To determine the value of this attribute, use the MQIA\_TRIGGER\_DEPTH selector with the MQINQ call. To change the value of this attribute, use the MQSET call.

### **TriggerMsgPriority (MQLONG)**

This is the message priority below which messages do not contribute to the generation of trigger messages (that is, the queue manager ignores these messages when deciding whether to generate a trigger message).

Table 625. Queue types to which this attribute applies				
Local	Model	Alias	Remote	Cluster
X	X			

*TriggerMsgPriority* can be in the range zero (lowest) through *MaxPriority* (highest; see *MaxPriority* attribute ); a value of zero causes all messages to contribute to the generation of trigger messages.

To determine the value of this attribute, use the MQIA\_TRIGGER\_MSG\_PRIORITY selector with the MQINQ call. To change the value of this attribute, use the MQSET call.

### **TriggerType (MQLONG)**

This controls the conditions under which trigger messages are written as a result of messages arriving on this queue.

Table 626. Queue types to which this attribute applies				
Local	Model	Alias	Remote	Cluster
X	X			

It has one of the following values:

**MQTT\_NONE**

No trigger messages are written as a result of messages on this queue. This has the same effect as setting *TriggerControl* to MQTC\_OFF.

**MQTT\_FIRST**

A trigger message is written whenever the number of messages of priority *TriggerMsgPriority* or greater on the queue changes from 0 to 1.

**MQTT EVERY**

A trigger message is written whenever a message of priority *TriggerMsgPriority* or greater arrives on the queue.

**MQTT\_DEPTH**

A trigger message is written whenever the number of messages of priority *TriggerMsgPriority* or greater on the queue equals or exceeds *TriggerDepth*. After the trigger message has been written, *TriggerControl* is set to MQTC\_OFF to prevent further triggering until it is explicitly turned on again.

To determine the value of this attribute, use the MQIA\_TRIGGER\_TYPE selector with the MQINQ call. To change the value of this attribute, use the MQSET call.

**Usage (MQLONG)**

This indicates what the queue is used for.

Table 627. Queue types to which this attribute applies

Local	Model	Alias	Remote	Cluster
X	X			

The value is one of the following:

**MQUS\_NORMAL**

This is a queue that applications use when putting and getting messages; the queue is not a transmission queue.

**MQUS\_TRANSMISSION**

This is a queue used to hold messages destined for remote queue managers. When an application sends a message to a remote queue, the local queue manager stores the message temporarily on the appropriate transmission queue in a special format. A message channel agent then reads the message from the transmission queue, and transports the message to the remote queue manager. For more information about configuring remote administration, see [Configuring queue managers for remote administration](#).

Only privileged applications can open a transmission queue for MQOO\_OUTPUT to put messages on it directly. Usually, only utility applications do this. Ensure that the message data format is correct (see “MQXQH - Transmission-queue header” on page 619) or errors might occur during the transmission process. Context is not passed or set unless one of the MQPMO\_\*\_CONTEXT context options is specified.

To determine the value of this attribute, use the MQIA\_USAGE selector with the MQINQ call.

**XmitQName (MQCHAR48)**

This is the transmission queue name. If this attribute is nonblank when an open occurs, either for a remote queue or for a queue manager alias definition, it specifies the name of the local transmission queue to be used for forwarding the message.

Table 628. Queue types to which this attribute applies

Local	Model	Alias	Remote	Cluster
			X	

If **XmitQName** is blank, the local queue with a name that is the same as **RemoteQMgrName** is used as the transmission queue. If there is no queue with the name **RemoteQMgrName**, the queue identified by the **DefXmitQName** queue manager attribute is used.

This attribute is ignored if the definition is being used as a queue manager alias and **RemoteQMgrName** is the name of the local queue manager. It is also ignored if the definition is used as a reply-to queue alias definition.

To determine the value of this attribute, use the MQCA\_XMIT\_Q\_NAME selector with the MQINQ call. The length of this attribute is given by MQ\_Q\_NAME\_LENGTH.

## Attributes for namelists

The following table summarizes the attributes that are specific to namelists. The attributes are described in alphabetical order.

Namelists are supported on all IBM MQ systems, plus IBM MQ MQI clients connected to these systems.

**Note:** The names of the attributes shown in this section are descriptive names used with the MQINQ and MQSET calls; the names are the same as for the PCF commands. When MQSC commands are used to define, alter, or display attributes, alternative short names are used; see [MQSC commands](#) for more information.

Attribute	Description
<u>AlterationDate</u>	Date when definition was last changed
<u>AlterationTime</u>	Time when definition was last changed
<u>NameCount</u>	Number of names in namelist
<u>NamelistDesc</u>	Namelist description
<u>NamelistName</u>	Namelist name
<u>Names</u>	A list of <i>NameCount</i> names
<u>NamelistType</u>	Namelist type
<u>QSGDisp</u>	Queue sharing group disposition

### ***AlterationDate (MQCHAR12)***

This is the date when the definition was last changed. The format of the date is YYYY-MM-DD, padded with two trailing blanks to make the length 12 bytes.

To determine the value of this attribute, use the MQCA\_ALTERATION\_DATE selector with the MQINQ call. The length of this attribute is given by MQ\_DATE\_LENGTH.

### ***AlterationTime (MQCHAR8)***

This is the time when the definition was last changed. The format of the time is HH.MM.SS.

To determine the value of this attribute, use the MQCA\_ALTERATION\_TIME selector with the MQINQ call. The length of this attribute is given by MQ\_TIME\_LENGTH.

### ***NameCount (MQLONG)***

This is the number of names in the namelist. It is greater than or equal to zero. The following value is defined:

#### **MQNC\_MAX\_NAMELIST\_NAME\_COUNT**

Maximum number of names in a namelist.

To determine the value of this attribute, use the MQIA\_NAME\_COUNT selector with the MQINQ call.

### ***NamelistDesc (MQCHAR64)***

Use this field for descriptive commentary; its value is established by the definition process. The content of the field is of no significance to the queue manager, but the queue manager might require that the field contain only characters that can be displayed. It cannot contain any null characters; if necessary, it is padded to the right with blanks. In a DBCS installation, this field can contain DBCS characters (subject to a maximum field length of 64 bytes).

**Note:** If this field contains characters that are not in the queue manager's character set (as defined by the **CodedCharSetId** queue manager attribute), those characters might be translated incorrectly if this field is sent to another queue manager.

To determine the value of this attribute, use the MQCA\_NAMELIST\_DESC selector with the MQINQ call.

The length of this attribute is given by MQ\_NAMELIST\_DESC\_LENGTH.

### ***NamelistName (MQCHAR48)***

This is the name of a namelist that is defined on the local queue manager. For more information about namelist names, see the [Other object names](#) section.

Each namelist has a name that is different from the names of other namelists belonging to the queue manager, but might duplicate the names of other queue manager objects of different types (for example, queues).

To determine the value of this attribute, use the MQCA\_NAMELIST\_NAME selector with the MQINQ call.

The length of this attribute is given by MQ\_NAMELIST\_NAME\_LENGTH.

### ***NamelistType (MQLONG)***

This specifies the nature of the names in the namelist, and indicates how the namelist is used. It is one of the following values:

#### **MQNT\_NONE**

Namelist with no assigned type.

#### **MQNT\_Q**

Namelist containing the names of queues.

#### **MQNT\_CLUSTER**

Namelist containing the names of clusters.

#### **MQNT\_AUTH\_INFO**

Namelist containing the names of authentication-information objects.

To determine the value of this attribute, use the MQIA\_NAMELIST\_TYPE selector with the MQINQ call.

 This attribute is supported only on z/OS.

### ***Names (MQCHAR48xNameCount)***

This is a list of *NameCount* names, where each name is the name of an object that is defined to the local queue manager. For more information about object names, see [Rules for naming IBM MQ objects](#).

To determine the value of this attribute, use the MQCA\_NAMES selector with the MQINQ call.

The length of each name in the list is given by MQ\_OBJECT\_NAME\_LENGTH.

### ***QSGDisp (MQLONG)***

This specifies the disposition of the namelist. The value is one of the following:

#### **MQQSGD\_Q\_MGR**

The object has queue manager disposition: the object definition is known only to the local queue manager; the definition is not known to other queue managers in the queue sharing group.

Each queue manager in the queue sharing group can have an object with the same name and type as the current object, but these are separate objects and there is no correlation between them. Their attributes are not constrained to be the same as each other.

### **MQQSGD\_COPY**

The object is a local copy of a master object definition that exists in the shared repository. Each queue manager in the queue sharing group can have its own copy of the object. Initially, all copies have the same attributes, but you can alter each copy, using MQSC commands, so that its attributes differ from those of the other copies. The attributes of the copies are resynchronized when the master definition in the shared repository is altered.

To determine the value of this attribute, use the MQIA\_QSG\_DISP selector with the MQINQ call.

 This attribute is supported only on z/OS.

## **Attributes for process definitions**

The following table summarizes the attributes that are specific to process definitions. The attributes are described in alphabetical order.

**Note:** The names of the attributes in this section are descriptive names used with the MQINQ and MQSET calls; the names are the same as for the PCF commands. When MQSC commands are used to define, alter, or display attributes, alternative short names are used; see [MQSC commands](#) for more information.

Attribute	Description
<a href="#">AlterationDate</a>	Date when definition was last changed
<a href="#">AlterationTime</a>	Time when definition was last changed
<a href="#">AppId</a>	Application identifier
<a href="#">AppType</a>	Application type
<a href="#">EnvData</a>	Environment data
<a href="#">ProcessDesc</a>	Process description
<a href="#">ProcessName</a>	Process name
<a href="#">QSGDisp</a>	Queue sharing group disposition
<a href="#">UserData</a>	User data

### ***AlterationDate (MQCHAR12)***

This is the date when the definition was last changed. The format of the date is YYYY-MM-DD, padded with two trailing blanks to make the length 12 bytes.

To determine the value of this attribute, use the MQCA\_ALTERATION\_DATE selector with the MQINQ call. The length of this attribute is given by MQ\_DATE\_LENGTH.

### ***AlterationTime (MQCHAR8)***

This is the time when the definition was last changed. The format of the time is HH.MM.SS.

To determine the value of this attribute, use the MQCA\_ALTERATION\_TIME selector with the MQINQ call. The length of this attribute is given by MQ\_TIME\_LENGTH.

### ***AppId (MQCHAR256)***

This is a character string that identifies the application to be started. This information is for use by a trigger-monitor application that processes messages on the initiation queue; the information is sent to the initiation queue as part of the trigger message.

The meaning of *ApplId* is determined by the trigger-monitor application. The trigger monitor provided by IBM MQ requires *ApplId* to be the name of an executable program. The following notes apply to the environments indicated:

- On z/OS, *ApplId* must be:
  - A CICS transaction identifier, for applications started using the CICS trigger-monitor transaction CKTI
  - An IMS transaction identifier, for applications started using the IMS trigger monitor CSQQTRMN
- On Windows, the program name can be prefixed with a drive and directory path.
- On AIX and Linux, the program name can be prefixed with a directory path.

The character string cannot contain any nulls. It is padded to the right with blanks if necessary.

To determine the value of this attribute, use the MQCA\_APPL\_ID selector with the MQINQ call. The length of this attribute is given by MQ\_PROCESS\_APPL\_ID\_LENGTH.

### ***ApplType* (MQLONG)**

This identifies the nature of the program to be started in response to the receipt of a trigger message. This information is for use by a trigger-monitor application that processes messages on the initiation queue; the information is sent to the initiation queue as part of the trigger message.

*ApplType* can have any value, but the following values are recommended for standard types; restrict user-defined application types to values in the range MQAT\_USER\_FIRST through MQAT\_USER\_LAST:

#### **MQAT\_AIX**

AIX application (same value as MQAT\_UNIX).

#### **MQAT\_BATCH**

Batch application

#### **MQAT\_CICS**

CICS transaction.

#### **MQAT\_IMS**

IMS application.

#### **MQAT\_IMS\_BRIDGE**

IMS bridge application.

#### **MQAT\_JAVA**

Java application.

#### **MQAT\_MVS**

MVS or TSO application (same value as MQAT\_ZOS).

#### **MQAT\_OS390**

OS/390 application (same value as MQAT\_ZOS).

#### **MQAT\_OS400**

IBM i application.

#### **MQAT\_UNIX**

UNIX application.

#### **MQAT\_UNKNOWN**

Application of unknown type.

#### **MQAT\_USER**

User application.

#### **MQAT\_WINDOWS**

64-bit Windows application.

#### **MQAT\_WINDOWS\_NT**

32-bit Windows application.

**MQAT\_WLM**

z/OS workload manager application.

**MQAT\_ZOS**

z/OS application.

**MQAT\_USER\_FIRST**

Lowest value for user-defined application type.

**MQAT\_USER\_LAST**

Highest value for user-defined application type.

To determine the value of this attribute, use the MQIA\_APPL\_TYPE selector with the MQINQ call.

***EnvData (MQCHAR128)***

This is a character string that contains environment-related information pertaining to the application to be started. This information is for use by a trigger-monitor application that processes messages on the initiation queue; the information is sent to the initiation queue as part of the trigger message.

The meaning of *EnvData* is determined by the trigger-monitor application. The trigger monitor provided by IBM MQ appends *EnvData* to the parameter list passed to the started application. The parameter list consists of the MQTMC2 structure, followed by one blank, followed by *EnvData* with trailing blanks removed. The following notes apply to the environments indicated:

- On z/OS:
  - *EnvData* is not used by the trigger-monitor applications provided by IBM MQ.
  - If ApplType is MQAT\_WLM, you can supply default values in *EnvData* for the ServiceName and ServiceStep fields in the work information header (MQWIH).
- On AIX and Linux, *EnvData* can be set to the & character to run the started application in the background.

The character string cannot contain any nulls. It is padded to the right with blanks if necessary.

To determine the value of this attribute, use the MQCA\_ENV\_DATA selector with the MQINQ call. The length of this attribute is given by MQ\_PROCESS\_ENV\_DATA\_LENGTH.

***ProcessDesc (MQCHAR64)***

Use this field for descriptive commentary. The content of the field is of no significance to the queue manager, but the queue manager might require that the field contain only characters that can be displayed. It cannot contain any null characters; if necessary, it is padded to the right with blanks. In a DBCS installation, the field can contain DBCS characters (subject to a maximum field length of 64 bytes).

**Note:** If this field contains characters that are not in the queue manager's character set (as defined by the **CodedCharSetId** queue manager attribute), those characters might be translated incorrectly if this field is sent to another queue manager.

To determine the value of this attribute, use the MQCA\_PROCESS\_DESC selector with the MQINQ call.

The length of this attribute is given by MQ\_PROCESS\_DESC\_LENGTH.

***ProcessName (MQCHAR48)***

This is the name of a process definition that is defined on the local queue manager.

Each process definition has a name that is different from the names of other process definitions belonging to the queue manager. But the name of the process definition might be the same as the names of other queue manager objects of different types (for example, queues).

To determine the value of this attribute, use the MQCA\_PROCESS\_NAME selector with the MQINQ call.

The length of this attribute is given by MQ\_PROCESS\_NAME\_LENGTH.

## **QSGDisp (MQLONG)**

This specifies the disposition of the process definition. The value is one of the following:

### **MQQSGD\_Q\_MGR**

The object has queue manager disposition: the object definition is known only to the local queue manager; the definition is not known to other queue managers in the queue sharing group.

Each queue manager in the queue sharing group can have an object with the same name and type as the current object, but these are separate objects and there is no correlation between them. Their attributes are not constrained to be the same as each other.

### **MQQSGD\_COPY**

The object is a local copy of a master object definition that exists in the shared repository. Each queue manager in the queue sharing group can have its own copy of the object. Initially, all copies have the same attributes, but you can alter each copy, using MQSC commands, so that its attributes differ from those of the other copies. The attributes of the copies are resynchronized when the master definition in the shared repository is altered.

To determine the value of this attribute, use the MQIA\_QSG\_DISP selector with the MQINQ call.

 This attribute is supported only on z/OS.

## **UserData (MQCHAR128)**

`UserData` is a character string that contains user information pertaining to the application to be started. This information is for use by a trigger-monitor application that processes messages on the initiation queue, or the application that is started by the trigger monitor. The information is sent to the initiation queue as part of the trigger message.

The meaning of `UserData` is determined by the trigger-monitor application. The trigger monitor provided by IBM MQ passes `UserData` to the started application as part of the parameter list. The parameter list consists of the MQTMC2 structure (containing `UserData`), followed by one blank, followed by `EnvData` with trailing blanks removed.

The character string cannot contain any nulls. It is padded to the right with blanks if necessary. For Microsoft Windows, the character string must not contain double quotation marks if the process definition is going to be passed to `runmqtrm`.

To determine the value of this attribute, use the MQCA\_USER\_DATA selector with the MQINQ call. The length of this attribute is given by MQ\_PROCESS\_USER\_DATA\_LENGTH.

## **Return codes**

For each IBM MQ Message Queue Interface (MQI) and IBM MQ Administration Interface (MQAI) call, a **completion** code and a **reason** code are returned by the queue manager or by an exit routine, to indicate the success or failure of the call.

Applications must not depend upon errors being checked for in a specific order, except where specifically noted. If more than one completion code or reason code could arise from a call, the particular error reported depends on the implementation.

Applications checking for successful completion following an IBM MQ API call must always check the completion code. Do not assume the completion code value, based on the value of the reason code.

## **Completion codes**

The completion code parameter (*CompCode*) allows the caller to see quickly whether the call completed successfully, completed partially, or failed. The following is a list of completion codes, with more detail than is given in the call descriptions:

### **MQCC\_OK**

The call completed fully; all output parameters have been set. The **Reason** parameter always has the value MQRC\_NONE in this case.

### **MQCC\_WARNING**

The call completed partially. Some output parameters might have been set in addition to the *CompCode* and *Reason* output parameters. The **Reason** parameter gives additional information about the partial completion.

### **MQCC\_FAILED**

The processing of the call did not complete. The state of the queue manager is unchanged, except where specifically noted. The *CompCode* and *Reason* output parameters have been set; other parameters are unchanged, except where noted.

The reason might be a fault in the application program, or it might be the result of some situation external to the program, for example the user's authority might have been revoked. The **Reason** parameter gives additional information about the error.

## **Reason codes**

The reason code parameter (*Reason*) qualifies the completion code parameter (*CompCode*).

If there is no special reason to report, MQRC\_NONE is returned. A successful call returns MQCC\_OK and MQRC\_NONE.

If the completion code is either MQCC\_WARNING or MQCC\_FAILED, the queue manager always reports a qualifying reason; details are given under each call description.

Where user exit routines set completion codes and reasons, they must adhere to these rules. In addition, any special reason values defined by user exits must be less than zero, to ensure that they do not conflict with values defined by the queue manager. Exits can set reasons already defined by the queue manager, where appropriate.

Reason codes also occur in:

- The *Reason* field of the MQDLH structure
- The *Feedback* field of the MQMD structure

For complete descriptions of reason codes, see [Messages and reason codes](#).

## **Rules for validating MQI options**

This section lists the situations that produce an MQRC\_OPTIONS\_ERROR reason code from an MQOPEN, MQPUT, MQPUT1, MQGET, MQCLOSE, or MQSUB call.

### **MQOPEN call**

For the options of the MQOPEN call:

- At least *one* of the following must be specified:
  - MQOO\_BROWSE
  - MQOO\_INPUT\_EXCLUSIVE <sup>1</sup>
  - MQOO\_INPUT\_SHARED <sup>1</sup>
  - MQOO\_INPUT\_AS\_Q\_DEF <sup>1</sup>
  - MQOO\_INQUIRE
  - MQOO\_OUTPUT
  - MQOO\_SET
  - MQOO\_BIND\_ON\_OPEN <sup>2</sup>
  - MQOO\_BIND\_NOT\_FIXED <sup>2</sup>

- MQOO\_BIND\_ON\_GROUP <sup>2</sup>
- MQOO\_BIND\_AS\_Q\_DEF <sup>2</sup>
- Only *one* of the following is allowed:
  - MQOO\_READ\_AHEAD
  - MQOO\_NO\_READ\_AHEAD
  - MQOO\_READ\_AHEAD\_AS\_Q\_DEF

1. Only *one* of the following is allowed:

- MQOO\_INPUT\_EXCLUSIVE
- MQOO\_INPUT\_SHARED
- MQOO\_INPUT\_AS\_Q\_DEF

2. Only *one* of the following is allowed:

- MQOO\_BIND\_ON\_OPEN
- MQOO\_BIND\_NOT\_FIXED
- MQOO\_BIND\_ON\_GROUP
- MQOO\_BIND\_AS\_Q\_DEF

**Note:** The options that are listed previously are mutually exclusive. However, as the value of MQOO\_BIND\_AS\_Q\_DEF is zero, specifying it with either of the other two bind options does not result in reason code MQRC\_OPTIONS\_ERROR. MQOO\_BIND\_AS\_Q\_DEF is provided to aid program documentation.

