperty(string name); public Object GetObjectProperty(string name, MQPropertyDescriptor pd);  public void SetObjectProperty(string name, Object value); public void SetObjectProperty(string name, MQPropertyDescriptor pd, Object value);</pre>
<b>Short</b>	<pre>public short GetShortProperty(string name); public short GetShortProperty(string name, MQPropertyDescriptor pd);  public void SetShortProperty(string name, short value); public void SetShortProperty(string name, MQPropertyDescriptor pd, short value);</pre>
<b>string</b>	<pre>public string GetStringProperty(string name); public string GetStringProperty(string name, MQPropertyDescriptor pd);  public void SetStringProperty(string name, string value); public void SetStringProperty(string name, MQPropertyDescriptor pd, string value);</pre>

## Constructors

### **public MQMessage();**

Creates an MQMessage object with default message descriptor information and an empty message buffer.

## MQProcess.NET class

Use MQProcess to query the attributes of an IBM MQ process. Create an MQProcess object using a constructor, or an MQQueueManager AccessProcess method.

### Class

```
System.Object
├── IBM.WMQ.MQBase
│   └── IBM.WMQ.MQBaseObject
│       └── IBM.WMQ.MQManagedObject
│           └── IBM.WMQ.MQProcess
```

```
public class IBM.WMQ.MQProcess extends IBM.WMQ.MQManagedObject;
```

- [“Properties” on page 1745](#)
- [“Constructors” on page 1746](#)

## Properties

Test for MQException being thrown when getting properties.

**public string ApplicationId {get;}**

Gets the character string that identifies the application to be started. `ApplicationId` is used by a trigger monitor application. `ApplicationId` is sent to the initiation queue as part of the trigger message.

The default value is null.

**public int ApplicationType {get;}**

Identifies the type of the process to be started by a trigger monitor application. Standard types are defined, but others can be used:

- MQAT\_AIX
- MQAT\_CICS
- MQAT\_IMS
- MQAT\_MVS
- MQAT\_NATIVE
- MQAT\_OS400
- MQAT\_UNIX
- MQAT\_WINDOWS
- MQAT\_JAVA
- MQAT\_USER\_FIRST
- MQAT\_USER\_LAST

The default value is `MQAT_NATIVE`.

**public string EnvironmentData {get;}**

Gets information about the environment of the application that is to be started.

The default value is null.

**public string UserData {get;}**

Gets information the user has provided about the application to be started.

The default value is null.

**Constructors**

```
public MQProcess(MQQueueManager queueManager, string processName, int openOptions);
```

```
public MQProcess(MQQueueManager qMgr, string processName, int openOptions, string queueManagerName, string alternateUserId);
```

Throws `MQException`.

Access an IBM MQ process on queue manager `qMgr` to inquire on process attributes.

**qMgr**

Queue manager to access.

**processName**

The name of the process to open.

**openOptions**

Options that control the opening of the process. The valid options that can be added, or combined using a bitwise OR, are:

- `MQC.MQ00_FAIL_IF QUIESCING`
- `MQC.MQ00_INQUIRE`
- `MQC.MQ00_SET`

- MQC.MQ00\_ALTERNATE\_USER\_AUTHORITY

#### **queueManagerName**

The name of the queue manager on which the process is defined. You can leave a blank or null queue manager name if the queue manager is the same as the one the process is accessing.

#### **alternateUserId**

If MQC.MQ00\_ALTERNATE\_USER\_AUTHORITY is specified in the **openOptions** parameter, *alternateUserId* specifies the alternative user ID used to check the authorization for the action. If MQ00\_ALTERNATE\_USER\_AUTHORITY is not specified, *alternateUserId* can be blank or null.

Default user authority is used for connection to the queue manager if MQC.MQ00\_ALTERNATE\_USER\_AUTHORITY is not specified.

```
public MQProcess MQQueueManager.AccessProcess(string processName, int openOptions);
public MQProcess MQQueueManager.AccessProcess(string processName, int openOptions, string queueManagerName, string alternateUserId);
```

Throws MQException.

Access an IBM MQ process on this queue manager to inquire on process attributes.

#### **processName**

The name of the process to open.

#### **openOptions**

Options that control the opening of the process. The valid options that can be added, or combined using a bitwise OR, are:

- MQC.MQ00\_FAIL\_IF QUIESCING
- MQC.MQ00\_INQUIRE
- MQC.MQ00\_SET
- MQC.MQ00\_ALTERNATE\_USER\_AUTHORITY

#### **queueManagerName**

The name of the queue manager on which the process is defined. You can leave a blank or null queue manager name if the queue manager is the same as the one the process is accessing.

#### **alternateUserId**

If MQC.MQ00\_ALTERNATE\_USER\_AUTHORITY is specified in the **openOptions** parameter, *alternateUserId* specifies the alternative user ID used to check the authorization for the action. If MQ00\_ALTERNATE\_USER\_AUTHORITY is not specified, *alternateUserId* can be blank or null.

Default user authority is used for connection to the queue manager if MQC.MQ00\_ALTERNATE\_USER\_AUTHORITY is not specified.

## **MQPropertyDescriptor.NET class**

Use MQPropertyDescriptor as a parameter to MQMessage GetProperty and SetProperty methods. MQPropertyDescriptor describes an MQMessage property.

### **Class**

```
System.Object
└─ IBM.WMQ.MQPropertyDescriptor
```

```
public class IBM.WMQ.MQPropertyDescriptor extends System.Object;
```

- [“Properties” on page 1748](#)
- [“Constructors” on page 1749](#)

## Properties

Test for `MQException` being thrown when getting properties.

```
public int Context {get; set;}
```

The message context the property belongs to. Possible values are:

### **MQC.MQPD\_NO\_CONTEXT**

The property is not associated with a message context.

### **MQC.MQPD\_USER\_CONTEXT**

The property is associated with the user context.

If the user is authorized, a property associated with the user context is saved when a message is retrieved. A subsequent `Put` method referencing the saved context, can pass the property into the new message.

```
public int CopyOptions {get; set;}
```

`CopyOptions` describes which type of message the property can be copied into.

When a queue manager receives a message containing an IBM MQ defined property that the queue manager recognizes as being incorrect, the queue manager corrects the value of the `CopyOptions` field.

Any combination of the following options can be specified. Combine the options by adding the values, or using bitwise OR.

### **MQC.MQCOPY\_ALL**

The property is copied into all types of subsequent messages.

### **MQC.MQCOPY\_FORWARD**

The property is copied into a message being forwarded.

### **MQC.MQCOPY\_PUBLISH**

The property is copied into the message received by a subscriber when a message is being published.

### **MQC.MQCOPY\_REPLY**

The property is copied into a reply message.

### **MQC.MQCOPY\_REPORT**

The property is copied into a report message.

### **MQC.MQCOPY\_DEFAULT**

The value indicated no other copy options have been specified. No relationship exists between the property and subsequent messages. `MQC.MQCOPY_DEFAULT` is always returned for message descriptor properties.

### **MQC.MQCOPY\_NONE**

The same as `MQC.MQCOPY_DEFAULT`

```
public int Options { set; }
```

`Options` defaults to `CMQC.MQPD_NONE`. You cannot set any other value.

```
public int Support { get; set; }
```

Set `Support` to specify the level of support required for IBM MQ-defined message properties. Support for all other properties is optional. Any or none of the following values can be specified

### **MQC.MQPD\_SUPPORT\_OPTIONAL**

The property is accepted by a queue manager even if it is not supported. The property can be discarded in order for the message to flow to a queue manager that does not support message properties. This value is also assigned to properties that are not IBM MQ defined.

### **MQC.MQPD\_SUPPORT\_REQUIRED**

Support for the property is required. If you put the message to a queue manager that does not support the IBM MQ-defined property, the method fails. It returns completion code MQC.MQCC\_FAILED and reason code MQC.MQRC\_UNSUPPORTED\_PROPERTY.

### **MQC.MQPD\_SUPPORT\_REQUIRED\_IF\_LOCAL**

Support for the property is required, if the message is destined for a local queue. If you put the message to a local queue on a queue manager that does not support the IBM MQ-defined property, the method fails. It returns completion code MQC.MQCC\_FAILED and reason code MQC.MQRC\_UNSUPPORTED\_PROPERTY.

No check is made if the message is put to a remote queue manager.

## **Constructors**

### **PropertyDescriptor();**

Create a property descriptor.

## **MQPutMessageOptions.NET class**

Use MQPutMessageOptions to specify how messages are sent. It modifies the behavior of MQDestination.Put.

## **Class**

```
public class IBM.WMQ.MQPutMessageOptions extends IBM.WMQ.MQBaseObject;
```

- [“Properties” on page 1749](#) [“Constructors” on page 1751](#)

## **Properties**

Test for MQException being thrown when getting properties.

**Note:** The behavior of some of the options available in this class depends on the environment in which they are used. These elements are marked with an asterisk, \*.

### **public MQQueue ContextReference {get; set;}**

If the options field includes MQC.MQPMO\_PASS\_IDENTITY\_CONTEXT or MQC.MQPMO\_PASS\_ALL\_CONTEXT, set this field to refer to the MQQueue from which to take the context information.

The initial value of this field is null.

### **public int InvalidDestCount {get;} \***

Generally, used for distribution lists, InvalidDestCount indicates the number of messages that could not be sent to queues in a distribution list. The count includes queues that failed to open and also the queues that were opened successfully, but for which the put operation had failed.

.NET does not support distribution lists, but InvalidDestCount is set when opening a single queue.

### **public int KnownDestCount {get;} \***

Generally used for distribution lists, KnownDestCount indicates the number of messages that the current call has sent successfully to queues that resolve to local queues.

.NET does not support distribution lists, but `InvalidDestCount` is set when opening a single queue.

```
public int Options {get; set;}
```

Options that control the action of `MQDestination.put` and `MQQueueManager.put`. Any or none of the following values can be specified. If more than one option is required, the values can be added or combined using the bitwise OR operator.

**MQC.MQPMO\_ASYNC\_RESPONSE**

This option causes the `MQDestination.put` call to be made asynchronously, with some response data.

**MQC.MQPMO\_DEFAULT\_CONTEXT**

Associate default context with the message.

**MQC.MQPMO\_FAIL\_IF QUIESCING**

Fail if the queue manager is quiescing.

**MQC.MQPMO\_LOGICAL\_ORDER \***

Put logical messages and segments in message groups into their logical order.

If you use the `MQPMO_LOGICAL_ORDER` option in a reconnectable client, the `MQRC_RECONNECT_INCOMPATIBLE` reason code is returned to the application.

**MQC.MQPMO\_NEW\_CORREL\_ID \***

Generate a new correlation ID for each sent message.

**MQC.MQPMO\_NEW\_MSG\_ID \***

Generate a new message ID for each sent message.

**MQC.MQPMO\_NONE**

No options specified. Do not use with other options.

**MQC.MQPMO\_NO\_CONTEXT**

No context is to be associated with the message.

**MQC.MQPMO\_NO\_SYNCPOINT**

Put a message without sync point control. If the sync point control option is not specified, a default of no sync point is assumed.

**MQC.MQPMO\_PASS\_ALL\_CONTEXT**

Pass all context from an input queue handle.

**MQC.MQPMO\_PASS\_IDENTITY\_CONTEXT**

Pass identity context from an input queue handle.

**MQC.MQPMO\_RESPONSE\_AS\_Q\_DEF**

For an `MQDestination.put` call, this option takes the put response type from `DEFPRESP` attribute of the queue.

For an `MQQueueManager.put` call, this option causes the call to be made synchronously.

**MQC.MQPMO\_RESPONSE\_AS\_TOPIC\_DEF**

`MQC.MQPMO_RESPONSE_AS_TOPIC_DEF` is a synonym for `MQC.MQPMO_RESPONSE_AS_Q_DEF` for use with topic objects.

**MQC.MQPMO\_RETAIN**

The publication being sent is to be retained by the queue manager. If this option is used and the publication cannot be retained, the message is not published and the call fails with `MQC.MQRC_PUT_NOT_RETAINED`.

Request a copy of this publication after the time it was published, by calling the `MQSubscription.RequestPublicationUpdate` method. The saved publication is sent to applications that create a subscription without setting the `MQC.MQSO_NEW_PUBLICATIONS_ONLY` option. Check the `MQIsRetained` message property of a publication, when it is received, to find out if it was the retained publication.

When retained publications are requested by a subscriber, the subscription used might contain a wildcard in the topic string. If there are multiple retained publications in the topic tree that match the subscription, they are all sent.

**MQC.MQPMO\_SET\_ALL\_CONTEXT**

Set all context from the application.

**MQC.MQPMO\_SET\_IDENTITY\_CONTEXT**

Set identity context from the application.

**MQC.MQPMO\_SYNC\_RESPONSE**

This option causes the `MQDestination.put` or `MQQueueManager.put` call to be made synchronously, with full response data.

**MQC.MQPMO\_SUPPRESS\_REPLYTO**

Any information filled into the `ReplyToQueueName` and `ReplyToQueueManagerName` fields of the publication is not passed on to subscribers. If this option is used in combination with a report option that requires a `ReplyToQueueName`, the call fails with `MQC.MQRC_MISSING_REPLY_TO_Q`.

**MQC.MQPMO\_SYNCPOINT**

Put a message with sync point control. The message is not visible outside the unit of work until the unit of work is committed. If the unit of work is backed out, the message is deleted.

**public int RecordFields {get; set;} \***

Information about distribution lists. Distribution lists are not supporting in .NET.

**public string ResolvedQueueManagerName {get;}**

An output field set by the queue manager to the name of the queue manager that owns the queue specified by the remote queue name. `ResolvedQueueManagerName` might be different from the name of the queue manager from which the queue was accessed if the queue is a remote queue.

A nonblank value is returned only if the object is a single queue. If the object is a distribution list or a topic, the value returned is undefined.

**public string ResolvedQueueName {get;}**

An output field that is set by the queue manager to the name of the queue on which the message is placed. `ResolvedQueueName` might be different from the name used to open the queue if the opened queue was an alias or model queue.

A non-blank value is returned only if the object is a single queue. If the object is a distribution list or a topic, the value returned is undefined.

**public int UnknownDestCount {get;} \***

Generally used for distribution lists, `UnknownDestCount` is an output field set by the queue manager. It reports the number of messages that the current call has sent successfully to queues that resolve to remote queues.

.NET does not support distribution lists, but `InvalidDestCount` is set when opening a single queue.

## Constructors

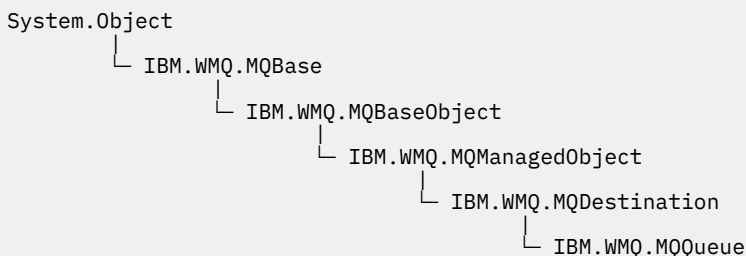

**public MQPutMessageOptions();**

Construct a new `MQPutMessageOptions` object with no options set, and a blank `ResolvedQueueName` and `ResolvedQueueManagerName`.

## MQQueue.NET class

Use MQQueue to send and receive messages, and query attributes of an IBM MQ queue. Create an MQQueue object using a constructor, or an MQQueueManager . AccessProcess method.

### Class

```
public class IBM.WMQ.MQQueue extends IBM.WMQ.MQDestination;
```

- [“Properties” on page 1752](#)
- [“Methods” on page 1754](#)
- [“Constructors” on page 1756](#)

### Properties

Test for MQException being thrown when getting properties.

**public int ClusterWorkLoadPriority {get;}**

Specifies the priority of the queue. This parameter is valid only for local, remote, and alias queues.

**public int ClusterWorkLoadRank {get;}**

Specifies the rank of the queue. This parameter is valid only for local, remote, and alias queues.

**public int ClusterWorkLoadUseQ {get;}**

Specifies the behavior of an MQPUT operation when the target queue has a local instance and at least one remote cluster instance. This parameter does not apply if the MQPUT originates from a cluster channel. This parameter is valid only for local queues.

**public DateTime CreationDateTime {get;}**

The date and time that this queue was created.

**public int CurrentDepth {get;}**

Gets the number of messages currently on the queue. This value is incremented during a put call, and during backout of a get call. It is decremented during a non-browse get and during backout of a put call.

**public int DefinitionType {get;}**

How the queue was defined. The possible values are:

- MQC.MQQDT\_PREDEFINED
- MQC.MQQDT\_PERMANENT\_DYNAMIC
- MQC.MQQDT\_TEMPORARY\_DYNAMIC

**public int InhibitGet {get; set;}**

Controls whether you can get messages on this queue or for this topic. The possible values are:

- MQC.MQQA\_GET\_INHIBITED
- MQC.MQQA\_GET\_ALLOWED

**public int InhibitPut {get; set;}**

Controls whether you can put messages on this queue or for this topic. The possible values are:

- MQQA\_PUT\_INHIBITED
- MQQA\_PUT\_ALLOWED

**public int MaximumDepth {get;}**

The maximum number of messages that can exist on the queue at any one time. An attempt to put a message to a queue that already contains this many messages fails with reason code MQC.MQRC\_Q\_FULL.

**public int MaximumMessageLength {get;}**

The maximum length of the application data that can exist in each message on this queue. An attempt to put a message larger than this value fails with reason code MQC.MQRC\_MSG\_TOO\_BIG\_FOR\_Q.

**public int NonPersistentMessageClass {get;}**

The level of reliability for non-persistent messages put to this queue.

**public int OpenInputCount {get;}**

The number of handles that are currently valid for removing messages from the queue. OpenInputCount is the total number of valid input handles known to the local queue manager, not just handles created by the application.

**public int OpenOutputCount {get;}**

The number of handles that are currently valid for adding messages to the queue. OpenOutputCount is the total number of valid output handles known to the local queue manager, not just handles created by the application.

**public int QueueAccounting {get;}**

Specifies whether you can enable the collection of accounting information for the queue.

**public int QueueMonitoring {get;}**

Specifies whether you can enable the monitoring for the queue.

**public int QueueStatistics {get;}**

Specifies whether you can enable the collection of statistics for the queue.

**public int QueueType {get;}**

The type of this queue with one of the following values:

- MQC.MQQT\_ALIAS
- MQC.MQQT\_LOCAL
- MQC.MQQT\_REMOTE
- MQC.MQQT\_CLUSTER

**public int Shareability {get;}**

Whether the queue can be opened for input multiple times. The possible values are:

- MQC.MQQA\_SHAREABLE
- MQC.MQQA\_NOT\_SHAREABLE

**public string TPIPE {get;}**

The TPIPE name used for communication with OTMA using the IBM MQ IMS bridge.

**public int TriggerControl {get; set;}**

Whether trigger messages are written to an initiation queue, to start an application to service the queue. The possible values are:

- MQC.MQTC\_OFF
- MQC.MQTC\_ON

**public string TriggerData {get; set;}**

The free-format data that the queue manager inserts into the trigger message. It inserts TriggerData when a message arriving on this queue causes a trigger message to be written to the initiation queue. The maximum permissible length of the string is given by MQC.MQ\_TRIGGER\_DATA\_LENGTH.

**public int TriggerDepth {get; set;}**

The number of messages that must be on the queue before a trigger message is written when trigger type is set to MQC.MQTT\_DEPTH.

**public int TriggerMessagePriority {get; set;}**

The message priority under which messages do not contribute to the generation of trigger messages. That is, the queue manager ignores these messages when deciding whether to generate a trigger. A value of zero causes all messages to contribute to the generation of trigger messages.

**public int TriggerType {get; set;}**

The conditions under which trigger messages are written as a result of messages arriving on this queue. The possible values are:

- MQC.MQTT\_NONE
- MQC.MQTT\_FIRST
- MQC.MQTT EVERY
- MQC.MQTT\_DEPTH

## Methods

**public void Get(MQMessage message);**

**public void Get(MQMessage message, MQGetMessageOptions getMessageOptions);**

**public void Get(MQMessage message, MQGetMessageOptions getMessageOptions, int MaxMsgSize);**

Throws MQException.

Gets a message from a queue.

If the get fails, the MQMessage object is unchanged. If it succeeds, the message descriptor and message data portions of the MQMessage are replaced with the message descriptor and message data from the incoming message.

All calls to IBM MQ from a particular MQQueueManager are synchronous. Therefore, if you perform a get with wait, all other threads using the same MQQueueManager are blocked from making further IBM MQ calls until the Get call is accomplished. If you need multiple threads to access IBM MQ simultaneously, each thread must create its own MQQueueManager object.

### message

Contains the message descriptor and the returned message data. Some of the fields in the message descriptor are input parameters. It is important to ensure that the MessageId and CorrelationId input parameters are set as required.

A reconnectable client returns the reason code MQRC\_BACKED\_OUT after successful reconnection, for messages received under MQGM\_SYNCPOINT.

### getMessageOptions

Options controlling the action of the get.

Using option MQC.MQGMO\_CONVERT might result in an exception with reason code MQC.MQRC\_CONVERTED\_STRING\_TOO\_BIG when converting from single-byte character codes to double byte codes. In this case, the message is copied into the buffer without conversion.

If *getMessageOptions* is not specified, the message option used is MQGMO\_NOWAIT.

If you use the MQGMO\_LOGICAL\_ORDER option in a reconnectable client, the MQRC\_RECONNECT\_INCOMPATIBLE reason code is returned.

### MaxMsgSize

The largest message this message object is to receive. If the message on the queue is larger than this size, one of two things occurs:

- If the MQGMO\_ACCEPT\_TRUNCATED\_MSG flag is set in the MQGetMessageOptions object, the message is filled with as much of the message data as possible. An exception is thrown with the MQCC\_WARNING completion code and MQRC\_TRUNCATED\_MSG\_ACCEPTED reason code.

- If the MQGMO\_ACCEPT\_TRUNCATED\_MSG flag is not set, the message remains on the queue. An exception is thrown with the MQCC\_WARNING completion code and MQRC\_TRUNCATED\_MSG\_FAILED reason code.

If *MaxMsgSize* is not specified, the whole message is retrieved.

```
public void Put(MQMessage message);  
public void Put(MQMessage message, MQPutMessageOptions putMessageOptions);
```

Throws MQException.

Puts a message to a queue.

Modifications to the MQMessage object after the Put call has been accomplished do not affect the actual message on the IBM MQ queue or publication topic.

Put updates the MessageId and CorrelationId properties of the MQMessage object and does not clear message data. Further Put or Get calls refer to the updated information in the MQMessage object. For example, in the following code snippet, the first message contains a and the second ab.

```
msg.WriteString("a");  
q.Put(msg, pmo);  
msg.WriteString("b");  
q.Put(msg, pmo);
```

#### **message**

An MQMessage object containing the message descriptor data, and message to be sent. The message descriptor can be altered as a consequence of this method. The values in the message descriptor immediately after the completion of this method are the values that were put to the queue or published to the topic.

The following reason codes are returned to a reconnectable client:

- MQRC\_CALL\_INTERRUPTED if the connection is broken while running a Put call on a persistent message and the reconnection is successful.
- MQRC\_NONE if the connection is successful while running a Put call on a non-persistent message (see [Application Recovery](#)).

#### **putMessageOptions**

Options controlling the action of the put.

If *putMessageOptions* is not specified the default instance of MQPutMessageOptions is used.

If you use the MQPMO\_LOGICAL\_ORDER option in a reconnectable client, the MQRC\_RECONNECT\_INCOMPATIBLE reason code is returned.

**Note:** For simplicity and performance, if you want to put a single message to a queue, use MQQueueManager.Put object. You should have an MQQueue object for this.

```
public void PutForwardMessage(MQMessage message);  
public void PutForwardMessage(MQMessage message, MQPutMessageOptions  
putMessageOptions);
```

Throws MQException

Put a message being forwarded onto the queue, where *message* is the original message.

#### **message**

An MQMessage object containing the message descriptor data, and message to be sent. The message descriptor can be altered as a consequence of this method. The values in the message descriptor immediately after the completion of this method are the values that were put to the queue or published to the topic.

The following reason codes are returned to a reconnectable client:

- MQRC\_CALL\_INTERRUPTED if the connection is broken while running a Put call on a persistent message and the reconnection is successful.

- MQRC\_NONE if the connection is successful while running a Put call on a non-persistent message (see [Application Recovery](#)).

#### **putMessageOptions**

Options controlling the action of the put.

If *putMessageOptions* is not specified the default instance of MQPutMessageOptions is used.

If you use the MQPMO\_LOGICAL\_ORDER option in a reconnectable client, the MQRC\_RECONNECT\_INCOMPATIBLE reason code is returned.

```
public void PutReplyMessage(MQMessage message)
public void PutReplyMessage(MQMessage message, MQPutMessageOptions
putMessageOptions)
```

Throws MQException.

Put a reply message onto the queue, where *message* is the original message.

#### **message**

Contains the message descriptor and the returned message data. Some of the fields in the message descriptor are input parameters. It is important to ensure that the MessageId and CorrelationId input parameters are set as required.

A reconnectable client returns the reason code MQRC\_BACKED\_OUT after successful reconnection, for messages received under MQGM\_SYNCPOINT.

#### **putMessageOptions**

Options controlling the action of the put.

If *putMessageOptions* is not specified the default instance of MQPutMessageOptions is used.

If you use the MQPMO\_LOGICAL\_ORDER option in a reconnectable client, the MQRC\_RECONNECT\_INCOMPATIBLE reason code is returned.

```
public void PutReportMessage(MQMessage message)
public void PutReportMessage(MQMessage message, MQPutMessageOptions
putMessageOptions)
```

Throws MQException.

Put a report message onto the queue, where *message* is the original message.

#### **message**

Contains the message descriptor and the returned message data. Some of the fields in the message descriptor are input parameters. It is important to ensure that the MessageId and CorrelationId input parameters are set as required.

A reconnectable client returns the reason code MQRC\_BACKED\_OUT after successful reconnection, for messages received under MQGM\_SYNCPOINT.

#### **putMessageOptions**

Options controlling the action of the put.

If *putMessageOptions* is not specified the default instance of MQPutMessageOptions is used.

If you use the MQPMO\_LOGICAL\_ORDER option in a reconnectable client, the MQRC\_RECONNECT\_INCOMPATIBLE reason code is returned.

## **Constructors**

```
public MQQueue MQQueueManager.AccessQueue(string queueName, int openOptions);
public MQQueue MQQueueManager.AccessQueue(string queueName, int openOptions,
string queueManagerName, string dynamicQueueName, string alternateUserId);
```

Throws MQException.

Accesses a queue on this queue manager.

You can get or browse messages, put messages, inquire about the attributes of the queue or set the attributes of the queue. If the queue named is a model queue, a dynamic local queue is created. Query the name attribute of the resultant MQQueue object to find out the name of the dynamic queue.

**queueName**

Name of queue to open.

**openOptions**

Options that control the opening of the queue.

**MQC.MQOO\_ALTERNATE\_USER\_AUTHORITY**

Validate with the specified user identifier.

**MQC.MQOO\_BIND\_AS\_QDEF**

Use default binding for queue.

**MQC.MQOO\_BIND\_NOT\_FIXED**

Do not bind to a specific destination.

**MQC.MQOO\_BIND\_ON\_OPEN**

Bind handle to destination when queue is opened.

**MQC.MQOO\_BROWSE**

Open to browse message.

**MQC.MQOO\_FAIL\_IF QUIESCING**

Fail if the queue manager is quiescing.

**MQC.MQOO\_INPUT\_AS\_Q\_DEF**

Open to get messages using queue-defined default.

**MQC.MQOO\_INPUT\_SHARED**

Open to get messages with shared access.

**MQC.MQOO\_INPUT\_EXCLUSIVE**

Open to get messages with exclusive access.

**MQC.MQOO\_INQUIRE**

Open for inquiry - required if you want to query properties.

**MQC.MQOO\_OUTPUT**

Open to put messages.

**MQC.MQOO\_PASS\_ALL\_CONTEXT**

Allow all context to be passed.

**MQC.MQOO\_PASS\_IDENTITY\_CONTEXT**

Allow identity context to be passed.

**MQC.MQOO\_SAVE\_ALL\_CONTEXT**

Save context when message retrieved.

**MQC.MQOO\_SET**

Open to set attributes - required if you want to set properties.

**MQC.MQOO\_SET\_ALL\_CONTEXT**

Allows all context to be set.

**MQC.MQOO\_SET\_IDENTITY\_CONTEXT**

Allows identity context to be set.

**queueManagerName**

Name of the queue manager on which the queue is defined. A name that is entirely blank or null denotes the queue manager to which the MQQueueManager object is connected.

**dynamicQueueName**

*dynamicQueueName* is ignored unless *queueName* specifies the name of a model queue. If it does, *dynamicQueueName* specifies the name of the dynamic queue to be created. A blank or null name is not valid if *queueName* specifies the name of a model queue. If the last non-blank character in the name is an asterisk, \*, the queue manager replaces the asterisk with a string of

characters. The characters guarantee that the name generated for the queue is unique on this queue manager.

#### **alternateUserId**

If MQC.MQOO\_ALTERNATE\_USER\_AUTHORITY is specified in the openOptions parameter, *alternateUserId* specifies the alternate user identifier that is used to check the authorization for the open. If MQC.MQOO\_ALTERNATE\_USER\_AUTHORITY is not specified, *alternateUserId* can be left blank, or null.

```
public MQQueue(MQQueueManager queueManager, string queueName, int openOptions,  
string queueManagerName, string dynamicQueueName, string alternateUserId);
```

Throws MQException.

Accesses a queue on queueManager.

You can get or browse messages, put messages, inquire about the attributes of the queue or set the attributes of the queue. If the queue named is a model queue, a dynamic local queue is created. Query the name attribute of the resultant MQQueue object to find out the name of the dynamic queue.

#### **queueManager**

Queue manager to access queue on.

#### **queueName**

Name of queue to open.

#### **openOptions**

Options that control the opening of the queue.

##### **MQC.MQOO\_ALTERNATE\_USER\_AUTHORITY**

Validate with the specified user identifier.

##### **MQC.MQOO\_BIND\_AS\_QDEF**

Use default binding for queue.

##### **MQC.MQOO\_BIND\_NOT\_FIXED**

Do not bind to a specific destination.

##### **MQC.MQOO\_BIND\_ON\_OPEN**

Bind handle to destination when queue is opened.

##### **MQC.MQOO\_BROWSE**

Open to browse message.

##### **MQC.MQOO\_FAIL\_IF QUIESCING**

Fail if the queue manager is quiescing.

##### **MQC.MQOO\_INPUT\_AS\_Q\_DEF**

Open to get messages using queue-defined default.

##### **MQC.MQOO\_INPUT\_SHARED**

Open to get messages with shared access.

##### **MQC.MQOO\_INPUT\_EXCLUSIVE**

Open to get messages with exclusive access.

##### **MQC.MQOO\_INQUIRE**

Open for inquiry - required if you want to query properties.

##### **MQC.MQOO\_OUTPUT**

Open to put messages.

##### **MQC.MQOO\_PASS\_ALL\_CONTEXT**

Allow all context to be passed.

##### **MQC.MQOO\_PASS\_IDENTITY\_CONTEXT**

Allow identity context to be passed.

##### **MQC.MQOO\_SAVE\_ALL\_CONTEXT**

Save context when message retrieved.

### **MQC.MQOO\_SET**

Open to set attributes - required if you want to set properties.

### **MQC.MQOO\_SET\_ALL\_CONTEXT**

Allows all context to be set.

### **MQC.MQOO\_SET\_IDENTITY\_CONTEXT**

Allows identity context to be set.

### **queueManagerName**

Name of the queue manager on which the queue is defined. A name that is entirely blank or null denotes the queue manager to which the MQQueueManager object is connected.

### **dynamicQueueName**

*dynamicQueueName* is ignored unless *queueName* specifies the name of a model queue. If it does, *dynamicQueueName* specifies the name of the dynamic queue to be created. A blank or null name is not valid if *queueName* specifies the name of a model queue. If the last non-blank character in the name is an asterisk, \*, the queue manager replaces the asterisk with a string of characters. The characters guarantee that the name generated for the queue is unique on this queue manager.

### **alternateUserId**

If MQC.MQOO\_ALTERNATE\_USER\_AUTHORITY is specified in the openOptions parameter, *alternateUserId* specifies the alternate user identifier that is used to check the authorization for the open. If MQC.MQOO\_ALTERNATE\_USER\_AUTHORITY is not specified, *alternateUserId* can be left blank, or null.

## **MQQueueManager.NET class**

Use MQQueueManager to connect to a queue manager and access queue manager objects. It also controls transactions. The MQQueueManager constructor creates either a client or server connection.

### **Class**

```
public class IBM.WMQ.MQQueueManager extends IBM.WMQ.MQManagedObject;
```

- [“Properties” on page 1759](#)
- [“Methods” on page 1763](#)
- [“Constructors” on page 1768](#)

### **Properties**

Test for MQException being thrown when getting properties.

```
public int AccountingConnOverride {get;}
```

Whether applications can override the setting of the MQI accounting and queue accounting values.

```
public int AccountingInterval {get;}
```

How long before intermediate accounting records are written (in seconds).

```
public int ActivityRecording {get;}
```

Controls the generation of activity reports.

**public int AdoptNewMCACheck {get;}**  
 Specifies which elements are checked to determine whether the MCA is adopted when a new inbound channel is detected. To be adopted, the MCA name must match the name of an active MCA.

**public int AdoptNewMCAInterval {get;}**  
 The amount of time, in seconds, that the new channel waits for the orphaned channel to end.

**public int AdoptNewMCAType {get;}**  
 Whether an orphaned MCA instance is to be adopted (restarted) when a new inbound channel request is detected matching the AdoptNewMCACheck value.

**public int BridgeEvent {get;}**  
 Whether IMS bridge events are generated.

**public int ChannelEvent {get;}**  
 Whether channel events are generated.

**public int ChannelInitiatorControl {get;}**  
 Whether the channel initiator starts automatically when the queue manager starts.

**public int ChannelInitiatorAdapters {get;}**  
 The number of adapter subtasks to process IBM MQ calls.

**public int ChannelInitiatorDispatchers {get;}**  
 The number of dispatchers to use for the channel initiator.

**public int ChannelInitiatorTraceAutoStart {get;}**  
 Specifies whether the channel initiator trace starts automatically.

**public int ChannelInitiatorTraceTableSize {get;}**  
 The size, in megabytes, of the trace data space of a channel initiator.

**public int ChannelMonitoring {get;}**  
 Whether channel monitoring is used.

**public int ChannelStatistics {get;}**  
 Controls the collection of statistics data for channels.

**public int CharacterSet {get;}**  
 Returns the coded character set identifier (CCSID) of the queue manager. CharacterSet is used by the queue manager for all character string fields in the application programming interface.

**public int ClusterSenderMonitoring {get;}**  
 Controls the collection of online monitoring data for automatically defined cluster sender channels.

**public int ClusterSenderStatistics {get;}**  
 Controls the collection of statistics data for automatically defined cluster sender channels.

**public int ClusterWorkLoadMRU {get;}**  
 The maximum number of outbound cluster channels.

**public int ClusterWorkLoadUseQ {get;}**  
 The default value of the MQQueue property, ClusterWorkLoadUseQ, if it specifies a value of QMGR.

**public int CommandEvent {get;}**  
 Specifies whether command events are generated.

**public string CommandInputQueueName {get;}**  
 Returns the name of the command input queue defined on the queue manager. Applications can send commands to this queue, if authorized to do so.

**public int CommandLevel {get;}**  
 Indicates the function level of the queue manager. The set of functions that correspond to a particular function level depends on the platform. On a particular platform, you can rely on every queue manager supporting the functions at the lowest functional level common to all the queue managers.

**public int CommandLevel {get;}**  
 Whether the command server starts automatically when the queue manager starts.

**public string DNSGroup {get;}**  
 No longer used.

**public int DNSWLM {get;}**

No longer used.

**public int IPAddressVersion {get;}**

Which IP protocol (IPv4 or IPv6) to use for a channel connection.

**public boolean IsConnected {get;}**

Returns the value of the `isConnected`.

If true, a connection to the queue manager has been made, and is not known to be broken. Any calls to `IsConnected` do not actively attempt to reach the queue manager, so it is possible that physical connectivity can break, but `IsConnected` can still return true. The `IsConnected` state is only updated when activity, for example, putting a message, getting a message, is performed on the queue manager.

If false, a connection to the queue manager has not been made, or has been broken, or has been disconnected.

**public int KeepAlive {get;}**

Specifies whether the TCP KEEPALIVE facility is to be used to check that the other end of the connection is still available. If it is unavailable, the channel is closed.

**public int ListenerTimer {get;}**

The time interval, in seconds, between attempts by IBM MQ to restart the listener after an APPC or TCP/IP failure.

**public int LoggerEvent {get;}**

Whether logger events are generated.

**public string LU62ARMSuffix {get;}**

The suffix of the APPCPM member of SYS1.PARMLIB. This suffix nominates the LUADD for this channel initiator. When automatic restart manager (ARM) restarts the channel initiator, the z/OS command SET APPC=xx is issued.

**public string LUGroupName {get; z/os}**

The generic LU name to be used by the LU 6.2 listener that handles inbound transmissions for the queue sharing group.

**public string LUName {get;}**

The name of the LU to use for outbound LU 6.2 transmissions.

**public int MaximumActiveChannels {get;}**

The maximum number of channels that can be active at any time.

**public int MaximumCurrentChannels {get;}**

The maximum number of channels that can be current at any time (including server-connection channels with connected clients).

**public int MaximumLU62Channels {get;}**

The maximum number of channels that can be current, or clients that can be connected, that use the LU 6.2 transmission protocol.

**public int MaximumMessageLength {get;}**

Returns the maximum length of a message (in bytes) that can be handled by the queue manager. No queue can be defined with a maximum message length greater than `MaximumMessageLength`.

**public int MaximumPriority {get;}**

Returns the maximum message priority supported by the queue manager. Priorities range from zero (lowest) to this value. Throws `MQException` if you call this method after disconnecting from the queue manager.

**public int MaximumTCPChannels {get;}**

The maximum number of channels that can be current, or clients that can be connected, that use the TCP/IP transmission protocol.

**public int MQIAccounting {get;}**

Controls the collection of accounting information for MQI data.

**public int MQIStatistics {get;}**

Controls the collection of statistics monitoring information for the queue manager.

**public int OutboundPortMax {get;}**

The maximum value in the range of port numbers to be used when binding outgoing channels.

**public int OutboundPortMin {get;}**

The minimum value in the range of port numbers to be used when binding outgoing channels.

**public int QueueAccounting {get;}**

Whether class 3 accounting (thread-level and queue-level accounting) data is to be used for all queues.

**public int QueueMonitoring {get;}**

Controls the collection of online monitoring data for queues.

**public int QueueStatistics {get;}**

Controls the collection of statistics data for queues.

**public int ReceiveTimeout {get;}**

The length of time that a TCP/IP channel waits to receive data, including heartbeats, from its partner before returning to the inactive state.

**public int ReceiveTimeoutMin {get;}**

The minimum length of time that a TCP/IP channel waits to receive data, including heartbeats, from its partner before returning to an inactive state.

**public int ReceiveTimeoutType {get;}**

The qualifier to apply to the value in ReceiveTimeout.

**public int SharedQueueQueueManagerName {get;}**

Specifies how to deliver messages to a shared queue. If the put specifies a different queue manager from the same queue sharing group as the target queue manager, the message is delivered in two ways:

**MQC.MQSQQM\_USE**

Messages are delivered to the object queue manager before being put on the shared queue.

**MQCMQSQQM\_IGNORE**

Messages are put directly on the shared queue.

**public int SSLEvent {get;}**

Whether TLS events are generated.

**public int SSLFips {get;}**

Whether only FIPS-certified algorithms are to be used if cryptography is performed in IBM MQ, rather than cryptographic hardware.

**public int SSLKeyResetCount {get;}**

Indicates the number of unencrypted bytes sent and received within a TLS conversation before the secret key is renegotiated.

**public int ClusterSenderStatistics {get;}**

Specifies the interval, in minutes, between consecutive gatherings of statistics.

**public int SyncpointAvailability {get;}**

Indicates whether the queue manager supports units of work and sync points with the MQQueue.get and MQQueue.put methods.

**public string TCPName {get;}**

The name of either the only, or default, TCP/IP system to be used, depending on the value of TCPStackType.

**public int TCPStackType {get;}**

Specifies whether the channel initiator uses only the TCP/IP address space specified in TCPName. Alternatively, the channel initiator can bind to any TCP/IP address.

**public int TraceRouteRecording {get;}**

Controls the recording of route tracing information.

## Methods

```
public MQProcess AccessProcess(string processName, int openOptions);  
public MQProcess AccessProcess(string processName, int openOptions, string  
queueManagerName, string alternateUserId);
```

Throws MQException.

Access an IBM MQ process on this queue manager to inquire on process attributes.

### **processName**

The name of the process to open.

### **openOptions**

Options that control the opening of the process. The valid options that can be added, or combined using a bitwise OR, are:

- `MQC.MQOO_FAIL_IF_QUIESCING`
- `MQC.MQOO_INQUIRE`
- `MQC.MQOO_SET`
- `MQC.MQOO_ALTERNATE_USER_AUTHORITY`

### **queueManagerName**

The name of the queue manager on which the process is defined. You can leave a blank or null queue manager name if the queue manager is the same as the one the process is accessing.

### **alternateUserId**

If `MQC.MQOO_ALTERNATE_USER_AUTHORITY` is specified in the **openOptions** parameter, *alternateUserId* specifies the alternative user ID used to check the authorization for the action. If `MQOO_ALTERNATE_USER_AUTHORITY` is not specified, *alternateUserId* can be blank or null.

Default user authority is used for connection to the queue manager if `MQC.MQOO_ALTERNATE_USER_AUTHORITY` is not specified.

```
public MQQueue AccessQueue(string queueName, int openOptions);  
public MQQueue AccessQueue(string queueName, int openOptions, string  
queueManagerName, string dynamicQueueName, string alternateUserId);
```

Throws MQException.

Accesses a queue on this queue manager.

You can get or browse messages, put messages, inquire about the attributes of the queue or set the attributes of the queue. If the queue named is a model queue, a dynamic local queue is created. Query the name attribute of the resultant MQQueue object to find out the name of the dynamic queue.

### **queueName**

Name of queue to open.

### **openOptions**

Options that control the opening of the queue.

#### **MQC.MQOO\_ALTERNATE\_USER\_AUTHORITY**

Validate with the specified user identifier.

#### **MQC.MQOO\_BIND\_AS\_QDEF**

Use default binding for queue.

#### **MQC.MQOO\_BIND\_NOT\_FIXED**

Do not bind to a specific destination.

#### **MQC.MQOO\_BIND\_ON\_OPEN**

Bind handle to destination when queue is opened.

#### **MQC.MQOO\_BROWSE**

Open to browse message.

**MQC.MQOO\_FAIL\_IF QUIESCING**

Fail if the queue manager is quiescing.

**MQC.MQOO\_INPUT\_AS\_Q\_DEF**

Open to get messages using queue-defined default.

**MQC.MQOO\_INPUT\_SHARED**

Open to get messages with shared access.

**MQC.MQOO\_INPUT\_EXCLUSIVE**

Open to get messages with exclusive access.

**MQC.MQOO\_INQUIRE**

Open for inquiry - required if you want to query properties.

**MQC.MQOO\_OUTPUT**

Open to put messages.

**MQC.MQOO\_PASS\_ALL\_CONTEXT**

Allow all context to be passed.

**MQC.MQOO\_PASS\_IDENTITY\_CONTEXT**

Allow identity context to be passed.

**MQC.MQOO\_SAVE\_ALL\_CONTEXT**

Save context when message retrieved.

**MQC.MQOO\_SET**

Open to set attributes - required if you want to set properties.

**MQC.MQOO\_SET\_ALL\_CONTEXT**

Allows all context to be set.

**MQC.MQOO\_SET\_IDENTITY\_CONTEXT**

Allows identity context to be set.

**queueManagerName**

Name of the queue manager on which the queue is defined. A name that is entirely blank or null denotes the queue manager to which the MQQueueManager object is connected.

**dynamicQueueName**

*dynamicQueueName* is ignored unless *queueName* specifies the name of a model queue. If it does, *dynamicQueueName* specifies the name of the dynamic queue to be created. A blank or null name is not valid if *queueName* specifies the name of a model queue. If the last non-blank character in the name is an asterisk, \*, the queue manager replaces the asterisk with a string of characters. The characters guarantee that the name generated for the queue is unique on this queue manager.

**alternateUserId**

If MQC.MQOO\_ALTERNATE\_USER\_AUTHORITY is specified in the *openOptions* parameter, *alternateUserId* specifies the alternate user identifier that is used to check the authorization for the open. If MQC.MQOO\_ALTERNATE\_USER\_AUTHORITY is not specified, *alternateUserId* can be left blank, or null.

```

public MQTopic AccessTopic( MQDestination destination, string topicName, string
topicObject, int options);
public MQTopic AccessTopic( MQDestination destination, string topicName, string
topicObject, int options, string alternateUserId);
public MQTopic AccessTopic( MQDestination destination, string topicName, string
topicObject, int options, string alternateUserId, string subscriptionName);
public MQTopic AccessTopic( MQDestination destination, string topicName, string
topicObject, int options, string alternateUserId, string subscriptionName,
System.Collections.Hashtable properties);
public MQTopic AccessTopic(string topicName, string topicObject, int openAs,
int options);
public MQTopic AccessTopic(string topicName, string topicObject, int openAs,
int options, string alternateUserId);
public MQTopic AccessTopic(string topicName, string topicObject, int options,
string alternateUserId, string subscriptionName);
public MQTopic AccessTopic(string topicName, string topicObject, int options,
string alternateUserId, string subscriptionName, System.Collections.Hashtable
properties);

```

Access a topic on this queue manager.

MQTopic objects are closely related to administrative topic objects, which are sometimes called topic objects. On input, *topicObject* points to an administrative topic object. The MQTopic constructor obtains a topic string from the topic object and combines it with *topicName* to create a topic name. Either or both *topicObject* or *topicName* can be null. The topic name is matched to the topic tree, and the name of the closest matching administrative topic object is returned in *topicObject*.

The topics that are associated with the MQTopic object are the result of combining two topic strings. The first topic string is defined by the administrative topic object identified by *topicObject*. The second topic string is *topicString*. The resulting topic string associated with the MQTopic object can identify multiple topics by including wildcards.

Depending on whether the topic is opened for publishing or subscribing, you can use the MQTopic .Put methods to publish on topics, or MQTopic .Get methods to receive publications on topics. If you want to publish and subscribe to the same topic, you must access the topic twice, once for publish and once for subscribe.

If you create an MQTopic object for subscription, without providing an MQDestination object, a managed subscription is assumed. If you pass a queue as an MQDestination object, an unmanaged subscription is assumed. You must ensure the subscription options you set are consistent with the subscription being managed or unmanaged.

#### **destination**

*destination* is an MQQueue instance. By providing *destination*, MQTopic is opened as an unmanaged subscription. Publications on the topic are delivered to the queue accessed as *destination*.

#### **topicName**

A topic string that is the second part of the topic name. *topicName* is concatenated with the topic string defined in the *topicObject* administrative topic object. You can set *topicName* to null, in which case the topic name is defined by the topic string in *topicObject*.

#### **topicObject**

On input, *topicObject* is the name of the topic object that contains the topic string that forms the first part of the topic name. The topic string in *topicObject* is concatenated with *topicName*. The rules for constructing topic strings are defined in [Combining topic strings](#).

On output, *topicObject* contains the name of the administrative topic object that is the closest match in the topic tree to the topic identified by the topic string.

#### **openAs**

Access the topic to publish or subscribe. The parameter can contain only one of these options:

- MQC.MQTOPIC\_OPEN\_AS\_SUBSCRIPTION

- MQC.MQTOPIC\_OPEN\_AS\_PUBLICATION

### options

Combine the options that control the opening of the topic for either publication or subscription. Use MQC.MQSO\_\* constants to access a topic for subscription and MQC.MQOO\_\* constants to access a topic for publication.

If more than one option is required, add the values together, or combine the option values using the bitwise OR operator.

### alternateUserId

Specify the alternate user ID that is used to check for the required authorization to finish the operation. You must specify *alternateUserId*, if either MQC.MQOO\_ALTERNATE\_USER\_AUTHORITY or MQC.MQSO\_ALTERNATE\_USER\_AUTHORITY is set in the options parameter.

### subscriptionName

*subscriptionName* is required if the options MQC.MQSO\_DURABLE or MQC.MQSO\_ALTER are provided. In both cases, MQTopic is implicitly opened for subscription. An exception is thrown if the MQC.MQSO\_DURABLE is set, and the subscription exists, or if MQC.MQSO\_ALTER is set, and the subscription does not exist.

### properties

Set any of the special subscription properties listed using a hash table. Specified entries in the hash table are updated with output values. Entries are not added to the hash table to report output values.

- MQC.MQSUB\_PROP\_ALTERNATE\_SECURITY\_ID
- MQC.MQSUB\_PROP\_SUBSCRIPTION\_EXPIRY
- MQC.MQSUB\_PROP\_SUBSCRIPTION\_USER\_DATA
- MQC.MQSUB\_PROP\_SUBSCRIPTION\_CORRELATION\_ID
- MQC.MQSUB\_PROP\_PUBLICATION\_PRIORITY
- MQC.MQSUB\_PROP\_PUBLICATION\_ACCOUNTING\_TOKEN
- MQC.MQSUB\_PROP\_PUBLICATION\_APPLICATIONID\_DATA

### **public MQAsyncStatus GetAsyncStatus();**

Throws MQException

Returns an MQAsyncStatus object, which represents the asynchronous activity for the queue manager connection.

### **public void Backout();**

Throws MQException.

Backout any messages that were read or written within sync point since the last sync point.

Messages that were written with the MQC.MQPMO\_SYNCPOINT flag set are removed from queues. Messages read with the MQC.MQGMO\_SYNCPOINT flag are reinstated on the queues they came from. If the messages are persistent, the changes are logged.

For reconnectable clients, the MQRC\_NONE reason code is returned to a client after reconnection is successful.

### **public void Begin();**

Throws MQException.

Begin is supported only in server bindings mode. It starts a global unit of work.

### **public void Commit();**

Throws MQException.

Commit any messages that were read or written within sync point since the last sync point.

Messages written with the `MQC.MQPMO_SYNCPOINT` flag set are made available to other applications. Messages retrieved with the `MQC.MQGMO_SYNCPOINT` flag set are deleted. If the messages are persistent, the changes are logged.

The following reason codes are returned to a reconnectable client:

- `MQRC_CALL_INTERRUPTED` if connection is lost while carrying out the commit call.
- `MQRC_BACKED_OUT` if the commit call is issued after reconnection.

### **Disconnect();**

Throws `MQException`.

Close the connection to the queue manager. All objects accessed on this queue manager are no longer accessible to this application. To reaccess the objects, create a `MQQueueManager` object.

Generally, any work performed as part of a unit of work is committed. However, if the unit of work is managed by .NET, the unit of work might be rolled back.

```
public void Put(int type, string destinationName, MQMessage message);  
public void Put(int type, string destinationName, MQMessage message  
MQPutMessageOptions putMessageOptions);  
public void Put(int type, string destinationName, string queueManagerName,  
string topicString, MQMessage message);  
public void Put(string queueName, MQMessage message);  
public void Put(string queueName, MQMessage message, MQPutMessageOptions  
putMessageOptions);  
public void Put(string queueName, string queueManagerName, MQMessage message);  
public void Put(string queueName, string queueManagerName, MQMessage message,  
MQPutMessageOptions putMessageOptions);  
public void Put(string queueName, string queueManagerName, MQMessage message,  
MQPutMessageOptions putMessageOptions, string alternateUserId);
```

Throws `MQException`.

Places a single message onto a queue or topic without creating an `MQQueue` or `MQTopic` object first.

#### **queueName**

The name of the queue onto which to place the message.

#### **destinationName**

The name of a destination object. It is either a queue or a topic depending on the value of *type*.

#### **type**

The type of destination object. You must not combine the options.

#### **MQC.MQOT\_Q**

Queue

#### **MQC.MQOT\_TOPIC**

Topic

#### **queueManagerName**

The name of the queue manager or queue manager alias, on which the queue is defined. If type `MQC.MQOT_TOPIC` is specified this parameter is ignored.

If the queue is a model queue, and the resolved queue manager name is not this queue manager, an `MQException` is thrown.

#### **topicString**

*topicString* is combined with the topic name in the *destinationName* topic object.

*topicString* is ignored if *destinationName* is a queue.

## message

The message to send. Message is an input/output object.

The following reason codes are returned to a reconnectable client:

- MQRC\_CALL\_INTERRUPTED if the connection is broken while performing a Put call on a persistent message.
- MQRC\_NONE if the connection is successful while performing a Put call on a non-persistent message (see [Application Recovery](#)).

## putMessageOptions

Options controlling the actions of the put.

If you omit *putMessageOptions*, a default instance of *putMessageOptions* is created. *putMessageOptions* is an input/output object.

If you use the MQPMO\_LOGICAL\_ORDER option in a reconnectable client, the MQRC\_RECONNECT\_INCOMPATIBLE reason code is returned.

## alternateUserId

Specifies an alternate user identifier used to check authorization when placing the message on a queue.

You can omit *alternateUserId* if you do not set MQC.MQOO\_ALTERNATE\_USER\_AUTHORITY in *putMessageOptions*. If you set MQC.MQOO\_ALTERNATE\_USER\_AUTHORITY, you must also set *alternateUserId*. *alternateUserId* has not effect unless you also set MQC.MQOO\_ALTERNATE\_USER\_AUTHORITY.

## Constructors

```
public MQQueueManager();  
public MQQueueManager(string queueManagerName);  
public MQQueueManager(string queueManagerName, Int options);  
public MQQueueManager(string queueManagerName, Int options, string channel,  
string connName);  
public MQQueueManager(string queueManagerName, string channel, string  
connName);  
public MQQueueManager(string queueManagerName, System.Collections.Hashtable  
properties);
```

Throws MQException.

Creates a connection to a queue manager. Select between creating a client connection or a server connection.

You must have inquire (inq) authority on the queue manager when attempting to connect to the queue manager. Without inquire authority, the connection attempt fails.

A client connection is created if one of the following conditions is true:

1. *channel* or *connName* are specified in the constructor.
2. *HostName*, *Port*, or *Channel* are specified in *properties*.
3. *MQEnvironment.HostName*, *MQEnvironment.Port*, or *MQEnvironment.Channel* are specified.

The values of the connection properties are defaulted in the order shown. The *channel* and *connName* in the constructor take precedence over the property values in the constructor. The constructor property values take precedence of the MQEnvironment properties.

The host name, channel name, and port are defined in the MQEnvironment class.

## queueManagerName

Name of the queue manager, or queue manager group to connect to.

Omit the parameter, or leave it null, or blank to make a default queue manager selection. The default queue manager connection on a server is to the default queue manager on the server. The default queue manager connection on a client connection is to the queue manager the listener is connected to.

### **options**

Specify MQCNO connection options. The values must be applicable to the type of connection being made. For example, if you specify the following server connection properties for a client connection an `MQException` is thrown.

- `MQC.MQCNO_FASTPATH_BINDING`
- `MQC.MQCNO_STANDARD_BINDING`

### **properties**

The `properties` parameter takes a series of key/value pairs that override the properties set by `MQEnvironment`; see the example, [“Override MQEnvironment properties” on page 1771](#). The following properties can be overridden:

- `MQC.CONNECT_OPTIONS_PROPERTY`
- `MQC.CONNECTION_NAME_PROPERTY`
- `MQC.ENCRYPTION_POLICY_SUITE_B`
- `MQC.HOST_NAME_PROPERTY`
- `MQC.PORT_PROPERTY`
- `MQC.CHANNEL_PROPERTY`
- `MQC.SSL_CIPHER_SPEC_PROPERTY`
- `MQC.SSL_PEER_NAME_PROPERTY`
- `MQC.SSL_CERT_STORE_PROPERTY`
- `MQC.SSL_CRYPTOHARDWARE_PROPERTY`
- `MQC.SECURITY_EXIT_PROPERTY`
- `MQC.SECURITY_USERDATA_PROPERTY`
- `MQC.SEND_EXIT_PROPERTY`
- `MQC.SEND_USERDATA_PROPERTY`
- `MQC.RECEIVE_EXIT_PROPERTY`
- `MQC.RECEIVE_USERDATA_PROPERTY`
- `MQC.USER_ID_PROPERTY`
- `MQC.PASSWORD_PROPERTY`
- `MQC.MQAIR_ARRAY`
- `MQC.KEY_RESET_COUNT`
- `MQC.FIPS_REQUIRED`
- `MQC.HDR_CMP_LIST`
- `MQC.MSG_CMP_LIST`
- `MQC.TRANSPORT_PROPERTY`

### **channel**

Name of a server connection channel

### **connName**

Connection name in the format *HostName (Port)*.

You can supply a list of *hostnames* and *ports* as an argument to the constructor `MQQueueManager` (`String queueManagerName, Hashtable properties`) using `CONNECTION_NAME_PROPERTY`.

For example:

```
ConnectionName = "fred.mq.com(2344),nick.mq.com(3746),tom.mq.com(4288)";
Hashtable Properties=new Hashtable();
properties.Add(MQC.CONNECTION_NAME_PROPERTY,ConnectionName);
MQQueueManager qmgr=new MQQueueManager("qmgrname",properties);
```

When a connection attempt is made, the connection name list is processed in order. If the connection attempt to the first host name and port fails, then connection to the second pair of attributes is attempted. The client repeats this process until either a successful connection is made or the list is exhausted. If the list is exhausted, an appropriate reason code and completion code is returned to the client application.

When a port number is not provided for the connection name, the default port (configured in `mqclient.ini`) is used.

## Set the Connection List

You can set the connection list by using the following methods when the automatic client reconnection options are set:

### Set the connection list through MQSERVER

You can set the connection list through the command prompt.

At the command prompt, set the following command:

```
MQSERVER=SYSTEM.DEF.SVRCONN/TCP/Hostname1(Port1),Hostname2(Por2),Hostname3(Port3)
```

For example:

```
MQSERVER=SYSTEM.DEF.SVRCONN/TCP/fred.mq.com(5266),nick.mq.com(6566),jack.mq.com(8413)
```

If you set the connection in the MQSERVER, do not set it in the application.

If you set the connection list in the application, the application overwrites whatever is set in the MQSERVER environment variable.

### Set the connection list through the application

You can set the connection list in the application by specifying the host name and port properties.

```
String connName = "fred.mq.com(2344), nick.mq.com(3746), chris.mq.com(4288)";
MQQueueManager qm = new MQQueueManager("QM1", "TestChannel", connName);
```

### Set the connection list through app.config

`App.config` is an XML file where you specify the key-value pairs.

In the connection list specify

```
<app.Settings>
<add key="Connection1" value="Hostname1(Port1)"/>
<add key="Connection2" value="Hostname2(Port2)"/>
</app.Settings>
```

For example:

```
<app.Settings>
<add key="Connection1" value="fred.mq.com(2966)"/>
<add key="Connection2" value="alex.mq.com(6533)"/>
</app.Settings>
```

You can directly change the connection list in the `app.config` file.

## Set the connection list through MQEnvironment

To set the Connection list through the MQEnvironment, use the *ConnectionName* property.

```
MQEnvironment.ConnectionName = "fred.mq.com(4288),alex.mq.com(5211);
```

The *ConnectionName* property overwrites the host name and port properties set in the MQEnvironment.

## Create a client connection

The following example shows you how to create a client connection to a queue manager. You can create a client connection by setting the MQEnvironment variables before creating a new MQQueueManager Object.

```
MQEnvironment.Hostname = "fred.mq.com"; // host to connect to
MQEnvironment.Port      = 1414;         // port to connect to
                                   // If not explicitly set,
                                   // defaults to 1414
                                   // (the default IBM MQ port)
MQEnvironment.Channel   = "channel.name"; // the case sensitive
                                   // name of the
                                   // SVR CONN channel on
                                   // the queue manager
MQQueueManager qMgr     = new MQQueueManager("MYQM");
```

Figure 11. Client connection

## Override MQEnvironment properties

The following example shows you how to create a queue manager with its user ID and password defined in a hash table.

```
Hashtable properties = new Hashtable();

properties.Add( MQC.USER_ID_PROPERTY, "ExampleUserId" );
properties.Add( MQC.PASSWORD_PROPERTY, "ExamplePassword" );

try
{
    MQQueueManager qMgr = new MQQueueManager("qmgrname", properties);
}
catch (MQException mqe)
{
    System.Console.WriteLine("Connect failed with " + mqe.Message);
    return((int)mqe.Reason);
}
```

Figure 12. Overriding MQEnvironment properties

## Create a reconnectable connection

The following example shows you how to automatically reconnect a client to a Queue Manager.

```
Hashtable properties = new Hashtable(); // The queue manager name and the
                                   // properties how it has to be connected

properties.Add(MQC.CONNECT_OPTIONS_PROPERTY, MQC.MQCNO_RECONNECT); // Options
                                   // through which reconnection happens

properties.Add(MQC.CONNECTION_NAME_PROPERTY, "fred.mq.com(4789),nick.mq.com(4790)"); // The list
                                   // of queue managers through which reconnection happens

MQ QueueManager qmgr = new MQQueueManager("qmgrname", properties);
```

Figure 13. Automatically reconnecting a client to a queue manager

## MQSubscription.NET class

Use MQSubscription to request that retained publications are sent to the subscriber. MQSubscription is a property of an MQTopic object opened for subscription.

### Class

```
public class IBM.WMQ.MQSubscription extends IBM.WMQ.MQManagedObject;
```

- [“Properties” on page 1772](#)
- [“Methods” on page 1772](#)
- [“Constructors” on page 1772](#)

### Properties

Access subscription properties using the MQManagedObject class; see [“Properties” on page 1731](#).

### Methods

Access subscription Inquire, Set and Get methods using the MQManagedObject class; see [“Methods” on page 1732](#).

```
public int RequestPublicationUpdate(int options);
```

Throws MQException.

Request an updated publication for the current topic. If the queue manager has a retained publications for the topic, they are sent to the subscriber.

Before calling RequestPublicationUpdate, open a topic for subscription to obtain an MQSubscription object.

Typically, open the subscription with the MQC.MQSO\_PUBLICATIONS\_ON\_REQUEST option. If no wildcards are present in the topic string, then only one publication is sent as a result of this call. If the topic string contains wildcards, many publications might be sent. The method returns the number of retained publications that are sent to the subscription queue. There is no guarantee that this many publications are received, especially if they are non-persistent messages.

#### options

##### **MQC.MQSRO\_FAIL\_IF QUIESCING**

The method fails if the queue manager is in a quiescent state. On z/OS, for a CICS or IMS application, MQC.MQSRO\_FAIL\_IF QUIESCING also forces the method to fail if the connection is in a quiescent state.

##### **MQC.MQSRO\_NONE**

No options are specified.

### Constructors

No Public constructor.

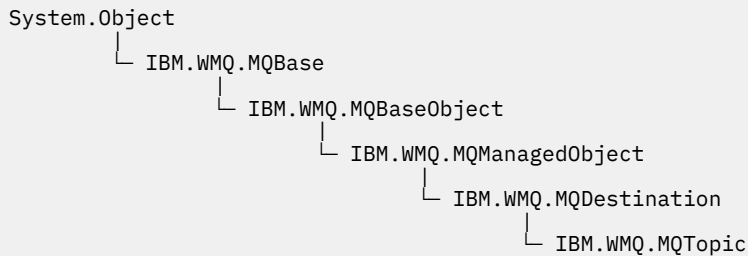

An MQSubscription object is returned in the SubscriptionReference property of an MQTopic object that is opened for subscription,

Call the RequestPublicationUpdate method. MQSubscription is a subclass of MQManagedObject. Use the reference to access the properties and methods of MQManagedObject.

## MQTopic.NET class

Use MQTopic to publish or subscribe messages on a topic, or to query or set attributes of a topic. Create an MQTopic object for publishing or subscribing by using a constructor or the MQQueueManager.AccessTopic method.

### Class

```
public class IBM.WMQ.MQTopic extends IBM.WMQ.MQDestination;
```

- [“Properties” on page 1773](#)
- [“Methods” on page 1773](#)
- [“Constructors” on page 1775](#)

### Properties

Test for MQException being thrown when getting properties.

**public Boolean IsDurable {get;}**

Read only property that returns True if the subscription is durable or False otherwise. If the topic was opened for publication, the property is ignored and would always return False.

**public Boolean IsManaged {get;};**

Read only property that returns True if the subscription is managed by the queue manager, or False otherwise. If the topic was opened for publication, the property is ignored and would always return False.

**public Boolean IsSubscribed {get;};**

Read only property that returns True if the topic was opened for subscription and False if the topic was opened for publication.

**public MQSubscription SubscriptionReference {get;};**

Read only property that returns the MQSubscription object associated with a topic object opened for subscription. The reference is available if you want to modify the close options or start any of the objects methods.

**public MQDestination UnmanagedDestinationReference {get;};**

Read only property that returns the MQQueue associated with an unmanaged subscription. It is the destination specified when the topic object was created. The property returns null for any topic objects opened for publication or with a managed subscription.

### Methods

**public void Put(MQMessage message);**

**public void Put(MQMessage message, MQPutMessageOptions putMessageOptions);**

Throws MQException.

Publishes a message to the topic.

Modifications to the MQMessage object after the Put call has been accomplished do not affect the actual message on the IBM MQ queue or publication topic.

Put updates the MessageId and CorrelationId properties of the MQMessage object and does not clear message data. Further Put or Get calls refer to the updated information in the MQMessage object. For example, in the following code snippet, the first message contains a and the second ab.

```
msg.WriteString("a");
q.Put(msg, pmo);
msg.WriteString("b");
q.Put(msg, pmo);
```

### **message**

An MQMessage object containing the message descriptor data, and message to be sent. The message descriptor can be altered as a consequence of this method. The values in the message descriptor immediately after the completion of this method are the values that were put to the queue or published to the topic.

The following reason codes are returned to a reconnectable client:

- MQRC\_CALL\_INTERRUPTED if the connection is broken while running a Put call on a persistent message and the reconnection is successful.
- MQRC\_NONE if the connection is successful while running a Put call on a non-persistent message (see [Application Recovery](#)).

### **putMessageOptions**

Options controlling the action of the put.

If *putMessageOptions* is not specified the default instance of MQPutMessageOptions is used.

If you use the MQPMO\_LOGICAL\_ORDER option in a reconnectable client, the MQRC\_RECONNECT\_INCOMPATIBLE reason code is returned.

**Note:** For simplicity and performance, if you want to put a single message to a queue, use MQQueueManager.Put object. You should have an MQQueue object for this.

```
public void Get(MQMessage message);  
public void Get(MQMessage message, MQGetMessageOptions getMessageOptions);  
public void Get(MQMessage message, MQGetMessageOptions getMessageOptions, int  
MaxMsgSize);
```

Throws MQException.

Retrieves a message from the topic.

This method uses a default instance of MQGetMessageOptions to do the get. The message option used is MQGMO\_NOWAIT.

If the get fails, the MQMessage object is unchanged. If it succeeds, the message descriptor and message data portions of the MQMessage are replaced with the message descriptor and message data from the incoming message.

All calls to IBM MQ from a particular MQQueueManager are synchronous. Therefore, if you perform a get with wait, all other threads using the same MQQueueManager are blocked from making further IBM MQ calls until the Get call is accomplished. If you need multiple threads to access IBM MQ simultaneously, each thread must create its own MQQueueManager object.

### **message**

Contains the message descriptor and the returned message data. Some of the fields in the message descriptor are input parameters. It is important to ensure that the MessageId and CorrelationId input parameters are set as required.

A reconnectable client returns the reason code MQRC\_BACKED\_OUT after successful reconnection, for messages received under MQGM\_SYNCPOINT.

### **getMessageOptions**

Options controlling the action of the get.

Using option `MQC.MQGMO_CONVERT` might result in an exception with reason code `MQC.MQRC_CONVERTED_STRING_TOO_BIG` when converting from single-byte character codes to double byte codes. In this case, the message is copied into the buffer without conversion.

If `getMessageOptions` is not specified, the message option used is `MQGMO_NOWAIT`.

If you use the `MQGMO_LOGICAL_ORDER` option in a reconnectable client, the `MQRC_RECONNECT_INCOMPATIBLE` reason code is returned.

### MaxMsgSize

The largest message this message object is to receive. If the message on the queue is larger than this size, one of two things occurs:

- If the `MQGMO_ACCEPT_TRUNCATED_MSG` flag is set in the `MQGetMessageOptions` object, the message is filled with as much of the message data as possible. An exception is thrown with the `MQCC_WARNING` completion code and `MQRC_TRUNCATED_MSG_ACCEPTED` reason code.
- If the `MQGMO_ACCEPT_TRUNCATED_MSG` flag is not set, the message remains on the queue. An exception is thrown with the `MQCC_WARNING` completion code and `MQRC_TRUNCATED_MSG_FAILED` reason code.

If `MaxMsgSize` is not specified, the whole message is retrieved.

## Constructors

```
public MQTopic(MQQueueManager queueManager, MQDestination destination, string
topicName, string topicObject, int options);
public MQTopic(MQQueueManager queueManager, MQDestination destination, string
topicName, string topicObject, int options, string alternateUserId);
public MQTopic(MQQueueManager queueManager, MQDestination destination, string
topicName, string topicObject, int options, string alternateUserId, string
subscriptionName);
public MQTopic(MQQueueManager queueManager, MQDestination destination, string
topicName, string topicObject, int options, string alternateUserId, string
subscriptionName, System.Collections.Hashtable properties);
public MQTopic(MQQueueManager queueManager, string topicName, string
topicObject, int openAs, int options);
public MQTopic(MQQueueManager queueManager, string topicName, string
topicObject, int openAs, int options, string alternateUserId);
public MQTopic(MQQueueManager queueManager, string topicName, string
topicObject, int options, string alternateUserId, string subscriptionName);
public MQTopic(MQQueueManager queueManager, string topicName, string
topicObject, int options, string alternateUserId, string subscriptionName,
System.Collections.Hashtable properties);
```

Access a topic on `queueManager`.

`MQTopic` objects are closely related to administrative topic objects, which are sometimes called topic objects. On input, `topicObject` points to an administrative topic object. The `MQTopic` constructor obtains a topic string from the topic object and combines it with `topicName` to create a topic name. Either or both `topicObject` or `topicName` can be null. The topic name is matched to the topic tree, and the name of the closest matching administrative topic object is returned in `topicObject`.

The topics that are associated with the `MQTopic` object are the result of combining two topic strings. The first topic string is defined by the administrative topic object identified by `topicObject`. The second topic string is `topicString`. The resulting topic string associated with the `MQTopic` object can identify multiple topics by including wildcards.

Depending on whether the topic is opened for publishing or subscribing, you can use the `MQTopic.Put` methods to publish on topics, or `MQTopic.Get` methods to receive publications on topics. If you want to publish and subscribe to the same topic, you must access the topic twice, once for publish and once for subscribe.

If you create an MQTopic object for subscription, without providing an MQDestination object, a managed subscription is assumed. If you pass a queue as an MQDestination object, an unmanaged subscription is assumed. You must ensure the subscription options you set are consistent with the subscription being managed or unmanaged.

**queueManager**

Queue manager to access a topic on.

**destination**

*destination* is an MQQueue instance. By providing *destination*, MQTopic is opened as an unmanaged subscription. Publications on the topic are delivered to the queue accessed as *destination*.

**topicName**

A topic string that is the second part of the topic name. *topicName* is concatenated with the topic string defined in the *topicObject* administrative topic object. You can set *topicName* to null, in which case the topic name is defined by the topic string in *topicObject*.

**topicObject**

On input, *topicObject* is the name of the topic object that contains the topic string that forms the first part of the topic name. The topic string in *topicObject* is concatenated with *topicName*. The rules for constructing topic strings are defined in [Combining topic strings](#).

On output, *topicObject* contains the name of the administrative topic object that is the closest match in the topic tree to the topic identified by the topic string.

**openAs**

Access the topic to publish or subscribe. The parameter can contain only one of these options:

- MQC.MQTOPIC\_OPEN\_AS\_SUBSCRIPTION
- MQC.MQTOPIC\_OPEN\_AS\_PUBLICATION

**options**

Combine the options that control the opening of the topic for either publication or subscription. Use MQC.MQSO\_\* constants to access a topic for subscription and MQC.MQOO\_\* constants to access a topic for publication.

If more than one option is required, add the values together, or combine the option values using the bitwise OR operator.

**alternateUserId**

Specify the alternate user ID that is used to check for the required authorization to finish the operation. You must specify *alternateUserId*, if either MQC.MQOO\_ALTERNATE\_USER\_AUTHORITY or MQC.MQSO\_ALTERNATE\_USER\_AUTHORITY is set in the options parameter.

**subscriptionName**

*subscriptionName* is required if the options MQC.MQSO\_DURABLE or MQC.MQSO\_ALTER are provided. In both cases, MQTopic is implicitly opened for subscription. An exception is thrown if the MQC.MQSO\_DURABLE is set, and the subscription exists, or if MQC.MQSO\_ALTER is set, and the subscription does not exist.

**properties**

Set any of the special subscription properties listed using a hash table. Specified entries in the hash table are updated with output values. Entries are not added to the hash table to report output values.

- MQC.MQSUB\_PROP\_ALTERNATE\_SECURITY\_ID
- MQC.MQSUB\_PROP\_SUBSCRIPTION\_EXPIRY
- MQC.MQSUB\_PROP\_SUBSCRIPTION\_USER\_DATA
- MQC.MQSUB\_PROP\_SUBSCRIPTION\_CORRELATION\_ID
- MQC.MQSUB\_PROP\_PUBLICATION\_PRIORITY
- MQC.MQSUB\_PROP\_PUBLICATION\_ACCOUNTING\_TOKEN

- MQC.MQSUB\_PROP\_PUBLICATION\_APPLICATIONID\_DATA

```

public MQTopic MQQueueManager.AccessTopic(MQDestination destination, string
topicName, string topicObject, int options);
public MQTopic MQQueueManager.AccessTopic(MQDestination destination, string
topicName, string topicObject, int options, string alternateUserId);
public MQTopic MQQueueManager.AccessTopic(MQDestination destination, string
topicName, string topicObject, int options, string alternateUserId, string
subscriptionName);
public MQTopic MQQueueManager.AccessTopic(MQDestination destination, string
topicName, string topicObject, int options, string alternateUserId, string
subscriptionName, System.Collections.Hashtable properties);
public MQTopic MQQueueManager.AccessTopic(string topicName, string topicObject,
int openAs, int options);
public MQTopic MQQueueManager.AccessTopic(string topicName, string topicObject,
int openAs, int options, string alternateUserId);
public MQTopic MQQueueManager.AccessTopic(string topicName, string topicObject,
int options, string alternateUserId, string subscriptionName);
public MQTopic MQQueueManager.AccessTopic(string topicName, string
topicObject, int options, string alternateUserId, string subscriptionName,
System.Collections.Hashtable properties);

```

Access a topic on this queue manager.

MQTopic objects are closely related to administrative topic objects, which are sometimes called topic objects. On input, *topicObject* points to an administrative topic object. The MQTopic constructor obtains a topic string from the topic object and combines it with *topicName* to create a topic name. Either or both *topicObject* or *topicName* can be null. The topic name is matched to the topic tree, and the name of the closest matching administrative topic object is returned in *topicObject*.

The topics that are associated with the MQTopic object are the result of combining two topic strings. The first topic string is defined by the administrative topic object identified by *topicObject*. The second topic string is *topicString*. The resulting topic string associated with the MQTopic object can identify multiple topics by including wildcards.

Depending on whether the topic is opened for publishing or subscribing, you can use the MQTopic .Put methods to publish on topics, or MQTopic .Get methods to receive publications on topics. If you want to publish and subscribe to the same topic, you must access the topic twice, once for publish and once for subscribe.

If you create an MQTopic object for subscription, without providing an MQDestination object, a managed subscription is assumed. If you pass a queue as an MQDestination object, an unmanaged subscription is assumed. You must ensure the subscription options you set are consistent with the subscription being managed or unmanaged.

#### **destination**

*destination* is an MQQueue instance. By providing *destination*, MQTopic is opened as an unmanaged subscription. Publications on the topic are delivered to the queue accessed as *destination*.

#### **topicName**

A topic string that is the second part of the topic name. *topicName* is concatenated with the topic string defined in the *topicObject* administrative topic object. You can set *topicName* to null, in which case the topic name is defined by the topic string in *topicObject*.

#### **topicObject**

On input, *topicObject* is the name of the topic object that contains the topic string that forms the first part of the topic name. The topic string in *topicObject* is concatenated with *topicName*. The rules for constructing topic strings are defined in [Combining topic strings](#).

On output, *topicObject* contains the name of the administrative topic object that is the closest match in the topic tree to the topic identified by the topic string.

### openAs

Access the topic to publish or subscribe. The parameter can contain only one of these options:

- MQC.MQTOPIC\_OPEN\_AS\_SUBSCRIPTION
- MQC.MQTOPIC\_OPEN\_AS\_PUBLICATION

### options

Combine the options that control the opening of the topic for either publication or subscription. Use MQC.MQSO\_\* constants to access a topic for subscription and MQC.MQOO\_\* constants to access a topic for publication.

If more than one option is required, add the values together, or combine the option values using the bitwise OR operator.

### alternateUserId

Specify the alternate user ID that is used to check for the required authorization to finish the operation. You must specify *alternateUserId*, if either MQC.MQOO\_ALTERNATE\_USER\_AUTHORITY or MQC.MQSO\_ALTERNATE\_USER\_AUTHORITY is set in the options parameter.

### subscriptionName

*subscriptionName* is required if the options MQC.MQSO\_DURABLE or MQC.MQSO\_ALTER are provided. In both cases, MQTopic is implicitly opened for subscription. An exception is thrown if the MQC.MQSO\_DURABLE is set, and the subscription exists, or if MQC.MQSO\_ALTER is set, and the subscription does not exist.

### properties

Set any of the special subscription properties listed using a hash table. Specified entries in the hash table are updated with output values. Entries are not added to the hash table to report output values.

- MQC.MQSUB\_PROP\_ALTERNATE\_SECURITY\_ID
- MQC.MQSUB\_PROP\_SUBSCRIPTION\_EXPIRY
- MQC.MQSUB\_PROP\_SUBSCRIPTION\_USER\_DATA
- MQC.MQSUB\_PROP\_SUBSCRIPTION\_CORRELATION\_ID
- MQC.MQSUB\_PROP\_PUBLICATION\_PRIORITY
- MQC.MQSUB\_PROP\_PUBLICATION\_ACCOUNTING\_TOKEN
- MQC.MQSUB\_PROP\_PUBLICATION\_APPLICATIONID\_DATA

## IMQObjectTrigger.NET interface

Implement IMQObjectTrigger to process messages passed by the **runmqdmn**.NET monitor.

### Interface

```
public interface IBM.WMQMonitor.IMQObjectTrigger();
```

Depending on whether sync point control is specified in the **runmqdmn** command the message is removed from the queue before or after the Execute method returns.

### Methods

```
void Execute (MQQueueManager queueManager, MQQueue queue, MQMessage message, string param);
```

#### queueManager

Queue manager hosting the queue being monitored.

**queue**

Queue being monitored.

**message**

Message read from the queue.

**param**Data passed from `UserParameter`.

## MQC.NET interface

Refer to an MQI constant by prefixing the constant name with `MQC..` `MQC` defines all the constants used by the MQI.

### Interface

```
System.Object
└─ IBM.WMQ.MQC
```

```
public interface IBM.WMQ.MQC extends System.Object;
```

### Example

```
MQQueue queue;
queue.closeOptions = MQC.MQCO_DELETE;
```

## Character set identifiers for .NET applications

Descriptions of the character sets you can select to encode .NET IBM MQ messages

Character set	Description
37	ibm037
437	ibm437 / PC Original
500	ibm500
819	iso-8859-1 / latin1 / ibm819
1200	Unicode
1208	UTF-8
273	ibm273
277	ibm277
278	ibm278
280	ibm280
284	ibm284
285	ibm285
297	ibm297
420	ibm420
424	ibm424
737	ibm737 / PC Greek

<b>Character set</b>	<b>Description</b>
775	ibm775 / PC Baltic
813	iso-8859-7 / greek / ibm813
838	ibm838
850	ibm850 / PC Latin 1
852	ibm852 / PC Latin 2
855	ibm855 / PC Cyrillic
856	ibm856
857	ibm857 / PC Turkish
860	ibm860 / PC Portuguese
861	ibm861 / PC Icelandic
862	ibm862 / PC Hebrew
863	ibm863 / PC Canadian French
864	ibm864 / PC Arabic
865	ibm865 / PC Nordic
866	ibm866 / PC Russian
868	ibm868
869	ibm869 / PC Modern Greek
870	ibm870
871	ibm871
874	ibm874
875	ibm875
912	iso-8859-2 / latin2 / ibm912
913	iso-8859-3 / latin3 / ibm913
914	iso-8859-4 / latin4 / ibm914
915	iso-8859-5 / cyrillic / ibm915
916	iso-8859-8 / hebrew / ibm916
918	ibm918
920	iso-8859-9 / latin5 / ibm920
921	ibm921
922	ibm922
930	ibm930

1383	ibm1383
2022	JIS
5601	ksc-5601 Korean
33722	ibm33722

## IBM MQ C++ classes

---

The IBM MQ C++ classes encapsulate the IBM MQ Message Queue Interface (MQI). There is a single C++ header file, **imqi.hpp**, which covers all of these classes.

For each class, the following information is shown:

### **Class hierarchy diagram**

A class diagram showing the class in its inheritance relation to its immediate parent classes, if any.

### **Other relevant classes**

Document links to other relevant classes, such as parent classes, and the classes of objects used in method signatures.

### **Object attributes**

Attributes of the class. These are in addition to those attributes defined for any parent classes. Many attributes reflect IBM MQ data-structure members (see [“C++ and MQI cross-reference”](#) on page 1783). For detailed descriptions, see [“Attributes of objects”](#) on page 798.

### **Constructors**

Signatures of the special methods used to create an object of the class.

### **Object methods (public)**

Signatures of methods that require an instance of the class for their operation, and that have no usage restrictions.

Where it applies, the following information is also shown:

### **Class methods (public)**

Signatures of methods that do not require an instance of the class for their operation, and that have no usage restrictions.

### **Overloaded (parent class) methods**

Signatures of those virtual methods that are defined in parent classes, but exhibit different, polymorphic, behavior for this class.

### **Object methods (protected)**

Signatures of methods that require an instance of the class for their operation, and are reserved for use by the implementations of derived classes. This section is of interest only to class writers, as opposed to class users.

### **Object data (protected)**

Implementation details for object instance data available to the implementations of derived classes. This section is of interest only to class writers, as opposed to class users.

### **Reason codes**

MQRC\_\* values (see API completion and reason codes) that can be expected from those methods that fail. For an exhaustive list of reason codes that can occur for an object of a class, consult the parent class documentation. The documented list of reason codes for a class does not include the reason codes for parent classes.

### **Note:**

1. Objects of these classes are not thread-safe. This ensures optimal performance, but take care not to access any object from more than one thread.
2. It is recommended that, for a multithreaded program, a separate `ImqQueueManager` object is used for each thread. Each manager object must have its own independent collection of other objects, ensuring that objects in different threads are isolated from one another.

The classes are:

- [“ImqAuthenticationRecord C++ class”](#) on page 1799
- [“ImqBinary C++ class”](#) on page 1801
- [“ImqCache C++ class”](#) on page 1803
- [“ImqChannel C++ class”](#) on page 1806

- [“ImqCICSBridgeHeader C++ class” on page 1811](#)
- [“ImqDeadLetterHeader C++ class” on page 1817](#)
- [“ImqDistributionList C++ class” on page 1820](#)
- [“ImqError C++ class” on page 1821](#)
- [“ImqGetMessageOptions C++ class” on page 1822](#)
- [“ImqHeader C++ class” on page 1826](#)

## C++ and MQI cross-reference

This collection of topics contains information relating C++ to the MQI.

Read this information together with [“Data types used in the MQI” on page 235](#).

This table relates MQI data structures to the C++ classes and include files. The following topics show cross-reference information for each C++ class. These cross-references relate to the use of the underlying IBM MQ procedural interfaces. The classes `ImqBinary`, `ImqDistributionList`, and `ImqString` have no attributes that fall into this category and are excluded.

<b>Data structure</b>	<b>Class</b>	<b>Include file</b>
MQAIR	<code>ImqAuthenticationRecord</code>	<code>imqair.hpp</code>
	<code>ImqBinary</code>	<code>imqbin.hpp</code>
	<code>ImqCache</code>	<code>imqcac.hpp</code>
MQCD	<code>ImqChannel</code>	<code>imqchl.hpp</code>
MQCIH	<code>ImqCICSBridgeHeader</code>	<code>imqcih.hpp</code>
MQDLH	<code>ImqDeadLetterHeader</code>	<code>imqdlh.hpp</code>
MQOR	<code>ImqDistributionList</code>	<code>imqdst.hpp</code>
	<code>ImqError</code>	<code>imqerr.hpp</code>
MQGMO	<code>ImqGetMessageOptions</code>	<code>imqgmo.hpp</code>
	<code>ImqHeader</code>	<code>imqhdr.hpp</code>
MQIIH	<code>ImqIMSBridgeHeader</code>	<code>imqiih.hpp</code>

Table 845. Data structure, class, and include-file cross-reference (continued)

Data structure	Class	Include file
	ImqItem	imqitm.hpp
MQMD	ImqMessage	imqmsg.hpp
	ImqMessageTracker	imqmtr.hpp
	ImqNamelist	imqnml.hpp
MQOD, MQRR	ImqObject	imqobj.hpp
MQPMO, MQPMR, MQRR	ImqPutMessageOptions	imqpmo.hpp
	ImqProcess	imqpro.hpp
	ImqQueue	imqque.hpp
MQBO, MQCNO, MQCSP	ImqQueueManager	imqmgr.hpp
MQRMH	ImqReferenceHeader	imqrfh.hpp
	ImqString	imqstr.hpp
MQTM	ImqTrigger	imqtrg.hpp
MQTMC		
MQTMC2	ImqTrigger	imqtrg.hpp
MQXQH		
MQWIH	ImqWorkHeader	imqwih.hpp

## ImqAuthenticationRecord cross-reference

Cross-reference of attributes, data structures, fields, and calls for the ImqAuthenticationRecord C++ class.

Table 846. Attributes, data structures, fields, and calls

Attribute	Data structure	Field	Call
connection name	MQAIR	AuthInfoConnName	MQCONN
password	MQAIR	LDAPPassword	MQCONN
type	MQAIR	AuthInfoType	MQCONN
user name	MQAIR	LDAPUserNamePtr	MQCONN
	MQAIR	LDAPUserNameOffset	MQCONN
	MQAIR	LDAPUserNameLength	MQCONN

## ImqCache cross-reference

Cross-reference of attributes and calls for the ImqCache C++ class.

Table 847. Attributes and calls

Attribute	Call
automatic buffer	MQGET
buffer length	MQGET

Table 847. Attributes and calls (continued)

Attribute	Call
buffer pointer	MQGET, MQPUT
data length	MQGET
data offset	MQGET
data pointer	MQGET
message length	MQGET, MQPUT

## ImqChannel cross-reference

Cross-reference of attributes, data structures, fields, and calls for the ImqChannel C++ class.

Table 848. Attributes, data structures, fields, and calls

Attribute	Data structure	Field	Call
batch heart-beat	MQCD	BatchHeartbeat	MQCONN
channel name	MQCD	ChannelName	MQCONN
connection name	MQCD	ConnectionName	MQCONN
	MQCD	ShortConnectionName	MQCONN
header compression	MQCD	HdrCompList	MQCONN
heart-beat interval	MQCD	HeartbeatInterval	MQCONN
keep alive interval	MQCD	KeepAliveInterval	MQCONN
local address	MQCD	LocalAddress	MQCONN
maximum message length	MQCD	MaxMsgLength	MQCONN
message compression	MQCD	MsgCompList	MQCONN
mode name	MQCD	ModeName	MQCONN
password	MQCD	Password	MQCONN
receive exit count	MQCD		MQCONN
receive exit names	MQCD	ReceiveExit	MQCONN
	MQCD	ReceiveExitsDefined	MQCONN
	MQCD	ReceiveExitPtr	MQCONN
receive user data	MQCD	ReceiveUserData	MQCONN
	MQCD	ReceiveUserDataPtr	MQCONN
security exit name	MQCD	SecurityExit	MQCONN
security user data	MQCD	SecurityUserData	MQCONN
send exit count	MQCD		MQCONN
send exit names	MQCD	SendExit	MQCONN
	MQCD	SendExitsDefined	MQCONN
	MQCD	SendExitPtr	MQCONN

Table 848. Attributes, data structures, fields, and calls (continued)

Attribute	Data structure	Field	Call
send user data	MQCD	SendUserData	MQCONN
	MQCD	SendUserDataPtr	MQCONN
SSL CipherSpec	MQCD	sslCipherSpecification	MQCONN
SSL client authentication type	MQCD	sslClientAuthentication	MQCONN
SSL peer name	MQCD	sslPeerName	MQCONN
transaction program name	MQCD	TpName	MQCONN
transport type	MQCD	TransportType	MQCONN
user id	MQCD	UserIdentifier	MQCONN

### ImqCICSBridgeHeader cross-reference

Cross-reference of attributes, data structures, and fields for the ImqCICSBridgeHeader C++ class.

Table 849. Mapping of attributes, data structures, and fields

Attribute	Data structure	Field
bridge abend code	MQCIH	AbendCode
ADS descriptor	MQCIH	AdsDescriptor
attention identifier	MQCIH	AttentionId
authenticator	MQCIH	Authenticator
bridge completion code	MQCIH	BridgeCompletionCode
bridge error offset	MQCIH	ErrorOffset
bridge reason code	MQCIH	BridgeReason
bridge cancel code	MQCIH	CancelCode
conversational task	MQCIH	ConversationalTask
cursor position	MQCIH	CursorPosition
facility token	MQCIH	Facility
facility keep time	MQCIH	FacilityKeepTime
facility like	MQCIH	FacilityLike
function	MQCIH	Function
get wait interval	MQCIH	GetWaitInterval
link type	MQCIH	LinkType
next transaction identifier	MQCIH	NextTransactionId
output data length	MQCIH	OutputDataLength
reply-to format	MQCIH	ReplyToFormat
bridge return code	MQCIH	ReturnCode
start code	MQCIH	StartCode

Table 849. Mapping of attributes, data structures, and fields (continued)

Attribute	Data structure	Field
task end status	MQCIH	TaskEndStatus
transaction identifier	MQCIH	TransactionId
uow control	MQCIH	UowControl
version	MQCIH	Version

### ImqDeadLetterHeader cross-reference

Cross-reference of attributes, data structures, and fields for the ImqDeadLetterHeader C++ class.

Table 850. Mapping of attributes, data structures, and fields

Attribute	Data structure	Field
dead-letter reason code	MQDLH	Reason
destination queue manager name	MQDLH	DestQMgrName
destination queue name	MQDLH	DestQName
put application name	MQDLH	PutApplName
put application type	MQDLH	PutApplType
put date	MQDLH	PutDate
put time	MQDLH	PutTime

### ImqError cross-reference

Cross-reference of attributes and calls for the ImqError C++ class.

Table 851. Attributes and calls

Attribute	Call
completion code	MQBACK, MQBEGIN, MQCLOSE, MQCMIT, MQCONN, MQCONNX, MQDISC, MQGET, MQINQ, MQOPEN, MQPUT, MQSET
reason code	MQBACK, MQBEGIN, MQCLOSE, MQCMIT, MQCONN, MQCONNX, MQDISC, MQGET, MQINQ, MQOPEN, MQPUT, MQSET

### ImqGetMessageOptions cross-reference

Cross-reference of attributes, data structures, and fields for the ImqGetMessageOptions C++ class.

Table 852. Mapping of attributes, data structures, and fields

Attribute	Data structure	Field
group status	MQGMO	GroupStatus
match options	MQGMO	MatchOptions
message token	MQGMO	MessageToken
options	MQGMO	Options
resolved queue name	MQGMO	ResolvedQName
returned length	MQGMO	ReturnedLength

Table 852. Mapping of attributes, data structures, and fields (continued)

Attribute	Data structure	Field
segmentation	MQGMO	Segmentation
segment status	MQGMO	SegmentStatus
	MQGMO	Signal1
	MQGMO	Signal2
syncpoint participation	MQGMO	Options
wait interval	MQGMO	WaitInterval

### ImqHeader cross-reference

Cross-reference of attributes, data structures, and fields for the ImqHeader C++ class.

Table 853. Mapping of attributes, data structures, and fields

Attribute	Data structure	Field
character set	MQDLH, MQIIH	CodedCharSetId
encoding	MQDLH, MQIIH	Encoding
format	MQDLH, MQIIH	Format
header flags	MQIIH, MQRMH	Flags

### ImqIMSBridgeHeader cross-reference

Cross-reference of attributes, data structures, and fields for the ImqAuthenticationRecord C++ class.

Table 854. Mapping of attributes, data structures, and fields

Attribute	Data structure	Field
authenticator	MQIIH	Authenticator
commit mode	MQIIH	CommitMode
logical terminal override	MQIIH	LTermOverride
message format services map name	MQIIH	MFSMapName
reply-to format	MQIIH	ReplyToFormat
security scope	MQIIH	SecurityScope
transaction instance id	MQIIH	TranInstanceId
transaction state	MQIIH	TranState

### ImqItem cross-reference

Cross-reference of attributes and calls for the ImqItem C++ class.

Table 855. Attributes and calls

Attribute	Call
structure id	MQGET

## ImqMessage cross-reference

Cross-reference of attributes, data structures, fields, and calls for the ImqMessage C++ class.

*Table 856. Attributes, data structures, fields, and calls*

Attribute	Data structure	Field	Call
application ID data	MQMD	ApplIdentityData	
application origin data	MQMD	ApplOriginData	
backout count	MQMD	BackoutCount	
character set	MQMD	CodedCharSetId	
encoding	MQMD	Encoding	
expiry	MQMD	Expiry	
format	MQMD	Format	
message flags	MQMD	MsgFlags	
message type	MQMD	MsgType	
offset	MQMD	Offset	
original length	MQMD	OriginalLength	
persistence	MQMD	Persistence	
priority	MQMD	Priority	
put application name	MQMD	PutApplName	
put application type	MQMD	PutApplType	
put date	MQMD	PutDate	
put time	MQMD	PutTime	
reply-to queue manager name	MQMD	ReplyToQMgr	
reply-to queue name	MQMD	ReplyToQ	
report	MQMD	Report	
sequence number	MQMD	MsgSeqNumber	
total message length		DataLength	MQGET
user id	MQMD	UserIdentifier	

## ImqMessageTracker cross-reference

Cross-reference of attributes, data structures, and fields for the ImqMessageTracker C++ class.