- If MQOO\_SAVE\_ALL\_CONTEXT is specified, one of the MQOO\_INPUT\_\* options must also be specified.
- If one of the MQOO\_SET\_\*\_CONTEXT or MQOO\_PASS\_\*\_CONTEXT options are specified, MQOO\_OUTPUT must also be specified.
- If MQOO\_CO\_OP is specified, MQOO\_BROWSE must also be specified
- If MQOO\_NO\_MULTICAST is specified, MQOO\_OUTPUT must also be specified.

## MQPUT call

For the put-message options:

- The combination of MQPMO\_SYNCPOINT and MQPMO\_NO\_SYNCPOINT is not allowed.
- Only *one* of the following is allowed:
  - MQPMO\_DEFAULT\_CONTEXT
  - MQPMO\_NO\_CONTEXT
  - MQPMO\_PASS\_ALL\_CONTEXT
  - MQPMO\_PASS\_IDENTITY\_CONTEXT
  - MQPMO\_SET\_ALL\_CONTEXT
  - MQPMO\_SET\_IDENTITY\_CONTEXT
- Only *one* of the following is allowed:
  - MQPMO\_ASYNC\_RESPONSE
  - MQPMO\_SYNC\_RESPONSE
  - MQPMO\_RESPONSE\_AS\_TOPIC\_DEF
  - MQPMO\_RESPONSE\_AS\_Q\_DEF
- MQPMO\_ALTERNATE\_USER\_AUTHORITY is not allowed (it is valid only on the MQPUT1 call).

## **MQPUT1 call**

For the put-message options, the rules are the same as for the MQPUT call, except for the following:

- MQPMO\_ALTERNATE\_USER\_AUTHORITY is allowed.
- MQPMO\_LOGICAL\_ORDER is not allowed.

## **MQGET call**

For the get-message options:

- Only *one* of the following is allowed:
  - MQGMO\_NO\_SYNCPOINT
  - MQGMO\_SYNCPOINT
  - MQGMO\_SYNCPOINT\_IF\_PERSISTENT
- Only *one* of the following is allowed:
  - MQGMO\_BROWSE\_FIRST
  - MQGMO\_BROWSE\_MSG\_UNDER\_CURSOR
  - MQGMO\_BROWSE\_NEXT
  - MQGMO\_MSG\_UNDER\_CURSOR
- MQGMO\_SYNCPOINT is not allowed with any of the following:
  - MQGMO\_BROWSE\_FIRST
  - MQGMO\_BROWSE\_MSG\_UNDER\_CURSOR
  - MQGMO\_BROWSE\_NEXT
  - MQGMO\_LOCK
  - MQGMO\_UNLOCK
- MQGMO\_SYNCPOINT\_IF\_PERSISTENT is not allowed with any of the following:
  - MQGMO\_BROWSE\_FIRST
  - MQGMO\_BROWSE\_MSG\_UNDER\_CURSOR
  - MQGMO\_BROWSE\_NEXT
  - MQGMO\_COMPLETE\_MSG
  - MQGMO\_UNLOCK
- MQGMO\_MARK\_SKIP\_BACKOUT requires MQGMO\_SYNCPOINT to be specified.
- The combination of MQGMO\_WAIT and MQGMO\_SET\_SIGNAL is not allowed.
- If MQGMO\_LOCK is specified, one of the following must also be specified:
  - MQGMO\_BROWSE\_FIRST
  - MQGMO\_BROWSE\_MSG\_UNDER\_CURSOR
  - MQGMO\_BROWSE\_NEXT
- If MQGMO\_UNLOCK is specified, only the following values are allowed:
  - MQGMO\_NO\_SYNCPOINT
  - MQGMO\_NO\_WAIT

## **MQCLOSE call**

For the options of the MQCLOSE call:

- The combination of MQCO\_DELETE and MQCO\_DELETE\_PURGE is not allowed.
- Only one of the following is allowed:

- MQCO\_KEEP\_SUB
- MQCO\_REMOVE\_SUB

## MQSUB call

For the options of the MQSUB call:

- At least one of the following must be specified:
    - MQSO\_ALTER
    - MQSO\_RESUME
    - MQSO\_CREATE
  - Only one of the following is allowed:
    - MQSO\_DURABLE
    - MQSO\_NON\_DURABLE
- Note:** The options that are listed previously are mutually exclusive. However, as the value of MQSO\_NON\_DURABLE is zero, specifying it with MQSO\_DURABLE does not result in reason code MQRC\_OPTIONS\_ERROR. MQSO\_NON\_DURABLE is provided to aid program documentation.
- The combination of MQSO\_GROUP\_SUB and MQSO\_MANAGED is not allowed.
  - MQSO\_GROUP\_SUB requires MQSO\_SET\_CORREL\_ID to be specified.
  - Only one of the following is allowed:
    - MQSO\_ANY\_USERID
    - MQSO\_FIXED\_USERID
  - MQSO\_NEW\_PUBLICATIONS\_ONLY is allowed in combination with:
    - MQSO\_CREATE
    - MQSO\_ALTER, if MQSO\_NEW\_PUBLICATIONS\_ONLY was set on the original subscription
  - The combination of MQSO\_PUBLICATIONS\_ON\_REQUEST and SubLevel greater than 1 is not allowed.
  - Only one of the following is allowed:
    - MQSO\_WILDCARD\_CHAR
    - MQSO\_WILDCARD\_TOPIC
  - MQSO\_NO\_MULTICAST requires MQSO\_MANAGED to be specified.

## Queued publish/subscribe command messages

An application can use MQRFH2 command messages to control a queued publish/subscribe application.

An application that is using MQRFH2 for publish/subscribe can send the following command messages to the SYSTEM.BROKER.CONTROL.QUEUE:

- [“Delete Publication message” on page 880](#)
- [“Deregister Subscriber message” on page 881](#)
- [“Publish message” on page 885](#)
- [“Register Subscriber message” on page 887](#)
- [“Request Update message” on page 891](#)

If you are writing queued publish/subscribe applications, you must understand these messages, the queue manager response message, and the message descriptor (MQMD); see the following information:

- [“Queue Manager Response message” on page 893](#)
- [“MQMD settings for publications forwarded by a queue manager” on page 899](#)

- [“MQMD settings in queue manager response messages” on page 900](#)
- [“Publish/subscribe reason codes” on page 895](#)

The commands are contained in a `psc` folder in the **NameValueData** field of the MQRFH2 header. The message that can be sent by a broker in response to a command message is contained in a `psc.r` folder.

The descriptions of each command list the properties that can be contained in a folder. Unless otherwise specified, the properties are optional and can occur only once.

Names of properties are shown as `<Command>`.

Values must be in string format, for example: `Publish`.

A string constant representing the value of a property is shown in parentheses, for example: `(MQPSC_PUBLISH)`.

String constants are defined in the header file `cmqpsc.h` which is supplied with the queue manager.

## Delete Publication message

The **Delete Publication** command message is sent to a queue manager from a publisher, or from another queue manager, to tell the queue manager to delete any retained publications for the specified topics.

This message is sent to a queue monitored by the queue manager's queued publish/subscribe interface.

The input queue should be the queue that the original publication was sent to.

If you have the authority for some, but not all, of the topics that are specified in the **Delete Publication** command message, only those topics are deleted. A **Broker Response** message indicates which topics are not deleted.

Similarly, if a **Publish** command contains more than one topic, a **Delete Publication** command matching some, but not all, of those topics deletes only the publications for the topics that are specified in the **Delete Publication** command.

See [“MQMD settings for publications forwarded by a queue manager” on page 899](#) for details of the message descriptor (MQMD) parameters that are needed when sending a command message to the queue manager.

### Properties

#### Command (*MQPSC\_COMMAND*)

The value is `DeletePub` (*MQPSC\_DELETE\_PUBLICATION*).

This property must be specified.

#### Topic> (*MQPSC\_TOPIC*)

The value is a string that contains a topic for which retained publications are to be deleted. Wildcard characters can be included in the string to delete publications on more than one topic.

This property must be specified; it can be repeated for as many topics as needed.

#### DelOpt (*MQPSC\_DELETE\_OPTION*)

The delete options property can take one of the following values:

##### Local (*MQPSC\_LOCAL*)

All retained publications for the specified topics are deleted at the local queue manager (that is, the queue manager to which this message is sent), whether they were published with the `Local` option or not.

Publications at other queue managers are not affected.

##### None (*MQPSC\_NONE*)

All options take their default values. This has the same effect as omitting the `DelOpt` property. If other options are specified at the same time, `None` is ignored.

The default if this property is omitted is that all retained publications for the specified topics are deleted at all queue managers in the network, regardless of whether they were published with the Local option.

### Example

Here is an example of NameValueData for a **Delete Publication** command message. This is used by the sample application to delete, at the local queue manager, the retained publication that contains the latest score in the match between Team1 and Team2.

```
<psc>
  <Command>DeletePub</Command>
  <Topic>Sport/Soccer/State/LatestScore/Team1 Team2</Topic>
  <DelOpt>Local</DelOpt>
</psc>
```

### Deregister Subscriber message

The **Deregister Subscriber** command message is sent to a queue manager by a subscriber, or by another application on behalf of a subscriber, to indicate that it no longer wants to receive messages matching the given parameters.

This message is sent to SYSTEM.BROKER.CONTROL.QUEUE, the queue manager's control queue. The user must have the necessary authority to put a message onto this queue.

See [MQMD settings for publications forwarded by a queue manager](#) for details of the message descriptor (MQMD) parameters that are needed when sending a command message to the queue manager.

An individual subscription can be deregistered by specifying the corresponding topic, subscription point and filter values of the original subscription. If any of the values were not specified (that is, they took the default values) in the original subscription, they should be omitted when the subscription is deregistered.

All subscriptions for a subscriber, or a group of subscribers, can be deregistered by using the DeregAll option. For example, if DeregAll is specified, together with a subscription point (but no topic or filter), then all subscriptions for the subscriber on the specified subscription point are deregistered, regardless of the topic and filter. Any combination of topic, filter and subscription point is allowed; if all three are specified only one subscription can match, and the DeregAll option is ignored.

The message must be sent by the subscriber that registered the subscription; this is confirmed by checking the subscriber's user ID.

Subscriptions can also be deregistered by a system administrator using MQSC or PCF commands. However, the subscriptions registered with a temporary dynamic queue are associated with the queue, not just the queue name. If the queue is deleted, either explicitly, or by the application disconnecting from the queue manager, it is no longer possible to use the **Deregister Subscriber** command to deregister the subscriptions for that queue. The subscriptions can be deregistered using the developer workbench, and they are removed automatically by the queue manager the next time that it matches a publication to the subscription, or the next time the queue manager restarts. Under normal circumstances, applications should deregister their subscriptions before deleting the queue, or disconnecting from the queue manager.

If a subscriber sends a message to deregister a subscription, and receives a response message to say that this was processed successfully, some publications might still reach the subscriber queue if they were being processed by the queue manager at the same time as the subscription was being deregistered. If the messages are not removed from the queue, there might be a buildup of unprocessed messages on the subscriber queue. If the application executes a loop that includes an MQGET call with the appropriate CorrelId after sleeping for a while, these messages are cleared off the queue.

Similarly, if the subscriber uses a permanent dynamic queue, and deregisters and closes the queue with the MQCO\_DELETE\_PURGE option on an MQCLOSE call, the queue might not be empty. If any publications from the queue manager are not yet committed when the queue is deleted, an MQRC\_Q\_NOT\_EMPTY return code is issued by the MQCLOSE call. The application can avoid this problem by sleeping and reissuing the MQCLOSE call from time to time.

## **Properties**

### **Command (MQPSC\_COMMAND)**

The value is DeregSub (MQPSC\_DEREGISTER\_SUBSCRIBER).

This property must be specified.

### **Topic (MQPSC\_TOPIC)**

The value is a string that contains the topic to be deregistered.

This property can, optionally, be repeated if multiple topics are to be deregistered. It can be omitted if DeregAll is specified in <RegOpt>.

The topics that are specified can be a subset of those that are registered if the subscriber wants to retain subscriptions for other topics. Wildcard characters are allowed, but a topic string that contains wildcard characters must exactly match the corresponding string that was specified in the **Deregister Subscriber** command message.

### **SubPoint (MQPSC\_SUBSCRIPTION\_POINT)**

The value is a string that specifies the subscription point from which the subscription is to be detached.

This property must not be repeated. It can be omitted if a <Topic> is specified, or if DeregAll is specified in <RegOpt>. If you omit this property, the following happens:

- If you do **not** specify DeregAll, subscriptions matching the <Topic> property (and the <Filter> property, if present) are deregistered from the default subscription point.
- If you specify DeregAll, all subscriptions (matching the <Topic> and <Filter> properties if present) are deregistered from all subscription points.

Note that you cannot specify the default subscription point explicitly. Therefore, there is no way of deregistering all subscriptions from this subscription point only; you must specify the topics.

### **SubIdentity (MQPSC\_SUBSCRIPTION\_IDENTITY)**

This is a variable-length string with a maximum length of 64 characters. It is used to represent an application with an interest in a subscription. The queue manager maintains a set of subscriber identities for each subscription. Each subscription can allow its identity set to hold only a single identity, or an unlimited number of identities.

If the SubIdentity is in the identity set for the subscription then it is removed from the set. If the identity set becomes empty as a result of this, the subscription is removed from the queue manager, unless LeaveOnly is specified as a value of the RegOpt property. If the identity set still contains other identities then the subscription is not removed from the queue manager, and publication flow is not interrupted.

If SubIdentity is specified, but the SubIdentity is not in the identity set for the subscription, then the **Deregister Subscriber** command fails with the return code MQRCCF\_SUB\_IDENTITY\_ERROR.

### **Filter (MQPSC\_FILTER)**

The value is a string specifying the filter to be deregistered. It must match exactly, including case and any spaces, a subscription filter that has been previously registered.

This property can, optionally, be repeated if more than one filter is to be deregistered. It can be omitted if a <Topic> is specified, or if DeregAll is specified in <RegOpt>.

The filters specified can be a subset of those registered if the subscriber wants to retain subscriptions for other filters.

### **RegOpt (MQPSC\_REGISTRATION\_OPTION)**

The registration options property can take the following values:

#### **DeregAll**

(MQPSC\_DEREGISTER\_ALL)

All matching subscriptions registered for this subscriber are to be deregistered.

If you specify `DeregAll`:

- `<Topic>`, `<SubPoint>`, and `<Filter>` can be omitted.
- `<Topic>` and `<Filter>` can be repeated, if required.
- `<SubPoint>` must not be repeated.

If you do **not** specify `DeregAll`:

- `<Topic>` must be specified, and can be repeated if required.
- `<SubPoint>` and `<Filter>` can be omitted.
- `<SubPoint>` must not be repeated.
- `<Filter>` can be repeated, if required.

If topics and filters are both repeated, then all subscriptions matching all combinations of the two are removed. For example, a **Deregister Subscriber** command that specifies three topics and three filters will attempt to remove nine subscriptions.

### **CorrelAsId**

(*MQPSC\_CORREL\_ID\_AS\_IDENTITY*)

The `CorrelId` in the message descriptor (MQMD), which must not be zero, is used to identify the subscriber. It must match the `CorrelId` used in the original subscription.

### **FullResp**

(*MQPSC\_FULL\_RESPONSE*)

When `FullResp` is specified all attributes of the subscription are returned in the response message, if the command does not fail.

When `FullResp` is specified `DeregAll` is not permitted in the **Deregister Subscriber** command. It is also not possible to specify multiple topics. The command fails with return code *MQRCCF\_REG\_OPTIONS\_ERROR*, in both cases.

### **LeaveOnly**

(*MQPSC\_LEAVE\_ONLY*)

When you specify this with a `SubIdentity` which is in the identity set for the subscription the `SubIdentity` is removed from the identity set for the subscription. The subscription is not removed from the queue manager, even if the resulting identity set is empty. If the `SubIdentity` value is not in the identity set the command fails with return code *MQRCCF\_SUB\_IDENTITY\_ERROR*.

If `LeaveOnly` is specified with no `SubIdentity`, the command fails with return code *MQRCCF\_REG\_OPTIONS\_ERROR*.

If neither `LeaveOnly` nor a `SubIdentity` are specified, then the subscription is removed regardless of the contents of the identity set for the subscription.

### **None**

(*MQPSC\_NONE*)

All options take their default values. This has the same effect as omitting the registration options property. If other options are specified at the same time, `None` is ignored.

### **VariableUserId**

(*MQPSC\_VARIABLE\_USER\_ID*)

When specified the identity of the subscriber (queue, queue manager and correlid) is not restricted to a single userid. This differs from the existing behavior of the queue manager that associates the userid of the original registration message with the subscriber's identity and from then on prevents any other user using that identity. If a new subscriber tries to use the same identity, the return code *MQRCCF\_DUPLICATE\_SUBSCRIPTION* is returned.

Any user can modify or deregister the subscription when they have suitable authority, avoiding the existing check that the userid must match that of the original subscriber.

To add this option to an existing subscription the command must come from the same userid as the original subscription itself.

If the subscription to be deregistered has `VariableUserId` set this must be set at deregister time to indicate which subscription is being deregistered. Otherwise, the userid of the **Deregister Subscriber** command is used to identify the subscription. This is overridden, along with the other subscriber identifiers, if a subscription name is supplied.

The default, if this property is omitted, is that no registration options are set.

#### **QMgrName (MQPSC\_Q\_MGR\_NAME)**

The value is the queue manager name for the subscriber queue. It must match the `QMgrName` used in the original subscription.

If this property is omitted, the default is the `ReplyToQMgr` name in the message descriptor (MQMD). If the resulting name is blank, it defaults to the name of the queue manager.

#### **QName (MQPSC\_Q\_NAME)**

The value is the name of the subscriber queue. It must match the `QName` used in the original subscription.

If this property is omitted, the default is the `ReplyToQ` name in the message descriptor (MQMD), which must not be blank.

#### **SubName (MQPSC\_SUBSCRIPTION\_NAME)**

If you specify `SubName` on a **Deregister Subscriber** command the `SubName` value takes precedence over all other identifier fields except the `userid`, unless `VariableUserId` is set on the subscription itself. If `VariableUserId` is not set, the **Deregister Subscriber** command succeeds only if the `userid` of the command message matches that of the subscription, if not the command fails with return code `MQRCCF_DUPLICATE_IDENTITY`.

If a subscription exists that matches the traditional identity of this command but has no `SubName` the **Deregister Subscriber** command fails with return code `MQRCCF_SUB_NAME_ERROR`. If an attempt is made to deregister a subscription that has a `SubName` using a command message that matches the traditional identity but with no `SubName` specified the command succeeds.

#### **SubUserData (MQPSC\_SUBSCRIPTION\_USER\_DATA)**

This is a variable-length text string. The value is stored by the queue manager with the subscription but has no influence on the delivery of the publication to the subscriber. The value can be altered by re-registering to the same subscription with a new value. This attribute is for the use of the application.

`SubUserData` is returned in the Metatopic information (`MQCACF_REG_SUB_USER_DATA`) for a subscription, if `SubUserData` is present.

### **Example**

Here is an example of `NameValueData` for a **Deregister Subscriber** command message. In this example, the sample application is deregistering its subscription to the topics which contain the latest score for all matches. The subscriber's identity, including the `CorrelId`, is taken from the defaults in the MQMD.

```
<psc>
  <Command>DeregSub</Command>
  <RegOpt>CorrelAsId</RegOpt>
  <Topic>Sport/Soccer/State/LatestScore/#</Topic>
</psc>
```

## Publish message

The **Publish** command message is put to a queue, or from a queue manager to a subscriber, to publish information on a specified topic or topics.

Authority to put a message onto a queue and authority to publish information on a specified topic or topics is necessary.

If the user has authority to publish information on some, but not all, topics, only those topics are used to publish; a warning response indicates which topics are not used to publish.

If a subscriber has any matching subscriptions, the queue manager forwards the **Publish** message to the subscriber queues defined in the corresponding **Register Subscriber** command messages.

See [Queue Manager Response message](#) for details of the message descriptor (MQMD) parameters needed when sending a command message to the queue manager, and used when a queue manager forwards a publication to a subscriber.

The queue manager forwards the **Publish** message to other queue managers in the network that have matching subscriptions, unless it is a local publication.

Publication data, if any, is included in the body of the message. The data can be described in an <mcd> folder in the NameValueData field of the MQRFH2 header.

## Properties

### Command (*MQPSC\_COMMAND*)

The value is Publish (*MQPSC\_PUBLISH*).

This property must be specified.

### Topic (*MQPSC\_TOPIC*)

The value is a string that contains a topic that categorizes this publication. No wildcard characters are allowed.

You must add the topic to the namelist SYSTEM.QPUBSUB.QUEUE.NAMELIST, see [Adding a stream](#) for instructions on how to complete this task.

This property must be specified, and can optionally be repeated for as many topics as needed.

### SubPoint (*MQPSC\_SUBSCRIPTION\_POINT*)

The subscription point on which the publication is published.

In WebSphere Event Broker 6.0, the value of the <SubPoint> property is the value of the Subscription Point attribute of the Publication node that is handling the publishing.

In IBM WebSphere MQ 7.0.1, the value of the <SubPoint> property must match the name of a subscription point. See [Adding a subscription point](#).

### PubOpt (*MQPSC\_PUBLICATION\_OPTION*)

The publication options property can take the following values:

#### RetainPub

(*MQPSC\_RETAIN\_PUB*)

The queue manager is to retain a copy of the publication. If this option is not set, the publication is deleted as soon as the queue manager has sent the publication to all its current subscribers.

#### IsRetainedPub

(*MQPSC\_IS\_RETAINED\_PUB*)

(Can only be set by a queue manager.) This publication has been retained by the queue manager. The queue manager sets this option to notify a subscriber that this publication was published earlier and has been retained, provided that the subscription has been registered with the InformIfRetained option. It is set only in response to a Register Subscriber or Request Update command message. Retained publications that are sent directly to subscribers do not have this option set.

**Local***(MQPSC\_LOCAL)*

This option tells the queue manager that this publication must not be sent to other queue managers. All subscribers that registered at this queue manager receive this publication if they have matching subscriptions.

**OtherSubsOnly***(MQPSC\_OTHER\_SUBS\_ONLY)*

This option allows simpler processing of conference-type applications, where a publisher is also a subscriber to the same topic. It tells the queue manager not to send the publication to the publisher's subscriber queue even if it has a matching subscription. The publisher's subscriber queue consists of its QMgrName, QName, and optional CorrelId, as described in the following list.

**CorrelAsId***(MQPSC\_CORREL\_ID\_AS\_IDENTITY)*

The CorrelId in the MQMD (which must not be zero) is part of the publisher's subscriber queue, in applications where the publisher is also a subscriber.

**None***(MQPSC\_NONE)*

All options take their default values. This has the same effect as omitting the publication options property. If other options are specified at the same time, None is ignored.

You can have more than one publication option by introducing additional <PubOpt> elements.

The default, if this property is omitted, is that no publication options are set.

**PubTime (MQPSC\_PUBLISH\_TIMESTAMP)**

The value is an optional publication timestamp set by the publisher. It is 16 characters long with format:

```
YYYYMMDDHHMSSSTH
```

using Universal Time. This information is not checked by the queue manager before being sent to the subscribers.

**SeqNum (MQPSC\_SEQUENCE\_NUMBER)**

The value is an optional sequence number set by the publisher.

It must be incremented by 1 with each publication. However, this is not checked by the queue manager, which merely transmits this information to subscribers.

If publications on the same topic are published to different interconnected queue managers, it is the responsibility of the publishers to ensure that sequence numbers, if used, are meaningful.

**QMgrName (MQPSC\_Q\_MGR\_NAME)**

The value is a string containing the name of the queue manager for the publisher's subscriber queue, in applications where the publisher is also a subscriber (see OtherSubsOnly).

If this property is omitted, the default is the ReplyToQMgr name in the message descriptor (MQMD). If the resulting name is blank, it defaults to the name of the queue manager.

**QName (MQPSC\_Q\_NAME)**

The value is a string containing the name of the publisher's subscriber queue, in applications where the publisher is also a subscriber (see OtherSubsOnly).

If this property is omitted, the default is the ReplyToQ name in the message descriptor (MQMD), which must not be blank if OtherSubsOnly is set.

**Example**

Here are some examples of *NameValueData* for a **Publish** command message.

The first example is for a publication sent by the match simulator in the sample application to indicate that a match has started.

```
<psc>
  <Command>Publish</Command>
  <Topic>Sport/Soccer/Event/MatchStarted</Topic>
</psc>
```

The second example is for a retained publication. The latest score in the match between Team1 and Team2 is published.

```
<psc>
  <Command>Publish</Command>
  <PubOpt>RetainPub</PubOpt>
  <Topic>Sport/Soccer/State/LatestScore/Team1 Team2</Topic>
</psc>
```

## Register Subscriber message

The **Register Subscriber** command message is sent to a queue manager by a subscriber, or by another application on behalf of a subscriber, to indicate that it wants to subscribe to one or more topics at a subscription point. A message content filter can also be specified.

In publish/subscribe filter expressions, nesting parentheses causes performance to decrease exponentially. Avoid nesting parentheses to a depth greater than about 6.

The message is sent to SYSTEM.BROKER.CONTROL.QUEUE, which is the queue manager's control queue. Authority to put a message to this queue is required, in addition to access authority (set by the queue manager's system administrator) for the topic, or topics, in the subscription.

If the user has authority on some, but not all, topics, only those with authority are registered; a warning response indicates those that are not registered.

See [“MQMD settings in command messages to the queue manager” on page 898](#) for details of the message descriptor (MQMD) parameters that are needed when sending a command message to the queue manager.

If the reply to queue is a temporary dynamic queue, the subscription is deregistered automatically by the queue manager when the queue is closed.

## Properties

### Command (*MQPSC\_COMMAND*)

The value is RegSub (*MQPSC\_REGISTER\_SUBSCRIBER*). This property must be specified.

### Topic (*MQPSC\_TOPIC*)

The topic for which the subscriber wants to receive publications. Wildcard characters can be specified as part of the topic.

If you use the MQSC command **display sub** to examine the subscription created in this way, the value of the <Topic> tag is shown as the TOPICSTR property of the subscription.

This property is required, and can optionally be repeated for as many topics as needed.

### SubPoint (*MQPSC\_SUBSCRIPTION\_POINT*)

The value is the subscription point to which the subscription is attached.

If this property is omitted, the default subscription point is used.

In WebSphere Event Broker 6.0, the value of the <SubPoint> property must match the value of the Subscription Point attribute of the Publication nodes that are subscribed to.

In IBM WebSphere MQ 7.0.1, the value of the <SubPoint> property must match the name of a subscription point. See [Adding a subscription point](#).

**Filter (MQPSC\_FILTER)**

The value is an SQL expression that is used as a filter on the contents of publication messages.

If a publication on the specified topic matches the filter, it is sent to the subscriber. This property corresponds to the Selection String that is used in MQSUB and MQOPEN calls. For more information, see [Selecting on the content of a message](#)

If this property is omitted, no content filtering takes place.

**RegOpt (MQPSC\_REGISTRATION\_OPTION)**

This Registration Options property can take the following values:

**AddName**

(MQPSC\_ADD\_NAME)

When specified for an existing subscription that matches the traditional identity of this Register Subscription command, but with no current SubName value, the SubName specified in this command is added to the subscription.

If AddName is specified the SubName field is mandatory, otherwise MQRCCF\_REG\_OPTIONS\_ERROR is returned.

**CorrelAsId**

(MQPSC\_CORREL\_ID\_AS\_IDENTITY)

The CorrelId in the message descriptor (MQMD) is used when sending matching publications to the subscriber queue. The CorrelId must not be zero,

**FullResp**

(MQPSC\_FULL\_RESPONSE)

When specified all attributes of the subscription are returned in the response message, if the command does not fail.

FullResp is valid only when the command message refers to a single subscription. Therefore, only one topic is permitted in the command; otherwise the command fails with return code MQRCCF\_REG\_OPTIONS\_ERROR.

**InformIfRet**

(MQPSC\_INFORM\_IF\_RETAINED)

The queue manager informs the subscriber if a publication is retained when it sends a Publish message in response to a **Register Subscriber** or **Request Update** command message. The queue manager does this by including the IsRetainedPub publication option in the message.

**JoinExcl**

(MQPSC\_JOIN\_EXCLUSIVE)

This option indicates that the specified SubIdentity should be added as the exclusive member of the identity set for the subscription, and that no other identities can be added to the set.

If the identity has already joined 'shared' and is the sole entry in the set, the set is changed to an exclusive lock held by this identity. Otherwise, if the subscription currently has other identities in the identity set (with shared access) the command fails with return code MQRCCF\_SUBSCRIPTION\_IN\_USE.

**JoinShared**

(MQPSC\_JOIN\_SHARED)

This option indicates that the specified SubIdentity should be added to the identity set for the subscription.

If the subscription is currently locked exclusively (using the JoinExcl option), the command fails with return code MQRCCF\_SUBSCRIPTION\_LOCKED, unless the identity that has the subscription locked is the same identity as that in this command message. In this case the lock is automatically modified to a shared lock.

**Local**

*(MQPSC\_LOCAL)*

The subscription is local and is not distributed to other queue managers in the network. Publications made at other queue managers are not delivered to this subscriber, unless it also has a corresponding global subscription.

**NewPubsOnly**

*(MQPSC\_NEW\_PUBS\_ONLY)*

Retained publications that exist at the time the subscription is registered are not sent to the subscriber; only new publications are sent.

If a subscriber re-registers and changes this option so that it is no longer set, a publication that has already been sent to it might be sent again.

**NoAlter**

*(MQPSC\_NO\_ALTER)*

The attributes of an existing matching subscription is not changed.

When a subscription is being created, this option is ignored. All other options specified apply to the new subscription.

If a `SubIdentity` also has one of the join options (`JoinExcl` or `JoinShared`) specified, the identity is added to the identity set regardless of whether `NoAlter` is specified.

**None**

*(MQPSC\_NONE)*

All registration options take their default values.

If the subscriber is already registered, its options are reset to their default values (note that this does not have the same affect as omitting the registration options property), and the subscription expiry is updated from the MQMD of the **Register Subscriber** message.

If other registration options are specified at the same time, `None` is ignored.

**NonPers**

*(MQPSC\_NON\_PERSISTENT)*

Publications matching this subscription are delivered to the subscriber as non-persistent messages.

**Pers**

*(MQPSC\_PERSISTENT)*

Publications matching this subscription are delivered to the subscriber as persistent messages.

**PersAsPub**

*(MQPSC\_PERSISTENT\_AS\_PUBLISH)*

Publications matching this subscription are delivered to the subscriber with the persistence specified by the publisher. This is the default behavior.

**PersAsQueue**

*(MQPSC\_PERSISTENT\_AS\_Q)*

Publications matching this subscription are delivered to the subscriber with the persistence specified on the subscriber queue.

**PubOnReqOnly**

*(MQPSC\_PUB\_ON\_REQUEST\_ONLY)*

The queue manager does not send publications to the subscriber, except in response to a **Request Update** command message.

**VariableUserId**

*(MQPSC\_VARIABLE\_USER\_ID)*

When specified the identity of the subscriber (queue, queue manager and correlid) is not restricted to a single userid. This differs from the existing behavior of the queue manager that associates the userid of the original registration message with the subscriber's identity and from then on prevents any other user using that identity. If a new subscriber tries to use the same identity *MQRCCF\_DUPLICATE\_SUBSCRIPTION* is returned.

This allows any user to modify or deregister the subscription if the user has suitable authority. There is therefore no need to check that the userid matches that of the original subscriber.

To add this option to an existing subscription the command must come from the same userid as the original subscription itself.

If the subscription of the **Request Update** command has `VariableUserId` set, this must be set at request update time to indicate which subscription is referred to. Otherwise, the userid of the **Request Update** command is used to identify the subscription. This is overridden, along with the other subscriber identifiers, if a subscription name is supplied.

If a **Register Subscriber** command message without this option set refers to an existing subscription which has this option set, the option is removed from this subscription and the userid of the subscription is now fixed. If there already exists a subscriber which has the same identity (queue, queue manager and correlation identifier) but with a different user ID associated to it, the command fails with return code *MQRCCF\_DUPLICATE\_IDENTITY* because there can only be one userid associated with a subscriber identity.

If the registration options property is omitted and the subscriber is already registered, its registration options are not changed and the subscription expiry is updated from the MQMD of the **Register Subscriber** message.

If the subscriber is not already registered, a new subscription is created with all registration options taking their default values.

The default values are `PersAsPub` and no other options set.

#### **QMgrName (MQPSC\_Q\_MGR\_NAME)**

The value is the name of the queue manager for the subscriber queue, to which matching publications are sent by the queue manager.

If this property is omitted, the default is the `ReplyToQMgr` name in the message descriptor (MQMD). If the resulting name is blank, it defaults to the queue manager's `QMgrName`.

#### **QName (MQPSC\_Q\_NAME)**

The value is the name of the subscriber queue, to which matching publications are sent by the queue manager.

If this property is omitted, the default is the `ReplyToQ` name in the message descriptor (MQMD), which must not be blank in this case.

If the queue is a temporary dynamic queue, nonpersistent delivery of publications (`NonPers`) must be specified in the `<RegOpt>` property.

If the queue is a temporary dynamic queue, the subscription is deregistered automatically by the queue manager when the queue is closed.

#### **SubName (MQPSC\_SUBSCRIPTION\_NAME)**

This is a name given to a particular subscription. You can use it instead of the queue manager, queue and optional `correlId` to refer to a subscription.

If a subscription already exists with this **SubName**, any other attributes of the subscription (`Topic`, `QMgrName`, `QName`, `CorrelId`, `UserId`, `RegOpts`, `UserSubData`, and `Expiry`) are overridden with the attributes, if specified, that are passed in the new **Register Subscriber** command message. However, if **SubName** is used with no `QName` field specified, and a `ReplyToQ` is specified in the MQMD header, the subscriber queue is changed to be the `ReplyToQ`.

If a subscription that matches the traditional identity of this command already exists, but has no **SubName**, the Registration command fails with return code *MQRCCF\_DUPLICATE\_SUBSCRIPTION*, unless the **AddName** option is specified.

If you try to alter an existing named subscription by using another `Register Subscriber` command that specifies the same **SubName**, and the values of `Topic`, `QMgrName`, `QName`, and `CorrelId` in the new command match a different existing subscription, with or without a `SubName` defined, the command fails with return code `MQRCCF_DUPLICATE_SUBSCRIPTION`. This prevents two subscription names referring to the same subscription.

### **SubIdentity (MQPSC\_SUBSCRIPTION\_IDENTITY)**

This string is used to represent an application with an interest in a subscription. It is a variable-length character string with a maximum length of 64 characters, and is optional. The queue manager maintains a set of subscriber identities for each subscription. Each subscription can allow its identity set to contain only one identity, or an unlimited number of identities (see the **JoinShared** and **JoinExcl** options).

A subscribe command that specifies the **JoinShared** or **JoinExcl** option adds the **SubIdentity** to the subscription's identity set, if it is not already there and if the existing set of identities allows such an action; that is, no other subscriber has joined exclusively or the identity set is empty.

Any alteration of the subscription's attributes as the result of a `Register Subscriber` command in which a **SubIdentity** is specified, only succeeds if it would be the only member of the set of identities for this subscription. Otherwise the command fails with return code `MQRCCF_SUBSCRIPTION_IN_USE`. This prevents a subscription's attributes from changing without other interested subscribers being aware.

If you specify a character string that is longer than 64 characters, the command fails with return code `MQRCCF_SUB_IDENTITY_ERROR`.

### **SubUserData (MQPSC\_SUBSCRIPTION\_USER\_DATA)**

This is a variable-length text string. The value is stored by the queue manager with the subscription, but has no influence on publication delivery to the subscriber. The value can be altered by re-registering to the same subscription with a new value. This attribute is there for the use of the application.

The **SubUserData** is returned in the Metatopic information (`MQCACF_REG_SUB_USER_DATA`) for a subscription if present.

If you specify more than one of the registration option values `NonPers`, `PersAsPub`, `PersAsQueue`, and `Pers`, then only the last one is used. You cannot combine these options in an individual subscription.

## **Example**

Here is an example of `NameValueData` for a **Register Subscriber** command message. In the sample application, the results service uses this message to register a subscription to the topics containing the latest scores in all matches, with the 'Persistent as publish' option set. The subscriber's identity, including the `CorrelId`, is taken from the defaults in the MQMD.

```
<psc>
  <Command>RegSub</Command>
  <RegOpt>PersAsPub</RegOpt>
  <RegOpt>CorrelAsId</RegOpt>
  <Topic>Sport/Soccer/State/LatestScore/#</Topic>
</psc>
```

## **Request Update message**

The **Request Update** command message is sent from a subscriber to a queue manager, to request the current retained publications for the specified topic and subscription point that match the given (optional) filter.

This message is sent to `SYSTEM.BROKER.CONTROL.QUEUE`, the queue manager's control queue. Authority to put a message to this queue is required, in addition to access authority for the topic in the request update; this is set by the queue manager's system administrator.

This command is normally used if the subscriber specified the option `PubOnReqOnly` when it registered. If the queue manager has any matching retained publications, they are sent to the subscriber. If the queue manager has no matching retained publications, the request fails with return code `MQRCCF_NO_RETAINED_MSG`. The requester must have previously registered a subscription with the same Topic, SubPoint, and Filter values.

## Properties

### Command (`MQPSC_COMMAND`)

The value is `ReqUpdate` (`MQPSC_REQUEST_UPDATE`). This property must be specified.

### Topic (`MQPSC_TOPIC`)

The value is the topic that the subscriber is requesting; wildcard characters are allowed.

This property must be specified, but only one occurrence is allowed in this message.

### SubPoint (`MQPSC_SUBSCRIPTION_POINT`)

The value is the subscription point to which the subscription is attached.

If this property is omitted, the default subscription point is used.

### Filter (`MQPSC_FILTER`)

The value is an ESQL expression that is used as a filter on the contents of publication messages. If a publication on the specified topic matches the filter, it is sent to the subscriber.

The `<Filter>` property should have the same value as that specified on the original subscription for which you are now requesting an update.

If this property is omitted, no content filtering takes place.

### RegOpt (`MQPSC_REGISTRATION_OPTION`)

The registration options property can take the following value:

#### CorrelAsId

(`MQPSC_CORREL_ID_AS_IDENTITY`)

The `CorrelId` in the message descriptor (MQMD), which must not be zero, is used when sending matching publications to the subscriber queue.

#### None

(`MQPSC_NONE`)

All options take their default values. This has the same effect as omitting the `<RegOpt>` property. If other options are specified at the same time, `None` is ignored.

#### VariableUserId

(`MQPSC_VARIABLE_USER_ID`)

When specified the identity of the subscriber (queue, queue manager, and correlid) is not restricted to a single userid. This differs from the existing behavior of the queue manager that associates the userid of the original registration message with the subscriber's identity and from then on prevents any other user using that identity. If a new subscriber tries to use the same identity, the command fails with return code `MQRCCF_DUPLICATE_SUBSCRIPTION`.

This allows any user to modify or deregister the subscription when they have suitable authority. Therefore, there is no need to check that the userid matches that of the original subscriber.

To add this option to an existing subscription, the command must come from the same userid as the original subscription.

If the subscription of the **Request Update** command has `VariableUserId` set, this must be set at request update time to indicate which subscription is referred to. Otherwise, the userid of the **Request Update** command is used to identify the subscription. This is overridden, along with the other subscriber identifiers, if a subscription name is supplied.

The default, if this property is omitted, is that no registration options are set.

### **QMgrName (MQPSC\_Q\_MGR\_NAME)**

The value is the name of the queue manager for the subscriber queue, to which the matching retained publication is sent by the queue manager.

If this property is omitted, the default is the ReplyToQMgr name in the message descriptor (MQMD). If the resulting name is blank, it defaults to the queue manager's QMgrName.

### **QName (MQPSC\_Q\_NAME)**

The value is the name of the subscriber queue, to which the matching retained publication is sent by the queue manager.

If this property is omitted, the default is the ReplyToQ name in the message descriptor (MQMD), which must not be blank in this case.

### **SubName (MQPSC\_SUBSCRIPTION\_NAME)**

This is a name given to a particular subscription. If specified on a **Request Update** command the SubName value takes precedence over all other identifier fields except the userid, unless VariableUserId is set on the subscription itself. If VariableUserId is not set, the *Request Update* command succeeds only if the userid of the command message matches that of the subscription. If the userid of the command message does not match that of the subscription, the command fails with return code *MQRCCF\_DUPLICATE\_IDENTITY*.

If VariableUserId is set, and the userid differs from that of the subscription, the command succeeds if the userid of the new command message has authority to browse the stream queue and put to the subscriber queue of the subscription. Otherwise, the command fails with return code *MQRCCF\_NOT\_AUTHORIZED*.

If a subscription exists that matches the traditional identity of this command, but has no SubName, the **Request Update** command fails with return code *MQRCCF\_SUB\_NAME\_ERROR*.

If an attempt is made to request an update for a subscription that has a SubName using a command message that matches the traditional identity, but with no SubName specified, the command succeeds.