*Table 857. Mapping of attributes, data structures, and fields*

Attribute	Data structure	Field
accounting token	MQMD	AccountingToken
correlation id	MQMD	CorrelId
feedback	MQMD	Feedback
group id	MQMD	GroupId

Table 857. Mapping of attributes, data structures, and fields (continued)

Attribute	Data structure	Field
message id	MQMD	MsgId

### ImqNamelist cross-reference

Cross-reference of attributes, inquiries, and calls for the ImqNamelist C++ class.

Table 858. Attributes, inquiries, and calls

Attribute	Inquiry	Call
name count	MQIA_NAME_COUNT	MQINQ
namelist name	MQCA_NAMELIST_NAME	MQINQ

### ImqObject cross-reference

Cross-reference of attributes, data structures, fields, inquiries, and calls for the ImqObject C++ class.

Table 859. Attributes, data structures, fields, inquiries, and calls

Attribute	Data structure	Field	Inquiry	Call
alteration date			MQCA_ALTERATION_DATE	MQINQ
alteration time			MQCA_ALTERATION_TIME	MQINQ
alternate user id	MQOD	AlternateUserId		
alternate security id				
close options				MQCLOSE
description			MQCA_Q_DESC, MQCA_Q_MGR_DESC, MQCA_PROCESS_DESC	MQINQ
name	MQOD	ObjectName	MQCA_Q_MGR_NAME, MQCQ_Q_NAME, MQCA_PROCESS_NAME	MQINQ
open options				MQOPEN
open status				MQOPEN, MQCLOSE
queue manager identifier	queue manager identifier		MQCA_Q_MGR_IDENTIFIER	MQINQ

### ImqProcess cross-reference

Cross-reference of attributes, inquiries, and calls for the ImqAuthenticationRecord C++ class.

Table 860. Attributes, inquiries, and calls

Attribute	Inquiry	Call
application id	MQCA_APPL_ID	MQINQ
application type	MQIA_APPL_TYPE	MQINQ
environment data	MQCA_ENV_DATA	MQINQ

Table 860. Attributes, inquiries, and calls (continued)

Attribute	Inquiry	Call
user data	MQCA_USER_DATA	MQINQ

## ImqPutMessageOptions cross-reference

Cross-reference of attributes, data structures, and fields for the ImqAuthenticationRecord C++ class.

Table 861. Mapping of attributes, data structures, and fields

Attribute	Data structure	Field
context reference	MQPMO	Context
	MQPMO	InvalidDestCount
	MQPMO	KnownDestCount
options	MQPMO	Options
record fields	MQPMO	PutMsgRecFields
resolved queue manager name	MQPMO	ResolvedQMgrName
resolved queue name	MQPMO	ResolvedQName
	MQPMO	Timeout
	MQPMO	UnknownDestCount
syncpoint participation	MQPMO	Options

## ImqQueue cross-reference

Cross-reference of attributes, data structures, fields, inquiries, and calls for the ImqQueue C++ class.

Table 862. ImqQueue cross-reference

Attribute	Data structure	Field	Inquiry	Call
backout requeue name			MQCA_BACKOUT_REQ_Q_NAME	MQINQ
backout threshold			MQIA_BACKOUT_THRESHOLD	MQINQ
base queue name			MQCA_BASE_Q_NAME	MQINQ

## ImqReferenceHeader cross-reference

Cross-reference of attributes, data structures, and fields for the ImqAuthenticationRecord C++ class.

Attribute	Data structure	Field
destination environment	MQRMH	DestEnvLength, DestEnvOffset
destination name	MQRMH	DestNameLength, DestNameOffset
instance id	MQRMH	ObjectInstanceId
logical length	MQRMH	DataLogicalLength
logical offset	MQRMH	DataLogicalOffset
logical offset 2	MQRMH	DataLogicalOffset2
reference type	MQRMH	ObjectType
source environment	MQRMH	SrcEnvLength, SrcEnvOffset
source name	MQRMH	SrcNameLength, SrcNameOffset

## ImqTrigger cross-reference

Cross-reference of attributes, data structures, and fields for the ImqAuthenticationRecord C++ class.

Attribute	Data structure	Field
application id	MQTM	ApplId
application type	MQTM	ApplType
environment data	MQTM	EnvData
process name	MQTM	ProcessName
queue name	MQTM	QName
trigger data	MQTM	TriggerData
user data	MQTM	UserData

## ImqWorkHeader cross-reference

Cross-reference of attributes, data structures, and fields for the ImqAuthenticationRecord C++ class.

Attribute	Data structure	Field
message token	MQWIH	MessageToken
service name	MQWIH	ServiceName
service step	MQWIH	ServiceStep

## ImqAuthenticationRecord C++ class

This class encapsulates an authentication information record (MQAIR) for use during execution of the `ImqQueueManager::connect` method, for custom TLS client connections.

Figure 14. *ImqAuthenticationRecord* class

See the description of the `ImqQueueManager::connect` method for more details. This class is not available on the z/OS platform.

- [“Object attributes” on page 1799](#)
- [“Constructors” on page 1800](#)
- [“Object methods \(public\)” on page 1800](#)
- [“Object methods \(protected\)” on page 1800](#)

### Object attributes

#### connection name

The name of the connection to the LDAP CRL server. This is the IP address or DNS name, followed optionally by the port number, in parentheses.

#### connection reference

A reference to an `ImqQueueManager` object that provides the required connection to a (local) queue manager. The initial value is zero. Do not confuse this with the queue manager name that identifies a queue manager (possibly remote) for a named queue.

#### next authentication record

Next object of this class, in no particular order, having the same **connection reference** as this object. The initial value is zero.

#### password

A password supplied for connection authentication to the LDAP CRL server.

#### previous authentication record

Previous object of this class, in no particular order, having the same **connection reference** as this object. The initial value is zero.

#### type

The type of authentication information contained in the record.

#### user name

A user identifier supplied for authorization to the LDAP CRL server.

## Constructors

**ImqAuthenticationRecord();**

The default constructor.

## Object methods (public)

**void operator = ( const ImqAuthenticationRecord & *air* );**

Copies instance data from *air*, replacing the existing instance data.

**const ImqString & connectionName ( ) const ;**

Returns the **connection name**.

**void setConnectionName ( const ImqString & *name* );**

Sets the **connection name**.

**void setConnectionName ( const char \* *name* = 0 );**

Sets the **connection name**.

**ImqQueueManager \* connectionReference ( ) const ;**

Returns the **connection reference**.

**void setConnectionReference ( ImqQueueManager & *manager* );**

Sets the **connection reference**.

**void setConnectionReference ( ImqQueueManager \* *manager* = 0 );**

Sets the **connection reference**.

**void copyOut ( MQAIR \* *pAir* );**

Copies instance data to *pAir*, replacing the existing instance data. This might involve allocating dependent storage.

**void clear ( MQAIR \* *pAir* );**

Clears the structure and releases dependent storage referenced by *pAir*.

**ImqAuthenticationRecord \* nextAuthenticationRecord ( ) const ;**

Returns the **next authentication record**.

**const ImqString & password ( ) const ;**

Returns the **password**.

**void setPassword ( const ImqString & *password* );**

Sets the **password**.

**void setPassword ( const char \* *password* = 0 );**

Sets the **password**.

**ImqAuthenticationRecord \* previousAuthenticationRecord ( ) const ;**

Returns the **previous authentication record**.

**MQLONG type ( ) const ;**

Returns the **type**.

**void setType ( const MQLONG *type* );**

Sets the **type**.

**const ImqString & userName ( ) const ;**

Returns the **user name**.

**void setUsername ( const ImqString & *name* );**

Sets the **user name**.

**void setUsername ( const char \* *name* = 0 );**

Sets the **user name**.

## Object methods (protected)

**void setNextAuthenticationRecord ( ImqAuthenticationRecord \* *pAir* = 0 );**

Sets the **next authentication record**.

**Attention:** Use this function only if you are sure that it will not break the authentication record list.

**void setPreviousAuthenticationRecord ( ImqAuthenticationRecord \* pAir = 0 );**

Sets the **previous authentication record**.

**Attention:** Use this function only if you are sure that it will not break the authentication record list.

## ImqBinary C++ class

This class encapsulates a binary byte array that can be used for ImqMessage **accounting token**, **correlation id**, and **message id** values. It allows easy assignment, copying, and comparison.

Figure 15. ImqBinary class

- [“Object attributes” on page 1801](#)
- [“Constructors” on page 1801](#)
- [“Overloaded ImqItem methods” on page 1802](#)
- [“Object methods \(public\)” on page 1802](#)
- [“Object methods \(protected\)” on page 1802](#)
- [“Reason codes” on page 1802](#)

### Object attributes

#### **data**

An array of bytes of binary data. The initial value is null.

#### **data length**

The number of bytes. The initial value is zero.

#### **data pointer**

The address of the first byte of the **data**. The initial value is zero.

### Constructors

#### **ImqBinary();**

The default constructor.

#### **ImqBinary( const ImqBinary & binary );**

The copy constructor.

#### **ImqBinary( const void \* data, const size\_t length );**

Copies *length* bytes from *data*.

## Overloaded ImqItem methods

### virtual ImqBoolean copyOut ( ImqMessage & msg );

Copies the **data** to the message buffer, replacing any existing content. Sets the *msg format* to MQFMT\_NONE.

See the ImqItem class method description for further details.

### virtual ImqBoolean pasteIn ( ImqMessage & msg );

Sets the **data** by transferring the remaining data from the message buffer, replacing the existing **data**.

To be successful, the ImqMessage **format** must be MQFMT\_NONE.

See the ImqItem class method description for further details.

## Object methods (public)

### void operator = ( const ImqBinary & binary );

Copies bytes from *binary*.

### ImqBoolean operator == ( const ImqBinary & binary );

Compares this object with *binary*. It returns FALSE if not equal and TRUE otherwise. The objects are equal if they have the same **data length** and the bytes match.

### ImqBoolean copyOut ( void \* buffer, const size\_t length, const char pad = 0 );

Copies up to *length* bytes from the **data pointer** to *buffer*. If the **data length** is insufficient, the remaining space in *buffer* is filled with *pad* bytes. *buffer* can be zero if *length* is also zero. *length* must not be negative. It returns TRUE if successful.

### size\_t dataLength ( ) const ;

Returns the **data length**.

### ImqBoolean setDataLength ( const size\_t length );

Sets the **data length**. If the **data length** is changed as a result of this method, the data in the object is uninitialized. It returns TRUE if successful.

### void \* dataPointer ( ) const ;

Returns the **data pointer**.

### ImqBoolean isNull ( ) const ;

Returns TRUE if the **data length** is zero, or if all the **data** bytes are zero. Otherwise it returns FALSE.

### ImqBoolean set ( const void \* buffer, const size\_t length );

Copies *length* bytes from *buffer*. It returns TRUE if successful.

## Object methods (protected)

### void clear ( );

Reduces the **data length** to zero.

## Reason codes

- MQRC\_NO\_BUFFER
- MQRC\_STORAGE\_NOT\_AVAILABLE
- MQRC\_INCONSISTENT\_FORMAT

## ImqCache C++ class

Use this class to hold or marshal data in memory.

Figure 16. ImqCache class

Use this class to hold or marshal data in memory. You can nominate a buffer of memory of fixed size, or the system can provide a flexible amount of memory automatically. This class relates to the MQI calls listed in [“ImqCache cross-reference”](#) on page 1784.

- [“Object attributes”](#) on page 1803
- [“Constructors”](#) on page 1804
- [“Object methods \(public\)”](#) on page 1804
- [“Reason codes”](#) on page 1805

### Object attributes

#### automatic buffer

Indicates whether buffer memory is managed automatically by the system (TRUE) or is supplied by the user (FALSE). It is initially set to TRUE.

This attribute is not set directly. It is set indirectly using either the **useEmptyBuffer** or the **useFullBuffer** method.

If user storage is supplied, this attribute is FALSE, buffer memory cannot grow, and buffer overflow errors can occur. The address and length of the buffer remain constant.

If user storage is not supplied, this attribute is TRUE, and buffer memory can grow incrementally to accommodate an arbitrary amount of message data. However, when the buffer grows, the address of the buffer might change, so be careful when using the **buffer pointer** and **data pointer**.

#### buffer length

The number of bytes of memory in the buffer. The initial value is zero.

#### buffer pointer

The address of the buffer memory. The initial value is null.

#### data length

The number of bytes succeeding the **data pointer**. This must be equal to or less than the **message length**. The initial value is zero.

**data offset**

The number of bytes preceding the **data pointer**. This must be equal to or less than the **message length**. The initial value is zero.

**data pointer**

The address of the part of the buffer that is to be written to or read from next. The initial value is null.

**message length**

The number of bytes of significant data in the buffer. The initial value is zero.

**Constructors****ImqCache();**

The default constructor.

**ImqCache( const ImqCache & cache );**

The copy constructor.

**Object methods (public)****void operator = ( const ImqCache & cache );**

Copies up to **message length** bytes of data from the *cache* object to the object. If **automatic buffer** is FALSE, the **buffer length** must already be sufficient to accommodate the copied data.

**ImqBoolean automaticBuffer ( ) const ;**

Returns the **automatic buffer** value.

**size\_t bufferLength ( ) const ;**

Returns the **buffer length**.

**char \* bufferPointer ( ) const ;**

Returns the **buffer pointer**.

**void clearMessage ( );**

Sets the **message length** and **data offset** to zero.

**size\_t dataLength ( ) const ;**

Returns the **data length**.

**size\_t dataOffset ( ) const ;**

Returns the **data offset**.

**ImqBoolean setDataOffset ( const size\_t offset );**

Sets the **data offset**. The **message length** is increased if necessary to ensure that it is no less than the **data offset**. This method returns TRUE if successful.

**char \* dataPointer ( ) const ;**

Returns a copy of the **data pointer**.

**size\_t messageLength ( ) const ;**

Returns the **message length**.

**ImqBoolean setMessageLength ( const size\_t length );**

Sets the **message length**. Increases the **buffer length** if necessary to ensure that the **message length** is no greater than the **buffer length**. Reduces the **data offset** if necessary to ensure that it is no greater than the **message length**. It returns TRUE if successful.

**ImqBoolean moreBytes ( const size\_t bytes-required );**

Assures that *bytes-required* more bytes are available (for writing) between the **data pointer** and the end of the buffer. It returns TRUE if successful.

If **automatic buffer** is TRUE, more memory is acquired as required; otherwise, the **buffer length** must already be adequate.

**ImqBoolean read ( const size\_t length, char \* & external-buffer );**

Copies *length* bytes, from the buffer starting at the **data pointer** position, into the *external-buffer*.

After the data has been copied, the **data offset** is increased by *length*. This method returns TRUE if successful.

**ImqBoolean resizeBuffer ( const size\_t length );**

Varies the **buffer length**, provided that **automatic buffer** is TRUE. This is achieved by reallocating the buffer memory. Up to **message length** bytes of data from the existing buffer are copied to the new one. The maximum number copied is *length* bytes. The **buffer pointer** is changed. The **message length** and **data offset** are preserved as closely as possible within the confines of the new buffer. It returns TRUE if successful, and FALSE if **automatic buffer** is FALSE.

**Note:** This method can fail with MQRC\_STORAGE\_NOT\_AVAILABLE if there is any problem with system resources.

**ImqBoolean useEmptyBuffer ( const char \* external-buffer, const size\_t length );**

Identifies an empty user buffer, setting the **buffer pointer** to point to *external-buffer*, the **buffer length** to *length*, and the **message length** to zero. Performs a **clearMessage**. If the buffer is fully primed with data, use the **useFullBuffer** method instead. If the buffer is partially primed with data, use the **setMessageLength** method to indicate the correct amount. This method returns TRUE if successful.

This method can be used to identify a fixed amount of memory, as described previously ( *external-buffer* is not null and *length* is nonzero), in which case **automatic buffer** is set to FALSE, or it can be used to revert to system-managed flexible memory ( *external-buffer* is null and *length* is zero), in which case **automatic buffer** is set to TRUE.

**ImqBoolean useFullBuffer ( const char \* externalBuffer, const size\_t length );**

As for **useEmptyBuffer**, except that the **message length** is set to *length*. It returns TRUE if successful.

**ImqBoolean write ( const size\_t length, const char \* external-buffer );**

Copies *length* bytes, from the *external-buffer*, into the buffer starting at the **data pointer** position. After the data has been copied, the **data offset** is increased by *length*, and the **message length** is increased if necessary to ensure that it is no less than the new **data offset** value. This method returns TRUE if successful.

If **automatic buffer** is TRUE, an adequate amount of memory is guaranteed; otherwise, the ultimate **data offset** must not exceed the **buffer length**.

**Reason codes**

- MQRC\_BUFFER\_NOT\_AUTOMATIC
- MQRC\_DATA\_TRUNCATED
- MQRC\_INSUFFICIENT\_BUFFER
- MQRC\_INSUFFICIENT\_DATA
- MQRC\_NULL\_POINTER
- MQRC\_STORAGE\_NOT\_AVAILABLE
- MQRC\_ZERO\_LENGTH

## ImqChannel C++ class

This class encapsulates a channel definition (MQCD) for use during execution of the `Manager::connect` method, for custom client connections.

Figure 17. `ImqChannel` class

See the description of the `Manager::connect` method, and [Sample program HELLO WORLD \(imqwrl.cpp\)](#), for more details.

Not all the listed methods are applicable to all platforms. See the descriptions of the [DEFINE CHANNEL](#) and [ALTER CHANNEL](#) commands for more information.

The `ImqChannel` class is not supported on z/OS.

- [“Object attributes” on page 1806](#)
- [“Constructors” on page 1807](#)
- [“Object methods \(public\)” on page 1808](#)
- [“Reason codes” on page 1811](#)

### Object attributes

#### **batch heart-beat**

The number of milliseconds between checks that a remote channel is active. The initial value is 0.

#### **channel name**

The name of the channel. The initial value is null.

#### **connection name**

The name of the connection. For example, the IP address of a host computer. The initial value is null.

#### **header compression**

The list of header data compression techniques supported by the channel. The initial values are all set to `MQCOMPRESS_NOT_AVAILABLE`.

#### **heart-beat interval**

The number of seconds between checks that a connection is still working. The initial value is 300.

#### **keep alive interval**

The number of seconds passed to the communications stack specifying the keep alive timing for the channel. The initial value is `MQKAI_AUTO`.

**local address**

The local communications address for the channel.

**maximum message length**

The maximum length of message supported by the channel in a single communication. The initial value is 4 194 304.

**message compression**

The list of message data compression techniques supported by the channel. The initial values are all set to MQCOMPRESS\_NOT\_AVAILABLE.

**mode name**

The name of the mode. The initial value is null.

**password**

A password supplied for connection authentication. The initial value is null.

**receive exit count**

The number of receive exits. The initial value is zero. This attribute is read-only.

**receive exit names**

The names of receive exits.

**receive user data**

Data associated with receive exits.

**security exit name**

The name of a security exit to be invoked on the server side of the connection. The initial value is null.

**security user data**

Data to be passed to the security exit. The initial value is null.

**send exit count**

The number of send exits. The initial value is zero. This attribute is read-only.

**send exit names**

The names of send exits.

**send user data**

Data associated with send exits.

**SSL CipherSpec**

CipherSpec for use with TLS.

**SSL client authentication type**

Client authentication type for use with TLS.

**SSL peer name**

Peer name for use with TLS.

**transaction program name**

The name of the transaction program. The initial value is null.

**transport type**

The transport type of the connection. The initial value is MQXPT\_LU62.

**user id**

A user identifier supplied for authorization. The initial value is null.

**Constructors****ImqChannel( ) ;**

The default constructor.

**ImqChannel( const ImqChannel & channel );**

The copy constructor.

## Object methods (public)

**void operator = ( const ImqChannel & channel );**

Copies instance data from *channel*, replacing any existing instance data.

**MQLONG batchHeartBeat() const ;**

Returns the **batch heart-beat**.

**ImqBoolean setBatchHeartBeat( const MQLONG heartbeat = 0L );**

Sets the **batch heart-beat**. This method returns TRUE if successful.

**ImqString channelName() const ;**

Returns the **channel name**.

**ImqBoolean setChannelName( const char \* name = 0 );**

Sets the **channel name**. This method returns TRUE if successful.

**ImqString connectionName() const ;**

Returns the **connection name**.

**ImqBoolean setConnectionName( const char \* name = 0 );**

Sets the **connection name**. This method returns TRUE if successful.

**size\_t headerCompressionCount() const ;**

Returns the supported header data compression techniques count.

**ImqBoolean headerCompression( const size\_t count, MQLONG compress [ ] ) const ;**

Returns copies of the supported header data compression techniques in **compress**. This method returns TRUE if successful.

**ImqBoolean setHeaderCompression( const size\_t count, const MQLONG compress [ ] );**

Sets the supported header data compression techniques to **compress**.

Sets the supported header data compression techniques count to **count**.

This method returns TRUE if successful.

**MQLONG heartBeatInterval() const ;**

Returns the **heart-beat interval**.

**ImqBoolean setHeartBeatInterval( const MQLONG interval = 300L );**

Sets the **heart-beat interval**. This method returns TRUE if successful.

**MQLONG keepAliveInterval() const ;**

Returns the **keep alive interval**.

**ImqBoolean setKeepAliveInterval( const MQLONG interval = MQKAI\_AUTO );**

Sets the **keep alive interval**. This method returns TRUE if successful.

**ImqString localAddress() const ;**

Returns the **local address**.

**ImqBoolean setLocalAddress ( const char \* address = 0 );**

Sets the **local address**. This method returns TRUE if successful.

**MQLONG maximumMessageLength() const ;**

Returns the **maximum message length**.

**ImqBoolean setMaximumMessageLength( const MQLONG length = 4194304L );**

Sets the **maximum message length**. This method returns TRUE if successful.

**size\_t messageCompressionCount() const ;**

Returns the supported message data compression techniques count.

**ImqBoolean messageCompression( const size\_t count, MQLONG compress [ ] ) const ;**

Returns copies of the supported message data compression techniques in **compress**. This method returns TRUE if successful.

**ImqBoolean setMessageCompression( const size\_t count, const MQLONG compress [ ] );**

Sets the supported message data compression techniques to **compress**.

Sets the supported message data compression techniques count to **count**.

This method returns TRUE if successful.

**ImqString modeName( ) const ;**

Returns the **mode name**.

**ImqBoolean setModeName( const char \* name = 0 );**

Sets the **mode name**. This method returns TRUE if successful.

**ImqString password( ) const ;**

Returns the **password**.

**ImqBoolean setPassword( const char \* password = 0 );**

Sets the **password**. This method returns TRUE if successful.

**size\_t receiveExitCount( ) const ;**

Returns the **receive exit count**.

**ImqString receiveExitName( );**

Returns the first of the **receive exit names**, if any. If the **receive exit count** is zero, it returns an empty string.

**ImqBoolean receiveExitNames( const size\_t count, ImqString \* names [ ] );**

Returns copies of the **receive exit names** in *names*. Sets any *names* in excess of **receive exit count** to null strings. This method returns TRUE if successful.

**ImqBoolean setReceiveExitName( const char \* name = 0 );**

Sets the **receive exit names** to the single *name*. *name* can be blank or null. Sets the **receive exit count** to either 1 or zero. Clears the **receive user data**. This method returns TRUE if successful.

**ImqBoolean setReceiveExitNames( const size\_t count, const char \* names [ ] );**

Sets the **receive exit names** to *names*. Individual *names* values must not be blank or null. Sets the **receive exit count** to *count*. Clears the **receive user data**. This method returns TRUE if successful.

**ImqBoolean setReceiveExitNames( const size\_t count, const ImqString \* names [ ] );**

Sets the **receive exit names** to *names*. Individual *names* values must not be blank or null. Sets the **receive exit count** to *count*. Clears the **receive user data**. This method returns TRUE if successful.

**ImqString receiveUserData( );**

Returns the first of the **receive user data** items, if any. If the **receive exit count** is zero, returns an empty string.

**ImqBoolean receiveUserData( const size\_t count, ImqString \* data [ ] );**

Returns copies of the **receive user data** items in *data*. Sets any *data* in excess of **receive exit count** to null strings. This method returns TRUE if successful.

**ImqBoolean setReceiveUserData( const char \* data = 0 );**

Sets the **receive user data** to the single item *data*. If *data* is not null, **receive exit count** must be at least 1. This method returns TRUE if successful.

**ImqBoolean setReceiveUserData( const size\_t count, const char \* data [ ] );**

Sets the **receive user data** to *data*. *count* must be no greater than the **receive exit count**. This method returns TRUE if successful.

**ImqBoolean setReceiveUserData( const size\_t count, const ImqString \* data [ ] );**

Sets the **receive user data** to *data*. *count* must be no greater than the **receive exit count**. This method returns TRUE if successful.

**ImqString securityExitName( ) const ;**

Returns the **security exit name**.

**ImqBoolean setSecurityExitName( const char \* name = 0 );**

Sets the **security exit name**. This method returns TRUE if successful.

**ImqString securityUserData( ) const ;**

Returns the **security user data**.

**ImqBoolean setSecurityUserData( const char \* data = 0 );**

Sets the **security user data**. This method returns TRUE if successful.

**size\_t sendExitCount( ) const ;**

Returns the **send exit count**.

**ImqString sendExitName();**

Returns the first of the **send exit names**, if any. Returns an empty string if the **send exit count** is zero.

**ImqBoolean sendExitNames( const size\_t count, ImqString \* names [ ] );**

Returns copies of the **send exit names** in *names*. Sets any *names* in excess of **send exit count** to null strings. This method returns TRUE if successful.

**ImqBoolean setSendExitName( const char \* name = 0 );**

Sets the **send exit names** to the single *name*. *name* can be blank or null. Sets the **send exit count** to either 1 or zero. Clears the **send user data**. This method returns TRUE if successful

**ImqBoolean setSendExitNames( const size\_t count, const char \* names [ ] );**

Sets the **send exit names** to *names*. Individual *names* values must not be blank or null. Sets the **send exit count** to *count*. Clears the **send user data**. This method returns TRUE if successful.

**ImqBoolean setSendExitNames( const size\_t count, const ImqString \* names [ ] );**

Sets the **send exit names** to *names*. Individual *names* values must not be blank or null. Sets the **send exit count** to *count*. Clears the **send user data**. This method returns TRUE if successful.

**ImqString sendUserData();**

Returns the first of the **send user data** items, if any. , Returns an empty string if the **send exit count** is zero.

**ImqBoolean sendUserData( const size\_t count, ImqString \* data [ ] );**

Returns copies of the **send user data** items in *data*. Sets any *data* in excess of **send exit count** to null strings. This method returns TRUE if successful.

**ImqBoolean setSendUserData( const char \* data = 0 );**

Sets the **send user data** to the single item *data*. If *data* is not null, **send exit count** must be at least 1. This method returns TRUE if successful.

**ImqBoolean setSendUserData( const size\_t count, const char \* data [ ] );**

Sets the **send user data** to *data*. *count* must be no greater than the **send exit count**. This method returns TRUE if successful.

**ImqBoolean setSendUserData( const size\_t count, const ImqString \* data [ ] );**

Sets the **send user data** to *data*. *count* must be no greater than the **send exit count**. This method returns TRUE if successful.

**ImqString sslCipherSpecification( ) const ;**

Returns the TLS cipher specification.

**ImqBoolean setSslCipherSpecification( const char \* name = 0 );**

Sets the TLS cipher specification. This method returns TRUE if successful.

**MQLONG sslClientAuthentication( ) const ;**

Returns the TLS client authentication type.

**ImqBoolean setSslClientAuthentication( const MQLONG auth = MQSCA\_REQUIRED);**

Sets the TLS client authentication type. This method returns TRUE if successful.

**ImqString sslPeerName( ) const ;**

Returns the TLS peer name.

**ImqBoolean setSslPeerName( const char \* name = 0 );**

Sets the TLS peer name. This method returns TRUE if successful.

**ImqString transactionProgramName( ) const ;**

Returns the **transaction program name**.

**ImqBoolean setTransactionProgramName( const char \* name = 0 );**

Sets the **transaction program name**. This method returns TRUE if successful.

**MQLONG transportType( ) const ;**

Returns the **transport type**.

**ImqBoolean setTransportType( const MQLONG type = MQXPT\_LU62 );**

Sets the **transport type**. This method returns TRUE if successful.

**ImqString userId( ) const ;**

Returns the **user id**.

**ImqBoolean setUserId( const char \* id = 0 );**

Sets the **user id**. This method returns TRUE if successful.

### Reason codes

- MQRC\_DATA\_LENGTH\_ERROR
- MQRC\_ITEM\_COUNT\_ERROR
- MQRC\_NULL\_POINTER
- MQRC\_SOURCE\_BUFFER\_ERROR

## ImqCICSBridgeHeader C++ class

This class encapsulates specific features of the MQCIH data structure.

Figure 18. *ImqCICSBridgeHeader* class

Objects of this class are used by applications that send messages to the CICS bridge through IBM MQ for z/OS.

- [“Object attributes” on page 1811](#)
- [“Constructors” on page 1814](#)
- [“Overloaded ImqItem methods” on page 1814](#)
- [“Object methods \(public\)” on page 1814](#)
- [“Object data \(protected\)” on page 1816](#)
- [“Reason codes” on page 1816](#)
- [“Return codes” on page 1816](#)

### Object attributes

#### ADS descriptor

Send/receive ADS descriptor. This is set using MQCADSD\_NONE. The initial value is MQCADSD\_NONE. The following additional values are possible:

- MQCADSD\_NONE
- MQCADSD\_SEND
- MQCADSD\_RECV

- MQCADSD\_MSGFORMAT

**attention identifier**

AID key. The field must be of length MQ\_ATTENTION\_ID\_LENGTH.

**authenticator**

RACF password or passticket. The initial value contains blanks, of length MQ\_AUTHENTICATOR\_LENGTH.

**bridge abend code**

Bridge abend code, of length MQ\_ABEND\_CODE\_LENGTH. The initial value is four blank characters. The value returned in this field is dependent on the return code. See [Table 867 on page 1816](#) for more details.

**bridge cancel code**

Bridge abend transaction code. The field is reserved, must contain blanks, and be of length MQ\_CANCEL\_CODE\_LENGTH.

**bridge completion code**

Completion code, which can contain either the IBM MQ completion code or the CICS EIBRESP value. The field has the initial value of MQCC\_OK. The value returned in this field is dependent on the return code. See [Table 867 on page 1816](#) for more details.

**bridge error offset**

Bridge error offset. The initial value is zero. This attribute is read-only.

**bridge reason code**

Reason code. This field can contain either the IBM MQ reason or the CICS EIBRESP2 value. The field has the initial value of MQRC\_NONE. The value returned in this field is dependent on the return code. See [Table 867 on page 1816](#) for more details.

**bridge return code**

Return code from the CICS bridge. The initial value is MQCRC\_OK.

**conversational task**

Whether the task can be conversational. The initial value is MQCCT\_NO. The following additional values are possible:

- MQCCT\_YES
- MQCCT\_NO

**cursor position**

Cursor position. The initial value is zero.

**facility keep time**

CICS bridge facility release time.

**facility like**

Terminal emulated attribute. The field must be of length MQ\_FACILITY\_LIKE\_LENGTH.

**facility token**

BVT token value. The field must be of length MQ\_FACILITY\_LENGTH. The initial value is MQCFAC\_NONE.

**function**

Function, which can contain either the IBM MQ call name or the CICS EIBFN function. The field has the initial value of MQCFUNC\_NONE, with length MQ\_FUNCTION\_LENGTH. The value returned in this field is dependent on the return code. See [Table 867 on page 1816](#) for more details.

The following additional values are possible when **function** contains an IBM MQ call name:

- MQCFUNC\_MQCONN
- MQCFUNC\_MQGET
- MQCFUNC\_MQINQ
- MQCFUNC\_NONE
- MQCFUNC\_MQOPEN

- MQCFUNC\_PUT
- MQCFUNC\_MQPUT1

**get wait interval**

Wait interval for an MQGET call issued by the CICS bridge task. The initial value is MQCGWI\_DEFAULT. The field applies only when **uow control** has the value MQCUOWC\_FIRST. The following additional values are possible:

- MQCGWI\_DEFAULT
- MQWI\_UNLIMITED

**link type**

Link type. The initial value is MQCLT\_PROGRAM. The following additional values are possible:

- MQCLT\_PROGRAM
- MQCLT\_TRANSACTION

**next transaction identifier**

ID of the next transaction to attach. The field must be of length MQ\_TRANSACTION\_ID\_LENGTH.

**output data length**

COMMAREA data length. The initial value is MQCODL\_AS\_INPUT.

**reply-to format**

Format name of the reply message. The initial value is MQFMT\_NONE with length MQ\_FORMAT\_LENGTH.

**start code**

Transaction start code. The field must be of length MQ\_START\_CODE\_LENGTH. The initial value is MQCSC\_NONE. The following additional values are possible:

- MQCSC\_START
- MQCSC\_STARTDATA
- MQCSC\_TERMINPUT
- MQCSC\_NONE

**task end status**

Task end status. The initial value is MQCTES\_NOSYNC. The following additional values are possible:

- MQCTES\_COMMIT
- MQCTES\_BACKOUT
- MQCTES\_ENDTASK
- MQCTES\_NOSYNC

**transaction identifier**

ID of the transaction to attach. The initial value must contain blanks, and must be of length MQ\_TRANSACTION\_ID\_LENGTH. The field applies only when **uow control** has the value MQCUOWC\_FIRST or MQCUOWC\_ONLY.

**UOW control**

UOW control. The initial value is MQCUOWC\_ONLY. The following additional values are possible:

- MQCUOWC\_FIRST
- MQCUOWC\_MIDDLE
- MQCUOWC\_LAST
- MQCUOWC\_ONLY
- MQCUOWC\_COMMIT
- MQCUOWC\_BACKOUT
- MQCUOWC\_CONTINUE

## version

The MQCIH version number. The initial value is MQCIH\_VERSION\_2. The only other supported value is MQCIH\_VERSION\_1.

## Constructors

### **ImqCICSBridgeHeader( );**

The default constructor.

### **ImqCICSBridgeHeader( const ImqCICSBridgeHeader & header );**

The copy constructor.

## Overloaded ImqItem methods

### **virtual ImqBoolean copyOut( ImqMessage & msg );**

Inserts an MQCIH data structure into the message buffer at the beginning, moving existing message data further along, and sets the message format to MQFMT\_CICS.

See the parent class method description for more details.

### **virtual ImqBoolean pasteIn( ImqMessage & msg );**

Reads an MQCIH data structure from the message buffer. To be successful, the encoding of the *msg* object must be MQENC\_NATIVE. Retrieve messages with MQGMO\_CONVERT to MQENC\_NATIVE. To be successful, the ImqMessage format must be MQFMT\_CICS.

See the parent class method description for more details.

## Object methods (public)

### **void operator = ( const ImqCICSBridgeHeader & header );**

Copies instance data from the *header*, replacing the existing instance data.

### **MQLONG ADSDescriptor( ) const;**

Returns a copy of the **ADS descriptor**.

### **void setADSDescriptor( const MQLONG descriptor = MQCADSD\_NONE );**

Sets the **ADS descriptor**.

### **ImqString attentionIdentifier( ) const;**

Returns a copy of the **attention identifier**, padded with trailing blanks to length MQ\_ATTENTION\_ID\_LENGTH.

### **void setAttentionIdentifier( const char \* data = 0 );**

Sets the **attention identifier**, padded with trailing blanks to length MQ\_ATTENTION\_ID\_LENGTH. If no *data* is supplied, resets **attention identifier** to the initial value.

### **ImqString authenticator( ) const;**

Returns a copy of the **authenticator**, padded with trailing blanks to length MQ\_AUTHENTICATOR\_LENGTH.

### **void setAuthenticator( const char \* data = 0 );**

Sets the **authenticator**, padded with trailing blanks to length MQ\_AUTHENTICATOR\_LENGTH. If no *data* is supplied, resets **authenticator** to the initial value.

### **ImqString bridgeAbendCode( ) const;**

Returns a copy of the **bridge abend code**, padded with trailing blanks to length MQ\_ABEND\_CODE\_LENGTH.

### **ImqString bridgeCancelCode( ) const;**

Returns a copy of the **bridge cancel code**, padded with trailing blanks to length MQ\_CANCEL\_CODE\_LENGTH.

### **void setBridgeCancelCode( const char \* data = 0 );**

Sets the **bridge cancel code**, padded with trailing blanks to length MQ\_CANCEL\_CODE\_LENGTH. If no *data* is supplied, resets the **bridge cancel code** to the initial value.

**MQLONG bridgeCompletionCode() const;**  
Returns a copy of the **bridge completion code**.

**MQLONG bridgeErrorOffset() const ;**  
Returns a copy of the **bridge error offset**.

**MQLONG bridgeReasonCode() const;**  
Returns a copy of the **bridge reason code**.

**MQLONG bridgeReturnCode() const;**  
Returns the **bridge return code**.

**MQLONG conversationalTask() const;**  
Returns a copy of the **conversational task**.

**void setConversationalTask( const MQLONG task = MQCCT\_NO );**  
Sets the **conversational task**.

**MQLONG cursorPosition() const ;**  
Returns a copy of the **cursor position**.

**void setCursorPosition( const MQLONG position = 0 );**  
Sets the **cursor position**.

**MQLONG facilityKeepTime() const;**  
Returns a copy of the **facility keep time**.

**void setFacilityKeepTime( const MQLONG time = 0 );**  
Sets the **facility keep time**.

**ImqString facilityLike() const;**  
Returns a copy of the **facility like**, padded with trailing blanks to length MQ\_FACILITY\_LIKE\_LENGTH.

**void setFacilityLike( const char \* name = 0 );**  
Sets the **facility like**, padded with trailing blanks to length MQ\_FACILITY\_LIKE\_LENGTH. If no *name* is supplied, resets **facility like** the initial value.

**ImqBinary facilityToken() const;**  
Returns a copy of the **facility token**.

**ImqBoolean setFacilityToken( const ImqBinary & token );**  
Sets the **facility token**. The **data length** of *token* must be either zero or MQ\_FACILITY\_LENGTH. It returns TRUE if successful.

**void setFacilityToken( const MQBYTE8 token = 0 );**  
Sets the **facility token**. *token* can be zero, which is the same as specifying MQCFAC\_NONE. If *token* is nonzero it must address MQ\_FACILITY\_LENGTH bytes of binary data. When using predefined values such as MQCFAC\_NONE, you might need to make a cast to ensure a signature match. For example, (MQBYTE \*)MQCFAC\_NONE.

**ImqString function() const;**  
Returns a copy of the **function**, padded with trailing blanks to length MQ\_FUNCTION\_LENGTH.

**MQLONG getWaitInterval() const;**  
Returns a copy of the **get wait interval**.

**void setGetWaitInterval( const MQLONG interval = MQCGWI\_DEFA**  
Sets the **get wait interval**.

**MQLONG linkType() const;**  
Returns a copy of the **link type**.

**void setLinkType( const MQLONG type = MQCLT\_PROGRAM );**  
Sets the **link type**.

**ImqString nextTransactionIdentifier() const ;**  
Returns a copy of the **next transaction identifier** data, padded with trailing blanks to length MQ\_TRANSACTION\_ID\_LENGTH.

**MQLONG outputDataLength() const;**  
Returns a copy of the **output data length**.

**void setOutputDataLength( const MQLONG length = MQCODL\_AS\_INPUT );**

Sets the **output data length**.

**ImqString replyToFormat( ) const;**

Returns a copy of the **reply-to format** name, padded with trailing blanks to length MQ\_FORMAT\_LENGTH.

**void setReplyToFormat( const char \* name = 0 );**

Sets the **reply-to format**, padded with trailing blanks to length MQ\_FORMAT\_LENGTH. If no *name* is supplied, resets **reply-to format** to the initial value.

**ImqString startCode( ) const;**

Returns a copy of the **start code**, padded with trailing blanks to length MQ\_START\_CODE\_LENGTH.

**void setStartCode( const char \* data = 0 );**

Sets the **start code** data, padded with trailing blanks to length MQ\_START\_CODE\_LENGTH. If no *data* is supplied, resets **start code** to the initial value.

**MQLONG taskEndStatus( ) const;**

Returns a copy of the **task end status**.

**ImqString transactionIdentifier( ) const;**

Returns a copy of the **transaction identifier** data, padded with trailing blanks to the length MQ\_TRANSACTION\_ID\_LENGTH.

**void setTransactionIdentifier( const char \* data = 0 );**

Sets the **transaction identifier**, padded with trailing blanks to length MQ\_TRANSACTION\_ID\_LENGTH. If no *data* is supplied, resets **transaction identifier** to the initial value.

**MQLONG UOWControl( ) const;**

Returns a copy of the **UOW control**.

**void setUOWControl( const MQLONG control = MQCUOWC\_ONLY );**

Sets the **UOW control**.

**MQLONG version( ) const;**

Returns the **version** number.

**ImqBoolean setVersion( const MQLONG version = MQCIH\_VERSION\_2 );**

Sets the **version** number. It returns TRUE if successful.

## Object data (protected)

**MQLONG olVersion**

The maximum MQCIH version number that can be accommodated in the storage allocated for *opcih*.

**PMQCIH opcih**

The address of an MQCIH data structure. The amount of storage allocated is indicated by *olVersion*.

## Reason codes

## ImqDeadLetterHeader C++ class

This class encapsulates features of the MQDLH data structure.

Figure 19. ImqDeadLetterHeader class

Objects of this class are typically used by an application that encounters a message that cannot be processed. A new message comprising a dead-letter header and the message content is placed on the dead-letter queue, and the message is discarded.

- [“Object attributes” on page 1818](#)
- [“Constructors” on page 1818](#)
- [“Overloaded ImqItem methods” on page 1818](#)
- [“Object methods \(public\)” on page 1818](#)
- [“Object data \(protected\)” on page 1819](#)
- [“Reason codes” on page 1819](#)

## Object attributes

### dead-letter reason code

The reason the message arrived on the dead-letter queue. The initial value is MQRC\_NONE.

### destination queue manager name

The name of the original destination queue manager. The name is a string of length MQ\_Q\_MGR\_NAME\_LENGTH. Its initial value is null.

### destination queue name

The name of the original destination queue. The name is a string of length MQ\_Q\_NAME\_LENGTH. Its initial value is null.

### put application name

The name of the application that put the message on the dead-letter queue. The name is a string of length MQ\_PUT\_APPL\_NAME\_LENGTH. Its initial value is null.

### put application type

The type of application that put the message on the dead-letter queue. The initial value is zero.

### put date

The date when the message was put on the dead-letter queue. The date is a string of length MQ\_PUT\_DATE\_LENGTH. Its initial value is a null string.

### put time

The time when the message was put on the dead-letter queue. The time is a string of length MQ\_PUT\_TIME\_LENGTH. Its initial value is a null string.

## Constructors

### ImqDeadLetterHeader();

The default constructor.

### ImqDeadLetterHeader( const ImqDeadLetterHeader & header );

The copy constructor.

## Overloaded ImqItem methods

### virtual ImqBoolean copyOut ( ImqMessage & msg );

Inserts an MQDLH data structure into the message buffer at the beginning, moving existing message data further along. Sets the *msg* format to MQFMT\_DEAD\_LETTER\_HEADER.

See the ImqHeader class method description on page [“ImqHeader C++ class” on page 1826](#) for further details.

### virtual ImqBoolean pasteIn ( ImqMessage & msg );

Reads an MQDLH data structure from the message buffer.

To be successful, the ImqMessage format must be MQFMT\_DEAD\_LETTER\_HEADER.

See the ImqHeader class method description on page [“ImqHeader C++ class” on page 1826](#) for further details.

## Object methods (public)

### void operator = ( const ImqDeadLetterHeader & header );

Copies instance data is copied from *header*, replacing the existing instance data.

### MQLONG deadLetterReasonCode ( ) const ;

Returns the dead-letter reason code.

### void setDeadLetterReasonCode ( const MQLONG reason );

Sets the dead-letter reason code.

### ImqString destinationQueueManagerName ( ) const ;

Returns the destination queue manager name, stripped of any trailing blanks.

**void setDestinationQueueManagerName ( const char \* name );**

Sets the destination queue manager name. Truncates data longer than MQ\_Q\_MGR\_NAME\_LENGTH (48 characters).

**ImqString destinationQueueName ( ) const ;**

Returns a copy of the destination queue name, stripped of any trailing blanks.

**void setDestinationQueueName ( const char \* name );**

Sets the destination queue name. Truncates data longer than MQ\_Q\_NAME\_LENGTH (48 characters).

**ImqString putApplicationName ( ) const ;**

Returns a copy of the put application name, stripped of any trailing blanks.

**void setPutApplicationName ( const char \* name = 0 );**

Sets the put application name. Truncates data longer than MQ\_PUT\_APPL\_NAME\_LENGTH (28 characters).

**MQLONG putApplicationType ( ) const ;**

Returns the put application type.

**void setPutApplicationType ( const MQLONG type = MQAT\_NO\_CONTEXT );**

Sets the put application type.

**ImqString putDate ( ) const ;**

Returns a copy of the put date, stripped of any trailing blanks.

**void setPutDate ( const char \* date = 0 );**

Sets the put date. Truncates data longer than MQ\_PUT\_DATE\_LENGTH (8 characters).

**ImqString putTime ( ) const ;**

Returns a copy of the put time, stripped of any trailing blanks.

**void setPutTime ( const char \* time = 0 );**

Sets the put time. Truncates data longer than MQ\_PUT\_TIME\_LENGTH (8 characters).

## Object data (protected)

**MQDLH omqdlh**

The MQDLH data structure.

## Reason codes

- MQRC\_INCONSISTENT\_FORMAT
- MQRC\_STRUC\_ID\_ERROR
- MQRC\_ENCODING\_ERROR

## ImqDistributionList C++ class

This class encapsulates a dynamic distribution list that references one or more queues for the purpose of sending a message or messages to multiple destinations.

Figure 20. *ImqDistributionList* class

- [“Object attributes” on page 1820](#)
- [“Constructors” on page 1820](#)
- [“Object methods \(public\)” on page 1820](#)
- [“Object methods \(protected\)” on page 1821](#)

### Object attributes

#### first distributed queue

The first of one or more objects of class , in no particular order, in which the **distribution list reference** addresses this object.

Initially there are no such objects. To open an *ImqDistributionList* successfully, there must be at least one such object.

**Note:** When an *ImqDistributionList* object is opened, any open objects that reference it are automatically closed.

### Constructors

#### **ImqDistributionList();**

The default constructor.

#### **ImqDistributionList( const ImqDistributionList & list );**

The copy constructor.

### Object methods (public)

#### **void operator = ( const ImqDistributionList & list );**

All objects that reference **this** object are dereferenced before copying. No objects will reference **this** object after the invocation of this method.

**\* firstDistributedQueue ( ) const ;**  
Returns the **first distributed queue**.

### Object methods (protected)

**void setFirstDistributedQueue ( \* queue = 0 );**  
Sets the **first distributed queue**.

## ImqError C++ class

This abstract class provides information on errors associated with an object.

Figure 21. *ImqError* class

- [“Object attributes” on page 1821](#)
- [“Constructors” on page 1821](#)
- [“Object methods \(public\)” on page 1821](#)
- [“Object methods \(protected\)” on page 1822](#)
- [“Reason codes” on page 1822](#)

### Object attributes

#### completion code

The most recent completion code. The initial value is zero. The following additional values are possible:

- MQCC\_OK
- MQCC\_WARNING
- MQCC\_FAILED

#### reason code

The most recent reason code. The initial value is zero.

### Constructors

#### **ImqError( );**

The default constructor.

#### **ImqError( const ImqError & error );**

The copy constructor.

### Object methods (public)

#### **void operator = ( const ImqError & error );**

Copies instance data from *error*, replacing the existing instance data.

#### **void clearErrorCodes ( );**

Sets the **completion code** and **reason code** both to zero.

**MQLONG completionCode ( ) const ;**

Returns the **completion code**.

**MQLONG reasonCode ( ) const ;**

Returns the **reason code**.

### Object methods (protected)

**ImqBoolean checkReadPointer ( const void \* *pointer*, const size\_t *length* );**

Verifies that the combination of pointer and length is valid for read-only access, and returns TRUE if successful.

**ImqBoolean checkWritePointer ( const void \* *pointer*, const size\_t *length* );**

Verifies that the combination of pointer and length is valid for read-write access, and returns TRUE if successful.

**void setCompletionCode ( const MQLONG *code* = 0 );**

Sets the **completion code**.

**void setReasonCode ( const MQLONG *code* = 0 );**

Sets the **reason code**.

### Reason codes

- MQRC\_BUFFER\_ERROR

## ImqGetMessageOptions C++ class

This class encapsulates the MQGMO data structure

Figure 22. *ImqGetMessageOptions* class

- [“Object attributes” on page 1823](#)
- [“Constructors” on page 1824](#)
- [“Object methods \(public\)” on page 1824](#)
- [“Object methods \(protected\)” on page 1825](#)
- [“Object data \(protected\)” on page 1825](#)
- [“Reason codes” on page 1825](#)

## Object attributes

### group status

Status of a message for a group of messages. The initial value is MQGS\_NOT\_IN\_GROUP. The following additional values are possible:

- MQGS\_MSG\_IN\_GROUP
- MQGS\_LAST\_MSG\_IN\_GROUP

### match options

Options for selecting incoming messages. The initial value is MQMO\_MATCH\_MSG\_ID | MQMO\_MATCH\_CORREL\_ID. The following additional values are possible:

- MQMO\_GROUP\_ID
- MQMO\_MATCH\_MSG\_SEQ\_NUMBER
- MQMO\_MATCH\_OFFSET
- MQMO\_MSG\_TOKEN
- MQMO\_NONE

### message token

Message token. A binary value (MQBYTE16) of length MQ\_MSG\_TOKEN\_LENGTH. The initial value is MQMTOK\_NONE.

### options

Options applicable to a message. The initial value is MQGMO\_NO\_WAIT. The following additional values are possible:

- MQGMO\_WAIT
- MQGMO\_SYNCPOINT
- MQGMO\_SYNCPOINT\_IF\_PERSISTENT
- MQGMO\_NO\_SYNCPOINT
- MQGMO\_MARK\_SKIP\_BACKOUT
- MQGMO\_BROWSE\_FIRST
- MQGMO\_BROWSE\_NEXT
- MQGMO\_BROWSE\_MSG\_UNDER\_CURSOR
- MQGMO\_MSG\_UNDER\_CURSOR
- MQGMO\_LOCK
- MQGMO\_UNLOCK
- MQGMO\_ACCEPT\_TRUNCATED\_MSG
- MQGMO\_SET\_SIGNAL
- MQGMO\_FAIL\_IF QUIESCING
- MQGMO\_CONVERT
- MQGMO\_LOGICAL\_ORDER
- MQGMO\_COMPLETE\_MSG
- MQGMO\_ALL\_MSGS\_AVAILABLE
- MQGMO\_ALL\_SEGMENTS\_AVAILABLE
- MQGMO\_NONE

### resolved queue name

Resolved queue name. This attribute is read-only. Names are never longer than 48 characters and can be padded to that length with nulls. The initial value is a null string.

### returned length

Returned length. The initial value is MQRL\_UNDEFINED. This attribute is read-only.

### **segmentation**

The ability to segment a message. The initial value is MQSEG\_INHIBITED. The additional value, MQSEG\_ALLOWED, is possible.

### **segment status**

The segmentation status of a message. The initial value is MQSS\_NOT\_A\_SEGMENT. The following additional values are possible:

- MQSS\_SEGMENT
- MQSS\_LAST\_SEGMENT

### **syncpoint participation**

TRUE when messages are retrieved under syncpoint control.

### **wait interval**

The length of time that the class get method pauses while waiting for a suitable message to arrive, if one is not already available. The initial value is zero, which effects an indefinite wait. The additional value, MQWI\_UNLIMITED, is possible. This attribute is ignored unless the options include MQGMO\_WAIT.

## **Constructors**

### **ImqGetMessageOptions( );**

The default constructor.

### **ImqGetMessageOptions( const ImqGetMessageOptions & gmo );**

The copy constructor.

## **Object methods (public)**

### **void operator = ( const ImqGetMessageOptions & gmo );**

Copies instance data from *gmo*, replacing the existing instance data.

### **MQCHAR groupStatus ( ) const ;**

Returns the group status.

### **void setGroupStatus ( const MQCHAR status );**

Sets the group status.

### **MQLONG matchOptions ( ) const ;**

Returns the match options.

### **void setMatchOptions ( const MQLONG options );**

Sets the match options.

### **ImqBinary messageToken ( ) const;**

Returns the message token.

### **ImqBoolean setMessageToken( const ImqBinary & token );**

Sets the message token. The data length of *token* must be either zero or MQ\_MSG\_TOKEN\_LENGTH. This method returns TRUE if successful.

### **void setMessageToken( const MQBYTE16 token = 0 );**

Sets the message token. *token* can be zero, which is the same as specifying MQMTOK\_NONE. If *token* is nonzero, then it must address MQ\_MSG\_TOKEN\_LENGTH bytes of binary data.

When using predefined values, such as MQMTOK\_NONE, you might not need to make a cast to ensure a signature match, for example (MQBYTE \*)MQMTOK\_NONE.

### **MQLONG options ( ) const ;**

Returns the options.

### **void setOptions ( const MQLONG options );**

Sets the options, including the syncpoint participation value.

### **ImqString resolvedQueueName ( ) const ;**

Returns a copy of the resolved queue name.

**MQLONG returnedLength( ) const;**

Returns the returned length.

**MQCHAR segmentation ( ) const ;**

Returns the segmentation.

**void setSegmentation ( const MQCHAR value );**

Sets the segmentation.

**MQCHAR segmentStatus ( ) const ;**

Returns the segment status.

**void setSegmentStatus ( const MQCHAR status );**

Sets the segment status.

**ImqBoolean syncPointParticipation ( ) const ;**

Returns the syncpoint participation value, which is TRUE if the options include either MQGMO\_SYNCPOINT or MQGMO\_SYNCPOINT\_IF\_PERSISTENT.

**void setSyncPointParticipation ( const ImqBoolean sync );**

Sets the syncpoint participation value. If *sync* is TRUE, alters the options to include MQGMO\_SYNCPOINT, and to exclude both MQGMO\_NO\_SYNCPOINT and MQGMO\_SYNCPOINT\_IF\_PERSISTENT. If *sync* is FALSE, alters the options to include MQGMO\_NO\_SYNCPOINT, and to exclude both MQGMO\_SYNCPOINT and MQGMO\_SYNCPOINT\_IF\_PERSISTENT.

**MQLONG waitInterval ( ) const ;**

Returns the wait interval.

**void setWaitInterval ( const MQLONG interval );**

Sets the wait interval.

**Object methods (protected)****static void setVersionSupported ( const MQLONG );**

Sets the MQGMO version. Defaults to MQGMO\_VERSION\_3.

**Object data (protected)****MQGMO omqgmo**

An MQGMO Version 2 data structure. Access MQGMO fields supported for MQGMO\_VERSION\_2 only.

**PMQGMO opgmo**

The address of an MQGMO data structure. The version number for this address is indicated in *olVersion*. Inspect the version number before accessing MQGMO fields, to ensure that they are present.

**MQLONG olVersion**

The version number of the MQGMO data structure addressed by *opgmo*.

**Reason codes**

- MQRC\_BINARY\_DATA\_LENGTH\_ERROR

## ImqHeader C++ class

This abstract class encapsulates common features of the MQDLH data structure.

Figure 23. ImqHeader class

- [“Object attributes” on page 1826](#)
- [“Constructors” on page 1826](#)
- [“Object methods \(public\)” on page 1827](#)

### Object attributes

#### character set

The original coded character set identifier. Initially MQCCSI\_Q\_MGR.

#### encoding

The original encoding. Initially MQENC\_NATIVE.

#### format

The original format. Initially MQFMT\_NONE.

#### header flags

The initial values are:

- Zero for objects of the ImqDeadLetterHeader class
- MQIIH\_NONE for objects of the ImqIMSBridgeHeader class
- MQRMHF\_LAST for objects of the ImqReferenceHeader class
- MQCIH\_NONE for objects of the ImqCICSBridgeHeader class
- MQWIH\_NONE for objects of the ImqWorkHeader class

### Constructors

#### ImqHeader();

The default constructor.

#### ImqHeader( const ImqHeader & header );

The copy constructor.

## Object methods (public)

**void operator = ( const ImqHeader & header );**

Copies instance data from *header*, replacing the existing instance data.

**virtual MQLONG characterSet ( ) const ;**

Returns the **character set**.

**virtual void setCharacterSet ( const MQLONG ccsid = MQCCSI\_Q\_MGR );**

Sets the **character set**.

**virtual MQLONG encoding ( ) const ;**

Returns the **encoding**.

**virtual void setEncoding ( const MQLONG encoding = MQENC\_NATIVE );**

Sets the **encoding**.

**virtual ImqString format ( ) const ;**

Returns a copy of the **format**, including trailing blanks.

**virtual void setFormat ( const char \* name = 0 );**

Sets the **format**, padded to 8 characters with trailing blanks.

**virtual MQLONG headerFlags ( ) const ;**

Returns the **header flags**.

**virtual void setHeaderFlags ( const MQLONG flags = 0 );**

Sets the **header flags**.

## ImqIMSBridgeHeader C++ class

This class encapsulates features of the MQIIH data structure.

Figure 24. *ImqIMSBridgeHeader* class

Objects of this class are used by applications that send messages to the IMS bridge through IBM MQ for z/OS.

**Note:** The *ImqHeader* character set and encoding must have default values and must not be set to any other values.

- [“Object attributes” on page 1828](#)
- [“Constructors” on page 1828](#)
- [“Overloaded \*ImqItem\* methods” on page 1828](#)

- [“Object methods \(public\)” on page 1829](#)
- [“Object data \(protected\)” on page 1829](#)
- [“Reason codes” on page 1829](#)

## Object attributes

### authenticator

RACF password or passticket, of length MQ\_AUTHENTICATOR\_LENGTH. The initial value is MQIAUT\_NONE.

### commit mode

Commit mode. See the *OTMA User's Guide* for more information about IMS commit modes. The initial value is MQICM\_COMMIT\_THEN\_SEND. The additional value, MQICM\_SEND\_THEN\_COMMIT, is possible.

### logical terminal override

Logical terminal override, of length MQ\_LTERM\_OVERRIDE\_LENGTH. The initial value is a null string.

### message format services map name

MFS map name, of length MQ\_MFS\_MAP\_NAME\_LENGTH. The initial value is a null string.

### reply-to format

Format of any reply, of length MQ\_FORMAT\_LENGTH. The initial value is MQFMT\_NONE.

### security scope

Scope of IMS security processing. The initial value is MQISS\_CHECK. The additional value, MQISS\_FULL, is possible.

### transaction instance id

Transaction instance identity, a binary (MQBYTE16) value of length MQ\_TRAN\_INSTANCE\_ID\_LENGTH. The initial value is MQITII\_NONE.

### transaction state

State of the IMS conversation. The initial value is MQITS\_NOT\_IN\_CONVERSATION. The additional value, MQITS\_IN\_CONVERSATION, is possible.

## Constructors

### ImqIMSBridgeHeader();

The default constructor.

### ImqIMSBridgeHeader( const ImqIMSBridgeHeader & header );

The copy constructor.

## Overloaded ImqItem methods

### virtual ImqBoolean copyOut ( ImqMessage & msg );

Inserts an MQIIH data structure into the message buffer at the beginning, moving existing message data further along. Sets the *msg* format to MQFMT\_IMS.

See the parent class method description for further details.

### virtual ImqBoolean pasteIn ( ImqMessage & msg );

Reads an MQIIH data structure from the message buffer.

To be successful, the encoding of the *msg* object must be MQENC\_NATIVE. Retrieve messages with MQGMO\_CONVERT to MQENC\_NATIVE.

To be successful, the ImqMessage format must be MQFMT\_IMS.

See the parent class method description for further details.

## Object methods (public)

**void operator = ( const ImqIMSBridgeHeader & header );**

Copies instance data from *header*, replacing the existing instance data.

**ImqString authenticator ( ) const ;**

Returns a copy of the authenticator, padded with trailing blanks to length MQ\_AUTHENTICATOR\_LENGTH.

**void setAuthenticator ( const char \* name );**

Sets the authenticator.

**MQCHAR commitMode ( ) const ;**

Returns the commit mode.

**void setCommitMode ( const MQCHAR mode );**

Sets the commit mode.

**ImqString logicalTerminalOverride ( ) const ;**

Returns a copy of the logical terminal override.

**void setLogicalTerminalOverride ( const char \* override );**

Sets the logical terminal override.

**ImqString messageFormatServicesMapName ( ) const ;**

Returns a copy of the message format services map name.

**void setMessageFormatServicesMapName ( const char \* name );**

Sets the message format services map name.

**ImqString replyToFormat ( ) const ;**

Returns a copy of the reply-to format, padded with trailing blanks to length MQ\_FORMAT\_LENGTH.

**void setReplyToFormat ( const char \* format );**

Sets the reply-to format, padded with trailing blanks to length MQ\_FORMAT\_LENGTH.

**MQCHAR securityScope ( ) const ;**

Returns the security scope.

**void setSecurityScope ( const MQCHAR scope );**

Sets the security scope.

**ImqBinary transactionInstanceId ( ) const ;**

Returns a copy of the transaction instance id.

**ImqBoolean setTransactionInstanceId ( const ImqBinary & id );**

Sets the transaction instance id. The data length of *token* must be either zero or MQ\_TRAN\_INSTANCE\_ID\_LENGTH. This method returns TRUE if successful.

**void setTransactionInstanceId ( const MQBYTE16 id = 0 );**

Sets the transaction instance id. *id* can be zero, which is the same as specifying MQITII\_NONE. If *id* is nonzero, it must address MQ\_TRAN\_INSTANCE\_ID\_LENGTH bytes of binary data. When using predefined values such as MQITII\_NONE, you might need to make a cast to ensure a signature match, for example (MQBYTE \*)MQITII\_NONE.

**MQCHAR transactionState ( ) const ;**

Returns the transaction state.

**void setTransactionState ( const MQCHAR state );**

Sets the transaction state.

## Object data (protected)

**MQIIH omqiih**

The MQIIH data structure.

## Reason codes

- MQRC\_BINARY\_DATA\_LENGTH\_ERROR

- MQRC\_INCONSISTENT\_FORMAT
- MQRC\_ENCODING\_ERROR
- MQRC\_STRUC\_ID\_ERROR

## ImqItem C++ class

This abstract class represents an item, perhaps one of several, within a message.

Figure 25. *ImqItem* class

Items are concatenated together in a message buffer. Each specialization is associated with a particular data structure that begins with a structure ID.

Polymorphic methods in this abstract class allow items to be copied to and from messages. The `ImqMessage` class **readItem** and **writeItem** methods provide another style of invoking these polymorphic methods that is more natural for application programs.

- [“Object attributes” on page 1830](#)
- [“Constructors” on page 1830](#)
- [“Class methods \(public\)” on page 1831](#)
- [“Object methods \(public\)” on page 1831](#)
- [“Reason codes” on page 1831](#)

### Object attributes

#### structure id

A string of four characters at the beginning of the data structure. This attribute is read-only. Consider this attribute for derived classes. It is not included automatically.

### Constructors

#### **ImqItem();**

The default constructor.

#### **ImqItem( const ImqItem & item );**

The copy constructor.

## Class methods (public)

**static ImqBoolean structureIdIs ( const char \* *structure-id-to-test*, const ImqMessage & *msg* );**

Returns TRUE if the **structure id** of the next ImqItem in the incoming *msg* is the same as *structure-id-to-test*. The next item is identified as that part of the message buffer currently addressed by the ImqCache **data pointer**. This method relies on the **structure id** and therefore is not guaranteed to work for all ImqItem derived classes.

## Object methods (public)

**void operator = ( const ImqItem & *item* );**

Copies instance data from *item*, replacing the existing instance data.

**virtual ImqBoolean copyOut ( ImqMessage & *msg* ) = 0 ;**

Writes this object as the next item in an outgoing message buffer, appending it to any existing items. If the write operation is successful, increases the ImqCache **data length**. This method returns TRUE if successful.

Override this method to work with a specific subclass.

**virtual ImqBoolean pasteIn ( ImqMessage & *msg* ) = 0 ;**

Reads this object *destructively* from the incoming message buffer. The read is destructive in that the ImqCache **data pointer** is moved on. However, the buffer content remains the same, so data can be re-read by resetting the ImqCache **data pointer**.

The (sub)class of this object must be consistent with the **structure id** found next in the message buffer of the *msg* object.

The **encoding** of the *msg* object should be MQENC\_NATIVE. It is recommended that messages be retrieved with the ImqMessage **encoding** set to MQENC\_NATIVE, and with the ImqGetMessageOptions **options** including MQGMO\_CONVERT.

If the read operation is successful, the ImqCache **data length** is reduced. This method returns TRUE if successful.

Override this method to work with a specific subclass.

## Reason codes

- MQRC\_ENCODING\_ERROR
- MQRC\_STRUC\_ID\_ERROR
- MQRC\_INCONSISTENT\_FORMAT
- MQRC\_INSUFFICIENT\_BUFFER
- MQRC\_INSUFFICIENT\_DATA

## ImqMessage C++ class

This class encapsulates an MQMD data structure and also handles the construction and reconstruction of message data.

Figure 26. *ImqMessage* class

- [“Object attributes”](#) on page 1832
- [“Constructors”](#) on page 1836
- [“Object methods \(public\)”](#) on page 1836
- [“Object methods \(protected\)”](#) on page 1838
- [“Object data \(protected\)”](#) on page 1838

### Object attributes

#### application ID data

Identity information associated with a message. The initial value is a null string.

#### application origin data

Origin information associated with a message. The initial value is a null string.

#### backout count

The number of times that a message has been tentatively retrieved and subsequently backed out. The initial value is zero. This attribute is read-only.

#### character set

Coded Character Set Id. The initial value is MQCCSI\_Q\_MGR. The following additional values are possible:

- MQCCSI\_INHERIT
- MQCCSI\_EMBEDDED

You can also use a Coded Character Set Id of your choice. For information about this, see [“Code page conversion”](#) on page 938.

#### encoding

The machine encoding of the message data. The initial value is MQENC\_NATIVE.

#### expiry

A time-dependent quantity that controls how long IBM MQ retains an unretrieved message before discarding it. The initial value is MQEI\_UNLIMITED.

**format**

The name of the format (template) that describes the layout of data in the buffer. Names longer than eight characters are truncated to eight characters. Names are always padded with blanks to eight characters. The initial constant value is MQFMT\_NONE. The following additional constants are possible:

- MQFMT\_ADMIN
- MQFMT\_CICS
- MQFMT\_COMMAND\_1
- MQFMT\_COMMAND\_2
- MQFMT\_DEAD\_LETTER\_HEADER
- MQFMT\_DIST\_HEADER
- MQFMT\_EVENT
- MQFMT\_IMS
- MQFMT\_IMS\_VAR\_STRING
- MQFMT\_MD\_EXTENSION
- MQFMT\_PCF
- MQFMT\_REF\_MSG\_HEADER
- MQFMT\_RF\_HEADER
- MQFMT\_STRING
- MQFMT\_TRIGGER
- MQFMT\_WORK\_INFO\_HEADER
- MQFMT\_XMIT\_Q\_HEADER

You can also use an application-specific string of your choice. For more information about this, see the [“Format \(MQCHAR8\) for MQMD” on page 448](#) field of the message descriptor (MQMD).

**message flags**

Segmentation control information. The initial value is MQMF\_SEGMENTATION\_INHIBITED. The following additional values are possible:

- MQMF\_SEGMENTATION\_ALLOWED
- MQMF\_MSG\_IN\_GROUP
- MQMF\_LAST\_MSG\_IN\_GROUP
- MQMF\_SEGMENT
- MQMF\_LAST\_SEGMENT
- MQMF\_NONE

**message type**

The broad categorization of a message. The initial value is MQMT\_DATAGRAM. The following additional values are possible:

- MQMT\_SYSTEM\_FIRST
- MQMT\_SYSTEM\_LAST
- MQMT\_DATAGRAM
- MQMT\_REQUEST
- MQMT\_REPLY
- MQMT\_REPORT
- MQMT\_APPL\_FIRST
- MQMT\_APPL\_LAST

You can also use an application-specific value of your choice. For more information about this, see the [“MsgType \(MQLONG\) for MQMD”](#) on page 438 field of the message descriptor (MQMD).

**offset**

Offset information. The initial value is zero.

**original length**

The original length of a segmented message. The initial value is MQOL\_UNDEFINED.

**persistence**

Indicates that the message is important and must at all times be backed up using persistent storage. This option implies a performance penalty. The initial value is MQPER\_PERSISTENCE\_AS\_Q\_DEF. The following additional values are possible:

- MQPER\_PERSISTENT
- MQPER\_NOT\_PERSISTENT

**priority**

The relative priority for transmission and delivery. Messages of the same priority are usually delivered in the same sequence as they were supplied (although there are several criteria that must be satisfied to guarantee this). The initial value is MQPRI\_PRIORITY\_AS\_Q\_DEF.

**property validation**

Specifies whether validation of properties should take place when a property of the message is set. The initial value is **MQCMHO\_DEFAULT\_VALIDATION**. The following additional values are possible:

- MQCMHO\_VALIDATE
- MQCMHO\_NO\_VALIDATION

The following methods act on **property validation**:

**MQLONG propertyValidation( ) const ;**

Returns the **property validation** option.

**void setPropertyValidation( const MQLONG option );**

Sets the **property validation** option.

**put application name**

The name of the application that put a message. The initial value is a null string.

**put application type**

The type of application that put a message. The initial value is MQAT\_NO\_CONTEXT. The following additional values are possible:

- MQAT\_AIX
- MQAT\_CICS
- MQAT\_CICS\_BRIDGE
- MQAT\_DOS
- MQAT\_IMS
- MQAT\_IMS\_BRIDGE
- MQAT\_MVS
- MQAT\_NOTES\_AGENT
- MQAT\_OS2
- MQAT\_OS390
- MQAT\_OS400
- MQAT\_QMGR
- MQAT\_UNIX
- MQAT\_WINDOWS
- MQAT\_WINDOWS\_NT

- MQAT\_XCF
- MQAT\_DEFAULT
- MQAT\_UNKNOWN
- MQAT\_USER\_FIRST
- MQAT\_USER\_LAST

You can also use an application-specific string of your choice. For more information about this, see the [“PutApplType \(MQLONG\) for MQMD”](#) on page 462 field of the message descriptor (MQMD).

**put date**

The date on which a message was put. The initial value is a null string.

**put time**

The time at which a message was put. The initial value is a null string.

**reply-to queue manager name**

The name of the queue manager to which any reply should be sent. The initial value is a null string.

**reply-to queue name**

The name of the queue to which any reply should be sent. The initial value is a null string.

**report**

Feedback information associated with a message. The initial value is MQRO\_NONE. The following additional values are possible:

- MQRO\_EXCEPTION
- MQRO\_EXCEPTION\_WITH\_DATA
- MQRO\_EXCEPTION\_WITH\_FULL\_DATA \*
- MQRO\_EXPIRATION
- MQRO\_EXPIRATION\_WITH\_DATA
- MQRO\_EXPIRATION\_WITH\_FULL\_DATA \*
- MQRO\_COA
- MQRO\_COA\_WITH\_DATA
- MQRO\_COA\_WITH\_FULL\_DATA \*
- MQRO\_COD
- MQRO\_COD\_WITH\_DATA
- MQRO\_COD\_WITH\_FULL\_DATA \*
- MQRO\_PAN
- MQRO\_NAN
- MQRO\_NEW\_MSG\_ID
- MQRO\_NEW\_CORREL\_ID
- MQRO\_COPY\_MSG\_ID\_TO\_CORREL\_ID
- MQRO\_PASS\_CORREL\_ID
- MQRO\_DEAD\_LETTER\_Q
- MQRO\_DISCARD\_MSG

where \* indicates values that are not supported on IBM MQ for z/OS.

**sequence number**

Sequence information identifying a message within a group. The initial value is one.

**total message length**

The number of bytes that were available during the most recent attempt to read a message. This number will be greater than the ImqCache **message length** if the last message was truncated, or if the last message was not read because truncation would have occurred. This attribute is read-only. The initial value is zero.

This attribute can be useful in any situation involving truncated messages.

#### **user id**

A user identity associated with a message. The initial value is a null string.

### **Constructors**

#### **ImqMessage( );**

The default constructor.

#### **ImqMessage( const ImqMessage & msg );**

The copy constructor. See the **operator =** method for details.

### **Object methods (public)**

#### **void operator = ( const ImqMessage & msg );**

Copies the MQMD and message data from *msg*. If a buffer has been supplied by the user for this object, the amount of data copied is restricted to the available buffer size. Otherwise, the system ensures that a buffer of adequate size is made available for the copied data.

#### **ImqString applicationIdData ( ) const ;**

Returns a copy of the **application ID data**.

#### **void setApplicationIdData ( const char \* data = 0 );**

Sets the **application ID data**.

#### **ImqString applicationOriginData ( ) const ;**

Returns a copy of the **application origin data**.

#### **void setApplicationOriginData ( const char \* data = 0 );**

Sets the **application origin data**.

#### **MQLONG backoutCount ( ) const ;**

Returns the **backout count**.

#### **MQLONG characterSet ( ) const ;**

Returns the **character set**.

#### **void setCharacterSet ( const MQLONG ccsid = MQCCSI\_Q\_MGR );**

Sets the **character set**.

#### **MQLONG encoding ( ) const ;**

Returns the **encoding**.

#### **void setEncoding ( const MQLONG encoding = MQENC\_NATIVE );**

Sets the **encoding**.

#### **MQLONG expiry ( ) const ;**

Returns the **expiry**.

#### **void setExpiry ( const MQLONG expiry );**

Sets the **expiry**.

#### **ImqString format ( ) const ;**

Returns a copy of the **format**, including trailing blanks.

#### **ImqBoolean formatIs ( const char \* format-to-test ) const ;**

Returns TRUE if the **format** is the same as *format-to-test*.

#### **void setFormat ( const char \* name = 0 );**

Sets the **format**, padded to eight characters with trailing blanks.

#### **MQLONG messageFlags ( ) const ;**

Returns the **message flags**.

#### **void setMessageFlags ( const MQLONG flags );**

Sets the **message flags**.

#### **MQLONG messageType ( ) const ;**

Returns the **message type**.

**void setMessageType ( const MQLONG *type* );**  
 Sets the **message type**.

**MQLONG offset ( ) const ;**  
 Returns the **offset**.

**void setOffset ( const MQLONG *offset* );**  
 Sets the **offset**.

**MQLONG originalLength ( ) const ;**  
 Returns the **original length**.

**void setOriginalLength ( const MQLONG *length* );**  
 Sets the **original length**.

**MQLONG persistence ( ) const ;**  
 Returns the **persistence**.

**void setPersistence ( const MQLONG *persistence* );**  
 Sets the **persistence**.

**MQLONG priority ( ) const ;**  
 Returns the **priority**.

**void setPriority ( const MQLONG *priority* );**  
 Sets the **priority**.

**ImqString putApplicationName ( ) const ;**  
 Returns a copy of the **put application name**.

**void setPutApplicationName ( const char \* *name* = 0 );**  
 Sets the **put application name**.

**MQLONG putApplicationType ( ) const ;**  
 Returns the **put application type**.

**void setPutApplicationType ( const MQLONG *type* = MQAT\_NO\_CONTEXT );**  
 Sets the **put application type**.

**ImqString putDate ( ) const ;**  
 Returns a copy of the **put date**.

**void setPutDate ( const char \* *date* = 0 );**  
 Sets the **put date**.

**ImqString putTime ( ) const ;**  
 Returns a copy of the **put time**.

**void setPutTime ( const char \* *time* = 0 );**  
 Sets the **put time**.

**ImqBoolean readItem ( ImqItem & *item* );**  
 Reads into the *item* object from the message buffer, using the ImqItem **pasteIn** method. It returns TRUE if successful.

**ImqString replyToQueueManagerName ( ) const ;**  
 Returns a copy of the **reply-to queue manager name**.

**void setReplyToQueueManagerName ( const char \* *name* = 0 );**  
 Sets the **reply-to queue manager name**.

**ImqString replyToQueueName ( ) const ;**  
 Returns a copy of the **reply-to queue name**.

**void setReplyToQueueName ( const char \* *name* = 0 );**  
 Sets the **reply-to queue name**.

**MQLONG report ( ) const ;**  
 Returns the **report**.

**void setReport ( const MQLONG *report* );**  
 Sets the **report**.

**MQLONG** `sequenceNumber ( ) const ;`

Returns the **sequence number**.

**void** `setSequenceNumber ( const MQLONG number );`

Sets the **sequence number**.

**size\_t** `totalMessageLength ( ) const ;`

Returns the **total message length**.

**ImqString** `userId ( ) const ;`

Returns a copy of the **user id**.

**void** `setUserId ( const char * id = 0 );`

Sets the **user id**.

**ImqBoolean** `writeItem ( ImqItem & item );`

Writes from the *item* object into the message buffer, using the ImqItem **copyOut** method. Writing can take the form of insertion, replacement, or an append: this depends on the class of the *item* object.

This method returns TRUE if successful.

### Object methods (protected)

**static void** `setVersionSupported ( const MQLONG );`

Sets the **MQMD version**. Defaults to **MQMD\_VERSION\_2**.

### Object data (protected)

**z/OS** **MQMD1** *omqmd*

The MQMD data structure on z/OS.

**Multi** **MQMD2** *omqmd*

The MQMD data structure on [Multiplatforms](#).

## ImqMessageTracker C++ class

This class encapsulates those attributes of an ImqMessage or ImqQueue object that can be associated with either object.

Figure 27. *ImqMessageTracker* class

This class relates to the MQI calls listed in [“ImqMessageTracker cross-reference”](#) on page 1789.

- [“Object attributes”](#) on page 1839

- [“Constructors” on page 1840](#)
- [“Object methods \(public\)” on page 1840](#)
- [“Reason codes” on page 1841](#)

## Object attributes

### accounting token

A binary value (MQBYTE32) of length MQ\_ACCOUNTING\_TOKEN\_LENGTH. The initial value is MQACT\_NONE.

### correlation id

A binary value (MQBYTE24) of length MQ\_CORREL\_ID\_LENGTH that you assign to correlate messages. The initial value is MQCI\_NONE. The additional value, MQCI\_NEW\_SESSION, is possible.

### feedback

Feedback information to be sent with a message. The initial value is MQFB\_NONE. The following additional values are possible:

- MQFB\_SYSTEM\_FIRST
- MQFB\_SYSTEM\_LAST
- MQFB\_APPL\_FIRST
- MQFB\_APPL\_LAST
- MQFB\_COA
- MQFB\_COD
- MQFB\_EXPIRATION
- MQFB\_PAN
- MQFB\_NAN
- MQFB\_QUIT
- MQFB\_DATA\_LENGTH\_ZERO
- MQFB\_DATA\_LENGTH\_NEGATIVE
- MQFB\_DATA\_LENGTH\_TOO\_BIG
- MQFB\_BUFFER\_OVERFLOW
- MQFB\_LENGTH\_OFF\_BY\_ONE
- MQFB\_IIH\_ERROR
- MQFB\_NOT\_AUTHORIZED\_FOR\_IMS
- MQFB\_IMS\_ERROR
- MQFB\_IMS\_FIRST
- MQFB\_IMS\_LAST
- MQFB\_CICS\_APPL\_ABENDED
- MQFB\_CICS\_APPL\_NOT\_STARTED
- MQFB\_CICS\_BRIDGE\_FAILURE
- MQFB\_CICS\_CCSID\_ERROR
- MQFB\_CICS\_CIH\_ERROR
- MQFB\_CICS\_COMMAREA\_ERROR
- MQFB\_CICS\_CORREL\_ID\_ERROR
- MQFB\_CICS\_DLQ\_ERROR
- MQFB\_CICS\_ENCODING\_ERROR
- MQFB\_CICS\_INTERNAL\_ERROR
- MQFB\_CICS\_NOT\_AUTHORIZED

- MQFB\_CICS\_UOW\_BACKED\_OUT
- MQFB\_CICS\_UOW\_ERROR

You can also use an application-specific string of your choice. For more information about this, see the [“Feedback \(MQLONG\) for MQMD”](#) on page 442 field of the message descriptor (MQMD).

#### **group id**

A binary value (MQBYTE24) of length MQ\_GROUP\_ID\_LENGTH unique within a queue. The initial value is MQGI\_NONE.

#### **message id**

A binary value (MQBYTE24) of length MQ\_MSG\_ID\_LENGTH unique within a queue. The initial value is MQMI\_NONE.

## **Constructors**

### **ImqMessageTracker();**

The default constructor.

### **ImqMessageTracker( const ImqMessageTracker & tracker );**

The copy constructor. See the **operator =** method for details.

## **Object methods (public)**

### **void operator = ( const ImqMessageTracker & tracker );**

Copies instance data from *tracker*, replacing the existing instance data.

### **ImqBinary accountingToken ( ) const ;**

Returns a copy of the **accounting token**.

### **ImqBoolean setAccountingToken ( const ImqBinary & token );**

Sets the **accounting token**. The **data length** of *token* must be either zero or MQ\_ACCOUNTING\_TOKEN\_LENGTH. This method returns TRUE if successful.

### **void setAccountingToken ( const MQBYTE32 token = 0 );**

Sets the **accounting token**. *token* can be zero, which is the same as specifying MQACT\_NONE. If *token* is nonzero, it must address MQ\_ACCOUNTING\_TOKEN\_LENGTH bytes of binary data. When using predefined values such as MQACT\_NONE, you might need to make a cast to ensure a signature match; for example, (MQBYTE \*)MQACT\_NONE.

### **ImqBinary correlationId ( ) const ;**

Returns a copy of the **correlation id**.

### **ImqBoolean setCorrelationId ( const ImqBinary & token );**

Sets the **correlation id**. The **data length** of *token* must be either zero or MQ\_CORREL\_ID\_LENGTH. This method returns TRUE if successful.

### **void setCorrelationId ( const MQBYTE24 id = 0 );**

Sets the **correlation id**. *id* can be zero, which is the same as specifying MQCI\_NONE. If *id* is nonzero, it must address MQ\_CORREL\_ID\_LENGTH bytes of binary data. When using predefined values such as MQCI\_NONE, you might need to make a cast to ensure a signature match; for example, (MQBYTE \*)MQCI\_NONE.

### **MQLONG feedback ( ) const ;**

Returns the **feedback**.

### **void setFeedback ( const MQLONG feedback );**

Sets the **feedback**.

### **ImqBinary groupId ( ) const ;**

Returns a copy of the **group id**.

### **ImqBoolean setGroupId ( const ImqBinary & token );**

Sets the **group id**. The **data length** of *token* must be either zero or MQ\_GROUP\_ID\_LENGTH. This method returns TRUE if successful.

**void setGroupId ( const MQBYTE24 id = 0 );**

Sets the **group id**. *id* can be zero, which is the same as specifying MQGI\_NONE. If *id* is nonzero, it must address MQ\_GROUP\_ID\_LENGTH bytes of binary data. When using predefined values such as MQGI\_NONE, you might need to make a cast to ensure a signature match, for example (MQBYTE \*)MQGI\_NONE.

**ImqBinary messageId ( ) const ;**

Returns a copy of the **message id**.

**ImqBoolean setMessageId ( const ImqBinary & token );**

Sets the **message id**. The **data length** of *token* must be either zero or MQ\_MSG\_ID\_LENGTH. This method returns TRUE if successful.

**void setMessageId ( const MQBYTE24 id = 0 );**

Sets the **message id**. *id* can be zero, which is the same as specifying MQMI\_NONE. If *id* is nonzero, it must address MQ\_MSG\_ID\_LENGTH bytes of binary data. When using predefined values such as MQMI\_NONE, you might need to make a cast to ensure a signature match, for example (MQBYTE \*)MQMI\_NONE.

## Reason codes

- MQRC\_BINARY\_DATA\_LENGTH\_ERROR

## ImqNamelist C++ class

This class encapsulates a namelist.

Figure 28. ImqNamelist class

This class relates to the MQI calls listed in [“ImqNamelist cross-reference”](#) on page 1790.

- [“Object attributes”](#) on page 1841
- [“Constructors”](#) on page 1842
- [“Object methods \(public\)”](#) on page 1842
- [“Reason codes”](#) on page 1842

## Object attributes

### name count

The number of object names in **namelist names**. This attribute is read-only.

## namelist names

Object names, the number of which is indicated by the **name count**. This attribute is read-only.

## Constructors

### ImqNamelist();

The default constructor.

### ImqNamelist( const ImqNamelist & list );

The copy constructor. The ImqObject **open status** is false.

### ImqNamelist( const char \* name );

Sets the ImqObject name to **name**.

## Object methods (public)

### void operator = ( const ImqNamelist & list );

Copies instance data from *list*, replacing the existing instance data. The ImqObject **open status** is false.

### ImqBoolean nameCount( MQLONG & count );

Provides a copy of the **name count**. It returns TRUE if successful.

### MQLONG nameCount ( );

Returns the **name count** without any indication of possible errors.

### ImqBoolean namelistName ( const MQLONG index, ImqString & name );

Provides a copy of one the **namelist names** by zero based index. It returns TRUE if successful.

### ImqString namelistName ( const MQLONG index );

Returns one of the **namelist names** by zero-based index without any indication of possible errors.

## Reason codes

- MQRC\_INDEX\_ERROR
- MQRC\_INDEX\_NOT\_PRESENT

## ImqObject C++ class

This class is abstract. When an object of this class is destroyed, it is automatically closed, and its ImqQueueManager connection severed.

Figure 29. ImqObject class

This class relates to the MQI calls listed in [“ImqObject cross-reference” on page 1790](#).

- [“Class attributes” on page 1843](#)
- [“Object attributes” on page 1843](#)
- [“Constructors” on page 1844](#)

- [“Object methods \(public\)” on page 1844](#)
- [“Object methods \(protected\)” on page 1846](#)
- [“Object data \(protected\)” on page 1847](#)
- [“Reason codes” on page 1847](#)
- 

## Class attributes

### behavior

Controls the behavior of implicit opening.

#### **IMQ\_IMPL\_OPEN (8L)**

Implicit opening is allowed. This is the default.

## Object attributes

### alteration date

The alteration date. This attribute is read-only.

### alteration time

The alteration time. This attribute is read-only.

### alternate user id

The alternate user ID, up to MQ\_USER\_ID\_LENGTH characters. The initial value is a null string.

### alternate security id

The alternate security ID. A binary value (MQBYTE40) of length MQ\_SECURITY\_ID\_LENGTH. The initial value is MQSID\_NONE.

### close options

Options that apply when an object is closed. The initial value is MQCO\_NONE. This attribute is ignored during implicit reopen operations, where a value of MQCO\_NONE is always used.

### connection reference

A reference to an ImqQueueManager object that provides the required connection to a (local) queue manager. For an ImqQueueManager object, it is the object itself. The initial value is zero.

**Note:** Do not confuse this with the queue manager name that identifies a queue manager (possibly remote) for a named queue.

### description

The descriptive name (up to 64 characters) of the queue manager, queue, namelist, or process. This attribute is read-only.

### name

The name (up to 48 characters) of the queue manager, queue, namelist, or process. The initial value is a null string. The name of a model queue changes after an **open** to the name of the resulting dynamic queue.

**Note:** An ImqQueueManager can have a null name, representing the default queue manager. The name changes to the actual queue manager after a successful open. An ImqDistributionList is dynamic and must have a null name.

### next managed object

This is the next object of this class, in no particular order, having the same connection reference as this object. The initial value is zero.

## open options

Options that apply when an object is opened. The initial value is MQOO\_INQUIRE. There are two ways to set appropriate values:

1. Do not set the open options and do not use the open method. IBM MQ automatically adjusts the open options and automatically opens, reopens, and closes objects as required. This can result in unnecessary reopen operations, because IBM MQ uses the openFor method, and this adds open options incrementally only.
2. Set the open options before using any methods that result in an MQI call (see [“C++ and MQI cross-reference” on page 1783](#)). This ensures that unnecessary reopen operations do not occur. Set open options explicitly if any of the potential reopen problems are likely to occur (see [Reopen](#)).

If you use the open method, you must ensure that the open options are appropriate first. However, using the open method is not mandatory; IBM MQ still exhibits the same behavior as in case 1, but in this circumstance, the behavior is efficient.

Zero is not a valid value; set the appropriate value before attempting to open the object. This can be done using either **setOpenOptions** (*IOpenOptions*) followed by **open** (), or **openFor** (*IRequiredOpenOption*).

### Note:

1. MQOO\_OUTPUT is substituted for MQOO\_INQUIRE during the **open** method for a distribution list, as MQOO\_OUTPUT is the only valid **open option** at this time. However, it is good practice always to set MQOO\_OUTPUT explicitly in application programs that use the **open** method.
2. Specify MQOO\_RESOLVE\_NAMES if you want to use the **resolved queue manager name** and **resolved queue name** attributes of the class.

## open status

Whether the object is open (TRUE) or closed (FALSE). The initial value is FALSE. This attribute is read-only.

## previous managed object

The previous object of this class, in no particular order, having the same connection reference as this object. The initial value is zero.

## queue-manager-identifier

The queue manager identifier. This attribute is read-only.

## Constructors

### ImqObject();

The default constructor.

### ImqObject( const ImqObject & object );

The copy constructor. The open status will be FALSE.

## Class methods (public)

### static MQLONG behavior();

Returns the behavior.

### void setBehavior( const MQLONG behavior = 0 );

Sets the behavior.

## Object methods (public)

### void operator = ( const ImqObject & object );

Performs a close if necessary, and copies the instance data from *object*. The open status will be FALSE.

### ImqBoolean alterationDate( ImqString & date );

Provides a copy of the alteration date. It returns TRUE if successful.

**ImqString alterationDate();**

Returns the alteration date without any indication of possible errors.

**ImqBoolean alterationTime( ImqString & time );**

Provides a copy of the alteration time. It returns TRUE if successful.

**ImqString alterationTime();**

Returns the alteration time without any indication of possible errors.

**ImqString alternateUserId ( ) const ;**

Returns a copy of the alternate user id.

**ImqBoolean setAlternateUserId ( const char \* id );**

Sets the alternate user id. The alternate user id can be set only while the open status is FALSE. This method returns TRUE if successful.

**ImqBinary alternateSecurityId ( ) const ;**

Returns a copy of the alternate security ID.

**ImqBoolean setAlternateSecurityId( const ImqBinary & token );**

Sets the alternate security id. The alternate security id can be set only while the open status is FALSE. The data length of *token* must be either zero or MQ\_SECURITY\_ID\_LENGTH. It returns TRUE if successful.

**ImqBoolean setAlternateSecurityId( const MQBYTE\* token = 0 );**

Sets the alternate security id. *token* can be zero, which is the same as specifying MQSID\_NONE. If *token* is nonzero, it must address MQ\_SECURITY\_ID\_LENGTH bytes of binary data. When using predefined values such as MQSID\_NONE, you might need to make a cast to ensure signature match; for example, (MQBYTE \*)MQSID\_NONE.

The alternate security id can be set only while the open status is TRUE. It returns TRUE if successful.

**ImqBoolean setAlternateSecurityId( const unsigned char \* id = 0 );**

Sets the alternate security id.

**ImqBoolean close ( );**

Sets the open status to FALSE. It returns TRUE if successful.

**MQLONG closeOptions ( ) const ;**

Returns the close options.

**void setCloseOptions ( const MQLONG options );**

Sets the close options.

**ImqQueueManager \* connectionReference ( ) const ;**

Returns the connection reference.

**void setConnectionReference ( ImqQueueManager & manager );**

Sets the connection reference.

**void setConnectionReference ( ImqQueueManager \* manager = 0 );**

Sets the connection reference.

**virtual ImqBoolean description ( ImqString & description ) = 0 ;**

Provides a copy of the description. It returns TRUE if successful.

**ImqString description ( );**

Returns a copy of the description without any indication of possible errors.

**virtual ImqBoolean name ( ImqString & name );**

Provides a copy of the name. It returns TRUE if successful.

**ImqString name ( );**

Returns a copy of the name without any indication of possible errors.

**ImqBoolean setName ( const char \* name = 0 );**

Sets the name. The name can only be set while the open status is FALSE, and, for an ImqQueueManager, while the connection status is FALSE. It returns TRUE if successful.

**ImqObject \* nextManagedObject ( ) const ;**

Returns the next managed object.

**ImqBoolean open ( );**

Changes the open status to TRUE by opening the object as necessary, using among other attributes the open options and the name. This method uses the connection reference information and the ImqQueueManager connect method if necessary to ensure that the ImqQueueManager connection status is TRUE. It returns the open status.

**ImqBoolean openFor ( const MQLONG *required-options* = 0 );**

Attempts to ensure that the object is open with open options, or with open options that guarantee the behavior implied by the *required-options* parameter value.

If *required-options* is zero, input is required, and any input option suffices. So, if the open options already contain one of:

- MQOO\_INPUT\_AS\_Q\_DEF
- MQOO\_INPUT\_SHARED
- MQOO\_INPUT\_EXCLUSIVE

the open options are already satisfactory and are not changed; if the open options do not already contain any of these options, MQOO\_INPUT\_AS\_Q\_DEF is set in the open options.

If *required-options* is nonzero, the required options are added to the open options ; if *required-options* is any of these options, the others are reset.

If any of the open options are changed and the object is already open, the object is closed temporarily and reopened in order to adjust the open options.

It returns TRUE if successful. Success indicates that the object is open with appropriate options.

**MQLONG openOptions ( ) const ;**

Returns the open options.

**ImqBoolean setOpenOptions ( const MQLONG *options* );**

Sets the open options. The open options can be set only while the open status is FALSE. It returns TRUE if successful.

**ImqBoolean openStatus ( ) const ;**

Returns the open status.

**ImqObject \* previousManagedObject ( ) const ;**

Returns the previous managed object.

**ImqBoolean queueManagerIdentifier( ImqString & *id* );**

Provides a copy of the queue manager identifier. It returns TRUE if successful.

**ImqString queueManagerIdentifier( );**

Returns the queue manager identifier without any indication of possible errors.

**Object methods (protected)****virtual ImqBoolean closeTemporarily ( );**

Closes an object safely before reopening. It returns TRUE if successful. This method assumes that the open status is TRUE.