### **Example**

Here is an example of NameValueData for a **Request Update** command message. In the sample application, the results service uses this message to request retained publications containing the latest scores for all teams. The subscriber's identity, including the CorrelId, is taken from the defaults in the MQMD.

```
<psc>
  <Command>ReqUpdate</Command>
  <RegOpt>CorrelAsId</RegOpt>
  <Topic>Sport/Soccer/State/LatestScore/#</Topic>
</psc>
```

## **Queue Manager Response message**

A **Queue Manager Response** message is sent from a queue manager to the ReplyToQ of a publisher or a subscriber, to indicate the success or failure of a command message received by the queue manager if the command message descriptor specified that a response is required.

The response message is contained within the NameValueData field of the MQRFH2 header, in a <psc> folder.

In the case of a warning or error, the response message contains the <psc> folder from the command message as well as the <psc> folder. The message data, if any, is not contained in the queue manager response message. In the case of an error, none of the message that caused an error has been processed; in the case of a warning, some of the message might have been processed successfully.

If there is a failure sending a response:

- For publication messages, the queue manager tries to send the response to the IBM MQ dead-letter queue if the MQPUT fails. This allows the publication to be sent to subscribers even if the response cannot be sent back to the publisher.
- For other messages, or if the publication response cannot be sent to the dead-letter queue, an error is logged and the command message is normally rolled back. Whether this happens depends on how the MQInput node has been configured.

## Properties

### Completion (MQPSCR\_COMPLETION)

The completion code, which can take one of three values:

**ok**

Command completed successfully

**warning**

Command completed but with warning

**error**

Command failed

### Response (MQPSCR\_RESPONSE)

The response to a command message, if that command produced a completion code of warning or error. It contains a <Reason> property, and might contain other properties that indicate the cause of the warning or error.

In the case of one or more errors, there is only one response folder, indicating the cause of the first error only. In the case of one or more warnings, there is a response folder for each warning.

### Reason (MQPSCR\_REASON)

The reason code qualifying the completion code, if the completion code is a warning or error. It is set to one of the error codes listed in the following example. The <Reason> property is contained within a <Response> folder. The reason code can be followed by any valid property from the <psc> folder (for example, a topic name), indicating the cause of the error or warning. If you get a reason code of ????, check the data for correctness, for example, matching angled brackets (< >).

## Examples

Here are some examples of NameValueData in a **Queue Manager Response** message. A successful response might be the following:

```
<pscr>
  <Completion>ok</Completion>
</pscr>
```

Here is an example of a failure response; the failure is a filter error. The first NameValueData string contains the response; the second contains the original command.

```
<pscr>
  <Completion>error</Completion>
  <Response>
    <Reason>3150</Reason>
  </Reponse>
</pscr>

<psc>
  ...
  command message (to which
  the queue manager is responding)
  ...
</psc>
```

Here is an example of a warning response (due to unauthorized topics). The first NameValueData string contains the response; the second NameValueData string contains the original command.

```
<pscr>
  <Completion>warning</Completion>
  <Response>
    <Reason>3081</Reason>
    <Topic>topic1</Topic>
  </Reponse>
  <Response>
    <Reason>3081</Reason>
    <Topic>topic2</Topic>
  </Reponse>
</pscr>

<psc>
  ...
  command message (to which
  the queue manager is responding)
  ...
</psc>
```

## Publish/subscribe reason codes

These reason codes might be returned in the Reason field of a publish/subscribe response <pscr> folder. Constants that can be used to represent these codes in the C or C++ programming languages are also listed.

The MQRC\_ constants require the IBM MQ cmqc . h header file. The MQRCCF\_ constants require the IBM MQ cmqcf . h header file (apart from MQRCCF\_FILTER\_ERROR and MQRCCF\_WRONG\_USER, which require the cmqpsc . h header file).

Reason code and text	Explanation	Issued by
2336 MQRC_RFH_COMMAND_ERROR	Valid values for the <Command> field of a <psc> folder are: RegSub, DeregSub, Publish, DeletePub, and ReqUpdate. Any other values result in this error code being issued.	Any command
2337 MQRC_RFH_PARM_ERROR	The <psc> and <mcd> folders both have a set of valid parameters that can be specified within them. Check the descriptions of these folders and ensure that you have not specified incorrect parameters.	Any command
2338 MQRC_RFH_DUPLICATE_PARM	Some parameters (for example, Topic) within a <psc> folder can be repeated, but others (for example, Command) cannot be repeated. Check that you have not duplicated a non-repeatable parameter.	Any command
2339 MQRC_RFH_PARM_MISSING	Some parameters within <psc> or <mcd> folders are optional and can be omitted; some are mandatory and must not be omitted. Check that you have included all mandatory parameters within your <psc> and <mcd> folders.	Any command

<b>Reason code and text</b>	<b>Explanation</b>	<b>Issued by</b>
2551 MQRC_SELECTION_NOT_AVAILABLE	No extended message selection provider was available to determine which subscribers with a filter specified should receive the publication.	Publish, Register Subscriber, and Request Update
	No extended message selection provider was available to handle the filter of the specified subscriber.	Register Subscriber and Request Update
2554 MQRC_CONTENT_ERROR	An extended message selection provider found an error in the current or retained publication.	Publish and Request Update
3008 MQRCCF_COMMAND_FAILED	An internal error occurred which prevented the command from executing correctly. The error might occur if the command is reissued. The system event log for the queue manager contains information which should be used when reporting the problem to IBM.	Any command
3072 MQRCCF_TOPIC_ERROR	One or more of the values you supplied for the Topic parameter are incorrect. Check that your values for Topic conform to the specified restrictions.	Any command
3073 MQRCCF_NOT_REGISTERED	The combination of SubPoint, Topic, and Filter that you specified on your DeregSub or ReqUpdate command was either not a combination with which you had previously registered or, for the DeregSub command if the DeregAll option was specified, one of the SubPoint, Topic, or Filter properties was not used to deregister any subscription.	Deregister Subscriber and Request Update commands
3074 MQRCCF_Q_MGR_NAME_ERROR	The specified queue manager was not valid, or the queue manager was not available or did not exist.	Deregister Subscriber, Publish, Register Subscriber, and Request Update commands
3076 MQRCCF_Q_NAME_ERROR	The specified queue name was not valid, or the queue did not exist on the specified queue manager.	Deregister Subscriber, Publish, Register Subscriber, and Request Update commands
3077 MQRCCF_NO_RETAINED_MSG	There were no retained messages for the topic you specified. This might or might not be an error, depending on the design of your application program.	Request Update command

Reason code and text	Explanation	Issued by
3079 MQRCCF_INCORRECT_Q	RegSub, DeregSub, and ReqUpdate commands are always sent to the SYSTEM.BROKER.CONTROL.QUEUE queue of the queue manager for which they are intended. Publish and Delete Publication commands are sent to the input queue for the particular publish/subscribe message flow for which they are intended; this is determined when the message flow is designed. This error code is returned if a command is sent to the wrong queue.	Any command
3080 MQRCCF_CORREL_ID_ERROR	You have specified CorrelAsId as one of your RegOpt parameters. However, the CorrelId field of the MQMD does not contain a valid correlation identifier (that is, it is set to MQCI_NONE).	Deregister Subscriber and Register Subscriber commands
3081 MQRCCF_NOT_AUTHORIZED	You are not authorized to perform the requested action. Authorization settings for the queue manager are handled by the system administrator using the Topics Hierarchy editor.	Publish and Register Subscriber commands
3083 MQRCCF_REG_OPTIONS_ERROR	You have specified an unrecognized RegOpt parameter in the <psc> folder that contains your RegSub or DeregSub command.	Deregister Subscriber and Register Subscriber commands
3084 MQRCCF_PUB_OPTIONS_ERROR	You have specified an unrecognized PubOpt parameter in the <psc> folder that contains your Publish command.	Publish command
3087 MQRCCF_DEL_OPTIONS_ERROR	You have specified an unrecognized DelOpt parameter in the <psc> folder that contains your DeletePub command.	Delete Publication command
3150 MQRCCF_FILTER_ERROR	The value specified for the Filter parameter is not valid. Check the section that describes the valid syntax for filter expressions and ensure that your expression conforms.	Deregister Subscriber, Register Subscriber, and Request Update commands
3151 MQRCCF_WRONG_USER	A subscription that matches the one specified already exists; however, it was registered by a different user. A subscription can only be changed or deregistered by the user who originally registered it.	Deregister Subscriber, Register Subscriber, and Request Update commands
3152 MQRCCF_DUPLICATE_SUBSCRIPTION	A matching subscription already exists with a different subscription name.	

Reason code and text	Explanation	Issued by
3153 MQRCCF_SUB_NAME_ERROR	Either the format of the subscription name is not valid, or a matching subscription already exists with no subscription name.	
3154 MQRCCF_SUB_IDENTITY_ERROR	The subscription identity parameter is in error. Either the supplied value exceeds the maximum length allowed, or the subscription identity is not currently a member of the subscription's identity set and a Join registration option was not specified.	
3155 MQRCCF_SUBSCRIPTION_IN_USE	An attempt to modify or deregister a subscription was attempted by a member of the identity set when it was not the only member of this set.	
3156 MQRCCF_SUBSCRIPTION_LOCKED	The subscription is currently exclusively locked by another identity.	
3157 MQRCCF_ALREADY_JOINED	A Join registration option was specified but the subscriber identity was already a member of the subscription's identity set.	

## MQMD settings in command messages to the queue manager

Applications that send command messages to the queue manager use the following settings of fields in the message descriptor (MQMD). Fields that are left as the default value, or can be set to any valid value in the usual way, are not listed here.

### Report

See `MsgType` and `CorrelId`.

### MsgType

`MsgType` should be set to either `MQMT_REQUEST` or `MQMT_DATAGRAM`. `MQRC_MSG_TYPE_ERROR` will be returned if `MsgType` is not set to one of these values.

`MsgType` should be set to `MQMT_REQUEST` for a command message if a response is always required. The `MQRO_PAN` and `MQRO_NAN` flags in the `Report` field are not significant in this case.

If `MsgType` is set to `MQMT_DATAGRAM`, responses depend on the setting of the `MQRO_PAN` and `MQRO_NAN` flags in the `Report` field:

- `MQRO_PAN` alone means that the queue manager sends a response only if the command succeeds.
- `MQRO_NAN` alone means that the queue manager sends a response only if the command fails.
- If a command completes with a warning, a response is sent if either `MQRO_PAN` or `MQRO_NAN` is set.
- `MQRO_PAN` + `MQRO_NAN` means that the queue manager sends a response whether the command succeeds or fails. This has the same effect from the queue manager's perspective as setting `MsgType` to `MQMT_REQUEST`.
- If neither `MQRO_PAN` nor `MQRO_NAN` is set, no response is ever sent.

### Format

Set to `MQFMT_RF_HEADER_2`

### MsgId

This field is normally set to `MQMI_NONE`, so that the queue manager generates a unique value.

**CorrelId**

This field can be set to any value. If the sender's identity includes a `CorrelId`, specify this value, together with `MQRO_PASS_CORREL_ID` in the `Report` field, to ensure that it is set in all response messages sent by the queue manager to the sender.

**ReplyToQ**

This field defines the queue to which responses, if any, are to be sent. This might be the sender's queue; this has the advantage that the `QName` parameter can be omitted from the message. If, however, responses are to be sent to a different queue, the `QName` parameter is needed.

**ReplyToQMgr**

This field defines the queue manager for responses. If you leave this field blank (the default value), the local queue manager puts its own name in this field.

**MQMD settings for publications forwarded by a queue manager**

A queue manager uses these settings of fields in the message descriptor (MQMD) when it sends a publication to a subscriber. All other fields in the MQMD are set to their default values.

**Report**

`Report` is set to `MQRO_NONE`.

**MsgType**

`MsgType` is set to `MQMT_DATAGRAM`.

**Expiry**

`Expiry` is set to the value in the `Publish` message received from the publisher. In the case of a retained message, the time outstanding is reduced by the approximate time that the message has been at the queue manager.

**Format**

`Format` is set to `MQFMT_RF_HEADER_2`

**MsgId**

`MsgId` is set to a unique value.

**CorrelId**

If `CorrelId` is part of the subscriber's identity, this is the value specified by the subscriber when registering. Otherwise, it is a non-zero value chosen by the queue manager.

**Priority**

`Priority` takes the value set by the publisher, or as resolved if the publisher specified `MQPRI_PRIORITY_AS_Q_DEF`.

**Persistence**

`Persistence` takes the value set by the publisher, or as resolved if the publisher specified `MQPER_PERSISTENCE_AS_Q_DEF`, unless specified otherwise in the `Register Subscriber` message for the subscriber to which this publication is being sent.

**ReplyToQ**

`ReplyToQ` is set to blanks.

**ReplyToQMgr**

`ReplyToQMgr` is set to the name of the queue manager.

**UserIdentifier**

`UserIdentifier` is the subscriber's user identifier, as set when the subscriber registered.

**AccountingToken**

`AccountingToken` is the subscriber's accounting token, as set when the subscriber first registered.

**AppIdentityData**

`AppIdentityData` is the subscriber's application identity data, as set when the subscriber first registered.

**PutApplType**

`PutApplType` is set to `MQAT_BROKER`.

**PutApplName**

PutApplName is set to the first 28 characters of the name of the queue manager.

**PutDate**

PutDate is the date when the message was put.

**PutTime**

PutTime is the time when the message was put.

**ApplOriginData**

ApplOriginData is set to blanks.

**MQMD settings in queue manager response messages**

A queue manager uses these settings of fields in the message descriptor (MQMD) when sending a reply to a publication message. All other fields in the MQMD are set to their default values.

**Report**

Report is set to all zeros.

**MsgType**

MsgType is set to MQMT\_REPLY.

**Format**

Format is set to MQFMT\_RF\_HEADER\_2

**MsgId**

The setting of MsgId depends on the Report options in the original command message. By default, it is set to MQMI\_NONE, so that the queue manager generates a unique value.

**CorrelId**

The setting of CorrelId depends on the Report options in the original command message. By default, this means that the CorrelId is set to the same value as the MsgId of the command message. This can be used to correlate commands with their responses.

**Priority**

Priority is set to the same value as in the original command message.

**Persistence**

Persistence is set to the value set in the original command message.

**Expiry**

Expiry is set to the same value as in the original command message received by the queue manager.

**PutApplType**

PutApplType is set to MQAT\_BROKER.

**PutApplName**

PutApplName is set to the first 28 characters of name of the queue manager.

Other context fields are set as if generated with MQPMO\_PASS\_IDENTITY\_CONTEXT.

**Machine encodings**

This section describes the structure of the *Encoding* field in the message descriptor.

See [“MQMD - Message descriptor” on page 422](#) for a summary of the fields in the structure.

The *Encoding* field is a 32-bit integer that is divided into four separate subfields; these subfields identify:

- The encoding used for binary integers
- The encoding used for packed-decimal integers
- The encoding used for floating-point numbers
- Reserved bits

Each subfield is identified by a bit mask that has 1-bits in the positions corresponding to the subfield, and 0-bits elsewhere. The bits are numbered such that bit 0 is the most significant bit, and bit 31 the least significant bit. The following masks are defined:

**MQENC\_INTEGER\_MASK**

Mask for binary-integer encoding.

This subfield occupies bit positions 28 through 31 within the *Encoding* field.

**MQENC\_DECIMAL\_MASK**

Mask for packed-decimal-integer encoding.

This subfield occupies bit positions 24 through 27 within the *Encoding* field.

**MQENC\_FLOAT\_MASK**

Mask for floating-point encoding.

This subfield occupies bit positions 20 through 23 within the *Encoding* field.

**MQENC\_RESERVED\_MASK**

Mask for reserved bits.

This subfield occupies bit positions 0 through 19 within the *Encoding* field.

## Binary-integer encoding

The following values are valid for the binary-integer encoding:

**MQENC\_INTEGER\_UNDEFINED**

Binary integers are represented using an encoding that is undefined.

**MQENC\_INTEGER\_NORMAL**

Binary integers are represented in the conventional way:

- The least significant byte in the number has the highest address of any of the bytes in the number; the most significant byte has the lowest address
- The least significant bit in each byte is adjacent to the byte with the next higher address; the most significant bit in each byte is adjacent to the byte with the next lower address

**MQENC\_INTEGER\_REVERSED**

Binary integers are represented in the same way as MQENC\_INTEGER\_NORMAL, but with the bytes arranged in reverse order. The bits within each byte are arranged in the same way as MQENC\_INTEGER\_NORMAL.

## Packed-decimal-integer encoding

The following values are valid for the packed-decimal-integer encoding:

**MQENC\_DECIMAL\_UNDEFINED**

Packed-decimal integers are represented using an encoding that is undefined.

**MQENC\_DECIMAL\_NORMAL**

Packed-decimal integers are represented in the conventional way:

- Each decimal digit in the printable form of the number is represented in packed decimal by a single hexadecimal digit in the range X'0' through X'9'. Each hexadecimal digit occupies four bits, and so each byte in the packed decimal number represents two decimal digits in the printable form of the number.
- The least significant byte in the packed-decimal number is the byte that contains the least significant decimal digit. Within that byte, the most significant four bits contain the least significant decimal digit, and the least significant four bits contain the sign. The sign is either X'C' (positive), X'D' (negative), or X'F' (unsigned).
- The least significant byte in the number has the highest address of any of the bytes in the number; the most significant byte has the lowest address.
- The least significant bit in each byte is adjacent to the byte with the next higher address; the most significant bit in each byte is adjacent to the byte with the next lower address.

### **MQENC\_DECIMAL\_REVERSED**

Packed-decimal integers are represented in the same way as MQENC\_DECIMAL\_NORMAL, but with the bytes arranged in reverse order. The bits within each byte are arranged in the same way as MQENC\_DECIMAL\_NORMAL.

## **Floating-point encoding**

The following values are valid for the floating-point encoding:

### **MQENC\_FLOAT\_UNDEFINED**

Floating-point numbers are represented using an encoding that is undefined.

### **MQENC\_FLOAT\_IEEE\_NORMAL**

Floating-point numbers are represented using the standard IEEE<sup>4</sup> floating-point format, with the bytes arranged as follows:

- The least significant byte in the mantissa has the highest address of any of the bytes in the number; the byte containing the exponent has the lowest address
- The least significant bit in each byte is adjacent to the byte with the next higher address; the most significant bit in each byte is adjacent to the byte with the next lower address

Details of the IEEE float encoding can be found in IEEE Standard 754.

### **MQENC\_FLOAT\_IEEE\_REVERSED**

Floating-point numbers are represented in the same way as MQENC\_FLOAT\_IEEE\_NORMAL, but with the bytes arranged in reverse order. The bits within each byte are arranged in the same way as MQENC\_FLOAT\_IEEE\_NORMAL.

### **MQENC\_FLOAT\_S390**

Floating-point numbers are represented using the standard System/390 floating-point format; this is also used by System/370.

## **Constructing encodings**

To construct a value for the *Encoding* field in MQMD, the relevant constants that describe the required encodings can be added together (do not add the same constant more than once), or combined using the bitwise OR operation (if the programming language supports bit operations).

Whichever method is used, combine only one of the MQENC\_INTEGER\_\* encodings with one of the MQENC\_DECIMAL\_\* encodings and one of the MQENC\_FLOAT\_\* encodings.

## **Analyzing encodings**

The *Encoding* field contains subfields; because of this, applications that need to examine the integer, packed decimal, or float encoding must use one of the techniques described.

## **Using bit operations**

If the programming language supports bit operations, perform the following steps:

1. Select one of the following values, according to the type of encoding required:

- MQENC\_INTEGER\_MASK for the binary integer encoding
- MQENC\_DECIMAL\_MASK for the packed decimal integer encoding
- MQENC\_FLOAT\_MASK for the floating point encoding

Call the value A.

2. Combine the *Encoding* field with A using the bitwise AND operation; call the result B.

---

<sup>4</sup> The Institute of Electrical and Electronics Engineers

3. B is the encoding required, and can be tested for equality with each of the values that is valid for that type of encoding.

## Using arithmetic

If the programming language *does not* support bit operations, perform the following steps using integer arithmetic:

1. Select one of the following values, according to the type of encoding required:

- 1 for the binary integer encoding
- 16 for the packed decimal integer encoding
- 256 for the floating point encoding

Call the value A.

2. Divide the value of the *Encoding* field by A ; call the result B.

3. Divide B by 16; call the result C.

4. Multiply C by 16 and subtract from B ; call the result D.

5. Multiply D by A ; call the result E.

6. E is the encoding required, and can be tested for equality with each of the values that is valid for that type of encoding.

## Summary of machine architecture encodings

Encodings for machine architectures are shown in [Table 631 on page 903](#).

Machine architecture	Binary integer encoding	Packed decimal integer encoding	Floating point encoding
IBM i	normal	normal	IEEE normal
Intel x86	reversed	reversed	IEEE reversed
PowerPC®	normal	normal	IEEE normal
System/390	normal	normal	System/390

## Report options and message flags

This section describes the *Report* and *MsgFlags* fields that are part of the message descriptor MQMD specified on the MQGET, MQPUT, and MQPUT1 calls.