**MQHCONN connectionHandle ( ) const ;**

Returns the MQHCONN associated with the connection reference. This value is zero if there is no connection reference or if the Manager is not connected.

**ImqBoolean inquire ( const MQLONG *int-attr*, MQLONG & *value* );**

Returns an integer value, the index of which is an MQIA\_\* value. In case of error, the value is set to MQIAV\_UNDEFINED.

**ImqBoolean inquire ( const MQLONG *char-attr*, char \* & *buffer*, const size\_t *length* );**

Returns a character string, the index of which is an MQCA\_\* value.

**Note:** Both of these methods return only a single attribute value. If a *snapshot* is required of more than one value, where the values are consistent with each other for an instant, IBM MQ C++ does not provide this facility and you must use the MQINQ call with appropriate parameters.

**virtual void openInformationDisperse ( );**

Disperses information from the variable section of the MQOD data structure immediately after an MQOPEN call.

**virtual ImqBoolean openInformationPrepare ( );**

Prepares information for the variable section of the MQOD data structure immediately before an MQOPEN call, and returns TRUE if successful.

**ImqBoolean set ( const MQLONG int-attr, const MQLONG value );**

Sets an IBM MQ integer attribute.

**ImqBoolean set ( const MQLONG char-attr, const char \* buffer, const size\_t required-length );**

Sets an IBM MQ character attribute.

**void setNextManagedObject ( const ImqObject \* object = 0 );**

Sets the next managed object.

Attention: Use this function only if you are sure it will not break the managed object list.

**void setPreviousManagedObject ( const ImqObject \* object = 0 );**

Sets the previous managed object.

Attention: Use this function only if you are sure it will not break the managed object list.

**Object data (protected)****MQHOBJ ohobj**

The IBM MQ object handle (valid only when open status is TRUE).

**MQOD omqod**

The embedded MQOD data structure. The amount of storage allocated for this data structure is that required for an MQOD Version 2. Inspect the version number (*omqod.Version*) and access the other fields as follows:

**MQOD\_VERSION\_1**

All other fields in *omqod* can be accessed.

**MQOD\_VERSION\_2**

All other fields in *omqod* can be accessed.

**MQOD\_VERSION\_3**

*omqod.pmqod* is a pointer to a dynamically allocated, larger, MQOD. No other fields in *omqod* can be accessed. All fields addressed by *omqod.pmqod* can be accessed.

**Note:** *omqod.pmqod.Version* can be less than *omqod.Version*, indicating that the IBM MQ MQI client has more functionality than the IBM MQ server.

**Reason codes**

## ImqProcess C++ class

This class encapsulates an application process (an IBM MQ object of type MQOT\_PROCESS) that can be triggered by a trigger monitor.

Figure 30. ImqProcess class

- [“Object attributes” on page 1848](#)
- [“Constructors” on page 1848](#)
- [“Object methods \(public\)” on page 1848](#)

### Object attributes

#### application id

The identity of the application process. This attribute is read-only.

#### application type

The type of the application process. This attribute is read-only.

#### environment data

The environment information for the process. This attribute is read-only.

#### user data

User data for the process. This attribute is read-only.

### Constructors

#### ImqProcess();

The default constructor.

#### ImqProcess(const ImqProcess & process);

The copy constructor. The ImqObject **open status** is FALSE.

#### ImqProcess(const char \* name);

Sets the ImqObject **name**.

### Object methods (public)

#### void operator = (const ImqProcess & process);

Performs a close if necessary, and then copies instance data from *process*. The ImqObject **open status** will be FALSE.

**ImqBoolean applicationId ( ImqString & id );**

Provides a copy of the **application id**. It returns TRUE if successful.

**ImqString applicationId ( );**

Returns the **application id** without any indication of possible errors.

**ImqBoolean applicationType ( MQLONG & type );**

Provides a copy of the **application type**. It returns TRUE if successful.

**MQLONG applicationType ( );**

Returns the **application type** without any indication of possible errors.

**ImqBoolean environmentData ( ImqString & data );**

Provides a copy of the **environment data**. It returns TRUE if successful.

**ImqString environmentData ( );**

Returns the **environment data** without any indication of possible errors.

**ImqBoolean userData ( ImqString & data );**

Provides a copy of the **user data**. It returns TRUE if successful.

**ImqString userData ( );**

Returns the **user data** without any indication of possible errors.

## ImqPutMessageOptions C++ class

This class encapsulates the MQPMO data structure.

Figure 31. *ImqPutMessageOptions* class

- [“Object attributes” on page 1849](#)
- [“Constructors” on page 1850](#)
- [“Object methods \(public\)” on page 1850](#)
- [“Object data \(protected\)” on page 1851](#)
- [“Reason codes” on page 1851](#)

### Object attributes

**context reference**

An ImqQueue that provides a context for messages. Initially there is no reference.

## options

The put message options. The initial value is MQPMO\_NONE. The following additional values are possible:

- MQPMO\_SYNCPOINT
- MQPMO\_NO\_SYNCPOINT
- MQPMO\_NEW\_MSG\_ID
- MQPMO\_NEW\_CORREL\_ID
- MQPMO\_LOGICAL\_ORDER
- MQPMO\_NO\_CONTEXT
- MQPMO\_DEFAULT\_CONTEXT
- MQPMO\_PASS\_IDENTITY\_CONTEXT
- MQPMO\_PASS\_ALL\_CONTEXT
- MQPMO\_SET\_IDENTITY\_CONTEXT
- MQPMO\_SET\_ALL\_CONTEXT
- MQPMO\_ALTERNATE\_USER\_AUTHORITY
- MQPMO\_FAIL\_IF QUIESCING

## record fields

The flags that control the inclusion of put message records when a message is put. The initial value is MQPMRF\_NONE. The following additional values are possible:

- MQPMRF\_MSG\_ID
- MQPMRF\_CORREL\_ID
- MQPMRF\_GROUP\_ID
- MQPMRF\_FEEDBACK
- MQPMRF\_ACCOUNTING\_TOKEN

ImqMessageTracker attributes are taken from the object for any field that is specified.

ImqMessageTracker attributes are taken from the ImqMessage object for any field that is not specified.

## resolved queue manager name

Name of a destination queue manager determined during a put. The initial value is null. This attribute is read-only.

## resolved queue name

Name of a destination queue determined during a put. The initial value is null. This attribute is read-only.

## syncpoint participation

TRUE when messages are put under syncpoint control.

## Constructors

### **ImqPutMessageOptions( );**

The default constructor.

### **ImqPutMessageOptions( const ImqPutMessageOptions & pmo );**

The copy constructor.

## Object methods (public)

### **void operator = ( const ImqPutMessageOptions & pmo );**

Copies instance data from *pmo*, replacing the existing instance data.

### **ImqQueue \* contextReference ( ) const ;**

Returns the context reference.

**void setContextReference ( const ImqQueue & *queue* );**

Sets the context reference.

**void setContextReference ( const ImqQueue \* *queue* = 0 );**

Sets the context reference.

**MQLONG options ( ) const ;**

Returns the options.

**void setOptions ( const MQLONG *options* );**

Sets the options, including the syncpoint participation value.

**MQLONG recordFields ( ) const ;**

Returns the record fields.

**void setRecordFields ( const MQLONG *fields* );**

Sets the record fields.

**ImqString resolvedQueueManagerName ( ) const ;**

Returns a copy of the resolved queue manager name.

**ImqString resolvedQueueName ( ) const ;**

Returns a copy of the resolved queue name.

**ImqBoolean syncPointParticipation ( ) const ;**

Returns the syncpoint participation value, which is TRUE if the options include MQPMO\_SYNCPOINT.

**void setSyncPointParticipation ( const ImqBoolean *sync* );**

Sets the syncpoint participation value. If *sync* is TRUE, the options are altered to include MQPMO\_SYNCPOINT, and to exclude MQPMO\_NO\_SYNCPOINT. If *sync* is FALSE, the options are altered to include MQPMO\_NO\_SYNCPOINT, and to exclude MQPMO\_SYNCPOINT.

## Object data (protected)

**MQPMO *omqpmo***

The MQPMO data structure.

## Reason codes

- MQRC\_STORAGE\_NOT\_AVAILABLE

## ImqQueue C++ class

This class encapsulates a message queue (an IBM MQ object of type MQOT\_Q).

Figure 32. ImqQueue class

This class relates to the MQI calls listed in [Table 862 on page 1791](#).

- [“Object attributes” on page 1852](#)
- [“Constructors” on page 1855](#)
- [“Object methods \(public\)” on page 1855](#)
- [“Object methods \(protected\)” on page 1861](#)
- [“Reason codes” on page 1861](#)

### Object attributes

#### backout requeue name

Excessive backout requeue name. This attribute is read-only.

#### backout threshold

Backout threshold. This attribute is read-only.

#### base queue name

Name of the queue that the alias resolves to. This attribute is read-only.

#### cluster name

Cluster name. This attribute is read-only.

#### cluster namelist name

Cluster namelist name. This attribute is read-only.

#### cluster workload rank

Cluster workload rank. This attribute is read-only.

#### cluster workload priority

Cluster workload priority. This attribute is read-only.

#### cluster workload use queue

Cluster workload use queue value. This attribute is read-only.

#### creation date

Queue creation data. This attribute is read-only.

**creation time**

Queue creation time. This attribute is read-only.

**current depth**

Number of messages on the queue. This attribute is read-only.

**default bind**

Default bind. This attribute is read-only.

**default input open option**

Default open-for-input option. This attribute is read-only.

**default persistence**

Default message persistence. This attribute is read-only.

**default priority**

Default message priority. This attribute is read-only.

**definition type**

Queue definition type. This attribute is read-only.

**depth high event**

Control attribute for queue depth high events. This attribute is read-only.

**depth high limit**

High limit for the queue depth. This attribute is read-only.

**depth low event**

Control attribute for queue depth low events. This attribute is read-only.

**depth low limit**

Low limit for the queue depth. This attribute is read-only.

**depth maximum event**

Control attribute for queue depth maximum events. This attribute is read-only.

**distribution list reference**

Optional reference to an ImqDistributionList that can be used to distribute messages to more than one queue, including this one. The initial value is null.

**Note:** When an ImqQueue object is opened, any open ImqDistributionList object that it references is automatically closed.

**distribution lists**

The capability of a transmission queue to support distribution lists. This attribute is read-only.

**dynamic queue name**

Dynamic queue name. The initial value is AMQ.\* for all AIX, Linux, and Windows platforms.

**harden get backout**

Whether to harden the backout count. This attribute is read-only.

**index type**

Index type. This attribute is read-only.

**inhibit get**

Whether get operations are allowed. The initial value is dependent on the queue definition. This attribute is valid for an alias or local queue only.

**inhibit put**

Whether put operations are allowed. The initial value is dependent on the queue definition.

**initiation queue name**

Name of the initiation queue. This attribute is read-only.

**maximum depth**

Maximum number of messages allowed on the queue. This attribute is read-only.

**maximum message length**

Maximum length for any message on this queue, which can be less than the maximum for any queue managed by the associated queue manager. This attribute is read-only.

**message delivery sequence**

Whether message priority is relevant. This attribute is read-only.

**next distributed queue**

Next object of this class, in no particular order, having the same **distribution list reference** as this object. The initial value is zero.

If an object in a chain is deleted, the previous object and next object are updated so that their distributed queue links no longer point to the deleted object.

**non-persistent message class**

Level of reliability for non-persistent messages put to this queue. This attribute is read-only.

**open input count**

Number of ImqQueue objects that are open for input. This attribute is read-only.

**open output count**

Number of ImqQueue objects that are open for output. This attribute is read-only.

**previous distributed queue**

Previous object of this class, in no particular order, having the same **distribution list reference** as this object. The initial value is zero.

If an object in a chain is deleted, the previous object and next object are updated so that their distributed queue links no longer point to the deleted object.

**process name**

Name of the process definition. This attribute is read-only.

**queue accounting**

Level of accounting information for queues. This attribute is read-only.

**queue-manager-name**

Name of the queue manager (possibly remote) where the queue resides. Do not confuse the queue manager named here with the ImqObject **connection reference**, which references the (local) queue manager providing a connection. The initial value is null.

**queue monitoring**

Level of monitoring data collection for the queue. This attribute is read-only.

**queue statistics**

Level of statistics data for the queue. This attribute is read-only.

**queue type**

Queue type. This attribute is read-only.

**remote queue manager name**

Name of the remote queue manager. This attribute is read-only.

**remote queue name**

Name of the remote queue as known on the remote queue manager. This attribute is read-only.

**resolved queue manager name**

Resolved queue manager name. This attribute is read-only.

**resolved queue name**

Resolved queue name. This attribute is read-only.

**retention interval**

Queue retention interval. This attribute is read-only.

**scope**

Scope of the queue definition. This attribute is read-only.

**service interval**

Service interval. This attribute is read-only.

**service interval event**

Control attribute for service interval events. This attribute is read-only.

**shareability**

Whether the queue can be shared. This attribute is read-only.

**storage class**

Storage class. This attribute is read-only.

**transmission queue name**

Name of the transmission queue. This attribute is read-only.

**trigger control**

Trigger control. The initial value depends on the queue definition. This attribute is valid for a local queue only.

**trigger data**

Trigger data. The initial value depends on the queue definition. This attribute is valid for a local queue only.

**trigger depth**

Trigger depth. The initial value depends on the queue definition. This attribute is valid for a local queue only.

**trigger message priority**

Threshold message priority for triggers. The initial value depends on the queue definition. This attribute is valid for a local queue only.

**trigger type**

Trigger type. The initial value depends on the queue definition. This attribute is valid for a local queue only.

**usage**

Usage. This attribute is read-only.

**Constructors****ImqQueue();**

The default constructor.

**ImqQueue( const ImqQueue & *queue* );**

The copy constructor. The ImqObject **open status** will be FALSE.

**ImqQueue( const char \* *name* );**

Sets the ImqObject **name**.

**Object methods (public)****void operator = ( const ImqQueue & *queue* );**

Performs a close if necessary, and then copies instance data from *queue*. The ImqObject **open status** will be FALSE.

**ImqBoolean backoutRequeueName ( ImqString & *name* );**

Provides a copy of the **backout requeue name**. It returns TRUE if successful.

**ImqString backoutRequeueName ();**

Returns the **backout requeue name** without any indication of possible errors.

**ImqBoolean backoutThreshold ( MQLONG & *threshold* );**

Provides a copy of the **backout threshold**. It returns TRUE if successful.

**MQLONG backoutThreshold ();**

Returns the **backout threshold** value without any indication of possible errors.

**ImqBoolean baseQueueName ( ImqString & *name* );**

Provides a copy of the **base queue name**. It returns TRUE if successful.

**ImqString baseQueueName ();**

Returns the **base queue name** without any indication of possible errors.

**ImqBoolean clusterName( ImqString & *name* );**

Provides a copy of the **cluster name**. It returns TRUE if successful.

**ImqString clusterName();**

Returns the **cluster name** without any indication of possible errors.

**ImqBoolean clusterNamelistName( ImqString & name );**  
Provides a copy of the **cluster namelist name**. It returns TRUE if successful.

**ImqString clusterNamelistName( );**  
Returns the **cluster namelist name** without any indication of errors.

**ImqBoolean clusterWorkLoadPriority ( MQLONG & priority );**  
Provides a copy of the cluster workload priority value. It returns TRUE if successful.

**MQLONG clusterWorkLoadPriority ( );**  
Returns the cluster workload priority value without any indication of possible errors.

**ImqBoolean clusterWorkLoadRank ( MQLONG & rank );**  
Provides a copy of the cluster workload rank value. It returns TRUE if successful.

**MQLONG clusterWorkLoadRank ( );**  
Returns the cluster workload rank value without any indication of possible errors.

**ImqBoolean clusterWorkLoadUseQ ( MQLONG & useq );**  
Provides a copy of the cluster workload use queue value. It returns TRUE if successful.

**MQLONG clusterWorkLoadUseQ ( );**  
Returns the cluster workload use queue value without any indication of possible errors.

**ImqBoolean creationDate ( ImqString & date );**  
Provides a copy of the **creation date**. It returns TRUE if successful.

**ImqString creationDate ( );**  
Returns the **creation date** without any indication of possible errors.

**ImqBoolean creationTime ( ImqString & time );**  
Provides a copy of the **creation time**. It returns TRUE if successful.

**ImqString creationTime ( );**  
Returns the **creation time** without any indication of possible errors.

**ImqBoolean currentDepth ( MQLONG & depth );**  
Provides a copy of the **current depth**. It returns TRUE if successful.

**MQLONG currentDepth ( );**  
Returns the **current depth** without any indication of possible errors.

**ImqBoolean defaultInputOpenOption ( MQLONG & option );**  
Provides a copy of the **default input open option**. It returns TRUE if successful.

**MQLONG defaultInputOpenOption ( );**  
Returns the **default input open option** without any indication of possible errors.

**ImqBoolean defaultPersistence ( MQLONG & persistence );**  
Provides a copy of the **default persistence**. It returns TRUE if successful.

**MQLONG defaultPersistence ( );**  
Returns the **default persistence** without any indication of possible errors.

**ImqBoolean defaultPriority ( MQLONG & priority );**  
Provides a copy of the **default priority**. It returns TRUE if successful.

**MQLONG defaultPriority ( );**  
Returns the **default priority** without any indication of possible errors.

**ImqBoolean defaultBind ( MQLONG & bind );**  
Provides a copy of the **default bind**. It returns TRUE if successful.

**MQLONG defaultBind ( );**  
Returns the **default bind** without any indication of possible errors.

**ImqBoolean definitionType ( MQLONG & type );**  
Provides a copy of the **definition type**. It returns TRUE if successful.

**MQLONG definitionType ( );**  
Returns the **definition type** without any indication of possible errors.

**ImqBoolean depthHighEvent ( MQLONG & event );**  
Provides a copy of the enablement state of the **depth high event**. It returns TRUE if successful.

**MQLONG depthHighEvent ( );**

Returns the enablement state of the **depth high event** without any indication of possible errors.

**ImqBoolean depthHighLimit ( MQLONG & limit );**

Provides a copy of the **depth high limit**. It returns TRUE if successful.

**MQLONG depthHighLimit ( );**

Returns the **depth high limit** value without any indication of possible errors.

**ImqBoolean depthLowEvent ( MQLONG & event );**

Provides a copy of the enablement state of the **depth low event**. It returns TRUE if successful.

**MQLONG depthLowEvent ( );**

Returns the enablement state of the **depth low event** without any indication of possible errors.

**ImqBoolean depthLowLimit ( MQLONG & limit );**

Provides a copy of the **depth low limit**. It returns TRUE if successful.

**MQLONG depthLowLimit ( );**

Returns the **depth low limit** value without any indication of possible errors.

**ImqBoolean depthMaximumEvent ( MQLONG & event );**

Provides a copy of the enablement state of the **depth maximum event**. It returns TRUE if successful.

**MQLONG depthMaximumEvent ( );**

Returns the enablement state of the **depth maximum event** without any indication of possible errors.

**ImqDistributionList \* distributionListReference ( ) const ;**

Returns the **distribution list reference**.

**void setDistributionListReference ( ImqDistributionList & list );**

Sets the **distribution list reference**.

**void setDistributionListReference ( ImqDistributionList \* list = 0 );**

Sets the **distribution list reference**.

**ImqBoolean distributionLists ( MQLONG & support );**

Provides a copy of the **distribution lists** value. It returns TRUE if successful.

**MQLONG distributionLists ( );**

Returns the **distribution lists** value without any indication of possible errors.

**ImqBoolean setDistributionLists ( const MQLONG support );**

Sets the **distribution lists** value. It returns TRUE if successful.

**ImqString dynamicQueueName ( ) const ;**

Returns a copy of the **dynamic queue name**.

**ImqBoolean setDynamicQueueName ( const char \* name );**

Sets the **dynamic queue name**. The **dynamic queue name** can be set only while the ImqObject **open status** is FALSE. It returns TRUE if successful.

**ImqBoolean get ( ImqMessage & msg, ImqGetMessageOptions & options );**

Retrieves a message from the queue, using the specified *options*. Invokes the ImqObject **openFor** method if necessary to ensure that the ImqObject **open options** include either one of the MQOO\_INPUT\_\* values, or the MQOO\_BROWSE value, depending on the *options*. If the *msg* object has an ImqCache **automatic buffer**, the buffer grows to accommodate any message retrieved. The **clearMessage** method is invoked against the *msg* object before retrieval.

This method returns TRUE if successful.

**Note:** The result of the method invocation is FALSE if the ImqObject **reason code** is MQRC\_TRUNCATED\_MSG\_FAILED, even though this **reason code** is classified as a warning. If a truncated message is accepted, the ImqCache **message length** reflects the truncated length. In either event, the ImqMessage **total message length** indicates the number of bytes that were available.

**ImqBoolean get ( ImqMessage & msg );**

As for the previous method, except that default get message options are used.

**ImqBoolean get ( ImqMessage & msg, ImqGetMessageOptions & options, const size\_t buffer-size );**  
 As for the previous two methods, except that an overriding *buffer-size* is indicated. If the *msg* object employs an ImqCache **automatic buffer**, the **resizeBuffer** method is invoked on the *msg* object prior to message retrieval, and the buffer does not grow further to accommodate any larger message.

**ImqBoolean get ( ImqMessage & msg, const size\_t buffer-size );**  
 As for the previous method, except that default get message options are used.

**ImqBoolean hardenGetBackout ( MQLONG & harden );**  
 Provides a copy of the **harden get backout** value. It returns TRUE if successful.

**MQLONG hardenGetBackout ( );**  
 Returns the **harden get backout** value without any indication of possible errors.

**ImqBoolean indexType( MQLONG & type );**  
 Provides a copy of the **index type**. It returns TRUE if successful.

**MQLONG indexType( );**  
 Returns the **index type** without any indication of possible errors.

**ImqBoolean inhibitGet ( MQLONG & inhibit );**  
 Provides a copy of the **inhibit get** value. It returns TRUE if successful.

**MQLONG inhibitGet ( );**  
 Returns the **inhibit get** value without any indication of possible errors.

**ImqBoolean setInhibitGet ( const MQLONG inhibit );**  
 Sets the **inhibit get** value. It returns TRUE if successful.

**ImqBoolean inhibitPut ( MQLONG & inhibit );**  
 Provides a copy of the **inhibit put** value. It returns TRUE if successful.

**MQLONG inhibitPut ( );**  
 Returns the **inhibit put** value without any indication of possible errors.

**ImqBoolean setInhibitPut ( const MQLONG inhibit );**  
 Sets the **inhibit put** value. It returns TRUE if successful.

**ImqBoolean initiationQueueName ( ImqString & name );**  
 Provides a copy of the **initiation queue name**. It returns TRUE if successful.

**ImqString initiationQueueName ( );**  
 Returns the **initiation queue name** without any indication of possible errors.

**ImqBoolean maximumDepth ( MQLONG & depth );**  
 Provides a copy of the **maximum depth**. It returns TRUE if successful.

**MQLONG maximumDepth ( );**  
 Returns the **maximum depth** without any indication of possible errors.

**ImqBoolean maximumMessageLength ( MQLONG & length );**  
 Provides a copy of the **maximum message length**. It returns TRUE if successful.

**MQLONG maximumMessageLength ( );**  
 Returns the **maximum message length** without any indication of possible errors.

**ImqBoolean messageDeliverySequence ( MQLONG & sequence );**  
 Provides a copy of the **message delivery sequence**. It returns TRUE if successful.

**MQLONG messageDeliverySequence ( );**  
 Returns the **message delivery sequence** value without any indication of possible errors.

**ImqQueue \* nextDistributedQueue ( ) const ;**  
 Returns the **next distributed queue**.

**ImqBoolean nonPersistentMessageClass ( MQLONG & monq );**  
 Provides a copy of the non persistent message class value. It returns TRUE if successful.

**MQLONG nonPersistentMessageClass ( );**  
 Returns the non persistent message class value without any indication of possible errors.

**ImqBoolean openInputCount ( MQLONG & count );**  
 Provides a copy of the **open input count**. It returns TRUE if successful.

**MQLONG openInputCount ( );**

Returns the **open input count** without any indication of possible errors.

**ImqBoolean openOutputCount ( MQLONG & count );**

Provides a copy of the **open output count**. It returns TRUE if successful.

**MQLONG openOutputCount ( );**

Returns the **open output count** without any indication of possible errors.

**ImqQueue \* previousDistributedQueue ( ) const ;**

Returns the **previous distributed queue**.

**ImqBoolean processName ( ImqString & name );**

Provides a copy of the **process name**. It returns TRUE if successful.

**ImqString processName ( );**

Returns the **process name** without any indication of possible errors.

**ImqBoolean put ( ImqMessage & msg );**

Places a message onto the queue, using default put message options. Uses the ImqObject **openFor** method if necessary to ensure that the ImqObject **open options** include MQOO\_OUTPUT.

This method returns TRUE if successful.

**ImqBoolean put ( ImqMessage & msg, ImqPutMessageOptions & pmo );**

Places a message onto the queue, using the specified *pmo*. Uses the ImqObject **openFor** method as necessary to ensure that the ImqObject **open options** include MQOO\_OUTPUT, and (if the *pmo options* include any of MQPMO\_PASS\_IDENTITY\_CONTEXT, MQPMO\_PASS\_ALL\_CONTEXT, MQPMO\_SET\_IDENTITY\_CONTEXT, or MQPMO\_SET\_ALL\_CONTEXT) corresponding MQOO\_\*\_CONTEXT values.

This method returns TRUE if successful.

**Note:** If the *pmo* includes a **context reference**, the referenced object is opened, if necessary, to provide a context.

**ImqBoolean queueAccounting ( MQLONG & acctq );**

Provides a copy of the queue accounting value. It returns TRUE if successful.

**MQLONG queueAccounting ( );**

Returns the queue accounting value without any indication of possible errors.

**ImqString queueManagerName ( ) const ;**

Returns the **queue manager name**.

**ImqBoolean setQueueManagerName ( const char \* name );**

Sets the **queue manager name**. The **queue manager name** can be set only while the ImqObject **open status** is FALSE. This method returns TRUE if successful.

**ImqBoolean queueMonitoring ( MQLONG & monq );**

Provides a copy of the queue monitoring value. It returns TRUE if successful.

**MQLONG queueMonitoring ( );**

Returns the queue monitoring value without any indication of possible errors.

**ImqBoolean queueStatistics ( MQLONG & statq );**

Provides a copy of the queue statistics value. It returns TRUE if successful.

**MQLONG queueStatistics ( );**

Returns the queue statistics value without any indication of possible errors.

**ImqBoolean queueType ( MQLONG & type );**

Provides a copy of the **queue type** value. It returns TRUE if successful.

**MQLONG queueType ( );**

Returns the **queue type** without any indication of possible errors.

**ImqBoolean remoteQueueManagerName ( ImqString & name );**

Provides a copy of the **remote queue manager name**. It returns TRUE if successful.

**ImqString remoteQueueManagerName ( );**

Returns the **remote queue manager name** without any indication of possible errors.

**ImqBoolean remoteQueueName ( ImqString & name );**

Provides a copy of the **remote queue name**. It returns TRUE if successful.

**ImqString remoteQueueName ( );**

Returns the **remote queue name** without any indication of possible errors.

**ImqBoolean resolvedQueueManagerName( ImqString & name );**

Provides a copy of the **resolved queue manager name**. It returns TRUE if successful.

**Note:** This method fails unless MQOO\_RESOLVE\_NAMES is among the ImqObject **open options**.

**ImqString resolvedQueueManagerName( );**

Returns the **resolved queue manager name**, without any indication of possible errors.

**ImqBoolean resolvedQueueName( ImqString & name );**

Provides a copy of the **resolved queue name**. It returns TRUE if successful.

**Note:** This method fails unless MQOO\_RESOLVE\_NAMES is among the ImqObject **open options**.

**ImqString resolvedQueueName( );**

Returns the **resolved queue name**, without any indication of possible errors.

**ImqBoolean retentionInterval ( MQLONG & interval );**

Provides a copy of the **retention interval**. It returns TRUE if successful.

**MQLONG retentionInterval ( );**

Returns the **retention interval** without any indication of possible errors.

**ImqBoolean scope ( MQLONG & scope );**

Provides a copy of the **scope**. It returns TRUE if successful.

**MQLONG scope ( );**

Returns the **scope** without any indication of possible errors.

**ImqBoolean serviceInterval ( MQLONG & interval );**

Provides a copy of the **service interval**. It returns TRUE if successful.

**MQLONG serviceInterval ( );**

Returns the **service interval** without any indication of possible errors.

**ImqBoolean serviceIntervalEvent ( MQLONG & event );**

Provides a copy of the enablement state of the **service interval event**. It returns TRUE if successful.

**MQLONG serviceIntervalEvent ( );**

Returns the enablement state of the **service interval event** without any indication of possible errors.

**ImqBoolean shareability ( MQLONG & shareability );**

Provides a copy of the **shareability** value. It returns TRUE if successful.

**MQLONG shareability ( );**

Returns the **shareability** value without any indication of possible errors.

**ImqBoolean storageClass( ImqString & class );**

Provides a copy of the **storage class**. It returns TRUE if successful.

**ImqString storageClass( );**

Returns the **storage class** without any indication of possible errors.

**ImqBoolean transmissionQueueName ( ImqString & name );**

Provides a copy of the **transmission queue name**. It returns TRUE if successful.

**ImqString transmissionQueueName ( );**

Returns the **transmission queue name** without any indication of possible errors.

**ImqBoolean triggerControl ( MQLONG & control );**

Provides a copy of the **trigger control** value. It returns TRUE if successful.

**MQLONG triggerControl ( );**

Returns the **trigger control** value without any indication of possible errors.

**ImqBoolean setTriggerControl ( const MQLONG control );**

Sets the **trigger control** value. It returns TRUE if successful.

**ImqBoolean triggerData ( ImqString & data );**

Provides a copy of the **trigger data**. It returns TRUE if successful.

**ImqString triggerData ( );**

Returns a copy of the **trigger data** without any indication of possible errors.

**ImqBoolean setTriggerData ( const char \* data );**

Sets the **trigger data**. It returns TRUE if successful.

**ImqBoolean triggerDepth ( MQLONG & depth );**

Provides a copy of the **trigger depth**. It returns TRUE if successful.

**MQLONG triggerDepth ( );**

Returns the **trigger depth** without any indication of possible errors.

**ImqBoolean setTriggerDepth ( const MQLONG depth );**

Sets the **trigger depth**. It returns TRUE if successful.

**ImqBoolean triggerMessagePriority ( MQLONG & priority );**

Provides a copy of the **trigger message priority**. It returns TRUE if successful.

**MQLONG triggerMessagePriority ( );**

Returns the **trigger message priority** without any indication of possible errors.

**ImqBoolean setTriggerMessagePriority ( const MQLONG priority );**

Sets the **trigger message priority**. It returns TRUE if successful.

**ImqBoolean triggerType ( MQLONG & type );**

Provides a copy of the **trigger type**. It returns TRUE if successful.

**MQLONG triggerType ( );**

Returns the **trigger type** without any indication of possible errors.

**ImqBoolean setTriggerType ( const MQLONG type );**

Sets the **trigger type**. It returns TRUE if successful.

**ImqBoolean usage ( MQLONG & usage );**

Provides a copy of the **usage** value. It returns TRUE if successful.

**MQLONG usage ( );**

Returns the **usage** value without any indication of possible errors.

**Object methods (protected)****void setNextDistributedQueue ( ImqQueue \* queue = 0 );**

Sets the **next distributed queue**.

**Attention:** Use this function only if you are sure it will not break the distributed queue list.

**void setPreviousDistributedQueue ( ImqQueue \* queue = 0 );**

Sets the **previous distributed queue**.

**Attention:** Use this function only if you are sure it will not break the distributed queue list.

## ImqQueueManager C++ class

This class encapsulates a queue manager (an IBM MQ object of type MQOT\_Q\_MGR).

Figure 33. *ImqQueueManager* class

This class relates to the MQI calls listed in [“ImqQueueManager cross-reference”](#) on page 1794. Not all the listed methods are applicable to all platforms; see [ALTER QMGR](#) for more details.

- [“Class attributes”](#) on page 1862

## Class attributes

### behavior

Controls the behavior of implicit connection and disconnection.

#### **IMQ\_EXPL\_DISC\_BACKOUT (0L)**

An explicit call to the disconnect method implies backout. This attribute is mutually exclusive with IMQ\_EXPL\_DISC\_COMMIT.

#### **IMQ\_EXPL\_DISC\_COMMIT (1L)**

An explicit call to the disconnect method implies commit (the default). This attribute is mutually exclusive with IMQ\_EXPL\_DISC\_BACKOUT.

**IMQ\_IMPL\_CONN (2L)**

Implicit connection is allowed (the default).

**IMQ\_IMPL\_DISC\_BACKOUT (0L)**

An implicit call to the disconnect method, which can occur during object destruction, implies backout. This attribute is mutually exclusive with the IMQ\_IMPL\_DISC\_COMMIT.

**IMQ\_IMPL\_DISC\_COMMIT (4L)**

An implicit call to the disconnect method, which can occur during object destruction, implies commit (the default). This attribute is mutually exclusive with IMQ\_IMPL\_DISC\_BACKOUT.

At IBM MQ V7.0 and above, C++ applications that make use of an implicit connection, need to specify IMQ\_IMPL\_CONN along with any other options provided in the `setBehavior()` method on an object of class `ImqQueueManager`. If your application does not use the `setBehavior()` method to explicitly set the behavior options, for example,

```
ImqQueueManager_object.setBehavior(IMQ_IMPL_DISC_COMMIT)
```

this change does not affect you since MQ\_IMPL\_CONN is enabled by default.

If your application explicitly sets the behavior options, for example,

```
ImqQueueManager_object.setBehavior(IMQ_IMPL_DISC_COMMIT)
```

you need to include IMQ\_IMPL\_CONN in the `setBehavior()` method as follows, to allow your application to complete an implicit connection:

```
ImqQueueManager_object.setBehavior(IMQ_IMPL_CONN | IMQ_IMPL_DISC_COMMIT)
```

**Object attributes****accounting connections override**

Allows applications to override the setting of the MQI accounting and queue accounting values. This attribute is read-only.

**accounting interval**

How long before intermediate accounting records are written (in seconds). This attribute is read-only.

**activity recording**

Controls the generation of activity reports. This attribute is read-only.

**adopt new mca check**

The elements checked to determine if an MCA should be adopted when a new inbound channel is detected that has the same name as an MCA that is already active. This attribute is read-only.

**adopt new mca type**

Whether an orphaned instance of an MCA of a particular channel type should be restarted automatically when a new inbound channel request matching the adopt new mca check parameters is detected. This attribute is read-only.

**authentication type**

Indicates the type of authentication which is being performed.

**authority event**

Controls authority events. This attribute is read-only.

**begin options**

Options that apply to the begin method. The initial value is MQBO\_NONE.

**bridge event**

Whether IMS bridge events are generated. This attribute is read-only.

**channel auto definition**

Channel auto definition value. This attribute is read-only.

**channel auto definition event**

Channel auto definition event value. This attribute is read-only.

**channel auto definition exit**

Channel auto definition exit name. This attribute is read-only.

**channel event**

Whether channel events are generated. This attribute is read-only.

**channel initiator adapters**

The number of adapter subtasks to use for processing IBM MQ calls. This attribute is read-only.

**channel initiator control**

Whether the Channel Initiator should be started automatically when the Queue Manager is started. This attribute is read-only.

**channel initiator dispatchers**

The number of dispatchers to use for the channel initiator. This attribute is read-only.

**channel initiator trace autostart**

Whether channel initiator trace should start automatically or not. This attribute is read-only.

**channel initiator trace table size**

The size of the channel initiator's trace data space (in MB). This attribute is read-only.

**channel monitoring**

Controls the collection of online monitoring data for channels. This attribute is read-only.

**channel reference**

A reference to a channel definition for use during client connection. While connected, this attribute can be set to null, but cannot be changed to any other value. The initial value is null.

**channel statistics**

Controls the collection of statistics data for channels. This attribute is read-only.

**character set**

Coded character set identifier (CCSID). This attribute is read-only.

**cluster sender monitoring**

Controls the collection of online monitoring data for automatically-defined cluster sender channels. This attribute is read-only.

**cluster sender statistics**

Controls the collection of statistics data for automatically defined cluster sender channels. This attribute is read-only.

**cluster workload data**

Cluster workload exit data. This attribute is read-only.

**cluster workload exit**

Cluster workload exit name. This attribute is read-only.

**cluster workload length**

Cluster workload length. This attribute is read-only.

**cluster workload mru**

Cluster workload most recently used channels value. This attribute is read-only.

**cluster workload use queue**

Cluster workload use queue value. This attribute is read-only.

**command event**

Whether command events are generated. This attribute is read-only.

**command input queue name**

System command input queue name. This attribute is read-only.

**command level**

Command level supported by the queue manager. This attribute is read-only.

**command server control**

Whether the Command Server should be started automatically when the Queue Manager is started. This attribute is read-only.

**connect options**

Options that apply to the connect method. The initial value is MQCNO\_NONE. The following additional values may be possible, depending on platform:

- MQCNO\_STANDARD\_BINDING
- MQCNO\_FASTPATH\_BINDING
- MQCNO\_HANDLE\_SHARE\_NONE
- MQCNO\_HANDLE\_SHARE\_BLOCK
- MQCNO\_HANDLE\_SHARE\_NO\_BLOCK
- MQCNO\_SERIALIZE\_CONN\_TAG\_Q\_MGR
- MQCNO\_SERIALIZE\_CONN\_TAG\_QSG
- MQCNO\_RESTRICT\_CONN\_TAG\_Q\_MGR
- MQCNO\_RESTRICT\_CONN\_TAG\_QSG

**connection id**

A unique identifier that allows MQ to reliably identify an application.

**connection status**

TRUE when connected to the queue manager. This attribute is read-only.

**connection tag**

A tag to be associated with a connection. This attribute can only be set when not connected. The initial value is null.

**cryptographic hardware**

Configuration details for cryptographic hardware. For MQ MQI client connections.

**dead-letter queue name**

Name of the dead-letter queue. This attribute is read-only.

**default transmission queue name**

Default transmission queue name. This attribute is read-only.

**distribution lists**

Capability of the queue manager to support distribution lists.

**dns group**

The name of the group that the TCP listener that handles inbound transmissions for the queue sharing group should join when using Workload Manager Dynamic Domain Name Services support. This attribute is read-only.

**dns wlm**

Whether the TCP listener that handles inbound transmissions for the queue sharing group should register with Workload Manager for Dynamic Domain Name Services. This attribute is read-only.

**first authentication record**

The first of one or more objects of class ImqAuthenticationRecord, in no particular order, in which the ImqAuthenticationRecord connection reference addresses this object. For MQ MQI client connections.

**first managed object**

The first of one or more objects of class ImqObject, in no particular order, in which the ImqObject connection reference addresses this object. The initial value is zero.

**inhibit event**

Controls inhibit events. This attribute is read-only.

**ip address version**

Which IP protocol (IPv4 or IPv6) to use for a channel connection. This attribute is read-only.

**key repository**

Location of the key database file in which keys and certificates are stored. For IBM MQ MQI client connections.

**key reset count**

The number of unencrypted bytes sent and received within a TLS conversation before the secret key is renegotiated. This attribute applies only to client connections using MQCONNX. See also [ssl key reset count](#).

**listener timer**

The time interval (in seconds) between attempts by IBM MQ to restart the listener if there has been an APPC or TCP/IP failure. This attribute is read-only.

**local event**

Controls local events. This attribute is read-only.

**logger event**

Controls whether recovery log events are generated. This attribute is read-only.

**lu group name**

The generic LU name that the LU 6.2 listener that handles inbound transmissions for the queue sharing group should use. This attribute is read-only.

**lu name**

The name of the LU to use for outbound LU 6.2 transmissions. This attribute is read-only.

**lu62 arm suffix**

The suffix of the SYS1.PARMLIB member APPCPMxx, that nominates the LUADD for this channel initiator. This attribute is read-only.

**lu62 channels**

The maximum number of channels that can be current or clients that can be connected, that use the LU 6.2 transmission protocol. This attribute is read-only.

**maximum active channels**

The maximum number of channels that can be active at any time. This attribute is read-only.

**maximum channels**

The maximum number of channels that can be current (including server-connection channels with connected clients). This attribute is read-only.

**maximum handles**

Maximum number of handles. This attribute is read-only.

**maximum message length**

Maximum possible length for any message on any queue managed by this queue manager. This attribute is read-only.

**maximum priority**

Maximum message priority. This attribute is read-only.

**maximum uncommitted messages**

Maximum number of uncommitted messages within a unit or work. This attribute is read-only.

**mqi accounting**

Controls the collection of accounting information for MQI data. This attribute is read-only.

**mqi statistics**

Controls the collection of statistics monitoring information for the queue manager. This attribute is read-only.

**outbound port maximum**

The higher end of the range of port numbers to be used when binding outgoing channels. This attribute is read-only.

**outbound port minimum**

The lower end of the range of port numbers to be used when binding outgoing channels. This attribute is read-only.

**password**

password associated with user ID

**performance event**

Controls performance events. This attribute is read-only.

**platform**

Platform on which the queue manager resides. This attribute is read-only.

**queue accounting**

Controls the collection of accounting information for queues. This attribute is read-only.

**queue monitoring**

Controls the collection of online monitoring data for queues. This attribute is read-only.

**queue statistics**

Controls the collection of statistics data for queues. This attribute is read-only.

**receive timeout**

Approximately how long a TCP/IP message channel will wait to receive data, including heartbeats, from its partner, before returning to the inactive state. This attribute is read-only.

**receive timeout minimum**

The minimum time that a TCP/IP channel will wait to receive data, including heartbeats, from its partner, before returning to the inactive state. This attribute is read-only.

**receive timeout type**

A qualifier applied to receive timeout. This attribute is read-only.

**remote event**

Controls remote events. This attribute is read-only.

**repository name**

Repository name. This attribute is read-only.

**repository namelist**

Repository namelist name. This attribute is read-only.

**shared queue manager name**

Whether MQOPENS of a shared queue where the ObjectQMGrName is another queue manager in the queue sharing group should resolve to an open of the shared queue on the local queue manager. This attribute is read-only.

**ssl event**

Whether SSL events are generated. This attribute is read-only.

**ssl FIPS required**

Whether only FIPS-certified algorithms should be used if the cryptography is executed in IBM MQ software. This attribute is read-only.

**ssl key reset count**

The number of unencrypted bytes sent and received within an SSL conversation before the secret key is renegotiated. This attribute is read-only.

**start-stop event**

Controls start-stop events. This attribute is read-only.

**statistics interval**

How often statistics monitoring data is written to the monitoring queue. This attribute is read-only.

**syncpoint availability**

Availability of syncpoint participation. This attribute is read-only.

**Note:** Queue manager-coordinated global units of work are not supported on the IBM i platform.

 You can program a unit of work, externally coordinated by IBM i, using the `_Rcommit` and `_Rback` native system calls. Start this type of unit of work by starting the IBM MQ application under job-level commitment control using the `STRCMTCTL` command. See [Interfaces to the IBM i external syncpoint manager](#) for further details. Backout and commit are supported on the IBM i platform for local units of work coordinated by a queue manager.

**tcp channels**

The maximum number of channels that can be current or clients that can be connected, that use the TCP/IP transmission protocol. This attribute is read-only.

**tcp keepalive**

Whether the TCP KEEPALIVE facility is to be used to check that the other end of the connection is still available. This attribute is read-only.

**tcp name**

The name of either the sole or default TCP/IP system to be used, depending on the value of tcp stack type. This attribute is read-only.

**tcp stack type**

Whether the channel initiator is permitted to only use the TCP/IP address space specified in tcp name or can bind to any selected TCP/IP address. This attribute is read-only.

**trace route recording**

Controls the recording of route tracing information. This attribute is read-only.

**trigger interval**

Trigger interval. This attribute is read-only.

**user id**

On AIX and Linux platforms, the application's real user ID. On Windows platforms, the application's user ID.

**Constructors****ImqQueueManager();**

The default constructor.

**ImqQueueManager( const ImqQueueManager & manager );**

The copy constructor. The connection status will be FALSE.

**ImqQueueManager( const char \* name );**

Sets the ImqObject name to *name*.

**Destructors**

When an ImqQueueManager object is destroyed, it is automatically disconnected.

**Class methods (public)****static MQLONG behavior();**

Returns the behavior.

**void setBehavior( const MQLONG behavior = 0 );**

Sets the behavior.

**Object methods (public)****void operator = ( const ImqQueueManager & mgr );**

Disconnects if necessary, and copies instance data from *mgr*. The connection status is be FALSE.

**ImqBoolean accountingConnOverride ( MQLONG & statint );**

Provides a copy of the accounting connections override value. It returns TRUE if successful.

**MQLONG accountingConnOverride ();**

Returns the accounting connections override value without any indication of possible errors.

**ImqBoolean accountingInterval ( MQLONG & statint );**

Provides a copy of the accounting interval value. It returns TRUE if successful.

**MQLONG accountingInterval ();**

Returns the accounting interval value without any indication of possible errors.

**ImqBoolean activityRecording ( MQLONG & rec );**

Provides a copy of the activity recording value. It returns TRUE if successful.

**MQLONG activityRecording ( );**

Returns the activity recording value without any indication of possible errors.

**ImqBoolean adoptNewMCACheck ( MQLONG & check );**

Provides a copy of the adopt new MCA check value. It returns TRUE if successful.

**MQLONG adoptNewMCACheck ( );**

Returns the adopt new MCA check value without any indication of possible errors.

**ImqBoolean adoptNewMCAType ( MQLONG & type );**

Provides a copy of the adopt new MCA type. It returns TRUE if successful.

**MQLONG adoptNewMCAType ( );**

Returns the adopt new MCA type without any indication of possible errors.

**QLONG authenticationType ( ) const;**

Returns the authentication type.

**void setAuthenticationType ( const MQLONG type = MQCSP\_AUTH\_NONE );**

Sets the authentication type.

**ImqBoolean authorityEvent( MQLONG & event );**

Provides a copy of the enablement state of the authority event. It returns TRUE if successful.

**MQLONG authorityEvent( );**

Returns the enablement state of the authority event without any indication of possible errors.

**ImqBoolean backout( );**

Backs out uncommitted changes. It returns TRUE if successful.

**ImqBoolean begin( );**

Begins a unit of work. The begin options affect the behavior of this method. It returns TRUE if successful, but it also returns TRUE even if the underlying MQBEGIN call returns MQRC\_NO\_EXTERNAL\_PARTICIPANTS or MQRC\_PARTICIPANT\_NOT\_AVAILABLE (which are both associated with MQCC\_WARNING).

**MQLONG beginOptions( ) const ;**

Returns the begin options.

**void setBeginOptions( const MQLONG options = MQBO\_NONE );**

Sets the begin options.

**ImqBoolean bridgeEvent ( MQLONG & event);**

Provides a copy of the bridge event value. It returns TRUE if successful.

**MQLONG bridgeEvent ( );**

Returns the bridge event value without any indication of possible errors.

**ImqBoolean channelAutoDefinition( MQLONG & value );**

Provides a copy of the channel auto definition value. It returns TRUE if successful.

**MQLONG channelAutoDefinition( );**

Returns the channel auto definition value without any indication of possible errors.

**ImqBoolean channelAutoDefinitionEvent( MQLONG & value );**

Provides a copy of the channel auto definition event value. It returns TRUE if successful.

**MQLONG channelAutoDefinitionEvent( );**

Returns the channel auto definition event value without any indication of possible errors.

**ImqBoolean channelAutoDefinitionExit( ImqString & name );**

Provides a copy of the channel auto definition exit name. It returns TRUE if successful.

**ImqString channelAutoDefinitionExit( );**

Returns the channel auto definition exit name without any indication of possible errors.

**ImqBoolean channelEvent ( MQLONG & event);**

Provides a copy of the channel event value. It returns TRUE if successful.

**MQLONG channelEvent( );**  
Returns the channel event value without any indication of possible errors.

**MQLONG channelInitiatorAdapters ( );**  
Returns the channel initiator adapters value without any indication of possible errors.

**ImqBoolean channelInitiatorAdapters ( MQLONG & adapters );**  
Provides a copy of the channel initiator adapters value. It returns TRUE if successful.

**MQLONG channelInitiatorControl ( );**  
Returns the channel initiator startup value without any indication of possible errors.

**ImqBoolean channelInitiatorControl ( MQLONG & init );**  
Provides a copy of the channel initiator control startup value. It returns TRUE if successful.

**MQLONG channelInitiatorDispatchers ( );**  
Returns the channel initiator dispatchers value without any indication of possible errors.

**ImqBoolean channelInitiatorDispatchers ( MQLONG & dispatchers );**  
Provides a copy of the channel initiator dispatchers value. It returns TRUE if successful.

**MQLONG channelInitiatorTraceAutoStart ( );**  
Returns the channel initiator trace auto start value without any indication of possible errors.

**ImqBoolean channelInitiatorTraceAutoStart ( MQLONG & auto);**  
Provides a copy of the channel initiator trace auto start value. It returns TRUE if successful.

**MQLONG channelInitiatorTraceTableSize ( );**  
Returns the channel initiator trace table size value without any indication of possible errors.

**ImqBoolean channelInitiatorTraceTableSize ( MQLONG & size);**  
Provides a copy of the channel initiator trace table size value. It returns TRUE if successful.

**ImqBoolean channelMonitoring ( MQLONG & monchl );**  
Provides a copy of the channel monitoring value. It returns TRUE if successful.

**MQLONG channelMonitoring ( );**  
Returns the channel monitoring value without any indication of possible errors.

**ImqBoolean channelReference( ImqChannel \* & pchannel );**  
Provides a copy of the channel reference. If the channel reference is invalid, sets *pchannel* to null. This method returns TRUE if successful.

**ImqChannel \* channelReference( );**  
Returns the channel reference without any indication of possible errors.

**ImqBoolean setChannelReference( ImqChannel & channel );**  
Sets the channel reference. This method returns TRUE if successful.

**ImqBoolean setChannelReference( ImqChannel \* channel = 0 );**  
Sets or resets the channel reference. This method returns TRUE if successful.

**ImqBoolean channelStatistics ( MQLONG & statchl );**  
Provides a copy of the channel statistics value. It returns TRUE if successful.

**MQLONG channelStatistics ( );**  
Returns the channel statistics value without any indication of possible errors.

**ImqBoolean characterSet( MQLONG & ccsid );**  
Provides a copy of the character set. It returns TRUE if successful.

**MQLONG characterSet( );**  
Returns a copy of the character set, without any indication of possible errors.

**MQLONG clientSslKeyResetCount ( ) const;**  
Returns the SSL key reset count value used on client connections.

**void setClientSslKeyResetCount( const MQLONG count );**  
Sets the SSL key reset count used on client connections.

**ImqBoolean clusterSenderMonitoring ( MQLONG & monacIs );**  
Provides a copy of the cluster sender monitoring default value. It returns TRUE if successful.

**MQLONG clusterSenderMonitoring ( );**

Returns the cluster sender monitoring default value without any indication of possible errors.

**ImqBoolean clusterSenderStatistics ( MQLONG & statacls );**

Provides a copy of the cluster sender statistics value. It returns TRUE if successful.

**MQLONG clusterSenderStatistics ( );**

Returns the cluster sender statistics value without any indication of possible errors.

**ImqBoolean clusterWorkloadData( ImqString & data );**

Provides a copy of the cluster workload exit data. It returns TRUE if successful.

**ImqString clusterWorkloadData( );**

Returns the cluster workload exit data without any indication of possible errors.

**ImqBoolean clusterWorkloadExit( ImqString & name );**

Provides a copy of the cluster workload exit name. It returns TRUE if successful.

**ImqString clusterWorkloadExit( );**

Returns the cluster workload exit name without any indication of possible errors.

**ImqBoolean clusterWorkloadLength( MQLONG & length );**

Provides a copy of the cluster workload length. It returns TRUE if successful.

**MQLONG clusterWorkloadLength( );**

Returns the cluster workload length without any indication of possible errors.

**ImqBoolean clusterWorkLoadMRU ( MQLONG & mru );**

Provides a copy of the cluster workload most recently used channels value. It returns TRUE if successful.

**MQLONG clusterWorkLoadMRU ( );**

Returns the cluster workload most recently used channels value without any indication of possible errors.

**ImqBoolean clusterWorkLoadUseQ ( MQLONG & useq );**

Provides a copy of the cluster workload use queue value. It returns TRUE if successful.

**MQLONG clusterWorkLoadUseQ ( );**

Returns the cluster workload use queue value without any indication of possible errors.

**ImqBoolean commandEvent ( MQLONG & event );**

Provides a copy of the command event value. It returns TRUE if successful.

**MQLONG commandEvent ( );**

Returns the command event value without any indication of possible errors.

**ImqBoolean commandInputQueueName( ImqString & name );**

Provides a copy of the command input queue name. It returns TRUE if successful.

**ImqString commandInputQueueName( );**

Returns the command input queue name without any indication of possible errors.

**ImqBoolean commandLevel( MQLONG & level );**

Provides a copy of the command level. It returns TRUE if successful.

**MQLONG commandLevel( );**

Returns the command level without any indication of possible errors.

**MQLONG commandServerControl ( );**

Returns the command server startup value without any indication of possible errors.

**ImqBoolean commandServerControl ( MQLONG & server );**

Provides a copy of the command server control startup value. It returns TRUE if successful.

**ImqBoolean commit( );**

Commits uncommitted changes. It returns TRUE if successful.

**ImqBoolean connect( );**

Connects to the queue manager with the given ImqObject name, the default being the local queue manager. If you want to connect to a specific queue manager, use the ImqObject setName method before connection. If there is a channel reference, it is used to pass information about the channel

definition to MQCONN in an MQCD. The ChannelType in the MQCD is set to MQCHT\_CLNTCONN. channel reference information, which is only meaningful for client connections, is ignored for server connections. The connect options affect the behavior of this method. This method sets the connection status to TRUE if successful. It returns the new connection status.

If there is a first authentication record, the chain of authentication records is used to authenticate digital certificates for secure client channels.

You can connect more than one ImqQueueManager object to the same queue manager. All use the same MQHCONN connection handle and share UOW functionality for the connection associated with the thread. The first ImqQueueManager to connect obtains the MQHCONN handle. The last ImqQueueManager to disconnect performs the MQDISC.

For a multithreaded program, it is recommended that a separate ImqQueueManager object is used for each thread.

**ImqBinary connectionId ( ) const ;**

Returns the connection ID.

**ImqBinary connectionTag ( ) const ;**

Returns the connection tag.

**ImqBoolean setConnectionTag ( const MQBYTE128 tag = 0 );**

Sets the connection tag. If *tag* is zero, clears the connection tag. This method returns TRUE if successful.

**ImqBoolean setConnectionTag ( const ImqBinary & tag );**

Sets the connection tag. The data length of *tag* must be either zero (to clear the connection tag) or MQ\_CONN\_TAG\_LENGTH. This method returns TRUE if successful.

**MQLONG connectOptions( ) const ;**

Returns the connect options.

**void setConnectOptions( const MQLONG options = MQCNO\_NONE );**

Sets the connect options.

**ImqBoolean connectionStatus( ) const ;**

Returns the connection status.

**ImqString cryptographicHardware ( );**

Returns the cryptographic hardware.

**ImqBoolean setCryptographicHardware ( const char \* hardware = 0 );**

Sets the cryptographic hardware. This method returns TRUE if successful.

**ImqBoolean deadLetterQueueName( ImqString & name );**

Provides a copy of the dead-letter queue name. It returns TRUE if successful.

**ImqString deadLetterQueueName( );**

Returns a copy of the dead-letter queue name, without any indication of possible errors.

**ImqBoolean defaultTransmissionQueueName( ImqString & name );**

Provides a copy of the default transmission queue name. It returns TRUE if successful.

**ImqString defaultTransmissionQueueName( );**

Returns the default transmission queue name without any indication of possible errors.

**ImqBoolean disconnect( );**

Disconnects from the queue manager and sets the connection status to FALSE. Closes all ImqProcess and ImqQueue objects associated with this object, and severs their connection reference before disconnection. If more than one ImqQueueManager object is connected to the same queue manager, only the last to disconnect performs a physical disconnection; others perform a logical disconnection. Uncommitted changes are committed on physical disconnection only.

This method returns TRUE if successful. If it is called when there is no existing connection, the return code is also true.

**ImqBoolean distributionLists( MQLONG & support );**

Provides a copy of the distribution lists value. It returns TRUE if successful.

**MQLONG distributionLists();**  
Returns the distribution lists value without any indication of possible errors.

**ImqBoolean dnsGroup ( ImqString & group );**  
Provides a copy of the DNS group name. It returns TRUE if successful.

**ImqString dnsGroup ();**  
Returns the DNS group name without any indication of possible errors.

**ImqBoolean dnsWlm ( MQLONG & wlm );**  
Provides a copy of the DNS WLM value. It returns TRUE if successful.

**MQLONG dnsWlm ();**  
Returns the DNS WLM value without any indication of possible errors.

**ImqAuthenticationRecord \* firstAuthenticationRecord ( ) const ;**  
Returns the first authentication record.

**void setFirstAuthenticationRecord ( const ImqAuthenticationRecord \* air = 0 );**  
Sets the first authentication record.

**ImqObject \* firstManagedObject() const ;**  
Returns the first managed object.

**ImqBoolean inhibitEvent( MQLONG & event );**  
Provides a copy of the enablement state of the inhibit event. It returns TRUE if successful.

**MQLONG inhibitEvent();**  
Returns the enablement state of the inhibit event without any indication of possible errors.

**ImqBoolean ipAddressVersion ( MQLONG & version );**  
Provides a copy of the IP address version value. It returns TRUE if successful.

**MQLONG ipAddressVersion ();**  
Returns the IP address version value without any indication of possible errors.

**ImqBoolean keepAlive ( MQLONG & keepalive );**  
Provides a copy of the keep alive value. It returns TRUE if successful.

**MQLONG keepAlive ();**  
Returns the keep alive value without any indication of possible errors.

**ImqString keyRepository ();**  
Returns the key repository.

**ImqBoolean setKeyRepository ( const char \* repository = 0 );**  
Sets the key repository. It returns TRUE if successful.

**ImqBoolean listenerTimer ( MQLONG & timer );**  
Provides a copy of the listener timer value. It returns TRUE if successful.

**MQLONG listenerTimer ();**  
Returns the listener timer value without any indication of possible errors.

**ImqBoolean localEvent( MQLONG & event );**  
Provides a copy of the enablement state of the local event. It returns TRUE if successful.

**MQLONG localEvent();**  
Returns the enablement state of the local event without any indication of possible errors.

**ImqBoolean loggerEvent ( MQLONG & count );**  
Provides a copy of the logger event value. It returns TRUE if successful.

**MQLONG loggerEvent ();**  
Returns the logger event value without any indication of possible errors.

**ImqBoolean luGroupName ( ImqString & name );**  
Provides a copy of the LU group name. It returns TRUE if successful.

**ImqString luGroupName ();**  
Returns the LU group name without any indication of possible errors.

**ImqBoolean lu62ARMSuffix ( ImqString & suffix );**  
Provides a copy of the LU62 ARM suffix. It returns TRUE if successful.

**ImqString lu62ARMSuffix ( );**  
Returns the LU62 ARM suffix without any indication of possible errors

**ImqBoolean luName ( ImqString & name );**  
Provides a copy of the LU name. It returns TRUE if successful.

**ImqString luName ( );**  
Returns the LU name without any indication of possible errors.

**ImqBoolean maximumActiveChannels ( MQLONG & channels);**  
Provides a copy of the maximum active channels value. It returns TRUE if successful.

**MQLONG maximumActiveChannels ( );**  
Returns the maximum active channels value without any indication of possible errors.

**ImqBoolean maximumCurrentChannels ( MQLONG & channels );**  
Provides a copy of the maximum current channels value. It returns TRUE if successful.

**MQLONG maximumCurrentChannels ( );**  
Returns the maximum current channels value without any indication of possible errors.

**ImqBoolean maximumHandles( MQLONG & number );**  
Provides a copy of the maximum handles. It returns TRUE if successful.

**MQLONG maximumHandles( );**  
Returns the maximum handles without any indication of possible errors.

**ImqBoolean maximumLu62Channels ( MQLONG & channels );**  
Provides a copy of the maximum LU62 channels value. It returns TRUE if successful.

**MQLONG maximumLu62Channels ( );.**  
Returns the maximum LU62 channels value without any indication of possible errors

**ImqBoolean maximumMessageLength( MQLONG & length );**  
Provides a copy of the maximum message length. It returns TRUE if successful.

**MQLONG maximumMessageLength( );**  
Returns the maximum message length without any indication of possible errors.

**ImqBoolean maximumPriority( MQLONG & priority );**  
Provides a copy of the maximum priority. It returns TRUE if successful.

**MQLONG maximumPriority( );**  
Returns a copy of the maximum priority, without any indication of possible errors.

**ImqBoolean maximumTcpChannels ( MQLONG & channels );**  
Provides a copy of the maximum TCP channels value. It returns TRUE if successful.

**MQLONG maximumTcpChannels ( );**  
Returns the maximum TCP channels value without any indication of possible errors.

**ImqBoolean maximumUncommittedMessages( MQLONG & number );**  
Provides a copy of the maximum uncommitted messages. It returns TRUE if successful.

**MQLONG maximumUncommittedMessages( );**  
Returns the maximum uncommitted messages without any indication of possible errors.

**ImqBoolean mqiAccounting ( MQLONG & statint );**  
Provides a copy of the MQI accounting value. It returns TRUE if successful.

**MQLONG mqiAccounting ( );**  
Returns the MQI accounting value without any indication of possible errors.

**ImqBoolean mqiStatistics ( MQLONG & statmqi );**  
Provides a copy of the MQI statistics value. It returns TRUE if successful.

**MQLONG mqiStatistics ( );**  
Returns the MQI statistics value without any indication of possible errors.

**ImqBoolean outboundPortMax ( MQLONG & max );**  
Provides a copy of the maximum outbound port value. It returns TRUE if successful.

**MQLONG outboundPortMax ( );**  
Returns the maximum outbound port value without any indication of possible errors.

**ImqBoolean outboundPortMin ( MQLONG & min );**

Provides a copy of the minimum outbound port value. It returns TRUE if successful.

**MQLONG outboundPortMin ( );**

Returns the minimum outbound port value without any indication of possible errors.

**ImqBinary password ( ) const;**

Returns the password used on client connections.

**ImqBoolean setPassword ( const ImqString & password );**

Sets the password used on client connections.

**ImqBoolean setPassword ( const char \* = 0 password );**

Sets the password used on client connections.

**ImqBoolean setPassword ( const ImqBinary & password );**

Sets the password used on client connections.

**ImqBoolean performanceEvent( MQLONG & event );**

Provides a copy of the enablement state of the performance event. It returns TRUE if successful.

**MQLONG performanceEvent( );**

Returns the enablement state of the performance event without any indication of possible errors.

**ImqBoolean platform( MQLONG & platform );**

Provides a copy of the platform. It returns TRUE if successful.

**MQLONG platform( );**

Returns the platform without any indication of possible errors.

**ImqBoolean queueAccounting ( MQLONG & acctq );**

Provides a copy of the queue accounting value. It returns TRUE if successful.

**MQLONG queueAccounting ( );**

Returns the queue accounting value without any indication of possible errors.

**ImqBoolean queueMonitoring ( MQLONG & monq );**

Provides a copy of the queue monitoring value. It returns TRUE if successful.

**MQLONG queueMonitoring ( );**

Returns the queue monitoring value without any indication of possible errors.

**ImqBoolean queueStatistics ( MQLONG & statq );**

Provides a copy of the queue statistics value. It returns TRUE if successful.

**MQLONG queueStatistics ( );**

Returns the queue statistics value without any indication of possible errors.

**ImqBoolean receiveTimeout ( MQLONG & timeout );**

Provides a copy of the receive timeout value. It returns TRUE if successful.

**MQLONG receiveTimeout ( );**

Returns the receive timeout value without any indication of possible errors.

**ImqBoolean receiveTimeoutMin ( MQLONG & min );**

Provides a copy of the minimum receive timeout value. It returns TRUE if successful.

**MQLONG receiveTimeoutMin ( );**

Returns the minimum receive timeout value without any indication of possible errors.

**ImqBoolean receiveTimeoutType ( MQLONG & type );**

Provides a copy of the receive timeout type. It returns TRUE if successful.

**MQLONG receiveTimeoutType ( );**

Returns the receive timeout type without any indication of possible errors.

**ImqBoolean remoteEvent( MQLONG & event );**

Provides a copy of the enablement state of the remote event. It returns TRUE if successful.

**MQLONG remoteEvent( );**

Returns the enablement state of the remote event without any indication of possible errors.

**ImqBoolean repositoryName( ImqString & name );**

Provides a copy of the repository name. It returns TRUE if successful.

**ImqString repositoryName( );**

Returns the repository name without any indication of possible errors.

**ImqBoolean repositoryNamelistName( ImqString & name );**

Provides a copy of the repository namelist name. It returns TRUE if successful.

**ImqString repositoryNamelistName( );**

Returns a copy of the repository namelist name without any indication of possible errors.

**ImqBoolean sharedQueueQueueManagerName ( MQLONG & name );**

Provides a copy of the shared queue queue manager name value. It returns TRUE if successful.

**MQLONG sharedQueueQueueManagerName ( );**

Returns the shared queue queue manager name value without any indication of possible errors.

**ImqBoolean sslEvent ( MQLONG & event );**

Provides a copy of the SSL event value. It returns TRUE if successful.

**MQLONG sslEvent ( );**

Returns the SSL event value without any indication of possible errors.

**ImqBoolean sslFips ( MQLONG & sslfips );**

Provides a copy of the SSL FIPS value. It returns TRUE if successful.

**MQLONG sslFips ( );**

Returns the SSL FIPS value without any indication of possible errors.

**ImqBoolean sslKeyResetCount ( MQLONG & count );**

Provides a copy of the SSL key reset count value. It returns TRUE if successful.

**MQLONG sslKeyResetCount ( );**

Returns the SSL key reset count value without any indication of possible errors.

**ImqBoolean startStopEvent( MQLONG & event );**

Provides a copy of the enablement state of the start-stop event. It returns TRUE if successful.

**MQLONG startStopEvent( );**

Returns the enablement state of the start-stop event without any indication of possible errors.

**ImqBoolean statisticsInterval ( MQLONG & statint );**

Provides a copy of the statistics interval value. It returns TRUE if successful.

**MQLONG statisticsInterval ( );**

Returns the statistics interval value without any indication of possible errors.

**ImqBoolean syncPointAvailability( MQLONG & sync );**

Provides a copy of the syncpoint availability value. It returns TRUE if successful.

**MQLONG syncPointAvailability( );**

Returns a copy of the syncpoint availability value, without any indication of possible errors.

**ImqBoolean tcpName ( ImqString & name );**

Provides a copy of the TCP system name. It returns TRUE if successful.

**ImqString tcpName ( );**

Returns the TCP system name without any indication of possible errors.

**ImqBoolean tcpStackType ( MQLONG & type );**

Provides a copy of the TCP stack type. It returns TRUE if successful.

**MQLONG tcpStackType ( );**

Returns the TCP stack type without any indication of possible errors.

**ImqBoolean traceRouteRecording ( MQLONG & routerec );**

Provides a copy of the trace route recording value. It returns TRUE if successful.

**MQLONG traceRouteRecording ( );**

Returns the trace route recording value without any indication of possible errors.

**ImqBoolean triggerInterval( MQLONG & interval );**

Provides a copy of the trigger interval. It returns TRUE if successful.

**MQLONG triggerInterval( );**

Returns the trigger interval without any indication of possible errors.

**ImqBinary userId ( ) const;**

Returns the user ID used on client connections.

**ImqBoolean setUserId ( const ImqString & id );**

Sets the user ID used on client connections.

**ImqBoolean setUserId ( const char \* = 0 id );**

Sets the user ID used on client connections.

**ImqBoolean setUserId ( const ImqBinary & id );**

Sets the user ID used on client connections.

**Object methods (protected)****void setFirstManagedObject ( const ImqObject \* *object* = 0 );**

Sets the first managed object.

**Object data (protected)****MQHCONN *ohconn***

The IBM MQ connection handle (meaningful only while the connection status is TRUE).

## ImqReferenceHeader C++ class

This class encapsulates features of the MQRMH data structure.

Figure 34. ImqReferenceHeader class

This class relates to the MQI calls listed in [“ImqReferenceHeader cross-reference”](#) on page 1798.

- [“Object attributes”](#) on page 1878
- [“Constructors”](#) on page 1879
- [“Overloaded ImqItem methods”](#) on page 1879
- [“Object methods \(public\)”](#) on page 1879
- [“Object data \(protected\)”](#) on page 1880
- [“Reason codes”](#) on page 1880

### Object attributes

#### destination environment

Environment for the destination. The initial value is a null string.

#### destination name

Name of the data destination. The initial value is a null string.

#### instance id

Instance identifier. A binary value (MQBYTE24) of length MQ\_OBJECT\_INSTANCE\_ID\_LENGTH. The initial value is MQOII\_NONE.

#### logical length

Logical, or intended, length of message data that follows this header. The initial value is zero.

#### logical offset

Logical offset for the message data that follows, to be interpreted in the context of the data as a whole, at the ultimate destination. The initial value is zero.

#### logical offset 2

High-order extension to the logical offset. The initial value is zero.

#### reference type

Reference type. The initial value is a null string.

#### source environment

Environment for the source. The initial value is a null string.

**source name**

Name of the data source. The initial value is a null string.

**Constructors****ImqReferenceHeader( );**

The default constructor.

**ImqReferenceHeader( const ImqReferenceHeader & header );**

The copy constructor.

**Overloaded ImqItem methods****virtual ImqBoolean copyOut ( ImqMessage & msg );**

Inserts an MQRMH data structure into the message buffer at the beginning, moving existing message data further along, and sets the *msg* format to MQFMT\_REF\_MSG\_HEADER.

See the ImqHeader class method description on [“ImqHeader C++ class” on page 1826](#) for further details.

**virtual ImqBoolean pasteIn ( ImqMessage & msg );**

Reads an MQRMH data structure from the message buffer.

To be successful, the ImqMessage format must be MQFMT\_REF\_MSG\_HEADER.

See the ImqHeader class method description on [“ImqHeader C++ class” on page 1826](#) for further details.

**Object methods (public)****void operator = ( const ImqReferenceHeader & header );**

Copies instance data from *header*, replacing the existing instance data.

**ImqString destinationEnvironment ( ) const ;**

Returns a copy of the destination environment.

**void setDestinationEnvironment ( const char \* environment = 0 );**

Sets the destination environment.

**ImqString destinationName ( ) const ;**

Returns a copy of the destination name.

**void setDestinationName ( const char \* name = 0 );**

Sets the destination name.

**ImqBinary instanceId ( ) const ;**

Returns a copy of the instance id.

**ImqBoolean setInstanceId ( const ImqBinary & id );**

Sets the instance id. The data length of *token* must be either 0 or MQ\_OBJECT\_INSTANCE\_ID\_LENGTH. This method returns TRUE if successful.

**void setInstanceId ( const MQBYTE24 id = 0 );**

Sets the instance id. *id* can be zero, which is the same as specifying MQOII\_NONE. If *id* is nonzero, it must address MQ\_OBJECT\_INSTANCE\_ID\_LENGTH bytes of binary data. When using pre-defined values such as MQOII\_NONE, you might need to make a cast to ensure a signature match, for example (MQBYTE \*)MQOII\_NONE.

**MQLONG logicalLength ( ) const ;**

Returns the logical length.

**void setLogicalLength ( const MQLONG length );**

Sets the logical length.

**MQLONG logicalOffset ( ) const ;**

Returns the logical offset.

**void setLogicalOffset ( const MQLONG offset );**

Sets the logical offset.

**MQLONG logicalOffset2 ( ) const ;**

Returns the logical offset 2.

**void setLogicalOffset2 ( const MQLONG offset );**

Sets the logical offset 2.

**ImqString referenceType ( ) const ;**

Returns a copy of the reference type.

**void setReferenceType ( const char \* name = 0 );**

Sets the reference type.

**ImqString sourceEnvironment ( ) const ;**

Returns a copy of the source environment.

**void setSourceEnvironment ( const char \* environment = 0 );**

Sets the source environment.

**ImqString sourceName ( ) const ;**

Returns a copy of the source name.

**void setSourceName ( const char \* name = 0 );**

Sets the source name.

## **Object data (protected)**

**MQRMH omqrmh**

The MQRMH data structure.

## **Reason codes**

- MQR\_C\_BINARY\_DATA\_LENGTH\_ERROR
- MQR\_C\_STRUC\_LENGTH\_ERROR
- MQR\_C\_STRUC\_ID\_ERROR
- MQR\_C\_INSUFFICIENT\_DATA
- MQR\_C\_INCONSISTENT\_FORMAT
- MQR\_C\_ENCODING\_ERROR

## ImqString C++ class

This class provides character string storage and manipulation for null-terminated strings.

Figure 35. *ImqString* class

Use an *ImqString* in place of a **char \*** in most situations where a parameter calls for a **char \***.

- [“Object attributes” on page 1881](#)
- [“Constructors” on page 1881](#)
- [“Class methods \(public\)” on page 1882](#)
- [“Overloaded \*ImqItem\* methods” on page 1882](#)
- [“Object methods \(public\)” on page 1882](#)
- [“Object methods \(protected\)” on page 1885](#)
- [“Reason codes” on page 1885](#)

### Object attributes

#### characters

Characters in the **storage** that precede a trailing null.

#### length

Number of bytes in the **characters**. If there is no **storage**, the **length** is zero. The initial value is zero.

#### storage

A volatile array of bytes of arbitrary size. A trailing null must always be present in the **storage** after the **characters**, so that the end of the **characters** can be detected. Methods ensure that this situation is maintained, but ensure, when setting bytes in the array directly, that a trailing null exists after modification. Initially, there is no **storage** attribute.

### Constructors

#### **ImqString();**

The default constructor.

#### **ImqString( const *ImqString* & *string* );**

The copy constructor.

#### **ImqString( const char *c* );**

The **characters** comprise *c*.

**ImqString( const char \* text );**

The **characters** are copied from *text*.

**ImqString( const void \* buffer, const size\_t length );**

Copies *length* bytes starting from *buffer* and assigns them to the **characters**. Substitution is made for any null characters copied. The substitution character is a period (.). No special consideration is given to any other non-printable or non-displayable characters copied.

## Class methods (public)

**static ImqBoolean copy( char \* destination-buffer, const size\_t length, const char \* source-buffer, const char pad = 0 );**

Copies up to *length* bytes from *source-buffer* to *destination-buffer*. If the number of characters in *source-buffer* is insufficient, fills the remaining space in *destination-buffer* with *pad* characters. *source-buffer* can be zero. *destination-buffer* can be zero if *length* is also zero. Any error codes are lost. This method returns TRUE if successful.

**static ImqBoolean copy ( char \* destination-buffer, const size\_t length, const char \* source-buffer, ImqError & error-object, const char pad = 0 );**

Copies up to *length* bytes from *source-buffer* to *destination-buffer*. If the number of characters in *source-buffer* is insufficient, fills the remaining space in *destination-buffer* with *pad* characters. *source-buffer* can be zero. *destination-buffer* can be zero if *length* is also zero. Any error codes are set in *error-object*. This method returns TRUE if successful.

## Overloaded ImqItem methods

**virtual ImqBoolean copyOut ( ImqMessage & msg );**

Copies the **characters** to the message buffer, replacing any existing content. Sets the *msg format* to MQFMT\_STRING.

See the parent class method description for further details.

**virtual ImqBoolean pasteIn ( ImqMessage & msg );**

Sets the **characters** by transferring the remaining data from the message buffer, replacing the existing **characters**.

To be successful, the **encoding** of the *msg* object must be MQENC\_NATIVE. Retrieve messages with MQGMO\_CONVERT to MQENC\_NATIVE.

To be successful, the *ImqMessage format* must be MQFMT\_STRING.

See the parent class method description for further details.

## Object methods (public)

**char & operator [ ] ( const size\_t offset ) const ;**

References the character at offset *offset* in the **storage**. Ensure that the relevant byte exists and is addressable.

**ImqString operator ( ) ( const size\_t offset, const size\_t length = 1 ) const ;**

Returns a substring by copying bytes from the **characters** starting at *offset*. If *length* is zero, returns the rest of the **characters**. If the combination of *offset* and *length* does not produce a reference within the **characters**, returns an empty *ImqString*.

**void operator = ( const ImqString & string );**

Copies instance data from *string*, replacing the existing instance data.

**ImqString operator + ( const char c ) const ;**

Returns the result of appending *c* to the **characters**.

**ImqString operator + ( const char \* text ) const ;**

Returns the result of appending *text* to the **characters**. This can also be inverted. For example:

```
strOne + "string two" ;  
"string one" + strTwo ;
```

**Note:** Although most compilers accept **strOne + "string two"**; Microsoft Visual C++ requires **strOne + (char \*)"string two"** ;

**ImqString operator + ( const ImqString & string1 ) const ;**

Returns the result of appending *string1* to the **characters**.

**ImqString operator + ( const double number ) const ;**

Returns the result of appending *number* to the **characters** after conversion to text.

**ImqString operator + ( const long number ) const ;**

Returns the result of appending *number* to the **characters** after conversion to text.

**void operator += ( const char c );**

Appends *c* to the **characters**.

**void operator += ( const char \* text );**

Appends *text* to the **characters**.

**void operator += ( const ImqString & string );**

Appends *string* to the **characters**.

**void operator += ( const double number );**

Appends *number* to the **characters** after conversion to text.

**void operator += ( const long number );**

Appends *number* to the **characters** after conversion to text.

**operator char \* ( ) const ;**

Returns the address of the first byte in the **storage**. This value can be zero, and is volatile. Use this method only for read-only purposes.

**ImqBoolean operator < ( const ImqString & string ) const ;**

Compares the **characters** with those of *string* using the **compare** method. The result is TRUE if less than and FALSE if greater than or equal to.

**ImqBoolean operator > ( const ImqString & string ) const ;**

Compares the **characters** with those of *string* using the **compare** method. The result is TRUE if greater than and FALSE if less than or equal to.

**ImqBoolean operator <= ( const ImqString & string ) const ;**

Compares the **characters** with those of *string* using the **compare** method. The result is TRUE if less than or equal to and FALSE if greater than.

**ImqBoolean operator >= ( const ImqString & string ) const ;**

Compares the **characters** with those of *string* using the **compare** method. The result is TRUE if greater than or equal to and FALSE if less than.

**ImqBoolean operator == ( const ImqString & string ) const ;**

Compares the **characters** with those of *string* using the **compare** method. It returns either TRUE or FALSE.

**ImqBoolean operator != ( const ImqString & string ) const ;**

Compares the **characters** with those of *string* using the **compare** method. It returns either TRUE or FALSE.

**short compare( const ImqString & string ) const ;**

Compares the **characters** with those of *string*. The result is zero if the **characters** are equal, negative if less than and positive if greater than. Comparison is case sensitive. A null ImqString is regarded as less than a nonnull ImqString.

**ImqBoolean copyOut( char \* *buffer*, const size\_t *length*, const char *pad* = 0 );**

Copies up to *length* bytes from the **characters** to the *buffer*. If the number of **characters** is insufficient, fills the remaining space in *buffer* with *pad* characters. *buffer* can be zero if *length* is also zero. It returns TRUE if successful.

**size\_t copyOut( long & *number* ) const ;**

Sets *number* from the **characters** after conversion from text, and returns the number of characters involved in the conversion. If this is zero, no conversion has been performed and *number* is not set. A convertible character sequence must begin with the following values:

```
<blank(s)>
<+|->
digit(s)
```

**size\_t copyOut( ImqString & *token*, const char *c* = ' ' ) const ;**

If the **characters** contain one or more characters that are different from *c*, identifies a token as the first contiguous sequence of such characters. In this case *token* is set to that sequence, and the value returned is the sum of the number of leading characters *c* and the number of bytes in the sequence. Otherwise, returns zero and does not set *token*.

**size\_t cutOut( long & *number* );**

Sets *number* as for the **copy** method, but also removes from **characters** the number of bytes indicated by the return value. For example, the string shown in the following example can be cut into three numbers by using **cutOut** (*number*) three times:

```
strNumbers = "-1 0 +55 "
while ( strNumbers.cutOut( number ) );
number becomes -1, then 0, then 55
leaving strNumbers == " "
```

**size\_t cutOut( ImqString & *token*, const char *c* = ' ' )**

Sets *token* as for the **copyOut** method, and removes from **characters** the *strToken* characters and also any characters *c* that precede the *token* characters. If *c* is not a blank, removes characters *c* that directly succeed the *token* characters. Returns the number of characters removed. For example, the string shown in the following example can be cut into three tokens by using **cutOut** (*token*) three times:

```
strText = " Program Version 1.1 "
while ( strText.cutOut( token ) );
// token becomes "Program", then "Version",
// then "1.1" leaving strText == " "
```

The following example shows how to parse a DOS path name:

```
strPath = "C:\OS2\BITMAP\OS2LOGO.BMP"
strPath.cutOut( strDrive, ':' );
strPath.stripLeading( ':' );
while ( strPath.cutOut( strFile, '\' ) );
// strDrive becomes "C".
// strFile becomes "OS2", then "BITMAP",
// then "OS2LOGO.BMP" leaving strPath empty.
```

**ImqBoolean find( const ImqString & *string* );**

Searches for an exact match for *string* anywhere within the **characters**. If no match is found, it returns FALSE. Otherwise, it returns TRUE. If *string* is null, it returns TRUE.

**ImqBoolean find( const ImqString & string, size\_t & offset );**

Searches for an exact match for *string* somewhere within the **characters** from offset *offset* onwards. If *string* is null, it returns TRUE without updating *offset*. If no match is found, it returns FALSE (the value of *offset* might have been increased). If a match is found, it returns TRUE and updates *offset* to the offset of *string* within the **characters**.

**size\_t length() const ;**

Returns the **length**.

**ImqBoolean pasteIn( const double number, const char \* format = "%f" );**

Appends *number* to the **characters** after conversion to text. It returns TRUE if successful.

The specification *format* is used to format the floating point conversion. If specified, it must be one suitable for use with **printf** and floating point numbers, for example **%3f**.

**ImqBoolean pasteIn( const long number );**

Appends *number* to the **characters** after conversion to text. It returns TRUE if successful.

**ImqBoolean pasteIn( const void \* buffer, const size\_t length );**

Appends *length* bytes from *buffer* to the **characters**, and adds a final trailing null. Substitutes any null characters copied. The substitution character is a period (.). No special consideration is given to any other nonprintable or nondisplayable characters copied. This method returns TRUE if successful.

**ImqBoolean set( const char \* buffer, const size\_t length );**

Sets the **characters** from a fixed-length character field, which might contain a null. Appends a null to the characters from the fixed-length field if necessary. This method returns TRUE if successful.

**ImqBoolean setStorage( const size\_t length );**

Allocates (or reallocates) the **storage**. Preserves any original **characters**, including any trailing null, if there is still room for them, but does not initialize any additional storage.

This method returns TRUE if successful.

**size\_t storage() const ;**

Returns the number of bytes in the **storage**.

**size\_t stripLeading( const char c = ' ' );**

Strips leading characters *c* from the **characters** and returns the number removed.

**size\_t stripTrailing( const char c = ' ' );**

Strips trailing characters *c* from the **characters** and returns the number removed.

**ImqString upperCase() const ;**

Returns an uppercase copy of the **characters**.

**Object methods (protected)****ImqBoolean assign ( const ImqString & string );**

Equivalent to the equivalent **operator =** method, but non-virtual. It returns TRUE if successful.

**Reason codes**

- MQRC\_DATA\_TRUNCATED
- MQRC\_NULL\_POINTER
- MQRC\_STORAGE\_NOT\_AVAILABLE
- MQRC\_BUFFER\_ERROR
- MQRC\_INCONSISTENT\_FORMAT

## ImqTrigger C++ class

This class encapsulates the MQTM (trigger message) data structure.

Figure 36. ImqTrigger class

Objects of this class are typically used by a trigger monitor program. The task of a trigger monitor program is to wait for these particular messages and act on them to ensure that other IBM MQ applications are started when messages are waiting for them.

See the IMQSTRG sample program for a usage example.

- [“Object attributes” on page 1886](#)
- [“Constructors” on page 1887](#)
- [“Overloaded ImqItem methods” on page 1887](#)
- [“Object methods \(public\)” on page 1887](#)
- [“Object data \(protected\)” on page 1888](#)
- [“Reason codes” on page 1888](#)

### Object attributes

#### application id

Identity of the application that sent the message. The initial value is a null string.

#### application type

Type of application that sent the message. The initial value is zero. The following additional values are possible:

- MQAT\_AIX
- MQAT\_CICS
- MQAT\_DOS
- MQAT\_IMS
- MQAT\_MVS
- MQAT\_NOTES\_AGENT
- MQAT\_OS2
- MQAT\_OS390
- MQAT\_OS400

- MQAT\_UNIX
- MQAT\_WINDOWS
- MQAT\_WINDOWS\_NT
- MQAT\_USER\_FIRST
- MQAT\_USER\_LAST

#### **environment data**

Environment data for the process. The initial value is a null string.

#### **process name**

Process name. The initial value is a null string.

#### **queue name**

Name of the queue to be started. The initial value is a null string.

#### **trigger data**

Trigger data for the process. The initial value is a null string.

#### **user data**

User data for the process. The initial value is a null string.

### **Constructors**

#### **ImqTrigger();**

The default constructor.

#### **ImqTrigger( const ImqTrigger & trigger );**

The copy constructor.

### **Overloaded ImqItem methods**

#### **virtual ImqBoolean copyOut ( ImqMessage & msg );**

Writes an MQTM data structure to the message buffer, replacing any existing content. Sets the *msg* format to MQFMT\_TRIGGER.

See the ImqItem class method description at [“ImqItem C++ class” on page 1830](#) for further details.

#### **virtual ImqBoolean pasteIn ( ImqMessage & msg );**

Reads an MQTM data structure from the message buffer.

To be successful, the ImqMessage format must be MQFMT\_TRIGGER.

See the ImqItem class method description at [“ImqItem C++ class” on page 1830](#) for further details.

### **Object methods (public)**

#### **void operator = ( const ImqTrigger & trigger );**

Copies instance data from *trigger*, replacing the existing instance data.

#### **ImqString applicationId ( ) const ;**

Returns a copy of the application id.

#### **void setApplicationId ( const char \* id );**

Sets the application id.

#### **MQLONG applicationType ( ) const ;**

Returns the application type.

#### **void setApplicationType ( const MQLONG type );**

Sets the application type.

#### **ImqBoolean copyOut ( MQTMC2 \* ptmc2 );**

Encapsulates the MQTM data structure, which is the one received on initiation queues. Fills in an equivalent MQTMC2 data structure provided by the caller, and sets the QMgrName field (which is not present in the MQTM data structure) to all blanks. The MQTMC2 data structure is traditionally used as a parameter to applications started by a trigger monitor. This method returns TRUE if successful.

**ImqString environmentData ( ) const ;**

Returns a copy of the environment data.

**void setEnvironmentData ( const char \* data );**

Sets the environment data.

**ImqString processName ( ) const ;**

Returns a copy of the process name.

**void setProcessName ( const char \* name );**

Sets the process name, padded with blanks to 48 characters.

**ImqString queueName ( ) const ;**

Returns a copy of the queue name.

**void setQueueName ( const char \* name );**

Sets the queue name, padding with blanks to 48 characters.

**ImqString triggerData ( ) const ;**

Returns a copy of the trigger data.

**void setTriggerData ( const char \* data );**

Sets the trigger data.

**ImqString userData ( ) const ;**

Returns a copy of the user data.

**void setUserData ( const char \* data );**

Sets the user data.

**Object data (protected)****MQTM *omqtm***

The MQTM data structure.

**Reason codes**

- MQRC\_NULL\_POINTER
- MQRC\_INCONSISTENT\_FORMAT
- MQRC\_ENCODING\_ERROR
- MQRC\_STRUC\_ID\_ERROR

## ImqWorkHeader C++ class

This class encapsulates specific features of the MQWIH data structure.

Figure 37. ImqWorkHeader class

Objects of this class are used by applications putting messages to the queue managed by the z/OS Workload Manager.

- [“Object attributes” on page 1889](#)
- [“Constructors” on page 1889](#)
- [“Overloaded ImqItem methods” on page 1890](#)
- [“Object methods \(public\)” on page 1890](#)
- [“Object data \(protected\)” on page 1890](#)
- [“Reason codes” on page 1890](#)

### Object attributes

#### message token

Message token for the z/OS Workload Manager, of length MQ\_MSG\_TOKEN\_LENGTH. The initial value is MQMTOK\_NONE.

#### service name

The 32-character name of a process. The name is initially blanks.

#### service step

The 8-character name of a step within the process. The name is initially blanks.

### Constructors

#### ImqWorkHeader();

The default constructor.

#### ImqWorkHeader( const ImqWorkHeader & header );

The copy constructor.

## Overloaded ImqItem methods

### **virtual ImqBoolean copyOut( ImqMessage & msg );**

Inserts an MQWIH data structure into the beginning of the message buffer, moving the existing message data further along, and sets the *msg format* to MQFMT\_WORK\_INFO\_HEADER.

See the parent class method description for more details.

### **virtual ImqBoolean pasteIn( ImqMessage & msg );**

Reads an MQWIH data structure from the message buffer.

To be successful, the encoding of the *msg* object must be MQENC\_NATIVE. Retrieve messages with MQGMO\_CONVERT to MQENC\_NATIVE.

The ImqMessage format must be MQFMT\_WORK\_INFO\_HEADER.

See the parent class method description for more details.

## Object methods (public)

### **void operator = ( const ImqWorkHeader & header );**

Copies instance data from *header*, replacing the existing instance data.

### **ImqBinary messageToken ( ) const;**

Returns the **message token**.

### **ImqBoolean setMessageToken( const ImqBinary & token );**

Sets the **message token**. The data length of *token* must be either zero or MQ\_MSG\_TOKEN\_LENGTH. It returns TRUE if successful.

### **void setMessageToken( const MQBYTE16 token = 0 );**

Sets the **message token**. *token* can be zero, which is the same as specifying MQMTOK\_NONE. If *token* is nonzero, it must address MQ\_MSG\_TOKEN\_LENGTH bytes of binary data.

When using predefined values such as MQMTOK\_NONE, you might need make a cast to ensure a signature match; for example, (MQBYTE \*)MQMTOK\_NONE.

### **ImqString serviceName ( ) const;**

Returns the **service name**, including trailing blanks.

### **void setServiceName( const char \* name );**

Sets the **service name**.

### **ImqString serviceStep ( ) const;**

Returns the **service step**, including trailing blanks.

### **void setServiceStep( const char \* step );**

Sets the **service step**.

## Object data (protected)

### **MQWIH omqwih**

The MQWIH data structure.

## Reason codes

- MQRC\_BINARY\_DATA\_LENGTH\_ERROR

## Properties of IBM MQ classes for JMS objects

All objects in IBM MQ classes for JMS have properties. Different properties apply to different object types. Different properties have different allowable values, and symbolic property values differ between the administration tool and program code.

IBM MQ classes for JMS provides facilities to set and query the properties of objects using the IBM MQ JMS administration tool, IBM MQ Explorer, or in an application. Many of the properties are relevant only to a specific subset of the object types.

For information on how you use the IBM MQ JMS administration tool, see [Configuring JMS objects using the administration tool](#).

Table 868 on page 1891 gives a brief description of each property and shows for each property which object types it applies to. The object types are identified using keywords; see [Configuring JMS objects using the administration tool](#) for an explanation of these objects.

Numbers refer to notes at the end of the table. See also [“Dependencies between properties of IBM MQ classes for JMS objects” on page 1894](#).

A property consists of a name-value pair in the format:

```
PROPERTY_NAME(property_value)
```

The topics in this section list, for each property, the name of the property and a brief description, and shows the valid property values used in the administration tool. and the set method that is used to set the value of the property in an application. The topics also show the valid property values for each property and the mapping between symbolic property values used in the tool and their programmable equivalents.

Property names are not case-sensitive, and are restricted to the set of recognized names shown in these topics.

Property	Short form	Object type

**Note:**

1. This property can be used with version 70 of IBM MQ classes for JMS but has no effect for an application connected to a IBM WebSphere MQ 7.0 queue manager unless the PROVIDERVERSION property of the connection factory is set to a version number less than 7.
2. Only the BROKERVER, CLIENTID, DESCRIPTION, DIRECTAUTH, HOSTNAME, LOCALADDRESS, MAXBUFFSIZE, MULTICAST, PORT, PROXYHOSTNAME, PROXYPORT, and TRANSPORT properties are supported for a ConnectionFactory or TopicConnectionFactory object when using a real-time connection to a broker.
3. The CCDURL and CHANNEL properties of an object must not both be set at the same time.

## Dependencies between properties of IBM MQ classes for JMS objects

The validity of some properties is dependent on the particular values of other properties.

This dependency can occur in the following groups of properties:

- Client properties
- Properties for a real-time connection to a broker
- Exit initialization strings

## Client properties

For a connection to a queue manager, the following properties are relevant only if TRANSPORT has the value CLIENT:

- HOSTNAME
- PORT
- CHANNEL
- LOCALADDRESS
- CCDTURL
- CCSID
- COMPHDR
- COMPMSG
- REEXIT
- REEXITINIT
- SEEXIT
- SEEXITINIT
- SENDEXIT
- SENDEXITINIT
- SHARECONVALLOWED
- SSLCIPHERSUITE
- SSLCRL
- SSLFIPSREQUIRED
- SSLPEERNAME
- SSLRESETCOUNT
- APPLICATIONNAME

You cannot set values for these properties by using the administration tool if TRANSPORT has the value BIND.

If TRANSPORT has the value CLIENT, the default value of the BROKERVER property is V1 and the default value of the PORT property is 1414. If you set the value of BROKERVER or PORT explicitly, a later change to the value of TRANSPORT does not override your choices.

## Properties for a real-time connection to a broker

Only the following properties are relevant if TRANSPORT has the value DIRECT or DIRECTHTTP:

- BROKERVER
- CLIENTID
- DESCRIPTION
- DIRECTAUTH
- HOSTNAME
- LOCALADDRESS
- MAXBUFFSIZE
- MULTICAST (supported only for DIRECT)
- PORT
- PROXYHOSTNAME (supported only for DIRECT)
- PROXYPORT (supported only for DIRECT)

If TRANSPORT has the value DIRECT or DIRECTHTTP, the default value of the BROKERVER property is V2, and the default value of the PORT property is 1506. If you set the value of BROKERVER or PORT explicitly, a later change to the value of TRANSPORT does not override your choices.

### Exit initialization strings

Do not set any of the exit initialization strings without supplying the corresponding exit name. The exit initialization properties are:

- REEXITINIT
- SEEXITINIT
- SENDEXITINIT

For example, specifying REEXITINIT(myString) without specifying REEXIT(some.exit.classname) causes an error.

### Related reference

[“TRANSPORT” on page 1945](#)

The nature of a connection to a queue manager or broker.

## APPLICATIONNAME

An application can set a name that identifies its connection to the queue manager. This application name is shown by the **DISPLAY CONN MQSC/PCF** command (where the field is called **APPLTAG**) or in the IBM MQ Explorer **Application Connections** display (where the field is called **App name**).

### Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: APPLICATIONNAME

JMS administration tool short name: APPNAME

### Programmatic access

Setters/getters

- MQConnectionFactory.setAppName()
- MQConnectionFactory.getAppName()

### Values

Any valid string that is no longer than 28 characters. Longer names are adjusted to fit by removing leading package names, if necessary. For example, if the invoking class is `com.example.MainApp`, the full name is used, but if the invoking class is `com.example.dictionaryAndThesaurus.multilingual.mainApp`, the name `multilingual.mainApp` is used, because it is the longest combination of class name and rightmost package name that fits into the available length.

If the class name itself is more than 28 characters long, it is truncated to fit. For example, `com.example.mainApplicationForSecondTestCase` becomes `mainApplicationForSecondTest`.

 On z/OS, the APPNAME in:

- Bindings mode is ignored if set and, if set, can only be set to blanks.
- Client mode can be set and used.

## ASYNCEXCEPTION

This property determines whether IBM MQ classes for JMS informs an ExceptionListener only when a connection is broken, or when any exception occurs asynchronously to a JMS API call. This applies to all Connections created from this ConnectionFactory that have an ExceptionListener registered.

### Applicable objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: ASYNCEXCEPTION

JMS administration tool short name: AEX

### Programmatic access

Setters/Getters

- MQConnectionFactory.setAsyncExceptions()
- MQConnectionFactory.getAsyncExceptions()

### Values

#### ASYNCEXCEPTIONS\_ALL

Any exception detected asynchronously, outside the scope of a synchronous API call, and all connection broken exceptions are sent to the ExceptionListener.

Environment	Value
JMS Administration Tool	ALL
Programmatic	WMQCONSTANTS.ASYNCEXCEPTIONS_ALL = -1
IBM MQ Explorer	All

#### ASYNCEXCEPTIONS\_CONNECTIONBROKEN

Only exceptions indicating a broken connection are sent to the ExceptionListener. Any other exceptions occurring during asynchronous processing are not reported to the ExceptionListener, and hence the application is not informed of these exceptions. This is the default value from IBM MQ 8.0.0 Fix Pack 2. See [JMS: Exception listener changes in IBM MQ 8.0](#).

Environment	Value
JMS Administration Tool	CONNECTIONBROKEN
Programmatic	WMQCONSTANTS.ASYNCEXCEPTIONS_CONNECTIONBROKEN = 1
IBM MQ Explorer	Connection Broken

The following additional constant is defined:

- From IBM MQ 8.0.0 Fix Pack 2: WMQCONSTANTS.ASYNCEXCEPTIONS\_DEFAULT = ASYNCEXCEPTIONS\_CONNECTIONBROKEN
- Before IBM MQ 8.0.0 Fix Pack 2: WMQCONSTANTS.ASYNCEXCEPTIONS\_DEFAULT = ASYNCEXCEPTIONS\_ALL

[Exceptions in IBM MQ classes for JMS](#)

### V 9.4.0 **BALOPTIONS**

Controls how IBM MQ classes for JMS applications that use the client transport are rebalanced in uniform clusters.

#### Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory.

JMS administration tool long name: **BALOPTIONS**

JMS administration tool short name: **OPTIONS**

#### Programmatic access

Setters/getters

- `MQConnectionFactory.setBalancingOptions()`
- `MQConnectionFactory.getBalancingOptions()`

#### Values

##### IGNNONE

The normal handling of transactions applies, and applications are not requested to move during a transaction.

This value maps to the IBM MQ *BalancingOption* `MQBNO_OPTIONS_NONE`.

##### IGNTRANS

Applications may be requested to move during a transaction.

This value maps to the IBM MQ *BalancingOption* `MQBNO_OPTIONS_IGNORE_TRANS`.

### V 9.4.0 **BALTYPE**

Controls how IBM MQ classes for JMS applications that use the client transport may be rebalanced in a uniform cluster.

#### Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory.

JMS administration tool long name: **BALTYPE**

JMS administration tool short name: **TYPE**

#### Programmatic access

Setters/getters

- `MQConnectionFactory.setBalancingApplicationType()`
- `MQConnectionFactory.getBalancingApplicationType()`

#### Values

##### SIMPLE

The default handling of applications in a uniform cluster applies.

This value maps to the IBM MQ *BalancingOption* MQBNO\_BALTYPE\_SIMPLE.

#### **REQUEST\_REPLY**

The application will not be requested to reconnect if an **MQPUT** has not been balanced by an **MQGET**, unless the timeout period has elapsed.

This value maps to the IBM MQ *BalancingOption* MQBNO\_BALTYPE\_REQREP.

## **V 9.4.0 BALTIMEOUT**

Controls how IBM MQ classes for JMS applications that use the client transport are rebalanced in a uniform cluster.

### **Applicable Objects**

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory.

JMS administration tool long name: **BALTIMEOUT**

JMS administration tool short name: **TIMEOUT**

### **Programmatic access**

Setters/getters

- `MQConnectionFactory.setBalancingTimeout()`
- `MQConnectionFactory.getBalancingTimeout()`

### **Values**

#### **NEVER**

The application never times out for the purposes of rebalancing in a uniform cluster.

This value maps to the IBM MQ *BalancingOption* MQBNO\_TIMEOUT\_NEVER.

#### **IMMEDIATE**

The application immediately times out for the purposes of rebalancing in a uniform cluster.

This value maps to the IBM MQ *BalancingOption* MQBNO\_TIMEOUT\_IMMEDIATE.

#### **DEFAULT**

The application times out for the purposes of rebalancing in a uniform cluster after the default period of 10 seconds.

This value maps to the IBM MQ *BalancingOption* MQBNO\_TIMEOUT\_AS\_DEFAULT.

#### **nn**

The application times out for the purposes of rebalancing in a uniform cluster after a period of *nn* seconds.

*nn* can be between 1 and 9999999999.

## **BROKERCCDURSUBQ**

The name of the queue from which durable subscription messages are retrieved for a `ConnectionFactory`.

### **Applicable objects**

Topic

JMS administration tool long name: BROKERCCDURSUBQ

JMS administration tool short name: CCDSUB

## Programmatic access

Setters/getters

- MQTopic.setBrokerCCDurSubQueue()
- MQTopic.getBrokerCCDurSubQueue()

## Values

### **SYSTEM.JMS.D.CC.SUBSCRIBER.QUEUE**

This is the default value.

**Any valid string**

## **BROKERCCSUBQ**

The name of the queue from which non-durable subscription messages are retrieved for a ConnectionConsumer.

## Applicable objects

ConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: BROKERCCSUBQ

JMS administration tool short name: CCSUB

## Programmatic access

Setters/getters

- MQConnectionFactory.setBrokerCCSubQueue()
- MQConnectionFactory.getBrokerCCSubQueue()

## Values

### **SYSTEM.JMS.ND.CC.SUBSCRIBER.QUEUE**

This is the default value.

**Any valid string**

## **BROKERCONQ**

The control queue name of the broker.

## Applicable Objects

ConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: BROKERCONQ

JMS administration tool short name: BCON

## Programmatic access

Setters/getters

- MQConnectionFactory.setBrokerControlQueue()
- MQConnectionFactory.getBrokerControlQueue()

## Values

### **SYSTEM.BROKER.CONTROL.QUEUE**

This is the default value.

**Any valid string**

## **BROKERDURSUBQ**

When the IBM MQ classes for JMS are being used in IBM MQ messaging provider migration mode, this property specifies the name of the queue from which durable subscription messages are retrieved.

### **Applicable objects**

Topic

JMS administration tool long name: BROKERDURSUBQ

JMS administration tool short name: BDSUB

### **Programmatic access**

Setters/getters

- MQTopic.setBrokerDurSubQueue()
- MQTopic.getBrokerDurSubQueue()

## Values

### **SYSTEM.JMS.D.SUBSCRIBER.QUEUE**

This is the default value.

**Any valid string**

Starting with SYSTEM.JMS.D

### **Related tasks**

[Configuring the JMS \*\*PROVIDERVERSION\*\* property](#)

## **BROKERPUBQ**

The name of the queue where published messages are sent (the stream queue).

### **Applicable Objects**

ConnectionFactory, TopicConnectionFactory, Topic, XAConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: BROKERPUBQ

JMS administration tool short name: BPUB

### **Programmatic access**

Setters/getters

- MQConnectionFactory.setBrokerPubQueue
- MQConnectionFactory.getBrokerPubQueue

## Values

### **SYSTEM.BROKER.DEFAULT.STREAM**

This is the default value.

**Any valid string**

## **BROKERPUBQMGR**

The name of the queue manager that owns the queue where messages published on the topic are sent.

### **Applicable Objects**

Topic

JMS administration tool long name: BROKERPUBQMGR

JMS administration tool short name: BPQM

### **Programmatic access**

Setters/getters

- MQTopic.setBrokerPubQueueManager()
- MQTopic.getBrokerPubQueueManager()

### **Values**

**null**

This is the default value.

**Any valid string**

## **BROKERQMGR**

The name of the queue manager on which the broker is running.

### **Applicable Objects**

ConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: BROKERQMGR

JMS administration tool short name: BQM

### **Programmatic access**

Setters/getters

- MQConnectionFactory.setBrokerQueueManager()
- MQConnectionFactory.getBrokerQueueManager()

### **Values**

**null**

This is the default value.

**Any valid string**

## **BROKERSUBQ**

When the IBM MQ classes for JMS are being used in IBM MQ messaging provider migration mode, this property specifies the name of the queue from which non-durable subscription messages are retrieved.

### **Applicable Objects**

ConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: BROKERSUBQ

JMS administration tool short name: BSUB

## Programmatic access

Setters/getters

- `MQConnectionFactory.setBrokerSubQueue()`
- `MQConnectionFactory.getBrokerSubQueue()`

## Values

### **SYSTEM.JMS.ND.SUBSCRIBER.QUEUE**

This is the default value.

### **Any valid string**

Starting with `SYSTEM.JMS.ND`

### **Related tasks**

[Configuring the JMS \*\*PROVIDERVERSION\*\* property](#)

## **BROKERVER**

The version of the broker being used.

## Applicable Objects

`ConnectionFactory`, `TopicConnectionFactory`, `Topic`, `XAConnectionFactory`, `XATopicConnectionFactory`

JMS administration tool long name: BROKERVER

JMS administration tool short name: BVER

## Programmatic access

Setters/getters

- `MQConnectionFactory.setBrokerVersion()`
- `MQConnectionFactory.getBrokerVersion()`

## Values

### **V1**

To use an IBM MQ Publish/Subscribe broker, or to use a broker of IBM MQ Integrator, WebSphere Event Broker, WebSphere Business Integration Event Broker, or WebSphere Business Integration Message Broker in compatibility mode. This is the default value if `TRANSPORT` is set to `BIND` or `CLIENT`.

### **V2**

To use a broker of IBM MQ Integrator, WebSphere Event Broker, WebSphere Business Integration Event Broker, or WebSphere Business Integration Message Broker in native mode. This is the default value if `TRANSPORT` is set to `DIRECT` or `DIRECTHTTP`.

### **unspecified**

After the broker has migrated from V6 to V7, set this property so that RFH2 headers are no longer used. After migration this property is no longer relevant.

## CCDTURL

A Uniform Resource Locator (URL) that identifies the name and location of the file containing the client channel definition table and specifies how the file can be accessed.

### Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: CCDTURL

JMS administration tool short name: CCDT

### Programmatic access

Setters/getters

- MQConnectionFactory.setCCDTURL()
- MQConnectionFactory.getCCDTURL()

### Values

**null**

This is the default value.

**A Uniform Resource Locator (URL)**

## CCSID

For connection factories, this property specifies the coded character set ID (CCSID) to be used for internal data flows with the queue manager. For destinations, the property defines the CCSID to be used to encode string data in MapMessages, StreamMessages, and TextMessages put to that destination.

**Note:** It is not normally necessary to change this property for connection factories.

### Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, Queue, Topic, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: CCSID

JMS administration tool short name: CCS

### Programmatic access

Setters/getters

- MQConnectionFactory.setCCSID()
- MQConnectionFactory.getCCSID()

### Values

**819**

The default value for a connection factory.

**1208**

The default value for a destination.

**Any positive integer**

**Related concepts**

[JMS message conversion](#)

The certificate validation policy to be used for a TLS connection.

### Applicable Objects

ConnectionFactory

JMS administration tool long name: CERTVALPO

JMS administration tool short name: CVAP

### Programmatic access

Setters/getters

- MQConnectionFactory.setCertificateValPolicy()
- MQConnectionFactory.getCertificateValPolicy()

### Values

#### 0/ANY

This is the default value for a connection factory.

#### 2 / NONE

This policy includes no certificate validation. Can only be set on client applications.

## CHANNEL

The name of the client connection channel being used.

### Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: CHANNEL

JMS administration tool short name: CHAN

### Programmatic access

Setters/getters

- MQConnectionFactory.setChannel()
- MQConnectionFactory.getChannel()

### Values

#### SYSTEM.DEF.SVRCONN

This is the default value.

#### Any valid string

## CLEANUP

Cleanup Level for BROKER or MIGRATE Subscription Stores.

### Applicable Objects

ConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: CLEANUP

JMS administration tool short name: CL

### **Programmatic access**

Setters/getters

- MQConnectionFactory.setCleanupLevel()
- MQConnectionFactory.getCleanupLevel()

### **Values**

#### **SAFE**

Use safe cleanup. This is the default value.

#### **ASPROP**

Use safe, strong, or no cleanup according to a property set on the Java command line.

#### **NONE**

Use no cleanup.

#### **STRONG**

Use strong cleanup.

## **CLEANUPINT**

The interval, in milliseconds, between background executions of the publish/subscribe cleanup utility.

### **Applicable Objects**

ConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: CLEANUPINT

JMS administration tool short name: CLINT

### **Programmatic access**

Setters/getters

- MQConnectionFactory.setCleanupInterval()
- MQConnectionFactory.getCleanupInterval()

### **Values**

#### **3600000**

This is the default value.

**Any positive integer**

## **CONNECTIONNAMELIST**

List of TCP/IP connection names. The list is tried in order, once per each reconnection retry attempt.

### **Applicable Objects**

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory

JMS administration tool long name: CONNECTIONNAMELIST

JMS administration tool short name: CNLIST

## Programmatic access

Setters/getters

- `MQConnectionFactory.setconnectionNameList()`
- `MQConnectionFactory.getconnectionNameList()`

## Values

Comma separated list of HOSTNAME(PORT). HOSTNAME can be either a DNS name or IP address.  
PORT defaults to 1414.

## CLIENTRECONNECTOPTIONS

Options governing reconnection.

### Applicable Objects

`ConnectionFactory`, `QueueConnectionFactory`, `TopicConnectionFactory`

JMS administration tool long name: CLIENTRECONNECTOPTIONS

JMS administration tool short name: CROPT

## Programmatic access

Setters/getters

- `MQConnectionFactory.setClientReconnectOptions()`
- `MQConnectionFactory.getClientReconnectOptions()`

## Values

### QMGR

The application can reconnect to the same queue manager that it is originally connected to.

An error with reason code `MQRC_RECONNECT_QMID_MISMATCH` is returned if the queue manager that the application tries to connect to, as specified in the connection name list, has a different QMID to the queue manager that it originally connected to.

Use this value if an application can be reconnected, but there is an affinity between the IBM MQ classes for JMS application, and the queue manager to which it first established a connection.

Choose this value if you want an application to automatically reconnect to the standby instance of a highly available queue manager.

To use this value programmatically, use the constant `WMQConstants.WMQ_CLIENT_RECONNECT_Q_MGR`.

### ANY

The application can reconnect to any of the queue managers specified in the connection name list.

Use the reconnect option only if there is no affinity between the IBM MQ classes for JMS application and the queue manager with which it initially established a connection.

To use this value from a program, use the constant `WMQConstants.WMQ_CLIENT_RECONNECT`.

### DISABLED

The application will not be reconnected.

To use this value programmatically, use the constant `WMQConstants.WMQ_CLIENT_RECONNECT_DISABLED`.

## ASDEF

Whether the application will reconnect automatically depends on the value of the IBM MQ channel attribute DefReconnect.

This is the default value.

To use this value from a program, use the constant `WMQConstants.WMQ_CLIENT_RECONNECT_AS_DEF`.

## CLIENTRECONNECTTIMEOUT

Time before reconnection retries cease.

### Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory

JMS administration tool long name: CLIENTRECONNECTTIMEOUT

JMS administration tool short name: CRT

### Programmatic access

Setters/getters

- `MQConnectionFactory.setClientReconnectTimeout()`
- `MQConnectionFactory.setClientReconnectTimeout()`

### Values

Interval in seconds. Default 1800 (30 minutes).

## CLIENTID

The client identifier is used to uniquely identify the application connection for durable subscriptions.

### Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: CLIENTID

JMS administration tool short name: CID

### Programmatic access

Setters/getters

- `MQConnectionFactory.setClientId()`
- `MQConnectionFactory.getClientId()`

### Values

**null**

This is the default value.

**Any valid string**

## CLONESUPP

Whether two or more instances of the same durable topic subscriber can run simultaneously.

### Applicable Objects

ConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: CLONESUPP

JMS administration tool short name: CLS

### Programmatic access

Setters/getters

- `MQConnectionFactory.setCloneSupport()`
- `MQConnectionFactory.getCloneSupport()`

### Values

#### DISABLED

Only one instance of a durable topic subscriber can run at a time. This is the default value.

#### ENABLED

Two or more instances of the same durable topic subscriber can run simultaneously, but each instance must run in a separate Java virtual machine (JVM).

## COMPHDR

A list of the techniques that can be used for compressing header data on a connection.

### Applicable Objects

ConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: COMPHDR

JMS administration tool short name: HC

### Programmatic access

Setters/getters

- `MQConnectionFactory.setHdrCompList()`
- `MQConnectionFactory.getHdrCompList()`

### Values

#### NONE

This is the default value.

#### SYSTEM

RLE message header compression is performed.

## COMPMSG

A list of the techniques that can be used for compressing message data on a connection.

### Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: COMPMSG

JMS administration tool short name: MC

### Programmatic access

Setters/getters

- MQConnectionFactory.setMsgCompList()
- MQConnectionFactory.getMsgCompList()

### Values

#### NONE

This is the default value.

**A list of one or more of the following values separated by blank characters:**

RLE ZLIBFAST ZLIBHIGH **V 9.4.0** LZ4FAST LZ4HIGH

## CONNOPT

Controls how IBM MQ classes for JMS applications that use the bindings transport connect to the queue manager.

### Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory.

JMS administration tool long name: CONNOPT

JMS administration tool short name: CNOPT

### Programmatic access

Setters/getters

- MQConnectionFactory.setMQConnectionFactoryOptions()
- MQConnectionFactory.getMQConnectionFactoryOptions()

### Values

#### STANDARD

The nature of the binding between the application and the queue manager depends on the value of the *DefaultBindType* attribute of the queue manager. The STANDARD value maps to the IBM MQ *ConnectOption* MQCNO\_STANDARD\_BINDING.

#### SHARED

The application and the local queue manager agent run in separate units of execution but share some resources. This value maps to the IBM MQ *ConnectOption* MQCNO\_SHARED\_BINDING.

## **ISOLATED**

The application and the local queue manager agent run in separate units of execution and share no resources. The ISOLATED value maps to the IBM MQ *ConnectOption* MQCNO\_ISOLATED\_BINDING.

## **FASTPATH**

The application and the local queue manager agent run in the same unit of execution. This value maps to the IBM MQ *ConnectOption* MQCNO\_FASTPATH\_BINDING.

## **SERIALQM**

The application requests exclusive use of the connection tag within the scope of the queue manager. This value maps to the IBM MQ *ConnectOption* MQCNO\_SERIALIZE\_CONN\_TAG\_Q\_MGR.

## **SERIALQSG**

The application requests exclusive use of the connection tag within the scope of the queue sharing group to which the queue manager belongs. The SERIALQSG value maps to the IBM MQ *ConnectOption* MQCNO\_SERIALIZE\_CONN\_TAG\_QSG.

## **RESTRICTQM**

The application requests shared use of the connection tag, but there are restrictions on the shared use of the connection tag within the scope of the queue manager. This value maps to the IBM MQ *ConnectOption* MQCNO\_RESTRICT\_CONN\_TAG\_Q\_MGR.

## **RESTRICTQSG**

The application requests shared use of the connection tag, but there are restrictions on the shared use of the connection tag within the scope of the queue sharing group to which the queue manager belongs. This value maps to the IBM MQ *ConnectOption* MQCNO\_RESTRICT\_CONN\_TAG\_QSG.

For further information on IBM MQ connection options, see [Connecting to a queue manager using the MQCONN call](#).

# **CONNTAG**

A tag that the queue manager associates with the resources updated by the application within a unit of work while the application is connected to the queue manager.

## **Applicable Objects**

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: CONNTAG

JMS administration tool short name: CNTAG

## **Programmatic access**

Setters/getters

- MQConnectionFactory.setConnTag()
- MQConnectionFactory.getConnTag()

## **Values**

**A byte array of 128 elements, where each element is 0**

This is the default value.

**Any string**

The value is truncated if it is longer than 128 bytes.

## DESCRIPTION

A description of the stored object.

### Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, Queue, Topic, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: DESCRIPTION

JMS administration tool short name: DESC

### Programmatic access

Setters/getters

- MQConnectionFactory.setDescription()
- MQConnectionFactory.getDescription()

### Values

**null**

This is the default value.

**Any valid string**

## DIRECTAUTH

Whether TLS authentication is used on a real-time connection to a broker.

### Applicable Objects

ConnectionFactory, TopicConnectionFactory

JMS administration tool long name: DIRECTAUTH

JMS administration tool short name: DAUTH

### Programmatic access

Setters/getters

- MQConnectionFactory.setDirectAuth()
- MQConnectionFactory.getDirectAuth()

### Values

**BASIC**

No authentication, username authentication, or password authentication. This is the default value.

**CERTIFICATE**

Public key certificate authentication.

# ENCODING

How numeric data in the body of a message is represented when the message is sent to this destination. The property specifies the representation of binary integers, packed decimal integers, and floating point numbers.

## Applicable Objects

Queue, Topic

JMS administration tool long name: ENCODING

JMS administration tool short name: ENC

## Programmatic access

Setters/getters

- `MQDestination.setEncoding()`
- `MQDestination.getEncoding()`

## Values

### ENCODING property

The valid values that the ENCODING property can take are constructed from the three sub-properties:

#### integer encoding

Either normal or reversed

#### decimal encoding

Either normal or reversed

#### floating-point encoding

IEEE normal, IEEE reversed, or z/OS

The ENCODING property is expressed as a three-character string with the following syntax:

```
{N|R}{N|R}{N|R|3}
```

In this string:

- N denotes normal
- R denotes reversed
- 3 denotes z/OS
- The first character represents *integer encoding*
- The second character represents *decimal encoding*
- The third character represents *floating-point encoding*

This provides a set of twelve possible values for the ENCODING property.

There is an additional value, the string NATIVE, which sets appropriate encoding values for the Java platform.

The following examples show valid combinations for ENCODING:

```
ENCODING(NNR)  
ENCODING(NATIVE)  
ENCODING(RR3)
```

## EXPIRY

The time after which messages at a destination expire.

### Applicable Objects

Queue, Topic

JMS administration tool long name: EXPIRY

JMS administration tool short name: EXP

### Programmatic access

Setters/getters

- `MQDestination.setExpiry()`
- `MQDestination.getExpiry()`

### Values

#### APP

Expiry can be defined by the JMS application. This is the default value.

#### UNLIM

No expiry occurs.

#### 0

No expiry occurs.

**Any positive integer representing expiry in milliseconds.**

## FAILIFQUIESCE

This property determines whether calls to certain methods fail if either the queue manager is in a quiescing state, or an application is connecting to a queue manager using the CLIENT transport and the channel that the application is using has been put into a quiescing state, for example, by using the **STOP CHANNEL** or **STOP CHANNEL MODE(QUIESCE)** MQSC command.

### Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, Queue, Topic, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: FAILIFQUIESCE

JMS administration tool short name: FIQ

### Programmatic access

Setters/getters

- `MQConnectionFactory.setFailIfQuiesce()`
- `MQConnectionFactory.getFailIfQuiesce()`

### Values

#### YES

Calls to certain methods fail if either the queue manager is in a quiescing state, or the channel being used to connect to a queue manager is quiescing. If an application detects either of these conditions, the application can complete its immediate task and close the connection, allowing the queue manager or channel instance to stop. This is the default value.

## **NO**

No method call fails because either the queue manager, or the channel being used to connect to a queue manager, is in a quiescing state. If you specify this value, an application cannot detect that the queue manager or channel is quiescing. The application might continue to perform operations against the queue manager, and therefore prevent the queue manager from stopping.

## **HOSTNAME**

For a connection to a queue manager, the host name or IP address of the system on which the queue manager is running or, for a real-time connection to a broker, the host name or IP address of the system on which the broker is running.

### **Applicable Objects**

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: HOSTNAME

JMS administration tool short name: HOST

### **Programmatic access**

Setters/getters

- MQConnectionFactory.setHostName()
- MQConnectionFactory.getHostName()

### **Values**

#### **localhost**

This is the default value.

#### **Any valid string**

## **LOCALADDRESS**

For a connection to a queue manager, this property specifies either the local network interface to be used, or the local port, or range of local ports, to be used.

### **Applicable Objects**

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: LOCALADDRESS

JMS administration tool short name: LA

### **Programmatic access**

Setters/getters

- MQConnectionFactory.setLocalAddress()
- MQConnectionFactory.getLocalAddress()

### **Values**

#### **"" (empty string)**

This is the default value.

### **A string in the format [ip-addr][(low-port[,high-port])]**

Here are some examples:

192.0.2.0

The channel binds to address 192.0.2.0 locally.

192.0.2.0(1000)

The channel binds to address 192.0.2.0 locally and uses port 1000.

192.0.2.0(1000,2000)

The channel binds to address 192.0.2.0 locally and uses a port in the range 1000 to 2000.

(1000)

The channel binds to port 1000 locally.

(1000,2000)

The channel binds to a port in the range 1000 to 2000 locally.

You can specify a host name instead of an IP address. For a real-time connection to a broker, this property is relevant only when multicast is used, and the value of the property must not contain a port number, or a range of port numbers. The only valid values of the property in this case are null, an IP address, or a host name.

## **MAPNAMESTYLE**

Allows compatibility style to be used for MapMessage element names.

### **Applicable Objects**

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: MAPNAMESTYLE

JMS administration tool short name: MNST

### **Programmatic access**

Setters/getters

- MQConnectionFactory.setMapNameStyle()
- MQConnectionFactory.getMapNameStyle()

### **Values**

#### **STANDARD**

The standard com.ibm.jms.JMSMapMessage element naming format is to be used. This is the default value and allows non-legal Java identifiers to be used as the element name.

#### **COMPATIBLE**

The older com.ibm.jms.JMSMapMessage element naming format is to be used. Only legal Java identifiers can be used as the element name. This is needed only if map messages are being sent to an application that is using a version of IBM MQ classes for JMS earlier than 5.3.

## MAXBUFFSIZE

The maximum number of received messages that can be stored in an internal message buffer while waiting to be processed by the application. This property applies only when TRANSPORT has the value DIRECT or DIRECTHTTP.

### Applicable Objects

ConnectionFactory, TopicConnectionFactory

JMS administration tool long name: MAXBUFFSIZE

JMS administration tool short name: MBSZ

### Programmatic access

Setters/getters

- MQConnectionFactory.setMaxBufferSize()
- MQConnectionFactory.getMaxBufferSize()

### Values

#### 1000

This is the default value.

**Any positive integer**

## MDREAD

This property determines whether a JMS application can extract the values of MQMD fields.

### Applicable Objects

JMS administration tool long name: MDREAD

JMS administration tool short name: MDR

### Programmatic access

Setters/getters

- MQDestination.setMQMDReadEnabled()
- MQDestination.getMQMDReadEnabled()

### Values

#### NO

When sending messages, the JMS\_IBM\_MQMD\* properties on a sent message are not updated to reflect the updated field values in the MQMD. When receiving messages, none of the JMS\_IBM\_MQMD\* properties are available on a received message, even if the sender had set some or all of them. This is the default value for administrative tools.

For programs, use False.

#### Yes

When sending messages, all of the JMS\_IBM\_MQMD\* properties on a sent message are updated to reflect the updated field values in the MQMD, including the properties that the sender did not set explicitly. When receiving messages, all of the JMS\_IBM\_MQMD\* properties are available on a received message, including the properties that the sender did not set explicitly.

For programs, use True.

## MDWRITE

This property determines whether a JMS application can set the values of MQMD fields.

### Applicable Objects

Queue, Topic

JMS administration tool long name: MDWRITE

JMS administration tool short name: MDR

### Programmatic access

Setters/getters

- `MQDestination.setMQMDWriteEnabled()`
- `MQDestination.getMQMDWriteEnabled()`

### Values

#### NO

All JMS\_IBM\_MQMD\* properties are ignored and their values are not copied into the underlying MQMD structure. This is the default value for administrative tools.

For programs, use `False`.

#### YES

JMS\_IBM\_MQMD\* properties are processed. Their values are copied into the underlying MQMD structure.

For programs, use `True`.

## MDMSGCTX

What level of message context is to be set by the JMS application. The application must be running with appropriate context authority for this property to take effect.

### Applicable Objects

JMS administration tool long name: MDMSGCTX

JMS administration tool short name: MDCTX

### Programmatic access

Setters/getters

- `MQDestination.setMQMDMessageContext()`
- `MQDestination.getMQMDMessageContext()`

### Values

#### DEFAULT

The MQOPEN API call and the MQPMO structure specify no explicit message context options. This is the default value for administrative tools.

For programs, use `WMQ_MDCTX_DEFAULT`.

#### SET\_IDENTITY\_CONTEXT

The MQOPEN API call specifies the message context option `MQOO_SET_IDENTITY_CONTEXT` and the MQPMO structure specifies `MQPMO_SET_IDENTITY_CONTEXT`.

For programs, use `WMQ_MDCTX_SET_IDENTITY_CONTEXT`.

## SET\_ALL\_CONTEXT

The MQOPEN API call specifies the message context option MQOO\_SET\_ALL\_CONTEXT and the MQPMO structure specifies MQPMO\_SET\_ALL\_CONTEXT.

For programs, use WMQ\_MDCTX\_SET\_ALL\_CONTEXT.

## MSGBATCHSZ

The maximum number of messages to be taken from a queue in one packet when using asynchronous message delivery.

### Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: MAXBUFFSIZE

JMS administration tool short name: MBSZ

### Programmatic access

Setters/getters

- MQConnectionFactory.setMsgBatchSize()
- MQConnectionFactory.getMsgBatchSize()

### Values

**10**

This is the default value.

**Any positive integer**

## MSGBODY

Determines whether a JMS application accesses the MQRFH2 of an IBM MQ message as part of the message payload.

### Applicable Objects

Queue, Topic

JMS administration tool long name: WMQ\_MESSAGE\_BODY

JMS administration tool short name: MBODY

### Programmatic access

Setters/getters

- MQConnectionFactory.setMessageBodyStyle()
- MQConnectionFactory.getMessageBodyStyle()

### Values

**UNSPECIFIED**

When sending, IBM MQ classes for JMS does or does not generate and include an MQRFH2 header, depending on the value of WMQ\_TARGET\_CLIENT. When receiving, acts as value JMS.

**JMS**

When sending, IBM MQ classes for JMS automatically generates an MQRFH2 header and includes it in the IBM MQ message.

When receiving, IBM MQ classes for JMS set the JMS message properties according to values in the MQRFH2 (if present); it does not present the MQRFH2 as part of the JMS message body.

## **MQ**

When sending, IBM MQ classes for JMS does not generate an MQRFH2.

When receiving, IBM MQ classes for JMS presents the MQRFH2 as part of the JMS message body.

## **MSGRETENTION**

Whether the connection consumer keeps undelivered messages on the input queue.

### **Applicable Objects**

ConnectionFactory, QueueConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory,

JMS administration tool long name: MSGRETENTION

JMS administration tool short name: MRET

### **Programmatic access**

Setters/getters

- MQConnectionFactory.setMessageRetention()
- MQConnectionFactory.getMessageRetention()

### **Values**

#### **Yes**

Undelivered messages remain on the input queue. This is the default value.

#### **No**

Undelivered messages are dealt with according to their disposition options.

## **MSGSELECTION**

Determines whether message selection is done by the IBM MQ classes for JMS or by the broker. If TRANSPORT has the value DIRECT, message selection is always done by the broker and the value of MSGSELECTION is ignored. Message selection by the broker is not supported when BROKERVER has the value V1.

### **Applicable Objects**

ConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: MSGSELECTION

JMS administration tool short name: MSEL

### **Programmatic access**

Setters/getters

- MQConnectionFactory.setMessageSelection()
- MQConnectionFactory.getMessageSelection()

### **Values**

#### **CLIENT**

Message selection is done by IBM MQ classes for JMS. This is the default value.

## **BROKER**

Message selection is done by the broker.

## **MULTICAST**

To enable multicast on a real-time connection to a broker and, if enabled, to specify the precise way in which multicast is used to deliver messages from the broker to a message consumer. The property has no effect on how a message producer sends messages to a broker.

### **Applicable Objects**

ConnectionFactory, TopicConnectionFactory, Topic

JMS administration tool long name: MULTICAST

JMS administration tool short name: MCAST

### **Programmatic access**

Setters/getters

- MQConnectionFactory.setMulticast()
- MQConnectionFactory.getMulticast()

### **Values**

#### **DISABLED**

Messages are not delivered to a message consumer using multicast transport. This is the default value for ConnectionFactory and TopicConnectionFactory objects.

#### **ASCF**

Messages are delivered to a message consumer according to the multicast setting for the connection factory associated with the message consumer. The multicast setting for the connection factory is noted at the time that the message consumer is created. This value is valid only for Topic objects, and is the default value for Topic objects.

#### **ENABLED**

If the topic is configured for multicast in the broker, messages are delivered to a message consumer using multicast transport. A reliable quality of service is used if the topic is configured for reliable multicast.

#### **RELIABLE**

If the topic is configured for reliable multicast in the broker, messages are delivered to the message consumer using multicast transport with a reliable quality of service. If the topic is not configured for reliable multicast, you cannot create a message consumer for the topic.

#### **NOTR**

If the topic is configured for multicast in the broker, messages are delivered to the message consumer using multicast transport. A reliable quality of service is not used even if the topic is configured for reliable multicast.

## **OPTIMISTICPUBLICATION**

This property determines whether IBM MQ classes for JMS returns control immediately to a publisher that has published a message, or whether it returns control only after it has completed all the processing associated with the call and can report the outcome to the publisher.

### **Applicable Objects**

ConnectionFactory, TopicConnectionFactory

JMS administration tool long name: OPTIMISTICPUBLICATION

JMS administration tool short name: OPTPUB

## Programmatic access

Setters/getters

- `MQConnectionFactory.setOptimisticPublication()`
- `MQConnectionFactory.getOptimisticPublication()`

## Values

### NO

When a publisher publishes a message, IBM MQ classes for JMS do not return control to the publisher until it has completed all the processing associated with the call and can report the outcome to the publisher. This is the default value.

### YES

When a publisher publishes a message, IBM MQ classes for JMS returns control to the publisher immediately, before it has completed all the processing associated with the call and can report the outcome to the publisher. IBM MQ classes for JMS reports the outcome only when the publisher commits the message.

## OUTCOMENOTIFICATION

This property determines whether IBM MQ classes for JMS return control immediately to a subscriber that has just acknowledged or committed a message, or whether it returns control only after it has completed all the processing associated with the call and can report the outcome to the subscriber.

## Applicable Objects

`ConnectionFactory`, `TopicConnectionFactory`

JMS administration tool long name: OUTCOMENOTIFICATION

JMS administration tool short name: NOTIFY

## Programmatic access

Setters/getters

- `MQConnectionFactory.setOutcomeNotification()`
- `MQConnectionFactory.getOutcomeNotification()`

## Values

### YES

When a subscriber acknowledges or commits a message, IBM MQ classes for JMS do not return control to the subscriber until it has completed all the processing associated with the call and can report the outcome to the subscriber. This is the default value.

### NO

When a subscriber acknowledges or commits a message, IBM MQ classes for JMS returns control to the subscriber immediately, before it has completed all the processing associated with the call and can report the outcome to the subscriber.

## PERSISTENCE

The persistence of messages sent to a destination.

### Applicable Objects

Queue, Topic

JMS administration tool long name: PERSISTENCE

JMS administration tool short name: PER

### Programmatic access

Setters/getters

- `MQDestination.setPersistence()`
- `MQDestination.getPersistence()`

### Values

#### APP

Persistence is defined by the JMS application. This is the default value.

#### QDEF

Persistence takes the value of the queue default.

#### PERS

Messages are persistent.

#### NON

Messages are nonpersistent.

#### HIGH

See [JMS persistent messages](#) for further information on the use of this value.

## POLLINGINT

If each message listener within a session has no suitable message on its queue, this is the maximum interval, in milliseconds, that elapses before each message listener tries again to get a message from its queue. If it frequently happens that no suitable message is available for any of the message listeners in a session, consider increasing the value of this property. This property is relevant only if `TRANSPORT` has the value `BIND` or `CLIENT`.

### Applicable Objects

`ConnectionFactory`, `QueueConnectionFactory`, `TopicConnectionFactory`, `XAConnectionFactory`, `XAQueueConnectionFactory`, `XATopicConnectionFactory`

JMS administration tool long name: POLLINGINT

JMS administration tool short name: PINT

### Programmatic access

Setters/getters

- `MQConnectionFactory.setPollingInterval()`
- `MQConnectionFactory.getPollingInterval()`

## Values

### 5000

This is the default value.

**Any positive integer**

## PORT

For a connection to a queue manager, the number of the port on which the queue manager is listening or, for a real-time connection to a broker, the number of the port on which the broker is listening for real-time connections.

### Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: PORT

JMS administration tool short name: PORT

### Programmatic access

Setters/getters

- MQConnectionFactory.setPort()
- MQConnectionFactory.getPort()

## Values

### 1414

This is the default value if TRANSPORT is set to CLIENT.

### 1506

This is the default value if TRANSPORT is set to DIRECT or DIRECTHTTP.

**Any positive integer**

## PRIORITY

The priority for messages sent to a destination.

### Applicable Objects

Queue, Topic

JMS administration tool long name: PRIORITY

JMS administration tool short name: PRI

### Programmatic access

Setters/getters

- MQDestination.setPriority()
- MQDestination.getPriority()

## Values

### APP

Priority is defined by the JMS application. This is the default value.

## **QDEF**

Priority takes the value of the queue default.

## **Any integer in the range 0-9**

Lowest to highest.

## **PROCESSDURATION**

This property determines whether a subscriber guarantees to process quickly any message it receives before returning control to IBM MQ classes for JMS.

### **Applicable Objects**

ConnectionFactory, TopicConnectionFactory

JMS administration tool long name: PROCESSDURATION

JMS administration tool short name: PROC DUR

### **Programmatic access**

Setters/getters

- MQConnectionFactory.setProcessDuration()
- MQConnectionFactory.getProcessDuration()

### **Values**

#### **UNKNOWN**

A subscriber can give no guarantee about how quickly it can process any message it receives. This is the default value.

#### **SHORT**

A subscriber guarantees to process quickly any message it receives before returning control to IBM MQ classes for JMS.

## **PROVIDERVERSION**

This property differentiates between the three IBM MQ messaging modes of operation: IBM MQ messaging provider normal mode, IBM MQ messaging provider normal mode with restrictions, and IBM MQ messaging provider migration mode.

The IBM MQ messaging provider normal mode uses all the features of an IBM MQ queue manager to implement JMS. This mode is optimized to use the JMS 2.0 API and functionality. The IBM MQ messaging provider normal mode with restrictions uses the JMS 2.0 API, but not the new features such as shared subscriptions, delayed delivery, or asynchronous send.

### **Applicable Objects**

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: PROVIDERVERSION

JMS administration tool short name: PVER

### **Programmatic access**

Setters/getters

- MQConnectionFactory.setProviderVersion()
- MQConnectionFactory.getProviderVersion()

## Values

You can set the **PROVIDERVERSION** property to any of the values 8 (normal mode), 7 (normal mode with restrictions), 6 (migration mode), or unspecified (the default value). The value that you specify for the **PROVIDERVERSION** property must be a string. If you are specifying an option of 8, 7 or 6, you can do this in any of the following formats:

- V.R.M.F
- V.R.M
- V.R
- V

where V, R, M and F are integer values greater than or equal to zero. The extra R, M and F values are optional and are available for you to use in case fine grained control is needed. For example, if you wanted to use a **PROVIDERVERSION** level of 7, you could set **PROVIDERVERSION=7, 7.0, 7.0.0** or **7.0.0.0**.

### 8 - Normal mode

The JMS application uses the IBM MQ messaging provider normal mode. Normal mode uses all the features of an IBM MQ queue manager to implement JMS. This mode is optimized to use the JMS 2.0 API and functionality.

If you are connecting to a queue manager with a command level of 800 or later, then all of the JMS 2.0 API and features, such as asynchronous send, delayed delivery, or shared subscription, can be used.

If the queue manager specified in the connection factory settings is not an IBM MQ 8.0.0 or later queue manager, the `createConnection` method fails with an exception `JMSFMQ0003`.

The IBM MQ messaging provider normal mode uses the sharing conversations feature and the number of conversations that can be shared is controlled by the **SHARECNV()** property on the server connection channel. If this property is set to 0, you cannot use IBM MQ messaging provider normal mode and the `createConnection` method fails with an exception `JMSCC5007`.

### 7 - Normal mode with restrictions

The JMS application uses the IBM MQ messaging provider normal mode with restrictions. This mode uses the JMS 2.0 API, but not the new features such as shared subscriptions, delayed delivery, or asynchronous send.

If you set **PROVIDERVERSION** to 7 only the IBM MQ messaging provider normal with restrictions mode of operation is available.

If you are connecting using normal mode with restrictions, to a queue manager with a command level lower than 800 then you can use the JMS 2.0 API, but not the asynchronous send, delayed delivery, or shared subscription features.

The IBM MQ messaging provider normal mode with restrictions uses the sharing conversations feature and the number of conversations that can be shared is controlled by the **SHARECNV()** property on the server connection channel. If this property is set to 0, you cannot use IBM MQ messaging provider normal mode with restrictions and the `createConnection` method fails with an exception `JMSCC5007`.

### 6 - Migration mode

The JMS application uses the IBM MQ messaging provider migration mode.

You can connect to an IBM MQ 8.0, or later, queue manager using this mode, but none of the new features of an IBM MQ classes for JMS queue manager are used, for example, read ahead or streaming.

If you have an IBM MQ 8.0 or later client connecting to an IBM MQ 8.0 or later queue manager, then the message selection is done by the queue manager rather than on the client system.

If IBM MQ messaging provider migration mode is specified and you attempt to use any of the JMS 2.0 API, the API method call fails with the exception `JMSCC5007`.

### **unspecified (default)**

The **PROVIDERVERSION** property is set to *unspecified* by default.

A connection factory that was created with a previous version of IBM MQ classes for JMS in JNDI takes this value when the connection factory is used with the new version of IBM MQ classes for JMS. The following algorithm is used to determine which mode of operation is used. This algorithm is used when the `createConnection` method is called and uses other aspects of the connection factory to determine if IBM MQ messaging provider normal mode, normal mode with restrictions, or IBM MQ messaging provider migration mode is required.

1. First, an attempt to use IBM MQ messaging provider normal mode is made.
2. If the queue manager connected is not IBM MQ 8.0 or later, an attempt to use IBM MQ messaging provider normal mode with restrictions is made.
3. If the queue manager connected is not IBM WebSphere MQ 7.0.1, or later, the connection is closed and IBM MQ messaging provider migration mode is used instead.
4. If the **SHARECNV** property on the server connection channel is set to 0, the connection is closed and IBM MQ messaging provider migration mode is used instead.
5. If **BROKERVER** is set to V1 or the default *unspecified* value, IBM MQ messaging provider normal mode continues to be used.

See [ALTER QMGR](#) for information about the PSMODE parameter of the ALTER QMGR command for further information on compatibility.

6. If **BROKERVER** is set to V2 the action taken depends on the value of **BROKERQMGR** :
  - If the **BROKERQMGR** is blank:

If the queue specified by the **BROKERCONQ** property can be opened for output (that is, MQOPEN for output succeeds) and **PSMODE** on the queue manager is set to COMPAT or DISABLED, then IBM MQ messaging provider migration mode is used.
  - If the queue specified by the **BROKERCONQ** property cannot be opened for output, or the **PSMODE** attribute is set to ENABLED:

IBM MQ messaging provider normal mode is used.
  - If **BROKERQMGR** is non-blank :

IBM MQ messaging provider migration mode is used.

If you cannot change the connection factory that you are using, you can use the `com.ibm.msg.client.wmq.overrideProviderVersion` property to override any setting on the connection factory. This override applies to all connection factories in the JVM but the actual connection factory objects are not modified.

### **Related tasks**

[Configuring the JMS \*\*PROVIDERVERSION\*\* property](#)

## **PROXYHOSTNAME**

The host name or IP address of the system on which the proxy server is running when using a real-time connection to a broker through a proxy server.

### **Applicable Objects**

ConnectionFactory, TopicConnectionFactory

JMS administration tool long name: PROXYHOSTNAME

JMS administration tool short name: PHOST

### **Programmatic access**

Setters/getters

- `MQConnectionFactory.setProxyHostName()`
- `MQConnectionFactory.getProxyHostName()`

## Values

### null

The host name of the proxy server. This is the default value.

## PROXYPORT

The number of the port on which the proxy server is listening when using a real-time connection to a broker through a proxy server.

### Applicable Objects

`ConnectionFactory`, `TopicConnectionFactory`

JMS administration tool long name: PROXYPORT

JMS administration tool short name: PPORT

### Programmatic access

Setters/getters

`MQConnectionFactory.setProxyPort()`

`MQConnectionFactory.getProxyPort()`

## Values

### 443

The port number of the proxy server. This is the default value.

## PUBACKINT

The number of messages published by a publisher before IBM MQ classes for JMS requests an acknowledgment from the broker.

When you lower the value of this property, IBM MQ classes for JMS requests acknowledgments more often, therefore the performance of the publisher decreases. When you raise the value, IBM MQ classes for JMS take a longer time to throw an exception if the broker fails. This property is relevant only if TRANSPORT has the value BIND or CLIENT.

### Applicable Objects

`ConnectionFactory`, `TopicConnectionFactory`, `XAConnectionFactory`, `XATopicConnectionFactory`

JMS administration tool long name: PROXYPORT

JMS administration tool short name: PPORT

### Programmatic access

Setters/getters

`MQConnectionFactory.setPubAckInterval()`

`MQConnectionFactory.getPubAckInterval()`

## Values

25

Any positive integer may be the default value.

## PUTASYNCALLOWED

This property determines whether message producers are allowed to use asynchronous puts to send messages to this destination.

### Applicable Objects

Queue, Topic

JMS administration tool long name: PUTASYNCALLOWED

JMS administration tool short name: PAALD

### Programmatic access

Setters/getters

`MQDestination.setPutAsyncAllowed()`

`MQDestination.getPutAsyncAllowed()`

## Values

### AS\_DEST

Determine whether asynchronous puts are allowed by referring to the queue or topic definition. This is the default value.

### AS\_Q\_DEF

Determine whether asynchronous puts are allowed by referring to the queue definition.

### AS\_TOPIC\_DEF

Determine whether asynchronous puts are allowed by referring to the topic definition.

### NO

Asynchronous puts are not allowed.

### YES

Asynchronous puts are allowed.

## QMANAGER

The name of the queue manager to connect to.

However, if your application uses a client channel definition table to connect to a queue manager, see [Using a client channel definition table with IBM MQ classes for JMS](#).

### Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, Queue, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: QMANAGER

JMS administration tool short name: QMGR

### Programmatic access

Setters/getters

- `MQConnectionFactory.setQueueManager()`

- `MQConnectionFactory.getQueueManager()`

## Values

### " " (empty string)

Any string can be the default value.

## QUEUE

The name of the JMS queue destination. This matches the name of the queue used by the queue manager.

### Applicable Objects

Queue

JMS administration tool long name: QUEUE

JMS administration tool short name: QU

## Values

### Any string

Any valid IBM MQ queue name.

### Related reference

[Rules for naming IBM MQ objects](#)>

## READAHEADALLOWED

This property determines whether message consumers and queue browsers are allowed to use read ahead to get nonpersistent messages from this destination into an internal buffer before receiving them.

### Applicable Objects

Queue, Topic

JMS administration tool long name: READAHEADALLOWED

JMS administration tool short name: RAALD

### Programmatic access

Setters/getters

- `MQDestination.setReadAheadAllowed()`
- `MQDestination.getReadAheadAllowed()`

## Values

### AS\_DEST

Determine whether read ahead is allowed by referring to the queue or topic definition. This is the default value in administrative tools.

Use `WMQConstants.WMQ_READ_AHEAD_ALLOWED_AS_DEST` in programs.

### AS\_Q\_DEF

Determine whether read ahead is allowed by referring to the queue definition.

Use `WMQConstants.WMQ_READ_AHEAD_ALLOWED_AS_Q_DEF` in programs.

### AS\_TOPIC\_DEF

Determine whether read ahead is allowed by referring to the topic definition.

Use `WMQConstants.WMQ_READ_AHEAD_ALLOWED_AS_TOPIC_DEF` in programs.

#### **NO**

Read ahead is not allowed.

Use `WMQConstants.WMQ_READ_AHEAD_ALLOWED_DISABLED` in programs.

#### **YES**

Read ahead is allowed.

Use `WMQConstants.WMQ_READ_AHEAD_ALLOWED_ENABLED` in programs.

## **READAHEADCLOSEPOLICY**

For messages being delivered to an asynchronous message listener, what happens to messages in the internal read ahead buffer when the message consumer is closed.

### **Applicable Objects**

Queue, Topic

JMS administration tool long name: READAHEADCLOSEPOLICY

JMS administration tool short name: RACP

### **Programmatic access**

Setters/getters

- `MQDestination.setReadAheadClosePolicy()`
- `MQDestination.getReadAheadClosePolicy()`

### **Values**

#### **DELIVER\_ALL**

All messages in the internal read ahead buffer are delivered to the message listener of the application before returning. This is the default value in administrative tools.

Use `WMQConstants.WMQ_READ_AHEAD_DELIVERALL` in programs.

#### **DELIVER\_CURRENT**

Only the current message listener invocation completes before returning, potentially leaving messages in the internal read ahead buffer, which are then discarded.

Use `WMQConstants.WMQ_READ_AHEAD_DELIVERCURRENT` in programs.

## **RECEIVECCSID**

Destination property that sets the target CCSID for queue manager message conversion. The value is ignored unless `RECEIVECONVERSION` is set to `WMQ_RECEIVE_CONVERSION_QMGR`

### **Applicable Objects**

Queue, Topic

JMS administration tool long name: RECEIVECCSID

JMS administration tool short name: RCCS

### **Programmatic access**

Setters/Getters

- `MQDestination.setReceiveCCSID`
- `MQDestination.getReceiveCCSID`

## Values

### **WMQConstants.WMQ\_RECEIVE\_CCSD\_JVM\_DEFAULT**

0 - Use `JVM Charset.defaultCharset`

### **1208**

UTF-8

### **CCSID**

Supported coded character set identifier.

## RECEIVECONVERSION

Destination property that determines if data conversion is going to be performed by the queue manager.

### Applicable Objects

Queue, Topic

JMS administration tool long name: RECEIVECONVERSION

JMS administration tool short name: RCNV

### Programmatic access

#### Setters/Getters

- `MQDestination.setReceiveConversion`
- `MQDestination.getReceiveConversion`

## Values

### **WMQConstants.WMQ\_RECEIVE\_CONVERSION\_CLIENT\_MSG**

1 - Only perform data conversion on the JMS client. The default value from up to V7.0, and from, and including, 7.0.1.5.

### **WMQConstants.WMQ\_RECEIVE\_CONVERSION\_QMGR**

2 - Perform data conversion on the queue manager before sending a message to the client. The default (and only) value from V7.0 to V7.0.1.4 inclusive, except if APAR IC72897 is applied.

## RECEIVEISOLATION

This property determines whether a subscriber might receive messages that have not been committed on the subscriber queue.

### Applicable Objects

ConnectionFactory, TopicConnectionFactory

JMS administration tool long name: RECEIVEISOLATION

JMS administration tool short name: RCVISOL

## Values

### **COMMITTED**

A subscriber receives only those messages on the subscriber queue that have been committed. This is the default value in administrative tools.

Use `WMQConstants.WMQ_RCVISOL_COMMITTED` in programs.

### **UNCOMMITTED**

A subscriber can receive messages that have not been committed on the subscriber queue.

Use `WMQConstants.WMQ_RCVISOL_UNCOMMITTED` in programs.

## RECEXIT

Identifies a channel receive exit, or a sequence of receive exits, to be run in succession.

Additional configuration might be required in order for the IBM MQ classes for JMS to locate receive exits. For more information, see [Configuring the IBM MQ classes for JMS to use channel exits](#).

### Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: RECEXIT

JMS administration tool short name: RCX

### Programmatic access

Setters/getters

- MQConnectionFactory.setReceiveExit()
- MQConnectionFactory.getReceiveExit()

### Values

- null. This is the default value.
- A string comprising one or more items separated by commas, where each item is either:
  - The name of a class that implements the WMQReceiveExit interface (for a channel receive exit written in Java).
  - A string in the format *libraryName(entryPointName)* (for a channel receive exit not written in Java).

## RECEXITINIT

The user data that is passed to channel receive exits when they are called.

### Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: RECEXITINIT

JMS administration tool short name: RCXI

### Programmatic access

Setters/getters

- MQConnectionFactory.setReceiveExitInit()
- MQConnectionFactory.getReceiveExitInit()

### Values

null

A string comprising one or more items of user data separated by commas. This is the default value.

## REPLYTOSTYLE

Determines how the JMSReplyTo field in a received message is constructed.

### Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: REPLYTOSTYLE

JMS administration tool short name: RTOST

### Programmatic access

Setters/getters

- MQConnectionFactory.setReplyToStyle()
- MQConnectionFactory.getReplyToStyle()

### Values

#### DEFAULT

Equivalent to MQMD.

#### RFH2

Use the value supplied in the RFH2 header. If a JMSReplyTo value has been set in the sending application, use that value.

#### MQMD

Use the MQMD supplied value. This behavior is equivalent to the default behavior of IBM WebSphere MQ 6.0.2.4 and 6.0.2.5.

If the JMSReplyTo value set by the sending application does not contain a queue manager name, the receiving queue manager inserts its own name in the MQMD. If you set this parameter to MQMD, the reply-to queue you use is on the receiving queue manager. If you set this parameter to RFH2, the reply-to queue you use is on the queue manager specified in the RFH2 of the sent message as originally set by the sending application.

If the JMSReplyTo value set by the sending application contains a queue manager name, the value of this parameter is unimportant because both the MQMD and RFH2 contain the same value.

## RESCANINT

When a message consumer in the point-to-point domain uses a message selector to select which messages it wants to receive, IBM MQ classes for JMS search the IBM MQ queue for suitable messages in the sequence determined by the `MsgDeliverySequence` attribute of the queue.

After IBM MQ classes for JMS find a suitable message and deliver it to the consumer, IBM MQ classes for JMS resume the search for the next suitable message from its current position in the queue. IBM MQ classes for JMS continue to search the queue in this way until it reaches the end of the queue, or until the interval of time in milliseconds, as determined by the value of this property, has expired. In each case, IBM MQ classes for JMS return to the beginning of the queue to continue the search, and a new time interval commences.

### Applicable Objects

ConnectionFactory, QueueConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory

JMS administration tool long name: RESCANINT

JMS administration tool short name: RINT

## Programmatic access

Setters/getters

- `MQConnectionFactory.setRescanInterval()`
- `MQConnectionFactory.getRescanInterval()`

## Values

**5000**

Any positive integer can be the default value.

## SECEXIT

Identifies a channel security exit.

Additional configuration might be required in order for the IBM MQ classes for JMS to locate security exits. For more information, see [Configuring the IBM MQ classes for JMS to use channel exits](#).

### Applicable Objects

`ConnectionFactory`, `QueueConnectionFactory`, `TopicConnectionFactory`, `XAConnectionFactory`, `XAQueueConnectionFactory`, `XATopicConnectionFactory`

JMS administration tool long name: SECEXIT

JMS administration tool short name: SXC

## Programmatic access

Setters/getters

- `MQConnectionFactory.setSecurityExit()`
- `MQConnectionFactory.getSecurityExit()`

## Values

- `null`. This is the default value.
- A string comprising one or more items separated by commas, where each item is either:
  - The name of a class that implements the `WMQSecurityExit` interface (for a channel security exit written in Java).
  - A string in the format `libraryName(entryPointName)` (for a channel security exit not written in Java).

## SECEXITINIT

The user data that is passed to a channel security exit when it is called.

### Applicable Objects

`ConnectionFactory`, `QueueConnectionFactory`, `TopicConnectionFactory`, `XAConnectionFactory`, `XAQueueConnectionFactory`, `XATopicConnectionFactory`

JMS administration tool long name: SECEXITINIT

JMS administration tool short name: SCXI

## Programmatic access

Setters/getters

- `MQConnectionFactory.setSecurityExitInit()`

- `MQConnectionFactory.getSecurityExitInit()`

## Values

`null`

Any string can be the default value.

## SENDCHECKCOUNT

The number of send calls to allow between checking for asynchronous put errors, within a single non-transacted JMS session.

### Applicable Objects

`ConnectionFactory`, `QueueConnectionFactory`, `TopicConnectionFactory`, `XAConnectionFactory`, `XAQueueConnectionFactory`, `XATopicConnectionFactory`

JMS administration tool long name: SENDCHECKCOUNT

JMS administration tool short name: SCC

### Programmatic access

Setters/getters

- `MQConnectionFactory.setSendCheckCount()`
- `MQConnectionFactory.getSendCheckCount()`

## Values

`null`

Any string can be the default value.

## SENDEXIT

Identifies a channel send exit, or a sequence of send exits to be run in succession.

Additional configuration might be required in order for the IBM MQ classes for JMS to locate send exits. For more information, see [Configuring the IBM MQ classes for JMS to use channel exits](#).

### Applicable Objects

`ConnectionFactory`, `QueueConnectionFactory`, `TopicConnectionFactory`, `XAConnectionFactory`, `XAQueueConnectionFactory`, `XATopicConnectionFactory`

JMS administration tool long name: SENDEXIT

JMS administration tool short name: SDX

### Programmatic access

Setters/getters

- `MQConnectionFactory.setSendExit()`
- `MQConnectionFactory.getSendExit()`

## Values

- `null`. This is the default value.
- A string comprising one or more items separated by commas, where each item is either:

- The name of a class that implements the `WMQSendExit` interface (for a channel send exit written in Java).
- A string in the format *libraryName(entryPointName)* (for a channel send exit not written in Java).

## SENDEXITINIT

The user data that is passed to channel send exits when they are called.

### Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: SENDEXITINIT

JMS administration tool short name: SDXI

### Programmatic access

Setters/getters

- `MQConnectionFactory.setSendExitInit()`
- `MQConnectionFactory.getSendExitInit()`

### Values

**null**

Any string comprising one or more items of user data separated by commas can be the default value.

## SHARECONVALLOWED

For applications that use IBM MQ messaging provider normal mode or normal mode with restrictions, this property determines whether the sharing conversations function is used for JMS connections, sessions, and contexts created from the connection factory.

### Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: SHARECONVALLOWED

JMS administration tool short name: SCALD

### Programmatic access

Setters/getters

- `MQConnectionFactory.setShareConvAllowed()`
- `MQConnectionFactory.getShareConvAllowed()`

### Values

**YES**

JMS connections, sessions, and contexts that are created from the connection factory within the same JVM can share a channel instance (which maps to a TCP/IP connection) where appropriate.

This is the default value for administrative tools.

For programs, use `WMQConstants.WMQ_SHARE_CONV_ALLOWED_YES`.

## **NO**

Every JMS connection created from the connection factory, and every JMS session that is created from those JMSconnections, has its own channel instance (TCP/IP connection) to a queue manager.

For JMS contexts, the first context that is created from the connection factory creates two channel instances (TCP/IP connections). Other JMS contexts that are created from the first one have their own channel instance (TCP/IP connection).

For programs, use WMQConstants.WMQ\_SHARE\_CONV\_ALLOWED\_NO.

### **Related concepts**

[IBM MQ messaging provider modes of operation](#)

[Sharing a TCP/IP connection in IBM MQ classes for JMS](#)

## **SPARSESUBS**

Controls the message retrieval policy of a TopicSubscriber object.

### **Applicable Objects**

ConnectionFactory, TopicConnectionFactory

JMS administration tool long name: SPARSESUBS

JMS administration tool short name: SSUBS

### **Programmatic access**

Setters/getters

- MQConnectionFactory.setSparseSubscriptions()
- MQConnectionFactory.getSparseSubscriptions()

### **Values**

#### **NO**

Subscriptions receive frequent matching messages. This is the default value for administrative tools.

For programs, use false.

#### **YES**

Subscriptions receive infrequent matching messages. This value requires that the subscription queue can be opened for browse.

For programs, use true.

## **SSLCIPHERSUITE**

The CipherSuite to use for a TLS connection.

### **Applicable Objects**

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: SSLCIPHERSUITE

JMS administration tool short name: SCPHS

### **Programmatic access**

Setters/getters

- MQConnectionFactory.setSSLCipherSuite()

- `MQConnectionFactory.getSSLCipherSuite()`

## Values

**null**

This is the default value. For more information, see [TLS properties of JMS objects](#).

## SSLCRL

CRL servers to check for TLS certificate revocation.

### Applicable Objects

`ConnectionFactory`, `QueueConnectionFactory`, `TopicConnectionFactory`, `XAConnectionFactory`, `XAQueueConnectionFactory`, `XATopicConnectionFactory`

JMS administration tool long name: SSLCRL

JMS administration tool short name: SCRL

### Programmatic access

Setters/getters

- `MQConnectionFactory.setSSLCertStores()`
- `MQConnectionFactory.getSSLCertStores()`

## Values

**null**

Space-separated list of LDAP URLs. This is the default value. For more information, see [TLS properties of JMS objects](#).

## SSLFIPSREQUIRED

This property determines whether a TLS connection must use a CipherSuite that is supported by the IBM Java JSSE FIPS provider (IBMJSSEFIPS).

**Note:** On AIX, Linux, and Windows, IBM MQ provides FIPS 140-2 compliance through the IBM Crypto for C (ICC) cryptographic module. The certificate for this module has been moved to the Historical status. Customers should view the IBM Crypto for C (ICC) certificate and be aware of any advice provided by NIST. A replacement FIPS 140-3 module is currently in progress and its status can be viewed by searching for it in the [NIST CMVP modules in process list](#).

The IBM MQ Operator 3.2.0 and queue manager container image 9.4.0.0 onwards are based on UBI 9. FIPS 140-3 compliance is currently pending and its status can be viewed by searching for "Red Hat Enterprise Linux 9 - OpenSSL FIPS Provider" in the [NIST CMVP modules in process list](#).

### Applicable Objects

`ConnectionFactory`, `QueueConnectionFactory`, `TopicConnectionFactory`, `XAConnectionFactory`, `XAQueueConnectionFactory`, `XATopicConnectionFactory`

JMS administration tool long name: SSLFIPSREQUIRED

JMS administration tool short name: SFIPS

### Programmatic access

Setters/getters

- `MQConnectionFactory.setSSLFipsRequired()`

- `MQConnectionFactory.getSSLFipsRequired()`

## Values

### NO

A TLS connection can use any CipherSuite that is not supported by the IBM Java JSSE FIPS provider (IBMJSSEFIPS).

This is the default value. In programs, use false.

### YES

A TLS connection must use a CipherSuite that is supported by IBMJSSEFIPS.

In programs, use true.

## SSLPEERNAME

For TLS, a *distinguished name* skeleton that must match that provided by the queue manager.

### Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: SSLPEERNAME

JMS administration tool short name: SPEER

### Programmatic access

Setters/getters

- `MQConnectionFactory.setSSLPeerName()`
- `MQConnectionFactory.getSSLPeerName()`

## Values

### null

This is the default value. For more information, see [TLS properties of JMS objects](#).

## SSLRESETCOUNT

For TLS, the total number of bytes sent and received by a connection before the secret key that is used for encryption is renegotiated.

### Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: SSLRESETCOUNT

JMS administration tool short name: SRC

### Programmatic access

Setters/getters

- `MQConnectionFactory.setSSLResetCount()`
- `MQConnectionFactory.getSSLResetCount()`

## Values

0

Zero, or any positive integer less than or equal to 999, 999, 999. This is the default value. For more information, see [TLS properties of JMS objects](#).

## STATREFRESHINT

The interval, in milliseconds, between refreshes of the long running transaction that detects when a subscriber loses its connection to the queue manager.

This property is relevant only if SUBSTORE has the value QUEUE.

### Applicable Objects

ConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: STATREFRESHINT

JMS administration tool short name: SRI

### Programmatic access

Setters/getters

- MQConnectionFactory.setStatusRefreshInterval()
- MQConnectionFactory.getStatusRefreshInterval()

## Values

60000

Any positive integer can be the default value. For more information, see [TLS properties of JMS objects](#).

## SUBSTORE

Where IBM MQ classes for JMS stores persistent data relating to active subscriptions.

### Applicable Objects

ConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: SUBSTORE

JMS administration tool short name: SS

### Programmatic access

Setters/getters

- MQConnectionFactory.setSubscriptionStore()
- MQConnectionFactory.getSubscriptionStore()

## Values

### BROKER

Use the broker-based subscription store to hold details of subscriptions. This is the default value for administrative tools.

For programs, use WMQConstants.WMQ\_SUBSTORE\_BROKER.

### MIGRATE

Transfer subscription information from the queue-based subscription store to the broker-based subscription store.

For programs, use `WMQConstants.WMQ_SUBSTORE_MIGRATE`.

### **QUEUE**

Use the queue-based subscription store to hold details of subscriptions.

For programs, use `WMQConstants.WMQ_SUBSTORE_QUEUE`.

## **SYNCPOINTALLGETS**

This property determines whether all gets are to be performed under syncpoint.

### **Applicable Objects**

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: SYNCPOINTALLGETS

JMS administration tool short name: SPAG

### **Programmatic access**

Setters/getters

- `MQConnectionFactory.setSyncpointAllGets()`
- `MQConnectionFactory.getSyncpointAllGets()`

### **Values**

#### **No**

This is the default value.

#### **Yes**

## **TARGCLIENT**

This property determines whether the IBM MQ RFH2 format is used to exchange information with target applications.

### **Applicable Objects**

Queue, Topic

JMS administration tool long name: TARGCLIENT

JMS administration tool short name: TC

### **Programmatic access**

Setters/getters

- `MQDestination.setTargetClient()`
- `MQDestination.getTargetClient()`

### **Values**

#### **JMS**

The target of the message is a JMS application. This is the default value for administrative tools.

For programs, use `WMQConstants.WMQ_CLIENT_JMS_COMPLIANT`.

#### **MQ**

The target of the message is a non-JMS IBM MQ application.

For programs, use `WMQConstants.WMQ_CLIENT_NONJMS_MQ`.

## TARGCLIENTMATCHING

This property determines whether a reply message, sent to the queue identified by the JMSReplyTo header field of an incoming message, has an MQRFH2 header only if the incoming message has an MQRFH2 header.

### Applicable Objects

ConnectionFactory, QueueConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory

JMS administration tool long name: TARGCLIENTMATCHING

JMS administration tool short name: TCM

### Programmatic access

Setters/getters

- MQConnectionFactory.setTargetClientMatching()
- MQConnectionFactory.getTargetClientMatching()

### Values

#### YES

If an incoming message does not have an MQRFH2 header, the TARGCLIENT property of the Queue object derived from the JMSReplyTo header field of the message is sent to MQ. If the message does have an MQRFH2 header, the TARGCLIENT property is set to JMS instead. This is the default value for administrative tools.

For programs, use true.

#### NO

The TARGCLIENT property of the Queue object derived from the JMSReplyTo header field of an incoming message is always set to JMS.

For programs, use false.

## TEMPMODEL

The name of the model queue from which JMS temporary queues are created.

### Applicable Objects

ConnectionFactory, QueueConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory

JMS administration tool long name: TEMPMODEL

JMS administration tool short name: TM

### Programmatic access

Setters/getters

- MQConnectionFactory.setTemporaryModel()
- MQConnectionFactory.getTemporaryModel()

### Values

#### SYSTEM.DEFAULT.MODEL.QUEUE

Any string can be the default value.

## TEMPQPREFIX

The prefix that is used to form the name of an IBM MQ dynamic queue.

### Applicable Objects

ConnectionFactory, QueueConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory

JMS administration tool long name: TEMPQPREFIX

JMS administration tool short name: TQP

### Programmatic access

Setters/getters

- MQConnectionFactory.setTempQPrefix()
- MQConnectionFactory.getTempQPrefix()

### Values

#### " " (empty string)

The prefix used is CSQ.\* on z/OS and AMQ.\* on all other platforms. These are the default values.

#### queue prefix

The queue prefix is any string that conforms to the rules for forming contents of the *DynamicQName* field in an IBM MQ object descriptor (structure MQOD), but the last non-blank character must be an asterisk.

## TEMPTOPICPREFIX

When creating temporary topics, JMS generates a topic string of the form "TEMP /TEMPTOPICPREFIX/*unique\_id*", or if this property is left with the default value, just "TEMP /*unique\_id*". Specifying a non-empty TEMPTOPICPREFIX allows specific model queues to be defined for creating the managed queues for subscribers to temporary topics created under this connection.

### Applicable Objects

ConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: TEMPTOPICPREFIX

JMS administration tool short name: TTP

### Programmatic access

Setters/getters

- MQConnectionFactory.setTempTopicPrefix()
- MQConnectionFactory.getTempTopicPrefix()

### Values

Any non-null string consisting only of valid characters for an IBM MQ topic string. The default value is " " (empty string).

## TOPIC

The name of the JMS topic destination, this value is used by the queue manager as the topic string of a publication or subscription.

### Applicable Objects

Topic

JMS administration tool long name: TOPIC

JMS administration tool short name: TOP

### Values

#### Any string

A string that forms a valid IBM MQ topic string. When using IBM MQ as a messaging provider with WebSphere Application Server, specify a value that matches the name by which the topic is known for administrative purposes within WebSphere Application Server.

#### Related reference

[Topic strings](#)

## TRANSPORT

The nature of a connection to a queue manager or broker.

### Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: TRANSPORT

JMS administration tool short name: TRAN

### Programmatic access

Setters/getters

- `MQConnectionFactory.setTransportType()`
- `MQConnectionFactory.getTransportType()`

### Values

#### BIND

For a connection to a queue manager in bindings mode. This is the default value for administrative tools.

For programs, use `WMQConstants.WMQ_CM_BINDINGS`.

#### CLIENT

For a connection to a queue manager in client mode.

For programs, use `WMQConstants.WMQ_CM_CLIENT`.

#### DIRECT

For a real-time connection to a broker not using HTTP tunnelling.

For programs, use `WMQConstants.WMQ_CM_DIRECT_TCPIP`.

#### DIRECTHTTP

For a real-time connection to a broker using HTTP tunnelling. Only HTTP 1.0 is supported.

For programs, use `WMQConstants.WMQ_CM_DIRECT_HTTP`.

## Related concepts

“Dependencies between properties of IBM MQ classes for JMS objects” on page 1894  
The validity of some properties is dependent on the particular values of other properties.

## WILDCARDFORMAT

This property determines which version of wildcard syntax is to be used.

### Applicable Objects

ConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: WILDCARDFORMAT

JMS administration tool short name: WCFMT

### Programmatic access

Setters/getters

- MQConnectionFactory.setWildcardFormat()
- MQConnectionFactory.getWildcardFormat()

### Values

#### TOPIC\_ONLY

Recognizes topic level wildcards only, as used in broker version 2. This is the default value for administrative tools.

For programs, use WMQConstants.WMQ\_WILDCARD\_TOPIC\_ONLY.

#### CHAR\_ONLY

Recognizes character wildcards only, as used in broker version 1.

For programs, use WMQConstants.WMQ\_WILDCARD\_CHAR\_ONLY.

## The ENCODING property

The ENCODING property comprises three sub-properties, in twelve possible combinations.

The valid values that the ENCODING property can take are constructed from the three sub-properties:

### integer encoding

Either normal or reversed

### decimal encoding

Either normal or reversed

### floating-point encoding

IEEE normal, IEEE reversed, or z/OS

The ENCODING property is expressed as a three-character string with the following syntax:

```
{N|R}{N|R}{N|R|3}
```

In this string:

- N denotes normal
- R denotes reversed
- 3 denotes z/OS
- The first character represents *integer encoding*
- The second character represents *decimal encoding*
- The third character represents *floating-point encoding*

This provides a set of twelve possible values for the ENCODING property.

There is an additional value, the string NATIVE, which sets appropriate encoding values for the Java platform.

The following examples show valid combinations for ENCODING:

```
ENCODING (NMR)
ENCODING (NATIVE)
ENCODING (RR3)
```

## TLS properties of JMS objects

Enable Transport Layer Security (TLS) encryption using the SSLCIPHERSUITE property. You can then change the characteristics of the TLS encryption using several other properties.

When you specify TRANSPORT(CLIENT), you can enable TLS encrypted communication using the SSLCIPHERSUITE property. Set this property to a valid CipherSuite provided by your JSSE provider; it must match the CipherSpec named on the SVRCONN channel named by the CHANNEL property.

However, CipherSpecs (as specified on the SVRCONN channel) and CipherSuites (as specified on ConnectionFactory objects) use different naming schemes to represent the same TLS encryption algorithms. If a recognized CipherSpec name is specified on the SSLCIPHERSUITE property, JMSAdmin issues a warning and maps the CipherSpec to its equivalent CipherSuite. See [TLS CipherSpecs and CipherSuites in IBM MQ classes for JMS](#) for a list of CipherSpecs recognized by IBM MQ and JMSAdmin.

If you require a connection to use a CipherSuite that is supported by the IBM Java JSSE FIPS provider (IBMJSSEFIPS), set the SSLFIPSREQUIRED property of the connection factory to YES. The default value of this property is NO, which means that a connection can use any supported CipherSuite. The property is ignored if SSLCIPHERSUITE is not set.

The SSLPEERNAME matches the format of the SSLPEER parameter, which can be set on channel definitions. It is a list of attribute name-value pairs separated by commas or semicolons. For example:

```
SSLPEERNAME (CN=QMGR.*, OU=IBM, OU=WEBSPPHERE)
```

The set of names and values makes up a *distinguished name*. For more details about distinguished names and their use with IBM MQ, see [Securing IBM MQ](#).

The example given checks the identifying certificate presented by the server at connect-time. For the connection to succeed, the certificate must have a Common Name beginning QMGR., and must have at least two Organizational Unit names, the first of which is IBM and the second WEBSPPHERE. Checking is not case-sensitive.

If SSLPEERNAME is not set, no such checking is performed. SSLPEERNAME is ignored if SSLCIPHERSUITE is not set.

The SSLCRL property specifies zero or more CRL (Certificate Revocation List) servers. Use of this property requires a JVM at Java 2 v1.4. This is a space-delimited list of entries of the form:

```
ldap:// hostname: [ port ]
```

optionally followed by a single /. If *port* is omitted, the default LDAP port of 389 is assumed. At connect-time, the TLS certificate presented by the server is checked against the specified CRL servers. See [Securing IBM MQ](#) for more about CRL security.

If SSLCRL is not set, no such checking is performed. SSLCRL is ignored if SSLCIPHERSUITE is not set.

The SSLRESETCOUNT property represents the total number of bytes sent and received by a connection before the secret key that is used for encryption is renegotiated. The number of bytes sent is the number before encryption, and the number of bytes received is the number after decryption. The number of bytes also includes control information sent and received by IBM MQ classes for JMS.

For example, to configure a `ConnectionFactory` object that can be used to create a connection over an TLS enabled MQI channel with a secret key that is renegotiated after 4 MB of data have flowed, issue the following command to JMSAdmin:

```
ALTER CF(my.cf) SSLRESETCOUNT(4194304)
```

If the value of `SSLRESETCOUNT` is zero, which is the default value, the secret key is never renegotiated. The `SSLRESETCOUNT` property is ignored if `SSLCIPHERSUITE` is not set.

## IBM MQ Message Service Client (XMS) for .NET reference

This reference section provides information about the IBM MQ Message Service Client (XMS) for .NET (XMS .NET) class interfaces and about the object properties defined by XMS.

### .NET interfaces

This section describes the .NET class interfaces and their properties and methods.

The following table summarizes the interfaces, which are defined within the `IBM.XMS` namespace.

Interface	Description
<a href="#">"IBytesMessage" on page 1950</a>	A bytes message is a message whose body comprises a stream of bytes.
<a href="#">"IConnection" on page 1960</a>	A <code>Connection</code> object represents the active connection of the application to a messaging server.
<a href="#">"IConnectionFactory" on page 1963</a>	An application uses a connection factory to create a connection.
<a href="#">"IConnectionMetaData" on page 1964</a>	A <code>ConnectionMetaData</code> object provides information about a connection.
<a href="#">"IDestination" on page 1964</a>	A destination is where an application sends messages, or it is a source from which an application receives messages, or both.
<a href="#">"ExceptionListener" on page 1965</a>	An application uses an exception listener to be notified asynchronously of a problem with a connection.
<a href="#">"IllegalStateException" on page 1966</a>	XMS throws this exception if an application calls a method at an incorrect or inappropriate time, or if XMS is not in an appropriate state for the requested operation.
<a href="#">"InitialContext" on page 1966</a>	An application uses an <code>InitialContext</code> object to create objects from object definitions that are retrieved from a repository of administered objects.
<a href="#">"InvalidClientIDException" on page 1968</a>	XMS throws this exception if an application attempts to set a client identifier for a connection, but the client identifier is not valid or is already in use.
<a href="#">"InvalidDestinationException" on page 1969</a>	XMS throws this exception if an application specifies a destination that is not valid.

Table 871. Summary of the .NET class interfaces (continued)

Interface	Description
<a href="#">“InvalidSelectorException” on page 1969</a>	XMS throws this exception if an application provides a message selector expression whose syntax is not valid.
<a href="#">“IMapMessage” on page 1969</a>	A map message is a message whose body comprises a set of name-value pairs, where each value has an associated data type.
<a href="#">“IMessage” on page 1978</a>	A Message object represents a message that an application sends or receives. IMessage is a superclass for the message classes such as IMapMessage.
<a href="#">“IMessageConsumer” on page 1984</a>	An application uses a message consumer to receive messages sent to a destination.
<a href="#">“MessageEOFException” on page 1986</a>	XMS throws this exception if XMS encounters the end of a bytes message stream when an application is reading the body of a bytes message.
<a href="#">“MessageFormatException” on page 1986</a>	XMS throws this exception if XMS encounters a message with a format that is not valid.
<a href="#">“IMessageListener (delegate)” on page 1987</a>	An application uses a message listener to receive messages asynchronously.
<a href="#">“MessageNotReadableException” on page 1987</a>	XMS throws this exception if an application attempts to read the body of a message that is write only.
<a href="#">“MessageNotWritableException” on page 1987</a>	XMS throws this exception if an application attempts to write to the body of a message that is read-only.
<a href="#">“IMessageProducer” on page 1988</a>	An application uses a message producer to send messages to a destination.
<a href="#">“IObjectMessage” on page 1993</a>	An object message is a message whose body comprises a serialized Java or .NET object.
<a href="#">“IPropertyContext” on page 1994</a>	IPropertyContext is an abstract superclass that contains methods that get and set properties. These methods are inherited by other classes.
<a href="#">“IQueueBrowser” on page 2003</a>	An application uses a queue browser to browse messages on a queue without removing them.
<a href="#">“Requestor” on page 2004</a>	An application uses a requestor to send a request message and then wait for, and receive, the reply.
<a href="#">“ResourceAllocationException” on page 2006</a>	XMS throws this exception if XMS cannot allocate the resources required by a method.
<a href="#">“SecurityException” on page 2006</a>	XMS throws this exception if the user identifier and password provided to authenticate an application are rejected. XMS also throws this exception if an authority check fails and prevents a method from completing.

Table 871. Summary of the .NET class interfaces (continued)

Interface	Description
<a href="#">“ISession” on page 2006</a>	A session is a single threaded context for sending and receiving messages.
<a href="#">“IStreamMessage” on page 2016</a>	A stream message is a message whose body comprises a stream of values, where each value has an associated data type.
<a href="#">“ITextMessage” on page 2025</a>	A text message is a message whose body comprises a string.
<a href="#">“TransactionInProgressException” on page 2026</a>	XMS throws this exception if an application requests an operation that is not valid because a transaction is in progress.
<a href="#">“TransactionRolledBackException” on page 2026</a>	XMS throws this exception if an application calls <code>Session.commit()</code> to commit the current transaction, but the transaction is then rolled back.
XMSC	For .NET, XMS property names and values are defined in this class as public constants. For further details, see <a href="#">“Properties of XMS objects” on page 2029</a> .
<a href="#">“XMSException” on page 2026</a>	<p>If XMS detects an error while processing a call to a .NET method, XMS throws an exception. An exception is an object that encapsulates information about the error.</p> <p>There are different types of XMS exception, and an <code>XMSException</code> object is just one type of exception. However, the <code>XMSException</code> class is a superclass of the other XMS exception classes. XMS throws an <code>XMSException</code> object in situations where none of the other types of exception are appropriate.</p>
<a href="#">“XMSFactoryFactory” on page 2027</a>	If an application is not using administered objects, use this class to create connection factories, queues, and topics.

The definition of each method lists the exception codes that XMS might return if it detects an error while processing a call to the method. Each exception code is represented by its named constant, which has a corresponding exception.

## IBytesMessage

A bytes message is a message whose body comprises a stream of bytes.

### Inheritance hierarchy:

```

IBM.XMS.IPropertyContext
|
+----IBM.XMS.IMessage
|
+----IBM.XMS.IBytesMessage
    
```

## .NET properties

## *BodyLength - Get Body Length*

### **Interface:**

```
Int64 BodyLength
{
    get;
}
```

Get the length of the body of the message in bytes when the body of the message is read-only.

The value returned is the length of the whole body regardless of where the cursor for reading the message is currently positioned.

### **Exceptions:**

- XMSEException
- MessageNotReadableException

### **Methods**

## *ReadBoolean - Read Boolean Value*

### **Interface:**

```
Boolean ReadBoolean();
```

Read a boolean value from the bytes message stream.

### **Parameters:**

None

### **Returns:**

The boolean value that is read.

### **Exceptions:**

- XMSEException
- MessageNotReadableException
- MessageEOFException

## *ReadSignedByte - Read Byte*

### **Interface:**

```
Int16 ReadSignedByte();
```

Read the next byte from the bytes message stream as a signed 8-bit integer.

### **Parameters:**

None

### **Returns:**

The byte that is read.

### **Exceptions:**

- XMSEException
- MessageNotReadableException
- MessageEOFException

## *ReadBytes - Read Bytes*

### **Interface:**

```
Int32 ReadBytes(Byte[] array);  
Int32 ReadBytes(Byte[] array, Int32 length);
```

Read an array of bytes from the bytes message stream starting from the current position of the cursor.

### **Parameters:**

#### **array (output)**

The buffer to contain the array of bytes that is read. If the number of bytes remaining to be read from the stream before the call is greater than or equal to the length of the buffer, the buffer is filled. Otherwise, the buffer is partially filled with all the remaining bytes.

If you specify a null pointer on input, the method skips over the bytes without reading them.

If the number of bytes remaining to be read from the stream before the call is greater than or equal to the length of the buffer, the number of bytes skipped is equal to the length of the buffer. Otherwise, all the remaining bytes are skipped. The cursor remains at the next position to read in the byte message stream.

#### **length (input)**

The length of the buffer in bytes

### **Returns:**

The number of bytes that are read into the buffer. If the buffer is partially filled, the value is less than the length of the buffer, indicating that there are no more bytes remaining to be read. If there are no bytes remaining to be read from the stream before the call, the value is `XMSC_END_OF_STREAM`.

If you specify a null pointer on input, the method returns no value.

### **Exceptions:**

- `XMSEException`
- `MessageNotReadableException`

## *ReadChar - Read Character*

### **Interface:**

```
Char ReadChar();
```

Read the next 2 bytes from the bytes message stream as a character.

### **Parameters:**

None

### **Returns:**

The character that is read.

### **Exceptions:**

- `XMSEException`
- `MessageNotReadableException`
- `MessageEOFException`

## *ReadDouble - Read Double Precision Floating Point Number*

### **Interface:**

```
Double ReadDouble();
```

Read the next 8 bytes from the bytes message stream as a double precision floating point number.

**Parameters:**

None

**Returns:**

The double precision floating point number that is read.

**Exceptions:**

- XMSEException
- MessageNotReadableException
- MessageEOFException

*ReadFloat - Read Floating Point Number*

**Interface:**

```
Single ReadFloat();
```

Read the next 4 bytes from the bytes message stream as a floating point number.

**Parameters:**

None

**Returns:**

The floating point number that is read.

**Exceptions:**

- XMSEException
- MessageNotReadableException
- MessageEOFException

*ReadInt - Read Integer*

**Interface:**

```
Int32 ReadInt();
```

Read the next 4 bytes from the bytes message stream as a signed 32-bit integer.

**Parameters:**

None

**Returns:**

The integer that is read.

**Exceptions:**

- XMSEException
- MessageNotReadableException
- MessageEOFException

*ReadLong - Read Long Integer*

**Interface:**

```
Int64 ReadLong();
```

Read the next 8 bytes from the bytes message stream as a signed 64-bit integer.

**Parameters:**

None

**Returns:**

The long integer that is read.

**Exceptions:**

- XMSEException
- MessageNotReadableException
- MessageEOFException

*ReadShort - Read Short Integer*

**Interface:**

```
Int16 ReadShort();
```

Read the next 2 bytes from the bytes message stream as a signed 16-bit integer.

**Parameters:**

None

**Returns:**

The short integer that is read.

**Exceptions:**

- XMSEException
- MessageNotReadableException
- MessageEOFException

*ReadByte - Read Unsigned Byte*

**Interface:**

```
Byte ReadByte();
```

Read the next byte from the bytes message stream as an unsigned 8-bit integer.

**Parameters:**

None

**Returns:**

The byte that is read.

**Exceptions:**

- XMSEException
- MessageNotReadableException
- MessageEOFException

*ReadUnsignedShort - Read Unsigned Short Integer*

**Interface:**

```
Int32 ReadUnsignedShort();
```

Read the next 2 bytes from the bytes message stream as an unsigned 16-bit integer.

**Parameters:**

None

**Returns:**

The unsigned short integer that is read.

**Exceptions:**

- XMSEException
- MessageNotReadableException
- MessageEOFException

*ReadUTF - Read UTF String*

**Interface:**

```
String ReadUTF();
```

Read a string, encoded in UTF-8, from the bytes message stream.

**Note:** Before calling ReadUTF(), ensure that the cursor of the buffer is pointing to beginning of the byte message stream.

**Parameters:**

None

**Returns:**

A String object encapsulating the string that is read.

**Exceptions:**

- XMSEException
- MessageNotReadableException
- MessageEOFException

*Reset - Reset*

**Interface:**

```
void Reset();
```

Put the body of the message into read-only mode and reposition the cursor at the beginning of the bytes message stream.

**Parameters:**

None

**Returns:**

Void

**Exceptions:**

- XMSEException
- MessageNotReadableException

*WriteBoolean - Write Boolean Value*

**Interface:**

```
void WriteBoolean(Boolean value);
```

Write a boolean value to the bytes message stream.

**Parameters:****value (input)**

The boolean value to be written.

**Returns:**

Void

**Exceptions:**

- XMSEException
- MessageNotWritableException

*WriteByte - Write Byte*

**Interface:**

```
void WriteByte(Byte value);  
void WriteSignedByte(Int16 value);
```

Write a byte to the bytes message stream.

**Parameters:****value (input)**

The byte to be written.

**Returns:**

Void

**Exceptions:**

- XMSEException
- MessageNotWritableException

*WriteBytes - Write Bytes*

**Interface:**

```
void WriteBytes(Byte[] value);
```

Write an array of bytes to the bytes message stream.

**Parameters:****value (input)**

The array of bytes to be written.

**Returns:**

Void

**Exceptions:**

- XMSEException
- MessageNotWritableException

*WriteBytes - Write Partial Bytes Array*

**Interface:**

```
void WriteBytes(Byte[] value, int offset, int length);
```

Write a partial array of bytes to the bytes message stream, as defined by the specified length.

**Parameters:****value (input)**

The array of bytes to be written.

**offset (input)**

The starting point for the array of bytes to be written.

**length (input)**

The number of bytes to write.

**Returns:**

Void

**Exceptions:**

- XMSEException
- MessageNotWritableException

*WriteChar - Write Character*

**Interface:**

```
void WriteChar(Char value);
```

Write a character to the bytes message stream as 2 bytes, high-order byte first.

**Parameters:****value (input)**

The character to be written.

**Returns:**

Void

**Exceptions:**

- XMSEException
- MessageNotWritableException

*WriteDouble - Write Double Precision Floating Point Number*

**Interface:**

```
void WriteDouble(Double value);
```

Convert a double precision floating point number to a long integer and write the long integer to the bytes message stream as 8 bytes, high-order byte first.

**Parameters:****value (input)**

The double precision floating point number to be written.

**Returns:**

Void

**Exceptions:**

- XMSEException
- MessageNotWritableException

*WriteFloat - Write Floating Point Number*

**Interface:**

```
void WriteFloat(Single value);
```

Convert a floating point number to an integer and write the integer to the bytes message stream as 4 bytes, high-order byte first.

**Parameters:****value (input)**

The floating point number to be written.

**Returns:**

Void

**Exceptions:**

- XMSEException
- MessageNotWritableException

*WriteInt - Write Integer*

**Interface:**

```
void WriteInt(Int32 value);
```

Write an integer to the bytes message stream as 4 bytes, high-order byte first.

**Parameters:****value (input)**

The integer to be written.

**Returns:**

Void

**Exceptions:**

- XMSEException
- MessageNotWritableException

*WriteLong - Write Long Integer*

**Interface:**

```
void WriteLong(Int64 value);
```

Write a long integer to the bytes message stream as 8 bytes, high-order byte first.

**Parameters:****value (input)**

The long integer to be written.

**Returns:**

Void

**Exceptions:**

- XMSEException
- MessageNotWritableException

*WriteObject - Write Object*

**Interface:**

```
void WriteObject(Object value);
```

Write the specified object into the byte message stream.

**Parameters:****value (input)**

The object to be written, which must be a reference to a primitive type.

**Returns:**

Void

**Exceptions:**

- XMSEException
- MessageNotWritableException

*WriteShort - Write Short Integer*

**Interface:**

```
void WriteShort(Int16 value);
```

Write a short integer to the bytes message stream as 2 bytes, high-order byte first.

**Parameters:****value (input)**

The short integer to be written.

**Returns:**

Void

**Exceptions:**

- XMSEException
- MessageNotWritableException

*WriteUTF - Write UTF String*

**Interface:**

```
void WriteUTF(String value);
```

Write a string, encoded in UTF-8, to the bytes message stream.

**Parameters:****value (input)**

A String object encapsulating the string to be written.

**Returns:**

Void

**Exceptions:**

- XMSEException
- MessageNotWritableException

***Inherited properties and methods***

The following properties are inherited from the IMessage interface:

JMSCorrelationID, JMSDeliveryMode, JMSDestination, JMSExpiration, JMSMessageID, JMSPriority, JMSRedelivered, JMSReplyTo, JMSTimestamp, JMSType, Properties

The following methods are inherited from the IMessage interface:

clearBody, clearProperties, PropertyExists

The following methods are inherited from the IPropertyContext interface:

GetBooleanProperty, GetByteProperty, GetBytesProperty, GetCharProperty, GetDoubleProperty, GetFloatProperty, GetIntProperty, GetLongProperty, GetObjectProperty, GetShortProperty, GetStringProperty, SetBooleanProperty, SetByteProperty, SetBytesProperty, SetCharProperty,

[SetDoubleProperty](#), [SetFloatProperty](#), [SetIntProperty](#), [SetLongProperty](#), [SetObjectProperty](#), [SetShortProperty](#), [SetStringProperty](#)

## ICConnection

A Connection object represents the active connection of the application to a messaging server.

### Inheritance hierarchy:

```
IBM.XMS.IPropertyContext
|
+----IBM.XMS.ICConnection
```

For a list of the XMS defined properties of a Connection object, see [“Properties of Connection”](#) on page 2030.

### .NET properties

*ClientID - Get and Set Client ID*

#### Interface:

```
String ClientID
{
    get;
    set;
}
```

Get and set the client identifier for the connection.

The client identifier can either be preconfigured by the administrator in a ConnectionFactory, or assigned by setting ClientID.

A client identifier is used only to support durable subscriptions in the publish/subscribe domain, and is ignored in the point-to-point domain.

If an application sets a client identifier for a connection, the application must do so immediately after creating the connection, and before performing any other operation on the connection. If the application tries to set a client identifier after this point, the call throws exception `IllegalStateException`.

This property is not valid for a real-time connection to a broker.

#### Exceptions:

- `XMSEException`
- `IllegalStateException`
- `InvalidClientIDException`

*ExceptionListener - Get and Set Exception Listener*

#### Interface:

```
ExceptionListener ExceptionListener
{
    get;
    set;
}
```

Get the exception listener that is registered with the connection, and register an exception listener with the connection.

If no exception listener is registered with the connection, the method returns null. If an exception listener is already registered with the connection, you can cancel the registration by specifying a null instead of the exception listener.

For more information about using exception listeners, see [Using message and exception listeners in .NET](#).

**Exceptions:**

- XMSEException

*Metadata - Get Metadata*

**Interface:**

```
IConnectionMetaData Metadata
{
    get;
}
```

Get the metadata for the connection.