The topics in this section describe:

- The structure of the report field and how the queue manager processes it
- How an application analyzes the report field
- The structure of the message-flags field

For more information about the MQMD message descriptor, see [“MQMD - Message descriptor” on page 422](#).

### Structure of the report field

This information describes the structure of the report field.

The *Report* field is a 32-bit integer that is divided into three separate subfields. These subfields identify:

- Report options that are rejected if the local queue manager does not recognize them

- Report options that are always accepted, even if the local queue manager does not recognize them
- Report options that are accepted only if certain other conditions are satisfied

Each subfield is identified by a bit mask that has 1-bits in the positions corresponding to the subfield, and 0-bits elsewhere. The bits in a subfield are not necessarily adjacent. The bits are numbered such that bit 0 is the most significant bit, and bit 31 the least significant bit. The following masks are defined to identify the subfields:

#### **MQRO\_REJECT\_UNSUP\_MASK**

This mask identifies the bit positions within the *Report* field where report options that are not supported by the local queue manager cause the MQPUT or MQPUT1 call to fail with completion code MQCC\_FAILED and reason code MQRC\_REPORT\_OPTIONS\_ERROR.

This subfield occupies bit positions 3, and 11 through 13.

#### **MQRO\_ACCEPT\_UNSUP\_MASK**

This mask identifies the bit positions within the *Report* field where report options that are not supported by the local queue manager are nevertheless accepted on the MQPUT or MQPUT1 calls. Completion code MQCC\_WARNING with reason code MQRC\_UNKNOWN\_REPORT\_OPTION are returned in this case.

This subfield occupies bit positions 0 through 2, 4 through 10, and 24 through 31.

The following report options are included in this subfield:

- MQRO\_ACTIVITY
- MQRO\_COPY\_MSG\_ID\_TO\_CORREL\_ID
- MQRO\_DEAD\_LETTER\_Q
- MQRO\_DISCARD\_MSG
- MQRO\_EXCEPTION
- MQRO\_EXCEPTION\_WITH\_DATA
- MQRO\_EXCEPTION\_WITH\_FULL\_DATA
- MQRO\_EXPIRATION
- MQRO\_EXPIRATION\_WITH\_DATA
- MQRO\_EXPIRATION\_WITH\_FULL\_DATA
- MQRO\_NAN
- MQRO\_NEW\_MSG\_ID
- MQRO\_NONE
- MQRO\_PAN
- MQRO\_PASS\_CORREL\_ID
- MQRO\_PASS\_MSG\_ID

#### **MQRO\_ACCEPT\_UNSUP\_IF\_XMIT\_MASK**

This mask identifies the bit positions within the *Report* field where report options that are not supported by the local queue manager are nevertheless accepted on the MQPUT or MQPUT1 calls *provided* that both of the following conditions are satisfied:

- The message is destined for a remote queue manager.
- The application is not putting the message directly on a local transmission queue (that is, the queue identified by the *ObjectQMgrName* and *ObjectName* fields in the object descriptor specified on the MQOPEN or MQPUT1 call is not a local transmission queue).

Completion code MQCC\_WARNING with reason code MQRC\_UNKNOWN\_REPORT\_OPTION are returned if these conditions are satisfied, and MQCC\_FAILED with reason code MQRC\_REPORT\_OPTIONS\_ERROR if not.

This subfield occupies bit positions 14 through 23.

The following report options are included in this subfield:

- MQRO\_COA
- MQRO\_COA\_WITH\_DATA
- MQRO\_COA\_WITH\_FULL\_DATA
- MQRO\_COD
- MQRO\_COD\_WITH\_DATA
- MQRO\_COD\_WITH\_FULL\_DATA

If any options are specified in the *Report* field that the queue manager does not recognize, the queue manager checks each subfield in turn by using the bitwise AND operation to combine the *Report* field with the mask for that subfield. If the result of that operation is not zero, the completion code and reason codes described previously are returned.

If MQCC\_WARNING is returned, it is not defined which reason code is returned if other warning conditions exist.

The ability to specify and have accepted report options that are not recognized by the local queue manager is useful when sending a message with a report option that is recognized and processed by a *remote* queue manager.

## Analyzing the report field

The *Report* field contains subfields; because of this, applications that need to check whether the sender of the message requested a particular report must use one of the techniques described.

## Using bit operations

If the programming language supports bit operations, perform the following steps:

1. Select one of the following values, according to the type of report to be checked:
  - MQRO\_COA\_WITH\_FULL\_DATA for COA report
  - MQRO\_COD\_WITH\_FULL\_DATA for COD report
  - MQRO\_EXCEPTION\_WITH\_FULL\_DATA for exception report
  - MQRO\_EXPIRATION\_WITH\_FULL\_DATA for expiration report

Call the value A.

On z/OS, use the MQRO\_\*\_WITH\_DATA values instead of the MQRO\_\*\_WITH\_FULL\_DATA values.

2. Combine the *Report* field with A using the bitwise AND operation; call the result B.
3. Test B for equality with each value that is possible for that type of report.

For example, if A is MQRO\_EXCEPTION\_WITH\_FULL\_DATA, test B for equality with each of the following to determine what was specified by the sender of the message:

- MQRO\_NONE
- MQRO\_EXCEPTION
- MQRO\_EXCEPTION\_WITH\_DATA
- MQRO\_EXCEPTION\_WITH\_FULL\_DATA

The tests can be performed in whatever order is most convenient for the application logic.

Use a similar method to test for the MQRO\_PASS\_MSG\_ID or MQRO\_PASS\_CORREL\_ID options; select as the value A whichever of these two constants is appropriate, and then proceed as described previously.

## Using arithmetic

If the programming language *does not* support bit operations, perform the following steps using integer arithmetic:

1. Select one of the following values, according to the type of report to be checked:

- MQRO\_COA for COA report
- MQRO\_COD for COD report
- MQRO\_EXCEPTION for exception report
- MQRO\_EXPIRATION for expiration report

Call the value A.

2. Divide the *Report* field by A ; call the result B.

3. Divide B by 8 ; call the result C.

4. Multiply C by 8 and subtract from B ; call the result D.

5. Multiply D by A ; call the result E.

6. Test E for equality with each value that is possible for that type of report.

For example, if A is MQRO\_EXCEPTION, test E for equality with each of the following to determine what was specified by the sender of the message:

- MQRO\_NONE
- MQRO\_EXCEPTION
- MQRO\_EXCEPTION\_WITH\_DATA
- MQRO\_EXCEPTION\_WITH\_FULL\_DATA

The tests can be performed in whatever order is most convenient for the application logic.

The following pseudocode illustrates this technique for exception report messages:

```
A = MQRO_EXCEPTION
B = Report/A
C = B/8
D = B - C*8
E = D*A
```

Use a similar method to test for the MQRO\_PASS\_MSG\_ID or MQRO\_PASS\_CORREL\_ID options; select as the value A whichever of these two constants is appropriate, and then proceed as described previously, but replacing the value 8 in the previous steps by the value 2.

## Structure of the message-flags field

This information describes the structure of the message-flags field.

The *MsgFlags* field is a 32-bit integer that is divided into three separate subfields. These subfields identify:

- Message flags that are rejected if the local queue manager does not recognize them
- Message flags that are always accepted, even if the local queue manager does not recognize them
- Message flags that are accepted only if certain other conditions are satisfied

**Note:** All subfields in *MsgFlags* are reserved for use by the queue manager.

Each subfield is identified by a bit mask that has 1-bits in the positions corresponding to the subfield, and 0-bits elsewhere. The bits are numbered such that bit 0 is the most significant bit, and bit 31 the least significant bit. The following masks are defined to identify the subfields:

### MQMF\_REJECT\_UNSUP\_MASK

This mask identifies the bit positions within the *MsgFlags* field where message flags that are not supported by the local queue manager cause the MQPUT or MQPUT1 call to fail with completion code MQCC\_FAILED and reason code MQRC\_MSG\_FLAGS\_ERROR.

This subfield occupies bit positions 20 through 31.

The following message flags are included in this subfield:

- MQMF\_LAST\_MSG\_IN\_GROUP
- MQMF\_LAST\_SEGMENT
- MQMF\_MSG\_IN\_GROUP
- MQMF\_SEGMENT
- MQMF\_SEGMENTATION\_ALLOWED
- MQMF\_SEGMENTATION\_INHIBITED

#### **MQMF\_ACCEPT\_UNSUP\_MASK**

This mask identifies the bit positions within the *MsgFlags* field where message flags that are not supported by the local queue manager are nevertheless accepted on the MQPUT or MQPUT1 calls. The completion code is MQCC\_OK.

This subfield occupies bit positions 0 through 11.

#### **MQMF\_ACCEPT\_UNSUP\_IF\_XMIT\_MASK**

This mask identifies the bit positions within the *MsgFlags* field where message flags that are not supported by the local queue manager are nevertheless accepted on the MQPUT or MQPUT1 calls *provided* that both of the following conditions are satisfied:

- The message is destined for a remote queue manager.
- The application is not putting the message directly on a local transmission queue (that is, the queue identified by the *ObjectQMgrName* and *ObjectName* fields in the object descriptor specified on the MQOPEN or MQPUT1 call is not a local transmission queue).

Completion code MQCC\_OK is returned if these conditions are satisfied, and MQCC\_FAILED with reason code MQRC\_MSG\_FLAGS\_ERROR if not.

This subfield occupies bit positions 12 through 19.

If there are flags specified in the *MsgFlags* field that the queue manager does not recognize, the queue manager checks each subfield in turn by using the bitwise AND operation to combine the *MsgFlags* field with the mask for that subfield. If the result of that operation is not zero, the completion code and reason codes described previously are returned.

## **Data-conversion exit**

This collection of topics describes the interface to the data-conversion exit, and the processing performed by the queue manager when data conversion is required.

For more information about data conversion, see *Data Conversion under IBM MQ* at <https://www.ibm.com/support/pages/node/317869>.

The data-conversion exit is invoked as part of the processing of the MQGET call in order to convert the application message data to the representation required by the receiving application. Conversion of the application message data is optional; it requires the MQGMO\_CONVERT option to be specified on the MQGET call.

The following subjects are described:

- The processing performed by the queue manager in response to the MQGMO\_CONVERT option; see [“Conversion processing” on page 908](#).
- Processing conventions used by the queue manager when processing a built-in format; these conventions are recommended for user-written exits too. See [“Processing conventions” on page 909](#).
- Special considerations for converting report messages; see [“Conversion of report messages” on page 913](#).
- The parameters passed to the data-conversion exit; see [“MQ\\_DATA\\_CONV\\_EXIT - Data conversion exit” on page 926](#).
- A call that can be used from the exit to convert character data between different representations; see [“MQXCNV - Convert characters” on page 919](#).

- The data-structure parameter that is specific to the exit; see “MQDXP - Data-conversion exit parameter” on page 914.

## Conversion processing

This information describes the processing performed by the queue manager in response to the MQGMO\_CONVERT option.

The queue manager performs the following actions if the MQGMO\_CONVERT option is specified on the MQGET call, and there is a message to be returned to the application:

1. If one or more of the following is true, no conversion is necessary:
  - The message data is already in the character set and encoding required by the application issuing the MQGET call. The application must set the *CodedCharSetId* and *Encoding* fields in the **MsgDesc** parameter of the MQGET call to the values required, before issuing the call.
  - The length of the message data is zero.
  - The length of the **Buffer** parameter of the MQGET call is zero.

In these cases the message is returned without conversion to the application issuing the MQGET call; the *CodedCharSetId* and *Encoding* values in the **MsgDesc** parameter are set to the values in the control information in the message, and the call completes with one of the following combinations of completion code and reason code:

Table 632. Completion code and reason code combinations

Completion code	Reason code
MQCC_OK	MQRC_NONE
MQCC_WARNING	MQRC_TRUNCATED_MSG_ACCEPTED
MQCC_WARNING	MQRC_TRUNCATED_MSG_FAILED

The following steps are performed only if the character set or encoding of the message data differs from the corresponding value in the **MsgDesc** parameter, and there is data to be converted:

2. If the *Format* field in the control information in the message has the value MQFMT\_NONE, the message is returned unconverted, with completion code MQCC\_WARNING and reason code MQRC\_FORMAT\_ERROR.

In all other cases conversion processing continues.

3. The message is removed from the queue and placed in a temporary buffer that is the same size as the **Buffer** parameter. For browse operations, the message is copied into the temporary buffer, instead of being removed from the queue.
4. If the message has to be truncated to fit in the buffer, the following is done:
  - If the MQGMO\_ACCEPT\_TRUNCATED\_MSG option was not specified, the message is returned unconverted, with completion code MQCC\_WARNING and reason code MQRC\_TRUNCATED\_MSG\_FAILED.
  - If the MQGMO\_ACCEPT\_TRUNCATED\_MSG option was specified, the completion code is set to MQCC\_WARNING, the reason code is set to MQRC\_TRUNCATED\_MSG\_ACCEPTED, and conversion processing continues.
5. If the message can be accommodated in the buffer without truncation, or the MQGMO\_ACCEPT\_TRUNCATED\_MSG option was specified, the following is done:
  - If the format is a built-in format, the buffer is passed to the queue manager's data-conversion service.
  - If the format is not a built-in format, the buffer is passed to a user-written exit with the same name as the format. If the exit cannot be found, the message is returned unconverted, with completion code MQCC\_WARNING and reason code MQRC\_FORMAT\_ERROR.

If no error occurs, the output from the data-conversion service or from the user-written exit is the converted message, plus the completion code and reason code to be returned to the application issuing the MQGET call.

6. If the conversion is successful, the queue manager returns the converted message to the application. In this case, the completion code and reason code returned by the MQGET call are one of the following combinations:

Table 633. Completion code and reason code combinations

Completion code	Reason code
MQCC_OK	MQRC_NONE
MQCC_WARNING	MQRC_TRUNCATED_MSG_ACCEPTED

However, if the conversion is performed by a user-written exit, other reason codes can be returned, even when the conversion is successful.

If the conversion fails, the queue manager returns the unconverted message to the application, with the *CodedCharSetId* and *Encoding* fields in the **MsgDesc** parameter set to the values in the control information in the message, and with completion code MQCC\_WARNING.

## Processing conventions

When converting a built-in format, the queue manager follows the processing conventions described.

User-written exits should also follow these conventions, although this is not enforced by the queue manager. The built-in formats converted by the queue manager are:

- MQFMT\_ADMIN
- MQFMT\_CICS (z/OS only)
- MQFMT\_COMMAND\_1
- MQFMT\_COMMAND\_2
- MQFMT\_DEAD\_LETTER\_HEADER
- MQFMT\_DIST\_HEADER
- MQFMT\_EVENT version 1
- MQFMT\_EVENT version 2
- MQFMT\_IMS
- MQFMT\_IMS\_VAR\_STRING
- MQFMT\_MD\_EXTENSION
- MQFMT\_PCF
- MQFMT\_REF\_MSG\_HEADER
- MQFMT\_RF\_HEADER
- MQFMT\_RF\_HEADER\_2
- MQFMT\_STRING
- MQFMT\_TRIGGER
- MQFMT\_WORK\_INFO\_HEADER (z/OS only)
- MQFMT\_XMIT\_Q\_HEADER

1. If the message expands during conversion, and exceeds the size of the **Buffer** parameter, the following is done:

- If the MQGMO\_ACCEPT\_TRUNCATED\_MSG option was not specified, the message is returned unconverted, with completion code MQCC\_WARNING and reason code MQRC\_CONVERTED\_MSG\_TOO\_BIG.

- If the MQGMO\_ACCEPT\_TRUNCATED\_MSG option was specified, the message is truncated, the completion code is set to MQCC\_WARNING, the reason code is set to MQRC\_TRUNCATED\_MSG\_ACCEPTED, and conversion processing continues.
2. If truncation occurs (either before or during conversion), the number of valid bytes returned in the **Buffer** parameter can be less than the length of the buffer.
 

This can occur, for example, if a 4-byte integer or a DBCS character straddles the end of the buffer. The incomplete element of information is not converted, and those bytes in the returned message do not contain valid information. This can also occur if a message that was truncated before conversion shrinks during conversion.

If the number of valid bytes returned is less than the length of the buffer, the unused bytes at the end of the buffer are set to nulls.
  3. If an array or string straddles the end of the buffer, as much of the data as possible is converted; only the particular array element or DBCS character which is incomplete is not converted; preceding array elements or characters are converted.
  4. If truncation occurs (either before or during conversion), the length returned for the **DataLength** parameter is the length of the unconverted message before truncation.
  5. When strings are converted between single-byte character sets (SBCS), double-byte character sets (DBCS), or multi-byte character sets (MBCS), the strings can expand or contract.
    - In the PCF formats MQFMT\_ADMIN, MQFMT\_EVENT, and MQFMT\_PCF, the strings in the MQCFST and MQCFSL structures expand or contract as necessary to accommodate the string after conversion.
 

For the string-list structure MQCFSL, the strings in the list might expand or contract by different amounts. If this happens, the queue manager pads the shorter strings with blanks to make them the same length as the longest string after conversion.
    - In the format MQFMT\_REF\_MSG\_HEADER, the strings addressed by the SrcEnvOffset, SrcNameOffset, DestEnvOffset, and DestNameOffset fields expand or contract as necessary to accommodate the strings after conversion.
    - In the format MQFMT\_RF\_HEADER, the NameValueString field expands or contracts as necessary to accommodate the name-value pairs after conversion.
    - In structures with fixed field sizes, the queue manager allows strings to expand or contract within their fixed fields, provided that no significant information is lost. In this regard, trailing blanks and characters following the first null character in the field are treated as insignificant.
      - If the string expands, but only insignificant characters need to be discarded to accommodate the converted string in the field, the conversion succeeds and the call completes with MQCC\_OK and reason code MQRC\_NONE (assuming no other errors).
      - If the string expands, but the converted string requires significant characters to be discarded in order to fit in the field, the message is returned unconverted and the call completes with MQCC\_WARNING and reason code MQRC\_CONVERTED\_STRING\_TOO\_BIG.
 

**Note:** Reason code MQRC\_CONVERTED\_STRING\_TOO\_BIG results in this case whether or not the MQGMO\_ACCEPT\_TRUNCATED\_MSG option was specified.
      - If the string contracts, the queue manager pads the string with blanks to the length of the field.
  6. For messages consisting of one or more MQ header structures followed by user data, one or more of the header structures might be converted, while the remainder of the message is not. However, (with two exceptions) the *CodedCharSetId* and *Encoding* fields in each header structure always correctly indicate the character set and encoding of the data that follows the header structure.
 

The two exceptions are the MQCIH and MQIIH structures, where the values in the *CodedCharSetId* and *Encoding* fields in those structures are not significant. For those structures, the data following the structure is in the same character set and encoding as the MQCIH or MQIIH structure itself.
  7. If the *CodedCharSetId* or *Encoding* fields in the control information of the message being retrieved, or in the **MsgDesc** parameter, specify values that are undefined or not supported, the

queue manager might ignore the error if the undefined or unsupported value does not need to be used in converting the message.

For example, if the *Encoding* field in the message specifies an unsupported float encoding, but the message contains only integer data, or contains floating-point data that does not require conversion (because the source and target float encodings are identical), the error might not be diagnosed.

If the error is diagnosed, the message is returned unconverted, with completion code MQCC\_WARNING and one of the MQRC\_SOURCE\_\*\_ERROR or MQRC\_TARGET\_\*\_ERROR reason codes (as appropriate); the *CodedCharSetId* and *Encoding* fields in the **MsgDesc** parameter are set to the values in the control information in the message.

If the error is not diagnosed and the conversion completes successfully, the values returned in the *CodedCharSetId* and *Encoding* fields in the **MsgDesc** parameter are those specified by the application issuing the MQGET call.

8. In all cases, if the message is returned to the application unconverted the completion code is set to MQCC\_WARNING, and the *CodedCharSetId* and *Encoding* fields in the **MsgDesc** parameter are set to the values appropriate to the unconverted data. This is done for MQFMT\_NONE also.

The **Reason** parameter is set to a code that indicates why the conversion could not be carried out, unless the message also had to be truncated; reason codes related to truncation take precedence over reason codes related to conversion. (To determine if a truncated message was converted, check the values returned in the *CodedCharSetId* and *Encoding* fields in the **MsgDesc** parameter.)

When an error is diagnosed, either a specific reason code is returned, or the general reason code MQRC\_NOT\_CONVERTED. The reason code returned depends on the diagnostic capabilities of the underlying data-conversion service.

9. If completion code MQCC\_WARNING is returned, and more than one reason code is relevant, the order of precedence is as follows:
  - a. The following reasons take precedence over all others; only one of the reasons in this group can arise:
    - MQRC\_SIGNAL\_REQUEST\_ACCEPTED
    - MQRC\_TRUNCATED\_MSG\_ACCEPTED
  - b. The order of precedence within the remaining reason codes is not defined.