**Exceptions:**

- XMSEException

**Methods**

*Close - Close Connection*

**Interface:**

```
void Close();
```

Close the connection.

If an application tries to close a connection that is already closed, the call is ignored.

**Parameters:**

None

**Returns:**

Void

**Exceptions:**

- XMSEException

*CreateSession - Create Session*

**Interface:**

```
ISession CreateSession(Boolean transacted,
                        AcknowledgeMode acknowledgeMode);
```

Create a session.

**Parameters:**

**transacted (input)**

The value `True` means that the session is transacted. The value `False` means that the session is not transacted.

For a real-time connection to a broker, the value must be `False`.

**acknowledgeMode (input)**

Indicates that how messages received by an application are acknowledged. The value must be one of the following from the `AcknowledgeMode` enumerator:

- `AcknowledgeMode.AutoAcknowledge`
- `AcknowledgeMode.ClientAcknowledge`

AcknowledgeMode.DupsOkAcknowledge

For a real-time connection to a broker, the value must be AcknowledgeMode.AutoAcknowledge or AcknowledgeMode.DupsOkAcknowledge

This parameter is ignored if the session is transacted. For more information about acknowledgment modes, see [Message acknowledgment](#).

**Returns:**

The Session object

**Exceptions:**

- XMSEException

*Start - Start Connection*

**Interface:**

```
void Start();
```

Start or restart the delivery of incoming messages for the connection. The call is ignored if the connection is already started.

**Parameters:**

None

**Returns:**

Void

**Exceptions:**

- XMSEException

*Stop - Stop Connection*

**Interface:**

```
void Stop();
```

Stop the delivery of incoming messages for the connection. The call is ignored if the connection is already stopped.

**Parameters:**

None

**Returns:**

Void

**Exceptions:**

- XMSEException

***Inherited properties and methods***

The following methods are inherited from the [IPropertyContext](#) interface:

[GetBooleanProperty](#), [GetByteProperty](#), [GetBytesProperty](#), [GetCharProperty](#), [GetDoubleProperty](#), [GetFloatProperty](#), [GetIntProperty](#), [GetLongProperty](#), [GetObjectProperty](#), [GetShortProperty](#), [GetStringProperty](#), [SetBooleanProperty](#), [SetByteProperty](#), [SetBytesProperty](#), [SetCharProperty](#), [SetDoubleProperty](#), [SetFloatProperty](#), [SetIntProperty](#), [SetLongProperty](#), [SetObjectProperty](#), [SetShortProperty](#), [SetStringProperty](#)

## IConnectionFactory

An application uses a connection factory to create a connection.

### Inheritance hierarchy:

```
IBM.XMS.IPropertyContext
|
+----IBM.XMS.IConnectionFactory
```

For a list of the XMS defined properties of a ConnectionFactory object, see [“Properties of ConnectionFactory”](#) on page 2030.

### Methods

*CreateConnection - Create Connection Factory (using the default user identity)*

#### Interface:

```
IConnectionFactory CreateConnection();
```

Create a connection factory with the default properties.

If you are connecting to IBM MQ and XMSC\_USERID is not set, then the queue manager uses the userID of the logged on user by default. If you require further connection-level authentication of individual users you can write a client authentication exit which is configured in IBM MQ.

#### Parameters:

None

#### Exceptions:

- XMSEException

*CreateConnection - Create Connection (using a specified user identity)*

#### Interface:

```
IConnectionFactory CreateConnection(String userId, String password);
```

Create a connection using a specified user identity.

If you are connecting to IBM MQ and XMSC\_USERID is not set, then the queue manager uses the userID of the logged on user by default. If you require further connection-level authentication of individual users you can write a client authentication exit which is configured in IBM MQ.

The connection is created in stopped mode. No messages are delivered until the application calls **Connection.start()**.

#### Parameters:

##### **userId (input)**

A String object encapsulating the user identifier to be used to authenticate the application. If you provide a null, an attempt is made to create the connection without authentication.

##### **password (input)**

A String object encapsulating the password to be used to authenticate the application. If you provide a null, an attempt is made to create the connection without authentication.

#### Returns:

The Connection object.

#### Exceptions:

- XMSEException

- XMS\_X\_SECURITY\_EXCEPTION

### ***Inherited properties and methods***

The following methods are inherited from the [IPropertyContext](#) interface:

[GetBooleanProperty](#), [GetByteProperty](#), [GetBytesProperty](#), [GetCharProperty](#), [GetDoubleProperty](#), [GetFloatProperty](#), [GetIntProperty](#), [GetLongProperty](#), [GetObjectProperty](#), [GetShortProperty](#), [GetStringProperty](#), [SetBooleanProperty](#), [SetByteProperty](#), [SetBytesProperty](#), [SetCharProperty](#), [SetDoubleProperty](#), [SetFloatProperty](#), [SetIntProperty](#), [SetLongProperty](#), [SetObjectProperty](#), [SetShortProperty](#), [SetStringProperty](#)

## **IConnectionMetaData**

A ConnectionMetaData object provides information about a connection.

### **Inheritance hierarchy:**

```
IBM.XMS.IPropertyContext
|
+---- IBM.XMS.IConnectionMetaData
```

For a list of the XMS defined properties of a ConnectionMetaData object, see [“Properties of ConnectionMetaData”](#) on page 2035.

### ***.NET properties***

*JMSXPropertyNames* - *Get JMS Defined Message Properties*

#### **Interface:**

```
System.Collections.IEnumerator JMSXPropertyNames
{
    get;
}
```

Return an enumeration of the names of the JMS defined message properties supported by the connection.

JMS defined message properties are not supported by a real-time connection to a broker.

#### **Exceptions:**

- XMSException

### ***Inherited properties and methods***

The following methods are inherited from the [IPropertyContext](#) interface:

[GetBooleanProperty](#), [GetByteProperty](#), [GetBytesProperty](#), [GetCharProperty](#), [GetDoubleProperty](#), [GetFloatProperty](#), [GetIntProperty](#), [GetLongProperty](#), [GetObjectProperty](#), [GetShortProperty](#), [GetStringProperty](#), [SetBooleanProperty](#), [SetByteProperty](#), [SetBytesProperty](#), [SetCharProperty](#), [SetDoubleProperty](#), [SetFloatProperty](#), [SetIntProperty](#), [SetLongProperty](#), [SetObjectProperty](#), [SetShortProperty](#), [SetStringProperty](#)

## **IDestination**

A destination is where an application sends messages, or it is a source from which an application receives messages, or both.

### **Inheritance hierarchy:**

```
IBM.XMS.IPropertyContext
```

```
|
+----IBM.XMS.IDestination
```

For a list of the XMS defined properties of a Destination object, see [“Properties of Destination”](#) on page 2035.

## **.NET properties**

*Name - Get Destination Name*

### **Interface:**

```
String Name
{
    get;
}
```

Get the name of the destination. The name is a string encapsulating either the name of a queue or the name of a topic.

### **Exceptions:**

- XMSEException

*TypeId - Get Destination Type*

### **Interface:**

```
DestinationType TypeId
{
    get;
}
```

Get the type of the destination. The type of the destination is one of the following values:

```
DestinationType.Queue
DestinationType.Topic
```

### **Exceptions:**

- XMSEException

## **Inherited properties and methods**

The following methods are inherited from the [IPropertyContext](#) interface:

[GetBooleanProperty](#), [GetByteProperty](#), [GetBytesProperty](#), [GetCharProperty](#), [GetDoubleProperty](#), [GetFloatProperty](#), [GetIntProperty](#), [GetLongProperty](#), [GetObjectProperty](#), [GetShortProperty](#), [GetStringProperty](#), [SetBooleanProperty](#), [SetByteProperty](#), [SetBytesProperty](#), [SetCharProperty](#), [SetDoubleProperty](#), [SetFloatProperty](#), [SetIntProperty](#), [SetLongProperty](#), [SetObjectProperty](#), [SetShortProperty](#), [SetStringProperty](#)

## **ExceptionListener**

An application uses an exception listener to be notified asynchronously of a problem with a connection.

### **Inheritance hierarchy:**

None

If an application uses a connection only to consume messages asynchronously, and for no other purpose, then the only way the application can learn about a problem with the connection is by using an exception listener. In other situations, an exception listener can provide a more immediate way of learning about a problem with a connection than waiting until the next synchronous call to XMS.

## Delegate

*ExceptionListener - Exception Listener*

### Interface:

```
public delegate void ExceptionListener(Exception ex)
```

Notify the application of a problem with a connection.

Methods that implement this delegate can be registered with the connection.

For more information about using exception listeners, see [Using message and exception listeners in .NET](#).

### Parameters:

#### exception (input)

A pointer to an exception created by XMS.

### Returns:

Void

## IllegalStateException

XMS throws this exception if an application calls a method at an incorrect or inappropriate time, or if XMS is not in an appropriate state for the requested operation.

### Inheritance hierarchy:

```
IBM.XMS.XMSEException
|
+----IBM.XMS.Exception
|
+----IBM.XMS.IllegalStateException
```

### Inherited properties and methods

The following methods are inherited from the [XMSEException](#) interface:

[GetErrorCode](#), [GetLinkedException](#)

## InitialContext

An application uses an InitialContext object to create objects from object definitions that are retrieved from a repository of administered objects.

### Inheritance hierarchy:

None

### .NET properties

*Environment - Get the environment*

### Interface:

```
Hashtable Environment
{
    get;
}
```

Get the environment.

**Exceptions:**

- Exceptions are specific to the directory service being used.

**Constructors**

*InitialContext - Create Initial Context*

**Interface:**

```
InitialContext(Hashtable env);
```

Create an InitialContext object.

**Parameters:**

The information required to establish a connection to the repository of administered objects is provided to the constructor in an environment Hashtable.

**Exceptions:**

- XMSEException

**Methods**

*AddToEnvironment - Add a New Property to the Environment*

**Interface:**

```
Object AddToEnvironment(String propName, Object propVal);
```

Add a new property to the environment.

**Parameters:****propName (input)**

A String object encapsulating the name of the property to be added.

**propVal (input)**

The value of the property to be added.

**Returns:**

The old value of the property.

**Exceptions:**

- Exceptions are specific to the directory service being used.

*Close - Close this context*

**Interface:**

```
void Close()
```

Close this context.

**Parameters:**

None

**Returns:**

None

**Exceptions:**

- Exceptions are specific to the directory service being used.

*Lookup - Look Up Object in Initial Context*

**Interface:**

```
Object Lookup(String name);
```

Create an object from an object definition that is retrieved from the repository of administered objects.

**Parameters:**

**name (input)**

A String object encapsulating the name of the administered object to be retrieved. The name can be either a simple name or a complex name. For further details, see [Retrieval of administered objects](#).

**Returns:**

Either an IConnectionFactory or an IDestination, depending on the type of object being retrieved. If the function can access the directory, but cannot find the required object, a null is returned.

**Exceptions:**

- Exceptions are specific to the directory service being used.

*RemoveFromEnvironment - Remove a Property from the Environment*

**Interface:**

```
Object RemoveFromEnvironment(String propName);
```

Remove a property from the environment.

**Parameters:**

**propName (input)**

A String object encapsulating the name of the property to be removed.

**Returns:**

The object that was removed.

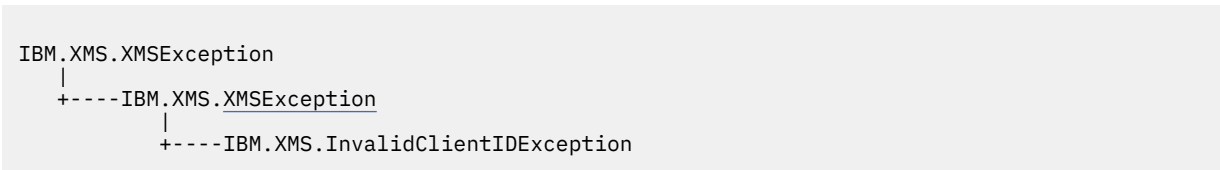

**Exceptions:**

- Exceptions are specific to the directory service being used.

### **InvalidClientIDException**

XMS throws this exception if an application attempts to set a client identifier for a connection, but the client identifier is not valid or is already in use.

**Inheritance hierarchy:**

### ***Inherited properties and methods***

The following methods are inherited from the [XMSEException](#) interface:

[GetErrorCode](#), [GetLinkedException](#)

## InvalidDestinationException

XMS throws this exception if an application specifies a destination that is not valid.

### Inheritance hierarchy:

```
IBM.XMS.XMSEException
|
+----IBM.XMS.XMSEException
|
+----IBM.XMS.InvalidDestinationException
```

### Inherited properties and methods

The following methods are inherited from the [XMSEException](#) interface:

[GetErrorCode](#), [GetLinkedException](#)

## InvalidSelectorException

XMS throws this exception if an application provides a message selector expression whose syntax is not valid.

### Inheritance hierarchy:

```
IBM.XMS.XMSEException
|
+----IBM.XMS.XMSEException
|
+----IBM.XMS.InvalidSelectorException
```

### Inherited properties and methods

The following methods are inherited from the [XMSEException](#) interface:

[GetErrorCode](#), [GetLinkedException](#)

## IMapMessage

A map message is a message whose body comprises a set of name-value pairs, where each value has an associated data type.

### Inheritance hierarchy:

```
IBM.XMS.IPropertyContext
|
+----IBM.XMS.IMessage
|
+----IBM.XMS.IMapMessage
```

When an application gets the value of name-value pair, the value can be converted by XMS into another data type. For more information about this form of implicit conversion, see the information about map messages in [The body of an XMS message](#).

### .NET properties

*MapNames* - Get Map Names

#### Interface:

```
System.Collections.IEnumerator MapNames
{
    get;
}
```

Get an enumeration of the names in the body of the map message.

**Exceptions:**

- XMSEException

**Methods**

*GetBoolean - Get Boolean Value*

**Interface:**

```
Boolean GetBoolean(String name);
```

Get the boolean value identified by name from the body of the map message.

**Parameters:**

**name (input)**

A String object encapsulating the name that identifies the boolean value.

**Returns:**

The boolean value retrieved from the body of the map message.

**Exceptions:**

- XMSEException

*GetByte - Get Byte*

**Interface:**

```
Byte    GetByte(String name);  
Int16   GetSignedByte(String name);
```

Get the byte identified by name from the body of the map message.

**Parameters:**

**name (input)**

A String object encapsulating the name that identifies the byte.

**Returns:**

The byte retrieved from the body of the map message. No data conversion is performed on the byte.

**Exceptions:**

- XMSEException

*GetBytes - Get Bytes*

**Interface:**

```
Byte[]  GetBytes(String name);
```

Get the array of bytes identified by name from the body of the map message.

**Parameters:**

**name (input)**

A String object encapsulating the name that identifies the array of bytes.

**Returns:**

The number of bytes in the array.

**Exceptions:**

- XMSEException

### *GetChar - Get Character*

#### **Interface:**

```
Char    GetChar(String name);
```

Get the character identified by name from the body of the map message.

#### **Parameters:**

##### **name (input)**

A String object encapsulating the name that identifies the character.

#### **Returns:**

The character retrieved from the body of the map message.

#### **Exceptions:**

- XMSEException

### *GetDouble - Get Double Precision Floating Point Number*

#### **Interface:**

```
Double  GetDouble(String name);
```

Get the double precision floating point number identified by name from the body of the map message.

#### **Parameters:**

##### **name (input)**

A String object encapsulating the name that identifies the double precision floating point number.

#### **Returns:**

The double precision floating point number retrieved from the body of the map message.

#### **Exceptions:**

- XMSEException

### *GetFloat - Get Floating Point Number*

#### **Interface:**

```
Single  GetFloat(String name);
```

Get the floating point number identified by name from the body of the map message.

#### **Parameters:**

##### **name (input)**

A String object encapsulating the name that identifies the floating point number.

#### **Returns:**

The floating point number retrieved from the body of the map message.

#### **Exceptions:**

- XMSEException

### *GetInt - Get Integer*

#### **Interface:**

```
Int32   GetInt(String name);
```

Get the integer identified by name from the body of the map message.

**Parameters:****name (input)**

A String object encapsulating the name that identifies the integer.

**Returns:**

The integer retrieved from the body of the map message.

**Exceptions:**

- XMSEException

*GetLong - Get Long Integer*

**Interface:**

```
Int64 GetLong(String name);
```

Get the long integer identified by name from the body of the map message.

**Parameters:****name (input)**

A String object encapsulating the name that identifies the long integer.

**Returns:**

The long integer retrieved from the body of the map message.

**Exceptions:**

- XMSEException

*GetObject - Get Object*

**Interface:**

```
Object GetObject(String name);
```

Get a reference to the value of a name-value pair, from the body of the map message. The name-value pair is identified by name.

**Parameters:****name (input)**

A String object encapsulating the name of the name-value pair.

**Returns:**

The value, which is one of the following object types:

- Boolean
- Byte
- Byte[]
- Char
- Double
- Single
- Int32
- Int64
- Int16
- String

**Exceptions:**

- XMSEException

### *GetShort - Get Short Integer*

#### **Interface:**

```
Int16 GetShort(String name);
```

Get the short integer identified by name from the body of the map message.

#### **Parameters:**

##### **name (input)**

A String object encapsulating the name that identifies the short integer.

#### **Returns:**

The short integer retrieved from the body of the map message.

#### **Exceptions:**

- XMSEException

### *GetString - Get String*

#### **Interface:**

```
String GetString(String name);
```

Get the string identified by name from the body of the map message.

#### **Parameters:**

##### **name (input)**

A String object encapsulating the name that identifies the string in the body of the map message.

#### **Returns:**

A String object encapsulating the string retrieved from the body of the map message. If data conversion is required, this value is the string after conversion.

#### **Exceptions:**

- XMSEException

### *ItemExists - Check Name-Value Pair Exists*

#### **Interface:**

```
Boolean ItemExists(String name);
```

Check whether the body of the map message contains a name-value pair with the specified name.

#### **Parameters:**

##### **name (input)**

A String object encapsulating the name of the name-value pair.

#### **Returns:**

- True, if the body of the map message contains a name-value pair with the specified name.
- False, if the body of the map message does not contain a name-value pair with the specified name.

#### **Exceptions:**

- XMSEException

## *SetBoolean - Set Boolean Value*

### **Interface:**

```
void SetBoolean(String name, Boolean value);
```

Set a boolean value in the body of the map message.

### **Parameters:**

#### **name (input)**

A String object encapsulating the name to identify the boolean value in the body of the map message.

#### **value (input)**

The boolean value to be set.

### **Returns:**

Void

### **Exceptions:**

- XMSEException

## *SetByte - Set Byte*

### **Interface:**

```
void SetByte(String name, Byte value);  
void SetSignedByte(String name, Int16 value);
```

Set a byte in the body of the map message.

### **Parameters:**

#### **name (input)**

A String object encapsulating the name to identify the byte in the body of the map message.

#### **value (input)**

The byte to be set.

### **Returns:**

Void

### **Exceptions:**

- XMSEException

## *SetBytes - Set Bytes*

### **Interface:**

```
void SetBytes(String name, Byte[] value);
```

Set an array of bytes in the body of the map message.

### **Parameters:**

#### **name (input)**

A String object encapsulating the name to identify the array of bytes in the body of the map message.

#### **value (input)**

The array of bytes to be set.

### **Returns:**

Void

**Exceptions:**

- XMSEException

*SetChar - Set Character*

**Interface:**

```
void SetChar(String name, Char value);
```

Set a 2-byte character in the body of the map message.

**Parameters:****name (input)**

A String object encapsulating the name to identify the character in the body of the map message.

**value (input)**

The character to be set.

**Returns:**

Void

**Exceptions:**

- XMSEException

*SetDouble - Set Double Precision Floating Point Number*

**Interface:**

```
void SetDouble(String name, Double value);
```

Set a double precision floating point number in the body of the map message.

**Parameters:****name (input)**

A String object encapsulating the name to identify the double precision floating point number in the body of the map message.

**value (input)**

The double precision floating point number to be set.

**Returns:**

Void

**Exceptions:**

- XMSEException

*SetFloat - Set Floating Point Number*

**Interface:**

```
void SetFloat(String name, Single value);
```

Set a floating point number in the body of the map message.

**Parameters:****name (input)**

A String object encapsulating the name to identify the floating point number in the body of the map message.

**value (input)**

The floating point number to be set.

**Returns:**

Void

**Exceptions:**

- XMSEException

*SetInt - Set Integer*

**Interface:**

```
void SetInt(String name, Int32 value);
```

Set an integer in the body of the map message.

**Parameters:****name (input)**

A String object encapsulating the name to identify the integer in the body of the map message.

**value (input)**

The integer to be set.

**Returns:**

Void

**Exceptions:**

- XMSEException

*SetLong - Set Long Integer*

**Interface:**

```
void SetLong(String name, Int64 value);
```

Set a long integer in the body of the map message.

**Parameters:****name (input)**

A String object encapsulating the name to identify the long integer in the body of the map message.

**value (input)**

The long integer to be set.

**Returns:**

Void

**Exceptions:**

- XMSEException

*SetObject - Set Object*

**Interface:**

```
void SetObject(String name, Object value);
```

Set a value, which must be an XMS primitive type, in the body of the map message.

**Parameters:****name (input)**

A String object encapsulating the name to identify the value in the body of the map message.

**value (input)**

An array of bytes containing the value to be set.

**Returns:**

Void

**Exceptions:**

- XMSEException

*SetShort - Set Short Integer*

**Interface:**

```
void SetShort(String name, Int16 value);
```

Set a short integer in the body of the map message.

**Parameters:****name (input)**

A String object encapsulating the name to identify the short integer in the body of the map message.

**value (input)**

The short integer to be set.

**Returns:**

Void

**Exceptions:**

- XMSEException

*SetString - Set String*

**Interface:**

```
void SetString(String name, String value);
```

Set a string in the body of the map message.

**Parameters:****name (input)**

A String object encapsulating the name to identify the string in the body of the map message.

**value (input)**

A String object encapsulating the string to be set.

**Returns:**

Void

**Exceptions:**

- XMSEException

***Inherited properties and methods***

The following properties are inherited from the [IMessage](#) interface:

[JMSCorrelationID](#), [JMSDeliveryMode](#), [JMSDestination](#), [JMSExpiration](#), [JMSMessageID](#), [JMSPriority](#), [JMSRedelivered](#), [JMSReplyTo](#), [JMSTimestamp](#), [JMSType](#), [Properties](#)

The following methods are inherited from the [IMessage](#) interface:

[clearBody](#), [clearProperties](#), [PropertyExists](#)

The following methods are inherited from the [IPropertyContext](#) interface:

[GetBooleanProperty](#), [GetByteProperty](#), [GetBytesProperty](#), [GetCharProperty](#), [GetDoubleProperty](#), [GetFloatProperty](#), [GetIntProperty](#), [GetLongProperty](#), [GetObjectProperty](#), [GetShortProperty](#), [GetStringProperty](#), [SetBooleanProperty](#), [SetByteProperty](#), [SetBytesProperty](#), [SetCharProperty](#), [SetDoubleProperty](#), [SetFloatProperty](#), [SetIntProperty](#), [SetLongProperty](#), [SetObjectProperty](#), [SetShortProperty](#), [SetStringProperty](#)

## IMessage

A Message object represents a message that an application sends or receives. IMessage is a superclass for the message classes such as IMapMessage.

### Inheritance hierarchy:

```
IBM.XMS.IPropertyContext
|
+----IBM.XMS.IMessage
```

For a list of the JMS message header fields in a Message object, see [Header fields of an XMS message](#). For a list of the JMS defined properties of a Message object, see [JMS-defined properties of a message](#). For a list of the IBM defined properties of a Message object, see [IBM-defined properties of a message](#). For a list of JMS\_IBM\_MQMD\* properties for the Message object, see [“JMS\\_IBM\\_MQMD\\* properties” on page 2039](#)

Messages are deleted by the garbage collector. When a message is deleted, this frees the resources it was using.

### .NET properties

*GetJMSCorrelationID - Get and Set JMSCorrelationID*

#### Interface:

```
String JMSCorrelationID
{
    get;
    set;
}
```

Get and set the correlation identifier of the message as a String object.

#### Exceptions:

- XMSEException

*JMSDeliveryMode - Get and Set JMSDeliveryMode*

#### Interface:

```
DeliveryMode JMSDeliveryMode
{
    get;
    set;
}
```

Get and set the delivery mode of the message.

The delivery mode of the message is one of the following values:

```
DeliveryMode.Persistent
DeliveryMode.NonPersistent
```

For a newly created message that was not sent, the delivery mode is `DeliveryMode.Persistent`, except for a real-time connection to a broker for which the delivery mode is `DeliveryMode.NonPersistent`. For a message that is received, the method returns the delivery mode

that was set by the `IMessageProducer.send()` call when the message was sent unless the receiving application changes the delivery mode by setting `JMSDeliveryMode`.

**Exceptions:**

- `XMSEException`

*JMSDestination - Get and Set JMSDestination*

**Interface:**

```
IDestination JMSDestination
{
    get;
    set;
}
```

Get and set the destination of the message.

The destination is set by the `IMessageProducer.send()` call when the message is sent. The value of `JMSDestination` is ignored. However, you can use `JMSDestination` to change the destination of a message that was received.

For a newly created message that was not sent, the method returns a null `Destination` object, unless the sending application sets a destination by setting `JMSDestination`. For a message that was received, the method returns a `Destination` object for the destination that was set by the `IMessageProducer.send()` call when the message was sent unless the receiving application changes the destination by setting `JMSDestination`.

**Exceptions:**

- `XMSEException`

*JMSEExpiration - Get and Set JMSEExpiration*

**Interface:**

```
Int64 JMSEExpiration
{
    get;
    set;
}
```

Get and set the expiration time of the message.

The expiration time is set by the `IMessageProducer.send()` call when the message is sent. Its value is calculated by adding the time to live, as specified by the sending application, to the time when the message is sent. The expiration time is expressed in milliseconds since 00:00:00 GMT on the 1 January 1970.

For a newly created message that was not sent, the expiration time is 0 unless the sending application sets a different expiration time by setting `JMSEExpiration`. For a message that was received, the method returns the expiration time that was set by the `IMessageProducer.send()` call when the message was sent unless the receiving application changes the expiration time by setting `JMSEExpiration`.

If the time to live is 0, the `IMessageProducer.send()` call sets the expiration time to 0 to indicate that the message does not expire.

XMS discards expired messages and does not deliver them to applications.

**Exceptions:**

- `XMSEException`

## *JMSMessageID - Get and Set JMSMessageID*

### **Interface:**

```
String JMSMessageID
{
    get;
    set;
}
```

Get and set the message identifier of the message as a string object encapsulating the message identifier.

The message identifier is set by the `IMessageProducer.send()` call when the message is sent. For a message that was received, the method returns the message identifier that was set by the `IMessageProducer.send()` call when the message was sent unless the receiving application changes the message identifier by setting `JMSMessageID`.

If the message has no message identifier, the method returns a null.

### **Exceptions:**

- `XMSEException`

## *JMSPriority - Get and Set JMSPriority*

### **Interface:**

```
Int32 JMSPriority
{
    get;
    set;
}
```

Get and set the priority of the message.

The priority is set by the `IMessageProducer.send()` call when the message is sent. The value is an integer in the range 0, the lowest priority, to 9, the highest priority.

For a newly created message that was not sent, the priority is 4 unless the sending application sets a different priority by setting `JMSPriority`. For a message that was received, the method returns the priority that was set by the `IMessageProducer.send()` call when the message was sent unless the receiving application changes the priority by setting `JMSPriority`.

### **Exceptions:**

- `XMSEException`

## *JMSRedelivered - Get and Set JMSRedelivered*

### **Interface:**

```
Boolean JMSRedelivered
{
    get;
    set;
}
```

Get an indication of whether the message is being redelivered, and indicate whether the message is being redelivered. The indication is set by the `IMessageConsumer.receive()` call when the message is received.

This property has the following values:

- `True`, if the message is being redelivered.
- `False`, if the message is not being redelivered.

For a real-time connection to a broker, the value is always `False`.

An indication of redelivery set by `JMSRedelivered` before the message is sent is ignored by the `IMessageProducer.send()` call when the message is sent, and is ignored and replaced by the `IMessageConsumer.receive()` call when the message is received. However, you can use `JMSRedelivered` to change the indication for a message that was received.

**Exceptions:**

- `XMSEException`

*JMSReplyTo - Get and Set JMSReplyTo*

**Interface:**

```
IDestination JMSReplyTo
{
    get;
    set;
}
```

Get and set the destination where a reply to the message is to be sent.

The value of this property is a `Destination` object for the destination where a reply to the message is to be sent. A null `Destination` object means that no reply is expected.

**Exceptions:**

- `XMSEException`

*JMSTimestamp - Get and Set JMSTimestamp*

**Interface:**

```
Int64 JMSTimestamp
{
    get;
    set;
}
```

Get and set the time when the message was sent.

The time stamp is set by the `IMessageProducer.send()` call when the message is sent and is expressed in milliseconds since 00:00:00 GMT on the 1 January 1970.

For a newly created message that was not sent, the time stamp is 0 unless the sending application sets a different time stamp by setting `JMSTimestamp`. For a message that was received, the method returns the time stamp that was set by the `IMessageProducer.send()` call when the message was sent unless the receiving application changes the time stamp by setting `JMSTimestamp`.

**Exceptions:**

- `XMSEException`

**Notes:**

1. If the time stamp is undefined, the method returns 0 but throws no exception.

*JMSType - Get and Set JMSType*

**Interface:**

```
String JMSType
{
    get;
    set;
}
```

Get and set the type of the message.

The value of JMSType is a string encapsulating the type of the message. If data conversion is required, this value is the type after conversion.

**Exceptions:**

- XMSEException

*PropertyNames - Get Properties*

**Interface:**

```
System.Collections.IEnumerator PropertyNames
{
    get;
}
```

Get an enumeration of the names properties of the message.

**Exceptions:**

- XMSEException

**Methods**

*Acknowledge - Acknowledge*

**Interface:**

```
void Acknowledge();
```

Acknowledge this message and all previously unacknowledged messages received by the session.

An application can call this method if the acknowledgment mode of the session is AcknowledgeMode.ClientAcknowledge. Calls to the method are ignored if the session has any other acknowledgment mode or is transacted.

Messages that were received but not acknowledged might be redelivered.

For more information about acknowledging messages, see [../develop/xms\\_cmesack.dita#xms\\_cmesack](#).

**Parameters:**

None

**Returns:**

Void

**Exceptions:**

- XMSEException
- IllegalStateException

*ClearBody - Clear Body*

**Interface:**

```
void ClearBody();
```

Clear the body of the message. The header fields and message properties are not cleared.

If an application clears a message body, the body remains in the same state as an empty body in a newly created message. The state of an empty body in a newly created message depends on the type of message body. For more information, see [The body of an XMS message](#).

An application can clear a message body at any time, no matter what state the body is in. If a message body is read-only, the only way that an application can write to the body is for the application to clear the body first.

**Parameters:**

None

**Returns:**

Void

**Exceptions:**

- XMSEException

*ClearProperties - Clear Properties*

**Interface:**

```
void ClearProperties();
```

Clear the properties of the message. The header fields and the message body are not cleared.

If an application clears the properties of a message, the properties become readable and writable.

An application can clear the properties of a message at any time, no matter what state the properties are in. If the properties of a message are read-only, the only way that the properties can become writable is for the application to clear the properties first.

**Parameters:**

None

**Returns:**

Void

**Exceptions:**

- XMSEException

*PropertyExists - Check Property Exists*

**Interface:**

```
Boolean PropertyExists(String propertyName);
```

Check whether the message has a property with the specified name.

**Parameters:**

**propertyName (input)**

A String object encapsulating the name of the property.

**Returns:**

- True, if the message has a property with the specified name.
- False, if the message does not have a property with the specified name.

**Exceptions:**

- XMSEException

***Inherited properties and methods***

The following methods are inherited from the [IPropertyContext](#) interface:

[GetBooleanProperty](#), [GetByteProperty](#), [GetBytesProperty](#), [GetCharProperty](#), [GetDoubleProperty](#), [GetFloatProperty](#), [GetIntProperty](#), [GetLongProperty](#), [GetObjectProperty](#), [GetShortProperty](#), [GetStringProperty](#), [SetBooleanProperty](#), [SetByteProperty](#), [SetBytesProperty](#), [SetCharProperty](#),

[SetDoubleProperty](#), [SetFloatProperty](#), [SetIntProperty](#), [SetLongProperty](#), [SetObjectProperty](#), [SetShortProperty](#), [SetStringProperty](#)

## IMessageConsumer

An application uses a message consumer to receive messages sent to a destination.

### Inheritance hierarchy:

```
IBM.XMS.IPropertyContext
|
+---- IBM.XMS.IMessageConsumer
```

For a list of the XMS defined properties of a MessageConsumer object, see [“Properties of MessageConsumer”](#) on page 2042.

## .NET properties

*MessageListener - Get and Set Message Listener*

### Interface:

```
MessageListener MessageListener
{
    get;
    set;
}
```

Get the message listener that is registered with the message consumer, and register a message listener with the message consumer.

If no message listener is registered with the message consumer, MessageListener is null. If a message listener is already registered with the message consumer, you can cancel the registration by specifying a null instead.

For more information about using message listeners, see [Using message and exception listeners in .NET](#).

### Exceptions:

- XMSEException

*MessageSelector - Get Message Selector*

### Interface:

```
String MessageSelector
{
    get;
}
```

Get the message selector for the message consumer. The return value is a String object encapsulating the message selector expression. If data conversion is required, this value is the message selector expression after conversion. If the message consumer does not have a message selector, the value of MessageSelector is a null String object.

### Exceptions:

- XMSEException

## Methods

## Close - Close Message Consumer

### Interface:

```
void Close();
```

Close the message consumer.

If an application tries to close a message consumer that is already closed, the call is ignored.

### Parameters:

None

### Returns:

Void

### Exceptions:

- XMSEException

## Receive - Receive

### Interface:

```
IMessage Receive();
```

Receive the next message for the message consumer. The call waits indefinitely for a message, or until the message consumer is closed.

### Parameters:

None

### Returns:

A pointer to the Message object. If the message consumer is closed while the call is waiting for a message, the method returns a pointer to a null Message object.

### Exceptions:

- XMSEException

## Receive - Receive (with a wait interval)

### Interface:

```
IMessage Receive(Int64 delay);
```

Receive the next message for the message consumer. The call waits only a specified period for a message, or until the message consumer is closed.

### Parameters:

#### **delay (input)**

The time, in milliseconds, that the call waits for a message. If you specify a wait interval of 0, the call waits indefinitely for a message.

### Returns:

A pointer to the Message object. If no message arrives during the wait interval, or if the message consumer is closed while the call is waiting for a message, the method returns a pointer to a null Message object but throws no exception.

### Exceptions:

- XMSEException

*ReceiveNoWait - Receive with No Wait*

**Interface:**

```
IMessage ReceiveNoWait();
```

Receive the next message for the message consumer if one is available immediately.

**Parameters:**

None

**Returns:**

A pointer to a Message object. If no message is available immediately, the method returns a pointer to a null Message object.

**Exceptions:**

- XMSEException

***Inherited properties and methods***

The following methods are inherited from the IPROPERTYContext interface:

GetBooleanProperty, GetByteProperty, GetBytesProperty, GetCharProperty, GetDoubleProperty, GetFloatProperty, GetIntProperty, GetLongProperty, GetObjectProperty, GetShortProperty, GetStringProperty, SetBooleanProperty, SetByteProperty, SetBytesProperty, SetCharProperty, SetDoubleProperty, SetFloatProperty, SetIntProperty, SetLongProperty, SetObjectProperty, SetShortProperty, SetStringProperty

**MessageEOFException**

XMS throws this exception if XMS encounters the end of a bytes message stream when an application is reading the body of a bytes message.

**Inheritance hierarchy:**

```
IBM.XMS.XMSEException
|
+----IBM.XMS.XMSEException
|
+----IBM.XMS.MessageEOFException
```

***Inherited properties and methods***

The following methods are inherited from the XMSEException interface:

GetErrorCode, GetLinkedException

**MessageFormatException**

XMS throws this exception if XMS encounters a message with a format that is not valid.

**Inheritance hierarchy:**

```
IBM.XMS.XMSEException
|
+----IBM.XMS.XMSEException
|
+----IBM.XMS.MessageFormatException
```

***Inherited properties and methods***

The following methods are inherited from the XMSEException interface:

GetErrorCode, GetLinkedException

## IMessageListener (delegate)

An application uses a message listener to receive messages asynchronously.

### Inheritance hierarchy:

None

### Delegate

*MessageListener - Message Listener*

### Interface:

```
public delegate void MessageListener(IMessage msg);
```

Deliver a message asynchronously to the message consumer.

Methods that implement this delegate can be registered with the connection.

For more information about using message listeners, see [Using message and exception listeners in .NET](#).

### Parameters:

#### **mesg (input)**

The Message object.

### Returns:

Void

## MessageNotReadableException

XMS throws this exception if an application attempts to read the body of a message that is write only.

### Inheritance hierarchy:

```
IBM.XMS.XMSEException
|
+----IBM.XMS.XMSEException
|
+----IBM.XMS.MessageNotReadableException
```

### *Inherited properties and methods*

The following methods are inherited from the [XMSEException](#) interface:

[GetErrorCode](#), [GetLinkedException](#)

## MessageNotWritableException

XMS throws this exception if an application attempts to write to the body of a message that is read-only.

### Inheritance hierarchy:

```
IBM.XMS.XMSEException
|
+----IBM.XMS.XMSEException
|
+----IBM.XMS.MessageNotWritableException
```

### *Inherited properties and methods*

The following methods are inherited from the [XMSEException](#) interface:

[GetErrorCode](#), [GetLinkedException](#)

## IMessageProducer

An application uses a message producer to send messages to a destination.

### Inheritance hierarchy:

```
IBM.XMS.IPropertyContext
|
+----IBM.XMS.IMessageProducer
```

For a list of the XMS defined properties of a MessageProducer object, see [“Properties of MessageProducer”](#) on page 2042.

### .NET properties

*DeliveryMode - Get and Set Default Delivery Mode*

#### Interface:

```
DeliveryMode DeliveryMode
{
    get;
    set;
}
```

Get and set the default delivery mode for messages sent by the message producer.

The default delivery mode has one of the following values:

```
DeliveryMode.Persistent
DeliveryMode.NonPersistent
```

For a real-time connection to a broker, the value must be `DeliveryMode.NonPersistent`.

The default value is `DeliveryMode.Persistent`, except for a real-time connection to a broker for which the default value is `DeliveryMode.NonPersistent`.

#### Exceptions:

- `XMSEException`

*Destination - Get Destination*

#### Interface:

```
IDestination Destination
{
    get;
}
```

Get the destination for the message producer.

#### Parameters:

None

#### Returns:

The `Destination` object. If the message producer does not have a destination, the method returns a null `Destination` object.

#### Exceptions:

- `XMSEException`

## *DisableMsgID - Get and Set Disable Message ID Flag*

### **Interface:**

```
Boolean DisableMessageID
{
    get;
    set;
}
```

Get an indication of whether a receiving application requires message identifiers to be included in messages sent by the message producer, and indicate whether a receiving application requires message identifiers to be included in messages sent by the message producer.

On a connection to a queue manager, or on a real-time connection to a broker, this flag is ignored. On a connection to a service integration bus, the flag is honored.

DisableMsgID has the following values:

- `True`, if a receiving application does not require message identifiers to be included in messages sent by the message producer.
- `False`, if a receiving application does require message identifiers to be included in messages sent by the message producer.

### **Exceptions:**

- `XMSEException`

## *DisableMsgTS - Get and Set Disable Time Stamp Flag*

### **Interface:**

```
Boolean DisableMessageTimestamp
{
    get;
    set;
}
```

Get an indication of whether a receiving application requires time stamps to be included in messages sent by the message producer, and indicate whether a receiving application requires time stamps to be included in messages sent by the message producer.

On a real-time connection to a broker, this flag is ignored. On a connection to a queue manager, or on a connection to a service integration bus, the flag is honored.

DisableMsgTS has the following values:

- `True`, if a receiving application does not require time stamps to be included in messages sent by the message producer.
- `False`, if a receiving application does require time stamps to be included in messages sent by the message producer.

### **Returns:**

### **Exceptions:**

- `XMSEException`

## *Priority - Get and Set Default Priority*

### **Interface:**

```
Int32 Priority
{
    get;
}
```

```
    set;
}
```

Get and set the default priority for messages sent by the message producer.

The value of the default message priority is an integer in the range 0, the lowest priority, to 9, the highest priority.

On a real-time connection to a broker, the priority of a message is ignored.

**Exceptions:**

- XMSEException

*TimeToLive - Get and Set Default Time to Live*

**Interface:**

```
Int64 TimeToLive
{
    get;
    set;
}
```

Get and set the default length of time that a message exists before it expires.

The time is measured from when the message producer sends the message and is the default time to live in milliseconds. A value of 0 means that a message never expires.

For a real-time connection to a broker, this value is always 0.

**Exceptions:**

- XMSEException

**Methods**

*Close - Close Message Producer*

**Interface:**

```
void Close();
```

Close the message producer.

If an application tries to close a message producer that is already closed, the call is ignored.

**Parameters:**

None

**Returns:**

Void

**Exceptions:**

- XMSEException

*Send - Send*

**Interface:**

```
void Send(IMessage msg) ;
```

Send a message to the destination that was specified when the message producer was created. Send the message using the message producer default delivery mode, priority, and time to live.

**Parameters:****msg (input)**

The Message object.

**Returns:**

Void

**Exceptions:**

- XMSEException
- MessageFormatException
- InvalidDestinationException

*Send - Send (specifying a delivery mode, priority, and time to live)*

**Interface:**

```
void Send(IMessage msg,
         DeliveryMode deliveryMode,
         Int32 priority,
         Int64 timeToLive);
```

Send a message to the destination that was specified when the message producer was created. Send the message using the specified delivery mode, priority, and time to live.

**Parameters:****msg (input)**

The Message object.

**deliveryMode (input)**

The delivery mode for the message, which must be one of the following values:

DeliveryMode.Persistent  
DeliveryMode.NonPersistent

For a real-time connection to a broker, the value must be DeliveryMode.NonPersistent.

**priority (input)**

The priority of the message. The value can be an integer in the range 0, for the lowest priority, to 9, for the highest priority. On a real-time connection to a broker, the value is ignored.

**timeToLive (input)**

The time to live for the message in milliseconds. A value of 0 means that the message never expires. For a real-time connection to a broker, the value must be 0.

**Returns:**

Void

**Exceptions:**

- XMSEException
- MessageFormatException
- InvalidDestinationException
- IllegalStateException

*Send - Send (to a specified destination)*

**Interface:**

```
void Send(IDestination dest, IMessage msg) ;
```

Send a message to a specified destination if you are using a message producer for which no destination was specified when the message producer was created. Send the message using the message producer default delivery mode, priority, and time to live.

Typically, you specify a destination when you create a message producer but, if you do not, you must specify a destination every time you send a message.

**Parameters:**

**dest (input)**

The Destination object.

**msg (input)**

The Message object.

**Returns:**

Void

**Exceptions:**

- XMSEException
- MessageFormatException
- InvalidDestinationException

*Send - Send (to a specified destination, specifying a delivery mode, priority, and time to live)*

**Interface:**

```
void Send(IDestination dest,
          IMessage msg,
          DeliveryMode deliveryMode,
          Int32 priority,
          Int64 timeToLive) ;
```

Send a message to a specified destination if you are using a message producer for which no destination was specified when the message producer was created. Send the message using the specified delivery mode, priority, and time to live.

Typically, you specify a destination when you create a message producer but, if you do not, you must specify a destination every time you send a message.

**Parameters:**

**dest (input)**

The Destination object.

**msg (input)**

The Message object.

**deliveryMode (input)**

The delivery mode for the message, which must be one of the following values:

DeliveryMode.Persistent  
DeliveryMode.NonPersistent

For a real-time connection to a broker, the value must be `DeliveryMode.NonPersistent`.

**priority (input)**

The priority of the message. The value can be an integer in the range 0, for the lowest priority, to 9, for the highest priority. On a real-time connection to a broker, the value is ignored.

**timeToLive (input)**

The time to live for the message in milliseconds. A value of 0 means that the message never expires. For a real-time connection to a broker, the value must be 0.

**Returns:**

Void

### Exceptions:

- XMSEException
- MessageFormatException
- InvalidDestinationException
- IllegalStateException

### ***Inherited properties and methods***

The following methods are inherited from the [IPropertyContext](#) interface:

[GetBooleanProperty](#), [GetByteProperty](#), [GetBytesProperty](#), [GetCharProperty](#), [GetDoubleProperty](#), [GetFloatProperty](#), [GetIntProperty](#), [GetLongProperty](#), [GetObjectProperty](#), [GetShortProperty](#), [GetStringProperty](#), [SetBooleanProperty](#), [SetByteProperty](#), [SetBytesProperty](#), [SetCharProperty](#), [SetDoubleProperty](#), [SetFloatProperty](#), [SetIntProperty](#), [SetLongProperty](#), [SetObjectProperty](#), [SetShortProperty](#), [SetStringProperty](#)

## **IObjectMessage**

An object message is a message whose body comprises a serialized Java or .NET object.

### Inheritance hierarchy:

```
IBM.XMS.IPropertyContext
|
+---- IBM.XMS.IMessage
      |
      +---- IBM.XMS.IObjectMessage
```

### ***.NET properties***

*Object - Get and Set Object as Bytes*

### Interface:

```
System.Object Object
{
    get;
    set;
}

Byte[] GetObject();
```

Get and set the object that forms the body of the object message.

### Exceptions:

- XMSEException
- MessageNotReadableException
- MessageEOFException
- MessageNotWritableException

### ***Inherited properties and methods***

The following properties are inherited from the [IMessage](#) interface:

[JMSCorrelationID](#), [JMSDeliveryMode](#), [JMSDestination](#), [JMSExpiration](#), [JMSPriority](#), [JMSPriority](#), [JMSRedelivered](#), [JMSReplyTo](#), [JMSTimestamp](#), [JMSType](#), [Properties](#)

The following methods are inherited from the [IMessage](#) interface:

[clearBody](#), [clearProperties](#), [PropertyExists](#)

The following methods are inherited from the `IPropertyContext` interface:

[GetBooleanProperty](#), [GetByteProperty](#), [GetBytesProperty](#), [GetCharProperty](#), [GetDoubleProperty](#), [GetFloatProperty](#), [GetIntProperty](#), [GetLongProperty](#), [GetObjectProperty](#), [GetShortProperty](#), [GetStringProperty](#), [SetBooleanProperty](#), [SetByteProperty](#), [SetBytesProperty](#), [SetCharProperty](#), [SetDoubleProperty](#), [SetFloatProperty](#), [SetIntProperty](#), [SetLongProperty](#), [SetObjectProperty](#), [SetShortProperty](#), [SetStringProperty](#)

## IPropertyContext

`IPropertyContext` is an abstract superclass that contains methods that get and set properties. These methods are inherited by other classes.

### Inheritance hierarchy:

None

### Methods

*GetBooleanProperty - Get Boolean Property*

#### Interface:

```
Boolean GetBooleanProperty(String property_name);
```

Get the value of the boolean property with the specified name.

#### Parameters:

**property\_name (input)**

A `String` object encapsulating the name of the property.

#### Returns:

The value of the property.

#### Thread context:

Determined by the subclass

#### Exceptions:

- `XMSEException`

*GetByteProperty - Get Byte Property*

#### Interface:

```
Byte    GetByteProperty(String property_name) ;  
Int16   GetSignedByteProperty(String property_name) ;
```

Get the value of the byte property identified by name.

#### Parameters:

**property\_name (input)**

A `String` object encapsulating the name of the property.

#### Returns:

The value of the property.

#### Thread context:

Determined by the subclass

#### Exceptions:

- `XMSEException`

### *GetBytesProperty - Get Byte Array Property*

#### **Interface:**

```
Byte[] GetBytesProperty(String property_name) ;
```

Get the value of the byte array property identified by name.

#### **Parameters:**

##### **property\_name (input)**

A String object encapsulating the name of the property.

#### **Returns:**

The number of bytes in the array.

#### **Thread context:**

Determined by the subclass

#### **Exceptions:**

- XMSEException

### *GetCharProperty - Get Character Property*

#### **Interface:**

```
Char GetCharProperty(String property_name) ;
```

Get the value of the 2-byte character property identified by name.

#### **Parameters:**

##### **property\_name (input)**

A String object encapsulating the name of the property.

#### **Returns:**

The value of the property.

#### **Thread context:**

Determined by the subclass

#### **Exceptions:**

- XMSEException

### *GetDoubleProperty - Get Double Precision Floating Point Property*

#### **Interface:**

```
Double GetDoubleProperty(String property_name) ;
```

Get the value of the double precision floating point property identified by name.

#### **Parameters:**

##### **property\_name (input)**

A String object encapsulating the name of the property.

#### **Returns:**

The value of the property.

#### **Thread context:**

Determined by the subclass

#### **Exceptions:**

- XMSEException

### *GetFloatProperty - Get Floating Point Property*

#### **Interface:**

```
Single GetFloatProperty(String property_name) ;
```

Get the value of the floating point property identified by name.

#### **Parameters:**

##### **property\_name (input)**

A String object encapsulating the name of the property.

#### **Returns:**

The value of the property.

#### **Thread context:**

Determined by the subclass

#### **Exceptions:**

- XMSEException

### *GetIntProperty - GetIntProperty*

#### **Interface:**

```
Int32 GetIntProperty(String property_name) ;
```

Get the value of the integer property identified by name.

#### **Parameters:**

##### **property\_name (input)**

A String object encapsulating the name of the property.

#### **Returns:**

The value of the property.

#### **Thread context:**

Determined by the subclass

#### **Exceptions:**

- XMSEException

### *GetLongProperty - Get Long Integer Property*

#### **Interface:**

```
Int64 GetLongProperty(String property_name) ;
```

Get the value of the long integer property identified by name.

#### **Parameters:**

##### **property\_name (input)**

A String object encapsulating the name of the property.

#### **Returns:**

The value of the property.

#### **Thread context:**

Determined by the subclass

#### **Exceptions:**

- XMSEException

## *GetObjectProperty - Get Object Property*

### **Interface:**

```
Object GetObjectProperty( String property_name) ;
```

Get the value and data type of the property identified by name.

### **Parameters:**

#### **property\_name (input)**

A String object encapsulating the name of the property.

### **Returns:**

The value of the property, which is one of the following object types:

- Boolean
- Byte
- Byte[]
- Char
- Double
- Single
- Int32
- Int64
- Int16
- String

### **Thread context:**

Determined by the subclass

### **Exceptions:**

- XMSEException

## *GetShortProperty - Get Short Integer Property*

### **Interface:**

```
Int16 GetShortProperty(String property_name) ;
```

Get the value of the short integer property identified by name.

### **Parameters:**

#### **property\_name (input)**

A String object encapsulating the name of the property.

### **Returns:**

The value of the property.

### **Thread context:**

Determined by the subclass

### **Exceptions:**

- XMSEException

## *GetStringProperty - GetStringProperty*

### **Interface:**

```
String GetStringProperty(String property_name) ;
```

Get the value of the string property identified by name.

**Parameters:****property\_name (input)**

A String object encapsulating the name of the property.

**Returns:**

A String object encapsulating the string that is the value of the property. If data conversion is required, this value is the string after conversion.

**Thread context:**

Determined by the subclass

**Exceptions:**

- XMSEException

*SetBooleanProperty - Set Boolean Property*

**Interface:**

```
void SetBooleanProperty( String property_name, Boolean value) ;
```

Set the value of the boolean property identified by name.

**Parameters:****property\_name (input)**

A String object encapsulating the name of the property.

**value (input)**

The value of the property.

**Returns:**

Void

**Thread context:**

Determined by the subclass

**Exceptions:**

- XMSEException
- MessageNotWritableException

*SetByteProperty - Set Byte Property*

**Interface:**

```
void SetByteProperty( String property_name, Byte value) ;  
void SetSignedByteProperty( String property_name, Int16 value) ;
```

Set the value of the byte property identified by name.

**Parameters:****property\_name (input)**

A String object encapsulating the name of the property.

**value (input)**

The value of the property.

**Returns:**

Void

**Thread context:**

Determined by the subclass

**Exceptions:**

- XMSEException

- MessageNotWritableException

#### *SetBytesProperty - Set Byte Array Property*

##### **Interface:**

```
void SetBytesProperty( String property_name, Byte[] value ) ;
```

Set the value of the byte array property identified by name.

##### **Parameters:**

###### **property\_name (input)**

A String object encapsulating the name of the property.

###### **value (input)**

The value of the property, which is an array of bytes.

##### **Returns:**

Void

##### **Thread context:**

Determined by the subclass

##### **Exceptions:**

- XMSEException
- MessageNotWritableException

#### *SetCharProperty - Set Character Property*

##### **Interface:**

```
void SetCharProperty( String property_name, Char value) ;
```

Set the value of the 2-byte character property identified by name.

##### **Parameters:**

###### **property\_name (input)**

A String object encapsulating the name of the property.

###### **value (input)**

The value of the property.

##### **Returns:**

Void

##### **Thread context:**

Determined by the subclass

##### **Exceptions:**

- XMSEException
- MessageNotWritableException

#### *SetDoubleProperty - Set Double Precision Floating Point Property*

##### **Interface:**

```
void SetDoubleProperty( String property_name, Double value) ;
```

Set the value of the double precision floating point property identified by name.

**Parameters:****property\_name (input)**

A String object encapsulating the name of the property.

**value (input)**

The value of the property.

**Returns:**

Void

**Thread context:**

Determined by the subclass

**Exceptions:**

- XMSEException
- MessageNotWritableException

*SetFloatProperty - Set Floating Point Property*

**Interface:**

```
void SetFloatProperty( String property_name, Single value) ;
```

Set the value of the floating point property identified by name.

**Parameters:****property\_name (input)**

A String object encapsulating the name of the property.

**value (input)**

The value of the property.

**Returns:**

Void

**Thread context:**

Determined by the subclass

**Exceptions:**

- XMSEException
- MessageNotWritableException

*SetIntProperty - Set Integer Property*

**Interface:**

```
void SetIntProperty( String property_name, Int32 value) ;
```

Set the value of the integer property identified by name.

**Parameters:****property\_name (input)**

A String object encapsulating the name of the property.

**value (input)**

The value of the property.

**Returns:**

Void

**Thread context:**

Determined by the subclass

**Exceptions:**

- XMSEException
- MessageNotWritableException

*SetLongProperty - Set Long Integer Property*

**Interface:**

```
void SetLongProperty( String property_name, Int64 value) ;
```

Set the value of the long integer property identified by name.

**Parameters:****property\_name (input)**

A String object encapsulating the name of the property.

**value (input)**

The value of the property.

**Returns:**

Void

**Thread context:**

Determined by the subclass

**Exceptions:**

- XMSEException
- MessageNotWritableException

*SetObjectProperty - Set Object Property*

**Interface:**

```
void SetObjectProperty( String property_name, Object value) ;
```

Set the value and data type of a property identified by name.

**Parameters:****property\_name (input)**

A String object encapsulating the name of the property.

**objectType (input)**

The value of the property, which must be one of the following object types:

Boolean  
Byte  
Byte[]  
Char  
Double  
Single  
Int32  
Int64  
Int16  
String

**value (input)**

The value of the property as an array of bytes.

**length (input)**

The number of bytes in the array.

**Returns:**

Void

**Thread context:**

Determined by the subclass

**Exceptions:**

- XMSEException
- MessageNotWritableException

*SetShortProperty - Set Short Integer Property*

**Interface:**

```
void SetShortProperty( String property_name, Int16 value) ;
```

Set the value of the short integer property identified by name.

**Parameters:****property\_name (input)**

A String object encapsulating the name of the property.

**value (input)**

The value of the property.

**Returns:**

Void

**Thread context:**

Determined by the subclass

**Exceptions:**

- XMSEException
- MessageNotWritableException

*SetStringProperty - Set String Property*

**Interface:**

```
void SetStringProperty( String property_name, String value);
```

Set the value of the string property identified by name.

**Parameters:****property\_name (input)**

A String object encapsulating the name of the property.

**value (input)**

A String object encapsulating the string that is the value of the property.

**Returns:**

Void

**Thread context:**

Determined by the subclass

**Exceptions:**

- XMSEException
- MessageNotWritableException

## IQueueBrowser

An application uses a queue browser to browse messages on a queue without removing them.

### Inheritance hierarchy:

```
IBM.XMS.IPropertyContext
System.Collections.IEnumerable
|
+----IBM.XMS.IQueueBrowser
```

### .NET properties

*MessageSelector* - Get Message Selector

#### Interface:

```
String MessageSelector
{
    get;
}
```

Get the message selector for the queue browser.

The message selector is a String object encapsulating the message selector expression. If data conversion is required, this value is the message selector expression after conversion. If the queue browser does not have a message selector, the method returns a null String object.

#### Exceptions:

- XMSEException

*Queue* - Get Queue

#### Interface:

```
IDestination Queue
{
    get;
}
```

Get the queue associated with the queue browser as a destination object representing the queue.

#### Exceptions:

- XMSEException

### Methods

*Close* - Close Queue Browser

#### Interface:

```
void Close();
```

Close the queue browser.

If an application tries to close a queue browser that is already closed, the call is ignored.

#### Parameters:

None

#### Returns:

Void

**Exceptions:**

- XMSEException

*GetEnumerator - Get Messages*

**Interface:**

```
IEnumerator GetEnumerator();
```

Get a list of the messages on the queue.

The method returns an enumerator that encapsulates a list of Message objects. The order of the Message objects is the same as the order in which the messages would be retrieved from the queue. The application can then use the enumerator to browse each message in turn.

The enumerator is updated dynamically as messages are put on the queue and removed from the queue. Each time the application calls `IEnumerator.MoveNext()` to browse the next message on the queue, the message reflects the current contents of the queue.

If an application calls this method more than once for a queue browser, each call returns a new enumerator. The application can therefore use more than one enumerator to browse the messages on a queue and maintain multiple positions within the queue.

**Parameters:**

None

**Returns:**

The Iterator object.

**Exceptions:**

- XMSEException

***Inherited properties and methods***

The following methods are inherited from the [IPropertyContext](#) interface:

[GetBooleanProperty](#), [GetByteProperty](#), [GetBytesProperty](#), [GetCharProperty](#), [GetDoubleProperty](#), [GetFloatProperty](#), [GetIntProperty](#), [GetLongProperty](#), [GetObjectProperty](#), [GetShortProperty](#), [GetStringProperty](#), [SetBooleanProperty](#), [SetByteProperty](#), [SetBytesProperty](#), [SetCharProperty](#), [SetDoubleProperty](#), [SetFloatProperty](#), [SetIntProperty](#), [SetLongProperty](#), [SetObjectProperty](#), [SetShortProperty](#), [SetStringProperty](#)

**Requestor**

An application uses a requestor to send a request message and then wait for, and receive, the reply.

**Inheritance hierarchy:**

None

***Constructors***

*Requestor - Create Requestor*

**Interface:**

```
Requestor(ISession sess, IDestination dest);
```

Create a requestor.

**Parameters:****sess (input)**

A Session object. The session must not be transacted and must have one of the following acknowledgment modes:

`AcknowledgeMode.AutoAcknowledge`

`AcknowledgeMode.DupsOkAcknowledge`

**dest (input)**

A Destination object representing the destination where the application can send request messages.

**Thread context:**

The session associated with the requestor

**Exceptions:**

- `XMSEException`

**Methods**

*Close - Close Requestor*

**Interface:**

```
void Close();
```

Close the requestor.

If an application tries to close a requestor that is already closed, the call is ignored.

**Note:** When an application closes a requestor, the associated session does not close as well. In this respect, XMS behaves differently compared to JMS.

**Parameters:**

None

**Returns:**

Void

**Thread context:**

Any

**Exceptions:**

- `XMSEException`

*Request - Request Response*

**Interface:**

```
IMessage Request(IMessage requestMessage);
```

Send a request message and then wait for, and receive, a reply from the application that receives the request message.

A call to this method blocks until a reply is received or until the session ends, whichever is the sooner.

**Parameters:****requestMessage (input)**

The Message object encapsulating the request message.

**Returns:**

A pointer to the Message object encapsulating the reply message.

**Thread context:**

The session associated with the requestor

**Exceptions:**

- XMSEException

**ResourceAllocationException**

XMS throws this exception if XMS cannot allocate the resources required by a method.

**Inheritance hierarchy:**

```

IBM.XMS.XMSEException
|
+----IBM.XMS.XMSEException
      |
      +----IBM.XMS.ResourceAllocationException
  
```

***Inherited properties and methods***

The following methods are inherited from the [XMSEException](#) interface:

[GetErrorCode](#), [GetLinkedException](#)

**SecurityException**

XMS throws this exception if the user identifier and password provided to authenticate an application are rejected. XMS also throws this exception if an authority check fails and prevents a method from completing.

**Inheritance hierarchy:**

```

IBM.XMS.XMSEException
|
+----IBM.XMS.XMSEException
      |
      +----IBM.XMS.SecurityException
  
```

***Inherited properties and methods***

The following methods are inherited from the [XMSEException](#) interface:

[GetErrorCode](#), [GetLinkedException](#)

**ISession**

A session is a single threaded context for sending and receiving messages.

**Inheritance hierarchy:**

```

IBM.XMS.IPropertyContext
|
+----IBM.XMS.ISession
  
```

For a list of the XMS defined properties of a Session object, see [“Properties of Session” on page 2042](#).

***.NET properties***

*AcknowledgeMode* - *Get Acknowledgement Mode*

**Interface:**

```

AcknowledgeMode AcknowledgeMode
  
```

```
{
    get;
}
```

Get the acknowledgment mode for the session.

The acknowledgment mode is specified when the session is created.

Provided the session is not transacted, the acknowledgment mode is one of the following values:

```
AcknowledgeMode.AutoAcknowledge
AcknowledgeMode.ClientAcknowledge
AcknowledgeMode.DupsOkAcknowledge
```

For more information about acknowledgment modes, see [Message acknowledgment](#).

A session that is transacted has no acknowledgment mode. If the session is transacted, the method returns `AcknowledgeMode.SessionTransacted` instead.

**Exceptions:**

- `XMSEException`

*Transacted - Determine Whether Transacted*

**Interface:**

```
Boolean Transacted
{
    get;
}
```

Determine whether the session is transacted.

The transacted stated is:

- True, if the session is transacted.
- False, if the session is not transacted.

For a real-time connection to a broker, the method always returns `False`.

**Exceptions:**

- `XMSEException`

**Methods**

*Close - Close Session*

**Interface:**

```
void Close();
```

Close the session. If the session is transacted, any transaction in progress is rolled back.

If an application tries to close a session that is already closed, the call is ignored.

**Parameters:**

None

**Returns:**

Void

**Thread context:**

Any

**Exceptions:**

- XMSEException

*Commit - Commit*

**Interface:**

```
void Commit();
```

Commit all messages processed in the current transaction.

The session must be a transacted session.

**Parameters:**

None

**Returns:**

Void

**Exceptions:**

- XMSEException
- IllegalStateException
- TransactionRolledBackException

*CreateBrowser - Create Queue Browser*

**Interface:**

```
IQueueBrowser CreateBrowser(IDestination queue) ;
```

Create a queue browser for the specified queue.

**Parameters:****queue (input)**

A Destination object representing the queue.

**Returns:**

The QueueBrowser object.

**Exceptions:**

- XMSEException
- InvalidDestinationException

*CreateBrowser - Create Queue Browser (with message selector)*

**Interface:**

```
IQueueBrowser CreateBrowser(IDestination queue, String selector) ;
```

Create a queue browser for the specified queue using a message selector.

**Parameters:****queue (input)**

A Destination object representing the queue.

**selector (input)**

A String object encapsulating a message selector expression. Only those messages with properties that match the message selector expression are delivered to the queue browser.

A null String object means that there is no message selector for the queue browser.

**Returns:**

The QueueBrowser object.

**Exceptions:**

- XMSEException
- InvalidDestinationException
- InvalidSelectorException

*CreateBytesMessage - Create Bytes Message*

**Interface:**

```
IBytesMessage CreateBytesMessage();
```

Create a bytes message.

**Parameters:**

None

**Returns:**

The BytesMessage object.

**Exceptions:**

- XMSEException
- IllegalStateException (The session is closed)

*CreateConsumer - Create Consumer*

**Interface:**

```
IMessageConsumer CreateConsumer(IDestination dest) ;
```

Create a message consumer for the specified destination.

**Parameters:****dest (input)**

The Destination object.

**Returns:**

The MessageConsumer object.

**Exceptions:**

- XMSEException
- InvalidDestinationException

*CreateConsumer - Create Consumer (with message selector)*

**Interface:**

```
IMessageConsumer CreateConsumer(IDestination dest,  
                                String selector) ;
```

Create a message consumer for the specified destination using a message selector.

**Parameters:****dest (input)**

The Destination object.

**selector (input)**

A String object encapsulating a message selector expression. Only those messages with properties that match the message selector expression are delivered to the message consumer.

A null String object means that there is no message selector for the message consumer.

**Returns:**

The MessageConsumer object.

**Exceptions:**

- XMSEException
- InvalidDestinationException
- InvalidSelectorException

*CreateConsumer - Create Consumer (with message selector and local message flag)*

**Interface:**

```
IMessageConsumer CreateConsumer(IDestination dest,  
                                String selector,  
                                Boolean noLocal) ;
```

Create a message consumer for the specified destination using a message selector and, if the destination is a topic, specifying whether the message consumer receives the messages published by its own connection.

**Parameters:**

**dest (input)**

The Destination object.

**selector (input)**

A String object encapsulating a message selector expression. Only those messages with properties that match the message selector expression are delivered to the message consumer.

A null String object means that there is no message selector for the message consumer.

**noLocal (input)**

The value True means that the message consumer does not receive the messages published by its own connection. The value False means that the message consumer does receive the messages published by its own connection. The default value is False.

**Returns:**

The MessageConsumer object.

**Exceptions:**

- XMSEException
- InvalidDestinationException
- InvalidSelectorException

*CreateDurableSubscriber - Create Durable Subscriber*

**Interface:**

```
IMessageConsumer CreateDurableSubscriber(IDestination dest,  
                                         String subscription) ;
```

Create a durable subscriber for the specified topic.

This method is not valid for a real-time connection to a broker.

For more information about durable subscribers, see [Durable subscribers](#).

**Parameters:**

**dest (input)**

A Destination object representing the topic. The topic must not be a temporary topic.

**subscription (input)**

A String object encapsulating a name that identifies the durable subscription. The name must be unique within the client identifier for the connection.

**Returns:**

The MessageConsumer object representing the durable subscriber.

**Exceptions:**

- XMSEException
- InvalidDestinationException

*CreateDurableSubscriber - Create Durable Subscriber (with message selector and local message flag)*

**Interface:**

```
IMessageConsumer CreateDurableSubscriber(IDestination dest,  
                                         String subscription,  
                                         String selector,  
                                         Boolean noLocal) ;
```

Create a durable subscriber for the specified topic using a message selector and specifying whether the durable subscriber receives the messages published by its own connection.

This method is not valid for a real-time connection to a broker.

For more information about durable subscribers, see [Durable subscribers](#).

**Parameters:****dest (input)**

A Destination object representing the topic. The topic must not be a temporary topic.

**subscription (input)**

A String object encapsulating a name that identifies the durable subscription. The name must be unique within the client identifier for the connection.

**selector (input)**

A String object encapsulating a message selector expression. Only those messages with properties that match the message selector expression are delivered to the durable subscriber.

A null String object means that there is no message selector for the durable subscriber.

**noLocal (input)**

The value True means that the durable subscriber does not receive the messages published by its own connection. The value False means that the durable subscriber does receive the messages published by its own connection. The default value is False.

**Returns:**

The MessageConsumer object representing the durable subscriber.

**Exceptions:**

- XMSEException
- InvalidDestinationException
- InvalidSelectorException

*CreateMapMessage - Create Map Message*

**Interface:**

```
IMapMessage CreateMapMessage();
```

Create a map message.

**Parameters:**

None

**Returns:**

The MapMessage object.

**Exceptions:**

- XMSEException
- IllegalStateException (The session is closed)

*CreateMessage - Create Message*

**Interface:**

```
IMessage CreateMessage();
```

Create a message that has no body.

**Parameters:**

None

**Returns:**

The Message object.

**Exceptions:**

- XMSEException
- IllegalStateException (The session is closed)

*CreateObjectMessage - Create Object Message*

**Interface:**

```
IObjectMessage CreateObjectMessage();
```

Create an object message.

**Parameters:**

None

**Returns:**

The ObjectMessage object.

**Exceptions:**

- XMSEException
- IllegalStateException (The session is closed)

*CreateProducer - Create Producer*

**Interface:**

```
IMessageProducer CreateProducer(IDestination dest) ;
```

Create a message producer to send messages to the specified destination.

**Parameters:****dest (input)**

The Destination object.

If you specify a null Destination object, the message producer is created without a destination. In this case, the application must specify a destination every time it uses the message producer to send a message.

**Returns:**

The MessageProducer object.

**Exceptions:**

- XMSEException
- InvalidDestinationException

*CreateQueue - Create Queue*

**Interface:**

```
IDestination CreateQueue(String queue) ;
```

Create a Destination object to represent a queue in the messaging server.

This method does not create the queue in the messaging server. You must create the queue before an application can call this method.

**Parameters:****queue (input)**

A String object encapsulating the name of the queue, or encapsulating a uniform resource identifier (URI) that identifies the queue.

**Returns:**

The Destination object representing the queue.

**Exceptions:**

- XMSEException

*CreateStreamMessage - Create Stream Message*

**Interface:**

```
IStreamMessage CreateStreamMessage();
```

Create a stream message.

**Parameters:**

None

**Returns:**

The StreamMessage object.

**Exceptions:**

- XMSEException
- XMS\_ILLEGAL\_STATE\_EXCEPTION

*CreateTemporaryQueue - Create Temporary Queue*

**Interface:**

```
IDestination CreateTemporaryQueue() ;
```

Create a temporary queue.

The scope of the temporary queue is the connection. Only the sessions created by the connection can use the temporary queue.

The temporary queue remains until it is explicitly deleted, or the connection ends, whichever is the sooner.

For more information about temporary queues, see [Temporary destinations](#).

**Parameters:**

None

**Returns:**

The Destination object representing the temporary queue.

**Exceptions:**

- XMSEException

*CreateTemporaryTopic - Create Temporary Topic*

**Interface:**

```
IDestination CreateTemporaryTopic() ;
```

Create a temporary topic.

The scope of the temporary topic is the connection. Only the sessions created by the connection can use the temporary topic.

The temporary topic remains until it is explicitly deleted, or the connection ends, whichever is the sooner.

For more information about temporary topics, see [Temporary destinations](#).

**Parameters:**

None

**Returns:**

The Destination object representing the temporary topic.

**Exceptions:**

- XMSEException

*CreateTextMessage - Create Text Message*

**Interface:**

```
ITextMessage CreateTextMessage();
```

Create a text message with an empty body.

**Parameters:**

None

**Returns:**

The TextMessage object.

**Exceptions:**

- XMSEException

*CreateTextMessage - Create Text Message (initialized)*

**Interface:**

```
ITextMessage CreateTextMessage(String initialValue);
```

Create a text message whose body is initialized with the specified text.

**Parameters:****initialValue (input)**

A String object encapsulating the text to initialize the body of the text message.

None

**Returns:**

The TextMessage object.

**Exceptions:**

- XMSEException

*CreateTopic - Create Topic*

**Interface:**

```
IDestination CreateTopic(String topic) ;
```

Create a Destination object to represent a topic.

**Parameters:****topic (input)**

A String object encapsulating the name of the topic, or encapsulating a uniform resource identifier (URI) that identifies the topic.

**Returns:**

The Destination object representing the topic.

**Exceptions:**

- XMSEException

*Recover - Recover*

**Interface:**

```
void Recover();
```

Recover the session. Message delivery is stopped and then restarted with the oldest unacknowledged message.

The session must not be a transacted session.

For more information about recovering a session, see [Message acknowledgment](#).

**Parameters:**

None

**Returns:**

Void

**Exceptions:**

- XMSEException
- IllegalStateException

*Rollback - Rollback*

**Interface:**

```
void Rollback();
```

Roll back all messages processed in the current transaction.

The session must be a transacted session.

**Parameters:**

None

**Returns:**

Void

**Exceptions:**

- XMSEException

- `IllegalStateException`

*Unsubscribe - Unsubscribe*

**Interface:**

```
void Unsubscribe(String subscription);
```

Delete a durable subscription. The messaging server deletes the record of the durable subscription that it is maintaining and does not send any more messages to the durable subscriber.

An application cannot delete a durable subscription in any of the following circumstances:

- While there is an active message consumer for the durable subscription
- While a consumed message is part of a pending transaction
- While a consumed message was not acknowledged

This method is not valid for a real-time connection to a broker.

**Parameters:**

**subscription (input)**

A String object encapsulating the name that identifies the durable subscription.

**Returns:**

Void

**Exceptions:**

- `XMSEException`
- `InvalidDestinationException`
- `IllegalStateException`

***Inherited properties and methods***

The following methods are inherited from the [IPropertyContext](#) interface:

[GetBooleanProperty](#), [GetByteProperty](#), [GetBytesProperty](#), [GetCharProperty](#), [GetDoubleProperty](#), [GetFloatProperty](#), [GetIntProperty](#), [GetLongProperty](#), [GetObjectProperty](#), [GetShortProperty](#), [GetStringProperty](#), [SetBooleanProperty](#), [SetByteProperty](#), [SetBytesProperty](#), [SetCharProperty](#), [SetDoubleProperty](#), [SetFloatProperty](#), [SetIntProperty](#), [SetLongProperty](#), [SetObjectProperty](#), [SetShortProperty](#), [SetStringProperty](#)

**IStreamMessage**

A stream message is a message whose body comprises a stream of values, where each value has an associated data type. The contents of the body are written and read sequentially.

**Inheritance hierarchy:**

When an application reads a value from the message stream, the value can be converted by XMS into another data type. For more information about this form of implicit conversion, see [The body of an XMS message](#).

**Methods**

## *ReadBoolean - Read Boolean Value*

### **Interface:**

```
Boolean ReadBoolean();
```

Read a boolean value from the message stream.

### **Parameters:**

None

### **Returns:**

The boolean value that is read.

### **Exceptions:**

- XMSEException
- MessageNotReadableException
- MessageEOFException

## *ReadByte - Read Byte*

### **Interface:**

```
Int16  ReadSignedByte();  
Byte   ReadByte();
```

Read a signed 8-bit integer from the message stream.

### **Parameters:**

None

### **Returns:**

The byte that is read.

### **Exceptions:**

- XMSEException
- MessageNotReadableException
- MessageEOFException

## *ReadBytes - Read Bytes*

### **Interface:**

```
Int32  ReadBytes(Byte[] array);
```

Read an array of bytes from the message stream.

### **Parameters:**

#### **array (input)**

The buffer containing the array of bytes that is read and the length of the buffer in bytes.

If the number of bytes in the array is less than or equal to the length of the buffer, the whole array is read into the buffer. If the number of bytes in the array is greater than the length of the buffer, the buffer is filled with part of the array, and an internal cursor marks the position of the next byte to be read. A subsequent call to `readBytes()` reads bytes from the array starting from the current position of the cursor.

If you specify a null pointer on input, the call skips over the array of bytes without reading it.

### **Returns:**

The number of bytes that are read into the buffer. If the buffer is partially filled, the value is less than the length of the buffer, indicating that there are no more bytes in the array remaining to

be read. If there are no bytes remaining to be read from the array before the call, the value is `XMSC_END_OF_BYTEARRAY`.

If you specify a null pointer on input, the method returns no value.

**Exceptions:**

- `XMSEException`
- `MessageNotReadableException`
- `MessageEOFException`

*ReadChar - Read Character*

**Interface:**

```
Char ReadChar();
```

Read a 2-byte character from the message stream.

**Parameters:**

None

**Returns:**

The character that is read.

**Exceptions:**

- `XMSEException`
- `MessageNotReadableException`
- `MessageEOFException`

*ReadDouble - Read Double Precision Floating Point Number*

**Interface:**

```
Double ReadDouble();
```

Read an 8-byte double precision floating point number from the message stream.

**Parameters:**

None

**Returns:**

The double precision floating point number that is read.

**Exceptions:**

- `XMSEException`
- `MessageNotReadableException`
- `MessageEOFException`

*ReadFloat - Read Floating Point Number*

**Interface:**

```
Single ReadFloat();
```

Read a 4-byte floating point number from the message stream.

**Parameters:**

None

**Returns:**

The floating point number that is read.

**Exceptions:**

- XMSEException
- MessageNotReadableException
- MessageEOFException

*ReadInt - Read Integer*

**Interface:**

```
Int32 ReadInt();
```

Read a signed 32-bit integer from the message stream.

**Parameters:**

None

**Returns:**

The integer that is read.

**Exceptions:**

- XMSEException
- MessageNotReadableException
- MessageEOFException

*ReadLong - Read Long Integer*

**Interface:**

```
Int64 ReadLong();
```

Read a signed 64-bit integer from the message stream.

**Parameters:**

None

**Returns:**

The long integer that is read.

**Exceptions:**

- XMSEException
- MessageNotReadableException
- MessageEOFException

*ReadObject - Read Object*

**Interface:**

```
Object ReadObject();
```

Read a value from the message stream, and return its data type.

**Parameters:**

None

**Returns:**

The value, which is one of the following object types:

Boolean  
Byte  
Byte[]

Char  
Double  
Single  
Int32  
Int64  
Int16  
String

**Exceptions:**

XMSEException

*ReadShort - Read Short Integer*

**Interface:**

```
Int16 ReadShort();
```

Read a signed 16-bit integer from the message stream.

**Parameters:**

None

**Returns:**

The short integer that is read.

**Exceptions:**

- XMSEException
- MessageNotReadableException
- MessageEOFException

*ReadString - Read String*

**Interface:**

```
String ReadString();
```

Read a string from the message stream. If required, XMS converts the characters in the string into the local code page.

**Parameters:**

None

**Returns:**

A String object encapsulating the string that is read. If data conversion is required, this is the string after conversion.

**Exceptions:**

- XMSEException
- MessageNotReadableException
- MessageEOFException

*Reset - Reset*

**Interface:**

```
void Reset();
```

Put the body of the message into read-only mode and reposition the cursor at the beginning of the message stream.

**Parameters:**

None

**Returns:**

Void

**Exceptions:**

- XMSEException
- MessageNotReadableException
- MessageEOFException

*WriteBoolean - Write Boolean Value*

**Interface:**

```
void WriteBoolean(Boolean value);
```

Write a boolean value to the message stream.

**Parameters:****value (input)**

The boolean value to be written.

**Returns:**

Void

**Exceptions:**

- XMSEException
- MessageNotWritableException

*WriteByte - Write Byte*

**Interface:**

```
void WriteByte(Byte value);  
void WriteSignedByte(Int16 value);
```

Write a byte to the message stream.

**Parameters:****value (input)**

The byte to be written.

**Returns:**

Void

**Exceptions:**

- XMSEException
- MessageNotWritableException

*WriteBytes - Write Bytes*

**Interface:**

```
void WriteBytes(Byte[] value);
```

Write an array of bytes to the message stream.

**Parameters:****value (input)**

The array of bytes to be written.

**length (input)**

The number of bytes in the array.

**Returns:**

Void

**Exceptions:**

- XMSEException
- MessageNotWritableException

*WriteChar - Write Character*

**Interface:**

```
void WriteChar(Char value);
```

Write a character to the message stream as 2 bytes, high-order byte first.

**Parameters:****value (input)**

The character to be written.

**Returns:**

Void

**Exceptions:**

- XMSEException
- MessageNotWritableException

*WriteDouble - Write Double Precision Floating Point Number*

**Interface:**

```
void WriteDouble(Double value);
```

Convert a double precision floating point number to a long integer and write the long integer to the message stream as 8 bytes, high-order byte first.

**Parameters:****value (input)**

The double precision floating point number to be written.

**Returns:**

Void

**Exceptions:**

- XMSEException
- MessageNotWritableException

*WriteFloat - Write Floating Point Number*

**Interface:**

```
void WriteFloat(Single value);
```

Convert a floating point number to an integer and write the integer to the message stream as 4 bytes, high-order byte first.

**Parameters:**

**value (input)**

The floating point number to be written.

**Returns:**

Void

**Exceptions:**

- XMSEException
- MessageNotWritableException

*WriteInt - Write Integer*

**Interface:**

```
void WriteInt(Int32 value);
```

Write an integer to the message stream as 4 bytes, high-order byte first.

**Parameters:**

**value (input)**

The integer to be written.

**Returns:**

Void

**Exceptions:**

- XMSEException
- MessageNotWritableException

*WriteLong - Write Long Integer*

**Interface:**

```
void WriteLong(Int64 value);
```

Write a long integer to the message stream as 8 bytes, high-order byte first.

**Parameters:**

**value (input)**

The long integer to be written.

**Returns:**

Void

**Exceptions:**

- XMSEException
- MessageNotWritableException

*WriteObject - Write Object*

**Interface:**

```
void WriteObject(Object value);
```

Write a value, with a specified data type, to the message stream.

**Parameters:****objectType (input)**

The value, which must be one of the following object types:

Boolean  
Byte  
Byte[]  
Char  
Double  
Single  
Int32  
Int64  
Int16  
String

**value (input)**

An array of bytes containing the value to be written.

**length (input)**

The number of bytes in the array.

**Returns:**

Void

**Exceptions:**

- XMSEException

*WriteShort - Write Short Integer*

**Interface:**

```
void WriteShort(Int16 value);
```

Write a short integer to the message stream as 2 bytes, high-order byte first.

**Parameters:****value (input)**

The short integer to be written.

**Returns:**

Void

**Exceptions:**

- XMSEException
- MessageNotWritableException

*WriteString - Write String*

**Interface:**

```
void WriteString(String value);
```

Write a string to the message stream.

**Parameters:****value (input)**

A String object encapsulating the string to be written.

**Returns:**

Void

### Exceptions:

- XMSException
- MessageNotWritableException

### ***Inherited properties and methods***

The following properties are inherited from the [IMessage](#) interface:

[JMSCorrelationID](#), [JMSDeliveryMode](#), [JMSTDestination](#), [JMSExpiration](#), [JMSMessageID](#), [JMSPriority](#), [JMSRedelivered](#), [JMSReplyTo](#), [JMSTimestamp](#), [JMSType](#), [Properties](#)

The following methods are inherited from the [IMessage](#) interface:

[clearBody](#), [clearProperties](#), [PropertyExists](#)

The following methods are inherited from the [IPropertyContext](#) interface:

[GetBooleanProperty](#), [GetByteProperty](#), [GetBytesProperty](#), [GetCharProperty](#), [GetDoubleProperty](#), [GetFloatProperty](#), [GetIntProperty](#), [GetLongProperty](#), [GetObjectProperty](#), [GetShortProperty](#), [GetStringProperty](#), [SetBooleanProperty](#), [SetByteProperty](#), [SetBytesProperty](#), [SetCharProperty](#), [SetDoubleProperty](#), [SetFloatProperty](#), [SetIntProperty](#), [SetLongProperty](#), [SetObjectProperty](#), [SetShortProperty](#), [SetStringProperty](#)

## **ITextMessage**

A text message is a message whose body comprises a string.

### **Inheritance hierarchy:**

## ***.NET properties***

*Text - Get and Set Text*

### **Interface:**

```
String Text
{
    get;
    set;
}
```

Get and set the string that forms the body of the text message.

If required, XMS converts the characters in the string into the local code page.

### Exceptions:

- XMSException
- MessageNotReadableException
- MessageNotWritableException
- MessageEOFException

### ***Inherited properties and methods***

The following properties are inherited from the [IMessage](#) interface:

[JMSCorrelationID](#), [JMSDeliveryMode](#), [JMSDestination](#), [JMSExpiration](#), [JMSMessageID](#), [JMSPriority](#), [JMSRedelivered](#), [JMSReplyTo](#), [JMSTimestamp](#), [JMSType](#), [Properties](#)

The following methods are inherited from the [IMessage](#) interface:

[clearBody](#), [clearProperties](#), [PropertyExists](#)

The following methods are inherited from the [IPropertyContext](#) interface:

[GetBooleanProperty](#), [GetByteProperty](#), [GetBytesProperty](#), [GetCharProperty](#), [GetDoubleProperty](#), [GetFloatProperty](#), [GetIntProperty](#), [GetLongProperty](#), [GetObjectProperty](#), [GetShortProperty](#), [GetStringProperty](#), [SetBooleanProperty](#), [SetByteProperty](#), [SetBytesProperty](#), [SetCharProperty](#), [SetDoubleProperty](#), [SetFloatProperty](#), [SetIntProperty](#), [SetLongProperty](#), [SetObjectProperty](#), [SetShortProperty](#), [SetStringProperty](#)

## TransactionInProgressException

XMS throws this exception if an application requests an operation that is not valid because a transaction is in progress.

### Inheritance hierarchy:

```
IBM.XMS.XMSException
|
+----IBM.XMS.XMSException
|
+----IBM.XMS.TransactionInProgressException
```

### Inherited properties and methods

The following methods are inherited from the [XMSException](#) interface:

[GetErrorCode](#), [GetLinkedException](#)

## TransactionRolledBackException

XMS throws this exception if an application calls `Session.commit()` to commit the current transaction, but the transaction is then rolled back.

### Inheritance hierarchy:

```
IBM.XMS.XMSException
|
+----IBM.XMS.XMSException
|
+----IBM.XMS.TransactionRolledBackException
```

### Inherited properties and methods

The following methods are inherited from the [XMSException](#) interface:

[GetErrorCode](#), [GetLinkedException](#)

## XMSException

If XMS detects an error while processing a call to a .NET method, XMS throws an exception. An exception is an object that encapsulates information about the error.

### Inheritance hierarchy:

```
System.Exception
|
+----IBM.XMS.XMSException
```

There are different types of XMS exception, and an XMSException object is just one type of exception. However, the XMSException class is a superclass of the other XMS exception classes. XMS throws an XMSException object in situations where none of the other types of exception are appropriate.

## **.NET properties**

*ErrorCode - Get Error Code*

### **Interface:**

```
public String ErrorCode
{
    get {return errorCode_;}
}
```

Get the error code.

### **Exceptions:**

- XMSException

*LinkedException - Get Linked Exception*

### **Interface:**

```
public Exception LinkedException
{
    get { return linkedException_;}
    set { linkedException_ = value;}
}
```

Get the next exception in the chain of exceptions.

The method returns a null if there are no more exceptions in the chain.

### **Exceptions:**

- XMSException

## **XMSFactoryFactory**

If an application is not using administered objects, use this class to create connection factories, queues, and topics.

### **Inheritance hierarchy:**

None

## **.NET properties**

*Metadata - Retrieve metadata*

### **Interface:**

```
IConnectionMetaData MetaData
```

Get the metadata that is appropriate to the connection type of the XMSFactoryFactory object.

### **Exceptions:**

None

### **Methods**

## *CreateConnectionFactory - Create Connection Factory*

### **Interface:**

```
ConnectionFactory CreateConnectionFactory();
```

Create a ConnectionFactory object of the declared type.

### **Parameters:**

None

### **Returns:**

The ConnectionFactory object.

### **Exceptions:**

- XMSEException

## *CreateQueue - Create Queue*

### **Interface:**

```
IDestination CreateQueue(String name);
```

Create a Destination object to represent a queue in the messaging server.

This method does not create the queue in the messaging server. You must create the queue before an application can call this method.

### **Parameters:**

#### **name (input)**

A String object encapsulating the name of the queue, or encapsulating a uniform resource identifier (URI) that identifies the queue.

### **Returns:**

The Destination object representing the queue.

### **Exceptions:**

- XMSEException

## *CreateTopic - Create Topic*

### **Interface:**

```
IDestination CreateTopic(String name);
```

Create a Destination object to represent a topic.

### **Parameters:**

#### **name (input)**

A String object encapsulating the name of the topic, or encapsulating a uniform resource identifier (URI) that identifies the topic.

### **Returns:**

The Destination object representing the topic.

### **Exceptions:**

- XMSEException

*GetInstance* - Get an instance of *XMSFactoryFactory*

**Interface:**

```
static XMSFactoryFactory GetInstance(int connectionType);
```

Create an instance of *XMSFactoryFactory*. An XMS application uses an *XMSFactoryFactory* object to get a reference to a *ConnectionFactory* object that is appropriate to the required type of protocol. This *ConnectionFactory* object can then produce connections for that protocol type only.

**Parameters:**

**connectionType (input)**

The type of connection for which the *ConnectionFactory* object produces connections:

- *XMSC.CT\_WPM*
- *XMSC.CT\_RTT*
- *XMSC.CT\_WMQ*

**Returns:**

The *XMSFactoryFactory* object dedicated to the declared connection type.

**Exceptions:**

- *NotSupportedException*

## Properties of XMS objects

This section documents the object properties defined by XMS.

This section contains information about the following types of object:

- [“Properties of Connection” on page 2030](#)
- [“Properties of ConnectionFactory” on page 2030](#)
- [“Properties of ConnectionMetaData” on page 2035](#)
- [“Properties of Destination” on page 2035](#)
- [“Properties of InitialContext” on page 2037](#)
- [“Properties of Message” on page 2037](#)
- [“Properties of MessageConsumer” on page 2042](#)
- [“Properties of MessageProducer” on page 2042](#)
- [“Properties of Session” on page 2042](#)

The description of each object type lists the properties of an object of the specified type and provides a short description of each property.

This section also provides a definition of each property (see [“Property definitions” on page 2043](#)).

If an application defines its own properties of the objects described in this section, it does not cause an error, but it might cause unpredictable results.

**Note:** The property names and values in this section are shown in the form *XMSC.NAME*, which is the form used for C and C++. However, in .NET, the form of the property name can be either *XMSC.NAME* or *XMSC\_NAME*, depending on how you are using it:

- If you are specifying a property, the property name must be in the form *XMSC.NAME* as shown in the following example:

```
cf.SetStringProperty(XMSC.WMQ_CHANNEL, "DOTNET.SVRCONN");
```

- If you are specifying a string, the property name must be in the form `XMSC_NAME` as shown in the following example:

```
cf.SetStringProperty("XMSC_WMQ_CHANNEL", "DOTNET.SVRCONN");
```

In .NET, property names and values are provided as constants in the XMSC class. These constants identify strings and would be used by any XMS .NET application. If you are using these predefined constants, the property names and values are in the form `XMSC.NAME`, so, for example, you would use `XMSC.USERID`, rather than `XMSC_USERID`.

The data types are also in the form used for C/C++. You can find the corresponding values for .NET in [Data types for .NET](#).

## Properties of Connection

An overview of the properties of the Connection object, with links to more detailed reference information.

Name of property	Description
<a href="#">"XMSC_WMQ_RESOLVED_QUEUE_MANAGER" on page 2076</a>	This property is used to obtain the name of the queue manager to which it is connected.
<a href="#">"XMSC_WMQ_RESOLVED_QUEUE_MANAGER_ID" on page 2076</a>	This property is populated with the ID of the queue manager after the connection.
<a href="#">XMSC_WPM_CONNECTION_PROTOCOL</a>	The communications protocol used for the connection to the messaging engine. This property is read-only.
<a href="#">XMSC_WPM_HOST_NAME</a>	The host name or IP address of the system that contains the messaging engine to which the application is connected. This property is read-only.
<a href="#">XMSC_WPM_ME_NAME</a>	The name of the messaging engine to which the application is connected. This property is read-only.
<a href="#">XMSC_WPM_PORT</a>	The number of the port listened on by the messaging engine to which the application is connected. This property is read-only.

A Connection object also has read-only properties that are derived from the properties of the connection factory that was used to create the connection. These properties are derived not only from the connection factory properties that were set at the time the connection was created, but also from the default values of the properties that were not set. The properties include only the ones that are relevant for the type of messaging server that the application is connected to. The names of the properties are the same as the names of the connection factory properties.

## Properties of ConnectionFactory

An overview of the properties of the ConnectionFactory object, with links to more detailed reference information.

Name of property	Description
<a href="#">"XMSC_ASYNC_EXCEPTIONS" on page 2052</a>	This property determines whether XMS informs an ExceptionListener only when a connection is broken, or when any exception occurs asynchronously to an XMS API call. This property applies to all Connections created from this ConnectionFactory that have an ExceptionListener registered.

Table 873. Properties of ConnectionFactory (continued)

Name of property	Description
<a href="#">“XMSC_WMQ_BALANCING_APPLICATION_TYPE”</a> on page 2060	Type of balancing option
<a href="#">“XMSC_WMQ_BALANCING_OPTIONS”</a> on page 2061	Balancing options set by the issuing application
<a href="#">“XMSC_WMQ_BALANCING_TIMEOUT”</a> on page 2061	Timeout after which re-balancing might interrupt application activity.
<a href="#">XMSC_CLIENT_ID</a>	The client identifier for a connection.
<a href="#">XMSC_CONNECTION_TYPE</a>	The type of messaging server to which an application connects.
<a href="#">XMSC_PASSWORD</a>	A password that can be used to authenticate the application when it attempts to connect to a messaging server.
<a href="#">“XMSC_RTT_BROKER_PING_INTERVAL”</a> on page 2057	The time interval, in milliseconds, after which XMS .NET checks the connection to a Real Time messaging server to detect any activity.
<a href="#">XMSC_RTT_CONNECTION_PROTOCOL</a>	The communications protocol used for a real-time connection to a broker.
<a href="#">XMSC_RTT_HOST_NAME</a>	The host name or IP address of the system on which a broker runs.
<a href="#">XMSC_RTT_LOCAL_ADDRESS</a>	The host name or IP address of the local network interface to be used for a real-time connection to a broker.
<a href="#">XMSC_RTT_MULTICAST</a>	The multicast setting for a connection factory or destination.
<a href="#">XMSC_RTT_PORT</a>	The number of the port on which a broker listens for incoming requests.
<a href="#">XMSC_USERID</a>	A user identifier that can be used to authenticate the application when it attempts to connect to a messaging server.
<a href="#">XMSC_WMQ_BROKER_CONTROLQ</a>	The name of the control queue used by a broker.
<a href="#">XMSC_WMQ_BROKER_PUBQ</a>	The name of the queue monitored by a broker where applications send messages that they publish.
<a href="#">XMSC_WMQ_BROKER_QMGR</a>	The name of the queue manager to which a broker is connected.
<a href="#">XMSC_WMQ_BROKER_SUBQ</a>	The name of the subscriber queue for a nondurable message consumer.
<a href="#">XMSC_WMQ_BROKER_VERSION</a>	The type of broker used by the application for a connection or for the destination.
<a href="#">“XMSC_WMQ_CCDTURL”</a> on page 2063	A Uniform Resource Locator (URL) that identifies the name and location of the file that contains the client channel definition table and also specifies how the file can be accessed.
<a href="#">XMSC_WMQ_CHANNEL</a>	The name of the channel to be used for a connection.

Table 873. Properties of ConnectionFactory (continued)

Name of property	Description
<a href="#">“XMSC_WMQ_CLIENT_RECONNECT_OPTIONS” on page 2064</a>	This property specifies the client reconnect options for new connections created by this factory
<a href="#">“XMSC_WMQ_CLIENT_RECONNECT_TIMEOUT” on page 2065</a>	This property specifies the duration of time, in seconds, that a client connection attempts to reconnect.
<a href="#">XMSC_WMQ_CONNECTION_MODE</a>	The mode by which an application connects to a queue manager.
<a href="#">“XMSC_WMQ_CONNECTION_NAME_LIST” on page 2065</a>	This property specifies the hosts to which the client attempts to reconnect to after its connection are broken.
<a href="#">XMSC_WMQ_FAIL_IF QUIESCE</a>	Whether calls to certain methods fail if the queue manager to which the application is connected is in a quiescing state.
<a href="#">XMSC_WMQ_HOST_NAME</a>	The host name or IP address of the system on which a queue manager runs.
<a href="#">XMSC_WMQ_LOCAL_ADDRESS</a>	For a connection to a queue manager, this property specifies the local network interface to be used, or the local port or range of local ports to be used, or both.
<a href="#">XMSC_WMQ_MESSAGE_SELECTION</a>	Determines whether message selection is done by the XMS client or by the broker.
<a href="#">XMSC_WMQ_MSG_BATCH_SIZE</a>	The maximum number of messages to be retrieved from a queue in one batch when using asynchronous message delivery.
<a href="#">XMSC_WMQ_POLLING_INTERVAL</a>	If each message listener within a session has no suitable message on its queue, this value is the maximum interval, in milliseconds, that elapses before each message listener tries again to get a message from its queue.
<a href="#">“XMSC_WMQ_PROVIDER_VERSION” on page 2074</a>	The version, release, modification level and fix pack of the queue manager to which the application intends to connect.
<a href="#">XMSC_WMQ_PORT</a>	The number of the port on which a queue manager listens for incoming requests.
<a href="#">XMSC_WMQ_PUB_ACK_INTERVAL</a>	The number of messages published by a publisher before the XMS client requests an acknowledgment from the broker.
<a href="#">“XMSC_WMQ_PUT_ASYNC_ALLOWED” on page 2070</a>	This property determines whether message producers are allowed to use asynchronous puts to send messages to this destination.
<a href="#">XMSC_WMQ_QMGR_CCSID</a>	The identifier (CCSID) of the coded character set, or code page, in which fields of character data defined in the Message Queue Interface (MQI) are exchanged between the XMS client and the IBM MQ client.
<a href="#">XMSC_WMQ_QUEUE_MANAGER</a>	The name of the queue manager to connect to.
<a href="#">XMSC_WMQ_RECEIVE_EXIT</a>	Identifies a channel receive exit to be run.
<a href="#">XMSC_WMQ_RECEIVE_EXIT_INIT</a>	The user data that is passed to a channel receive exit when it is called.

Table 873. Properties of ConnectionFactory (continued)

Name of property	Description
<a href="#">XMSC_WMQ_SECURITY_EXIT</a>	Identifies a channel security exit.
<a href="#">XMSC_WMQ_SECURITY_EXIT_INIT</a>	The user data that is passed to a channel security exit when it is called.
“ <a href="#">XMSC_WMQ_SEND_CHECK_COUNT</a> ” on page 2078	The number of send calls to allow between checking for asynchronous put errors, within a single non-transacted XMS session.
<a href="#">XMSC_WMQ_SEND_EXIT</a>	Identifies a channel send exit.
<a href="#">XMSC_WMQ_SEND_EXIT_INIT</a>	The user data that is passed to channel send exits when they are called.
“ <a href="#">XMSC_WMQ_SHARE_CONV_ALLOWED</a> ” on page 2078	Whether a client connection can share its socket with other top-level XMS connections from the same process to the same queue manager, if the channel definitions match. This property is provided to allow complete isolation of Connections in separate sockets if required for application development, maintenance, or operational reasons.
<a href="#">XMSC_WMQ_SSL_CERT_STORES</a>	The locations of the servers that hold the certificate revocation lists (CRLs) to be used on an SSL connection to a queue manager.
<a href="#">XMSC_WMQ_SSL_CIPHER_SPEC</a>	The name of the CipherSpec to be used on a secure connection to a queue manager.
<a href="#">XMSC_WMQ_SSL_CIPHER_SUITE</a>	The name of the CipherSuite to be used on a TLS connection to a queue manager. The protocol used in negotiating the secure connection depends on the specified CipherSuite.
<a href="#">XMSC_WMQ_SSL_CRYPT_HW</a>	Configuration details for the cryptographic hardware connected to the client system.
<a href="#">XMSC_WMQ_SSL_FIPS_REQUIRED</a>	The value of this property determines whether an application can or cannot use non-FIPS compliant cipher suites. If this property is set to true, only FIPS algorithms are used for the client-server connection.
<a href="#">XMSC_WMQ_SSL_KEY_REPOSITORY</a>	The location of the key database file in which keys and certificates are stored.
<a href="#">XMSC_WMQ_SSL_KEY_RESETCOUNT</a>	The KeyResetCount represents the total number of unencrypted bytes sent and received within an SSL conversation before the secret key is renegotiated.
<a href="#">XMSC_WMQ_SSL_PEER_NAME</a>	The peer name to be used on an SSL connection to a queue manager.
<a href="#">XMSC_WMQ_SYNCPOINT_ALL_GETS</a>	Whether all messages must be retrieved from queues within sync point control.
“ <a href="#">XMSC_WMQ_TARGET_CLIENT</a> ” on page 2084	
<a href="#">XMSC_WMQ_TEMP_Q_PREFIX</a>	The prefix used to form the name of the IBM MQ dynamic queue that is created when the application creates an XMS temporary queue.

Table 873. Properties of ConnectionFactory (continued)

Name of property	Description
<u>XMSC_WMQ_TEMP_TOPIC_PREFIX</u>	When creating temporary topics, XMS generates a topic string of the form "TEMP/TEMPTOPICPREFIX/unique_id", or if this property contains the default value, then this string, "TEMP/unique_id", is generated. Specifying a non-empty value allows specific model queues to be defined for creating the managed queues for subscribers to temporary topics created under this connection.
<u>XMSC_WMQ_TEMPORARY_MODEL</u>	The name of the IBM MQ model queue from which a dynamic queue is created when the application creates an XMS temporary queue.
<u>XMSC_WPM_BUS_NAME</u>	For a connection factory, the name of the service integration bus that the application connects to or, for a destination, the name of the service integration bus in which the destination exists.
<u>XMSC_WPM_CONNECTION_PROXIMITY</u>	The connection proximity setting for the connection.
<u>XMSC_WPM_DUR_SUB_HOME</u>	The name of the messaging engine where all durable subscriptions for a connection or a destination are managed.
<u>XMSC_WPM_LOCAL_ADDRESS</u>	For a connection to a service integration bus, this property specifies the local network interface to be used, or the local port or range of local ports to be used, or both.
<u>XMSC_WPM_NON_PERSISTENT_MAP</u>	The reliability level of nonpersistent messages that are sent using the connection.
<u>XMSC_WPM_PERSISTENT_MAP</u>	The reliability level of persistent messages that are sent using the connection.
<u>XMSC_WPM_PROVIDER_ENDPOINTS</u>	A sequence of one or more endpoint addresses of bootstrap servers.
<u>XMSC_WPM_TARGET_GROUP</u>	The name of a target group of messaging engines.
<u>XMSC_WPM_TARGET_SIGNIFICANCE</u>	The significance of the target group of messaging engines.
<u>XMSC_WPM_TARGET_TRANSPORT_CHAIN</u>	The name of the inbound transport chain that the application must use to connect to a messaging engine.
<u>XMSC_WPM_TARGET_TYPE</u>	The type of the target group of messaging engines.
<u>XMSC_WPM_TEMP_Q_PREFIX</u>	The prefix used to form the name of the temporary queue that is created in the service integration bus when the application creates an XMS temporary queue.
<u>XMSC_WPM_TEMP_TOPIC_PREFIX</u>	The prefix used to form the name of a temporary topic that is created by the application.

## Properties of ConnectionMetaData

An overview of the properties of the ConnectionMetaData object, with links to more detailed reference information.

Name of property	Description
<a href="#">XMSC_JMS_MAJOR_VERSION</a>	The major version number of the JMS specification upon which XMS is based. This property is read-only.
<a href="#">XMSC_JMS_MINOR_VERSION</a>	The minor version number of the JMS specification upon which XMS is based. This property is read-only.
<a href="#">XMSC_JMS_VERSION</a>	The version identifier of the JMS specification upon which XMS is based. This property is read-only.
<a href="#">XMSC_MAJOR_VERSION</a>	The version number of the XMS client. This property is read-only.
<a href="#">XMSC_MINOR_VERSION</a>	The release number of the XMS client. This property is read-only.
<a href="#">XMSC_PROVIDER_NAME</a>	The provider of the XMS client. This property is read-only.
<a href="#">XMSC_VERSION</a>	The version identifier of the cliXMSent. This property is read-only.

## Properties of Destination

An overview of the properties of the Destination object, with links to more detailed reference information.

Name of property	Description
<a href="#">XMSC_DELIVERY_MODE</a>	The delivery mode of messages sent to the destination.
<a href="#">XMSC_PRIORITY</a>	The priority of messages sent to the destination.
<a href="#">XMSC_RTT_MULTICAST</a>	The multicast setting for a connection factory or destination.
<a href="#">XMSC_TIME_TO_LIVE</a>	The time to live for messages sent to the destination.
<a href="#">XMSC_WMQ_BROKER_VERSION</a>	The type of broker used by the application for a connection or for the destination.
<a href="#">XMSC_WMQ_CCSID</a>	The identifier (CCSID) of the coded character set, or code page, that the strings of character data in the body of a message are in when the XMS client forwards the message to the destination.
<a href="#">XMSC_WMQ_DUR_SUBQ</a>	The name of the subscriber queue for a durable subscriber that is receiving messages from the destination.  <b>Note:</b> This property can be used with version 2.0 of IBM Message Service Client for .NET but has no effect for an application connected to an IBM WebSphere MQ 7.0 queue manager unless the XMSC_WMQ_PROVIDER_VERSION property of the connection factory is set to a version number less than 7.

<i>Table 875. Properties of Destination (continued)</i>	
<b>Name of property</b>	<b>Description</b>
<u>XMSC_WMQ_ENCODING</u>	How numerical data in the body of a message is represented when the XMS client forwards the message to the destination.
<u>XMSC_WMQ_FAIL_IF QUIESCE</u>	Whether calls to certain methods fail if the queue manager to which the application is connected is in a quiescing state.
<u>"XMSC_WMQ_MESSAGE_BODY" on page 2067</u>	This property determines whether an XMS application processes the MQRFH2 of an IBM MQ message as part of the message payload (that is, as part of the message body).
<u>"XMSC_WMQ_MQMD_MESSAGE_CONTEXT" on page 2068</u>	Determines what level of message context is to be set by the XMS application. The application must be running with appropriate context authority for this property to take effect.
<u>"XMSC_WMQ_MQMD_READ_ENABLED" on page 2069</u>	This property determines whether an XMS application can extract the values of MQMD fields or not.
<u>"XMSC_WMQ_MQMD_WRITE_ENABLED" on page 2069</u>	This property determines whether an XMS application can set the values of MQMD fields or not.
<u>"XMSC_WMQ_READ_AHEAD_ALLOWED" on page 2070</u>	This property determines whether message consumers and queue browsers are allowed to use read ahead to get non-persistent, non-transactional messages from this destination into an internal buffer before receiving them.
<u>"XMSC_WMQ_READ_AHEAD_CLOSE_POLICY" on page 2071</u>	This property determines, for messages being delivered to an asynchronous message listener, what happens to messages in the internal read ahead buffer when the message consumer is closed.
<u>"XMSC_WMQ_RECEIVE_CC SID" on page 2075</u>	Destination property that sets the target CCSID for queue manager message conversion. The value is ignored unless XMSC_WMQ_RECEIVE_CONVERSION is set to WMQ_RECEIVE_CONVERSION_QMGR.
<u>"XMSC_WMQ_RECEIVE_CONVERSION" on page 2075</u>	Destination property that determines whether data conversion is going to be performed by the queue manager.
<u>XMSC_WMQ_TARGET_CLIENT</u>	Whether messages sent to the destination contain an MQRFH2 header.
<u>XMSC_WMQ_TEMP_TOPIC_PREFIX</u>	When creating temporary topics, XMS generates a topic string of the form "TEMP/TEMPTOPICPREFIX/unique_id", or if this property contains the default value, then this string, "TEMP/unique_id", is generated. Specifying a non-empty value allows specific model queues to be defined for creating the managed queues for subscribers to temporary topics created under this connection.
<u>XMSC_WPM_BUS_NAME</u>	For a connection factory, the name of the service integration bus that the application connects to or, for a destination, the name of the service integration bus in which the destination exists.
<u>XMSC_WPM_TOPIC_SPACE</u>	The name of the topic space that contains the topic.

## Properties of InitialContext

An overview of the properties of the InitialContext object, with links to more detailed reference information.

Name of property	Description
<a href="#">XMSC_IC_PROVIDER_URL</a>	Used to locate the JNDI naming directory so that the COS naming service does not need to be on the same server as the web service.
<a href="#">XMSC_IC_SECURITY_AUTHENTICATION</a>	Based on the Java Context interface SECURITY_AUTHENTICATION. This property is only applicable to the COS naming context.
<a href="#">XMSC_IC_SECURITY_CREDENTIALS</a>	Based on the Java Context interface SECURITY_CREDENTIALS. This property is only applicable to the COS naming context.
<a href="#">XMSC_IC_SECURITY_PRINCIPAL</a>	Based on the Java Context interface SECURITY_PRINCIPAL. This property is only applicable to the COS naming context.
<a href="#">XMSC_IC_SECURITY_PROTOCOL</a>	Based on the Java Context interface SECURITY_PROTOCOL. This property is only applicable to the COS naming context.
<a href="#">XMSC_IC_URL</a>	For LDAP and FileSystem contexts, the address of the repository containing administered objects. For COS naming contexts, the address of the web service that looks up the objects in the directory.

## Properties of Message

An overview of the properties of the Message object, with links to more detailed reference information.

Name of property	Description
<a href="#">JMS_IBM_CHARACTER_SET</a>	The identifier (CCSID) of the coded character set, or code page, that the strings of character data in the body of the message is in when the XMS client forwards the message to its intended destination. In XMS, this property has a numeric value and maps to CCSID. However, this property is based on a JMS property so has a string type value and maps to the Java character set that represents this numeric CCSID.
<a href="#">JMS_IBM_ENCODING</a>	How numerical data in the body of the message is represented when the XMS client forwards the message to its intended destination.
<a href="#">JMS_IBM_EXCEPTIONMESSAGE</a>	Text that describes why the message was sent to the exception destination. This property is read-only.
<a href="#">JMS_IBM_EXCEPTIONPROBLEMDESTINATION</a>	The name of the destination that the message was at before the message was sent to the exception destination.
<a href="#">JMS_IBM_EXCEPTIONREASON</a>	A reason code indicating the reason why the message was sent to the exception destination.

Table 877. Properties of Message (continued)

Name of property	Description
<u>JMS_IBM_EXCEPTIONTIMESTAMP</u>	The time when the message was sent to the exception destination.
<u>JMS_IBM_FEEDBACK</u>	A code that indicates the nature of a report message.
<u>JMS_IBM_FORMAT</u>	The nature of the application data in the message.
<u>JMS_IBM_LAST_MSG_IN_GROUP</u>	Indicate whether the message is the last message in a message group.
<u>JMS_IBM_MSGTYPE</u>	The type of the message.
<u>JMS_IBM_PUTAPPLTYPE</u>	The type of application that sent the message.
<u>JMS_IBM_PUTDATE</u>	The date when the message was sent.
<u>JMS_IBM_PUTTIME</u>	The time when the message was sent.
<u>JMS_IBM_REPORT_COA</u>	Request 'confirm on arrival' report messages, specifying how much application data from the original message must be included in a report message.
<u>JMS_IBM_REPORT_COD</u>	Request 'confirm on delivery' report messages, specifying how much application data from the original message must be included in a report message.
<u>JMS_IBM_REPORT_DISCARD_MSG</u>	Request that the message is discarded if it cannot be delivered to its intended destination.
<u>JMS_IBM_REPORT_EXCEPTION</u>	Request exception report messages, specifying how much application data from the original message must be included in a report message.
<u>JMS_IBM_REPORT_EXPIRATION</u>	Request expiration report messages, specifying how much application data from the original message must be included in a report message.
<u>JMS_IBM_REPORT_NAN</u>	Request negative action notification report messages.
<u>JMS_IBM_REPORT_PAN</u>	Request positive action notification report messages.
<u>JMS_IBM_REPORT_PASS_CORREL_ID</u>	Request that the correlation identifier of any report or reply message is the same as the correlation identifier of the original message.
<u>JMS_IBM_REPORT_PASS_MSG_ID</u>	Request that the message identifier of any report or reply message is the same as the message identifier of the original message.
<u>JMS_IBM_RETAIN</u>	Setting this property indicates to the queue manager to treat a message as Retained Publication.
<u>JMS_IBM_SYSTEM_MESSAGEID</u>	An identifier that identifies the message uniquely within the service integration bus. This property is read-only.
<u>JMSX_APPID</u>	The name of the application that sent the message.
<u>JMSX_DELIVERY_COUNT</u>	The number of attempts to deliver the message.
<u>JMSX_GROUPID</u>	The identifier of the message group to which the message belongs.

Table 877. Properties of Message (continued)

Name of property	Description
JMSX_GROUPSEQ	The sequence number of the message within a message group.
JMSX_USERID	The user identifier associated with the application that sent the message.

## JMS\_IBM\_MQMD\* properties

IBM Message Service Client for .NET enables client applications to read/write MQMD fields using APIs. It also allows access to MQ message data. By default access to MQMD is disabled and must be enabled explicitly by the application using Destination properties XMSC\_WMQ\_MQMD\_WRITE\_ENABLED and XMSC\_WMQ\_MQMD\_READ\_ENABLED. These two properties are independent of each other.

All MQMD fields except StructId and Version are exposed as additional Message object properties and are prefixed JMS\_IBM\_MQMD.

JMS\_IBM\_MQMD\* properties take higher precedence over other properties like JMS\_IBM\* described in the previous table.

## Sending messages

All MQMD fields except StructId and Version are represented. These properties refer only to the MQMD fields; where a property occurs both in the MQMD and in the MQRFH2 header, the version in the MQRFH2 is not set or extracted. Any of these properties can be set, except JMS\_IBM\_MQMD\_BackoutCount. Any value set for JMS\_IBM\_MQMD\_BackoutCount is ignored.

If a property has a maximum length and you supply a value that is too long, the value is truncated.

For certain properties, you must also set the XMSC\_WMQ\_MQMD\_MESSAGE\_CONTEXT property on the Destination object. The application must be running with appropriate context authority for this property to take effect. If you do not set XMSC\_WMQ\_MQMD\_MESSAGE\_CONTEXT to an appropriate value, the property value is ignored. If you set XMSC\_WMQ\_MQMD\_MESSAGE\_CONTEXT to an appropriate value but you do not have sufficient context authority for the queue manager, an exception is issued. Properties requiring specific values of XMSC\_WMQ\_MQMD\_MESSAGE\_CONTEXT are as follows.

The following properties require XMSC\_WMQ\_MQMD\_MESSAGE\_CONTEXT to be set to XMSC\_WMQ\_MDCTX\_SET\_IDENTITY\_CONTEXT or XMSC\_WMQ\_MDCTX\_SET\_ALL\_CONTEXT:

- JMS\_IBM\_MQMD\_UserIdentifier
- JMS\_IBM\_MQMD\_AccountingToken
- JMS\_IBM\_MQMD\_ApplIdentityData

The following properties require XMSC\_WMQ\_MQMD\_MESSAGE\_CONTEXT to be set to XMSC\_WMQ\_MDCTX\_SET\_ALL\_CONTEXT:

- JMS\_IBM\_MQMD\_PutApplType
- JMS\_IBM\_MQMD\_PutApplName
- JMS\_IBM\_MQMD\_PutDate
- JMS\_IBM\_MQMD\_PutTime
- JMS\_IBM\_MQMD\_ApplOriginData

## Receiving messages

All these properties are available on a received message if XMSC\_WMQ\_MQMD\_READ\_ENABLED property is set to true, irrespective of the actual properties that the producing application set. An application

cannot modify the properties of a received message unless all properties are cleared first, according to the JMS specification. The received message can be forwarded without modifying the properties.

**Note:** If your application receives a message from a destination with XMSC\_WMQ\_MQMD\_READ\_ENABLED property set to true, and forwards it to a destination with XMSC\_WMQ\_MQMD\_WRITE\_ENABLED set to true, this results in all the MQMD field values of the received message being copied into the forwarded message. Table of properties

Property	Description	Type
JMS_IBM_MQMD_REPORT	Options for report messages	System.Int32
JMS_IBM_MQMD_MSGTYPE	Message type	System.Int32
JMS_IBM_MQMD_EXPIRY	message lifetime	System.Int32
JMS_IBM_MQMD_FEEDBACK	Feedback or reason code	System.Int32
JMS_IBM_MQMD_ENCODING	Numeric encoding of message data	System.Int32
JMS_IBM_MQMD_CODEDCHARSETID	Character set identifier of message data	System.Int32
JMS_IBM_MQMD_FORMAT	Format name of message data	System.String
JMS_IBM_MQMD_PRIORITY	Message priority	System.Int32
	<b>Note:</b> If you assign a value to JMS_IBM_MQMD_PRIORITY that is not within the range 0-9, this value violates the JMS specification.	
JMS_IBM_MQMD_PERSISTENCE	Message persistence	System.Int32
JMS_IBM_MQMD_MSGID	Message identifier	Byte Array
	<b>Note:</b> The JMS specification states that the message ID must be set by the JMS provider and that it must either be unique or null. If you assign a value to JMS_IBM_MQMD_MSGID, this value is copied to the JMSMessageID. Thus it is not set by the JMS provider and might not be unique: this value violates the JMS specification.	<b>Note:</b> The use of byte array properties on a message violates the JMS specification.
JMS_IBM_MQMD_CORRELID	Correlation identifier	Byte Array
	<b>Note:</b> If you assign a value to JMS_IBM_MQMD_CORRELID that starts with the string 'ID:', this value violates the JMS specification.	<b>Note:</b> The use of byte array properties on a message violates the JMS specification.
JMS_IBM_MQMD_BACKOUTCOUNT	Backout counter	System.Int32
JMS_IBM_MQMD_REPLYTOQ	Name of reply queue	System.String
JMS_IBM_MQMD_REPLYTOQMGR	Name of reply queue manager	System.String
JMS_IBM_MQMD_USERIDENTIFIER	User identifier	System.String

Table 878. Properties of the Message object representing the MQMD fields (continued)

Property	Description	Type
JMS_IBM_MQMD_ACCOUNTINGTOKEN	Accounting token	Byte Array <b>Note:</b> The use of byte array properties on a message violates the JMS specification.
JMS_IBM_MQMD_APPLIDENTITYDATA	Application data relating to identity	System.String
JMS_IBM_MQMD_PUTAPPLTYPE	Type of application that put the message	System.Int32
JMS_IBM_MQMD_PUTAPPLNAME	Name of the application that put the message	System.String
JMS_IBM_MQMD_PUTDATE	Date when message was put	System.String
JMS_IBM_MQMD_PUTTIME	Time when message was put	System.String
JMS_IBM_MQMD_APPLORIGINDATA	Application data relating to origin	System.String
JMS_IBM_MQMD_GROUPID	Group identifier	Byte Array <b>Note:</b> The use of byte array properties on a message violates the JMS specification.
JMS_IBM_MQMD_MSGSEQNUMBER	Sequence number of local message within group	System.Int32
JMS_IBM_MQMD_OFFSET	Offset of data in physical message from start of logical message	System.Int32
JMS_IBM_MQMD_MSGFLAGS	Message flags	System.Int32
JMS_IBM_MQMD_ORIGINALLENGTH	Length of original message	System.Int32

See [MQMD](#) for further details.

## Examples

This example results in a message being put to a queue or topic with `MQMD.UserIdIdentifier` set to "JoeBloggs".

```
// Create a ConnectionFactory, connection, session, producer, message
// ...

// Create a destination
// ...

// Enable MQMD write
dest.setBooleanProperty(XMSC_WMQ_MQMD_WRITE_ENABLED,
    XMSC_WMQ_MQMD_WRITE_ENABLED_YES);

// Optionally, set a message context if applicable for this MD field
dest.setIntProperty(XMSC_WMQ_MQMD_MESSAGE_CONTEXT,
    XMSC_WMQ_MDCTX_SET_IDENTITY_CONTEXT);

// On the message, set property to provide custom UserId
msg.setStringProperty(JMS_IBM_MQMD_USERIDENTIFIER, "JoeBloggs");
```

```
// Send the message
// ...
```

It is necessary to set XMSC\_WMQ\_MQMD\_MESSAGE\_CONTEXT before setting JMS\_IBM\_MQMD\_USERIDENTIFIER. For more information about the use of XMSC\_WMQ\_MQMD\_MESSAGE\_CONTEXT, see Message object properties.

Similarly, you can extract the contents of the MQMD fields by setting XMSC\_WMQ\_MQMD\_READ\_ENABLED to true before receiving a message and then using the get methods of the message, such as getStringProperty. Any properties received are read-only.

This example results in the value field holding the value of the MQMD.ApplIdentityData field of a message got from a queue or a topic.

```
// Create a ConnectionFactory, connection, session, consumer
// ...

// Create a destination
// ...

// Enable MQMD read
dest.setBooleanProperty(XMSC_WMQ_MQMD_READ_ENABLED, XMSC_WMQ_MQMD_READ_ENABLED_YES);

// Receive a message
// ...

// Get required MQMD field value using a property
System.String value = rcvMsg.getStringProperty(JMS_IBM_MQMD_APPLIDENTITYDATA);
```

## Properties of MessageConsumer

An overview of the properties of the MessageConsumer object, with links to more detailed reference information.

<i>Table 879. Properties of MessageConsumer</i>	
<b>Name of property</b>	<b>Description</b>
<u>XMSC_IS_SUBSCRIPTION_MULTICAST</u>	Indicates whether messages are being delivered to the message consumer using WebSphere MQ Multicast Transport. This property is read-only.
<u>XMSC_IS_SUBSCRIPTION_RELIABLE_MULTICAST</u>	Indicates whether messages are being delivered to the message consumer using WebSphere MQ Multicast Transport with a reliable quality of service. This property is read-only.

Refer to [.NET properties of IMessageConsumer](#) for more details.

## Properties of MessageProducer

An overview of the properties of the MessageProducer object, with links to more detailed reference information.

See [.NET properties of IMessageProducer](#) for more details.

## Properties of Session

An overview of the properties of the Session object, with links to more detailed reference information.

See [.NET properties of ISession](#) for more details.

## Property definitions

This section provides a definition of each object property.

Each property definition includes the following information:

- The data type of the property
- The types of object that have the property
- For a property of Destination, the name that can be used in a uniform resource identifier (URI)
- A more detailed description of the property
- The valid values of the property
- The default value of the property

Properties whose names commence with one of the following prefixes are relevant only for the specified type of connection:

### **XMSC\_RTT**

The properties are relevant only for a real-time connection to a broker. The names of the properties are defined as named constants in the header file `xmsc_rtt.h`.

### **XMSC\_WMQ**

The properties are relevant only when an application connects to an IBM MQ queue manager. The names of the properties are defined as named constants in the header file `xmsc_wmq.h`.

### **XMSC\_WPM**

The properties are relevant only when an application connects to a WebSphere service integration bus. The names of the properties are defined as named constants in the header file `xmsc_wpm.h`.

Unless stated otherwise in their definitions, the remaining properties are relevant for all types of connection. The names of the properties are defined as named constants in the header file `xmsc.h`. Properties whose names commence with the prefix `JMSX` are JMS defined properties of a message, and properties whose names commence with the prefix `JMS_IBM` are IBM defined properties of a message. For more information about the properties of messages, see [Properties of an XMS message](#).

Unless stated otherwise in its definition, each property is relevant in both the point-to-point and publish/subscribe domains.

An application can get and set the value of any property, unless the property is designated as read-only.

## ***JMS\_IBM\_CHARACTER\_SET***

### **Data type:**

`System.Int32`

### **Property of:**

Message

The identifier (CCSID) of the coded character set, or code page, that the strings of character data in the body of the message is in when the XMS client forwards the message to its intended destination. In XMS, this property has a numeric value and maps to CCSID. However, this property is based on a JMS property so has a string type value and maps to the Java character set that represents this numeric CCSID. This property overrides any CCSID specified for the destination by the `XMSC_WMQ_CCSID` property.

By default, the property is not set.

This property is not relevant when an application connects to a service integration bus.

## ***JMS\_IBM\_ENCODING***

### **Data type:**

`System.Int32`

### **Property of:**

Message

How numerical data in the body of the message is represented when the XMS client forwards the message to its intended destination. This property overrides any encoding specified for the destination by the `XMSC_WMQ_ENCODING` property. The property specifies the representation of binary integers, packed decimal integers, and floating point numbers.

The valid values of the property are the same as the values that can be specified in the **Encoding** field of a message descriptor.

An application can use the following named constants to set the property:

<b>Named constant</b>	<b>Meaning</b>
<code>MQENC_INTEGER_NORMAL</code>	Normal integer encoding
<code>MQENC_INTEGER_REVERSED</code>	Reversed integer encoding
<code>MQENC_DECIMAL_NORMAL</code>	Normal packed decimal encoding
<code>MQENC_DECIMAL_REVERSED</code>	Reversed packed decimal encoding
<code>MQENC_FLOAT_IEEE_NORMAL</code>	Normal IEEE floating point encoding
<code>MQENC_FLOAT_IEEE_REVERSED</code>	Reversed IEEE floating point encoding
 <code>MQENC_FLOAT_S390</code>	z/OS architecture floating point encoding
<code>MQENC_NATIVE</code>	Native machine encoding

To form a value for the property, the application can add three of these constants as follows:

- A constant whose name commences with `MQENC_INTEGER`, to specify the representation of binary integers
- A constant whose name commences with `MQENC_DECIMAL`, to specify the representation of packed decimal integers
- A constant whose name commences with `MQENC_FLOAT`, to specify the representation of floating point numbers

Alternatively, the application can set the property to `MQENC_NATIVE`, whose value is environment-dependent.

By default, the property is not set.

This property is not relevant when an application connects to a service integration bus.

## ***JMS\_IBM\_EXCEPTIONMESSAGE***

**Data type:**

String

**Property of:**

Message

Text that describes why the message was sent to the exception destination. This property is read-only.

This property is relevant only when an application connects to a service integration bus and receives a message from an exception destination.

## ***JMS\_IBM\_EXCEPTIONPROBLEMDESTINATION***

**Data type:**

String

**Property of:**

Message

The name of the destination that the message was at before the message was sent to the exception destination.

This property is relevant only when an application connects to a service integration bus and receives a message from an exception destination.

### ***JMS\_IBM\_EXCEPTIONREASON***

**Data type:**  
System.Int32

**Property of:**  
Message

A reason code indicating the reason why the message was sent to the exception destination.

This property is relevant only when an application connects to a service integration bus and receives a message from an exception destination.

### ***JMS\_IBM\_EXCEPTIONTIMESTAMP***

**Data type:**  
System.Int64

**Property of:**  
Message

The time when the message was sent to the exception destination.

The time is expressed in milliseconds since 00:00:00 GMT on the 1 January 1970.

This property is relevant only when an application connects to a service integration bus and receives a message from an exception destination.

### ***JMS\_IBM\_FEEDBACK***

**Data type:**  
System.Int32

**Property of:**  
Message

A code that indicates the nature of a report message.

The valid values of the property are the feedback codes and reason codes that can be specified in the **Feedback** field of a message descriptor.

By default, the property is not set.

### ***JMS\_IBM\_FORMAT***

**Data type:**  
String

**Property of:**  
Message

The nature of the application data in the message.

The valid values of the property are the same as the values that can be specified in the **Format** field of a message descriptor.

By default, the property is not set.

This property is not relevant when an application connects to a service integration bus.

### ***JMS\_IBM\_LAST\_MSG\_IN\_GROUP***

**Data type:**  
System.Boolean

**Property of:**

Message

Indicate whether the message is the last message in a message group.

Set the property to true if the message is the last message in a message group. Otherwise, set the property to false, or do not set the property. By default, the property is not set.

The value true corresponds to the status flag MQMF\_LAST\_MSG\_IN\_GROUP, which can be specified in the **MsgFlags** field of a message descriptor. .

This property is ignored in the publish/subscribe domain and is not relevant when an application connects to a service integration bus.

**JMS\_IBM\_MSGTYPE****Data type:**

System.Int32

**Property of:**

Message

The type of the message.

The valid values of the property are as follows:

<b>Valid value</b>	<b>Meaning</b>
MQMT_DATAGRAM	The message is one that does not require a reply.
MQMT_REQUEST	The message is one that requires a reply.
MQMT_REPLY	The message is a reply message.
MQMT_REPORT	The message is a report message.

These values correspond to the message types that can be specified in the **MsgType** field of a message descriptor.

By default, the property is not set.

This property is not relevant when an application connects to a service integration bus.

**JMS\_IBM\_PUTAPPLTYPE****Data type:**

System.Int32

**Property of:**

Message

The type of application that sent the message.

The valid values of the property are the application types that can be specified in the **PutApplType** field of a message descriptor.

By default, the property is not set.

This property is not relevant when an application connects to a service integration bus.

**JMS\_IBM\_PUTDATE****Data type:**

String

**Property of:**

Message

The date when the message was sent.

The valid values of the property are the same as the values that can be specified in the **PutDate** field of a message descriptor.

By default, the property is not set.

This property is not relevant when an application connects to a service integration bus.

### ***JMS\_IBM\_PUTTIME***

**Data type:**

String

**Property of:**

Message

The time when the message was sent.

The valid values of the property are the same as the values that can be specified in the **PutTime** field of a message descriptor.

By default, the property is not set.

This property is not relevant when an application connects to a service integration bus.

### ***JMS\_IBM\_REPORT\_COA***

**Data type:**

System.Int32

**Property of:**

Message

Request 'confirm on arrival' report messages, specifying how much application data from the original message must be included in a report message.

The valid values of the property are as follows:

<b>Valid value</b>	<b>Meaning</b>
MQRO_COA	Request 'confirm on arrival' report messages, with no application data from the original message included in a report message.
MQRO_COA_WITH_DATA	Request 'confirm on arrival' report messages, with the first 100 bytes of application data from the original message included in a report message.
MQRO_COA_WITH_FULL_DATA	Request 'confirm on arrival' report messages, with all the application data from the original message included in a report message.

These values correspond to report options that can be specified in the **Report** field of a message descriptor. For more information about these options, see [Report \(MQLONG\)](#).

By default, the property is not set.

### ***JMS\_IBM\_REPORT\_COD***

**Data type:**

System.Int32

**Property of:**

Message

Request 'confirm on delivery' report messages, specifying how much application data from the original message must be included in a report message.

The valid values of the property are as follows:

<b>Valid value</b>	<b>Meaning</b>
MQRO_COD	Request 'confirm on delivery' report messages, with no application data from the original message included in a report message.
MQRO_COD_WITH_DATA	Request 'confirm on delivery' report messages, with the first 100 bytes of application data from the original message included in a report message.
MQRO_COD_WITH_FULL_DATA	Request 'confirm on delivery' report messages, with all the application data from the original message included in a report message.

These values correspond to report options that can be specified in the **Report** field of a message descriptor.

By default, the property is not set.

### ***JMS\_IBM\_REPORT\_DISCARD\_MSG***

**Data type:**  
System.Int32

**Property of:**  
Message

Request that the message is discarded if it cannot be delivered to its intended destination.

Set the property to MQRO\_DISCARD\_MSG to request that the message is discarded if it cannot be delivered to its intended destination. If you require the message to be put on a dead letter queue instead, or sent to an exception destination, do not set the property. By default, the property is not set.

The value MQRO\_DISCARD\_MSG corresponds to a report option that can be specified in the **Report** field of a message descriptor.

### ***JMS\_IBM\_REPORT\_EXCEPTION***

**Data type:**  
System.Int32

**Property of:**  
Message

Request exception report messages, specifying how much application data from the original message must be included in a report message.

The valid values of the property are as follows:

<b>Valid value</b>	<b>Meaning</b>
MQRO_EXCEPTION	Request exception report messages, with no application data from the original message included in a report message.
MQRO_EXCEPTION_WITH_DATA	Request exception report messages, with the first 100 bytes of application data from the original message included in a report message.
MQRO_EXCEPTION_WITH_FULL_DATA	Request exception report messages, with all the application data from the original message included in a report message.

These values correspond to report options that can be specified in the **Report** field of a message descriptor.

By default, the property is not set.

### ***JMS\_IBM\_REPORT\_EXPIRATION***

**Data type:**  
System.Int32

**Property of:**  
Message

Request expiration report messages, specifying how much application data from the original message must be included in a report message.

The valid values of the property are as follows:

<b>Valid value</b>	<b>Meaning</b>
MQRO_EXPIRATION	Request expiration report messages, with no application data from the original message included in a report message.
MQRO_EXPIRATION_WITH_DATA	Request expiration report messages, with the first 100 bytes of application data from the original message included in a report message.
MQRO_EXPIRATION_WITH_FULL_DATA	Request expiration report messages, with all the application data from the original message included in a report message.

These values correspond to report options that can be specified in the **Report** field of a message descriptor.

By default, the property is not set.

### ***JMS\_IBM\_REPORT\_NAN***

**Data type:**  
System.Int32

**Property of:**  
Message

Request negative action notification report messages.

Set the property to MQRO\_NAN to request negative action notification report messages. If you do not require negative action notification report messages, do not set the property. By default, the property is not set.

The value MQRO\_NAN corresponds to a report option that can be specified in the **Report** field of a message descriptor.

### ***JMS\_IBM\_REPORT\_PAN***

**Data type:**  
System.Int32

**Property of:**  
Message

Request positive action notification report messages.

Set the property to MQRO\_PAN to request positive action notification report messages. If you do not require positive action notification report messages, do not set the property. By default, the property is not set.

The value MQRO\_PAN corresponds to a report option that can be specified in the **Report** field of a message descriptor.

## ***JMS\_IBM\_REPORT\_PASS\_CORREL\_ID***

**Data type:**

System.Int32

**Property of:**

Message

Request that the correlation identifier of any report or reply message is the same as the correlation identifier of the original message.

The valid values of the property are as follows:

<b>Valid value</b>	<b>Meaning</b>
MQRO_PASS_CORREL_ID	Request that the correlation identifier of any report or reply message is the same as the correlation identifier of the original message.
MQRO_COPY_MSG_ID_TO_CORREL_ID	Request that the correlation identifier of any report or reply message is the same as the message identifier of the original message.

These values correspond to report options that can be specified in the **Report** field of a message descriptor. .

The default value of the property is MQRO\_COPY\_MSG\_ID\_TO\_CORREL\_ID.

## ***JMS\_IBM\_REPORT\_PASS\_MSG\_ID***

**Data type:**

System.Int32

**Property of:**

Message

Request that the message identifier of any report or reply message is the same as the message identifier of the original message.

The valid values of the property are as follows:

<b>Valid value</b>	<b>Meaning</b>
MQRO_PASS_MSG_ID	Request that the message identifier of any report or reply message is the same as the message identifier of the original message.
MQRO_NEW_MSG_ID	Request that a new message identifier is generated for each report or reply message.

These values correspond to report options that can be specified in the **Report** field of a message descriptor.

The default value of the property is MQRO\_NEW\_MSG\_ID.

## ***JMS\_IBM\_RETAIN***

**Data type:**

System.Int32

**Property of:**

Message

Setting this property indicates to the queue manager to treat a message as Retained Publication. When a subscriber receives messages from topics, it might receive additional messages immediately after subscribing, beyond the messages received in previous releases. These messages are the optional retained publications for the topics subscribed. For each topic matching the subscription, if there is a retained publication the publication is made available for delivery to the subscribing message consumer.

RETAIN\_PUBLICATION is the only valid value for this property. By default this property is not set.

**Note:** This property is relevant only in publish/subscribe domain only

### ***JMS\_IBM\_SYSTEM\_MESSAGEID***

**Data type:**

String

**Property of:**

Message

An identifier that identifies the message uniquely within the service integration bus. This property is read-only.

This property is relevant only when an application connects to a service integration bus.

### ***JMSX\_APPID***

**Data type:**

String

**Property of:**

Message

The name of the application that sent the message.

This property is the JMS defined property with the JMS name JMSXAppID. For more information about the property, see the *Java Message Service Specification, Version 1.1*.

By default, the property is not set.

This property is not valid for a real-time connection to a broker.

### ***JMSX\_DELIVERY\_COUNT***

**Data type:**

System.Int32

**Property of:**

Message

The number of attempts to deliver the message.

This property is the JMS defined property with the JMS name JMSXDeliveryCount. For more information about the property, see the *Java Message Service Specification, Version 1.1*.

By default, the property is not set.

This property is not valid for a real-time connection to a broker.

### ***JMSX\_GROUPID***

**Data type:**

String

**Property of:**

Message

The identifier of the message group to which the message belongs.

This property is the JMS defined property with the JMS name JMSXGroupID. For more information about the property, see the *Java Message Service Specification, Version 1.1*.

By default, the property is not set.

This property is not valid for a real-time connection to a broker.

## **JMSX\_GROUPSEQ**

**Data type:**

System.Int32

**Property of:**

Message

The sequence number of the message within a message group.

This property is the JMS defined property with the JMS name JMSXGroupSeq. For more information about the property, see the *Java Message Service Specification, Version 1.1*.

By default, the property is not set.

This property is not valid for a real-time connection to a broker.

## **JMSX\_USERID**

**Data type:**

String

**Property of:**

Message

The user identifier associated with the application that sent the message.

This property is the JMS defined property with the JMS name JMSXUserID. For more information about the property, see the *Java Message Service Specification, Version 1.1*.

By default, the property is not set.

This property is not valid for a real-time connection to a broker.

## **XMSC\_ASYNC\_EXCEPTIONS**

**Data type:**

System.Int32

**Property of:**

ConnectionFactory

**Applicable objects:**

JMS administration tool long name: ASYNCEXCEPTION

JMS administration tool short name: AEX

This property determines whether XMS informs an ExceptionListener only when a connection is broken, or when any exception occurs asynchronously to an XMS API call. This property applies to all Connections created from this ConnectionFactory that have an ExceptionListener registered.

Valid values for this property are:

### **XMSC\_ASYNC\_EXCEPTIONS\_ALL**

Any exception detected asynchronously, outside the scope of a synchronous API call, and all connection broken exceptions are sent to the ExceptionListener.

### **XMSC\_ASYNC\_EXCEPTIONS\_CONNECTIONBROKEN**

Only exceptions indicating a broken connection are sent to the ExceptionListener. Any other exceptions occurring during asynchronous processing are not reported to the ExceptionListener, and hence the application is not informed of these exceptions.

By default this property is set to XMSC\_ASYNC\_EXCEPTIONS\_ALL.

## **XMSC\_CLIENT\_ID**

**Data type:**

String

**Property of:**

ConnectionFactory

**Applicable objects:**

JMS administration tool long name: CLIENTID

JMS administration tool short name: CID

The client identifier for a connection.

A client identifier is used only to support durable subscriptions in the publish/subscribe domain, and is ignored in the point-to-point domain. For more information about setting client identifiers, see [ConnectionFactory](#)s and [Connection](#) objects.

This property is not relevant for a real-time connection to a broker.

***XMSC\_CONNECTION\_TYPE*****Data type:**

System.Int32

**Property of:**

ConnectionFactory

The type of messaging server to which an application connects.

The valid values of the property are as follows:

<b>Valid value</b>	<b>Meaning</b>
XMSC_CT_RTT	A real-time connection to a broker.
XMSC_CT_WMQ	A connection to an IBM MQ queue manager.
XMSC_CT_WPM	A connection to a WebSphere Application Server service integration bus.

By default, the property is not set.

***XMSC\_DELIVERY\_MODE*****Data type:**

System.Int32

**Property of:**

Destination

**Name used in a URI:**

persistence (for an IBM MQ destination)

deliveryMode (for a WebSphere default messaging provider destination)

**Applicable objects:**

JMS administration tool long name: PERSISTENCE

JMS administration tool short name: PER

The delivery mode of messages sent to the destination.

The valid values of the property are as follows:

<b>Valid value</b>	<b>Meaning</b>
XMSC_DELIVERY_NOT_PERSISTENT	A message sent to the destination is nonpersistent. The default delivery mode of the message producer, or any delivery mode specified on the Send call, is ignored. If the destination is an IBM MQ queue, the value of the queue attribute <i>DefPersistence</i> is also ignored.

**Valid value**

XMSC\_DELIVERY\_PERSISTENT

XMSC\_DELIVERY\_AS\_APP

XMSC\_DELIVERY\_AS\_DEST

**Meaning**

A message sent to the destination is persistent. The default delivery mode of the message producer, or any delivery mode specified on the Send call, is ignored. If the destination is an IBM MQ queue, the value of the queue attribute *DefPersistence* is also ignored.

A message sent to the destination has the delivery mode specified on the Send call. If the Send call specifies no delivery mode, the default delivery mode of the message producer is used instead. If the destination is an IBM MQ queue, the value of the queue attribute *DefPersistence* is ignored.

If the destination is an IBM MQ queue, a message put on the queue has the delivery mode specified by the value of the queue attribute *DefPersistence*. The default delivery mode of the message producer, or any delivery mode specified on the Send call, is ignored.

If the destination is not an IBM MQ queue, the meaning is the same as that of XMSC\_DELIVERY\_AS\_APP.

The default value is XMSC\_DELIVERY\_AS\_APP.

***XMSC\_IC\_PROVIDER\_URL*****Data type:**

String

**Property of:**

InitialContext

Used to locate the JNDI naming directory so that the COS naming service does not need to be on the same server as the web service.

***XMSC\_IC\_SECURITY\_AUTHENTICATION*****Data type:**

String

**Property of:**

InitialContext

Based on the Java Context interface SECURITY\_AUTHENTICATION. This property is only applicable to the COS naming context.

***XMSC\_IC\_SECURITY\_CREDENTIALS*****Data type:**

String

**Property of:**

InitialContext

Based on the Java Context interface SECURITY\_CREDENTIALS. This property is only applicable to the COS naming context.

## ***XMSC\_IC\_SECURITY\_PRINCIPAL***

**Data type:**

String

**Property of:**

InitialContext

Based on the Java Context interface SECURITY\_PRINCIPAL. This property is only applicable to the COS naming context.

## ***XMSC\_IC\_SECURITY\_PROTOCOL***

**Data type:**

String

**Property of:**

InitialContext

Based on the Java Context interface SECURITY\_PROTOCOL This property is only applicable to the COS naming context.

## ***XMSC\_IC\_URL***

**Data type:**

String

**Property of:**

InitialContext

For LDAP and FileSystem contexts, the address of the repository containing administered objects.

For LDAP and FileSystem contexts, the address of the repository containing administered objects.

## ***XMSC\_IS\_SUBSCRIPTION\_MULTICAST***

**Data type:**

System.Boolean

**Property of:**

MessageConsumer

Indicates whether messages are being delivered to the message consumer using WebSphere MQ Multicast Transport. This property is read-only.

The value of the property is true if messages are being delivered to the message consumer using WebSphere MQ Multicast Transport. Otherwise, the value is false.

This property is relevant only for a real-time connection to a broker.

## ***XMSC\_IS\_SUBSCRIPTION\_RELIABLE\_MULTICAST***

**Data type:**

System.Boolean

**Property of:**

MessageConsumer

Indicates whether messages are being delivered to the message consumer using WebSphere MQ Multicast Transport with a reliable quality of service. This property is read-only.

The value of the property is true if messages are being delivered to the message consumer using WebSphere MQ Multicast Transport with a reliable quality of service. Otherwise, the value is false.

This property is relevant only for a real-time connection to a broker.

## ***XMSC\_JMS\_MAJOR\_VERSION***

**Data type:**

System.Int32

**Property of:**

ConnectionMetaData

The major version number of the JMS specification upon which XMS is based. This property is read-only.

## ***XMSC\_JMS\_MINOR\_VERSION***

**Data type:**

System.Int32

**Property of:**

ConnectionMetaData

The minor version number of the JMS specification upon which XMS is based. This property is read-only.

## ***XMSC\_JMS\_VERSION***

**Data type:**

String

**Property of:**

ConnectionMetaData

The version identifier of the JMS specification upon which XMS is based. This property is read-only.

## ***XMSC\_MAJOR\_VERSION***

**Data type:**

System.Int32

**Property of:**

ConnectionMetaData

The version number of the XMS client. This property is read-only.

## ***XMSC\_MINOR\_VERSION***

**Data type:**

System.Int32

**Property of:**

ConnectionMetaData

The release number of the XMS client. This property is read-only.

## ***XMSC\_PASSWORD***

**Data type:**

Byte array

**Property of:**

ConnectionFactory

A password that can be used to authenticate the application when it attempts to connect to a messaging server. The password is used with the [XMSC\\_USERID](#) property.

By default, the property is not set.

 If you are connecting to IBM MQ on [Multiplatforms](#), and you set the XMSC\_USERID property of the connection factory, it must match the **userid** of the logged on user. If you do not set these properties, the queue manager uses the **userid** of the logged on user by default. If you require further connection-level authentication of individual users you can write a client authentication exit which is

configured in IBM MQ. For more information about creating a client authentication exit, see [Planning authentication for a client application](#).

 To authenticate the user when connecting to IBM MQ for z/OS you need to use a security exit.

## ***XMSC\_PRIORITY***

**Data type:**

System.Int32

**Property of:**

Destination

**Name used in a URI:**

priority

The priority of messages sent to the destination.

The valid values of the property are as follows:

<b>Valid value</b>	<b>Meaning</b>
An integer in the range 0, the lowest priority, to 9, the highest priority	A message sent to the destination has the specified priority. The default priority of the message producer, or any priority specified on the Send call, is ignored. If the destination is an IBM MQ queue, the value of the queue attribute <b>DefPriority</b> is also ignored.
XMSC_PRIORITY_AS_APP	A message sent to the destination has the priority specified on the Send call. If the Send call specifies no priority, the default priority of the message producer is used instead. If the destination is an IBM MQ queue, the value of the queue attribute <b>DefPriority</b> is ignored.
XMSC_PRIORITY_AS_DEST	If the destination is an IBM MQ queue, a message put on the queue has the priority specified by the value of the queue attribute <b>DefPriority</b> . The default priority of the message producer, or any priority specified on the Send call, is ignored.  If the destination is not an IBM MQ queue, the meaning is the same as that of XMSC_PRIORITY_AS_APP.

The default value is XMSC\_PRIORITY\_AS\_APP.

WebSphere MQ Real-Time Transport and WebSphere MQ Multicast Transport take no action based upon the priority of a message.

## ***XMSC\_PROVIDER\_NAME***

**Data type:**

String

**Property of:**

ConnectionMetaData

The provider of the XMS client. This property is read-only.

## ***XMSC\_RTT\_BROKER\_PING\_INTERVAL***

**Data type:**

System.Int32

**Property of:**

ConnectionFactory

The time interval, in milliseconds, after which XMS .NET checks the connection to a Real Time messaging server to detect any activity. If no activity is detected, the client initiates a ping; the connection is closed if no response is detected to the ping.

The default value of the property is 30000.

### ***XMSC\_RTT\_CONNECTION\_PROTOCOL***

**Data type:**

System.Int32

**Property of:**

ConnectionFactory

The communications protocol used for a real-time connection to a broker.

The value of the property must be XMSC\_RTT\_CP\_TCP, which means a real-time connection to a broker over TCP/IP. The default value is XMSC\_RTT\_CP\_TCP.

### ***XMSC\_RTT\_HOST\_NAME***

**Data type:**

String

**Property of:**

ConnectionFactory

The host name or IP address of the system on which a broker runs.

This property is used with the [XMSC\\_RTT\\_PORT](#) property to identify the broker.

By default, the property is not set.

### ***XMSC\_RTT\_LOCAL\_ADDRESS***

**Data type:**

String

**Property of:**

ConnectionFactory

The host name or IP address of the local network interface to be used for a real-time connection to a broker.

This property is useful only if the system on which the application is running has two or more network interfaces and you need to be able to specify which interface must be used for a real-time connection. If the system has only one network interface, only that interface can be used. If the system has two or more network interfaces and the property is not set, the interface is selected at random.

By default, the property is not set.

### ***XMSC\_RTT\_MULTICAST***

**Data type:**

System.Int32

**Property of:**

ConnectionFactory and Destination

**Name used in a URI:**

multicast

The multicast setting for a connection factory or destination. Only a destination that is a topic can have this property.

An application uses this property to enable multicast in association with a real-time connection to a broker and, if multicast is enabled, to specify the precise way in which multicast is used to deliver

messages from the broker to a message consumer. The property has no effect on how a message producer sends messages to the broker.

The valid values of the property are as follows:

<b>Valid value</b>	<b>Meaning</b>
XMSC_RTT_MULTICAST_DISABLED	Messages are not delivered to a message consumer using WebSphere MQ Multicast Transport. This value is the default value for a ConnectionFactory object.
XMSC_RTT_MULTICAST_ASCF	Messages are delivered to a message consumer according to the multicast setting for the connection factory associated with the message consumer. The multicast setting for the connection factory is noted at the time that the connection is created. This value is valid only for a Destination object, and is the default value for a Destination object.
XMSC_RTT_MULTICAST_ENABLED	If the topic is configured for multicast in the broker, messages are delivered to a message consumer using WebSphere MQ Multicast Transport. A reliable quality of service is used if the topic is configured for reliable multicast.
XMSC_RTT_MULTICAST_RELIABLE	If the topic is configured for reliable multicast in the broker, messages are delivered to a message consumer using WebSphere MQ Multicast Transport with a reliable quality of service. If the topic is not configured for reliable multicast, you cannot create a message consumer for the topic.
XMSC_RTT_MULTICAST_NOT_RELIABLE	If the topic is configured for multicast in the broker, messages are delivered to a message consumer using WebSphere MQ Multicast Transport. A reliable quality of service is not used even if the topic is configured for reliable multicast.

### ***XMSC\_RTT\_PORT***

**Data type:**  
System.Int32

**Property of:**  
ConnectionFactory

The number of the port on which a broker listens for incoming requests. On the broker, you must configure a Real-timeInput or Real-timeOptimizedFlow message processing node to listen on this port.

This property is used with the [XMSC\\_RTT\\_HOST\\_NAME](#) property to identify the broker.

The default value of the property is XMSC\_RTT\_DEFAULT\_PORT, or 1506.

### ***XMSC\_TIME\_TO\_LIVE***

**Data type:**  
System.Int32

**Property of:**  
Destination

**Name used in a URI:**

expiry (for an IBM MQ destination)

timeToLive (for a WebSphere default messaging provider destination)

The time to live for messages sent to the destination.

The valid values of the property are as follows:

Valid value	Meaning
0	A message sent to the destination never expires.
A positive integer	A message sent to the destination has the specified time to live in milliseconds. The default time to live of the message producer, or any time to live specified on the Send call, is ignored.
XMSC_TIME_TO_LIVE_AS_APP	A message sent to the destination has the time to live specified on the Send call. If the Send call specifies no time to live, the default time to live of the message producer is used instead.

The default value is XMSC\_TIME\_TO\_LIVE\_AS\_APP.

***XMSC\_USERID*****Data type:**

String

**Property of:**

ConnectionFactory

A user identifier that can be used to authenticate the application when it attempts to connect to a messaging server. The user identifier is used with the [XMSC\\_PASSWORD](#) property.

By default, the property is not set.

**Multi** If you are connecting to IBM MQ for Multiplatforms, and you set the XMSC\_USERID property of the connection factory, it must match the **userid** of the logged on user. If you do not set these properties, the queue manager uses the **userid** of the logged on user by default. If you require further connection-level authentication of individual users, you can write a client authentication exit that is configured in IBM MQ. For more information about creating a client authentication exit, see [Planning authentication for a client application](#).

**z/OS** To authenticate the user when connecting to IBM MQ for z/OS you need to use a security exit.

***XMSC\_VERSION*****Data type:**

String

**Property of:**

ConnectionMetaData

The version identifier of the cliXMSent. This property is read-only.

***XMSC\_WMQ\_BALANCING\_APPLICATION\_TYPE*****Data type:**

System.Int32

**Property of:**

ConnectionFactory

The valid values of the property are as follows:

<b>Valid value</b>	<b>Meaning</b>
XMSC_WMQ_BALANCING_APPLICATION_TYPE_SIMPLE	Simple balancing; no specific rules are applied in addition to those described in <a href="#">Influencing application re-balancing in uniform clusters</a> . This is the default value.
XMSC_WMQ_BALANCING_APPLICATION_TYPE_REQUEST_REPLY	Request-Reply balancing; after each MQPUT call, a matching MQGET call is expected for a response message. Balancing is delayed until such a message is received, or the request message EXPIRY has been exceeded

Additionally, this property can be set in the `client.ini` file. The order of preference is:

1. Properties set in the application
2. Matching named [Application stanza](#) in the `mqclient.ini` file.
3. [Application defaults stanza](#) in the `mqclient.ini` file.

### ***XMSC\_WMQ\_BALANCING\_OPTIONS***

**Data type:**  
System.Int32

**Property of:**  
ConnectionFactory

The valid values of the property are as follows:

<b>Valid value</b>	<b>Corresponding value</b>
XMSC_WMQ_BALANCING_OPTIONS_NONE	No options are set. This is the default value
XMSC_WMQ_BALANCING_OPTIONS_IGNORE_TRANSACTIONS	Setting this option allows applications to be rebalanced even if in the middle of a transaction.

Additionally, this property can be set in the `client.ini` file. The order of preference is:

1. Properties set in the application
2. Matching named [Application stanza](#) in the `mqclient.ini` file.
3. [Application defaults stanza](#) in the `mqclient.ini` file.

### ***XMSC\_WMQ\_BALANCING\_TIMEOUT***

**Data type:**  
System.Int32

**Property of:**  
ConnectionFactory

The valid values of the property are as follows:

<b>Valid value</b>	<b>Meaning</b>
XMSC_WMQ_BALANCING_TIMEOUT_IMMEDIATE	Immediate timeout occurs
XMSC_WMQ_BALANCING_TIMEOUT_AS_DEFAULT	The set default timeout value. This is the default value

<b>Valid value</b>	<b>Meaning</b>
XMSC_WMQ_BALANCING_TIMEOUT_NEVER	No timeout occurs

**Note:** You must provide one value only from the defined values, or a value of 0-999999999 seconds.

Additionally, this property can be set in the `client.ini` file. The order of preference is:

1. Properties set in the application
2. Matching named Application stanza in the `mqclient.ini` file.
3. Application defaults stanza in the `mqclient.ini` file.

### ***XMSC\_WMQ\_BROKER\_CONTROLQ***

**Data type:**

String

**Property of:**

ConnectionFactory

The name of the control queue used by a broker.

The default value of the property is `SYSTEM.BROKER.CONTROL.QUEUE`.

This property is relevant only in the publish/subscribe domain.

### ***XMSC\_WMQ\_BROKER\_PUBQ***

**Data type:**

String

**Property of:**

ConnectionFactory

The name of the queue monitored by a broker where applications send messages that they publish.

The default value of the property is `SYSTEM.BROKER.DEFAULT.STREAM`.

This property is relevant only in the publish/subscribe domain.

### ***XMSC\_WMQ\_BROKER\_QMGR***

**Data type:**

String

**Property of:**

ConnectionFactory

The name of the queue manager to which a broker is connected.

By default, the property is not set.

This property is relevant only in the publish/subscribe domain.

### ***XMSC\_WMQ\_BROKER\_SUBQ***

**Data type:**

String

**Property of:**

ConnectionFactory

The name of the subscriber queue for a nondurable message consumer.

The name of the subscriber queue must start with the following characters:

`SYSTEM.JMS.ND`.

If you want all nondurable message consumers to share a subscriber queue, specify the complete name of the shared queue. A queue with the specified name must exist before an application can create a nondurable message consumer.

If you want each nondurable message consumer to retrieve messages from its own exclusive subscriber queue, specify a queue name that ends with an asterisk (\*). Then, when an application creates a nondurable message consumer, the XMS client creates a dynamic queue for exclusive use by the message consumer. The XMS client uses the value of the property to set the contents of the **DynamicQueueName** field in the object descriptor that is used to create the dynamic queue.

The default value of the property is SYSTEM.JMS.ND.SUBSCRIBER.QUEUE, which means that XMS uses the shared queue approach by default.

This property is relevant only in the publish/subscribe domain.

### ***XMSC\_WMQ\_BROKER\_VERSION***

**Data type:**

System.Int32

**Property of:**

ConnectionFactory and Destination

**Name used in a URI:**

brokerVersion

The type of broker used by the application for a connection or for the destination. Only a destination that is a topic can have this property.

The valid values of the property are as follows:

<b>Valid value</b>	<b>Meaning</b>
XMSC_WMQ_BROKER_V1	The application is using an IBM MQ publish/subscribe broker.  The application can also use this value if you migrate from IBM MQ publish/subscribe to WebSphere Message Broker but did not change the application.
XMSC_WMQ_BROKER_V2	The application is using a broker of IBM Integration Bus.
XMSC_WMQ_BROKER_UNSPECIFIED	After the broker is migrated, set this property so that RFH2 headers are no longer used. After migration, this property is no longer relevant.

The default value for a connectionfactory is XMSC\_WMQ\_BROKER\_UNSPECIFIED but, by default, the property is not set for a destination. Setting the property for a destination overrides any value specified by the connection factory property.

### ***XMSC\_WMQ\_CCDTURL***

**Data type:**

System.String

**Property of:**

ConnectionFactory

**Applicable objects:**

JMS administration tool long name: CCDTURL

JMS administration tool short name: CCDT

A Uniform Resource Locator (URL) that identifies the name and location of the file that contains the client channel definition table and also specifies how the file can be accessed.

By default, this property is not set.

## ***XMSC\_WMQ\_CCSID***

**Data type:**

System.Int32

**Property of:**

Destination

**Name used in a URI:**

CCSID

The identifier (CCSID) of the coded character set, or code page, that the strings of character data in the body of a message are in when the XMS client forwards the message to the destination. If set for an individual message, the [JMS\\_IBM\\_CHARACTER\\_SET](#) property overrides the CCSID specified for the destination by this property.

The default value of the property is 1208.

This property is relevant only to messages sent to the destination, not to messages received from the destination.

## ***XMSC\_WMQ\_CHANNEL***

**Data type:**

String

**Property of:**

ConnectionFactory

**Applicable objects:**

JMS administration tool long name: CHANNEL

JMS administration tool short name: CHAN

The name of the channel to be used for a connection.

By default, the property is not set.

This property is relevant only when an application connects to a queue manager in client mode.

## ***XMSC\_WMQ\_CLIENT\_RECONNECT\_OPTIONS***

**Data type:**

String

**Property of:**

ConnectionFactory

**Applicable objects:**

JMS administration tool long name: CLIENTRECONNECTOPTIONS

JMS administration tool short name: CROPT

This property specifies the client reconnect options for new connections created by this factory. It is found in XMSC, and is one of:

- **WMQ\_CLIENT\_RECONNECT\_AS\_DEF** (default). Use the value specified in the `mqclient.ini` file. Set the value by using the **DefRecon** property within the Channels stanza. It can be set to one of:
  1. **YES**. Behaves as the `WMQ_CLIENT_RECONNECT` option
  2. **NO**. Default. Does not specify any reconnection options
  3. **QMGR**. Behaves as the `WMQ_CLIENT_RECONNECT_Q_MGR` option
  4. **DISABLED**. Behaves as the `WMQ_CLIENT_RECONNECT_DISABLED` option
- **WMQ\_CLIENT\_RECONNECT**. Reconnect to any of the queue managers specified in the connection name list.
- **WMQ\_CLIENT\_RECONNECT\_Q\_MGR**. Reconnects to the same queue manager that it is originally connected to. It returns `MQRC_RECONNECT_QMID_MISMATCH` if the queue manager it tries to connect

to (specified in the connection name list) has a different QMID to the queue manager originally connected to.

- WMQ\_CLIENT\_RECONNECT\_DISABLED. Reconnection is disabled.

### ***XMSC\_WMQ\_CLIENT\_RECONNECT\_TIMEOUT***

**Data type:**

String

**Property of:**

ConnectionFactory

**Applicable objects:**

JMS administration tool long name: CLIENTRECONNECTTIMEOUT

JMS administration tool short name: CRT

The XMSC\_WMQ\_CLIENT\_RECONNECT\_TIMEOUT property is valid only for the Managed XMS .NET client.

This property specifies the duration of time, in seconds, that a client connection attempts to reconnect.

After attempting to reconnect for this duration of time, the client will fail with MQRC\_RECONNECT\_FAILED. The default setting for this property is XMSC.WMQ\_CLIENT\_RECONNECT\_TIMEOUT\_DEFAULT.

The default value of this property is 1800.

### ***XMSC\_WMQ\_CONNECTION\_MODE***

**Data type:**

System.Int32

**Property of:**

ConnectionFactory

The mode by which an application connects to a queue manager.

The valid values of the property are as follows:

<b>Valid value</b>	<b>Meaning</b>
XMSC_WMQ_CM_BINDINGS	A connection to a queue manager in bindings mode, for optimal performance. This value is the default value for C/C++.
XMSC_WMQ_CM_CLIENT	A connection to a queue manager in client mode, to ensure a fully managed stack. This value is the default value for .NET.
XMSC_WMQ_CM_CLIENT_UNMANAGED (for .NET only)	A connection to a queue manager which forces an unmanaged client stack.

### ***XMSC\_WMQ\_CONNECTION\_NAME\_LIST***

**Data type:**

String

**Property of:**

ConnectionFactory

**Applicable objects:**

JMS administration tool long name: CONNECTIONNAMELIST

JMS administration tool short name: CNLIST

This property specifies the hosts to which the client attempts to reconnect to after its connection are broken.

The connection name list is a comma-separated list of host/ip port pairs. The default setting for this property is WMQ\_CONNECTION\_NAME\_LIST\_DEFAULT.

For example, 127.0.0.1 (1414), host2.example.com (1400)

The default setting of this property is localhost (1414).

## ***XMSC\_WMQ\_DUR\_SUBQ***

### **Data type:**

String

### **Property of:**

Destination

The name of the subscriber queue for a durable subscriber that is receiving messages from the destination. Only a destination that is a topic can have this property.

The name of the subscriber queue must start with the following characters:

SYSTEM.JMS.D.

If you want all durable subscribers to share a subscriber queue, specify the complete name of the shared queue. A queue with the specified name must exist before an application can create a durable subscriber.

If you want each durable subscriber to retrieve messages from its own exclusive subscriber queue, specify a queue name that ends with an asterisk (\*). Then, when an application creates a durable subscriber, the XMS client creates a dynamic queue for exclusive use by the durable subscriber. The XMS client uses the value of the property to set the contents of the **DynamicQName** field in the object descriptor that is used to create the dynamic queue.

The default value of the property is SYSTEM.JMS.D.SUBSCRIBER.QUEUE, which means that XMS uses the shared queue approach by default.

This property is relevant only in the publish/subscribe domain.

## ***XMSC\_WMQ\_ENCODING***

### **Data type:**

System.Int32

### **Property of:**

Destination

How numerical data in the body of a message is represented when the XMS client forwards the message to the destination. If set for an individual message, the `JMS_IBM_ENCODING` property overrides the encoding specified for the destination by this property. The property specifies the representation of binary integers, packed decimal integers, and floating point numbers.

The valid values of the property are the same as the values that can be specified in the **Encoding** field of a message descriptor.

An application can use the following named constants to set the property:

<b>Named constant</b>	<b>Meaning</b>
MQENC_INTEGER_NORMAL	Normal integer encoding
MQENC_INTEGER_REVERSED	Reversed integer encoding
MQENC_DECIMAL_NORMAL	Normal packed decimal encoding
MQENC_DECIMAL_REVERSED	Reversed packed decimal encoding
MQENC_FLOAT_IEEE_NORMAL	Normal IEEE floating point encoding
MQENC_FLOAT_IEEE_REVERSED	Reversed IEEE floating point encoding
 MQENC_FLOAT_S390	z/OS architecture floating point encoding
MQENC_NATIVE	Native machine encoding

To form a value for the property, the application can add three of these constants as follows:

- A constant whose name commences with MQENC\_INTEGER, to specify the representation of binary integers
- A constant whose name commences with MQENC\_DECIMAL, to specify the representation of packed decimal integers
- A constant whose name commences with MQENC\_FLOAT, to specify the representation of floating point numbers

Alternatively, the application can set the property to MQENC\_NATIVE, whose value is environment-dependent.

The default value of the property is MQENC\_NATIVE.

This property is relevant only to messages sent to the destination, not to messages received from the destination.

### ***XMSC\_WMQ\_FAIL\_IF\_QUIESCE***

**Data type:**

System.Int32

**Property of:**

ConnectionFactory and Destination

**Name used in a URI:**

failIfQuiesce

**Applicable objects:**

JMS administration tool long name: FAILIFQUIESCE

JMS administration tool short name: FIQ

Whether calls to certain methods fail if the queue manager to which the application is connected is in a quiescing state.

The valid values of the property are as follows:

<b>Valid value</b>	<b>Meaning</b>
XMSC_WMQ_FIQ_YES	Calls to certain methods fail if the queue manager is in a quiescing state. When the application detects that the queue manager is quiescing, the application can complete its immediate task and close the connection, allowing the queue manager to stop.
XMSC_WMQ_FIQ_NO	No method calls fail because the queue manager is in a quiescing state. If you specify this value, the application cannot detect that the queue manager is quiescing. The application might continue to perform operations against the queue manager and therefore prevent the queue manager from stopping.

The default value for a connection factory is XMSC\_WMQ\_FIQ\_YES but, by default, the property is not set for a destination. Setting the property for a destination overrides any value specified by the connection factory property.

### ***XMSC\_WMQ\_MESSAGE\_BODY***

**Data type:**

System.Int32

**Property of:**

Destination

This property determines whether an XMS application processes the MQRFH2 of an IBM MQ message as part of the message payload (that is, as part of the message body).

**Note:** When sending messages to a destination, XMSC\_WMQ\_MESSAGE\_BODY property supersedes existing XMS Destination property XMSC\_WMQ\_TARGET\_CLIENT.

Valid values for this property are:

#### **XMSC\_WMQ\_MESSAGE\_BODY\_JMS**

**Receive:** The inbound XMS message type and body are determined by the contents of the MQRFH2 (if present) or the MQMD (if there is no MQRFH2) in the received IBM MQ message.

**Send:** The outbound XMS message body contains a prepended and auto-generated MQRFH2 header based on XMS Message properties and header fields.

#### **XMSC\_WMQ\_MESSAGE\_BODY\_MQ**

**Receive:** The inbound XMS message type is always ByteMessage, irrespective of the contents of received IBM MQ message or the format field of the received MQMD. The XMS message body is the unaltered message data returned by the underlying messaging provider API call. The character set and encoding of the data in the message body is determined by the CodedCharSetId and Encoding fields of the MQMD. The format of the data in the message body is determined by the Format field of the MQMD.

**Send:** The outbound XMS message body contains the application payload as-is; and no auto-generated IBM MQ header is added to the body.

#### **XMSC\_WMQ\_MESSAGE\_BODY\_UNSPECIFIED**

**Receive:** The XMS client determines a suitable value for this property. On receive path, this value is the WMQ\_MESSAGE\_BODY\_JMS property value.

**Send:** The XMS client determines a suitable value for this property. On send path, this value is the XMSC\_WMQ\_TARGET\_CLIENT property value.

By default this property is set to XMSC\_WMQ\_MESSAGE\_BODY\_UNSPECIFIED.

### ***XMSC\_WMQ\_MQMD\_MESSAGE\_CONTEXT***

#### **Data type:**

System.Int32

#### **Property of:**

Destination

Determines what level of message context is to be set by the XMS application. The application must be running with appropriate context authority for this property to take effect.

The valid values for this property are:

#### **XMSC\_WMQ\_MDCTX\_DEFAULT**

For outbound messages, the MQOPEN API call and the MQPMO structure specifies no explicit message context options.

#### **XMSC\_WMQ\_MDCTX\_SET\_IDENTITY\_CONTEXT**

The MQOPEN API call specifies the message context option MQOO\_SET\_IDENTITY\_CONTEXT and the MQPMO structure specifies MQPMO\_SET\_IDENTITY\_CONTEXT.

#### **XMSC\_WMQ\_MDCTX\_SET\_ALL\_CONTEXT**

The MQOPEN API call specifies the message context option MQOO\_SET\_ALL\_CONTEXT and the MQPMO structure specifies MQPMO\_SET\_ALL\_CONTEXT.

By default this property is set to XMSC\_WMQ\_MDCTX\_DEFAULT.

**Note:** This property is not relevant when an application connects to WebSphere Application Server service integration bus.

The following properties require XMSC\_WMQ\_MQMD\_MESSAGE\_CONTEXT property to be set to XMSC\_WMQ\_MDCTX\_SET\_IDENTITY\_CONTEXT property value or XMSC\_WMQ\_MDCTX\_SET\_ALL\_CONTEXT property value when sending a message for in order to have wanted effect:

- JMS\_IBM\_MQMD\_USERIDENTIFIER
- JMS\_IBM\_MQMD\_ACCOUNTINGTOKEN
- JMS\_IBM\_MQMD\_APPLIDENTITYDATA

Following properties require XMSC\_WMQ\_MQMD\_MESSAGE\_CONTEXT property to be set to XMSC\_WMQ\_MDCTX\_SET\_ALL\_CONTEXT property value when sending a message for in order to have wanted effect:

- JMS\_IBM\_MQMD\_PUTAPPLTYPE
- JMS\_IBM\_MQMD\_PUTAPPLNAME
- JMS\_IBM\_MQMD\_PUTDATE
- JMS\_IBM\_MQMD\_PUTTIME
- JMS\_IBM\_MQMD\_APPLORIGINDATA

### ***XMSC\_WMQ\_MQMD\_READ\_ENABLED***

**Data type:**

System.Int32

**Property of:**

Destination

This property determines whether an XMS application can extract the values of MQMD fields or not.

The valid values for this property are:

#### **XMSC\_WMQ\_READ\_ENABLED\_NO**

When sending messages, the JMS\_IBM\_MQMD\* properties on a sent message are not updated to reflect the updated field values in the MQMD.

When receiving messages, none of the JMS\_IBM\_MQMD\* properties are available on a received message, even if some or all of them are set by the sender.

#### **XMSC\_WMQ\_READ\_ENABLED\_YES**

When sending messages, all of the JMS\_IBM\_MQMD\* properties on a sent message are updated to reflect the updated field values in the MQMD, including those properties that the sender did not set explicitly.

When receiving messages, all of the JMS\_IBM\_MQMD\* properties are available on a received message, including those properties that the sender did not set explicitly.

By default this property is set to XMSC\_WMQ\_READ\_ENABLED\_NO.

### ***XMSC\_WMQ\_MQMD\_WRITE\_ENABLED***

**Data type:**

System.Int32

**Property of:**

Destination

This property determines whether an XMS application can set the values of MQMD fields or not.

The valid values for this property are:

#### **XMSC\_WMQ\_WRITE\_ENABLED\_NO**

All JMS\_IBM\_MQMD\* properties are ignored and their values are not copied into the underlying MQMD structure.

#### **XMSC\_WMQ\_WRITE\_ENABLED\_YES**

JMS\_IBM\_MQMD\* properties are processed. Their values are copied into the underlying MQMD structure.

By default this property is set to XMSC\_WMQ\_WRITE\_ENABLED\_NO.

## ***XMSC\_WMQ\_PUT\_ASYNC\_ALLOWED***

**Data type:**

System.Int32

**Property of:**

Destination

This property determines whether message producers are allowed to use asynchronous puts to send messages to this destination.

The valid values for this property are:

***XMSC\_WMQ\_PUT\_ASYNC\_ALLOWED\_AS\_DEST***

Determine whether asynchronous puts are allowed by referring to the queue or topic definition.

***XMSC\_WMQ\_PUT\_ASYNC\_ALLOWED\_AS\_Q\_DEF***

Determine whether asynchronous puts are allowed by referring to the queue definition.

***XMSC\_WMQ\_PUT\_ASYNC\_ALLOWED\_AS\_TOPIC\_DEF***

Determine whether asynchronous puts are allowed by referring to the topic definition.

***XMSC\_WMQ\_PUT\_ASYNC\_ALLOWED\_DISABLED***

Asynchronous puts are not allowed.

***XMSC\_WMQ\_PUT\_ASYNC\_ALLOWED\_ENABLED***

Asynchronous puts are allowed.

By default this property is set to *XMSC\_WMQ\_PUT\_ASYNC\_ALLOWED\_AS\_DEST*.

**Note:** This property is not relevant when an application is connecting to WebSphere Application Server service integration bus.

## ***XMSC\_WMQ\_READ\_AHEAD\_ALLOWED***

**Data type:**

System.Int32

**Property of:**

Destination

This property determines whether message consumers and queue browsers are allowed to use read ahead to get non-persistent, non-transactional messages from this destination into an internal buffer before receiving them.

The valid values for this property are:

***XMSC\_WMQ\_READ\_AHEAD\_ALLOWED\_AS\_Q\_DEF***

Determine whether read ahead is allowed by referring to the queue definition.

***XMSC\_WMQ\_READ\_AHEAD\_ALLOWED\_AS\_TOPIC\_DEF***

Determine whether read ahead is allowed by referring to the topic definition.

***XMSC\_WMQ\_READ\_AHEAD\_ALLOWED\_AS\_DEST***

Determine whether read ahead is allowed by referring to the queue or topic definition.

***XMSC\_WMQ\_READ\_AHEAD\_ALLOWED\_DISABLED***

Read ahead is not allowed while consuming or browsing messages.

***XMSC\_WMQ\_READ\_AHEAD\_ALLOWED\_ENABLED***

Read ahead is allowed.

By default this property is set to *XMSC\_WMQ\_READ\_AHEAD\_ALLOWED\_AS\_DEST*.

## ***XMSC\_WMQ\_READ\_AHEAD\_CLOSE\_POLICY***

**Data type:**

System.Int32

**Property of:**

Destination

This property determines, for messages being delivered to an asynchronous message listener, what happens to messages in the internal read ahead buffer when the message consumer is closed.

This property is applicable in specifying closing queue options when consuming messages from a destination and not applicable when sending messages to a destination.

This property is ignored for queue browsers since during browse the messages are still available in the queues.

The valid values for this property are:

***XMSC\_WMQ\_READ\_AHEAD\_CLOSE\_POLICY\_DELIVER\_CURRENT***

Only the current message listener invocation completes before returning, potentially leaving messages in the internal read ahead buffer, which are then discarded.

***XMSC\_WMQ\_READ\_AHEAD\_CLOSE\_POLICY\_DELIVER\_ALL***

All messages in the internal read ahead buffer are delivered to the application message listener before returning.

By default this property is set to *XMSC\_WMQ\_READ\_AHEAD\_CLOSE\_POLICY\_DELIVER\_CURRENT*.

**Note:**

**Abnormal application termination**

All the messages in the read ahead buffer are lost when an XMS application terminates abruptly.

**Implications for transactions**

The read ahead is disabled when the applications use transactions. So, the application is not seeing any difference in the behavior when they use transacted sessions.

**Implications of session acknowledgement modes**

The read ahead is enabled on a non-transacted session when the acknowledgment modes are either *XMSC\_AUTO\_ACKNOWLEDGE* or *XMSC\_DUPS\_OK\_ACKNOWLEDGE*. The read ahead is disabled if the session acknowledgment mode is *XMSC\_CLIENT\_ACKNOWLEDGE* irrespective of transacted or non-transacted sessions.

**Implications for queue browsers and queue browser selectors**

The queue browsers and queue browser selectors, used in XMS applications, get the performance advantage from read ahead. Closing the queue browser does not degrade performance because the message is still available in the queue for any further operations. There are no other implications for queue browsers and queue browser selectors apart from performance benefits of read ahead.

## ***XMSC\_WMQ\_HOST\_NAME***

**Data type:**

String

**Property of:**

ConnectionFactory

**Applicable objects:**

JMS administration tool long name: HOSTNAME

JMS administration tool short name: HOST

The host name or IP address of the system on which a queue manager runs.

This property is used only when an application connects to a queue manager in client mode. The property is used with the *XMSC\_WMQ\_PORT* property to identify the queue manager.

The default value of the property is localhost.

## ***XMSC\_WMQ\_LOCAL\_ADDRESS***

**Data type:**

String

**Property of:**

ConnectionFactory

**Applicable objects:**

JMS administration tool long name: LOCALADDRESS

JMS administration tool short name: LA

For a connection to a queue manager, this property specifies the local network interface to be used, or the local port or range of local ports to be used, or both.

The value of the property is a string with the following format:

*[host\_name][(low\_port)[,high\_port]]*

The meanings of the variables are as follows:

***host\_name***

The host name or IP address of the local network interface to be used for the connection.

Providing this information is necessary only if the system on which the application is running has two or more network interfaces and you need to be able to specify which interface must be used for the connection. If the system has only one network interface, only that interface can be used. If the system has two or more network interfaces and you do not specify which interface must be used, the interface is selected at random.

***low\_port***

The number of the local port to be used for the connection.

If *high\_port* is also specified, *low\_port* is interpreted the lowest port number in a range of port numbers.

***high\_port***

The highest port number in a range of port numbers. One of the ports in the specified range must be used for the connection.

The maximum length of the string is 48 characters.

Here are some examples of valid values of the property:

JUPITER  
9.20.4.98  
JUPITER(1000)  
9.20.4.98(1000,2000)  
(1000)  
(1000,2000)

By default, the property is not set.

This property is relevant only when an application connects to a queue manager in client mode.

## ***XMSC\_WMQ\_MESSAGE\_SELECTION***

**Data type:**

System.Int32

**Property of:**

ConnectionFactory

Determines whether message selection is done by the XMS client or by the broker.

The valid values of the property are as follows:

<b>Valid value</b>	<b>Meaning</b>
XMSC_WMQ_MSEL_CLIENT	Message selection is done by the XMS client.
XMSC_WMQ_MSEL_BROKER	Message selection is done by the broker.

The default value is XMSC\_WMQ\_MSEL\_CLIENT.

This property is relevant only in the publish/subscribe domain. Message selection by the broker is not supported if the [XMSC\\_WMQ\\_BROKER\\_VERSION](#) property is set to XMSC\_WMQ\_BROKER\_V1.

### ***XMSC\_WMQ\_MSG\_BATCH\_SIZE***

**Data type:**

System.Int32

**Property of:**

ConnectionFactory

The maximum number of messages to be retrieved from a queue in one batch when using asynchronous message delivery.

When an application is using asynchronous message delivery, under certain conditions, the XMS client retrieves a batch of messages from a queue before forwarding each message individually to the application. This property specifies the maximum number of messages that can be in the batch.

The value of the property is a positive integer, and the default value is 10. Consider setting the property to a different value only if you have a specific performance problem that you need to address.

If an application is connected to a queue manager over a network, raising the value of this property can reduce network overheads and response times, but increase the amount of memory required to store the messages on the client system. Conversely, lowering the value of this property might increase network overheads and response times, but reduce the amount of memory required to store the messages.

### ***XMSC\_WMQ\_POLLING\_INTERVAL***

**Data type:**

System.Int32

**Property of:**

ConnectionFactory

If each message listener within a session has no suitable message on its queue, this value is the maximum interval, in milliseconds, that elapses before each message listener tries again to get a message from its queue.

If it frequently happens that no suitable message is available for any of the message listeners in a session, consider increasing the value of this property.

The value of the property is a positive integer. The default value is 5000.

### ***XMSC\_WMQ\_PORT***

**Data type:**

System.Int32

**Property of:**

ConnectionFactory

**Applicable objects:**

JMS administration tool long name: PORT

JMS administration tool short name: PORT

The number of the port on which a queue manager listens for incoming requests.

This property is used only when an application connects to a queue manager in client mode. The property is used with the [XMSC\\_WMQ\\_HOST\\_NAME](#) property to identify the queue manager.

The default value of the property is XMSC\_WMQ\_DEFAULT\_CLIENT\_PORT, or 1414.

### ***XMSC\_WMQ\_PROVIDER\_VERSION***

**Data type:**

String

**Property of:**

ConnectionFactory

The version, release, modification level and fix pack of the queue manager to which the application intends to connect. Valid values for this property are:

- Unspecified

Or a string in one of the following formats

- V.R.M.F
- V.R.M
- V.R
- V

Where V, R, M and F are integer values greater than or equal to zero.

By default this property is set to "unspecified".

The version of IBM MQ Client also plays major role in whether an XMS client application can use IBM MQ specific features.

**Note:** A system property XMSC\_WMQ\_OVERRIDEPROVIDERVERSION overrides the XMSC\_WMQ\_PROVIDER\_VERSION property. This property can be used if you are unable to change connection factory setting.

### ***XMSC\_WMQ\_PUB\_ACK\_INTERVAL***

**Data type:**

System.Int32

**Property of:**

ConnectionFactory

The number of messages published by a publisher before the XMS client requests an acknowledgment from the broker.

If you decrease the value of this property, the client requests acknowledgments more often, and therefore the performance of the publisher decreases. If you raise the value, the client takes a longer time to throw an exception if the broker fails.

The value of the property is a positive integer. The default value is 25.

### ***XMSC\_WMQ\_QMGR\_CCSID***

**Data type:**

System.Int32

**Property of:**

ConnectionFactory

The identifier (CCSID) of the coded character set, or code page, in which fields of character data defined in the Message Queue Interface (MQI) are exchanged between the XMS client and the IBM MQ client. This property does not apply to the strings of character data in the bodies of messages.

When XMS application connects to a queue manager in client mode, the XMS client links to the IBM MQ client. The information exchanged between the two clients contains fields of character data that are defined in the MQI. Under normal circumstances, the IBM MQ client assumes that these fields are in

the code page of the system on which the clients are running. If the XMS client provides and expects to receive these fields in a different code page, you must set this property to inform the IBM MQ client.

When the IBM MQ client forwards these fields of character data to the queue manager, the data in them must be converted if necessary into the code page used by the queue manager. Similarly, when the IBM MQ client receives these fields from the queue manager, the data in them must be converted if necessary into the code page in which the XMS client expects to receive the data. The IBM MQ client uses this property to perform these data conversions.

By default, the property is not set.

Setting this property is equivalent to setting the MQCCSID environment variable for an IBM MQ client that is supporting native IBM MQ client applications. For more information about this environment variable, see [MQCCSID](#).

## ***XMSC\_WMQ\_QUEUE\_MANAGER***

**Data type:**

String

**Property of:**

ConnectionFactory

**Applicable objects:**

JMS administration tool long name: QMANAGER

JMS administration tool short name: QMGR

The name of the queue manager to connect to.

By default, the property is not set.

## ***XMSC\_WMQ\_RECEIVE\_CCSID***

Destination property that sets the target CCSID for queue manager message conversion. The value is ignored unless XMSC\_WMQ\_RECEIVE\_CONVERSION is set to WMQ\_RECEIVE\_CONVERSION\_QMGR.

**Data type:**

Integer

**Value:**

Any positive integer.

The default value is 1208.

Specifying a GMO\_CONVERT value in a message is optional. If a GMO\_CONVERT value is specified, conversion takes place according to the value specified.

## ***XMSC\_WMQ\_RECEIVE\_CONVERSION***

Destination property that determines whether data conversion is going to be performed by the queue manager.

**Data type:**

Integer

**Values:**

XMSC\_WMQ\_RECEIVE\_CONVERSION\_CLIENT\_MSG (DEFAULT): Perform data conversion on the XMS client only. Conversion is always done using codepage 1208.

XMSC\_WMQ\_RECEIVE\_CONVERSION\_QMGR: Perform data conversion on the queue manager before sending a message to the XMS client.

## ***XMSC\_WMQ\_RECEIVE\_EXIT***

**Data type:**

String

**Property of:**

ConnectionFactory

Identifies a channel receive exit to be run.

The value of the property is a string that identifies a channel receive exit and has the following format:

**libraryName**(entryPointName)

where,

- **libraryName** is the full path of the managed exit .dll
- **entryPointName** is the class name qualified by the namespace

For example, C:\MyReceiveExit.dll(MyReceiveExitNameSpace.MyReceiveExitClassName)

By default, the property is not set.

This property is relevant only when an application connects to a queue manager in managed client mode. Also, only managed exits are supported.

***XMSC\_WMQ\_RECEIVE\_EXIT\_INIT*****Data type:**

String

**Property of:**

ConnectionFactory

The user data that is passed to a channel receive exit when it is called.

The value of the property is a string. By default, the property is not set.

This property is relevant only when an application connects to a queue manager in managed client mode and the [“XMSC\\_WMQ\\_RECEIVE\\_EXIT”](#) on page 2075 property is set.

***XMSC\_WMQ\_RESOLVED\_QUEUE\_MANAGER*****Data type:**

String

**Property of:**

ConnectionFactory

This property is used to obtain the name of the queue manager to which it is connected.

When used with a CCDT (Client Channel Definition Table), this name might be different from the queue manager name specified in the Connection Factory.

***XMSC\_WMQ\_RESOLVED\_QUEUE\_MANAGER\_ID*****Data type:**

String

**Property of:**

ConnectionFactory

This property is populated with the ID of the queue manager after the connection.

***XMSC\_WMQ\_SECURITY\_EXIT*****Data type:**

String

**Property of:**

ConnectionFactory

Identifies a channel security exit.

The value of the property is a string that identifies a channel security exit and has the following format:

**libraryName**(entryPointName)

where,

- **libraryName** is the full path of the managed exit .dll
- **entryPointName** is the class name qualified by the namespace

For example, C:\MySecurityExit.dll(MySecurityExitNameSpace.MySecurityExitClassName)

The maximum length of the string is 128 characters.

By default, the property is not set.

This property is relevant only when an application connects to a queue manager in managed client mode. Also, only managed exits are supported.

### ***XMSC\_WMQ\_SECURITY\_EXIT\_INIT***

**Data type:**

String

**Property of:**

ConnectionFactory

The user data that is passed to a channel security exit when it is called.

The maximum length of the string of user data is 32 characters.

By default, the property is not set.

This property is relevant only when an application connects to a queue manager in managed client mode and the [“XMSC\\_WMQ\\_SECURITY\\_EXIT”](#) on page 2076 property is set.

### ***XMSC\_WMQ\_SEND\_EXIT***

**Data type:**

String

**Property of:**

ConnectionFactory

Identifies a channel send exit.

The value of the property is a string. A channel send exit has the following format:

**libraryName**(entryPointName)

where,

- **libraryName** is the full path of the managed exit .dll
- **entryPointName** is the class name qualified by the namespace

For example, C:\MySendExit.dll(MySendExitNameSpace.MySendExitClassName)

By default, the property is not set.

This property is relevant only when an application connects to a queue manager in managed client mode. Also, only managed exits are supported.

### ***XMSC\_WMQ\_SEND\_EXIT\_INIT***

**Data type:**

String

**Property of:**

ConnectionFactory

The user data that is passed to channel send exits when they are called.

The value of the property is a string of one or more items of user data separated by commas. By default, the property is not set.

The rules for specifying user data that is passed to a sequence of channel send exits, are the same as the rules for specifying user data that is passed to a sequence of channel receive exits. For the rules therefore, see “[XMSC\\_WMQ\\_RECEIVE\\_EXIT\\_INIT](#)” on page 2076.

This property is relevant only when an application connects to a queue manager in managed client mode and the “[XMSC\\_WMQ\\_SEND\\_EXIT](#)” on page 2077 property is set.

### ***XMSC\_WMQ\_SEND\_CHECK\_COUNT***

**Data type:**

System.Int32

**Property of:**

ConnectionFactory

The number of send calls to allow between checking for asynchronous put errors, within a single non-transacted XMS session.

By default this property is set to 0.

### ***XMSC\_WMQ\_SHARE\_CONV\_ALLOWED***

**Data type:**

System.Int32

**Property of:**

ConnectionFactory

**Applicable objects:**

JMS administration tool long name: SHARECONVALLOWED

JMS administration tool short name: SCALD

Whether a client connection can share its socket with other top-level XMS connections from the same process to the same queue manager, if the channel definitions match. This property is provided to allow complete isolation of Connections in separate sockets if required for application development, maintenance, or operational reasons. Setting this property merely indicates to XMS to make the underlying socket shared. It does not indicate how many connections shares a single socket. The number of connections sharing a socket is determined by SHARECNV value which is negotiated between IBM MQ client and IBM MQ server.

An application can set the following named constants to set the property:

- XMSC\_WMQ\_SHARE\_CONV\_ALLOWED\_FALSE - Connections do not share a socket.
- XMSC\_WMQ\_SHARE\_CONV\_ALLOWED\_TRUE - Connections share a socket.

By default the property is set to XMSC\_WMQ\_SHARE\_CONV\_ALLOWED\_ENABLED.

This property is relevant only when an application connects to a queue manager in client mode.

### ***XMSC\_WMQ\_SSL\_CERT\_STORES***

**Data type:**

String

**Property of:**

ConnectionFactory

The locations of the servers that hold the certificate revocation lists (CRLs) to be used on an SSL connection to a queue manager.

The value of the property is a list of one or more URLs separated by commas. Each URL has the following format:

```
[user[/password]@]ldap://[serveraddress][:portnum][, ...]
```

This format is compatible with, but extended from, the basic MQJMS format.

It is valid to have an empty `serveraddress`. In this case, XMS assumes that the value is the string "localhost".

An example list is:

```
myuser/mypassword@ldap://server1.mycom.com:389
ldap://server1.mycom.com
ldap://
ldap://:389
```

For .NET only: Managed connections to IBM MQ (WMQ\_CM\_CLIENT) and unmanaged connections to IBM MQ (WMQ\_CM\_CLIENT\_UNMANAGED) both support TLS/SSL connections.

By default, the property is not set.

### Related concepts

[SSL and TLS support for the managed .NET client](#)

## ***XMSC\_WMQ\_SSL\_CIPHER\_SPEC***

### Data type:

String

### Property of:

ConnectionFactory

The name of the CipherSpec to be used on a secure connection to a queue manager.