10. On completion of the MQGET call:

- The following reason code indicates that the message was converted successfully:
  - MQRC\_NONE
- The following reason codes indicate that the message *might* have been converted successfully (check the *CodedCharSetId* and *Encoding* fields in the **MsgDesc** parameter to find out):
  - MQRC\_MSG\_MARKED\_BROWSE\_CO\_OP
  - MQRC\_TRUNCATED\_MSG\_ACCEPTED
- All other reason codes indicate that the message was not converted.

The following processing is specific to the built-in formats; it does not apply to user-defined formats:

11. With the exception of the following formats:

- MQFMT\_ADMIN
- MQFMT\_COMMAND\_1
- MQFMT\_COMMAND\_2
- MQFMT\_EVENT
- MQFMT\_IMS\_VAR\_STRING
- MQFMT\_PCF
- MQFMT\_STRING

none of the built-in formats can be converted from or to character sets that do not have SBCS characters for the characters that are valid in queue names. If an attempt is made to perform such a conversion, the message is returned unconverted, with completion code MQCC\_WARNING and reason code MQRC\_SOURCE\_CCSID\_ERROR or MQRC\_TARGET\_CCSID\_ERROR, as appropriate.

The Unicode character set UTF-16 is an example of a character set that does not have SBCS characters for the characters that are valid in queue names.

12. If the message data for a built-in format is truncated, fields within the message that contain lengths of strings, or counts of elements or structures, are not adjusted to reflect the length of the data actually returned to the application; the values returned for such fields within the message data are the values applicable to the message *before truncation*.

When processing messages such as a truncated MQFMT\_ADMIN message, ensure that the application does not attempt to access data beyond the end of the data returned.

13. If the format name is MQFMT\_DEAD\_LETTER\_HEADER, the message data begins with an MQDLH structure, possibly followed by zero or more bytes of application message data. The format, character set, and encoding of the application message data are defined by the Format, CodedCharSetId, and Encoding fields in the MQDLH structure at the start of the message. Because the MQDLH structure and application message data can have different character sets and encodings, one, other, or both of the MQDLH structure and application message data might require conversion.

The queue manager converts the MQDLH structure first, as necessary. If conversion is successful, or the MQDLH structure does not require conversion, the queue manager checks the CodedCharSetId and Encoding fields in the MQDLH structure to see if conversion of the application message data is required. If conversion is required, the queue manager invokes the user-written exit with the name given by the Format field in the MQDLH structure, or performs the conversion itself (if Format is the name of a built-in format).

If the MQGET call returns a completion code of MQCC\_WARNING, and the reason code is one of those indicating that conversion was not successful, one of the following applies:

- The MQDLH structure could not be converted. In this case the application message data will not have been converted either.
- The MQDLH structure was converted, but the application message data was not.

The application can examine the values returned in the CodedCharSetId and Encoding fields in the **MsgDesc** parameter, and those in the MQDLH structure, in order to determine which of the previously applies.

14. If the format name is MQFMT\_XMIT\_Q\_HEADER, the message data begins with an MQXQH structure, possibly followed by zero or more bytes of additional data. This additional data is usually the application message data (which may be of zero length), but there can also be one or more further MQ header structures present, at the start of the additional data.

The MQXQH structure must be in the character set and encoding of the queue manager. The format, character set, and encoding of the data following the MQXQH structure are given by the Format, CodedCharSetId, and Encoding fields in the MQMD structure contained within the MQXQH. For each subsequent MQ header structure present, the Format, CodedCharSetId, and Encoding fields in the structure describe the data that follows that structure; that data is either another MQ header structure, or the application message data.

If the MQGMO\_CONVERT option is specified for an MQFMT\_XMIT\_Q\_HEADER message, the application message data and certain of the MQ header structures are converted, *but the data in the MQXQH structure is not*. On return from the MQGET call, therefore:

- The values of the Format, CodedCharSetId, and Encoding fields in the **MsgDesc** parameter describe the data in the MQXQH structure, and not the application message data; the values are therefore not the same as those specified by the application that issued the MQGET call.

The effect of this is that an application that repeatedly gets messages from a transmission queue with the MQGMO\_CONVERT option specified must reset the CodedCharSetId and Encoding

fields in the **MsgDesc** parameter to the values required for the application message data, before each MQGET call.

- The values of the `Format`, `CodedCharSetId`, and `Encoding` fields in the last MQ header structure present describe the application message data. If there are no other MQ header structures present, the application message data is described by these fields in the MQMD structure within the MQXQH structure. If conversion is successful, the values will be the same as those specified in the **MsgDesc** parameter by the application that issued the MQGET call.

If the message is a distribution-list message, the MQXQH structure is followed by an MQDH structure (plus its arrays of MQOR and MQPMR records), which in turn might be followed by zero or more further MQ header structures and zero or more bytes of application message data. Like the MQXQH structure, the MQDH structure must be in the character set and encoding of the queue manager, and it is not converted on the MQGET call, even if the MQGMO\_CONVERT option is specified.

The processing of the MQXQH and MQDH structures described previously is primarily intended for use by message channel agents when they get messages from transmission queues.

## Conversion of report messages

In general a report message can contain varying amounts of application message data, according to the report options specified by the sender of the original message. However, an activity report can contain data but without the report option mentioning `*_WITH_DATA` in the constant.

In particular, a report message can contain either:

1. No application message data

2. Some of the application message data from the original message

This occurs when the sender of the original message specifies `MQRO*_WITH_DATA` and the message is longer than 100 bytes.

3. All the application message data from the original message

This occurs when the sender of the original message specifies `MQRO*_WITH_FULL_DATA`, or specifies `MQRO*_WITH_DATA` and the message is 100 bytes or shorter.

When the queue manager or message channel agent generates a report message, it copies the format name from the original message into the *Format* field in the control information in the report message. The format name in the report message might therefore imply a length of data that is different from the length actually present in the report message (cases 1 and 2 previously).

If the MQGMO\_CONVERT option is specified when the report message is retrieved:

- For case 1 previously, the data-conversion exit is not invoked (because the report message has no data).
- For case 3 previously, the format name correctly implies the length of the message data.
- But for case 2 previously, the data-conversion exit is invoked to convert a message that is *shorter* than the length implied by the format name.

In addition, the reason code passed to the exit is usually `MQRC_NONE` (that is, the reason code does not indicate that the message has been truncated). This happens because the message data was truncated by the *sender* of the report message, and not by the receiver's queue manager in response to the MQGET call.

Because of these possibilities, the data-conversion exit must not use the format name to deduce the length of data passed to it; instead the exit must check the length of data provided, and be prepared to convert less data than the length implied by the format name. If the data can be converted successfully, completion code `MQCC_OK` and reason code `MQRC_NONE` must be returned by the exit. The length of the message data to be converted is passed to the exit as the **InBufferLength** parameter.

### Product-sensitive programming interface

## MQDXP - Data-conversion exit parameter

The MQDXP structure is a parameter that the queue manager passes to the data-conversion exit when the exit is invoked to convert the message data as part of the processing of the MQGET call. See the description of the MQ\_DATA\_CONV\_EXIT call for details of the data conversion exit.

Character data in MQDXP is in the character set of the local queue manager; this is given by the **CodedCharSetId** queue manager attribute. Numeric data in MQDXP is in the native machine encoding; this is given by MQENC\_NATIVE.

Only the *DataLength*, *CompCode*, *Reason*, and *ExitResponse* fields in MQDXP can be changed by the exit; changes to other fields are ignored. However, the *DataLength* field cannot be changed if the message being converted is a segment that contains only part of a logical message.

When control returns to the queue manager from the exit, the queue manager checks the values returned in MQDXP. If the values returned are not valid, the queue manager continues processing as though the exit had returned MQXDR\_CONVERSION\_FAILED in *ExitResponse*; however, the queue manager ignores the values of the *CompCode* and *Reason* fields returned by the exit in this case, and uses instead the values those fields had on *input* to the exit. The following values in MQDXP cause this processing to occur:

- *ExitResponse* field not MQXDR\_OK and not MQXDR\_CONVERSION\_FAILED
- *CompCode* field not MQCC\_OK and not MQCC\_WARNING
- *DataLength* field less than zero, or *DataLength* field changed when the message being converted is a segment that contains only part of a logical message.

The following table summarizes the fields in the structure.

Field	Description	Topic
<i>StrucId</i>	Structure identifier	<a href="#">StrucId</a>
<i>Version</i>	Structure version number	<a href="#">Version</a>
<i>AppOptions</i>	Application options	<a href="#">AppOptions</a>
<i>Encoding</i>	Numeric encoding required by application	<a href="#">Encoding</a>
<i>CodedCharSetId</i>	Character set required by application	<a href="#">CodedCharSetId</a>
<i>DataLength</i>	Length in bytes of message data	<a href="#">DataLength</a>
<i>CompCode</i>	Completion code	<a href="#">CompCode</a>
<i>Reason</i>	Reason code qualifying <i>CompCode</i>	<a href="#">Reason</a>
<i>ExitResponse</i>	Response from exit	<a href="#">ExitResponse</a>
<i>Hconn</i>	Connection handle	<a href="#">Hconn</a>
<i>pEntryPoints</i>	Address of the MQIEP structure	<a href="#">pEntryPoints</a>

### Fields

The MQDXP structure contains the following fields; the fields are described in alphabetical order.

#### AppOptions

Type: MQLONG

This is a copy of the *Options* field of the MQGMO structure specified by the application issuing the MQGET call. The exit might need to examine these to ascertain whether the MQGMO\_ACCEPT\_TRUNCATED\_MSG option was specified.

This is an input field to the exit.

### **CodedCharSetId**

Type: MQLONG

This is the coded character-set identifier of the character set required by the application issuing the MQGET call; see the *CodedCharSetId* field in the MQMD structure for more details. If the application specifies the special value MQCCSI\_Q\_MGR on the MQGET call, the queue manager changes this to the actual character-set identifier of the character set used by the queue manager, before invoking the exit.

If the conversion is successful, the exit must copy this to the *CodedCharSetId* field in the message descriptor.

This is an input field to the exit.

### **CompCode**

Type: MQLONG

When the exit is invoked, this contains the completion code that is returned to the application that issued the MQGET call, if the exit does nothing. It is always MQCC\_WARNING, because either the message was truncated, or the message requires conversion and this has not yet been done.

On output from the exit, this field contains the completion code to be returned to the application in the **CompCode** parameter of the MQGET call; only MQCC\_OK and MQCC\_WARNING are valid. See the description of the *Reason* field for suggestions on how the exit can set this field on output.

This is an input/output field to the exit.

### **DataLength**

Type: MQLONG

When the exit is invoked, this field contains the original length of the application message data. If the message was truncated to fit into the buffer provided by the application, the size of the message provided to the exit is *smaller* than the value of *DataLength*. The size of the message provided to the exit is always given by the **InBufferLength** parameter of the exit, irrespective of any truncation that has occurred.

Truncation is indicated by the *Reason* field having the value MQRC\_TRUNCATED\_MSG\_ACCEPTED on input to the exit.

Most conversions do not need to change this length, but an exit can do so if necessary; the value set by the exit is returned to the application in the **DataLength** parameter of the MQGET call. However, this length cannot be changed if the message being converted is a segment that contains only part of a logical message. This is because changing the length would cause the offsets of later segments in the logical message to be incorrect.

Note that, if the exit wants to change the length of the data, be aware that the queue manager has already decided whether the message data fits into the application's buffer, based on the length of the *unconverted* data. This decision determines whether the message is removed from the queue (or the browse cursor moved, for a browse request), and is not affected by any change to the data length caused by the conversion. For this reason it is recommended that conversion exits do not cause a change in the length of the application message data.

If character conversion does imply a change of length, a string can be converted into another string with the same length in bytes, truncating trailing blanks, or padding with blanks as necessary.

The exit is not invoked if the message contains no application message data; hence *DataLength* is always greater than zero.

This is an input/output field to the exit.

## Encoding

Type: MQLONG

Numeric encoding required by application.

This is the numeric encoding required by the application issuing the MQGET call; see the *Encoding* field in the MQMD structure for more details.

If the conversion is successful, the exit copies this to the *Encoding* field in the message descriptor.

This is an input field to the exit.

## ExitOptions

Type: MQLONG

This is a reserved field; its value is 0.

## ExitResponse

Type: MQLONG

Response from exit. This is set by the exit to indicate the success or otherwise of the conversion. It must be one of the following:

### MQXDR\_OK

Conversion was successful.

If the exit specifies this value, the queue manager returns the following to the application that issued the MQGET call:

- The value of the *CompCode* field on output from the exit
- The value of the *Reason* field on output from the exit
- The value of the *DataLength* field on output from the exit
- The contents of the exit's output buffer *OutBuffer*. The number of bytes returned is the lesser of the exit's **OutBufferLength** parameter, and the value of the *DataLength* field on output from the exit.

If the *Encoding* and *CodedCharSetId* fields in the exit's message descriptor parameter are *both* unchanged, the queue manager returns:

- The value of the *Encoding* and *CodedCharSetId* fields in the MQDXP structure on *input* to the exit.

If one or both of the *Encoding* and *CodedCharSetId* fields in the exit's message descriptor parameter has been changed, the queue manager returns:

- The value of the *Encoding* and *CodedCharSetId* fields in the exit's message descriptor parameter on output from the exit

### MQXDR\_CONVERSION\_FAILED

Conversion was unsuccessful.

If the exit specifies this value, the queue manager returns the following to the application that issued the MQGET call:

- The value of the *CompCode* field on output from the exit
- The value of the *Reason* field on output from the exit
- The value of the *DataLength* field on *input* to the exit
- The contents of the exit's input buffer *InBuffer*. The number of bytes returned is given by the **InBufferLength** parameter

If the exit has altered *InBuffer*, the results are undefined.

*ExitResponse* is an output field from the exit.

## Hconn

Type: MQHCONN

This is a connection handle which can be used on the MQXCNVC call. This handle is not necessarily the same as the handle specified by the application which issued the MQGET call.

### **pEntryPoints**

Type: PMQIEP

The address of an MQIEP structure through which MQI and DCI calls can be made.

### **Reason**

Type: MQLONG

Reason code qualifying *CompCode*.

When the exit is invoked, this contains the reason code that is returned to the application that issued the MQGET call, if the exit chooses to do nothing. Among possible values are MQRC\_TRUNCATED\_MSG\_ACCEPTED, indicating that the message was truncated in order to fit into the buffer provided by the application, and MQRC\_NOT\_CONVERTED, indicating that the message requires conversion but that this has not yet been done.

On output from the exit, this field contains the reason to be returned to the application in the **Reason** parameter of the MQGET call; the following is recommended:

- If *Reason* had the value MQRC\_TRUNCATED\_MSG\_ACCEPTED on input to the exit, the *Reason* and *CompCode* fields must not be altered, irrespective of whether the conversion succeeds or fails.

(If the *CompCode* field is not MQCC\_OK, the application which retrieves the message can identify a conversion failure by comparing the returned *Encoding* and *CodedCharSetId* values in the message descriptor with the values requested; in contrast, the application cannot distinguish a truncated message from a message that fitted the buffer. For this reason, MQRC\_TRUNCATED\_MSG\_ACCEPTED must be returned in preference to any of the reasons that indicate conversion failure.)

- If *Reason* had any other value on input to the exit:
  - If the conversion succeeds, *CompCode* must be set to MQCC\_OK and *Reason* set to MQRC\_NONE.
  - If the conversion fails, or the message expands and has to be truncated to fit in the buffer, *CompCode* must be set to MQCC\_WARNING (or left unchanged), and *Reason* set to one of the values listed, to indicate the nature of the failure.

Note if the message after conversion is too large for the buffer, it must be truncated only if the application that issued the MQGET call specified the MQGMO\_ACCEPT\_TRUNCATED\_MSG option:

- If it did specify that option, reason MQRC\_TRUNCATED\_MSG\_ACCEPTED is returned.
- If it did not specify that option, the message is returned unconverted, with reason code MQRC\_CONVERTED\_MSG\_TOO\_BIG.

The reason codes listed are recommended for use by the exit to indicate the reason that conversion failed, but the exit can return other values from the set of MQRC\_\* codes if deemed appropriate. In addition, the range of values MQRC\_APPL\_FIRST through MQRC\_APPL\_LAST are allocated for use by the exit to indicate conditions that the exit wants to communicate to the application issuing the MQGET call.

**Note:** If the message cannot be converted successfully, the exit must return MQXDR\_CONVERSION\_FAILED in the *ExitResponse* field, in order to cause the queue manager to return the unconverted message. This is true regardless of the reason code returned in the *Reason* field.

### **MQRC\_APPL\_FIRST**

(900, X'384') Lowest value for application-defined reason code.

### **MQRC\_APPL\_LAST**

(999, X'3E7') Highest value for application-defined reason code.

### **MQRC\_CONVERTED\_MSG\_TOO\_BIG**

(2120, X'848') Converted data too large for buffer.

**MQRC\_NOT\_CONVERTED**

(2119, X'847') Message data not converted.

**MQRC\_SOURCE\_CCSID\_ERROR**

(2111, X'83F') Source coded character set identifier not valid.

**MQRC\_SOURCE\_DECIMAL\_ENC\_ERROR**

(2113, X'841') Packed-decimal encoding in message not recognized.

**MQRC\_SOURCE\_FLOAT\_ENC\_ERROR**

(2114, X'842') Floating-point encoding in message not recognized.

**MQRC\_SOURCE\_INTEGER\_ENC\_ERROR**

(2112, X'840') Source integer encoding not recognized.

**MQRC\_TARGET\_CCSID\_ERROR**

(2115, X'843') Target coded character set identifier not valid.

**MQRC\_TARGET\_DECIMAL\_ENC\_ERROR**

(2117, X'845') Packed-decimal encoding specified by receiver not recognized.

**MQRC\_TARGET\_FLOAT\_ENC\_ERROR**

(2118, X'846') Floating-point encoding specified by receiver not recognized.

**MQRC\_TARGET\_INTEGER\_ENC\_ERROR**

(2116, X'844') Target integer encoding not recognized.

**MQRC\_TRUNCATED\_MSG\_ACCEPTED**

(2079, X'81F') Truncated message returned (processing completed).

This is an input/output field to the exit.

**StrucId**

Type: MQCHAR4

Structure identifier. The value must be:

**MQDXP\_STRUC\_ID**

Identifier for data conversion exit parameter structure.

For the C programming language, the constant MQDXP\_STRUC\_ID\_ARRAY is also defined; this has the same value as MQDXP\_STRUC\_ID, but is an array of characters instead of a string.

This is an input field to the exit.

**Version**

Type: MQLONG

Structure version number. The value must be:

**MQDXP\_VERSION\_1**

Version number for data-conversion exit parameter structure.

The following constant specifies the version number of the current version:

**MQDXP\_CURRENT\_VERSION**

Current version of data-conversion exit parameter structure.

**Note:** When a new version of this structure is introduced, the layout of the existing part is not changed. The exit must therefore check that the *Version* field is equal to or greater than the lowest version which contains the fields that the exit needs to use.

This is an input field to the exit.

**C declaration**

```
typedef struct tagMQDXP MQDXP;
struct tagMQDXP {
    MQCHAR4  StrucId;           /* Structure identifier */
    MQLONG   Version;         /* Structure version number */
    MQLONG   ExitOptions;     /* Reserved */
}
```

```

MQLONG  AppOptions;      /* Application options */
MQLONG  Encoding;       /* Numeric encoding required by
                        application */
MQLONG  CodedCharSetId; /* Character set required by application */
MQLONG  DataLength;     /* Length in bytes of message data */
MQLONG  CompCode;       /* Completion code */
MQLONG  Reason;         /* Reason code qualifying CompCode */
MQLONG  ExitResponse;   /* Response from exit */
MQHCONN Hconn;          /* Connection handle */
PMQIEP  pEntryPoints;   /* Address of the MQIEP structure */
};

```

## MQXCNVC - Convert characters

The MQXCNVC call converts characters from one character set to another using the C programming language.

This call is part of the IBM MQ Data Conversion Interface (DCI), which is one of the IBM MQ framework interfaces.

Note: The call can be used from both application, and data-conversion exit environments.

## Syntax

MQXCNVC (*Hconn*, *Options*, *SourceCCSID*, *SourceLength*, *SourceBuffer*, *TargetCCSID*, *TargetLength*, *TargetBuffer*, *DataLength*, *CompCode*, *Reason*)

## Parameters

### Hconn

Type: MQHCONN - input

This handle represents the connection to the queue manager.

In a data-conversion exit, Hconn is normally the handle that is passed to the data-conversion exit in the Hconn field of the MQDXP structure; this handle is not necessarily the same as the handle specified by the application which issued the MQGET call.

 On IBM i, the following special value can be specified for Hconn:

#### **MQHC\_DEF\_HCONN**

Default connection handle.