Cipher specifications that you can use with IBM MQ TLS support are listed in the following table. When you request a personal certificate, you specify a key size for the public and private key pair. The key size that is used during the SSL handshake is the size stored in the certificate unless it is determined by the CipherSpec, as noted in the table. By default, this property is not set.

CipherSpec name	Protocol used	Hash algorithm	Encryption algorithm	Encryption bits	FIPS <sup>1</sup>	Suite B 128 bit	Suite B 192 bit
TLS_RSA_WITH_AES_128_CBC_SHA	TLS 1.0	SHA-1	AES	128	Yes	No	No
TLS_RSA_WITH_AES_256_CBC_SHA <sup>2</sup>	TLS 1.0	SHA-1	AES	256	Yes	No	No
TLS_RSA_WITH_DES_CBC_SHA	TLS 1.0	SHA-1	DES	56	No	No	No
TLS_RSA_WITH_3DES_EDE_CBC_SHA <sup>4</sup>	TLS 1.0	SHA-1	3DES	168	Yes	No	No
TLS_RSA_WITH_AES_128_GCM_SHA256	TLS 1.2	SHA-256	AES	128	Yes	No	No
TLS_RSA_WITH_AES_256_GCM_SHA384	TLS 1.2	SHA-384	AES	256	Yes	No	No
TLS_RSA_WITH_AES_128_CBC_SHA256	TLS 1.2	SHA-256	AES	128	Yes	No	No
TLS_RSA_WITH_AES_256_CBC_SHA256	TLS 1.2	SHA-256	AES	256	Yes	No	No

<b>CipherSpec name</b>	<b>Protocol used</b>	<b>Hash algorithm</b>	<b>Encryption algorithm</b>	<b>Encryption bits</b>	<b>FIPS<sup>1</sup></b>	<b>Suite B 128 bit</b>	<b>Suite B 192 bit</b>
ECDHE_ECDSA_RC4_128_SHA256	TLS 1.2	SHA-256	RC4	128	No	No	No
ECDHE_ECDSA_3DES_EDE_CBC_SHA256	TLS 1.2	SHA-256	3DES	168	Yes	No	No
ECDHE_RSA_RC4_128_SHA256	TLS 1.2	SHA-256	RC4	128	No	No	No
ECDHE_RSA_3DES_EDE_CBC_SHA256	TLS 1.2	SHA-256	3DES	168	Yes	No	No
ECDHE_ECDSA_AES_128_CBC_SHA256	TLS 1.2	SHA-256	AES	128	Yes	No	No
ECDHE_ECDSA_AES_256_CBC_SHA384	TLS 1.2	SHA-384	AES	256	Yes	No	No
ECDHE_RSA_AES_128_CBC_SHA256	TLS 1.2	SHA-256	AES	128	Yes	No	No
ECDHE_RSA_AES_256_CBC_SHA384	TLS 1.2	SHA-384	AES	256	Yes	No	No
ECDHE_ECDSA_AES_128_GCM_SHA256	TLS 1.2	SHA-256	AES	128	Yes	Yes	No
ECDHE_ECDSA_AES_256_GCM_SHA384	TLS 1.2	SHA-384	AES	256	Yes	No	Yes
ECDHE_RSA_AES_128_GCM_SHA256	TLS 1.2	SHA-256	AES	128	Yes	No	No
ECDHE_RSA_AES_256_GCM_SHA384	TLS 1.2	SHA-384	AES	256	Yes	No	No

TLS_RSA_WITH_NULL_NULL	TLS 1.2	None	None	0	No	No	No
TLS_RSA_WITH_RC4_128_SHA256	TLS 1.2	SHA-256	RC4	128	No	No	No

CipherSpec name	Protocol used	Hash algorithm	Encryption algorithm	Encryption bits	FIPS <sup>1</sup>	Suite B 128 bit	Suite B 192 bit
-----------------	---------------	----------------	----------------------	-----------------	-------------------	-----------------	-----------------

**Notes:**

1. Specifies whether the CipherSpec complies with Federal Information Processing Standards (FIPS) 140-2. For an explanation of FIPS and information about how to configure IBM MQ for FIPS 140-2 compliant operation, see [Federal Information Processing Standards \(FIPS\)](#).
2. This CipherSpec cannot be used to secure a connection from the IBM MQ Explorer to a queue manager unless the appropriate unrestricted policy files are applied to the JRE used by the IBM MQ Explorer.
3. This CipherSpec was FIPS 140-2 certified before 19 May 2007.
4. When IBM MQ is configured for FIPS 140-2 compliant operation, this CipherSpec can be used to transfer up to 32 GB of data before the connection is terminated with error AMQ9288. To avoid this error, either avoid using triple DES (which is deprecated), or enable secret key reset when using this CipherSpec in a FIPS 140-2 configuration.

[Specifying CipherSpecs](#)

***XMSC\_WMQ\_SSL\_CIPHER\_SUITE***

**Data type:**

String

**Property of:**

ConnectionFactory

The name of the CipherSuite to be used on a TLS connection to a queue manager. The protocol used in negotiating the secure connection depends on the specified CipherSuite.

This property has the following canonical values:

- SSL\_RSA\_WITH\_DES\_CBC\_SHA
- SSL\_RSA\_EXPORT1024\_WITH\_DES\_CBC\_SHA
- SSL\_RSA\_EXPORT1024\_WITH\_RC4\_56\_SHA
- SSL\_RSA\_EXPORT\_WITH\_RC4\_40\_MD5
- SSL\_RSA\_WITH\_RC4\_128\_MD5
- SSL\_RSA\_WITH\_RC4\_128\_SHA
- SSL\_RSA\_WITH\_3DES\_EDE\_CBC\_SHA
- SSL\_RSA\_WITH\_AES\_128\_CBC\_SHA
- SSL\_RSA\_WITH\_AES\_256\_CBC\_SHA
- SSL\_RSA\_WITH\_DES\_CBC\_SHA
- SSL\_RSA\_WITH\_3DES\_EDE\_CBC\_SHA

This value can be supplied as an alternative to `XMSC_WMQ_SSL_CIPHER_SPEC`.

If a non-empty value is specified for `XMSC_WMQ_SSL_CIPHER_SPEC`, this value overrides the setting for `XMSC_WMQ_SSL_CIPHER_SUITE`. If `XMSC_WMQ_SSL_CIPHER_SPEC` does not have a value, the value of `XMSC_WMQ_SSL_CIPHER_SUITE` is used as the cipher suite to be given to IBM Global Security Kit (GSKit). In this case, the value is mapped on to the equivalent CipherSpec value, as described in [CipherSuite and CipherSpec name mappings for XMS connections to an IBM MQ queue manager](#).

If both XMSC\_WMQ\_SSL\_CIPHER\_SPEC and XMSC\_WMQ\_SSL\_CIPHER\_SUITE are empty, the field pChDef->SSLCipherSpec is filled with spaces.

For .NET only: Managed connections to IBM MQ (WMQ\_CM\_CLIENT) and unmanaged connections to IBM MQ (WMQ\_CM\_CLIENT\_UNMANAGED) both support TLS/SSL connections.

By default, the property is not set.

#### **Related concepts**

[SSL and TLS support for the unmanaged .NET client](#)

[SSL and TLS support for the managed .NET client](#)

### ***XMSC\_WMQ\_SSL\_CRYPTO\_HW***

#### **Data type:**

String

#### **Property of:**

ConnectionFactory

Configuration details for the cryptographic hardware connected to the client system.

This property has the following canonical values:

- GSK\_ACCELERATOR\_RAINBOW\_CS\_OFF
- GSK\_ACCELERATOR\_RAINBOW\_CS\_ON
- GSK\_ACCELERATOR\_NCIPHER\_NF\_OFF
- GSK\_ACCELERATOR\_NCIPHER\_NF\_ON

There is a special format for PKCS11 cryptographic hardware (where DriverPath, TokenLabel, and TokenPassword are user-specified strings):

```
GSK_PKCS11=PKCS#11 DriverPath; PKCS#11 TokenLabel;PKCS#11 TokenPassword
```

XMS does not interpret or alter the contents of the string. It copies the value supplied, up to a limit of 256 single-byte characters, into the MQSCO.CryptoHardware field.

For .NET only: Managed connections to IBM MQ (WMQ\_CM\_CLIENT) and unmanaged connections to IBM MQ (WMQ\_CM\_CLIENT\_UNMANAGED) both support TLS/SSL connections.

By default, the property is not set.

#### **Related concepts**

[SSL and TLS support for the unmanaged .NET client](#)

[SSL and TLS support for the managed .NET client](#)

### ***XMSC\_WMQ\_SSL\_FIPS\_REQUIRED***

#### **Data type:**

Boolean

#### **Property of:**

ConnectionFactory

The value of this property determines whether an application can or cannot use non-FIPS compliant cipher suites. If this property is set to true, only FIPS algorithms are used for the client-server connection.

This property can have the following values, which translate to the two canonical values for MQSCO.FipsRequired:

Table 880. Table of values for MQSCO.FlipsRequired property

Value	Description	Corresponding value of MQSCO.FlipsRequired
false	Any CipherSpec can be used.	MQSSL_FIPS_NO (the default)
true	Only FIPS-certified cryptographic algorithms can be used in the CipherSpec applying to this client connection.	MQSSL_FIPS_YES

XMS copies the relevant value into MQSCO.FlipsRequired before calling MQCONN.

For .NET only: Managed connections to IBM MQ (WMQ\_CM\_CLIENT) and unmanaged connections to IBM MQ (WMQ\_CM\_CLIENT\_UNMANAGED) both support TLS/SSL connections.

**Related concepts**

[SSL and TLS support for the unmanaged .NET client](#)

[SSL and TLS support for the managed .NET client](#)

***XMSC\_WMQ\_SSL\_KEY\_REPOSITORY***

**Data type:**

String

**Property of:**

ConnectionFactory

The location of the key database file in which keys and certificates are stored.

XMS copies the string, up to a limit of 256 single-byte characters, into the MQSCO.KeyRepository field. IBM MQ interprets this string as a filename, including the full path.

For .NET only: Managed connections to IBM MQ (WMQ\_CM\_CLIENT) and unmanaged connections to IBM MQ (WMQ\_CM\_CLIENT\_UNMANAGED) both support TLS/SSL connections.

By default, the property is not set.

**Related concepts**

[SSL and TLS support for the unmanaged .NET client](#)

[SSL and TLS support for the managed .NET client](#)

***XMSC\_WMQ\_SSL\_KEY\_RESETCOUNT***

**Data type:**

System.Int32

**Property of:**

ConnectionFactory

The KeyResetCount represents the total number of unencrypted bytes sent and received within an SSL conversation before the secret key is renegotiated. The number of bytes includes control information sent by the MCA.

XMS copies the value that you supply for this property into MQSCO.KeyResetCount before calling MQCONN.

The parameter MQSCO.KeyRestCount is only available from IBM MQ version 6. If IBM MQ version 5.3, if this property is set, XMS does not attempt to make the connection to the queue manager, and throws an appropriate exception instead.

For .NET only: Managed connections to IBM MQ (WMQ\_CM\_CLIENT) and unmanaged connections to IBM MQ (WMQ\_CM\_CLIENT\_UNMANAGED) both support TLS/SSL connections.

The default value of this property is zero, which means that secret keys are never renegotiated.

## Related concepts

[SSL and TLS support for the unmanaged .NET client](#)

[SSL and TLS support for the managed .NET client](#)

## ***XMSC\_WMQ\_SSL\_PEER\_NAME***

### Data type:

String

### Property of:

ConnectionFactory

The peer name to be used on an SSL connection to a queue manager.

There is no list of canonical values for this property. Instead, you must build this string according to the rules for SSLPEER.

An example of a peer name is:

```
"CN=John Smith, O=IBM ,OU=Test , C=GB"
```

XMS copies the string into the correct single-byte code page, and places the correct values into MQCD.SSLPeerNamePtr and MQCD.SSLPeerNameLength before calling MQCONN.

This property is relevant only if the application connects to a queue manager in client mode.

For .NET only: Managed connections to IBM MQ (WMQ\_CM\_CLIENT) and unmanaged connections to IBM MQ (WMQ\_CM\_CLIENT\_UNMANAGED) both support TLS/SSL connections.

By default, the property is not set.

[SSLPEERNAME](#)

## ***XMSC\_WMQ\_SYNCPOINT\_ALL\_GETS***

### Data type:

System.Boolean

### Property of:

ConnectionFactory

Whether all messages must be retrieved from queues within sync point control.

The valid values of the property are as follows:

Valid value	Meaning
false	When the circumstances are appropriate, the XMS client can retrieve messages from queues outside of sync point control.
true	The XMS client must retrieve all messages from queues within sync point control.

The default value is false.

## ***XMSC\_WMQ\_TARGET\_CLIENT***

### Data type:

System.Int32

**Property of:**  
Destination

**Name used in a URI:**  
targetClient

Whether messages sent to the destination contain an MQRFH2 header.

If an application sends a message containing an MQRFH2 header, the receiving application must be able to handle the header.

The valid values of the property are as follows:

Valid value	Meaning
XMSC_WMQ_TARGET_DEST_JMS	Messages sent to the destination contain an MQRFH2 header. Specify this value if the application is sending the messages to another XMS application, an IBM MQ classes for JMS application, or a native IBM MQ application that is designed to handle an MQRFH2 header.
XMSC_WMQ_TARGET_DEST_MQ	Messages sent to the destination do not contain an MQRFH2 header. Specify this value if the application is sending the messages to a native IBM MQ application that is not designed to handle an MQRFH2 header.

The default value is XMSC\_WMQ\_TARGET\_DEST\_JMS.

### ***XMSC\_WMQ\_TEMP\_Q\_PREFIX***

**Data type:**  
String

**Property of:**  
ConnectionFactory

The prefix used to form the name of the IBM MQ dynamic queue that is created when the application creates an XMS temporary queue.

The rules for forming the prefix are the same as the rules for forming the contents of the **DynamicQName** field in an object descriptor, but the last non-blank character must be an asterisk(\*). By default, the property is not set. If it is not set, the following value is used:

-  AMQ.\* on Multiplatforms
-  CSQ.\* on z/OS

This property is relevant only in the point-to-point domain.

### ***XMSC\_WMQ\_TEMP\_TOPIC\_PREFIX***

**Data type:**  
String

**Property of:**  
ConnectionFactory, Destination

When creating temporary topics, XMS generates a topic string of the form "TEMP/TEMPTOPICPREFIX/unique\_id", or if this property contains the default value, then this string, "TEMP/unique\_id", is generated. Specifying a non-empty value allows specific model queues to be defined for creating the managed queues for subscribers to temporary topics created under this connection.

Any non-null string consisting only of valid characters for an IBM MQ topic string is a valid value for this property.

By default this property is set to "" (empty string).

**Note:** This property is relevant only in the publish/subscribe domain.

### ***XMSC\_WMQ\_TEMPORARY\_MODEL***

**Data type:**

String

**Property of:**

ConnectionFactory

The name of the IBM MQ model queue from which a dynamic queue is created when the application creates an XMS temporary queue.

The default value of the property is SYSTEM.DEFAULT.MODEL.QUEUE.

This property is relevant only in the point-to-point domain.

### ***XMSC\_WMQ\_WILDCARD\_FORMAT***

**Data type:**

System.Int32

**Property of:**

ConnectionFactory, Destination

This property determines which version of wildcard syntax is to be used.

When using publish/subscribe with IBM MQ '\*' and '?' are treated as wildcards. Whereas '#' and '+' are treated as wildcards when using publish subscribe with IBM Integration Bus. This property replaces the XMSC\_WMQ\_BROKER\_VERSION property.

The valid values for this property are:

#### ***XMSC\_WMQ\_WILDCARD\_TOPIC\_ONLY***

Recognizes the topic level wildcards only i.e. '#' and '+' are treated as wildcards. This value is same as XMSC\_WMQ\_BROKER\_V2.

#### ***XMSC\_WMQ\_WILDCARD\_CHAR\_ONLY***

Recognizes the character wildcards only i.e. '\*' and '?' are treated as wildcards. This value is same as XMSC\_WMQ\_BROKER\_V1.

By default this property is set to XMSC\_WMQ\_WILDCARD\_TOPIC\_ONLY.

### ***XMSC\_WPM\_BUS\_NAME***

**Data type:**

String

**Property of:**

ConnectionFactory and Destination

**Name used in a URI:**

busName

For a connection factory, the name of the service integration bus that the application connects to or, for a destination, the name of the service integration bus in which the destination exists.

For a destination that is a topic, this property is the name of the service integration bus in which the associated topic space exists. This topic space is specified by the [XMSC\\_WPM\\_TOPIC\\_SPACE](#) property.

If the property is not set for a destination, the queue or associated topic space is assumed to exist in the service integration bus to which the application connects.

By default, the property is not set.

### ***XMSC\_WPM\_CONNECTION\_PROTOCOL***

**Data type:**

System.Int32

**Property of:**

Connection

The communications protocol used for the connection to the messaging engine. This property is read-only.

The possible values of the property are as follows:

<b>Value</b>	<b>Meaning</b>
XMSC_WPM_CP_HTTP	The connection uses HTTP over TCP/IP.
XMSC_WPM_CP_TCP	The connection uses TCP/IP.

***XMSC\_WPM\_CONNECTION\_PROXIMITY*****Data type:**

System.Int32

**Property of:**

ConnectionFactory

The connection proximity setting for the connection. This property determines how close the messaging engine that the application connects to must be to the bootstrap server.

The valid values of the property are as follows:

<b>Valid value</b>	<b>Connection proximity setting</b>
XMSC_WPM_CONNECTION_PROXIMITY_BUS	Bus
XMSC_WPM_CONNECTION_PROXIMITY_CLUSTER	Cluster
XMSC_WPM_CONNECTION_PROXIMITY_HOST	Host
XMSC_WPM_CONNECTION_PROXIMITY_SERVER	Server

The default value is XMSC\_WPM\_CONNECTION\_PROXIMITY\_BUS.

***XMSC\_WPM\_DUR\_SUB\_HOME*****Data type:**

String

**Property of:**

ConnectionFactory

**Name used in a URI:**

durableSubscriptionHome

The name of the messaging engine where all durable subscriptions for a connection or a destination are managed. Messages to be delivered to the durable subscribers are stored at the publication point of the same messaging engine.

A durable subscription home must be specified for a connection before an application can create a durable subscriber that uses the connection. Any value specified for a destination overrides the value specified for the connection.

By default, the property is not set.

This property is relevant only in the publish/subscribe domain.

***XMSC\_WPM\_HOST\_NAME*****Data type:**

String

**Property of:**

Connection

The host name or IP address of the system that contains the messaging engine to which the application is connected. This property is read-only.

***XMSC\_WPM\_LOCAL\_ADDRESS*****Data type:**

String

**Property of:**

ConnectionFactory

For a connection to a service integration bus, this property specifies the local network interface to be used, or the local port or range of local ports to be used, or both.

The value of the property is a string with the following format:

*[host\_name][(*low\_port*),*high\_port*]*

The meanings of the variables are as follows:

***host\_name***

The host name or IP address of the local network interface to be used for the connection.

Providing this information is necessary only if the system on which the application is running has two or more network interfaces and you need to be able to specify which interface must be used for the connection. If the system has only one network interface, only that interface can be used. If the system has two or more network interfaces and you do not specify which interface must be used, the interface is selected at random.

***low\_port***

The number of the local port to be used for the connection.

If *high\_port* is also specified, *low\_port* is interpreted the lowest port number in a range of port numbers.

***high\_port***

The highest port number in a range of port numbers. One of the ports in the specified range must be used for the connection.

Here are some examples of valid values of the property:

JUPITER  
9.20.4.98  
JUPITER(1000)  
9.20.4.98(1000,2000)  
(1000)  
(1000,2000)

By default, the property is not set.

***XMSC\_WPM\_ME\_NAME*****Data type:**

String

**Property of:**

Connection

The name of the messaging engine to which the application is connected. This property is read-only.

***XMSC\_WPM\_NON\_PERSISTENT\_MAP*****Data type:**

System.Int32

**Property of:**

ConnectionFactory

The reliability level of nonpersistent messages that are sent using the connection.

The valid values of the property are as follows:

<b>Valid value</b>	<b>Reliability level</b>
XMSC_WPM_MAPPING_AS_DESTINATION	Determined by the default reliability level specified for the queue or topic space in the service integration bus
XMSC_WPM_MAPPING_BEST_EFFORT_NON_PERSISTENT	Best effort nonpersistent
XMSC_WPM_MAPPING_EXPRESS_NON_PERSISTENT	Express nonpersistent
XMSC_WPM_MAPPING_RELIABLE_NON_PERSISTENT	Reliable nonpersistent
XMSC_WPM_MAPPING_RELIABLE_PERSISTENT	Reliable persistent
XMSC_WPM_MAPPING_ASSURED_PERSISTENT	Assured persistent

The default value is XMSC\_WPM\_MAPPING\_EXPRESS\_NON\_PERSISTENT.

***XMSC\_WPM\_PERSISTENT\_MAP*****Data type:**

System.Int32

**Property of:**

ConnectionFactory

The reliability level of persistent messages that are sent using the connection.

The valid values of the property are as follows:

<b>Valid value</b>	<b>Reliability level</b>
XMSC_WPM_MAPPING_AS_DESTINATION	Determined by the default reliability level specified for the queue or topic space in the service integration bus
XMSC_WPM_MAPPING_BEST_EFFORT_NON_PERSISTENT	Best effort nonpersistent
XMSC_WPM_MAPPING_EXPRESS_NON_PERSISTENT	Express nonpersistent
XMSC_WPM_MAPPING_RELIABLE_NON_PERSISTENT	Reliable nonpersistent
XMSC_WPM_MAPPING_RELIABLE_PERSISTENT	Reliable persistent
XMSC_WPM_MAPPING_ASSURED_PERSISTENT	Assured persistent

The default value is XMSC\_WPM\_MAPPING\_RELIABLE\_PERSISTENT.

## ***XMSC\_WPM\_PORT***

**Data type:**

System.Int32

**Property of:**

Connection

The number of the port listened on by the messaging engine to which the application is connected. This property is read-only.

## ***XMSC\_WPM\_PROVIDER\_ENDPOINTS***

**Data type:**

String

**Property of:**

ConnectionFactory

A sequence of one or more endpoint addresses of bootstrap servers. The endpoint addresses are separated by commas.

A bootstrap server is an application server that is responsible for selecting the messaging engine to which the application connects. The endpoint address of a bootstrap server has the following format:

*host\_name:port\_number:chain\_name*

The meanings of the components of an endpoint address are as follows:

***host\_name***

The host name or IP address of the system on which the bootstrap server resides. If no host name or IP address is specified, the default is localhost.

***port\_number***

The number of the port on which the bootstrap server listens for incoming requests. If no port number is specified, the default is 7276.

***chain\_name***

The name of a bootstrap transport chain used by the bootstrap server. The valid values are as follows:

<b>Valid value</b>	<b>Name of the bootstrap transport chain</b>
XMSC_WPM_BOOTSTRAP_HTTP	BootstrapTunneledMessaging
XMSC_WPM_BOOTSTRAP_HTTPS	BootstrapTunneledSecureMessaging
XMSC_WPM_BOOTSTRAP_SSL	BootstrapSecureMessaging
XMSC_WPM_BOOTSTRAP_TCP	BootstrapBasicMessaging

If no name is specified, the default value is XMSC\_WPM\_BOOTSTRAP\_TCP.

If no endpoint address is specified, the default is localhost:7276:BootstrapBasicMessaging.

## ***XMSC\_WPM\_SSL\_CIPHER\_SUITE***

**Data type:**

String

**Property of:**

ConnectionFactory

The name of the CipherSuite to be used on a TLS connection to a WebSphere Application Server service integration bus messaging engine. The protocol used in negotiating the secure connection depends on the specified CipherSuite.

Table 881. CipherSuite options for connection to a WebSphere Application Server service integration bus messaging engine

Cipher suite	Protocol used
TLS_RSA_WITH_DES_CBC_SHA	TLSv1
TLS_RSA_WITH_3DES_EDE_CBC_SHA	TLSv1
TLS_RSA_WITH_AES_128_CBC_SHA	TLSv1
TLS_RSA_WITH_AES_256_CBC_SHA	TLSv1

**Notes:**

1. **Windows** TLS\_RSA\_WITH\_AES\_128\_CBC\_SHA and TLS\_RSA\_WITH\_AES\_256\_CBC\_SHA CipherSuites are supported on Windows only. (This is dictated by GSKit.)
2. **Deprecated** TLS\_RSA\_WITH\_3DES\_EDE\_CBC\_SHA is deprecated. However, it can still be used to transfer up to 32 GB of data before the connection is terminated with error AMQ9288. To avoid this error, you need to either avoid using triple DES, or enable secret key reset when using this CipherSpec.

There is no default for this property. If you want to use SSL or TLS, you must specify a value for this property, otherwise your application is not able to connect successfully to the server.

***XMSC\_WPM\_SSL\_FIPS\_REQUIRED***

**Note:** On AIX, Linux, and Windows, IBM MQ provides FIPS 140-2 compliance through the IBM Crypto for C (ICC) cryptographic module. The certificate for this module has been moved to the Historical status. Customers should view the IBM Crypto for C (ICC) certificate and be aware of any advice provided by NIST. A replacement FIPS 140-3 module is currently in progress and its status can be viewed by searching for it in the [NIST CMVP modules in process list](#).

The IBM MQ Operator 3.2.0 and queue manager container image 9.4.0.0 onwards are based on UBI 9. FIPS 140-3 compliance is currently pending and its status can be viewed by searching for "Red Hat Enterprise Linux 9 - OpenSSL FIPS Provider" in the [NIST CMVP modules in process list](#).

**Data type:**

Boolean

**Property of:**

ConnectionFactory

The value of this property determines whether an application can or cannot use non-FIPS compliant cipher suites. If this property is set to true, only FIPS algorithms are used for the client-server connection. Setting the value of this property to TRUE prevents the application from using non-FIPS compliant cipher suites.

By default, the property is set to FALSE (that is, FIPS mode off).

***XMSC\_WPM\_SSL\_KEY\_REPOSITORY***

**Data type:**

String

**Property of:**

ConnectionFactory

A path to the file that is the keyring file containing the public or private keys to be used in the secure connection.

Setting the keyring file property to the special value of XMSC\_WPM\_SSL\_MS\_CERTIFICATE\_STORE specifies the use the Microsoft Windows key database. Using the Microsoft Windows key database, which is found under **Control Panel > Internet Options > Content > Certificates**, removes the need for a separate key file database. Use of this constant on Windows x64 and other platforms is not permitted.

By default, the property is not set.

### ***XMSC\_WPM\_SSL\_KEYRING\_LABEL***

**Data type:**

String

**Property of:**

ConnectionFactory

The certificate to be used when authenticating with the server. If no value is specified, the default certificate is used.

By default, the property is not set.

### ***XMSC\_WPM\_SSL\_KEYRING\_PW***

**Data type:**

String

**Property of:**

ConnectionFactory

The password for the keyring file.

This property can be used as an alternative to using [XMSC\\_WPM\\_SSL\\_KEYRING\\_STASH\\_FILE](#) to configure the password for the keyring file.

By default, the property is not set.

### ***XMSC\_WPM\_SSL\_KEYRING\_STASH\_FILE***

**Data type:**

String

**Property of:**

ConnectionFactory

The name of a binary file containing the password of the key repository file.

This property can be used as an alternative to using [XMSC\\_WPM\\_SSL\\_KEYRING\\_PW](#) to configure the password for the keyring file.

By default, the property is not set.

### ***XMSC\_WPM\_TARGET\_GROUP***

**Data type:**

String

**Property of:**

ConnectionFactory

The name of a target group of messaging engines. The nature of the target group is determined by the [XMSC\\_WPM\\_TARGET\\_TYPE](#) property.

Set this property if you want to restrict the search for a messaging engine to a subgroup of the messaging engines in the service integration bus. If you want your application to be able to connect to any messaging engine in the service integration bus, do not set this property.

By default, the property is not set.

### ***XMSC\_WPM\_TARGET\_SIGNIFICANCE***

**Data type:**

System.Int32

**Property of:**

ConnectionFactory

The significance of the target group of messaging engines.

The valid values of the property are as follows:

<b>Valid value</b>	<b>Meaning</b>
XMSC_WPM_TARGET_SIGNIFICANCE_PREFERRED	A messaging engine in the target group is selected if one is available. Otherwise, a messaging engine outside the target group is selected, provided it is in the same service integration bus.
XMSC_WPM_TARGET_SIGNIFICANCE_REQUIRED	The selected messaging engine must be in the target group. If a messaging engine in the target group is not available, the connection process fails.

The default value of the property is XMSC\_WPM\_TARGET\_SIGNIFICANCE\_PREFERRED.

### ***XMSC\_WPM\_TARGET\_TRANSPORT\_CHAIN***

**Data type:**

String

**Property of:**

ConnectionFactory

The name of the inbound transport chain that the application must use to connect to a messaging engine.

The value of the property can be the name of any inbound transport chain that is available in the application server that hosts the messaging engine. The following named constant is provided for one of the predefined inbound transport chains:

<b>Named constant</b>	<b>Name of transport chain</b>
XMSC_WPM_TARGET_TRANSPORT_CHAIN_BASIC	InboundBasicMessaging

The default value of the property is XMSC\_WPM\_TARGET\_TRANSPORT\_CHAIN\_BASIC.

### ***XMSC\_WPM\_TARGET\_TYPE***

**Data type:**

System.Int32

**Property of:**

ConnectionFactory

The type of the target group of messaging engines. This property determines the nature of the target group identified by the XMSC\_WPM\_TARGET\_GROUP property.

The valid values of the property are as follows:

<b>Valid value</b>	<b>Meaning</b>
XMSC_WPM_TARGET_TYPE_BUSMEMBER	The name of the target group is the name of a bus member. The target group is all the messaging engines in the bus member.
XMSC_WPM_TARGET_TYPE_CUSTOM	The name of the target group is the name of a user-defined group of messaging engines. The target group is all the messaging engines that are registered with the user-defined group.
XMSC_WPM_TARGET_TYPE_ME	The name of the target group is the name of a messaging engine. The target group is the specified messaging engine.

By default, the property is not set.

### ***XMSC\_WPM\_TEMP\_Q\_PREFIX***

**Data type:**

String

**Property of:**

ConnectionFactory

The prefix used to form the name of the temporary queue that is created in the service integration bus when the application creates an XMS temporary queue. The prefix can contain up to 12 characters.

The name of a temporary queue starts with the characters "\_Q" followed by the prefix. The remainder of the name consists of system generated characters.

By default, the property is not set, which means that the name of a temporary queue does not have a prefix.

This property is relevant only in the point-to-point domain.

### ***XMSC\_WPM\_TEMP\_TOPIC\_PREFIX***

**Data type:**

String

**Property of:**

ConnectionFactory

The prefix used to form the name of a temporary topic that is created by the application. The prefix can contain up to 12 characters.

The name of a temporary topic starts with the characters "\_T" followed by the prefix. The remainder of the name consists of system generated characters.

By default, the property is not set, which means that the name of a temporary topic does not have a prefix.

This property is relevant only in the publish/subscribe domain.

### ***XMSC\_WPM\_TOPIC\_SPACE***

**Data type:**

String

**Property of:**

Destination

**Name used in a URI:**

topicSpace

The name of the topic space that contains the topic. Only a destination that is a topic can have this property.

By default, the property is not set, which means that the default topic space is assumed.

This property is relevant only in the publish/subscribe domain.

## **Managed File Transfer developing applications reference**

---

Reference information to help you develop applications for Managed File Transfer.

### **Examples of using `fteCreateTransfer` to start programs**

You can use the **`fteCreateTransfer`** command to specify programs to run before or after a transfer.

In addition to using **`fteCreateTransfer`**, there are other ways to invoke a program before or after a transfer. For more information, see [Specifying programs to run with MFT](#).

All these examples use the following syntax to specify a program:

```
[type:]commandspec[, [retrycount][, [retrywait][, successrc]]]
```

For more information about this syntax, see [fteCreateTransfer: start a new file transfer](#).

### Running an executable program

The following example specifies an executable program called `mycommand` and passes two arguments, `a` and `b`, to the program.

```
mycommand(a,b)
```

To run this program at the source agent `AGENT1` before the transfer starts, use the following command:

```
fteCreateTransfer -sa AGENT1 -da AGENT2 -presrc mycommand(a,b)
destinationSpecification sourceSpecification
```

### Running, and retrying, an executable program

The following example specifies an executable program called `simple`, which does not take any arguments. A value of `1` is specified for `retrycount` and a value of `5` is specified for `retrywait`. These values mean that the program will be retried once if it does not return a successful return code, after a wait of five seconds. No value is specified for `successrc`, so the only successful return code is the default value of `0`.

```
executable:simple,1,5
```

To run this program at the source agent `AGENT1` after the transfer has completed, use the following command:

```
fteCreateTransfer -sa AGENT1 -da AGENT2 -postsrc executable:simple,1,5
destinationSpecification sourceSpecification
```

### Running an Ant script and specifying successful return codes

The following example specifies an Ant script called `myscript` and passes two properties to the script. The script is run using the `fteAnt` command. The value for `successrc` is specified as `>2<7&!5|0|14`, which specifies that return codes of `0`, `3`, `4`, `6`, and `14` indicate success.

```
antscript:myscript(prop1=fred,prop2=bob),,,>2<7&!5|0|14
```

To run this program at the destination agent `AGENT2` before the transfer has started, use the following command:

```
fteCreateTransfer -sa AGENT1 -da AGENT2 -predst
"antscript:myscript(prop1=fred,prop2=bob),,,>2<7&!5|0|14"destinationSpecification sourceSpecification
```

### Running an Ant script and specifying targets to call

The following example specifies an Ant script called `script2` and two targets, `target1` and `target2`, to call. The property `prop1` is also passed in, with a value of `recmfm(F,B)`. Parentheses (`)` and backslashes (`\`) are special characters in MFT commands, and must be escaped with a backslash (`\`) character.  File paths on Windows can be specified either using double backslashes (`\\`) as a separator, or using single forward slashes (`/`). In the following example, the comma (`,`) and parentheses (`()`) are escaped using a backslash character (`\`).

```
antscript:script2(target1,target2,prop1=recmfm\F\B\),,,>2<7&!5|0|14
```

To run this program at the destination agent AGENT2 after the transfer has completed, use the following command:

```
fteCreateTransfer -sa AGENT1 -da AGENT2
-postdst "antscript:script2(target1,target2,prop1=recmfm\F\,B\),,,>2&<7&!5|0|14"
destinationSpecification sourceSpecification
```

### Using metadata in an Ant script

You can specify an Ant task as any of the following calls for a transfer:

- pre source
- post source
- predestination
- post destination

When the Ant task is run, the user meta data of the transfer is made available using environment variables. You can access this data using, for example, the following code:

```
<property environment="environment" />
<echo>${environment.mymetadata}</echo>
```

where mymetadata is the name of some meta data inserted into the transfer.

### Running a JCL script

The following example specifies a JCL script called ZOSBATCH. A value of 3 is specified for `retrycount`, a value of 30 is specified for `retrywait` and a value of 0 is specified for `successrc`. These values mean that the script is retried three times if it does not return a successful return code of 0, with a wait of thirty seconds between each attempt.

```
jcl:ZOSBATCH,3,30,0
```

where ZOSBATCH is a member of a PDS called MYSYS.JCL, and the `agent.properties` file contains the line `commandPath=...:/'MYSYS.JCL':...`

To run this program at the source agent AGENT1 after the transfer has completed, use the following command:

```
fteCreateTransfer -sa AGENT1 -da AGENT2 -postsrc jcl:ZOSBATCH,3,30,0
destinationSpecification sourceSpecification
```

### Related tasks

[Specifying programs to run with MFT](#)

### Related reference

**[fteCreateTransfer](#)**: start a new file transfer

## fteAnt: run Ant tasks in MFT

The **fteAnt** command runs Ant scripts in an environment that has Managed File Transfer Ant tasks available. Unlike the standard **ant** command, **fteAnt** requires that you define a script file.

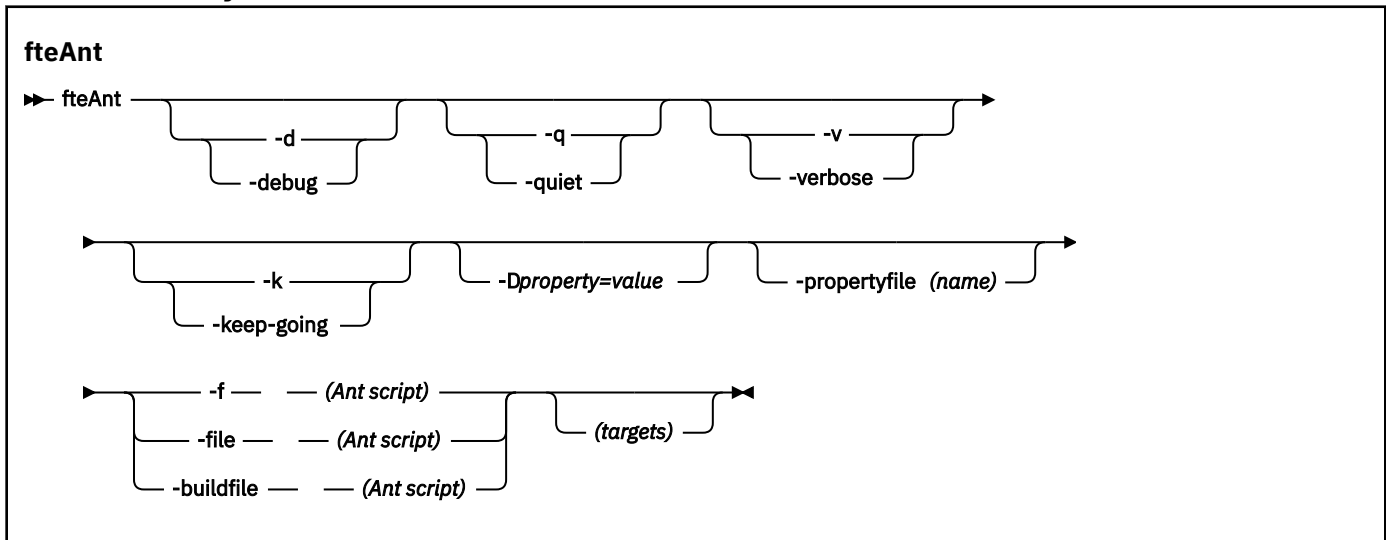

### MFT Ant tasks and nested parameters

Managed File Transfer provides a number of Ant tasks that you can use to access file transfer capabilities. There is also a set of nested parameters available; these parameters describe nested sets of elements that are common across several of the supplied Ant tasks.

The **fteAnt** command syntax, parameters, usage example and return codes are described in the rest of this topic. For details of the Ant tasks and nested parameters that are provided by MFT, see the subtopics.

## fteAnt syntax

## Parameters

### -debug or -d

Optional. Generate debugging output.

### -quiet or -q

Optional. Generate minimal output.

### -verbose or -v

Optional. Generate verbose output.

### -keep-going or -k

Optional. Execute all targets that do not depend on failed targets.

### -D *property=value*

Optional. Use *value* for a given *property*. Properties that are set with **-D** take precedence over those set in a properties file.

Use the property **com.ibm.wmqfte.propertyset** to specify the set of configuration options that are used for Ant tasks. Use the name of a non-default coordination queue manager as the value for this property. Ant tasks then use the set of configuration options that are associated with this non-default coordination queue manager. If you do not specify this property, the default set of configuration options that are based on the default coordination queue manager is used. If you specify the **cmdqm** attribute for an Ant task, this attribute takes precedence over the set of configuration options that are specified for the **fteAnt** command. This behavior applies regardless of whether you are using the default set of configuration options or specifying a set with the **com.ibm.wmqfte.propertyset** property.

### -propertyfile (*name*)

Optional. Load all properties from a file with **-D** properties taking precedence.

### -f (*Ant script*), -file (*Ant script*), or -buildfile (*Ant script*)

Required. Specifies the name of the Ant script to run.

### targets

Optional. The name of one or more targets to run from the Ant script. If you do not specify a value for this parameter, the default target for the script is run.

### -version

Optional. Displays the Managed File Transfer command and Ant versions.

## **-? or -h**

Optional. Displays command syntax.

## **Example**

In this example, the target **copy** in Ant script `fte_script.xml` is run and the command writes debugging output to standard out.

```
fteAnt -d -f fte_script.xml copy
```

## **Return codes**

### **0**

Command completed successfully.

### **1**

Command ended unsuccessfully.

Other status return codes can also be specified from Ant scripts, for example by using the Ant fail task.

See [Fail](#) for more information.

## **Related concepts**

[Getting started using Ant scripts with MFT](#)

## **Related tasks**

[Using Apache Ant with MFT](#)

## **Related reference**

[Sample Ant tasks for MFT](#)

## **fte:awaitoutcome Ant task**

Waits for a **fte:filecopy**, **fte:filemove**, or **fte:call** operation to complete.

## **Attributes**

### **id**

Required. Identifies the transfer to await an outcome from. Typically, this is a property set by the `idProperty` attribute of the [fte:filecopy](#), [fte:filemove](#), or [fte:call](#) tasks.

### **rcproperty**

Required. Names a property to store the return code of the **fte:awaitoutcome** task in.

### **timeout**

Optional. The maximum amount of time, in seconds, to wait for the operation to complete. The minimum timeout is one second. If you do not specify a timeout value, the **fte:awaitoutcome** task waits forever for the outcome of the operation to be determined.

## **Example**

In this example a file copy is started, and its identifier is stored in the `copy.id` property. While the copy is progressing, other processing can take place. The **fte:awaitoutcome** statement is used to wait until the copy operation completes. The **fte:awaitoutcome** statement identifies which operation to wait for using the identifier stored in the `copy.id` property. The **fte:awaitoutcome** stores a return code indicating the outcome of the copy operation into a property called `copy.result`.

```
<!-- issue a file copy request -->
<fte:filecopy
src="AGENT1@QM1"
dst="AGENT2@QM2"
idproperty="copy.id"
outcome="defer">

<fte:filespec
```

```

srcfilespec="/home/fteuser1/file.bin"
dstdir="/home/fteuser2"/>

</fte:filecopy>

<fte:awaitoutcome id="{copy.id}" rcProperty="copy.rc"/>

<echo>Copy id="{copy.id}" rc="{copy.rc}</echo>

```

## Related tasks

[Using Apache Ant with MFT](#)

## fte:call Ant task

You can use the **fte:call** task to remotely call scripts and programs.

This task allows you to send a **fte:call** request to an agent. The agent processes this request by running a script or program and returning the outcome. The commands to call must be accessible to the agent. Ensure the `commandPath` property value in the `agent.properties` file includes the location of the commands to call. Any path information specified by the command nested element must be relative to the locations specified by the `commandPath` property. By default `commandPath` is empty so that the agent cannot call any commands. For more information about this property, see [commandPath MFT property](#).

For more information about the `agent.properties` file, see [The MFT agent.properties file](#).

## Attributes

### agent

Required. Specifies the agent to submit the **fte:call** request to. Specify the agent information in the form: `agentname@qmgrname` where `agentname` is the name of the agent and `qmgrname` is the name of the queue manager that this agent is directly connected to.

### cmdqm

Optional. The command queue manager to submit the request to. Specify this information in the form `qmgrname@host@port@channel`, where:

- `qmgrname` is the name of the queue manager
- `host` is the optional host name of the system where the queue manager is running
- `port` is the optional port number that the queue manager is listening on
- `channel` is the optional SVRCONN channel to use

If you omit the `host`, `port`, or `channel` information for the command queue manager, the connection information specified in the `command.properties` file is used.

**Attention:** If no value is specified for the:

- `host` variable, bindings mode is used
- `port` variable, the value 1414 is used
- `channel` variable, the `SYSTEM.DEF.SVRCONN` is used.

See [The MFT command.properties file](#) for more information.

However, you cannot skip the attributes in the middle, for example, `qmgrname@host@@channel`. You can have, for example, `qmgrname@host`, or `qmgrname@host@port`, or `qmgrname@hostport@@channel`.

MFT splits the given attribute using the @ delimiter. Depending on the number of tokens found, it takes the first token as `qmgrname`, the second one as `host`, the third one as `port` and finally `channel`.

For more information, see [The MFT command.properties file](#).

You can use the **com.ibm.wmqfte.propertySet** property to specify which `command.properties` file to use. For more information, see [com.ibm.wmqfte.propertySet](#).

If you do not use the `cmdqmq` attribute, the task defaults to using the `com.ibm.wmqfte.ant.commandQueueManager` property, if this property is set. If the `com.ibm.wmqfte.ant.commandQueueManager` property is not set, a connection to the default queue manager, defined in the `command.properties` file, is attempted. The format of the `com.ibm.wmqfte.ant.commandQueueManager` property is the same as the `cmdqmq` attribute, that is, `qmgrname@host@port@channel`.

### **idproperty**

Optional unless you have specified an outcome of `defer`. Specifies the name of a property to assign the transfer identifier to. Transfer identifiers are generated at the point a transfer request is submitted and you can use transfer identifiers to track the progress of a transfer, diagnose problems with a transfer, and cancel a transfer.

You cannot specify this property if you have also specified an outcome property of `ignore`. However, you must specify `idproperty` if you have also specified an outcome property of `defer`.

### **jobname**

Optional. Assigns a job name to the **`fte:call`** request. You can use job names to create logical groups of transfers. Use the “[fte:uuid Ant task](#)” on page 2111 task to generate pseudo-unique job names. If you do not use the `jobname` attribute, the task defaults to using the `com.ibm.wmqfte.ant.jobName` property value, if this property is set. If you do not set this property, no job name is associated with the **`fte:call`** request.

### **origuser**

Optional. Specifies the originating user identifier to associate with the **`fte:call`** request. If you do not use the `origuser` attribute, the task defaults to using the user ID that is used to run the Ant script.

### **outcome**

Optional. Determines whether the task waits for the **`fte:call`** operation to complete before returning control to the Ant script. Specify one of the following options:

#### **await**

The task waits for the **`fte:call`** operation to complete before returning. When an outcome of `await` is specified the `idproperty` attribute is optional.

#### **defer**

The task returns as soon as the **`fte:call`** request has been submitted and assumes that the outcome of the call operation is dealt with later using either the [awaitoutcome](#) or [ignoreoutcome](#) tasks. When an outcome of `defer` is specified the `idproperty` attribute is required.

#### **ignore**

If the outcome of the **`fte:call`** operation is not important, you can specify a value of `ignore`. The task then returns as soon as the **`fte:call`** request has been submitted, without allocating any resources for tracking the outcome of the command. When an outcome of `ignore` is specified the `idproperty` attribute cannot be specified.

If you do not specify the outcome attribute, the task defaults to using the value `await`.

### **rcproperty**

Optional. Specifies the name of a property to assign the result code of the **`fte:call`** request to. The result code reflects the overall outcome of the **`fte:call`** request.

You cannot specify this property if you have also specified an outcome property of `ignore` or `defer`. However, you must specify `rcproperty` if you have specified an outcome of `await`.

## **Parameters specified as nested elements**

### **fte:command**

Specifies the command to be called by the agent. You can only associate a single `fte:command` element with a given **`fte:call`** operation. The command to be called must be located on the path specified by the `commandPath` property in the agent's `agent.properties` file.

## **fte:metadata**

You can specify metadata to associate with the call operation. This metadata is recorded in the log messages generated by the call operation. You can only associate a single block of metadata with a given transfer element; however this block can contain many pieces of metadata.

### **Example**

This example shows how to call a command at AGENT1 running on queue manager QM1. The command to call is the script `command.sh`, and the script is called with a single argument of `xyz`. The command `command.sh` is located on the path specified by the `commandPath` property in the agent's `agent.properties` file.

```
<fte:call cmdqm="QM0@localhost@1414@SYSTEM.DEF.SVRCONN"
  agent="AGENT1@QM1"
  rcproperty="call.rc"
  origuser="bob"
  jobname="${job.id}">

  <fte:command command="command.sh" successrc="1" retrycount="5" retrywait="30">
    <fte:arg value="xyz"/>
  </fte:command>

  <fte:metadata>
    <fte:entry name="org.foo.accountName" value="BDG3R"/>
  </fte:metadata>

</fte:call>
```

### **Related tasks**

[Using Apache Ant with MFT](#)

## **fte:cancel Ant task**

Cancels a Managed File Transfer managed transfer or managed call. A managed transfer might have been created using the **fte:filecopy** or **fte:filemove** tasks. A managed call might have been created using the **fte:call** task.

### **Attributes**

#### **agent**

Required. Specifies the agent to submit the **fte:cancel** request to. The value is in the form: *agentname@qmgrname* where *agentname* is the name of the agent and *qmgrname* is the name of the queue manager that this agent is directly connected to.

#### **cmdqm**

Optional. The command queue manager to submit the request to. Specify this information in the form *qmgrname@host@port@channel*, where:

- *qmgrname* is the name of the queue manager
- *host* is the optional host name of the system where the queue manager is running
- *port* is the optional port number that the queue manager is listening on
- *channel* is the optional SVRCONN channel to use

If you omit the *host*, *port*, or *channel* information for the command queue manager, the connection information specified in the `command.properties` file is used.

**Attention:** If no value is specified for the:

- *host* variable, bindings mode is used
- *port* variable, the value 1414 is used
- *channel* variable, the SYSTEM.DEF.SVRCONN is used.

See [The MFT command.properties file](#) for more information.

However, you cannot skip the attributes in the middle, for example, `qmgrname@host@@channel`. You can have, for example, `qmgrname@host`, or `qmgrname@host@port`, or `qmgrname@hostport@@channel`.

MFT splits the given attribute using the `@` delimiter. Depending on the number of tokens found, it takes the first token as *qmgrname*, the second one as *host*, the third one as *port* and finally *channel*.

For more information, see [The MFT command.properties file](#).

You can use the **com.ibm.wmqfte.propertySet** property to specify which `command.properties` file to use. For more information, see [com.ibm.wmqfte.propertySet](#).

If you do not use the `cmdqm` attribute, the task defaults to using the `com.ibm.wmqfte.ant.commandQueueManager` property, if this property is set. If the `com.ibm.wmqfte.ant.commandQueueManager` property is not set, a connection to the default queue manager, defined in the `command.properties` file, is attempted. The format of the `com.ibm.wmqfte.ant.commandQueueManager` property is the same as the `cmdqm` attribute, that is, `qmgrname@host@port@channel`.

#### **id**

Required. Specifies the transfer identifier of the transfer to cancel. Transfer identifiers are generated at the point a transfer request is submitted by both the `fte:filecopy` and `fte:filemove` tasks.

#### **origuser**

Optional. Specifies the originating user identifier to associate with the **cancel** request. If the `origuser` attribute is not used, the task defaults to using the user ID that is used to run the Ant script.

#### **Example**

The example sends a **fte:cancel** request to the command queue manager `qm0`. The **fte:cancel** request is targeted at `agent1` on queue manager `qm1` for the transfer identifier populated by the `transfer.id` variable. The request is run using the "bob" user ID.

```
<fte:cancel cmdqm="qm0@localhost@1414@SYSTEM.DEF.SVRCONN"
  agent="agent1@qm1"
  id="{transfer.id}"
  origuser="bob"/>
```

#### **Related tasks**

[Using Apache Ant with MFT](#)

### **fte:filecopy Ant task**

The **fte:filecopy** task copies files between Managed File Transfer agents. The file is not deleted from the source agent.

#### **Attributes**

##### **cmdqm**

Optional. The command queue manager to submit the request to. Specify this information in the form `qmgrname@host@port@channel`, where:

- *qmgrname* is the name of the queue manager
- *host* is the optional host name of the system where the queue manager is running
- *port* is the optional port number that the queue manager is listening on
- *channel* is the optional SVRCONN channel to use

If you omit the *host*, *port*, or *channel* information for the command queue manager, the connection information specified in the `command.properties` file is used.

**Attention:** If no value is specified for the:

- *host* variable, bindings mode is used
- *port* variable, the value 1414 is used
- *channel* variable, the SYSTEM.DEF.SVRCONN is used.

See [The MFT command.properties file](#) for more information.

However, you cannot skip the attributes in the middle, for example, `qmgrname@host@@channel`. You can have, for example, `qmgrname@host`, or `qmgrname@host@port`, or `qmgrname@hostport@@channel`.

MFT splits the given attribute using the @ delimiter. Depending on the number of tokens found, it takes the first token as *qmgrname*, the second one as *host*, the third one as *port* and finally *channel*.

For more information, see [The MFT command.properties file](#).

You can use the **com.ibm.wmqfte.propertySet** property to specify which `command.properties` file to use. For more information, see [com.ibm.wmqfte.propertySet](#).

If you do not use the `cmdqm` attribute, the task defaults to using the `com.ibm.wmqfte.ant.commandQueueManager` property, if this property is set. If the `com.ibm.wmqfte.ant.commandQueueManager` property is not set, a connection to the default queue manager, defined in the `command.properties` file, is attempted. The format of the `com.ibm.wmqfte.ant.commandQueueManager` property is the same as the `cmdqm` attribute, that is, `qmgrname@host@port@channel`.

#### **dst**

Required. Specifies the destination agent for the copy operation. Specify this information in the form: `agentname@qmgrname` where `agentname` is the name of the destination agent and `qmgrname` is the name of the queue manager that this agent is directly connected to.

#### **idproperty**

Optional unless you have specified an outcome of `defer`. Specifies the name of a property to assign the transfer identifier to. Transfer identifiers are generated at the point a transfer request is submitted and you can use transfer identifiers to track the progress of a transfer, diagnose problems with a transfer, and cancel a transfer.

You cannot specify this property if you have also specified an outcome property of `ignore`. However, you must specify `idproperty` if you have also specified an outcome property of `defer`.

#### **jobname**

Optional. Assigns a job name to the copy request. You can use job names to create logical groups of transfers. Use the [“fte:uuid Ant task” on page 2111](#) task to generate pseudo-unique job names. If you do not use the `jobname` attribute, the task defaults to using the `com.ibm.wmqfte.ant.jobName` property value, if this property is set. If you do not set this property, no job name is associated with the copy request.

#### **origuser**

Optional. Specifies the originating user identifier to associate with the copy request. If you do not use the `origuser` attribute, the task defaults to using the user ID that is used to run the Ant script.

#### **outcome**

Optional. Determines whether the task waits for the copy operation to complete before returning control to the Ant script. Specify one of the following options:

##### **await**

The task waits for the copy operation to complete before returning. When an outcome of `await` is specified the `idproperty` attribute is optional.

##### **defer**

The task returns as soon as the copy request has been submitted and assumes that the outcome of the copy operation is dealt with later using either the [“fte:awaitoutcome Ant task” on page 2098](#) or [“fte:ignoreoutcome Ant task” on page 2109](#) tasks. When an outcome of `defer` is specified the `idproperty` attribute is required.

**ignore**

If the outcome of the copy operation is not important, you can specify a value of `ignore`. The task then returns as soon as the copy request has been submitted, without allocating any resources for tracking the outcome of the transfer. When an outcome of `ignore` is specified the `idproperty` attribute cannot be specified.

If you do not specify the outcome attribute, the task defaults to using the value `await`.

**priority**

Optional. Specifies the priority to associate with the copy request. In general, higher priority transfer requests take precedence over lower priority requests. The priority value must be in the range 0 - 9 (inclusive). A priority value of 0 is the lowest priority and a value of 9 is the highest priority. If you do not specify the `priority` attribute, the transfer defaults to a priority of 0.

**rcproperty**

Optional. Specifies the name of a property to assign the result code of the copy request to. The result code reflects the overall outcome of the copy request.

You cannot specify this property if you have also specified an outcome property of `ignore` or `defer`. However, you must specify `rcproperty` if you specify an outcome of `await`.

**transferRecoveryTimeout**

Optional. Sets the amount of time, in seconds, during which a source agent keeps trying to recover a stalled file transfer. Specify one of the following options:

**-1**

The agent continues to attempt to recover the stalled transfer until the transfer is complete. Using this option is the equivalent of the default behavior of the agent when the property is not set.

**0**

The agent stops the file transfer as soon as it enters recovery.

**>0**

The agent continues to attempt to recover the stalled transfer for the amount of time in seconds as set by the positive integer value specified. For example,

```
<fte:filecopy cmdqm="qm0@localhost@1414@SYSTEM.DEF.SVRCONN"
  src="agent1@qm1" dst="agent2@qm2"
  rcproperty="copy.result" transferRecoveryTimeout="21600">
  <fte:filespec srcfilespec="/home/fteuser1/file.bin" dstfile="/home/fteuser2/
file.bin"/>
</fte:filecopy>
```

indicates that the agent keeps trying to recover the transfer for 6 hours from when it enters recovery. Maximum value for this attribute is 999999999.

Specifying the transfer recovery timeout value in this way sets it on a per transfer basis. To set a global value for all transfers in a Managed File Transfer network, you can add a property to the [Transfer recovery timeout properties](#). For more information, see [Timeout option for transfers in recovery](#).

**src**

Required. Specifies the source agent for the copy operation. Specify this information in the form: `agentname@qmgrname` where `agentname` is the name of the source agent and `qmgrname` is the name of the queue manager that this agent is directly connected to.

**Parameters specified as nested elements****fte:filespec**

Required. You must specify at least one file specification that identifies the files to copy. You can specify more than one file specification if required. See [“fte:filespec Ant nested element” on page 2112](#) for more information.

**fte:metadata**

You can specify metadata to associate with the copy operation. This metadata is carried with the transfer and is recorded in the log messages generated by the transfer. You can only associate a

single block of metadata with a given transfer element; however this block can contain many pieces of metadata. See the [fte:metadata](#) topic for more information.

**fte:presrc**

Specifies a program invocation to take place at the source agent before the transfer starts. You can only associate a single `fte:presrc` element with a given transfer. See the [program invocation](#) topic for more information.

**fte:predst**

Specifies a program invocation to take place at the destination agent before the transfer starts. You can only associate a single `fte:predst` element with a given transfer. See the [program invocation](#) topic for more information.

**fte:postsrc**

Specifies a program invocation to take place at the source agent after the transfer has completed. You can only associate a single `fte:postsrc` element with a given transfer. See the [program invocation](#) topic for more information.

**fte:postdst**

Specifies a program invocation to take place at the destination agent after the transfer has completed. You can only associate a single `fte:postdst` element with a given transfer. See the [program invocation](#) topic for more information.

If `fte:presrc`, `fte:predst`, `fte:postsrc`, `fte:postdst`, and `exits` do not return a success status, the rules are as follows in the order specified:

1. Run the source start exits. If source start exits fail the transfer fails and nothing further is run.
2. Run the pre-source call (when present). If the pre-source call fails, the transfer fails and nothing further is run.
3. Run the destination start exits. If the destination start exits fail the transfer fails and nothing further is run.
4. Run the pre-destination call (when present). If the pre-destination call fails, the transfer fails and nothing further is run.
5. Perform the file transfers.
6. Run the destination end exits. There is no failure status for these exits.
7. If the transfer is successful (if some files transfer successfully, it is deemed successful) run the post-destination call (if present). If the post-destination call fails, the transfer fails.
8. Run the source end exits. There is no failure status for these exits.
9. If the transfer is successful run the post-source call (if present). If the post-source call fails, the transfer fails.

**Examples**

This example shows a basic file transfer between `agent1` and `agent2`. The command to start the file transfer is sent to a queue manager called `qm0`, using a client transport mode connection. The result of the file transfer operation is assigned to the property called `copy.result`.

```
<fte:filecopy cmdqm="qm0@localhost@1414@SYSTEM.DEF.SVRCONN"
  src="agent1@qm1" dst="agent2@qm2"
  rcproperty="copy.result">
  <fte:filespec srcfilespec="/home/fteuser1/file.bin" dstfile="/home/fteuser2/file.bin"/>
</fte:filecopy>
```

This example shows the same file transfer, but with the addition of metadata and a program start to take place at the source agent after the transfer has completed.

```
<fte:filecopy cmdqm="qm0@localhost@1414@SYSTEM.DEF.SVRCONN"
  src="agent1@qm1" dst="agent2@qm2"
```

```

rcproperty="copy.result">

<fte:metadata>
  <fte:entry name="org.example.departId" value="ACCOUNTS"/>
  <fte:entry name="org.example.batchGroup" value="A1"/>
</fte:metadata>

<fte:filespec srcfilespec="/home/fteuser1/file.bin" dstfile="/home/fteuser2/file.bin"/>

<fte:postsrc command="/home/fteuser2/scripts/post.sh" successsrc="1" >
  <fte:arg value="/home/fteuser2/file.bin"/>
</fte:postsrc>
</fte:filecopy>

```

## Related concepts

[Timeout option for file transfers in recovery](#)

## Related tasks

[Using Apache Ant with MFT](#)

## fte:filemove Ant task

The **fte:filemove** task moves files between Managed File Transfer agents. When a file has been successfully transferred from the source agent to the destination agent, the file is deleted from the source agent.

## Attributes

### cmdqm

Optional. The command queue manager to submit the request to. Specify this information in the form *qmgrname@host@port@channel*, where:

- *qmgrname* is the name of the queue manager
- *host* is the optional host name of the system where the queue manager is running
- *port* is the optional port number that the queue manager is listening on
- *channel* is the optional SVRCONN channel to use

If you omit the *host*, *port*, or *channel* information for the command queue manager, the connection information specified in the `command.properties` file is used.

**Attention:** If no value is specified for the:

- *host* variable, bindings mode is used
- *port* variable, the value 1414 is used
- *channel* variable, the SYSTEM.DEF.SVRCONN is used.

See [The MFT command.properties file](#) for more information.

However, you cannot skip the attributes in the middle, for example, `qmgrname@host@@channel`. You can have, for example, `qmgrname@host`, or `qmgrname@host@port`, or `qmgrname@hostport@@channel`.

MFT splits the given attribute using the @ delimiter. Depending on the number of tokens found, it takes the first token as *qmgrname*, the second one as *host*, the third one as *port* and finally *channel*.

For more information, see [The MFT command.properties file](#).

You can use the **com.ibm.wmqfte.propertySet** property to specify which `command.properties` file to use. For more information, see [com.ibm.wmqfte.propertySet](#).

If you do not use the `cmdqm` attribute, the task defaults to using the `com.ibm.wmqfte.ant.commandQueueManager` property, if this property is set. If the `com.ibm.wmqfte.ant.commandQueueManager` property is not set, a connection to the default queue manager, defined in the `command.properties` file, is attempted. The format of the

`com.ibm.wmqfte.ant.commandQueueManager` property is the same as the `cmdqm` attribute, that is, `qmgrname@host@port@channel`.

**dst**

Required. Specifies the destination agent for the copy operation. Specify this information in the form: `agentname@qmgrname` where `agentname` is the name of the destination agent and `qmgrname` is the name of the queue manager that this agent is directly connected to.

**idproperty**

Optional unless you have specified an outcome of `defer`. Specifies the name of a property to assign the transfer identifier to. Transfer identifiers are generated at the point a transfer request is submitted and you can use transfer identifiers to track the progress of a transfer, diagnose problems with a transfer, and cancel a transfer.

You cannot specify this property if you have also specified an outcome property of `ignore`. However, you must specify `idproperty` if you have also specified an outcome property of `defer`.

**jobname**

Optional. Assigns a job name to the move request. You can use job names to create logical groups of transfers. Use the `fte:uuid` task to generate pseudo-unique job names. If you do not use the `jobname` attribute, the task defaults to using the `com.ibm.wmqfte.ant.jobName` property value, if this property is set. If you do not set this property, no job name is associated with the move request.

**origuser**

Optional. Specifies the originating user identifier to associate with the move request. If you do not use the `origuser` attribute, the task defaults to using the user ID that is used to run the Ant script.

**outcome**

Optional. Determines whether the task waits for the move operation to complete before returning control to the Ant script. Specify one of the following options:

**await**

The task waits for the move operation to complete before returning. When an outcome of `await` is specified the `idproperty` attribute is optional.

**defer**

The task returns as soon as the move request has been submitted and assumes that the outcome of the move operation is dealt with later using either the “[fte:awaitoutcome Ant task](#)” on page 2098 or “[fte:ignoreoutcome Ant task](#)” on page 2109 task. When an outcome of `defer` is specified the `idproperty` attribute is required.

**ignore**

If the outcome of the move operation is not important, you can specify a value of `ignore`. The task then returns as soon as the move request has been submitted, without allocating any resources for tracking the outcome of the transfer. When an outcome of `ignore` is specified the `idproperty` attribute cannot be specified.

If you do not specify the outcome attribute, the task defaults to using the value `await`.

**priority**

Optional. Specifies the priority to associate with the move request. In general, higher priority transfer requests take precedence over lower priority requests. The priority value must be in the range 0 - 9 (inclusive). A priority value of 0 is the lowest priority and a value of 9 is the highest priority. If you do not specify the `priority` attribute, the transfer defaults to a priority of 0.

**rcproperty**

Optional. Specifies the name of a property to assign the result code of the move request to. The result code reflects the overall outcome of the move request.

You cannot specify this property if you have also specified an outcome property of `ignore` or `defer`. However, you must specify `rcproperty` if you have specified an outcome of `await`.

**transferRecoveryTimeout**

Optional. Sets the amount of time, in seconds, during which a source agent keeps trying to recover a stalled file transfer. Specify one of the following options:

-1

The agent continues to attempt to recover the stalled transfer until the transfer is complete. Using this option is the equivalent of the default behavior of the agent when the property is not set.

0

The agent stops the file transfer as soon as it enters recovery.

>0

The agent continues to attempt to recover the stalled transfer for the amount of time in seconds as set by the positive integer value specified. For example,

```
<fte:filemove cmdqm="qm0@localhost@1414@SYSTEM.DEF.SVRCONN"
  src=agent1@qm1 dst="agent2@qm2"
  rcproperty="move.result" transferRecoveryTimeout="21600">
  <fte:filespec srcfilespec="/home/fteuser1/file.bin" dstfile="/home/fteuser2/
file.bin"/>
</fte:filemove
```

indicates that the agent keeps trying to recover the transfer for 6 hours from when it enters recovery. Maximum value for this attribute is 999999999.

Specifying the transfer recovery timeout value in this way sets it on a per transfer basis. To set a global value for all transfers in a Managed File Transfer network, you can add a property to the [Transfer recovery timeout properties](#). For more information, see [Timeout option for transfers in recovery](#).

**src**

Required. Specifies the source agent for the move operation. Specify this information in the form: *agentname@qmgrname* where *agentname* is the name of the source agent and *qmgrname* is the name of the queue manager that this agent is directly connected to.

## Parameters specified as nested elements

**fte:filespec**

Required. You must specify at least one file specification that identifies the files to move. You can specify more than one file specification if required. See [“fte:filespec Ant nested element”](#) on page 2112 for more information.

**fte:metadata**

Optional. You can specify metadata to associate with the file move operation. This metadata is carried with the transfer and is recorded in the log messages generated by the transfer. You can only associate a single block of metadata with a given transfer element; however this block can contain many pieces of metadata. See the [fte:metadata](#) topic for more information.

**fte:presrc**

Optional. Specifies a program invocation to take place at the source agent before the transfer starts. You can only associate a single `fte:presrc` element with a given transfer. See the [program invocation](#) topic for more information.

**fte:predst**

Optional. Specifies a program invocation to take place at the destination agent before the transfer starts. You can only associate a single `fte:predst` element with a given transfer. See the [program invocation](#) topic for more information.

**fte:postsrc**

Optional. Specifies a program invocation to take place at the source agent after the transfer has completed. You can only associate a single `fte:postsrc` element with a given transfer. See the [program invocation](#) topic for more information.

**fte:postdst**

Optional. Specifies a program invocation to take place at the destination agent after the transfer has completed. You can only associate a single `fte:postdst` element with a given transfer. See the [program invocation](#) topic for more information.

If `fte:presrc`, `fte:predst`, `fte:postsrc`, `fte:postdst`, and `exits` do not return a success status, the rules are as follows in the order specified:

1. Run the source start exits. If source start exits fail the transfer fails and nothing further is run.
2. Run the pre-source call (when present). If the pre-source call fails, the transfer fails and nothing further is run.
3. Run the destination start exits. If the destination start exits fail the transfer fails and nothing further is run.
4. Run the pre-destination call (when present). If the pre-destination call fails, the transfer fails and nothing further is run.
5. Perform the file transfers.
6. Run the destination end exits. There is no failure status for these exits.
7. If the transfer is successful (if some files transfer successfully, the transfer is considered successful), run the post-destination call (if present). If the post-destination call fails, the transfer fails.
8. Run the source end exits. There is no failure status for these exits.
9. If the transfer is successful, run the post-source call (if present). If the post-source call fails, the transfer fails.

## Examples

This example shows a basic file move between `agent1` and `agent2`. The command to start the file move is sent to a queue manager called `qm0`, using a client transport mode connection. The result of the file transfer operation is assigned to the property called `move.result`.

```
<fte:filemove cmdqm="qm0@localhost@1414@SYSTEM.DEF.SVRCONN"
  src="agent1@qm1" dst="agent2@qm2"
  rcproperty="move.result">

  <fte:filespec srcfilespec="/home/fteuser1/file.bin" dstfile="/home/fteuser2/file.bin"/>
</fte:filemove>
```

## Related concepts

[Timeout option for file transfers in recovery](#)

## Related tasks

[Using Apache Ant with MFT](#)

## fte:ignoreoutcome Ant task

Ignore the outcome of an **fte:filecopy**, **fte:filemove**, or **fte:call** command. When you specify an **fte:filecopy**, **fte:filemove**, or **fte:call** task to have an outcome of `defer`, the Ant task allocates resources to tracking this outcome. If you are no longer interested in the outcome, you can use the **fte:ignoreoutcome** task to free those resources.

## Attributes

### id

Required. Identifies the outcome that is no longer of interest. Typically you specify this identifier using a property that you set using the `idproperty` attribute of the [“fte:filecopy Ant task” on page 2102](#), [“fte:filemove Ant task” on page 2106](#), or [“fte:call Ant task” on page 2099](#) task.

## Example

This example shows how you can use the `fte:ignoreoutcome` task to free the resources allocated to tracking the outcome of the earlier [“fte:filecopy Ant task” on page 2102](#) task.

```
<!-- issue a file copy request -->
```

```

<fte:filecopy cmdqm="qm1@localhost@1414@SYSTEM.DEF.SVRCONN"
    src="agent1@qm1" dst="agent1@qm1"
    idproperty="copy.id"
    outcome="defer"/>

<!-- do some other things -->

<!-- decide that the result of the copy is not interesting -->
<fte:ignoreoutcome id="{copy.id}"/>

```

## Related tasks

[Using Apache Ant with MFT](#)

## fte:ping Ant task

This IBM MQ Managed File Transfer Ant task pings an agent to elicit a response, and so determines if the agent is able to process transfers.

**Note:** IBM WebSphere MQ File Transfer Edition (FTE) is no longer a supported product. To migrate from FTE to the Managed File Transfer component in IBM MQ, see [Migrating Managed File Transfer](#).

## Attributes

### agent

Required. Specifies the agent to submit the **fte:ping** request to. The value is in the form: *agentname@qmgrname* where *agentname* is the name of the agent and *qmgrname* is the name of the queue manager that this agent is directly connected to.

### cmdqm

Optional. The command queue manager to submit the request to. Specify this information in the form *qmgrname@host@port@channel*, where:

- *qmgrname* is the name of the queue manager
- *host* is the optional host name of the system where the queue manager is running
- *port* is the optional port number that the queue manager is listening on
- *channel* is the optional SVRCONN channel to use

If you omit the *host*, *port*, or *channel* information for the command queue manager, the connection information specified in the `command.properties` file is used.

**Attention:** If no value is specified for the:

- *host* variable, bindings mode is used
- *port* variable, the value 1414 is used
- *channel* variable, the SYSTEM.DEF.SVRCONN is used.

See [The MFT command.properties file](#) for more information.

However, you cannot skip the attributes in the middle, for example, *qmgrname@host@@channel*. You can have, for example, *qmgrname@host*, or *qmgrname@host@port*, or *qmgrname@hostport@@channel*.

MFT splits the given attribute using the @ delimiter. Depending on the number of tokens found, it takes the first token as *qmgrname*, the second one as *host*, the third one as *port* and finally *channel*.

For more information, see [The MFT command.properties file](#).

You can use the **com.ibm.wmqfte.propertySet** property to specify which `command.properties` file to use. For more information, see [com.ibm.wmqfte.propertySet](#).

If you do not use the `cmdqm` attribute, the task defaults to using the `com.ibm.wmqfte.ant.commandQueueManager` property, if this property is set. If the `com.ibm.wmqfte.ant.commandQueueManager` property is not set, a connection to the default queue manager, defined in the `command.properties` file, is attempted. The format of the

`com.ibm.wmqfte.ant.commandQueueManager` property is the same as the `cmdqm` attribute, that is, `qmgrname@host@port@channel`.

### **rcproperty**

Required. Names a property to store the return code of the **ping** operation in.

### **timeout**

Optional. The maximum amount of time, in seconds, for the task to wait for the agent to respond. The minimum timeout is zero seconds, however a timeout of minus one can also be specified such that the command waits forever for the agent to respond. If no value is specified for the `timeout` then the default is to wait up to 5 seconds for the agent to respond.

### **Example**

This example sends a **fte:ping** request to `agent1` hosted by `qm1`. The **fte:ping** request waits 15 seconds for the agent to respond. The outcome of the **fte:ping** request is stored in a property called `ping.rc`.

```
<fte:ping agent="agent1@qm1" rcproperty="ping.rc" timeout="15"/>
```

### **Return codes**

**0**

Command completed successfully.

**2**

Command timed out.

### **Related tasks**

[Using Apache Ant with MFT](#)

### **fte:uuid Ant task**

Generates a pseudo-random unique identifier and assigns it to a given property. For example, you can use this identifier to generate job names for other file transfer operations.

### **Attributes**

#### **length**

Required. The numeric length of UUID to generate. This length value does not include the length of any prefix, specified by the **prefix** parameter.

#### **property**

Required. The name of the property to assign the generated UUID to.

#### **prefix**

Optional. A prefix to add to the generated UUID. This prefix is not counted as part of the length of the UUID, as specified by the **length** parameter.

### **Example**

This example defines a UUID that starts with the letters ABC followed by 16 pseudo-random hex characters. The UUID is assigned to a property named `uuid.property`.

```
<fte:uuid length="16" property="uuid.property" prefix="ABC"/>
```

### **Related tasks**

[Using Apache Ant with MFT](#)

## **fte:filespec Ant nested element**

The **fte:filespec** parameter is used as a nested element in other tasks. Use **fte:filespec** to describe a mapping between one or more source files, directories  or data sets, and a destination. Typically this element is used when expressing a set of files or directories  or data sets to move or copy.

### **Nested by:**

- The [fte:filecopy](#) task
- The [fte:filemove](#) task

### **Source specification attributes**

You must specify one of `srcfilespec` or `srcqueue`.

#### **srcfilespec**

Specifies the source of the file operation. The value of this attribute can include a wildcard.

#### **srcqueue**

Specifies the source of the transfer is a queue. The transfer moves data from messages stored on the queue specified by this attribute. You cannot specify this attribute if the **fte:filespec** task is nested within the **fte:filecopy** task.

The `srcqueue` attribute is not supported when the source agent is a protocol bridge agent.

### **Destination specification attributes**

You must specify one of `dstdir`, `dstds`, `dstfilespace`, `dstfile`, `dstqueue` or `dstpds`.

#### **dstdir**

Specifies a directory as the destination for a file operation.

#### **dstds**

Specifies a data set as the destination for a file operation.

This attribute is supported only when the destination agent is running on the z/OS platform.

#### **dstfile**

Specifies a file as the destination for a file operation.

#### **dstfilespace**

Specifies a file space as the destination for a file operation.

This attribute applies only if the destination agent is an IBM MQ 8.0 web agent that has access to the web gateway file space.

#### **dstpds**

Specifies a partitioned data set as the destination for a file operation.

This attribute is supported only when the destination agent is running on the z/OS platform.

#### **dstqueue**

Specifies a queue as the destination for a file to message operation. You can optionally include a queue manager name in this specification, using the format `QUEUE@QUEUEMANAGER`. If you do not specify a queue manager name the destination agent queue manager is used if you have not set the `enableClusterQueueInputOutput` agent property to true. If the `enableClusterQueueInputOutput` property is set to true, the destination agent uses standard IBM MQ procedures to determine where the queue is located. You must specify a valid queue name that exists on the queue manager.

If you specify the `dstqueue` attribute, you cannot specify the `srcqueue` attributes because these attributes are mutually exclusive.

The `dstqueue` attribute is not supported when the destination agent is a protocol bridge agent.

## Source option attributes

### **srcencoding**

Optional. The character set encoding used by the file to transfer.

You can specify this attribute only when the `conversion` attribute is set to a value of `text`.

If you do not specify the `srcencoding` attribute, the character set of the source system is used for text transfers.

### **srceol**

Optional. The end of line delimiter used by the file being transferred. The valid values are as follows:

- `CRLF` - Use a carriage return character followed by a line-feed character as the end of line delimiter. This convention is typical for Windows systems.
- `LF` - Use a line-feed character as the end of line delimiter. This convention is typical for UNIX systems.

You can specify this attribute only when the `conversion` attribute is set to a value of `text`. If you do not specify the `srceol` attribute, text transfers automatically determine the correct value based on the operating system of the source agent.

### **z/OS srckeeptrailingspaces**

Optional. Determines whether trailing spaces are kept on source records read from a fixed-length-format data set as part of a text mode transfer. The valid values are as follows:

- `true` - trailing spaces are kept.
- `false` - trailing spaces are stripped.

If you do not specify the `srckeeptrailingspaces` attribute, a default value of `false` is specified.

You can specify this attribute only if you also specify the `srcfilespec` attribute and you set the `conversion` attribute to a value of `text`.

### **srcmsgdelimbytes**

Optional. Specifies one or more byte values to insert as the delimiter when appending multiple messages to a binary file. Each value must be specified as two hexadecimal digits in the range 00-FF, prefixed by `x`. Multiple bytes must be comma-separated. For example, `srcmsgdelimbytes="x08,xA4"`. You can specify the `srcmsgdelimbytes` attribute only if you have also specified the `srcqueue` attribute. You cannot specify the `srcmsgdelimbytes` attribute if you have also specified the value `text` for the `conversion` attribute.

### **srcmsgdelimtext**

Optional. Specifies a sequence of text to insert as the delimiter when appending multiple messages to a text file. You can include Java escape sequences for String literals in the delimiter. For example, `srcmsgdelimtext="\u007d\n"`. The text delimiter is inserted after each message by the source agent. The text delimiter is encoded to binary format using the source encoding of the transfer. Each message is read in binary format, the encoded delimiter is appended in binary format to the message, and the result is transferred in binary format to the destination agent. If the source agent code page includes shift-in and shift-out states, the agent assumes that each message is in the shift-out state at the end of the message. At the destination agent the binary data is converted in the same way as a file to file text transfer. You can only specify the `srcmsgdelimtext` attribute if you have also specified the `srcqueue` attribute and a value of `text` for the `conversion` attribute.

### **srcmsgdelimposition**

Optional. Specifies the position that the text or binary delimiter is inserted into. The valid values are as follows:

- `prefix` - the delimiters are inserted into the destination file before the data from each message.
- `postfix` - the delimiters are inserted into the destination file after the data from each message.

You can specify the `srcmsgdelimposition` attribute only if you have also specified one of the `srcmsgdelimbytes` or `srcmsgdelimtext` attributes.

### **srcmsggroups**

Optional. Specifies that the messages are grouped by IBM MQ group ID. The first complete group is written to the destination file. If this attribute is not specified, all messages on the source queue are written to the destination file. You can specify the `srcmsggroups` attribute only if you have also specified the `srcqueue` attribute.

### **srcqueuetimeout**

Optional. Specifies the time, in seconds, to wait for one of the following conditions to be met:

- For a new message to be written to the queue.
- If the `srcmsggroups` attribute was specified, for a complete group to be written on the queue.

If neither of these conditions are met within the time specified by the value of `srcqueuetimeout`, the source agent stops reading from the queue and completes the transfer. If the `srcqueuetimeout` attribute is not specified, the source agent stops reading from the source queue immediately if the source queue is empty or, in the case where the `srcmsggroups` attribute is specified, if there is no complete group on the queue. You can specify the `srcqueuetimeout` attribute only if you have also specified the `srcqueue` attribute.

For information about setting the `srcqueuetimeout` value, see [Guidance for specifying a wait time on a message-to-file transfer](#).

### **z/OS srcrcdelimbytes**

Optional. Specifies one or more byte values to insert as the delimiter when appending multiple records from a record-oriented source file to a binary file. You must specify each value as two hexadecimal digits in the range 00-FF, prefixed by x. Multiple bytes must be comma-separated. For example:

```
srcrcdelimbytes="x08,xA4"
```

You can specify the `srcrcdelimbytes` attribute only if the transfer source file is record oriented, for example a z/OS data set, and the destination file is a normal, non-record-oriented file. You cannot specify the `srcrcdelimbytes` attribute if you have also specified the value `text` for the conversion attribute.

### **srcrcdelimpos**

Optional. Specifies the position that the binary delimiter is inserted into. The valid values are as follows:

- `prefix` - the delimiters are inserted into the destination file before the data from each source record-oriented file record.
- `postfix` - the delimiters are inserted into the destination file after the data from each source record-oriented file record.

You can specify the `srcrcdelimpos` attribute only if you have also specified the `srcrcdelimbytes` attribute.

## **Destination option attributes**

### **dstencoding**

Optional. The character set encoding to use for the transferred file.

You can specify this attribute only when the conversion attribute is set to a value of `text`.

If the `dstencoding` attribute is not specified, the character set of the destination system is used for text transfers.

### **dsteol**

Optional. The end of line delimiter to use for the transferred file. The valid values are as follows:

- CRLF - Use a carriage return character followed by a line-feed character as the end of line delimiter. This convention is typical for Windows systems.
- LF - Use a line-feed character as the end of line delimiter. This convention is typical for UNIX systems.

You can specify this attribute only when the conversion attribute is set to a value of text .

If you do not specify the `dsteol` attribute, text transfers automatically determine the correct value based on the operating system of the destination agent.

### **dstmsgdelimbytes**

Optional. Specifies the hexadecimal delimiter to use when splitting a binary file into multiple messages. All the messages have the same IBM MQ group ID; the last message in the group has the IBM MQ `LAST_MSG_IN_GROUP` flag set. The format for specifying a hexadecimal byte as a delimiter is `xNN`, where N is a character in the range 0-9 or a-f. You can specify a sequence of hexadecimal bytes as a delimiter by specifying a comma-separated list of hexadecimal bytes, for example: `x3e , x20 , x20 , xbf`.

You can specify the `dstmsgdelimbytes` attribute only if you have also specified the `dstqueue` attribute and the transfer is in binary mode. You can specify only one of the `dstmsgsize`, `dstmsgdelimbytes`, and `dstmsgdelimpattern` attributes.

### **dstmsgdelimpattern**

Optional. Specifies the Java regular expression to use when splitting a text file into multiple messages. All the messages have the same IBM MQ group ID; the last message in the group has the IBM MQ `LAST_MSG_IN_GROUP` flag set. The format for specifying a regular expression as a delimiter is a regular expression enclosed in parentheses, (*regular\_expression*), or enclosed in double quotation marks, "*regular\_expression*". For more information, see [Regular expressions used by MFT](#).

By default, the length of the string that the regular expression can match is limited by the destination agent to five characters. You can change this behavior using the `maxDelimiterMatchLength` agent property. For more information, see [MFT advanced agent properties](#).

You can specify the `dstmsgdelimpattern` attribute only if you have also specified the `dstqueue` attribute and the transfer is in text mode. You can specify only one of the `dstmsgsize`, `dstmsgdelimbytes`, and `dstmsgdelimpattern` attributes.

### **dstmsgdelimposition**

Optional. Specifies the position that the text or binary delimiter is expected to be in. The valid values are as follows:

- `prefix` - The delimiters are expected at the beginning of each line.
- `postfix` - The delimiters are expected at the end of each line.

You can specify the `dstmsgdelimposition` attribute only if you have also specified the `dstmsgdelimpattern` attribute.

### **dstmsgincludedelim**

Optional. Specifies whether to include the delimiter that is used to split the file into multiple messages in the messages. If the `dstmsgincludedelim` attribute is specified, the delimiter is included at the end of the message that contains the file data preceding the delimiter. By default the delimiter is not included in the messages. You can specify the `dstmsgincludedelim` attribute only if you have also specified one of the `dstmsgdelimpattern` and `dstmsgdelimbytes` attributes.

### **dstmsgpersist**

Optional. Specifies whether messages written to the destination queue are persistent. The valid values are as follows:

- `true` - Write persistent messages to the destination queue. This is the default value.
- `false` - Write non-persistent messages to the destination queue.
- `qdef` - The persistence value is taken from the `DefPersistence` attribute of the destination queue.

You can specify this attribute only when the `dstqueue` attribute is also specified.

### **dstmsgprops**

Optional. Specifies whether the first message written to the destination queue by the transfer has IBM MQ message properties set. Possible values are:

- `true` - Set message properties on the first message created by the transfer.
- `false` - Do not set message properties on the first message created by the transfer. This is the default value.

For more information, see [MQ message properties set by MFT on messages written to destination queues](#).

You can specify this attribute only when the `dstqueue` attribute is also specified.

### **dstmsgsize**

Optional. Specifies whether to split the file into multiple fixed-length messages. All of the messages have the same IBM MQ group ID; the last message in the group has the IBM MQ `LAST_MSG_IN_GROUP` flag set. The size of the messages is specified by the value of `dstmsgsize`. The format of `dstmsgsize` is *lengthunits*, where *length* is a positive integer value and *units* is one of the following values:

- `B` - Bytes. The minimum value allowed is two times the maximum bytes-per-character value of the code page of the destination messages.
- `K` - Kibibytes. This is equivalent to 1024 bytes.
- `M` - Mebibytes. This is equivalent to 1024 kibibytes.

If the file is transferred in text mode, and is in a double-byte character set or multibyte character set, the file is split into messages on the closest character boundary to the specified message size.

You can specify the `dstmsgsize` attribute only if you have also specified the `dstqueue` attribute. You can specify only one of the `dstmsgsize`, `dstmsgdelimbytes`, and `dstmsgdelimpattern` attributes.

### **dstunsupportedcodepage**

Optional. Specifies the action to take if the destination queue manager, as specified by the `dstqueue` attribute, does not support the code page used when transferring file data to a queue as a text transfer. The valid values for this attribute are as follows:

- `binary` - continue the transfer but do not apply code page conversion to the data being transferred. Specifying this value is equivalent to not setting the conversion attribute to `text`.
- `fail` - do not continue with the transfer operation. The file is recorded as having failed to transfer. This is the default.

You can only specify the `dstunsupportedcodepage` attribute if you have also specified the `dstqueue` attribute and a value of `text` for the conversion attribute.

### **dsttruncaterecords**

Optional. Specifies that destination records longer than the `LRECL` data set attribute are truncated. If set to `true`, the records are truncated. If set to `false`, the records are wrapped. The default setting is `false`. This parameter is valid only for text mode transfers where the destination is a data set.

## **Other attributes**

### **checksum**

Optional. Determines the algorithm used to checksum transferred files.

- `MD5` - use the MD5 hashing algorithm.
- `NONE` - do not use a checksum algorithm.

If you do not specify the checksum attribute, a default value of `MD5` is used.

### **conversion**

Optional. Specifies the type of conversion to apply to the file as it is being transferred. Possible values are:

- `binary` - apply no conversion.
- `text` - apply code page conversion between the source and destination systems. Also apply conversion of line delimiters. The `srcencoding`, `dstencoding`, `srceol` and `dsteol` attributes influence the conversion that is applied.

If you do not specify the conversion attribute, a default value of `binary` is specified.

### overwrite

Optional. Determines whether an existing destination file `> z/OS` or data set can be overwritten by the operation. When you specify a value of `true`, any existing destination file `> z/OS` or data sets are overwritten. When you specify a value of `false`, the existence of a duplicate file `> z/OS` or data set at the destination results in the operation failing. If the `overwrite` attribute is not specified, a default value of `false` is specified.

### recurse

Optional. Determines whether the file transfer recurses into subdirectories. When you specify a value of `true`, the transfer recurses into subdirectories. When you specify a value of `false`, the transfer does not recurse into subdirectories. If the `recurse` attribute is not specified, a default value of `false` is specified.

### Example

This example specifies a `fte:filespec` with a source file of `file1.bin` and a destination file of `file2.bin`.

```
<fte:filespec srcfilespec="/home/fteuser/file1.bin" dstfile="/home/fteuser/file2.bin"/>
```

### Related tasks

[Using Apache Ant with MFT](#)

## fte:metadata Ant nested elements

Metadata is used to carry additional user-defined information with a file transfer operation.

See [“Metadata for MFT user exits” on page 2121](#) for more information about how Managed File Transfer uses metadata.

### Nested by:

- The [fte:filecopy](#) task
- The [fte:filemove](#) task
- The [fte:call](#) task

## Parameters specified as nested elements

### fte:entry

You must specify at least one entry inside the `fte:metadata` nested element. You can choose to specify more than one entry. Entries associate a key name with a value. Keys must be unique in a block of `fte:metadata`

## Entry attributes

### name

Required. The name of the key belonging to this entry. This name must be unique across all **entry** parameters nested inside a `fte:metadata` element.

### value

Required. The value to assign to this entry.

## Example

This example shows a `fte:metadata` definition that contains two entries.

```
<fte:metadata>
  <fte:entry name="org.foo.partColor" value="red"/>
  <fte:entry name="org.foo.partSize" value="medium"/>
</fte:metadata>
```

## Related tasks

[Using Apache Ant with MFT](#)

## Program invocation nested elements

Programs can be started using one of five nested elements: `fte:presrc`, `fte:predst`, `fte:postdst`, `fte:postsrc`, and `fte:command`. These nested elements instruct an agent to call an external program as part of its processing. Before you can start a program, you must ensure that the command is in a location specified by the `commandPath` property in the `agent.properties` file of the agent that runs the command.

Even though each program invocation element has a different name, they share the same set of attributes and the same set of nested elements. Programs can be started by the **`fte:filecopy`**, **`fte:filemove`**, and **`fte:command`** Ant tasks.

You cannot invoke programs from a Connect:Direct® bridge agent.

## Ant tasks that can invoke programs:

- The `fte:filecopy` task nests program invocation parameters using the `fte:predst`, `fte:postdst`, `fte:presrc`, and `fte:postsrc` nested elements.
- The `fte:filemove` task nests program invocation parameters using the `fte:predst`, `fte:postdst`, `fte:presrc`, and `fte:postsrc` nested elements.
- The `fte:call` task nests program invocation parameters using the `fte:command` nested element.

## Attributes

### command

Required. Names the program to call. For the agent to be able to run a command, the command must be in a location specified by the `commandPath` property in the agent's `agent.properties` file. For more information, see `commandPath` MFT property. Any path information specified in the `command` attribute is considered relative to a location specified by the `commandPath` property. When `type` is `executable`, an executable program is expected otherwise a script appropriate for the `call` type is expected.

### retrycount

Optional. The number of times to retry calling the program if the program does not return a success return code. The program named by the `command` attribute is called up to this number of times. The value assigned to this attribute must be non-negative. If you do not specify the `retrycount` attribute, a default value of zero is used.

### retrywait

Optional. The time to wait, in seconds, before trying the program invocation again. If the program named by the `command` attribute does not return a success return code and the `retrycount` attribute specifies a non-zero value, this parameter determines the time to wait between retries. The value assigned to this attribute must be non-negative. If you do not specify the `retrywait` attribute, a default value of zero is used.

### successrc

Optional. The value of this attribute is used to determine when the program invocation successfully runs. The process return code for the command is evaluated using this expression. The value can be composed of one or more expressions combined with a vertical bar character (`|`) to signify Boolean

OR, or an ampersand (&) character to signify Boolean AND. Each expression can be one of the following types of expression:

- A number to indicate an equality test between the process return code and the number.
- A number prefixed with a ">" character to indicate a greater-than test between the number and the process return code.
- A number prefixed with a "<" character to indicate a less-than test between the number and the process return code.
- A number prefixed with a "!" character to indicate a not-equal-to test between the number and the process return code.

For example: >2&<7&!5|0|14 is interpreted as the following return codes being successful: 0, 3, 4, 6, 14. All other return codes are interpreted as being unsuccessful. If you do not specify the `successrc` attribute, a default value of zero is used. This means that the command is judged to have successfully run if, and only if, it returns a code of zero.

### type

Optional. The value of this attribute specifies what type of program is being called. Specify one of the following options:

#### executable

The task calls an executable program. Can have additional arguments specified using the `arg` nested element. The program is expected to be accessible on the `commandPath` and where applicable have execute permission set. UNIX scripts can be called as long as they specify a shell program (for example, first line of shell script file is: `#!/bin/sh`). Command output written to `stderr` or `stdout` is sent to the Managed File Transfer log for the call. However, the amount of data output is limited by the agent configuration. The default is 10K bytes of data, but you can override this default using the agent property: `maxCommandOutput`.

#### antscript

The task runs the specified Ant script, using the `fteAnt` command. Properties can be specified using the `property` nested element. Ant targets can be specified using the `target` nested element. The Ant script is expected to be accessible on the `commandPath`. Ant output written to `stderr` or `stdout` is sent to the Managed File Transfer log for the call. However, the amount of data output is limited by the agent configuration. The default is 10K bytes of data but you can override this default using the agent property: `maxCommandOutput`.

#### jcl

The value `jcl` is supported on z/OS only and runs the specified z/OS JCL script. The JCL is submitted as a job and requires the job card to be present. When the job is submitted successfully the JCL command output, written to the Managed File Transfer log, contains the following text: `JOB job_name(job_id)` where:

- `job_name` is the name of the job identified by the job card in the JCL.
- `job_id` is the z/OS system generated job ID.

If the job cannot be submitted successfully, the JCL script command fails and writes a message to the log indicating the reason for the failure (for example no job card is present). To understand whether the job has been run or completed successfully, use a system service such as SDSF. Managed File Transfer does not provide the information because it only submits the job; the system then determines when to run the job and how the job output is presented. Because a JCL script is submitted as a batch job it is not advisable to specify `jcl` for a `presrc` or `predst` nested element because you only know that the job has been submitted successfully and not whether it ran to completion successfully before the transfer starts. There are no nested elements that are valid with a type of `jcl`.

The following example shows a JCL job:

```
//MYJOB JOB  
//*  
//MYJOB EXEC PGM=IEBGENER
```

```
//SYSPRINT DD SYSOUT=H
//SYSUT1 DD DSN=FRED.DEMO.TXT,DISP=SHR
//SYSUT2 DD DSN=BOB.DEMO.TXT,DISP=(NEW,CATLG),
// RECFM=VB,LRECL=133,BLKSIZE=2048,
// SPACE=(TRK,(30,5),RLSE)
//SYSIN DD DUMMY
```

## Parameters specified as nested elements

### **fte:arg**

Only valid where the value of the `type` attribute is executable. Use nested `fte:arg` elements to specify arguments to the program that is being called as part of the program invocation. The program arguments are built from the values specified by the `fte:arg` elements in the order that the `fte:arg` elements are encountered. You can choose to specify zero or more `fte:arg` elements as nested elements of a program invocation.

### **fte:property**

Only valid where the value of the `type` attribute is `antscript`. Use the `name` and `value` attributes of the nested `fte:property` elements to pass in name-value pairs to the Ant script. You can choose to specify zero or more `property` elements as nested elements of a program invocation.

### **fte:target**

Only valid where the value of the `type` attribute is `antscript`. Specify a target in the Ant script to call. You can choose to specify zero or more `fte:target` elements as nested elements of a program invocation.

## Arg attributes

### **value**

Required. The value of the argument to pass to the program being called.

## Property attributes

### **name**

Required. The name of a property to pass to the Ant script.

### **value**

Required. The value to associate with the property name being passed to the Ant script.

## Examples

This example shows an `fte:postsrc` program invocation being specified as part of an `fte:filecopy` task. The program invocation is for a program called `post.sh` and is supplied a single argument of `/home/fteuser2/file.bin`.

```
<fte:filecopy
cmdqm="qm0@localhost@1414@SYSTEM.DEF.SVRCONN"
src="agent1@qm1" dst="agent2@qm2"
rcproperty="copy.result">
<fte:filespec srcfilespec="/home/fteuser1/file.bin" dstfile="/home/fteuser2/file.bin"/>
<fte:postsrc command="post.sh" successrc="1" >
  <fte:arg value="/home/fteuser2/file.bin"/>
</fte:postsrc>
</fte:filecopy>
```

This example shows an `fte:command` program invocation being specified as part of a `fte:call` task. The program invocation is for an executable called `command.sh`, which is not passed any command-line arguments. If `command.sh` does not return a success return code of 1, the command is tried again after 30 seconds.

```
<fte:call
cmdqm="qm0@localhost@1414@SYSTEM.DEF.SVRCONN"
agent="agent1@qm1"
rcproperty="call.rc"
```

```

origuser="bob"
jobname="${job.id}">
<fte:command command="command.sh" successsrc="1" retrycount="5" retrywait="30"/>
</fte:call>

```

This example shows an `fte:command` program invocation being specified as part of a `fte:call` task. The program invocation is for the copy and compress targets in an Ant script called `script.xml`, which is passed two properties.

```

<fte:call
cmdqm="qm0@localhost@1414@SYSTEM.DEF.SVRCONN"
agent="agent1@qm1"
rcproperty="call.rc"
origuser="bob"
jobname="${job.id}">
<fte:command command="script.xml" type="antscript">
  <property name="src" value="AGENT5@QM5"/>
  <property name="dst" value="AGENT3@QM3"/>
  <target name="copy"/>
  <target name="compress"/>
</fte:command>
</fte:call>

```

### Metadata for MFT user exits

There are three different types of metadata that can be supplied to user exit routines for Managed File Transfer: environment, transfer, and file metadata. This metadata is presented as maps of Java key-value pairs.

#### Environment metadata

Environment metadata is passed to all user exit routines and describes the agent runtime environment that the user exit routine is being called from. This metadata is read-only and cannot be updated by any user exit routine.

Key	Description
AGENT_CONFIGURATION_DIRECTORY_KEY	The name of the directory that contains the agent's configuration information.
AGENT_PRODUCT_DIRECTORY_KEY	The name of the directory that the agent code has been installed in.
AGENT_VERSION_KEY	Version number for the agent runtime that calls the exit routine.

The key names and value names given in Table 1 are constants that are defined in the `EnvironmentMetaDataConstants` interface.

## Transfer metadata

Transfer metadata is passed to all user exit routines. The metadata consists of system-supplied values and user-supplied values. If you change any system-supplied values, these changes are ignored. The initial user-supplied values for the source transfer start user exit are based on those values you supply when you define the transfer. The source agent can change user-supplied values as part of the processing of the source transfer start user exit. This user exit is called before the entire file transfer starts. These changes are used in subsequent calls to other exit routines that relate to that transfer. Transfer metadata is applied to an entire transfer.

Although all user exits can read values from the transfer metadata, only the source transfer start user exit can change transfer metadata

You cannot use transfer metadata to propagate information between different file transfers.

The system-supplied transfer metadata is detailed in Table 2:

Key	Description
DESTINATION_AGENT_KEY	The name of the agent that is the destination for the transfer.
JOB_NAME_KEY	The job name associated with the transfer request
MQMD_USER_KEY	The MQMD user field from the message used to submit the transfer request
ORIGINATING_HOST_KEY	The host name specified as the originating host name in the transfer request
ORIGINATING_USER_KEY	The user name specified as the originating user ID in the transfer request
SOURCE_AGENT_KEY	The name of the agent that is the source of the transfer
TRANSFER_ID_KEY	The identifier of the transfer

The key names and value names given in Table 2 are constants that are defined in the TransferMetaDataConstants interface.

## File metadata

The file metadata is passed to the source transfer start exit as part of the file specification. There is separate file metadata for the source and destination files.

You cannot use file metadata to propagate information between different file transfers.

Key	Permitted values	Description
CONVERT_LINE_SEPARATORS		Key value used for text transfers to indicate whether CRLF (carriage return-line feed) or LF (line feed) line separator sequences in source data are converted to the line separator sequence at the destination.
DELIMITER_KEY		Key value used to define a delimiter to separate record data when transferring record-oriented data to normal files.  Also used for message-to-file and file-to-message transfers.

Table 884. File metadata (continued)

Key	Permitted values	Description
DELIMITER_POSITION_KEY	DELIMITER_POSITION_PREFIX_VALUE DELIMITER_POSITION_POSTFIX_VALUE	Use with the DELIMITER_KEY to define the position of the delimiter; either prefix or postfix.
DELIMITER_TYPE_KEY	DELIMITER_TYPE_BINARY_VALUE DELIMITER_TYPE_TEXT_VALUE DELIMITER_TYPE_SIZE_VALUE	Use with the DELIMITER_KEY to define the type of delimiter.
DESTINATION_EXIST_KEY	DESTINATION_EXIST_KEY_ERROR_VALUE DESTINATION_EXIST_KEY_OVERWRITE_VALUE	Determines the file transfer behavior if the destination file exists.
FILE_ALIAS_KEY		Key value used to define an alias for the file being transferred.
FILE_CHECKSUM_METHOD_KEY	FILE_CHECKSUM_METHOD_NONE_VALUE FILE_CHECKSUM_METHOD_MD5_VALUE	Determines the checksum method to use when transferring the file.
FILE_CONVERSION_KEY	FILE_CONVERSION_TEXT_VALUE FILE_CONVERSION_BINARY_VALUE	Determines the type of conversion applied to the file contents.
FILE_ENCODING_KEY		Determines the encoding used for a text file.
FILE_END_OF_LINE_KEY	FILE_END_OF_LINE_LF_VALUE FILE_END_OF_LINE_CRLF_VALUE	Determines the character sequence that denotes the end of a line: <LF> or <CR><LF>.
FILE_SPACE_ALIAS		Determines the alias of a file in the file space. <b>Note:</b> This metadata can be used only if the FILE_TYPE_KEY is FILE_TYPE_FILE_SPACE_VALUE
FILE_SPACE_NAME		Determines the name of the file space. <b>Note:</b> This metadata can be used only if the FILE_TYPE_KEY is FILE_TYPE_FILE_SPACE_VALUE
FILE_TYPE_KEY	FILE_TYPE_FILE_VALUE FILE_TYPE_DIRECTORY_VALUE FILE_TYPE_DATASET_VALUE FILE_TYPE_PDS_VALUE FILE_TYPE_QUEUE_VALUE FILE_TYPE_FILE_SPACE_VALUE	Determines the destination file, queue, or file space specification.
GROUP_ID_KEY		Key value used for message-to-file transfers to determine the group of messages to read from the source queue. This attribute is valid only when the value of USE_GROUPS_KEY is USE_GROUPS_TRUE_VALUE.
INCLUDE_DELIMITER_IN_MESSAGE_KEY	INCLUDE_DELIMITER_IN_MESSAGE_TRUE_VALUE INCLUDE_DELIMITER_IN_MESSAGE_FALSE_VALUE	Key value used for file-to-message transfers to determine whether to include the delimiters that were used to split the file into multiple messages at the end of the messages. This attribute is valid only when the value of DELIMITER_TYPE_KEY is DELIMITER_TYPE_BINARY_VALUE DELIMITER_TYPE_TEXT_VALUE.
INSERT_RECORD_LINE_SEPARATOR_KEY		Key value used for text transfers from record-oriented files to specify whether line separators are inserted into the data after each record.

Table 884. File metadata (continued)		
Key	Permitted values	Description
KEEP_TRAILING_SPACES_KEY	KEEP_TRAILING_SPACES_TRUE_VALUE KEEP_TRAILING_SPACES_FALSE_VALUE	Key value used to determine whether trailing spaces are removed from records read from fixed-length-format data sets.
NEW_RECORD_ON_LINE_SEPARATOR_KEY		Key value used for text transfers to record-oriented files to specify whether line separators in the data are included with the record data or cause a new record (and are not written).
PERSISTENT_KEY	PERSISTENT_TRUE_VALUE PERSISTENT_FALSE_VALUE PERSISTENT_QDEF_VALUE	Key value used for file-to-message transfers to determine whether the messages are persistent.
SET_MQ_PROPS_KEY	SET_MQ_PROPS_TRUE_VALUE SET_MQ_PROPS_FALSE_VALUE	Key value used for file-to-message transfers to determine whether IBM MQ message properties are set on the first message in a file, and any messages written to the queue when an error occurs.
UNRECOGNISED_CODE_PAGE_KEY	UNRECOGNISED_CODE_PAGE_FAIL_VALUE UNRECOGNISED_CODE_PAGE_BINARY_VALUE	Key value used for file-to-message transfers to determine whether a text mode transfer fails or conversion is performed, if the code page of the data is not recognized by the destination queue manager.
USE_GROUPS_KEY	USE_GROUPS_TRUE_VALUE USE_GROUPS_FALSE_VALUE	Key value used for message-to-file transfers to determine whether to transfer only a complete group of messages from the source queue.
WAIT_TIME_KEY		Key value used for message-to-file transfers to determine the time, in seconds, for the source agent to wait for one of the following cases: <ul style="list-style-type: none"> <li>• A message to appear on the source queue, if the queue is empty or has become empty, if the value of USE_GROUPS_KEY is FALSE.</li> <li>• A complete group to appear on the source queue, if the value of USE_GROUPS_KEY is TRUE.</li> </ul>

The key names and value names given in Table 3 are constants that are defined in the FileMetaDataConstants interface.

### Related reference

“MFT resource monitor user exits” on page 2125

Resource monitor user exits allow you to configure custom code to run when a monitor's trigger condition is satisfied, before the associated task is started.

“MFT Agent properties for user exits” on page 2129

In addition to the standard properties in the agent.properties file, there are several advanced properties specifically for user exit routines. These properties are not included by default so if you

want to use any of them, you must manually edit the `agent.properties` file. If you make a change to `agent.properties` file while that agent is running, stop and restart the agent to pick up the changes.

## MFT resource monitor user exits

Resource monitor user exits allow you to configure custom code to run when a monitor's trigger condition is satisfied, before the associated task is started.

It is not recommended to invoke new transfers directly from user exit code. In some circumstances this causes files to be transferred multiple times as user exits are not resilient to agent restarts.

Resource monitor user exits use the existing infrastructure for user exits. The monitor user exits are called after a monitor has triggered but before the corresponding task has been run by the monitor's task. This allows the user exit to modify the task to be run and decide whether a task should proceed or not. You can modify the monitor task by updating the monitor metadata, which is then used for variable substitution in the task document created by the creation of the original monitor. Alternatively, the monitor exit can replace or update the task definition XML string passed as a parameter. The monitor exit can return a result code of either 'proceed' or 'cancel' for the task. If cancel is returned, the task will not be started and the monitor will not start again until the monitored resource matches the trigger conditions. If the resource has not changed, the trigger will not start. As with the other user exits, you can chain monitor exits together. If one of the exits returns a cancel result code, the overall result is cancel and the task is not started.

- A map of environment metadata (same as other user exits)
- A map of monitor metadata including immutable system metadata and mutable user metadata. The immutable system metadata is as follows:
  - FILENAME - name of the file that satisfied the trigger condition
  - FILEPATH - path to the file that satisfied the trigger condition
  - FILESIZE (in bytes - this metadata might not be present) - size of the file that satisfied the trigger condition
  - LASTMODIFIEDDATE (Local) - date that the file that satisfied the trigger condition was last changed. This date is expressed as the local date of the time zone the agent is running in and is formatted as an ISO 8601 date.
  - LASTMODIFIEDTIME (Local) - time in local format that the file that satisfied the trigger condition was last changed. This time is expressed as the local time of the time zone the agent is running in and is formatted as an ISO 8601 time.
  - LASTMODIFIEDDATEUTC - date in universal format that the file that satisfied the trigger condition was last changed. This date is expressed as the local date converted to the UTC time zone and is formatted as an ISO 8601 date.
  - LASTMODIFIEDTIMEUTC - time in universal format that the file that satisfied the trigger condition was last changed. This time is expressed the local time converted to the UTC time zone and is formatted as an ISO 8601 time.
  - AGENTNAME - the monitor agent name
- An XML string representing the task to be run as a result of the monitor trigger.

Monitor exits return the following data:

- An indicator that specifies whether to progress further (proceed or cancel)
- A string to insert into the trigger-satisfied log message

As a result of running the monitor exit code, the monitor metadata and task definition XML string that were originally passed as parameters might also have been updated.

The value of the agent property `monitorExitClasses` (in the `agent.properties` file) specifies which monitor exit classes to load, with each exit class separated by a comma. For example:

```
monitorExitClasses=testExits.TestExit1,testExits.testExit2
```

The interface to the monitor user exit is:

```
package com.ibm.wmqfte.exitroutine.api;

import java.util.Map;

/**
 * An interface that is implemented by classes that want to be invoked as part of
 * user exit routine processing. This interface defines a method that will be
 * invoked immediately prior to starting a task as the result of a monitor trigger
 */
public interface MonitorExit {

    /**
     * Invoked immediately prior to starting a task as the result of a monitor
     * trigger.
     *
     * @param environmentMetaData
     *        meta data about the environment in which the implementation
     *        of this method is running. This information can only be read,
     *        it cannot be updated by the implementation. The constant
     *        defined in <code>EnvironmentMetaDataConstants</code> class can
     *        be used to access the data held by this map.
     *
     * @param monitorMetaData
     *        meta data to associate with the monitor. The meta data passed
     *        to this method can be altered, and the changes will be
     *        reflected in subsequent exit routine invocations. This map
     *        also contains keys with IBM reserved names. These entries are
     *        defined in the <code>MonitorMetaDataConstants</code> class and
     *        have special semantics. The the values of the IBM reserved names
     *        cannot be modified by the exit
     *
     * @param taskDetails
     *        An XML String representing the task to be executed as a result of
     *        the monitor triggering. This XML string may be modified by the
     *        exit
     *
     * @return
     *        a monitor exit result object which is used to determine if the
     *        task should proceed, or be cancelled.
     */
    MonitorExitResult onMonitor(Map<String, String> environmentMetaData,
                               Map<String, String> monitorMetaData,
                               Reference<String> taskDetails);
}

```

The constants for the IBM-reserved values in the monitor metadata are as follows:

```
package com.ibm.wmqfte.exitroutine.api;

/**
 * Constants for IBM reserved values placed into the monitor meta data
 * maps used by the monitor exit routines.
 */
public interface MonitorMetaDataConstants {

    /**
     * The value associated with this key is the name of the trigger
     * file associated with the monitor. Any modification performed
     * to this property by user exit routines will be ignored.
     */
    final String FILE_NAME_KEY = "FILENAME";

    /**
     * The value associated with this key is the path to the trigger
     * file associated with the monitor. Any modification performed
     * to this property by user exit routines will be ignored.
     */
}

```

```

final String FILE_PATH_KEY = "FILEPATH";

/**
 * The value associated with this key is the size of the trigger
 * file associated with the monitor. This will not be present in
 * the cases where the size cannot be determined. Any modification
 * performed to this property by user exit routines will be ignored.
 */
final String FILE_SIZE_KEY = "FILESIZE";

/**
 * The value associated with this key is the local date on which
 * the trigger file associated with the monitor was last modified.
 * Any modification performed to this property by user exit routines
 * will be ignored.
 */
final String LAST_MODIFIED_DATE_KEY = "LASTMODIFIEDDATE";

/**
 * The value associated with this key is the local time at which
 * the trigger file associated with the monitor was last modified.
 * Any modification performed to this property by user exit routines
 * will be ignored.
 */
final String LAST_MODIFIED_TIME_KEY = "LASTMODIFIEDTIME";

/**
 * The value associated with this key is the UTC date on which
 * the trigger file associated with the monitor was last modified.
 * Any modification performed to this property by user exit routines
 * will be ignored.
 */
final String LAST_MODIFIED_DATE_KEY_UTC = "LASTMODIFIEDDATEUTC";

/**
 * The value associated with this key is the UTC time at which
 * the trigger file associated with the monitor was last modified.
 * Any modification performed to this property by user exit routines
 * will be ignored.
 */
final String LAST_MODIFIED_TIME_KEY_UTC = "LASTMODIFIEDTIMEUTC";

/**
 * The value associated with this key is the name of the agent on which
 * the monitor is running. Any modification performed to this property by
 * user exit routines will be ignored.
 */
final String MONITOR_AGENT_KEY = "AGENTNAME";
}

```

## Example monitor user exit

This example class implements the MonitorExit interface. This example adds a custom substitution variable into the monitor metadata called *REDIRECTEDAGENT* that will be populated with a value of LONDON if the hour of the day is odd, and a value of PARIS for even hours. The monitor exit result code is set to always return proceed.

```

package com.ibm.wmqfte.monitor;

import java.util.Calendar;
import java.util.Map;

import com.ibm.wmqfte.exitroutine.api.MonitorExit;
import com.ibm.wmqfte.exitroutine.api.MonitorExitResult;
import com.ibm.wmqfte.exitroutine.api.Reference;

/**
 * Example resource monitor user exit that changes the monitor mutable
 * metadata value between 'LONDON' and 'PARIS' depending on the hour of the day.
 *
 */
public class TestMonitorExit implements MonitorExit {

    // custom variable that will substitute destination agent
    final static String REDIRECTED_AGENT = "REDIRECTEDAGENT";

```

```

    public MonitorExitResult onMonitor(
        Map<String, String> environmentMetaData,
        Map<String, String> monitorMetaData,
        Reference<String> taskDetails) {

        // always succeed
        final MonitorExitResult result = MonitorExitResult.PROCEED_RESULT;

        final int hour = Calendar.getInstance().get(Calendar.HOUR_OF_DAY);

        if (hour%2 == 1) {
            monitorMetaData.put(REDIRECTED_AGENT, "LONDON");
        } else {
            monitorMetaData.put(REDIRECTED_AGENT, "PARIS");
        }

        return result;
    }
}

```

The corresponding task for a monitor that makes use of the *REDIRECTEDAGENT* substitution variable could look similar to the following:

```

<?xml version="1.0" encoding="UTF-8"?>
<request version="4.00"
  xmlns:xsi="https://www.w3.org/2001/XMLSchema-instance"
  xsi:noNamespaceSchemaLocation="FileTransfer.xsd">
  <managedTransfer>
    <originator>
      <hostName>reportserver.com</hostName>
      <userID>USER1</userID>
    </originator>
    <sourceAgent agent="AGENT1"
      QMgr="QM1"/>
    <destinationAgent agent="${REDIRECTEDAGENT}"
      QMgr="QM2"/>
    <transferSet>
      <item mode="binary" checksumMethod="MD5">
        <source recursive="false" disposition="delete">
          <file>c:\sourcefiles\reports.doc</file>
        </source>
        <destination type="file" exist="overwrite">
          <file>c:\destinationfiles\reports.doc</file>
        </destination>
      </item>
    </transferSet>
  </managedTransfer>
</request>

```

Before this transfer is started, the value of the <destinationAgent> element's agent attribute is replaced with either LONDON or PARIS.

You must specify the substitution variable in the monitor exit class and the task definition XML in uppercase.

## MFT Agent properties for user exits

In addition to the standard properties in the `agent.properties` file, there are several advanced properties specifically for user exit routines. These properties are not included by default so if you want to use any of them, you must manually edit the `agent.properties` file. If you make a change to `agent.properties` file while that agent is running, stop and restart the agent to pick up the changes.

Environment variables can be used in some Managed File Transfer properties that represent file or directory locations. This allows the locations of files or directories used when running parts of the product, to vary depending on environment changes, such as which user is running the process. For more information, see [Environment variables in MFT properties](#).

## User exit routine properties

The user exit routines are called in the order listed in the following table. For more information about the `agent.properties` file, see [Advanced agent properties: User exit routine](#).

Property name	Description
<code>sourceTransferEndExitClasses</code>	Specifies a comma-separated list of classes that implement a source transfer end exit routine.
<code>sourceTransferStartExitClasses</code>	Specifies a comma-separated list of classes that implement a source transfer start exit routine.
<code>destinationTransferStartExitClasses</code>	Specifies a comma-separated list of classes that implement a destination transfer start user exit routine.
<code>destinationTransferEndExitClasses</code>	Specifies a comma-separated list of classes that implement a destination transfer user exit routine.
<code>exitClassPath</code>	<p>Specifies a platform-specific, character-delimited list of directories that act as the class path for user exit routines.</p> <p>The agent's exits directory is searched before any entries in this class path.</p> <p>Parentheses, commas (,) and backslashes (\) are special characters in MFT commands, and must be escaped with a backslash (\) character.  Windows</p> <p>File paths on Windows can be specified either using double backslashes (\\) as a separator, or using single forward slashes (/). For example:</p> <pre>exitClassPath=C:/mycomp/mqft/exits/encryptFileExit.jar; C:/mycomp/mqft/exits/fileFilter.jar.</pre> <p>The value of this property can contain environment variables.</p>
<code>exitNativeLibraryPath</code>	<p>Specifies a platform-specific, character-delimited list of directories that act as the native library path for user exit routines.</p> <p>The value of this property can contain environment variables.</p>
<code>monitorExitClasses</code>	Specifies a comma-separated list of classes that implement a monitor exit routine. For more information, see <a href="#">MFT resource monitor user exits</a> .
<code>protocolBridgeCredentialExitClasses</code>	Specifies a comma-separated list of classes that implement a protocol bridge credential user exit routine. For more information, see <a href="#">Mapping credentials for a file server by using exit classes</a> .
<code>protocolBridgePropertiesExitClasses</code>	Specifies a comma-separated list of classes that implement a protocol bridge server properties user exit routine. For more information, see <a href="#">ProtocolBridgePropertiesExit2: Looking up protocol file server properties</a> .

Table 885. Agent properties for user exits (continued)

Property name	Description
IOExitClasses	Specifies a comma-separated list of classes that implement an I/O user exit routine. List only the classes that implement the IOExit interface, that is, do not list classes that implement the other I/O user exit interfaces, for example IOExitResourcePath and IOExitChannel. For more information, see <a href="#">Using MFT transfer I/O user exits</a> .

## Order of exit invocation

The source and destination exits are invoked in the following order:

1. SourceTransferStartExit
2. DestinationTransferStartExit
3. DestinationTransferEndExit
4. SourceTransferEndExit

## Chaining source and destination exits

If you specify multiple exits, the first exit in the list is invoked first, followed by the second exit, and so on. Any changes made by the first exit are passed as input to the exit that is subsequently invoked and so on. For example, if there are two source transfer start exits any changes made to the transfer metadata by the first exit are input to the second exit. Each exit returns its own result. If all the exits of a given type return PROCEED as a transfer result code, the overall result is PROCEED. If one or more exits return CANCEL\_TRANSFER, the overall result is CANCEL\_TRANSFER. All of the result codes and strings returned by the exits are output in the transfer log.

If the overall result from the source transfer start exit is PROCEED, the transfer proceeds using any changes made by the exits. If the overall result is CANCEL\_TRANSFER, the source transfer end exits are invoked and then the transfer is canceled. The completion status in the transfer log is "cancelled".

If the overall result from the destination transfer start exits is PROCEED, the transfer proceeds using any changes made by the exits. If the overall result is CANCEL\_TRANSFER, the destination transfer end exits are invoked, then the source transfer end exits are invoked. Finally the transfer is canceled. The completion status in the transfer log is "cancelled".

If a source or destination exit needs to pass information to following exits either in the chain or in the order of execution it must be done by updating the transfer metadata. The usage of the transfer metadata is exit implementation specific. For instance, if an exit sets the return result to CANCEL\_TRANSFER and needs to communicate to the following exits that the transfer has been canceled it must be done by setting a transfer metadata value in a way understood by the other exits.

### Example

```
sourceTransferStartExitClasses=com.ibm.wmqfte.test.MFTTestSourceTransferStartExit
sourceTransferEndExitClasses=com.ibm.wmqfte.test.MFTTestSourceTransferEndExit
destinationTransferStartExitClasses=com.ibm.wmqfte.test.MFTTestDestinationTransferStartExit
destinationTransferEndExitClasses=com.ibm.wmqfte.test.MFTTestDestinationTransferEndExit
exitClassPath=C:/mycomp/mqft/exits/encryptFileExit.jar;C:/mycomp/mqft/exits/fileFilter.jar
```

 */
package com.ibm.wmqfte.exitroutine.api;

import java.io.IOException;
import java.util.Map;

import com.ibm.wmqfte.exitroutine.api.IOExitRecordResourcePath.RecordFormat;

/**
 * An interface that is implemented by classes that you want to be invoked as
 * part of user exit routine processing. This interface defines methods that
 * will be invoked during transfers to perform the underlying file system I/O
 * work for WMQFTE transfers.
 * <p>
 * The {@link #initialize(Map)} method will be called once when the exit is
 * first installed. The WMQFTE agent properties are passed to this method, thus
 * enabling the exit to understand its environment.
 * <p>
 * The {@link #isSupported(String)} method will be invoked during WMQFTE
 * transfers to determine whether the user exit should be used. If the
 * {@link #isSupported(String)} method returns a value of {@code true}, the
 * {@link #newPath(String)} method will be invoked for the paths specified for
 * the transfer request. The returned {@link IOExitPath} instance from a
 * {@link #newPath(String)} method invocation will then be used by the WMQFTE
 * transfer to obtain information about the resource and to transfer data to or
 * from the resource.
 * <p>
 * To obtain transfer context for an I/O exit, a {@link SourceTransferStartExit}
 * or {@link DestinationTransferStartExit} as appropriate, should be installed
 * to enable information to be seen by this exit. The
 * {@link SourceTransferStartExit} or {@link DestinationTransferStartExit} are
 * passed the transfer's environment, metadata, and a list of file
 * specifications for the transfer. The paths for the file specifications are
 * the paths passed to the I/O exit's {@link #newPath(String)} method.
 * <p>
 * Note also that the {@link #isSupported(String)} and {@link #newPath(String)}
 * methods might be called at other times by a WMQFTE agent and not just during
 * transfers. For example, at transfer setup time the I/O system is queried to
 * resolve the full resource paths for transfer.
 */

```

```

*/
public interface IOExit {

/**
 * Invoked once when the I/O exit is first required for use. It is intended
 * to initialize any resources that are required by the exit.
 *
 * @param agentProperties
 *         The values of properties defined for the WMQFTE agent. These
 *         values can only be read, they cannot be updated by the
 *         implementation.
 * @return {@code true} if the initialization is successful and {@code
 *         false} if unsuccessful. If {@code false} is returned from an
 *         exit, the exit will not be used.
 */

/**
 * Indicates whether this I/O user exit supports the specified path.
 * <p>
 * This method is used by WMQFTE to determine whether the I/O user exit
 * should be used within a transfer. If no I/O user exit returns true for
 * this method, the default WMQFTE file I/O function will be used.
 *
 * @param path
 *         The path to the required I/O resource.
 * @return {@code true} if the specified path is supported by the I/O exit,
 *         {@code false} otherwise
 */
boolean isSupported(String path);

/**
 * Obtains a new {@link IOExitPath} instance for the specified I/O resource
 * path.
 * <p>
 * This method will be invoked by WMQFTE only if the
 * {@link #isSupported(String)} method has been called for the path and
 * returned {@code true}.
 *
 * @param path
 *         The path to the required I/O resource.
 * @return A {@link IOExitPath} instance for the specified path.
 * @throws IOException
 *         If the path cannot be created for any reason.
 */
IOExitPath newPath(String path) throws IOException;

/**
 * Obtains a new {@link IOExitPath} instance for the specified I/O resource
 * path and passes record format and length information required by the
 * WMQFTE transfer.
 * <p>
 * Typically this method will be called for the following cases:
 * <ul>
 * <li>A path where a call to {@link #newPath(String)} has previously
 * returned a {@link IOExitRecordResourcePath} instance and WMQFTE is
 * re-establishing a new {@link IOExitPath} instance for the path, from an
 * internally-serialized state. The passed recordFormat and recordLength
 * will be the same as those for the original
 * {@link IOExitRecordResourcePath} instance.</li>
 * <li>A transfer destination path where the source of the transfer is
 * record oriented. The passed recordFormat and recordLength will be the
 * same as those for the source.</li>
 * </ul>
 * The implementation can act on the record format and length information as
 * deemed appropriate. For example, for a destination agent if the
 * destination does not already exist and the source of the transfer is
 * record oriented, the passed recordFormat and recordLength information
 * could be used to create an appropriate record-oriented destination path.
 * If the destination path already exists, the passed recordFormat and
 * recordLength information could be used to perform a compatibility check
 * and throw an {@link IOException} if the path is not compatible. A
 * compatibility check could ensure that a record oriented path's record
 * format is the same as the passed record format or that the record length
 * is greater or equal to the passed record length.
 * <p>
 * This method will be invoked by WMQFTE only if the
 * {@link #isSupported(String)} method has been called for the path and
 * returned {@code true}.
 *
 * @param path
 *         The path to the required I/O resource.

```

```

* @param recordFormat
*     The advised record format.
* @param recordLength
*     The advised record length.
* @return A {@link IOExitPath} instance for the specified path.
* @throws IOException
*     If the path cannot be created for any reason. For example,
*     the passed record format or length is incompatible with the
*     path's actual record format or length.
*/

## Message formats for messages you can put on the MFT Agent command queue

These XML schemas define the formats for messages that can be put on the agent command queue to request that the agent perform an action. The XML message can be placed on the agent command queue by using the command-line commands or by an application.

- [File transfer request message format](#)
- [MFT monitor request message formats](#)
- [Ping MFT agent request message format](#)
- [MFT agent reply message format](#)

## Messaging REST API reference

---

Reference information about the messaging REST API.

For more information about using the messaging REST API, see [Messaging using the REST API](#).

### REST API resources

This collection of topics provides reference information for each of the messaging REST API resources.

For more information about using the messaging REST API, see [Messaging using the REST API](#).

## **/messaging/qmgr/{qmgrName}/queue/{queueName}/message**

The messaging REST API allows messages to be put to a queue, or messages to be browsed or destructively got from a queue, using the `/messaging/qmgr/{qmgrName}/queue/{queueName}/message` resource.

### **POST /messaging/qmgr/{qmgrName}/queue/{queueName}/message**

You can use the HTTP POST method with the `/messaging/qmgr/{qmgrName}/queue/{queueName}/message` resource to put messages to the specified queue on the specified queue manager.

Puts an IBM MQ message containing the HTTP request body to the specified queue manager and queue. The queue manager must be on the same machine as the mqweb server. The method only supports text based HTTP request bodies. Messages are sent as MQSTR or JMS `TextMessage` formatted messages, and are put using the current user context.

REST API V3 adds the ability to specify user-defined message properties and to include message priority. The `ibm-mq-md-priority` and `ibm-mq-usr` request headers are only available with REST API V3. The `ibm-mq-md-correlationId` request header has a different format in REST API V3. The header can be an application-specific ID, or, if an encoded string, requires the `ID:` prefix. If your POST request contains user-defined messages, or application-specific correlation ID, the message is formatted as a JMS `TextMessage`.

- [“Resource URL” on page 2163](#)
- [“Request headers” on page 2164](#)
- [“Request body format” on page 2166](#)
- [“Security requirements” on page 2166](#)
- [“Response status codes” on page 2167](#)
- [“Response headers” on page 2167](#)
- [“Response body format” on page 2168](#)
- [“Examples” on page 2168](#)

### **Resource URL**

`https://host:port/ibmmq/rest/v1/messaging/qmgr/{qmgrName}/queue/{queueName}/message`

`https://host:port/ibmmq/rest/v2/messaging/qmgr/{qmgrName}/queue/{queueName}/message`

`https://host:port/ibmmq/rest/v3/messaging/qmgr/{qmgrName}/queue/{queueName}/message`

### **qmgrName**

Specifies the name of the queue manager to connect to for messaging. The queue manager must be on the same machine as the mqweb server.

**V 9.4.0** From IBM MQ 9.3.3, you can connect to either a local queue manager or a remote queue manager. The name that you specify for **qmgrName** depends on how your mqweb server is configured:

- If your mqweb server is configured to connect only to local queue managers, then use the name of the queue manager.
- If your mqweb server is configured to connect remote queue managers, then use the unique name for the queue manager as specified in the remote queue manager connection information.

You can determine whether your mqweb server is configured to connect to local queue managers or remote queue managers by using the **dspmweb properties** command and viewing the **mqRestMessagingConnectionMode** property.

The queue manager name is case-sensitive.

If the queue manager name includes a forward slash, a period, or a percent sign, these characters must be URL encoded:

- A forward slash must be encoded as %2F.
- A period must be encoded as %2E.
- A percent sign must be encoded as %25.

### **queueName**

Specifies the name of the queue on which to put the message.

The queue must be defined as being local, remote, or an alias to the specified queue manager - it may also reference a clustered queue.

The queue name is case sensitive.

If the queue name includes a forward slash or a percent sign, these characters must be URL encoded:

- A forward slash, /, must be encoded as %2F.
- A percent sign, %, must be encoded as %25.

You can use HTTP instead of HTTPS if you enable HTTP connections. For more information about enabling HTTP, see [Configuring HTTP and HTTPS ports](#).

## **Request headers**

The following headers must be sent with the request:

### **Authorization**

This header must be sent if you are using basic authentication. For more information, see [Using HTTP basic authentication with the REST API](#).

### **Content-Type**

This header must be sent with one of the following values:

- text/plain;charset=utf-8
- text/html;charset=utf-8
- text/xml;charset=utf-8
- application/json;charset=utf-8
- application/xml;charset=utf-8

### **ibm-mq-rest-csrf-token**

This header must be set, but the value can be anything, including being blank.

The following headers can optionally be sent with the request:

### **Accept-Language**

This header specifies the required language for any exceptions or error messages returned in the response message body.

### **REST API V1 - REST API V2: ibm-mq-md-correlationId**

This header sets the correlation ID of the created message. The header is specified as a 48 character hexadecimal encoded string, representing 24 bytes. Do not prefix the value with "ID: ", the REST API adds that string automatically.

For example: `ibm-mq-md-correlationId: 414d5120514d4144455620202020202067d8bf5923582e02`

### **REST API V3: ibm-mq-md-correlationId**

This header sets the correlation ID of the created message. The correlation ID can take one of the following forms:

- A 48 character hexadecimal encoded string, representing 24 bytes, prefixed with the string "ID: ". For example: `ibm-mq-md-correlationId: ID:414d5120514d4144455620202020202067d8bf5923582e02`

- An application-specific value. The value is an application-specific string: `ibm-mq-md-correlationId: My-Custom-CorrelId`

If you specify this form of correlation ID, the message destination is targeted as `WMQ_CLIENT_JMS_COMPLIANT`, and therefore incorporates an `MQRFH2` header.

### **ibm-mq-md-expiry**

This header sets the expiry duration for the created message. The expiry of a message starts from the time the message arrives on the queue. As a result network latency is ignored. The header must be specified as one of the following values:

#### **unlimited**

The message does not expire.

This value is the default value.

#### **Integer value**

Milliseconds before message expiry.

Limited to the range 0 - 99999999900.

### **ibm-mq-md-persistence**

This header sets the persistence for the created message. The header is specified as one of the following values:

#### **nonPersistent**

The message does not survive system failures or queue manager restarts.

This value is the default value.

#### **persistent**

The message survives system failures or queue manager restarts.

### **REST API V3: ibm-mq-md-priority**

For the REST API V3, this header sets the priority of the created message. The header is specified as one of the following values:

#### **asDestination**

The message uses the priority specified in the `DEFPRTY` attribute of the underlying IBM MQ queue object.

This value is the default value.

#### **Integer value**

Specify the actual priority as an integer in the range 0-9.

For example: `ibm-mq-md-priority: asDestination`

For the REST API V1 and REST API V2, the message priority for POST is always 4.

### **ibm-mq-md-replyTo**

This header sets the reply-to destination for the created message. The format of the header uses the standard notation of supplying the reply-to queue and an optional queue manager: `replyQueue[@replyQmgr]`

For example: `ibm-mq-md-replyTo: myReplyQueue@myReplyQMgr`

### **REST API V3: ibm-mq-usr**

This header sets the request message user-defined properties.

The properties have the following syntax:

`ibm-mq-usr: property_name; user_value; user_type`

#### **property\_name**

The name of the user property being specified. This must be a valid JMS property name.

#### **user\_value**

The value of the property.

## user\_type

The type of the property:

- `boolean` (true/false, MQBOOL)
- `byte` (8-bit integer, MQINT8)
- `short` (16-bit integer, MQINT16)
- `integer` (32-bit integer, MQINT32)
- `long` (64-bit integer, MQINT64)
- `float` (32-bit real, MQFLOAT32)
- `double` (64-bit real, MQFLOAT64)
- `string` (quoted string)

You can set multiple properties on a message. You can either specify multiple comma-separated properties in a single `ibm-mq-usr` request header, or you can use two or more separate instances of the `ibm-mq-usr` request header.

For example, you can set multiple user defined properties in a single header: `ibm-mq-usr: userPropertyA;5;byte,userPropertyB;-10;integer`

Or you can set multiple user defined properties in separate instances of the header: `ibm-mq-usr: userPropertyA;5;byte ibm-mq-usr: userPropertyB;-10;integer`

## Request body format

The request body must be text and use UTF-8 encoding. No specific text structure is required. An MQSTR formatted message containing the request body text is created and put to the specified queue.

**REST API V3** If the REST API V3 user-defined properties, or application-specific correlation ID features are used, then a JMS `TextMessage` formatted message containing the request body text is created and put to the specified queue.

For more information, see [examples](#).

## Security requirements

The caller must be authenticated to the mqweb server. The MQWebAdmin and MQWebAdminRO roles are not applicable for the messaging REST API. For more information about security for the REST API, see [IBM MQ Console and REST API security](#).

Once authenticated to the mqweb server the user is capable of using both the messaging REST API and the administrative REST API.

The security principal of the caller must be granted the ability to put messages to the specified queue:

- The queue that is specified by the `{queueName}` portion of the resource URL, must be PUT enabled.
- **MQ Appliance** **ALW** For the queue that is specified by the `{queueName}` portion of the resource URL, +PUT authority must be granted to the security principal of the caller.
- **z/OS** For the queue that is specified by the `{queueName}` portion of the resource URL, UPDATE access must be granted to the security principal of the caller.

This security principal might be the user that started the mqweb server, or the user that is logged into the mqweb server. If the queue manager you connect to is a remote queue manager, the security principal might instead be the user provided by credentials in the remote queue manager connection information, or another user that is determined by channel security rules. For more information, see [Determining the security principal that is used by the messaging REST API](#).

**ALW** On AIX, Linux, and Windows, you can grant authority to security principals to use IBM MQ resources by using the `setmqaut` command. For more information, see [setmqaut \(grant or revoke authority\)](#).

On z/OS, see [Setting up security on z/OS](#).

If you use Advanced Message Security (AMS) with the messaging REST API, note that all messages are encrypted by using the context of the mqweb server, not the context of the user that posts the message.

## Response status codes

### 201

Message created and sent successfully.

### 400

Invalid data provided.

For example, an invalid request header value was specified.

### 401

Not authenticated.

The caller must be authenticated to the mqweb server and must be a member of one or more of the MQWebAdmin, MQWebAdminRO, or MQWebUser roles. The `ibm-mq-rest-csrf-token` header must also be specified. For more information, see [“Security requirements” on page 2166](#).

### 403

Not authorized.

The caller is authenticated to the mqweb server and is associated with a valid principal. However, the principal does not have access to all, or a subset of the required IBM MQ resources, or is not in the MQWebUser role. For more information about the access that is required, see [“Security requirements” on page 2166](#).

### 404

Queue does not exist.

### 405

Queue is PUT inhibited.

### 415

A message header or body is an unsupported media type.

For example, the Content-Type header is set to an unsupported media type.

### 500

Server issue or error code from IBM MQ.

### 502

The current security principal cannot send the message as the messaging provider does not support the required function. For example, if the mqweb server class path is invalid.

### 503

Queue manager not running.

## Response headers

The following headers are returned with the response:

### Content-Language

Specifies the language identifier of the response message in the event of any errors or exceptions. Used in conjunction with Accept-Language request header to indicate the required language for any error or exception conditions. The mqweb server default is used if the requested language is unsupported.

### Content-Length

Specifies the length of the HTTP response body, even when there is no content. Upon success the value is zero.

### Content-Type

Specifies the type of response body. Upon success the value is `text/plain;charset=utf-8`. In the event of any errors or exceptions, the value is `application/json;charset=utf-8`.

### REST API V1 → REST API V2 **ibm-mq-md-messageId**

Specifies the message ID that is allocated by IBM MQ to this message. Like the `ibm-mq-md-correlationId` request header, it is represented as a 48 character hexadecimal encoded string, representing 24 bytes.

For example:

```
ibm-mq-md-messageId: 414d5120514d4144455620202020202067d8ce5923582f07
```

### REST API V3 **ibm-mq-md-messageId**

Specifies the message ID that is allocated by IBM MQ to this message. Like the `ibm-mq-md-correlationId` request header, it is represented as a 48 character hexadecimal encoded string, representing 24 bytes, prefixed by the string `ID:`.

For example:

```
ibm-mq-md-messageId: ID:414d5120514d4144455620202020202067d8ce5923582f07
```

### V 9.4.0 **ibm-mq-resolved-qmgr**

Specifies the name of the queue manager that was used for the request. If a unique name was used in the resource URL, this header identifies the name of the queue manager that is associated with that unique name. If the unique name used in the resource URL refers to a queue manager group, this header identifies which queue manager within the group was used.

## Response body format

The response body is empty if the message is sent successfully. If an error occurs, the response body contains an error message. For more information, see [REST API error handling](#).

## Examples

The following examples use the v2 resource URL. If you are using a version of IBM MQ earlier than IBM MQ 9.1.5 you must use the v1 resource URL instead. That is, in the resource URL, substitute v1 where the example URL uses v2.

The following example logs in a user called `mquser` with the password `mquser`. In cURL, the log in request might look like the following Windows example. The LTPA token is stored in the `cookiejar.txt` file by using the `-c` flag:

```
curl -k "https://localhost:9443/ibmmq/rest/v2/login" -X POST
-H "Content-Type: application/json" --data "{\"username\": \"mquser\", \"password\": \"mquser\"}"
-c c:\cookiejar.txt
```

After the user is logged in, the LTPA token and `ibm-mq-rest-csrf-token` HTTP header are used to authenticate further requests. The `ibm-mq-rest-csrf-token` `token_value` can be any value, including blank.

- The following Windows cURL example sends a message to queue Q1 on queue manager QM1, using default options. The message contains the text *"Hello World!"*:

```
curl -k "https://localhost:9443/ibmmq/rest/v2/messaging/qmgr/QM1/queue/Q1/message"
-X POST -b c:\cookiejar.txt -H "ibm-mq-rest-csrf-token: token_value"
-H "Content-Type: text/plain; charset=utf-8" --data "Hello World!"
```

- The following Windows cURL example sends a persistent message to queue Q1 on queue manager QM1, with an expiry of 2 minutes. The message contains the text *"Hello World!"*:

```
curl -k "https://localhost:9443/ibmmq/rest/v2/messaging/qmgr/QM1/queue/Q1/message"
-X POST -b c:\cookiejar.txt -H "ibm-mq-rest-csrf-token: token_value"
-H "Content-Type: text/plain; charset=utf-8" -H "ibm-mq-md-persistence: persistent"
-H "ibm-mq-md-expiry: 120000" --data "Hello World!"
```

- The following Windows cURL example sends a non-persistent message to queue Q1 on queue manager QM1, with no expiry and defined correlation ID. The message contains the text "Hello World!":

```
curl -k "https://localhost:9443/ibmmq/rest/v2/messaging/qmgr/QM1/queue/Q1/message"
-X POST -b c:\cookiejar.txt -H "ibm-mq-rest-csrf-token: token-value"
-H "Content-Type: text/plain;charset=utf-8" -H "ibm-mq-md-persistence: nonPersistent"
-H "ibm-mq-md-expiry: unlimited" -H "ibm-mq-md-correlationId:
414d5120514d41444556202020202067d8b
f5923582e02" --data "Hello World!"
```

### ***GET /messaging/qmgr/{qmgrName}/queue/{queueName}/message***

You can use the HTTP GET method with the `/messaging/qmgr/{qmgrName}/queue/{queueName}/message` resource to browse messages from the associated queue manager and queue.

Browses the first available message from the specified queue manager and queue. The queue manager must be on the same machine as the mqweb server. The message body is returned in the HTTP response body. The message must have a format of MQSTR or JMS `TextMessage` and is received using the current user context.

All messages are left on the queue and an appropriate status code is returned to the caller for any inappropriate messages. For example, a message which does not have a MQSTR or JMS `TextMessage` format.

REST API V3 adds the ability to specify user-defined message properties and to include message priority with messages. The `ibm-mq-md-priority` and `ibm-mq-usr` response headers are only available with REST API V3. The `ibm-mq-md-correlationId` request header has a different format in REST API V3. The header can be an application-specific ID, or, if an encoded string, retains the `ID:` prefix. The `ibm-mq-md-messageId` response header and query parameter has a different format in REST API V3, it retains the `ID:` prefix.

- [“Resource URL” on page 2169](#)
- [“Optional query parameters” on page 2170](#)
- [“Request headers” on page 2171](#)
- [“Request body format” on page 2171](#)
- [“Security requirements” on page 2171](#)
- [“Response status codes” on page 2172](#)
- [“Response headers” on page 2172](#)
- [“Response body format” on page 2175](#)
- [“Examples” on page 2175](#)

### **Resource URL**

`https://host:port/ibmmq/rest/v1/messaging/qmgr/{qmgrName}/queue/{queueName}/message`

`https://host:port/ibmmq/rest/v2/messaging/qmgr/{qmgrName}/queue/{queueName}/message`

`https://host:port/ibmmq/rest/v3/messaging/qmgr/{qmgrName}/queue/{queueName}/message`

### **qmgrName**

Specifies the name of the queue manager to connect to for messaging. The queue manager must be on the same machine as the mqweb server.

 From IBM MQ 9.3.3, you can connect to either a local queue manager or a remote queue manager. The name that you specify for **qmgrName** depends on how your mqweb server is configured:

- If your mqweb server is configured to connect only to local queue managers, then use the name of the queue manager.

- If your mqweb server is configured to connect remote queue managers, then use the unique name for the queue manager as specified in the remote queue manager connection information.

You can determine whether your mqweb server is configured to connect to local queue managers or remote queue managers by using the **dspmweb properties** command and viewing the **mqRestMessagingConnectionMode** property.

The queue manager name is case-sensitive.

If the queue manager name includes a forward slash, a period, or a percent sign, these characters must be URL encoded:

- A forward slash (/) must be encoded as %2F.
- A percent sign (%) must be encoded as %25.

### queueName

Specifies the name of the queue from which to browse the message.

The queue must be defined as being local or an alias that points to a local queue.

The queue name is case sensitive.

If the queue name includes a forward slash or a percent sign, these characters must be URL encoded:

- A forward slash, /, must be encoded as %2F.
- A percent sign, %, must be encoded as %25.

You can use HTTP instead of HTTPS if you enable HTTP connections. For more information about enabling HTTP, see [Configuring HTTP and HTTPS ports](#).

## Optional query parameters

### REST API V1 → REST API V2 **correlationId=hexValue**

Specifies that the HTTP method returns the next message with the corresponding correlation ID.

#### hexValue

The query parameter must be specified as a 48 character hexadecimal encoded string, representing 24 bytes.

For example:

```
../message?correlationId=414d5120514d414445562020202020202067d8bf5923582e02
```

### REST API V3 **correlationId=ID:hexValue** or **correlationId=application\_specific\_value**

Specifies that the HTTP method returns the next message with the corresponding correlation ID.

#### hexValue

The query parameter must be specified as a 48 character hexadecimal encoded string, representing 24 bytes, and preceded by the string "ID: ".

For example:

```
../message?correlationId=ID:414d5120514d414445562020202020202067d8bf5923582e02
```

#### application\_specific\_value

The query parameter can be specified as an application-specific string.

For example:

```
../message?correlationId=My-Custom-CorrelId
```

### REST API V1 → REST API V2 **messageId=hexValue**

Specifies that the HTTP method returns the next message with the corresponding message ID.

### hexValue

The query parameter must be specified as a 48 character hexadecimal encoded string, representing 24 bytes.

For example:

```
../message?messageId=414d5120514d4144455620202020202067d8ce5923582f07
```

### REST API V3 **messageId=ID:hexValue**

Specifies that the HTTP method returns the next message with the corresponding message ID.

### hexValue

The query parameter must be specified as a 48 character hexadecimal encoded string, representing 24 bytes, and preceded by the string "ID: ".

For example:

```
../message?messageId=ID:414d5120514d4144455620202020202067d8ce5923582f07
```

## Request headers

The following headers must be sent with the request:

### Authorization

This header must be sent if you are using basic authentication. For more information, see [Using HTTP basic authentication with the REST API](#).

### ibm-mq-rest-csrf-token

This header must be set, but the value can be anything, including being blank.

The following headers can optionally be sent with the request:

### Accept-Charset

This header can be used to indicate what character set is acceptable for the response. If specified, this header must be set as UTF-8.

### Accept-Language

This header specifies the required language for any exceptions or error messages returned in the response message body.

## Request body format

None.

## Security requirements

The caller must be authenticated to the mqweb server. The MQWebAdmin and MQWebAdminRO roles are not applicable for the messaging REST API. For more information about security for the REST API, see [IBM MQ Console and REST API security](#).

Once authenticated to the mqweb server the user is capable of using both the messaging REST API and the administrative REST API.

The security principal of the caller must be granted the ability to browse messages from the specified queue:

- The queue that is specified by the *{queueName}* portion of the resource URL, must be BROWSE enabled.
-   For the queue that is specified by the *{queueName}* portion of the resource URL, +GET, +INQ, and +BROWSE authority must be granted to the security principal of the caller.
-  For the queue that is specified by the *{queueName}* portion of the resource URL, UPDATE, access must be granted to the security principal of the caller.

This security principal might be the user that started the mqweb server, or the user that is logged into the mqweb server. If the queue manager you connect to is a remote queue manager, the security principal might instead be the user provided by credentials in the remote queue manager connection information, or another user that is determined by channel security rules. For more information, see [Determining the security principal that is used by the messaging REST API](#).

**ALW** On AIX, Linux, and Windows, you can grant authority to security principals to use IBM MQ resources by using the **setmqaut** command. For more information, see [setmqaut \(grant or revoke authority\)](#).

On z/OS, see [Setting up security on z/OS](#).

## Response status codes

### 200

Message received successfully.

### 204

No message available.

### 400

Invalid data provided.

For example, an invalid query parameter value was specified.

### 401

Not authenticated.

The caller must be authenticated to the mqweb server and must be a member of one or more of the MQWebAdmin, MQWebAdminRO, or MQWebUser roles. The `ibm-mq-rest-csrf-token` header must also be specified. For more information, see [“Security requirements” on page 2171](#).

### 403

Not authorized.

The caller is authenticated to the mqweb server and is associated with a valid principal. However, the principal does not have access to all, or a subset of the required IBM MQ resources, or is not in the MQWebUser role. For more information about the access that is required, see [“Security requirements” on page 2171](#).

### 404

Queue does not exist.

### 500

Server issue or error code from IBM MQ.

### 501

The HTTP response could not be constructed.

For example, the received message has an incorrect type, or has the correct type but the body could not be processed.

### 502

The current security principal cannot receive the message as the messaging provider does not support the required function. For example, if the mqweb server class path is invalid.

### 503

Queue manager not running.

## Response headers

The following headers are returned with the response:

### Content-Language

Specifies the language identifier of the response message in the event of any errors or exceptions. Used in conjunction with Accept-Language request header to indicate the required language for

any error or exception conditions. The mqweb server default is used if the requested language is unsupported.

### Content-Length

Specifies the length of the HTTP response body, even when there is no content. The value contains the length (bytes) of the message data.

### Content-Type

Specifies the type of content returned in the response body of the received message. Upon success the value is `text/plain;charset=utf-8`. In the event of any errors or exceptions, the value is `application/json;charset=utf-8`.

#### REST API V1 > REST API V2 **ibm-mq-md-correlationId**

Specifies the correlation ID of the received message. The header is returned if the received message contains a valid correlation ID. It is represented as a 48 character hexadecimal encoded string, representing 24 bytes.

For example:

```
ibm-mq-md-correlationId: 414d5120514d4144455620202020202067d8bf5923582e02
```

#### REST API V3 **ibm-mq-md-correlationId**

Specifies the correlation ID of the received message. The header is returned if the received message contains a valid correlation ID. The correlation ID can take one of the following forms:

- A 48 character hexadecimal encoded string, representing 24 bytes, prefixed with the string "ID: ".  
For example:

```
ibm-mq-md-correlationId: ID:414d5120514d4144455620202020202067d8bf5923582e02
```

- An application-specific value. The value is an application-specific string:

```
ibm-mq-md-correlationId: My-Custom-CorrelId
```

### ibm-mq-md-expiry

Specifies the remaining expiry duration of the received message. The header can be one of the following values:

#### **unlimited**

The message does not expire.

#### **Integer value**

Remaining milliseconds before message expiry.

#### REST API V1 > REST API V2 **ibm-mq-md-messageId**

Specifies the message ID that is allocated by IBM MQ to this message. Like the `ibm-mq-md-correlationId` header, it is represented as a 48 character hexadecimal encoded string, representing 24 bytes.

For example:

```
ibm-mq-md-messageId: 414d5120514d4144455620202020202067d8ce5923582f07
```

#### REST API V3 **ibm-mq-md-messageId**

Specifies the message ID that is allocated by IBM MQ to this message. Like the `ibm-mq-md-correlationId` header, it is represented as a 48 character hexadecimal encoded string, representing 24 bytes, prefixed with the string "ID: "

For example:

```
ibm-mq-md-messageId: ID:414d5120514d4144455620202020202067d8ce5923582f07
```

### **ibm-mq-md-persistence**

Specifies the persistence of the received message. The header can be one of the following values:

#### **nonPersistent**

The message does not survive system failures or queue manager restarts.

#### **persistent**

The message survives system failures or queue manager restarts.

### **REST API V3** **ibm-mq-md-priority**

Returns the setting of the message priority. For example:

```
ibm-mq-md-priority: 3
```

### **ibm-mq-md-replyTo**

Specifies the reply-to destination for the received message. The format of the header uses the standard notation of the reply-to queue and queue manager, `replyQueue@replyQmgr`.

For example:

```
ibm-mq-md-replyTo: myReplyQueue@myReplyQmgr
```

### **V 9.4.0** **ibm-mq-resolved-qmgr**

Specifies the name of the queue manager that was used for the request. If a unique name was used in the resource URL, this header identifies the name of the queue manager that is associated with that unique name. If the unique name used in the resource URL refers to a queue manager group, this header identifies which queue manager within the group was used.

### **REST API V3** **ibm-mq-usr**

Returns message user-defined properties. Multiple properties can be set on a message, in which case there will be two or more separate instances of the `ibm-mq-usr` response header.

For example:

```
ibm-mq-usr: myIPprop;5;short
ibm-mq-usr: mySProp;"hi";string
ibm-mq-usr: myBProp>true;boolean
```

The properties have the following syntax:

```
ibm-mq-usr: property_name; user_value; user_type
```

#### **property\_name**

The name of the user property being specified. This must be a valid JMS property name.

#### **user\_value**

The value of the property.

#### **user\_type**

The type of the property:

- `boolean` (true/false, MQBOOL)
- `byte` (8-bit integer, MQINT8)
- `short` (16-bit integer, MQINT16)
- `integer` (32-bit integer, MQINT32)
- `long` (64-bit integer, MQINT64)
- `float` (32-bit real, MQFLOAT32)
- `double` (64-bit real, MQFLOAT64)
- `string` (quoted string)

## ***DELETE /messaging/qmgr/{qmgrName}/queue/{queueName}/message***

You can use the HTTP DELETE method with the `/messaging/qmgr/{qmgrName}/queue/{queueName}/message` resource to destructively get messages from the associated queue manager and queue.

Destructively gets the next available message from the specified queue manager and queue, returning the message body in the HTTP response body. The queue manager must be on the same machine as the mqweb server. The message must have a format of MQSTR or JMS `TextMessage`, and is received using the current user context.

Incompatible messages are left on the queue and an appropriate status code returned to the caller. For example, a message which does not have a MQSTR or JMS `TextMessage` format.

REST API V3 adds the ability to specify user-defined message properties and to include message priority with messages. The `ibm-mq-md-priority` and `ibm-mq-usr` response headers are only available with REST API V3. The `ibm-mq-md-correlationId` request header has a different format in REST API V3. The header can be an application-specific ID, or, if an encoded string, retains the `ID:` prefix. The `ibm-mq-md-messageId` response header and query parameter has a different format in REST API V3, it retains the `ID:` prefix.

### **Resource URL**

`https://host:port/ibmmq/rest/v1/messaging/qmgr/{qmgrName}/queue/{queueName}/message`

`https://host:port/ibmmq/rest/v2/messaging/qmgr/{qmgrName}/queue/{queueName}/message`

`https://host:port/ibmmq/rest/v3/messaging/qmgr/{qmgrName}/queue/{queueName}/message`

### **qmgrName**

Specifies the name of the queue manager to connect to for messaging. The queue manager must be on the same machine as the mqweb server.

**V9.4.0** From IBM MQ 9.3.3, you can connect to either a local queue manager or a remote queue manager. The name that you specify for **qmgrName** depends on how your mqweb server is configured:

- If your mqweb server is configured to connect only to local queue managers, then use the name of the queue manager.
- If your mqweb server is configured to connect remote queue managers, then use the unique name for the queue manager as specified in the remote queue manager connection information.

You can determine whether your mqweb server is configured to connect to local queue managers or remote queue managers by using the **dspmweb properties** command and viewing the **mqRestMessagingConnectionMode** property.

The queue manager name is case-sensitive.

If the queue manager name includes a forward slash, a period, or a percent sign, these characters must be URL encoded:

- A forward slash (/) must be encoded as %2F.
- A percent sign (%) must be encoded as %25.

### **queueName**

Specifies the name of the queue from which to get the next message.

The queue must be defined as being local or an alias pointing to a local queue.

The queue name is case sensitive.

If the queue name includes a forward slash or a percent sign, these characters must be URL encoded:

- A forward slash, /, must be encoded as %2F.
- A percent sign, %, must be encoded as %25.

You can use HTTP instead of HTTPS if you enable HTTP connections. For more information about enabling HTTP, see [Configuring HTTP and HTTPS ports](#).

## **Optional query parameters**

### **REST API V1** ▶ **REST API V2** **correlationId=hexValue**

Specifies that the HTTP method returns the next message with the corresponding correlation ID.

#### **hexValue**

The query parameter must be specified as a 48 character hexadecimal encoded string, representing 24 bytes.

For example:

```
../message?correlationId=414d5120514d4144455620202020202067d8bf5923582e02
```

### **REST API V3** **correlationId=ID:hexValue** or **correlationId=application\_specific\_value**

Specifies that the HTTP method returns the next message with the corresponding correlation ID.

#### **hexValue**

The query parameter must be specified as a 48 character hexadecimal encoded string, representing 24 bytes, and preceded by the string "ID: ".

For example:

```
../message?correlationId=ID:414d5120514d4144455620202020202067d8bf5923582e02
```

#### **application\_specific\_value**

The query parameter can be specified as an application-specific string.

For example:

```
../message?correlationId=My-Custom-CorrelId
```

### **REST API V1** ▶ **REST API V2** **messageId=hexValue**

Specifies that the HTTP method returns the next message with the corresponding message ID.

#### **hexValue**

The query parameter must be specified as a 48 character hexadecimal encoded string, representing 24 bytes.

For example:

```
../message?messageId=414d5120514d4144455620202020202067d8ce5923582f07
```

### REST API V3 **messageId=ID:hexValue**

Specifies that the HTTP method returns the next message with the corresponding message ID.

#### **hexValue**

The query parameter must be specified as a 48 character hexadecimal encoded string, representing 24 bytes, and preceded by the string "ID: ".

For example:

```
../message?messageId=ID:414d5120514d41444556202020202067d8ce5923582f07
```

#### **wait=integerValue**

Specifies that the HTTP method will wait *integerValue* milliseconds for the next message to become available.

#### **integerValue**

The query parameter must be specified as an integer value representing the millisecond duration. The maximum value is 2147483647.

For example:

```
../message?wait=120000
```

## Request headers

The following headers must be sent with the request:

### **Authorization**

This header must be sent if you are using basic authentication. For more information, see [Using HTTP basic authentication with the REST API](#).

### **ibm-mq-rest-csrf-token**

This header must be set, but the value can be anything, including being blank.

The following headers can optionally be sent with the request:

### **Accept-Charset**

This header can be used to indicate what character set is acceptable for the response. If specified, this header must be set as UTF-8.

### **Accept-Language**

This header specifies the required language for any exceptions or error messages returned in the response message body.

## Request body format

None.

## Security requirements

The caller must be authenticated to the mqweb server. The MQWebAdmin and MQWebAdminRO roles are not applicable for the messaging REST API. For more information about security for the REST API, see [IBM MQ Console and REST API security](#).

Once authenticated to the mqweb server the user is capable of using both the messaging REST API and the administrative REST API.

The security principal of the caller must be granted the ability to get messages from the specified queue:

- The queue that is specified by the *{queueName}* portion of the resource URL, must be GET enabled.
-   For the queue that is specified by the *{queueName}* portion of the resource URL, +GET, +INQ, and +BROWSE authority must be granted to the security principal of the caller.

- **z/OS** For the queue that is specified by the *{queueName}* portion of the resource URL, UPDATE, access must be granted to the security principal of the caller.

This security principal might be the user that started the mqweb server, or the user that is logged into the mqweb server. If the queue manager you connect to is a remote queue manager, the security principal might instead be the user provided by credentials in the remote queue manager connection information, or another user that is determined by channel security rules. For more information, see [Determining the security principal that is used by the messaging REST API](#).

**ALW** On AIX, Linux, and Windows, you can grant authority to security principals to use IBM MQ resources by using the **setmqaut** command. For more information, see [setmqaut \(grant or revoke authority\)](#).

On z/OS, see [Setting up security on z/OS](#).

## Response status codes

### 200

Message received successfully.

### 204

No message available.

### 400

Invalid data provided.

For example, an invalid query parameter value was specified.

### 401

Not authenticated.

The caller must be authenticated to the mqweb server and must be a member of one or more of the MQWebAdmin, MQWebAdminRO, or MQWebUser roles. The `ibm-mq-rest-csrf-token` header must also be specified. For more information, see [“Security requirements” on page 2178](#).

### 403

Not authorized.

The caller is authenticated to the mqweb server and is associated with a valid principal. However, the principal does not have access to all, or a subset of the required IBM MQ resources, or is not in the MQWebUser role. For more information about the access that is required, see [“Security requirements” on page 2178](#).

### 404

Queue does not exist.

### 405

Queue is GET inhibited.

### 500

Server issue or error code from IBM MQ.

### 501

The HTTP response could not be constructed.

For example, the received message has an incorrect type, or has the correct type but the body could not be processed.

### 502

The current security principal cannot receive the message as the messaging provider does not support the required function. For example, if the mqweb server class path is invalid.

### 503

Queue manager not running.

## Response headers

The following headers are returned with the response:

## Content-Language

Specifies the language identifier of the response message in the event of any errors or exceptions. Used in conjunction with Accept-Language request header to indicate the required language for any error or exception conditions. The mqweb server default is used if the requested language is unsupported.

## Content-Length

Specifies the length of the HTTP response body, even when there is no content. The value contains the length (bytes) of the message data.

## Content-Type

Specifies the type of content returned in the response body of the received message. Upon success the value is text/plain;charset=utf-8. In the event of any errors or exceptions, the value is application/json;charset=utf-8.

### REST API V1 > REST API V2 **ibm-mq-md-correlationId**

Specifies the correlation ID of the received message. The header is returned if the received message contains a valid correlation ID. It is represented as a 48 character hexadecimal encoded string, representing 24 bytes.

For example:

```
ibm-mq-md-correlationId: 414d5120514d4144455620202020202067d8bf5923582e02
```

### REST API V3 **ibm-mq-md-correlationId**

Specifies the correlation ID of the received message. The header is returned if the received message contains a valid correlation ID. The correlation ID can take one of the following forms:

- A 48 character hexadecimal encoded string, representing 24 bytes, prefixed with the string "ID: ".  
For example:

```
ibm-mq-md-correlationId: ID:414d5120514d4144455620202020202067d8bf5923582e02
```

- An application-specific value. The value is an application-specific string:

```
ibm-mq-md-correlationId: My-Custom-CorrelId
```

## ibm-mq-md-expiry

Specifies the remaining expiry duration of the received message. The header can be one of the following values:

### **unlimited**

The message does not expire.

### **Integer value**

Remaining milliseconds before message expiry.

### REST API V1 > REST API V2 **ibm-mq-md-messageId**

Specifies the message ID that is allocated by IBM MQ to this message. Like the `ibm-mq-md-correlationId` header, it is represented as a 48 character hexadecimal encoded string, representing 24 bytes.

For example:

```
ibm-mq-md-messageId: 414d5120514d4144455620202020202067d8ce5923582f07
```

### REST API V3 **ibm-mq-md-messageId**

Specifies the message ID that is allocated by IBM MQ to this message. Like the `ibm-mq-md-correlationId` header, it is represented as a 48 character hexadecimal encoded string, representing 24 bytes, prefixed with the string "ID: "

For example:

```
ibm-mq-md-messageId: ID:414d5120514d4144455620202020202067d8ce5923582f07
```

### **ibm-mq-md-persistence**

Specifies the persistence of the received message. The header can be one of the following values:

#### **nonPersistent**

The message does not survive system failures or queue manager restarts.

#### **persistent**

The message survives system failures or queue manager restarts.

### **REST API V3** **ibm-mq-md-priority**

Returns the setting of the message priority. For example:

```
ibm-mq-md-priority: 3
```

### **ibm-mq-md-replyTo**

Specifies the reply-to destination for the received message. The format of the header uses the standard notation of the reply-to queue and queue manager, `replyQueue@replyQmgr`.

For example:

```
ibm-mq-md-replyTo: myReplyQueue@myReplyQMGr
```

### **V 9.4.0** **ibm-mq-resolved-qmgr**

Specifies the name of the queue manager that was used for the request. If a unique name was used in the resource URL, this header identifies the name of the queue manager that is associated with that unique name. If the unique name used in the resource URL refers to a queue manager group, this header identifies which queue manager within the group was used.

### **REST API V3** **ibm-mq-usr**

Returns message user-defined properties. Multiple properties can be set on a message, in which case there will be two or more separate instances of the `ibm-mq-usr` response header.

For example:

```
ibm-mq-usr: myIPprop;5;short  
ibm-mq-usr: mySProp;"hi";string  
ibm-mq-usr: myBProp>true;boolean
```

The properties have the following syntax:

```
ibm-mq-usr: property_name; user_value; user_type
```

#### **property\_name**

The name of the user property being specified. This must be a valid JMS property name.

#### **user\_value**

The value of the property.

#### **user\_type**

The type of the property:

- `boolean` (true/false, MQBOOL)
- `byte` (8-bit integer, MQINT8)
- `short` (16-bit integer, MQINT16)
- `integer` (32-bit integer, MQINT32)
- `long` (64-bit integer, MQINT64)
- `float` (32-bit real, MQFLOAT32)
- `double` (64-bit real, MQFLOAT64)

- string (quoted string)

## Response body format

Upon success, the response body contains the message body from the received message. If an error occurs, the response body contains a JSON formatted error message. Both responses are UTF-8 encoded. For more information, see [REST API error handling](#).

Be aware that when receiving a message only IBM MQ MQSTR and JMS TextMessage formatted messages are supported. Subsequently, all messages are received under sync-point and any unhandled messages are left on the queue. The IBM MQ queue can be configured to move these poison messages to an alternate destination. For further information, see [Handling poison messages in IBM MQ classes for JMS](#).

## Examples

The following examples use the v2 resource URL. If you are using a version of IBM MQ earlier than IBM MQ 9.1.5 you must use the v1 resource URL instead. That is, in the resource URL, substitute v1 where the example URL uses v2.

The following example logs in a user called mquser with the password mquser. In cURL, the log in request might look like the following Windows example. The LTPA token is stored in the cookiejar.txt file by using the -c flag:

```
curl -k "https://localhost:9443/ibmmq/rest/v2/login" -X POST
-H "Content-Type: application/json" --data "{\"username\":\"mquser\", \"password\":\"mquser\"}"
-c c:\cookiejar.txt
```

After the user is logged in, the LTPA token and ibm-mq-rest-csrf-token HTTP header are used to authenticate further requests. The ibm-mq-rest-csrf-token token\_value can be any value, including blank.

- The following Windows cURL example removes the next available message from queue Q1 on queue manager QM1, using default options:

```
curl -k "https://localhost:9443/ibmmq/rest/v2/messaging/qmgr/QM1/queue/Q1/message"
-X DELETE -b c:\cookiejar.txt -H "ibm-mq-rest-csrf-token: token-value"
-H "Accept: text/plain"
```

- The following Windows cURL example removes a message with a specific correlation ID, 00abcdabcd, from queue Q1 on queue manager QM1:

```
curl -k "https://localhost:9443/ibmmq/rest/v2/messaging/qmgr/QM1/queue/Q1/message?
correlationId=0000000000000000000000000000000000000000000000000000000000000000abcdabcd"
-X DELETE -b c:\cookiejar.txt -H "ibm-mq-rest-csrf-token: token-value"
-H "Accept: text/plain"
```

- The following Windows cURL example removes a message with a specific correlation ID, 00abcdabcd, from queue Q1 on queue manager QM1, waiting for up to 30 seconds for the message to become available. If 30 seconds passes without the specified message being put to the queue, the DELETE call returns without a message:

```
curl -k "https://localhost:9443/ibmmq/rest/v2/messaging/qmgr/QM1/queue/Q1/message?
correlationId=0000000000000000000000000000000000000000000000000000000000000000abcdabcd&wait=30000"
-X DELETE -b c:\cookiejar.txt -H "ibm-mq-rest-csrf-token: token-value"
-H "Accept: text/plain"
```

## /messaging/qmgr/{qmgrName}/queue/{queueName}/messagelist

You can use the HTTP GET method with the /messaging/qmgr/{qmgrName}/queue/{queueName}/messagelist resource to get a list of available messages from the specified queue on the specified queue manager.

## ***GET /messaging/qmgr/{qmgrName}/queue/{queueName}/messagelist***

You can use the HTTP GET method with the `/messaging/qmgr/{qmgrName}/queue/{queueName}/messagelist` resource to get a list of available messages from the specified queue on the specified queue manager.

Browses a summary list of messages from the specified queue manager and queue. The queue manager must be on the same machine as the mqweb server. The summary data is returned in the HTTP response body as a JSON formatted array. The data does not contain the payload of the messages and is received using the current user context. No messages are removed from the associated queue.

If a request is made to get a list of available messages from a queue that is GET inhibited, an empty JSON array is returned.

- [“Resource URL” on page 2183](#)
- [“Optional query parameters” on page 2184](#)
- [“Request headers” on page 2185](#)
- [“Request body format” on page 2185](#)
- [“Security requirements” on page 2185](#)
- [“Response status codes” on page 2186](#)
- [“Response headers” on page 2186](#)
- [“Response body format” on page 2187](#)
- [“Examples” on page 2187](#)

### **Resource URL**

`https://host:port/ibmmq/rest/v1/messaging/qmgr/{qmgrName}/queue/{queueName}/messagelist`

`https://host:port/ibmmq/rest/v2/messaging/qmgr/{qmgrName}/queue/{queueName}/messagelist`

`https://host:port/ibmmq/rest/v3/messaging/qmgr/{qmgrName}/queue/{queueName}/messagelist`

### **qmgrName**

Specifies the name of the queue manager to connect to for messaging. The queue manager must be on the same machine as the mqweb server.

 From IBM MQ 9.3.3, you can connect to either a local queue manager or a remote queue manager. The name that you specify for **qmgrName** depends on how your mqweb server is configured:

- If your mqweb server is configured to connect only to local queue managers, then use the name of the queue manager.
- If your mqweb server is configured to connect remote queue managers, then use the unique name for the queue manager as specified in the remote queue manager connection information.

You can determine whether your mqweb server is configured to connect to local queue managers or remote queue managers by using the **dspmweb properties** command and viewing the **mqRestMessagingConnectionMode** property.

The queue manager name is case-sensitive.

If the queue manager name includes a forward slash, a period, or a percent sign, these characters must be URL encoded:

- A forward slash (/) must be encoded as %2F.
- A percent sign (%) must be encoded as %25.

### **queueName**

Specifies the name of the queue from which to browse the messages.

The queue must be defined as being local or an alias that points to a local queue.

The queue name is case sensitive.

If the queue name includes a forward slash or a percent sign, these characters must be URL encoded:

- A forward slash, /, must be encoded as %2F.
- A percent sign, %, must be encoded as %25.

You can use HTTP instead of HTTPS if you enable HTTP connections. For more information about enabling HTTP, see [Configuring HTTP and HTTPS ports](#).

## Optional query parameters

### REST API V2 **correlationId=hexValue**

Specifies that the HTTP method returns the next message with the corresponding correlation ID.

#### hexValue

The query parameter must be specified as a 48 character hexadecimal encoded string, representing 24 bytes.

For example:

```
../messagelist?correlationId=414d5120514d4144455620202020202067d8bf5923582e02
```

### REST API V3 **correlationId=ID:hexValue** or **correlationId=application\_specific\_value**

Specifies that the HTTP method returns a list of messages with the corresponding correlation ID.

#### hexValue

The query parameter must be specified as a 48 character hexadecimal encoded string, representing 24 bytes, and preceded by the string "ID: ".

For example:

```
../message?correlationId=ID:414d5120514d4144455620202020202067d8bf5923582e02
```

#### application\_specific\_value

The query parameter can be specified as an application-specific string.

For example:

```
../message?correlationId=My-Custom-CorrelId
```

### REST API V1 > REST API V2 **messageId=hexValue**

Specifies that the HTTP method returns the next message with the corresponding message ID.

#### hexValue

The query parameter must be specified as a 48 character hexadecimal encoded string, representing 24 bytes.

For example:

```
../message?messageId=414d5120514d4144455620202020202067d8ce5923582f07
```

### REST API V3 **messageId=ID:hexValue**

Specifies that the HTTP method returns the next message with the corresponding message ID.

#### hexValue

The query parameter must be specified as a 48 character hexadecimal encoded string, representing 24 bytes, and preceded by the string "ID: ".

For example:

```
../message?messageId=ID:414d5120514d41444556202020202067d8ce5923582f07
```

**limit=*integerValue***

Specifies that the HTTP method response body is limited to *integerValue* JSON elements.

**integerValue**

The query parameter must be specified as an integer value that represents the maximum number of elements that are contained in the JSON response body.

The default value is 10, and the maximum value is 2147483647.

For example:

```
../messagelist?limit=250
```

## Request headers

The following headers must be sent with the request:

**Authorization**

This header must be sent if you are using basic authentication. For more information, see [Using HTTP basic authentication with the REST API](#).

**ibm-mq-rest-csrf-token**

This header must be set, but the value can be anything, including being blank.

The following headers can optionally be sent with the request:

**Accept-Charset**

This header can be used to indicate what character set is acceptable for the response. If specified, this header must be set as UTF-8.

**Accept-Language**

This header specifies the required language for any exceptions or error messages returned in the response message body.

## Request body format

None.

## Security requirements

The caller must be authenticated to the mqweb server. The MQWebAdmin and MQWebAdminRO roles are not applicable for the messaging REST API. For more information about security for the REST API, see [IBM MQ Console and REST API security](#).

Once authenticated to the mqweb server the user is capable of using both the messaging REST API and the administrative REST API.

The security principal of the caller must be granted the ability to browse messages from the specified queue:

- The queue that is specified by the *{queueName}* portion of the resource URL, must be BROWSE enabled.
-   For the queue that is specified by the *{queueName}* portion of the resource URL, +GET, +INQ, and +BROWSE authority must be granted to the security principal of the caller.
-  For the queue that is specified by the *{queueName}* portion of the resource URL, UPDATE, access must be granted to the security principal of the caller.

This security principal might be the user that started the mqweb server, or the user that is logged into the mqweb server. If the queue manager you connect to is a remote queue manager, the security principal might instead be the user provided by credentials in the remote queue manager connection information,

or another user that is determined by channel security rules. For more information, see [Determining the security principal that is used by the messaging REST API](#).

**ALW** On AIX, Linux, and Windows, you can grant authority to security principals to use IBM MQ resources by using the **setmqaut** command. For more information, see [setmqaut \(grant or revoke authority\)](#).

On z/OS, see [Setting up security on z/OS](#).

## Response status codes

### 200

Message list received successfully.

### 400

Invalid data provided.

For example, an invalid query parameter value was specified.

### 401

Not authenticated.

The caller must be authenticated to the mqweb server and must be a member of one or more of the MQWebAdmin, MQWebAdminRO, or MQWebUser roles. The `ibm-mq-rest-csrf-token` header must also be specified. For more information, see [“Security requirements” on page 2185](#).

### 403

Not authorized.

The caller is authenticated to the mqweb server and is associated with a valid principal. However, the principal does not have access to all, or a subset of the required IBM MQ resources, or is not in the MQWebUser role. For more information about the access that is required, see [“Security requirements” on page 2185](#).

### 404

Queue does not exist.

### 500

Server issue or error code from IBM MQ.

### 501

The HTTP response could not be constructed.

For example, the received message has an incorrect type, or has the correct type but the body could not be processed.

### 502

The current security principal cannot receive the message as the messaging provider does not support the required function. For example, if the mqweb server class path is invalid.

### 503

Queue manager not running.

## Response headers

### Content-Language

Specifies the language identifier of the response message in the event of any errors or exceptions. Used in conjunction with `Accept-Language` request header to indicate the required language for any error or exception conditions. The mqweb server default is used if the requested language is unsupported.

### Content-Length

Specifies the length of the HTTP response body, even when there is no content. The value contains the length of the message data, in bytes.

### Content-Type

Specifies the type of response body. The value is `application/json; charset=utf-8`.

V 9.4.0

## ibm-mq-resolved-qmgr

Specifies the name of the queue manager that was used for the request. If a unique name was used in the resource URL, this header identifies the name of the queue manager that is associated with that unique name. If the unique name used in the resource URL refers to a queue manager group, this header identifies which queue manager within the group was used.

## Response body format

Upon success, the response body is a UTF-8 encoded response. The response contains an outer JSON object that contains a single JSON array called `messages`. Each element in the array is a JSON object that contains information about a message on the queue. Each element contains the following attributes:

### REST API V1 > REST API V2 `correlationId`

Specifies the correlation ID of the message. The value is returned if the message contains a valid correlation ID.

### REST API V3 `correlationId`

Specifies the correlation ID of the message. The value is returned if the message contains a valid correlation ID. The correlation ID is prefixed with the "ID:" string, or can be an application-specific value.

### REST API V1 > REST API V2 `messageId`

Specifies the message ID that is allocated by IBM MQ to this message. It is represented as a 48-character hexadecimal encoded string, representing 24 bytes.

### REST API V3 `messageId`

Specifies the message ID that is allocated by IBM MQ to this message. It is represented as a 48-character hexadecimal encoded string, representing 24 bytes. The message ID is prefixed with the "ID:" string.

## format

Specifies the MQMD format field. Under normal circumstances text messages will contain the IBM MQ MQSTR value.

If a request is made to get a list of messages on a queue that is GET inhibited, an empty JSON array is returned.

If an error occurs, the response body contains a JSON formatted error message. For more information, see [REST API error handling](#).

## Examples

The following examples use the v2 resource URL. If you are using a version of IBM MQ earlier than IBM MQ 9.1.5 you must use the v1 resource URL instead. That is, in the resource URL, substitute v1 where the example URL uses v2.

The following example logs in a user called `mquser` with the password `mquser`. In cURL, the log in request might look like the following Windows example. The LTPA token is stored in the `cookiejar.txt` file by using the `-c` flag:

```
curl -k "https://localhost:9443/ibmmq/rest/v2/login" -X POST
-H "Content-Type: application/json" --data "{\"username\":\"mquser\", \"password\":\"mquser\"}"
-c c:\cookiejar.txt
```

After the user is logged in, the LTPA token and `ibm-mq-rest-csrf-token` HTTP header are used to authenticate further requests. The `ibm-mq-rest-csrf-token` `token_value` can be any value, including blank.

- “Request body format” on page 2191
- “Security requirements” on page 2192
- “Response status codes” on page 2192
- “Response headers” on page 2193
- “Response body format” on page 2193
- “Examples” on page 2193

## Resource URL

`https://host:port/ibmmq/rest/v2/messaging/qmgr/{qmgrName}/topic/{topicString}/message`

`https://host:port/ibmmq/rest/v3/messaging/qmgr/{qmgrName}/topic/{topicString}/message`

### qmgrName

Specifies the name of a queue manager to connect to for messaging.

**V 9.4.0** From IBM MQ 9.3.3, you can connect to either a local queue manager or a remote queue manager. The name that you specify for **qmgrName** depends on how your mqweb server is configured:

- If your mqweb server is configured to connect only to local queue managers, then use the name of the queue manager.
- If your mqweb server is configured to connect remote queue managers, then use the unique name for the queue manager as specified in the remote queue manager connection information.

You can determine whether your mqweb server is configured to connect to local queue managers or remote queue managers by using the **dspmweb properties** command and viewing the **mqRestMessagingConnectionMode** property.

The name is case-sensitive.

If the name includes a forward slash, a period, or a percent sign, these characters must be URL encoded:

- A forward slash must be encoded as %2F.
- A period must be encoded as %2E.
- A percent sign must be encoded as %25.

### topicString

Specifies the topic string on which to publish the message.

The topic string is case sensitive. The topic string can contain multiple topic levels, separated by the forward slash delimiter.

If the topic string contains a percent sign, a period, or a question mark, these characters must be URL encoded:

- A percent sign must be encoded as %25.
- A period must be encoded as %2E.
- A question mark must be encoded as %3F.

If the topic string starts or ends with a forwards slash, it must be encoded with a %2F.

For example, to publish to the topic string:

- `sport/football` on queue manager `MY.QMGR`, you use the following URL:

```
https://localhost:9443/ibmmq/rest/v2/messaging/qmgr/MY%2EQMGR/topic/sport/football/message
```

- /sport/football on queue manager MY.QMGR, you use the following URL:

```
https://localhost:9443/ibmmq/rest/v2/messaging/qmgr/MY%2EQMGR/topic/%2Fsport/football/  
message
```

You can use HTTP instead of HTTPS if you enable HTTP connections. For more information about enabling HTTP, see [Configuring HTTP and HTTPS ports](#).

## Request headers

The following headers must be sent with the request:

### Authorization

This header must be sent if you are using basic authentication. For more information, see [Using HTTP basic authentication with the REST API](#).

### Content-Type

This header must be sent with one of the following values:

- text/plain;charset=utf-8
- text/html;charset=utf-8
- text/xml;charset=utf-8
- application/json;charset=utf-8
- application/xml;charset=utf-8

### ibm-mq-rest-csrf-token

This header must be set, but the value can be anything, including being blank.

The following headers can optionally be sent with the request:

### Accept-Language

This header specifies the required language for any exceptions or error messages returned in the response message body.

### ibm-mq-md-expiry

This header sets the expiry duration for the created message. The expiry of a message starts from the time the message arrives at the queue manager. As a result network latency is ignored. The header must be specified as one of the following values:

#### unlimited

The message does not expire.

This value is the default value.

#### Integer value

Milliseconds before message expiry.

Limited to the range 0 - 99999999900.

### ibm-mq-md-persistence

This header sets the persistence for the created message. The header must be specified as one of the following values:

#### nonPersistent

The message does not survive system failures or queue manager restarts.

This value is the default value.

#### persistent

The message survives system failures or queue manager restarts.

### REST API V3 **ibm-mq-md-priority**

This header sets the priority of the created message. The header must be specified as one of the following values:

### **asDestination**

The message uses the priority specified in the DEFPRTY attribute of the underlying IBM MQ queue object.

### **Integer value**

Specify the actual priority as an integer in the range 0-9.

For example:

```
ibm-mq-md-priority: asDestination
```

### **ibm-mq-md-replyTo**

This header sets the reply-to destination for the created message. The format of the header uses the standard notation of supplying the reply-to queue and an optional queue manager: `replyQueue[@replyQmgr]`

For example:

```
ibm-mq-md-replyTo: myReplyQueue@myReplyQMgr
```

### **REST API V3** **ibm-mq-usr**

Set the request message user-defined properties. Multiple properties can be set on a message. You can specify multiple comma-separated properties in a single `ibm-mq-usr` request header, or you can use two or more separate instances of the `ibm-mq-usr` request header.

For example:

```
ibm-mq-usr: myIPprop;5;short  
ibm-mq-usr: mySProp;"hi";string  
ibm-mq-usr: myBProp>true;boolean  
ibm-mq-usr: myA;5;byte,myB;-10;integer
```

The properties have the following syntax:

```
ibm-mq-usr: property_name; user_value; user_type
```

#### **property\_name**

The name of the user property being specified. This must be a valid JMS property name.

#### **user\_value**

The value of the property.

#### **user\_type**

The type of the property:

- `boolean` (true/false, MQBOOL)
- `byte` (8-bit integer, MQINT8)
- `short` (16-bit integer, MQINT16)
- `integer` (32-bit integer, MQINT32)
- `long` (64-bit integer, MQINT64)
- `float` (32-bit real, MQFLOAT32)
- `double` (64-bit real, MQFLOAT64)
- `string` (quoted string)

### **Request body format**

The request body must be text and use UTF-8 encoding. No specific text structure is required. An MQSTR formatted message containing the request body text is created and published to the specified topic.

**REST API V3** If the REST API V3 user-defined properties, or application-specific correlation ID features are used, then an JMS `TextMessage` formatted message containing the request body text is created and put to the specified queue.

For more information, see [examples](#).

## Security requirements

The caller must be authenticated to the mqweb server. The `MQWebAdmin` and `MQWebAdminRO` roles are not applicable for the messaging REST API. For more information about security for the REST API, see [IBM MQ Console and REST API security](#).

Once authenticated to the mqweb server the user is capable of using both the messaging REST API and the administrative REST API.

The security principal of the caller must be granted the ability to publish messages to the specified topic:

- The topic that is specified by the `{topicString}` portion of the resource URL must be PUBLISH enabled.
- **MQ Appliance** **ALW** For the topic that is specified by the `{topicString}` portion of the resource URL, `+PUB` authority must be granted to the security principal of the caller.
- **z/OS** For the topic that is specified by the `{topicString}` portion of the resource URL, `UPDATE` access must be granted to the security principal of the caller.

This security principal might be the user that started the mqweb server, or the user that is logged into the mqweb server. If the queue manager you connect to is a remote queue manager, the security principal might instead be the user provided by credentials in the remote queue manager connection information, or another user that is determined by channel security rules. For more information, see [Determining the security principal that is used by the messaging REST API](#).

**ALW** On AIX, Linux, and Windows, you can grant authority to security principals to use IBM MQ resources by using the `setmqaut` command. For more information, see [setmqaut \(grant or revoke authority\)](#).

On z/OS, see [Setting up security on z/OS](#).

If you use Advanced Message Security (AMS) with the messaging REST API, note that all messages are encrypted by using the context of the mqweb server, not the context of the user that posts the message.

## Response status codes

### 201

Message created and published successfully.

### 400

Invalid data provided.

For example, an invalid request header value was specified.

### 401

Not authenticated.

The caller must be authenticated to the mqweb server and must be a member of one or more of the `MQWebAdmin`, `MQWebAdminRO`, or `MQWebUser` roles. The `ibm-mq-rest-csrf-token` header must also be specified. For more information, see [“Security requirements” on page 2192](#).

### 403

Not authorized.

The caller is authenticated to the mqweb server and is associated with a valid principal. However, the principal does not have access to all, or a subset of the required IBM MQ resources, or is not in the `MQWebUser` role. For more information about the access that is required, see [“Security requirements” on page 2192](#).

**404**

Queue manager does not exist.

**405**

Topic is PUBLISH inhibited.

**415**

A message header or body is an unsupported media type.

For example, the Content-Type header is set to an unsupported media type.

**500**

Server issue or error code from IBM MQ.

**502**

The current security principal cannot publish the message as the messaging provider does not support the required function. For example, if the mqweb server class path is invalid.

**503**

Queue manager not running.

## Response headers

The following headers are returned with the response:

### Content-Language

Specifies the language identifier of the response message in the event of any errors or exceptions. Used in conjunction with Accept-Language request header to indicate the required language for any error or exception conditions. The mqweb server default is used if the requested language is unsupported.

### Content-Length

Specifies the length of the HTTP response body, even when there is no content. Upon success the value is zero.

### Content-Type

Specifies the type of response body. Upon success the value is text/plain;charset=utf-8. In the event of any errors or exceptions, the value is application/json;charset=utf-8.

### **ibm-mq-resolved-qmgr**

Specifies the name of the queue manager that was used for the request. If a unique name was used in the resource URL, this header identifies the name of the queue manager that is associated with that unique name. If the unique name used in the resource URL refers to a queue manager group, this header identifies which queue manager within the group was used.

## Response body format

The response body is empty if the message is published successfully. If an error occurs, the response body contains an error message. For more information, see [REST API error handling](#).

## Examples

The following example logs in a user called mquser with the password mquser. In cURL, the log in request might look like the following Windows example. The LTPA token is stored in the cookiejar.txt file by using the -c flag:

```
curl -k "https://localhost:9443/ibmmq/rest/v1/login" -X POST
-H "Content-Type: application/json" --data "{\"username\":\"mquser\",\"password\":\"mquser\"}"
-c c:\cookiejar.txt
```

After the user is logged in, the LTPA token and ibm-mq-rest-csrf-token HTTP header are used to authenticate further requests. The ibm-mq-rest-csrf-token token\_value can be any value, including blank.

- The following Windows cURL example publishes a message to the topic string `myTopic` on queue manager `QM1`, using default options. The message contains the text *"Hello World!"*:

```
curl -k "https://localhost:9443/ibmmq/rest/v2/messaging/qmgr/QM1/topic/myTopic/message"
-X POST -b c:\cookiejar.txt -H "ibm-mq-rest-csrf-token: token_value"
-H "Content-Type: text/plain;charset=utf-8" --data "Hello World!"
```

- The following Windows cURL example publishes a persistent message to the topic string `myTopic/thisTopic` on queue manager `QM1`, with an expiry of 2 minutes. The message contains the text *"Hello World!"*:

```
curl -k "https://localhost:9443/ibmmq/rest/v2/messaging/qmgr/QM1/topic/myTopic%2FthisTopic/
message"
-X POST -b c:\cookiejar.txt -H "ibm-mq-rest-csrf-token: token_value"
-H "Content-Type: text/plain;charset=utf-8" -H "ibm-mq-md-persistence: persistent"
-H "ibm-mq-md-expiry: 120000" --data "Hello World!"
```

## Notices

---

This information was developed for products and services offered in the U.S.A.

IBM may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any IBM intellectual property right may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any non-IBM product, program, or service.

IBM may have patents or pending patent applications covering subject matter described in this document. The furnishing of this document does not grant you any license to these patents. You can send license inquiries, in writing, to:

IBM Director of Licensing  
IBM Corporation  
North Castle Drive  
Armonk, NY 10504-1785  
U.S.A.

For license inquiries regarding double-byte (DBCS) information, contact the IBM Intellectual Property Department in your country or send inquiries, in writing, to:

Such information may be available, subject to appropriate terms and conditions, including in some cases, payment of a fee.

The licensed program described in this information and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Program License Agreement, or any equivalent agreement between us.

Any performance data contained herein was determined in a controlled environment. Therefore, the results obtained in other operating environments may vary significantly. Some measurements may have been made on development-level systems and there is no guarantee that these measurements will be the same on generally available systems. Furthermore, some measurements may have been estimated through extrapolation. Actual results may vary. Users of this document should verify the applicable data for their specific environment.

Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to non-IBM products. Questions on the capabilities of non-IBM products should be addressed to the suppliers of those products.

All statements regarding IBM's future direction or intent are subject to change or withdrawal without notice, and represent goals and objectives only.

This information contains examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to the names and addresses used by an actual business enterprise is entirely coincidental.

#### COPYRIGHT LICENSE:

This information contains sample application programs in source language, which illustrate programming techniques on various operating platforms. You may copy, modify, and distribute these sample programs in any form without payment to IBM, for the purposes of developing, using, marketing or distributing application programs conforming to the application programming interface for the operating platform for which the sample programs are written. These examples have not been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs.

If you are viewing this information softcopy, the photographs and color illustrations may not appear.

## Programming interface information

---

Programming interface information, if provided, is intended to help you create application software for use with this program.

This book contains information on intended programming interfaces that allow the customer to write programs to obtain the services of IBM MQ.

However, this information may also contain diagnosis, modification, and tuning information. Diagnosis, modification and tuning information is provided to help you debug your application software.

**Important:** Do not use this diagnosis, modification, and tuning information as a programming interface because it is subject to change.

## Trademarks