If you run a CICS TS 3.2 or higher application, ensure that the character conversion exit program, which invokes the MQXCNVC call, is defined as OPENAPI. This definition prevents the 2018 MQRC\_HCONN\_ERROR error caused by from an incorrect connection, and allows the MQGET to complete.

### Options

Type: MQLONG - input

Options that control the action of MQXCNVC.

Zero or more of the options described can be specified. To specify more than one option, either add the values together (do not add the same constant more than once), or combine the values using the bitwise OR operation (if the programming language supports bit operations).

**Default-conversion option:** The following option controls the use of default character conversion:

#### **MQDCC\_DEFAULT\_CONVERSION**

Default conversion.

This option specifies that default character conversion can be used if one or both of the character sets specified on the call is not supported. This allows the queue manager to use an installation-specified default character set that approximates the specified character set, when converting the string.

**Note:** The result of using an approximate character set to convert the string is that some characters can be converted incorrectly. This can be avoided by using in the string only characters which are common to both the specified character set and the default character set.

The default character sets are defined by a configuration option when the queue manager is installed or restarted.

If MQDCC\_DEFAULT\_CONVERSION is not specified, the queue manager uses only the specified character sets to convert the string, and the call fails if one or both of the character sets is not supported.

This option is supported in the following environments:

-  AIX
-  IBM i
-  Linux
-  Windows

**Padding option:** The following option allows the queue manager to pad the converted string with blanks or discard insignificant trailing characters, in order to make the converted string fit the target buffer:

### **MQDCC\_FILL\_TARGET\_BUFFER**

Fill target buffer.

This option requests that conversion take place in such a way that the target buffer is filled completely:

- If the string contracts when it is converted, trailing blanks are added in order to fill the target buffer.
- If the string expands when it is converted, trailing characters that are not significant are discarded to make the converted string fit the target buffer. If this can be done successfully, the call completes with MQCC\_OK and reason code MQRC\_NONE.

If there are too few insignificant trailing characters, as much of the string as can fit is placed in the target buffer, and the call completes with MQCC\_WARNING and reason code MQRC\_CONVERTED\_MSG\_TOO\_BIG.

Insignificant characters are:

- Trailing blanks
- Characters following the first null character in the string (but excluding the first null character itself)
- If the string, TargetCCSID, and TargetLength are such that the target buffer cannot be set completely with valid characters, the call fails with MQCC\_FAILED and reason code MQRC\_TARGET\_LENGTH\_ERROR. This can occur when TargetCCSID is a pure DBCS character set (such as UTF-16), but TargetLength specifies a length that is an odd number of bytes.
- TargetLength can be less than or greater than SourceLength. On return from MQXCNV, DataLength has the same value as TargetLength.

If this option is not specified:

- The string is allowed to contract or expand within the target buffer as required. Insignificant trailing characters are not added or discarded.

If the converted string fits in the target buffer, the call completes with MQCC\_OK and reason code MQRC\_NONE.

If the converted string is too large for the target buffer, as much of the string as fits is placed in the target buffer, and the call completes with MQCC\_WARNING and reason code MQRC\_CONVERTED\_MSG\_TOO\_BIG. Note fewer than TargetLength bytes can be returned in this case.

- TargetLength can be less than or greater than SourceLength. On return from MQXCNV, DataLength is less than or equal to TargetLength.

This option is supported in the following environments:

-  AIX
-  IBM i
-  Linux
-  Windows

**Encoding options:** The options described can be used to specify the integer encodings of the source and target strings. The relevant encoding is used only when the corresponding character set identifier indicates that the representation of the character set in main storage is dependent on the encoding used for binary integers. This affects only certain multibyte character sets (for example, UTF-16 character sets).

The encoding is ignored if the character set is a single-byte character set (SBCS), or a multibyte character set with representation in main storage that is not dependent on the integer encoding.

Only one of the MQDCC\_SOURCE\_\* values must be specified, combined with one of the MQDCC\_TARGET\_\* values:

**MQDCC\_SOURCE\_ENC\_NATIVE**

Source encoding is the default for the environment and programming language.

**MQDCC\_SOURCE\_ENC\_NORMAL**

Source encoding is normal.

**MQDCC\_SOURCE\_ENC\_REVERSED**

Source encoding is reversed.

**MQDCC\_SOURCE\_ENC\_UNDEFINED**

Source encoding is undefined.

**MQDCC\_TARGET\_ENC\_NATIVE**

Target encoding is the default for the environment and programming language.

**MQDCC\_TARGET\_ENC\_NORMAL**

Target encoding is normal.

**MQDCC\_TARGET\_ENC\_REVERSED**

Target encoding is reversed.

**MQDCC\_TARGET\_ENC\_UNDEFINED**

Target encoding is undefined.

The encoding values defined previously can be added directly to the Options field. However, if the source or target encoding is obtained from the Encoding field in the MQMD or other structure, the following processing must be done:

1. The integer encoding must be extracted from the Encoding field by eliminating the float and packed-decimal encodings; see [“Analyzing encodings”](#) on page 902 for details of how to do this.
2. The integer encoding resulting from step 1 must be multiplied by the appropriate factor before being added to the Options field. These factors are:
  - MQDCC\_SOURCE\_ENC\_FACTOR for the source encoding
  - MQDCC\_TARGET\_ENC\_FACTOR for the target encoding

The following example code illustrates how this might be coded in the C programming language:

```
Options = (MsgDesc.Encoding & MQENC_INTEGER_MASK)
          * MQDCC_SOURCE_ENC_FACTOR
        + (DataConvExitParms.Encoding & MQENC_INTEGER_MASK)
          * MQDCC_TARGET_ENC_FACTOR;
```

If not specified, the encoding options default to undefined (MQDCC\_\*\_ENC\_UNDEFINED). In most cases, this does not affect the successful completion of the MQXCNVC call. However, if the corresponding character set is a multibyte character set with representation that is dependent on the encoding (for example, a UTF-16 character set), the call fails with reason code MQRC\_SOURCE\_INTEGER\_ENC\_ERROR or MQRC\_TARGET\_INTEGER\_ENC\_ERROR as appropriate.

The encoding options are supported in the following environments:

-  AIX
-  IBM i
-  Linux
-  Windows
-  z/OS

**Default option:** If none of the options described previously is specified, the following option can be used:

**MQDCC\_NONE**

No options specified.

MQDCC\_NONE is defined to aid program documentation. It is not intended that this option is used with any other, but as its value is zero, such use cannot be detected.

**SourceCCSID**

Type: MQLONG - input

This is the coded character set identifier of the input string in `SourceBuffer`.

**SourceLength**

Type: MQLONG - input

This is the length in bytes of the input string in `SourceBuffer`; it must be zero or greater.

**SourceBuffer**

Type: MQCHAR x `SourceLength` - input

This is the buffer containing the string to be converted from one character set to another.

**TargetCCSID**

Type: MQLONG - input

This is the coded character set identifier of the character set to which `SourceBuffer` is to be converted.

**TargetLength**

Type: MQLONG - input

This is the length in bytes of the output buffer `TargetBuffer`; it must be zero or greater. It can be less than or greater than `SourceLength`.

**TargetBuffer**

Type: MQCHAR x `TargetLength` - output

This is the string after it has been converted to the character set defined by `TargetCCSID`. The converted string can be shorter or longer than the unconverted string. The **DataLength** parameter indicates the number of valid bytes returned.

**DataLength**

Type: MQLONG - output

This is the length of the string returned in the output buffer `TargetBuffer`. The converted string can be shorter or longer than the unconverted string.

**CompCode**

Type: MQLONG - output

It is one of the following:

**MQCC\_OK**

Successful completion.

**MQCC\_WARNING**

Warning (partial completion).

**MQCC\_FAILED**

Call failed.

**Reason**

Type: MQLONG - output

Reason code qualifying `CompCode`.

If `CompCode` is `MQCC_OK`:

**MQRC\_NONE**

(0, X'000') No reason to report.

If CompCode is MQCC\_WARNING:

**MQRC\_CONVERTED\_MSG\_TOO\_BIG**

(2120, X'848') Converted data too large for buffer.

If CompCode is MQCC\_FAILED:

**MQRC\_DATA\_LENGTH\_ERROR**

(2010, X'7DA') Data length parameter not valid.

**MQRC\_DBCS\_ERROR**

(2150, X'866') DBCS string not valid.

**MQRC\_HCONN\_ERROR**

(2018, X'7E2') Connection handle not valid.

**MQRC\_OPTIONS\_ERROR**

(2046, X'7FE') Options not valid or not consistent.

**MQRC\_RESOURCE\_PROBLEM**

(2102, X'836') Insufficient system resources available.

**MQRC\_SOURCE\_BUFFER\_ERROR**

(2145, X'861') Source buffer parameter not valid.

**MQRC\_SOURCE\_CCSID\_ERROR**

(2111, X'83F') Source coded character set identifier not valid.

**MQRC\_SOURCE\_INTEGER\_ENC\_ERROR**

(2112, X'840') Source integer encoding not recognized.

**MQRC\_SOURCE\_LENGTH\_ERROR**

(2143, X'85F') Source length parameter not valid.

**MQRC\_STORAGE\_NOT\_AVAILABLE**

(2071, X'817') Insufficient storage available.

**MQRC\_TARGET\_BUFFER\_ERROR**

(2146, X'862') Target buffer parameter not valid.

**MQRC\_TARGET\_CCSID\_ERROR**

(2115, X'843') Target coded character set identifier not valid.

**MQRC\_TARGET\_INTEGER\_ENC\_ERROR**

(2116, X'844') Target integer encoding not recognized.

**MQRC\_TARGET\_LENGTH\_ERROR**

(2144, X'860') Target length parameter not valid.

**MQRC\_UNEXPECTED\_ERROR**

(2195, X'893') Unexpected error occurred.

For detailed information about these codes, see [Messages and reason codes](#).

## C invocation

```
MQXCNCV (Hconn, Options, SourceCCSID, SourceLength, SourceBuffer,
        TargetCCSID, TargetLength, TargetBuffer, &DataLength,
        &CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHCONN  Hconn;           /* Connection handle */
MQLONG   Options;        /* Options that control the action of
                          MQXCNCV */
MQLONG   SourceCCSID;    /* Coded character set identifier of string
                          before conversion */
```

```

MQLONG  SourceLength;      /* Length of string before conversion */
MQCHAR  SourceBuffer[n];  /* String to be converted */
MQLONG  TargetCCSID;      /* Coded character set identifier of string
                           after conversion */
MQLONG  TargetLength;     /* Length of output buffer */
MQCHAR  TargetBuffer[n];  /* String after conversion */
MQLONG  DataLength;       /* Length of output string */
MQLONG  CompCode;        /* Completion code */
MQLONG  Reason;          /* Reason code qualifying CompCode */

```

## COBOL declaration ( IBM i only)

IBM i

```

CALL 'MQXCNCV' USING HCONN, OPTIONS, SOURCECCSID, SOURCELENGTH,
                    SOURCEBUFFER, TARGETCCSID, TARGETLENGTH,
                    TARGETBUFFER, DATALENGTH, COMPCODE, REASON.

```

Declare the parameters as follows:

```

** Connection handle
01 HCONN          PIC S9(9) BINARY.
** Options that control the action of MQXCNCV
01 OPTIONS        PIC S9(9) BINARY.
** Coded character set identifier of string before conversion
01 SOURCECCSID   PIC S9(9) BINARY.
** Length of string before conversion
01 SOURCELENGTH  PIC S9(9) BINARY.
** String to be converted
01 SOURCEBUFFER  PIC X(n).
** Coded character set identifier of string after conversion
01 TARGETCCSID   PIC S9(9) BINARY.
** Length of output buffer
01 TARGETLENGTH  PIC S9(9) BINARY.
** String after conversion
01 TARGETBUFFER  PIC X(n).
** Length of output string
01 DATALENGTH  PIC S9(9) BINARY.
** Completion code
01 COMPCODE      PIC S9(9) BINARY.
** Reason code qualifying COMPCODE
01 REASON        PIC S9(9) BINARY.

```

## S/390 assembler declaration

```

CALL MQXCNCV, (HCONN, OPTIONS, SOURCECCSID, SOURCELENGTH,          X
              SOURCEBUFFER, TARGETCCSID, TARGETLENGTH, TARGETBUFFER, X
              DATALENGTH, COMPCODE, REASON)

```

Declare the parameters as follows:

```

HCONN      DS  F      Connection handle
OPTIONS     DS  F      Options that control the action of MQXCNCV
SOURCECCSID DS  F      Coded character set identifier of string before
*
SOURCELENGTH DS  F      Length of string before conversion
SOURCEBUFFER DS  CL(n) String to be converted
TARGETCCSID DS  F      Coded character set identifier of string after
*
TARGETLENGTH DS  F      Length of output buffer
TARGETBUFFER DS  CL(n) String after conversion
DATALENGTH  DS  F      Length of output string
COMPCODE    DS  F      Completion code
REASON      DS  F      Reason code qualifying COMPCODE

```

## MQ\_DATA\_CONV\_EXIT - Data conversion exit

The MQ\_DATA\_CONV\_EXIT call describes the parameters that are passed to the data-conversion exit.

No entry point called MQ\_DATA\_CONV\_EXIT is provided by the queue manager (see usage note [11](#)).

This definition is part of the IBM MQ Data Conversion Interface (DCI), which is one of the IBM MQ framework interfaces.

### Syntax

MQ\_DATA\_CONV\_EXIT (*DataConvExitParms*, *MsgDesc*, *InBufferLength*, *InBuffer*, *OutBufferLength*, *OutBuffer*)

### Parameters

#### DataConvExitParms

Type: MQDXP - input/output

This structure contains information relating to the invocation of the exit. The exit sets information in this structure to indicate the outcome of the conversion. See “[MQDXP - Data-conversion exit parameter](#)” on page 914 for details of the fields in this structure.

#### MsgDesc

Type: MQMD - input/output

On input to the exit, this is the message descriptor associated with the message data passed to the exit in the **InBuffer** parameter.

**Note:** The **MsgDesc** parameter passed to the exit is always the most recent version of MQMD supported by the queue manager which invokes the exit. If the exit is intended to be portable between different environments, the exit will check the **Version** field in **MsgDesc** to verify that the fields that the exit needs to access are present in the structure.

In the following environments, the exit is passed a version-2 MQMD:

-  AIX
-  IBM i
-  Linux
-  Windows

In all other environments that support the data conversion exit, the exit is passed a version-1 MQMD.

On output, the exit will change the **Encoding** and **CodedCharSetId** fields to the values requested by the application, if conversion was successful; these changes are reflected back to the application. Any other changes that the exit makes to the structure are ignored; they are not reflected back to the application.

If the exit returns **MQXDR\_OK** in the **ExitResponse** field of the MQDXP structure, but does not change the **Encoding** or **CodedCharSetId** fields in the message descriptor, the queue manager returns for those fields the values that the corresponding fields in the MQDXP structure had on input to the exit.

#### InBufferLength

Type: MQLONG - input

Length in bytes of **InBuffer**.

This is the length of the input buffer **InBuffer**, and specifies the number of bytes to be processed by the exit. **InBufferLength** is the lesser of the length of the message data before conversion, and the length of the buffer provided by the application on the MQGET call.

The value is always greater than zero.

## InBuffer

Type: MQBYTEXInBufferLength - input

Buffer containing the unconverted message.

This contains the message data before conversion. If the exit is unable to convert the data, the queue manager returns the contents of this buffer to the application after the exit has completed.

**Note:** The exit should not alter `InBuffer`; if this parameter is altered, the results are undefined.

In the C programming language, this parameter is defined as a pointer-to-void.

## OutBufferLength

Type: MQLONG - input

Length in bytes of `OutBuffer`.

This is the length of the output buffer `OutBuffer`, and is the same as the length of the buffer provided by the application on the MQGET call.

The value is always greater than zero.

## OutBuffer

Type: MQBYTEXOutBufferLength - output

Buffer containing the converted message.

On output from the exit, if the conversion was successful (as indicated by the value `MQXDR_OK` in the `ExitResponse` field of the **DataConvExitParms** parameter), `OutBuffer` contains the message data to be delivered to the application, in the requested representation. If the conversion was unsuccessful, any changes that the exit has made to this buffer are ignored.

In the C programming language, this parameter is defined as a pointer-to-void.

## Usage notes

1. A data-conversion exit is a user-written exit which receives control during the processing of an MQGET call. The function performed by the data-conversion exit is defined by the provider of the exit; however, the exit must conform to the rules described here, and in the associated parameter structure `MQDXP`.

The programming languages that can be used for a data-conversion exit are determined by the environment.

2. The exit is invoked only if all of the following statements are true:
  - The `MQGMO_CONVERT` option is specified on the MQGET call
  - The `Format` field in the message descriptor is not `MQFMT_NONE`
  - The message is not already in the required representation; that is, one or both of the message's `CodedCharSetId` and `Encoding` is different from the value specified by the application in the message descriptor supplied on the MQGET call
  - The queue manager has not already done the conversion successfully
  - The length of the application's buffer is greater than zero
  - The length of the message data is greater than zero
  - The reason code so far during the MQGET operation is `MQRC_NONE` or `MQRC_TRUNCATED_MSG_ACCEPTED`
3. When an exit is being written, consider coding the exit in a way that allows it to convert messages that have been truncated. Truncated messages can arise in the following ways:
  - The receiving application provides a buffer that is smaller than the message, but specifies the `MQGMO_ACCEPT_TRUNCATED_MSG` option on the MQGET call.

In this case, the `Reason` field in the **DataConvExitParms** parameter on input to the exit has the value `MQRC_TRUNCATED_MSG_ACCEPTED`.

- The sender of the message truncated it before sending it. This can happen with report messages, for example (see [“Conversion of report messages”](#) on page 913 for more details).

In this case, the Reason field in the **DataConvExitParms** parameter on input to the exit has the value MQRC\_NONE (if the receiving application provided a buffer that was large enough for the message).

Thus the value of the Reason field on input to the exit cannot always be used to decide whether the message has been truncated.

The distinguishing characteristic of a truncated message is that the length provided to the exit in the **InBufferLength** parameter is less than the length implied by the format name contained in the Format field in the message descriptor. The exit should therefore check the value of InBufferLength before attempting to convert any of the data; the exit should not assume that the full amount of data implied by the format name has been provided.

If the exit has not been written to convert truncated messages, and InBufferLength is less than the value expected, the exit will return MQXDR\_CONVERSION\_FAILED in the ExitResponse field of the **DataConvExitParms** parameter, with the CompCode and Reason fields set to MQCC\_WARNING and MQRC\_FORMAT\_ERROR.

If the exit has been written to convert truncated messages, the exit will convert as much of the data as possible (see next usage note), taking care not to attempt to examine or convert data beyond the end of InBuffer. If the conversion completes successfully, the exit will leave the Reason field in the **DataConvExitParms** parameter unchanged. This returns MQRC\_TRUNCATED\_MSG\_ACCEPTED if the message was truncated by the receiver's queue manager, and MQRC\_NONE if the message was truncated by the sender of the message.

It is also possible for a message to expand during conversion, to the point where it is bigger than OutBuffer. In this case the exit must decide whether to truncate the message; the AppOptions field in the **DataConvExitParms** parameter indicates whether the receiving application specified the MQGMO\_ACCEPT\_TRUNCATED\_MSG option.

4. Generally, all the data in the message provided to the exit in InBuffer is converted, or that none of it is. An exception to this, however, occurs if the message is truncated, either before conversion or during conversion; in this case there can be an incomplete item at the end of the buffer (for example: 1 byte of a double-byte character, or 3 bytes of a 4-byte integer). In this situation, consider omitting the incomplete item and set the unused bytes in the OutBuffer to nulls. However, complete elements or characters within an array or string should be converted.
5. When an exit is needed for the first time, the queue manager attempts to load an object that has the same name as the format (apart from extensions). The object loaded must contain the exit that processes messages with that format name. Consider making the exit name, and the name of the object that contains the exit identical, although not all environments require this.
6. A new copy of the exit is loaded when an application attempts to retrieve the first message that uses that Format since the application connected to the queue manager. For CICS or IMS applications, this means when the CICS or IMS subsystem connected to the queue manager. A new copy can also be loaded at other times, if the queue manager has discarded a previously loaded copy. For this reason, an exit must not attempt to use static storage to communicate information from one invocation of the exit to the next - the exit can be unloaded between the two invocations.
7. If there is a user-supplied exit with the same name as one of the built-in formats supported by the queue manager, the user-supplied exit does not replace the built-in conversion routine. The only circumstances in which such an exit is invoked are:
  - If the built-in conversion routine cannot handle conversions to or from either the CodedCharSetId or Encoding involved, or
  - If the built-in conversion routine has failed to convert the data (for example, because there is a field or character which cannot be converted).
8. The scope of the exit is environment-dependent. Format names must be chosen to minimize the risk of clashes with other formats. Consider starting with characters that identify the application defining the format name.

9. The data-conversion exit runs in an environment like that of the program which issued the MQGET call; environment includes address space and user profile (where applicable). The program could be a message channel agent sending messages to a destination queue manager that does not support message conversion. The exit cannot compromise the queue manager's integrity, since it does not run in the queue manager's environment.
10. The only MQI call which can be used by the exit is MQXCNVC; attempting to use other MQI calls fails with reason code MQRC\_CALL\_IN\_PROGRESS, or other unpredictable errors.
11. No entry point called MQ\_DATA\_CONV\_EXIT is provided by the queue manager. However, a typedef is provided for the name MQ\_DATA\_CONV\_EXIT in the C programming language, and this can be used to declare the user-written exit, to ensure that the parameters are correct. The name of the exit must be the same as the format name (the name contained in the Format field in MQMD), although this is not required in all environments.

The following example illustrates how the exit that processes the format MYFORMAT can be declared in the C programming language:

```
#include "cmqc.h"
#include "cmqxc.h"

MQ_DATA_CONV_EXIT MYFORMAT;

void MQENTRY MYFORMAT(
    PMQDXP  pDataConvExitParms, /* Data-conversion exit parameter
                                block */
    PMQMD   pMsgDesc,           /* Message descriptor */
    MQLONG  InBufferLength,     /* Length in bytes of InBuffer */
    PMQVOID pInBuffer,         /* Buffer containing the unconverted
                                message */
    MQLONG  OutBufferLength,    /* Length in bytes of OutBuffer */
    PMQVOID pOutBuffer)        /* Buffer containing the converted
                                message */
{
    /* C language statements to convert message */
}
```

12.  On z/OS, if an API-crossing exit is also in force, it is called after the data-conversion exit.

## C invocation

```
exitname (&DataConvExitParms, &MsgDesc, InBufferLength,
          InBuffer, OutBufferLength, OutBuffer);
```

The parameters passed to the exit are declared as follows:

```
MQDXP  DataConvExitParms; /* Data-conversion exit parameter block */
MQMD   MsgDesc;          /* Message descriptor */
MQLONG InBufferLength;   /* Length in bytes of InBuffer */
MQBYTE InBuffer[n];      /* Buffer containing the unconverted
                           message */
MQLONG OutBufferLength;  /* Length in bytes of OutBuffer */
MQBYTE OutBuffer[n];     /* Buffer containing the converted
                           message */
```

## COBOL declaration (IBM i only)

```
CALL 'exitname' USING DATACONVEXITPARMS, MSGDESC, INBUFFERLENGTH,
                     INBUFFER, OUTBUFFERLENGTH, OUTBUFFER.
```

The parameters passed to the exit are declared as follows:

```

** Data-conversion exit parameter block
01 DATACONVEXITPARMS.
   COPY CMQDXPV.
** Message descriptor
01 MSGDESC.
   COPY CMQMDV.
** Length in bytes of INBUFFER
01 INBUFFERLENGTH PIC S9(9) BINARY.
** Buffer containing the unconverted message
01 INBUFFER PIC X(n).
** Length in bytes of OUTBUFFER
01 OUTBUFFERLENGTH PIC S9(9) BINARY.
** Buffer containing the converted message
01 OUTBUFFER PIC X(n).

```

## System/390 assembler declaration

```

CALL EXITNAME, (DATACONVEXITPARMS, MSGDESC, INBUFFERLENGTH, INBUFFER, OUTBUFFERLENGTH, OUTBUFFER) X

```

The parameters passed to the exit are declared as follows:

```

DATACONVEXITPARMS CMQDXPA , Data-conversion exit parameter block
MSGDESC           CMQMDA  , Message descriptor
INBUFFERLENGTH   DS      F Length in bytes of INBUFFER
INBUFFER         DS      CL(n) Buffer containing the unconverted
*                *                message
OUTBUFFERLENGTH   DS      F Length in bytes of OUTBUFFER
OUTBUFFER        DS      CL(n) Buffer containing the converted
*                *                message

```

## Properties specified as MQRFH2 elements

Non-message descriptor properties can be specified as elements in MQRFH2 header folders. Overview of MQRFH2 elements being specified as properties.

This retains compatibility with the previous versions of the IBM MQ JMS and XMS clients. This section describes how to specify properties in MQRFH2 headers.

To use MQRFH2 elements as properties, specify the elements as described in [Using IBM MQ classes for Java](#). This information supplements the information described in [“MQRFH2 - Rules and formatting header 2” on page 529](#).

## Mapping property data types to MQRFH2 data types

This topic provides information on message property types mapped to their corresponding MQRFH2 data types.

Message property type	MQRFH2 data type
MQBYTE[]	bin.hex
MQBOOL	boolean
MQINT8	i1
MQINT16	i2
MQINT32	i4
MQINT64	i8
MQFLOAT32	r4

Table 635. Supported MQRFH2 data types (continued)

Message property type	MQRFH2 data type
MQFLOAT64	r8
MQCHAR[]	string

Any element without a data type is assumed to be of type "string".

An MQRFH2 data type of `int`, meaning an integer of unspecified size, is treated as if it were an `i8`.

A null value is indicated by the element attribute `xsi:nil='true'`. Do not use the attribute `xsi:nil='false'` for non-null values.

For example, the following property has a null value:

```
<NullProperty xsi:nil='true'></NullProperty>
```

A byte or character string property can have an empty value. This is represented by an MQRFH2 element with a zero length element value.

For example, the following property has an empty value:

```
<EmptyProperty></EmptyProperty>
```

## Supported MQRFH2 folders

Overview of the use of message descriptor fields as properties.

The folders `<jms>`, `<mcd>`, `<mqext>`, and `<usr>` are described in [The MQRFH2 header and JMS](#). The `<usr>` folder is used to transport any JMS application-defined properties that are associated with a message. Groups are not allowed in the `<usr>` folder.

[The MQRFH2 header and JMS](#) supports the following additional folders:

- `<mq>`

This folder is used and reserved for MQ-defined properties that are used by IBM MQ.

- `<mq_usr>`

This folder can be used to transport any application-defined properties that are not exposed as JMS user-defined properties, as the properties might not meet the requirements of a JMS property. This folder can contain groups that the `<usr>` folder cannot.

- Any folder marked with the `content='properties'` attribute.

Such a folder is equivalent to the `<mq_usr>` folder in content.

- `<mqps>`

This folder is used for IBM MQ publish/subscribe properties.

IBM MQ also supports the following folders that are already in use by WAS/SIB:

- `<sib>`

This folder is used and reserved for WAS/SIB system message properties that are not exposed as JMS properties, or are mapped to `JMS_IBM_*` properties, but are exposed to WAS/SIB applications; these include forward and reverse routing paths properties.

At least some cannot be exposed as JMS properties, because they are byte arrays. If your application adds properties to this folder, the value is either ignored or removed.

- `<sib_usr>`

This folder is used and reserved for WAS/SIB user message properties that cannot be exposed as JMS user properties because they are not of supported types; they are exposed to WAS/SIB applications.

These are user properties, that you can get or set through the `SIMessage` interface, but the content of the byte array is mapped to the required property value.

If your IBM MQ application writes an arbitrary `bin.hex` element to the folder, the application probably receives an `IOException`, as it is not of the format expected to restore. If you add anything other than a `bin.hex` element you receive a `ClassCastException`.

Do not attempt to make properties available to WAS/SIB by using this folder; instead use the `<usr>` folder for that purpose.

- `<sib_context>`

This folder is used for WAS/SIB system message properties that are not exposed to WAS/SIB user applications or as JMS properties. These include security and transactional properties that are used for web services and similar.

Your application must not add properties to this folder.

- `<mqema>`

This folder was used by WAS/SIB instead of the `<mqext>` folder.

MQRFH2 folder names are case-sensitive.

The following folders are reserved, in any mixture of lowercase or uppercase characters:

- Any folder prefixed by `mq` or `wmq`; reserved for use by IBM MQ.
- Any folder prefixed by `sib`; reserved for use by WAS/SIB.
- `<Root>` and `<Body>` folders; reserved but not used.

The following folders are not recognized as containing message properties:

- `<psc>`

Used by IBM Integration Bus to convey publish/subscribe command messages to the broker.

- `<pscr>`

Used by IBM Integration Bus to contain information from the broker, in response to publish/subscribe command messages.

- Any folder not defined by IBM, that is not marked with the `content='properties'` attribute.

Do not specify `content='properties'` on the `<psc>` or `<pscr>` folders. If you do so, these folders are treated as properties and IBM Integration Bus is likely to stop functioning as expected.

If your application is building messages with properties, in MQRFH2 headers to be recognized as an MQRFH2 header containing properties, the header must be in the list of headers that can be chained at the head of the message.

The MQRFH2 can be preceded by any number of MQH standard headers, or an MQCIH, an MQDLH, an MQIIH, an MQTM, an MQTMC2, or an MQXQH. A string or an MQCFH ends parsing because they cannot be chained.

It is possible for a message to contain multiple MQRFH2 headers all carrying message properties. Folders with the same name can coexist in different headers unless otherwise restricted, for example by WAS/SIB. The folders are treated as one logical folder, if they are all in significant headers.

While folders from the significant headers cannot be merged with those folders in nonsignificant headers, folders with the same name within the significant headers can be merged, removing any conflicting properties. Your applications must not depend on the layout of properties within their message.

MQRFH2 groups are parsed for properties in user-defined folders, that is, not the `<wmq>`, `<jms>`, `<mcd>`, `<usr>`, `<mqext>`, `<sib>`, `<sib_usr>`, `<sib_context>`, and `<mqema>` folders.

Groups in the IBM-defined properties folders, except for the `<wmq>` and `<mq>` folders, are parsed for properties.

An MQRFH2 folder cannot contain mixed content; a folder or group can contain either groups or properties, or a value, but not both.

A segment of a message, either the first or a subsequent segment, cannot contain IBM MQ -defined properties other than those properties in the message descriptor. Therefore putting a message containing such properties with either MQMF\_SEGMENT or MQMF\_SEGMENTATION\_ALLOWED set causes the put to fail with MQRC\_SEGMENTATION\_NOT\_ALLOWED.

However, message groups can contain IBM MQ -defined properties.

## Generation of MQRFH2 headers

If IBM MQ converts message properties to their MQRFH2 representation, it must add the MQRFH2 to the message. It adds the MQRFH2 either as a separate header, or merges it with an existing header.

Generation of new MQRFH2 headers by IBM MQ might disrupt existing headers in a message. Applications that parse a message buffer for headers must be aware that the number and position of headers in a buffer might change in some circumstances. IBM MQ attempts to minimize the impact of adding properties to a message by merging message properties into an existing MQRFH2 header, where it can. It also attempts to minimize the impact by inserting a generated MQRFH2 into a fixed position relative to other headers in the message buffer.

A generated MQRFH2 header is placed following the MQMD, and any number of MQXQH, MQRFH, and MQDLH headers, whatever order they are in. The generated MQRFH2 header is placed immediately before the first header that is not an MQMD, MQXQH, MQDLH, or MQRFH header.

 On z/OS systems, the generated MQRFH2 header is created in the application's CCSID. This is defined as follows:

- For batch LE applications using the DLL interface, the CCSID is the CODESET associated with the current locale at the time **MQCONN** is issued (default value is 1047).
- For batch LE applications bound with one of the batch MQ stubs, the CCSID is the CODESET associated with the current locale at the time of the first MQI call issued after **MQCONN** (default value is 1047).
- For batch non-LE applications running on a z/OS UNIX System Services (z/OS UNIX) thread, the CCSID is the value of THLICCSID at the time of the first MQI call issued after **MQCONN** (default value is 1047).
- For other batch applications, the CCSID is the CCSID of the queue manager.

For LE applications, the locale can be changed using the `setlocale()` / `CEESETL` LE callable service. For non-LE applications running on z/OS UNIX threads, the value of THLICCSID can be changed using z/OS UNIX mapping macro **BPXYTHLI**.

## Rules for merging generated MQRFH2

The following rules apply to merging a generated MQRFH2 with an existing MQRFH2. The generated MQRFH2 header is merged with an existing MQRFH2 header, if:

1. The existing MQRFH2 is in the same position IBM MQ would place a generated MQRFH2, or earlier in the header chain.
2. The CCSID of the generated properties is the same as the NameValueCCSID of the existing MQRFH2.

Otherwise, the generated header is placed separately in the buffer, in the position described before.

## Rules for merging folders in an existing MQRFH2

If message properties are merged into an existing MQRFH2, then the existing MQRFH2 is scanned for folders that match the message properties, and merges them. If a matching folder does not exist a new folder is added to the end of the existing folders. If a matching folder does exist, the folder is searched. Any matching properties are overwritten. Any new ones are added at the end of the folder.

## MQRFH2 folder restrictions

Overview of folder restrictions in MQRFH2 headers

The MQRFH2 restrictions apply to the following folders:

- Element names in the <usr> folder must not begin with the prefix JMS ; such property names are reserved for use by JMS and are not valid for user-defined properties.

Such an element name does not cause parsing of the MQRFH2 to fail, but is not accessible to the IBM MQ message property APIs.

- Element names in the <usr> folder must not be, in any mixture of lower or uppercase, NULL, TRUE, FALSE, NOT, AND, OR, BETWEEN, LIKE, IN, IS and ESCAPE. These names match SQL keywords and make parsing selectors harder, because <usr> is the default folder used when no folder is specified for a particular property in a selector.

Such an element name does not cause parsing of the MQRFH2 to fail, but is not accessible to the IBM MQ message property APIs.

- The content model of the <usr> folder is as follows:
  - Any valid XML name can be used as an element name, providing that it does not contain a colon.
  - Only simple elements, not nested folders, are allowed.
  - All elements take the default type of string, unless modified by a dt="xxx" attribute.
  - All elements are optional, but should occur no more than once in a folder.
- Element names in any folder considered to contain message properties must not contain a period (.) (Unicode character U+002E), because this is used in property names to indicate the hierarchy.

Such an element name does not cause parsing of the MQRFH2 to fail, but is not accessible to the IBM MQ message property APIs.

In general, MQRFH2 headers that contain valid XML-style data can be parsed by IBM MQ without failure, although certain elements of the MQRFH2 are not accessible through the IBM MQ message property APIs.

## MQRFH2 element name conflicts

Overview of conflicts within MQRFH2 element names.

Only one value can be attached to a message property. If an attempt to access a property leads to a conflict of values, one is chosen in preference over another.

The IBM MQ syntax for accessing MQRFH2 elements allows unique identification of an element, if a folder contains no elements with the same name. If a folder contains more than one element with the same name, the value of the property used is the one closest to the head of the message.

This applies if two or more folders of the same name are contained in different significant MQRFH2 headers within the same message.

A conflict can result when the MQGET call is processed after a non-message descriptor property has been set twice: both through an MQSETMP call and directly in the raw MQRFH2 header.

If this happens, the property associated with the message by an API call takes preference over one in the message data, that is, the one in the raw MQRFH2 header. If a conflict occurs, it is considered to come logically before the message data.

## Mapping from property names to MQRFH2 folder and element names

Overview of the differences between property names and element names in the MQRFH2 header.

When using any of the defined APIs that ultimately generate MQRFH2 headers, in order to specify message properties (for example, MQ JMS), the property name is not necessarily the element name in the MQRFH2 folder.

Therefore, a mapping occurs from the property name to the MQRFH2 element, and in the reverse way, taking into account both the folder name that contains the element, and the element name. Some examples from IBM MQ classes for JMS are already documented in [Using IBM MQ classes for Java](#).

Property name	MQRFH2 folder name	MQRFH2 element name
JMSDestination	jms	Dst
JMSType	mcd	Type, Set, Fmt
xxx (user defined, where xxx does not begin with JMS)	usr	xxx

Therefore, when a JMS application accesses the JMSDestination property this maps to the Dst element in the <jms> folder.

When specifying properties as MQRFH2 elements, IBM MQ defines its elements as follows:

Property name	MQRFH2 folder name	MQRFH2 group name	MQRFH2 element name
<Property>	<usr>	n/a	<Property>
<folder>. <Property>	<folder>	n/a	<Property>
<folder>. <group>. <Property>	<folder>	<group>	<Property>

For example, when an IBM MQ application attempts to access the Property1 property, this maps to the Property1 element in the <usr> folder. The wmq.Property2 property maps to the Property2 property in the <wmq> folder.

If the property name contains more than one . character, the MQRFH2 element name used is the one following the final . character, and MQRFH2 groups are used to form a hierarchy; nested MQRFH2 groups are permitted.

The JMS header and provider-specific properties that are contained in an MQRFH2 in the <mcd>, <jms>, and <mqext> folders are accessed by an IBM MQ application using the short names defined in [Using IBM MQ classes for Java](#).

JMS user-defined properties are accessed from the <usr> folder. An IBM MQ application can use the <usr> folder for its application properties if it is acceptable for the property to appear to JMS applications as one of its user-defined properties.

If it is not acceptable, choose another folder; the <wmq\_usr> folder is provided as a standard location for such non-JMS properties.

Your applications can specify and use any MQRFH2 folder with a well-defined use, not documented in [“Properties specified as MQRFH2 elements”](#) on page 930 if you note the following:

1. The folder might already be in use, or might be used in the future, by another application providing undefined access to properties contained inside it; see [Property names](#) for the suggested naming convention for property names.
2. The properties are not accessible to previous versions of the IBM MQ classes for JMS or XMS client that can only access the <usr> folder for user-defined properties
3. The folder must be marked with the attribute content with the value set to properties, for example, content='properties'.

[“MQSETMP - Set message property”](#) on page 780 automatically adds this attribute as required. This attribute must not be added to any of the IBM-defined folders, for example, <jms> and <usr>. Doing so, causes the message to be rejected by the IBM MQ classes for JMS client before IBM WebSphere MQ 7.0. with a MessageFormatException.

Because the <usr> folder is the default location for properties of the <Property> syntax, an IBM MQ application and a JMS application to access the same user-defined property value using the same name.

## Reserved folder names

There are several reserved folder names. You cannot use such names as your folder prefixes; for example, Root. Property1 does not access a valid property because Root is reserved. The following list contains reserved folder names:

- Root
- Body
- Properties
- Environment
- LocalEnvironment
- DestinationList
- ExceptionList
- InputBody
- InputRoot
- InputProperties
- InputLocalEnvironment
- InputDestinationList
- InputExceptionList
- OutputRoot
- OutputLocalEnvironment
- OutputDestinationList
- OutputExceptionList

## Mapping property descriptor fields into MQRFH2 headers

When a property is translated into an MQRFH2 element the following element attributes are used to specify the significant fields of the property descriptor: This describes how MQPD fields are translated to MQRFH2 element attributes.

### Support

The Support property descriptor field is split into three element attributes

- The **sr** element attribute specifies values in the MQPD\_REJECT\_UNSUP\_MASK bit mask.
- The **sa** element attribute specifies values in the MQPD\_ACCEPT\_UNSUP\_MASK bit mask.
- The **sx** element attribute specifies values in the MQPD\_ACCEPT\_UNSUP\_IF\_XMIT\_MASK bit mask.

These element attributes are only valid in the <mq> folder and are ignored if set on elements in the other folders containing properties.

Support value	MQRFH2 element attribute	MQRFH2 attribute value
MQPD_SUPPORT_OPTIONAL	sa	optional This is the default value.
MQPD_SUPPORT_REQUIRED	sr	required
MQPD_SUPPORT_REQUIRED_IF_LOCAL	sx	local

## Context

Use the **context** element attribute to indicate the message context to which a property belongs. Use one value only. This element attribute is valid on a property in any folder containing properties.

Context value	MQRFH2 attribute value
MQPD_NO_CONTEXT	none This is the default value.
MQPD_USER_CONTEXT	user

## CopyOptions

Use the **copy** element attribute to indicate messages into which a property should be copied. More than one value is acceptable; separate multiple values with a comma. For example **copy='reply'** and **copy='publish,report'** are both valid. This element attribute is valid on a property in any folder containing properties.

**Note:** In the attribute definition, single quotation marks or double quotation marks are valid use, for example **copy='reply'** or **copy="report"**

CopyOption value	MQRFH2 attribute value
MQPD_COPY_FORWARD	forward
MQPD_COPY_REPLY	reply
MQPD_COPY_REPORT	report
MQPD_COPY_PUBLISH	publish
MQPD_COPY_ALL	all Do not specify this with any other value. When used with another value, this takes precedence over any value except <b>none</b> .
MQPD_COPY_DEFAULT	default This is the default value. It is equivalent to specifying the three values MQCOPY_FORWARD, MQCOPY_REPORT and MQCOPY_PUBLISH. Do not specify this with any other value.
MQPD_COPY_NONE	none Do not specify this with any other value. When used with another value, this takes precedence.

## Restrictions to the <mq> MQRFH2 folder

When a message is put on to a queue, it is searched for an <mq> folder so that the message can be processed according to its MQ-defined properties. To allow the efficient parsing of MQ-defined properties, the following restrictions apply to the folder:

- Only properties in the first significant <mq> folder in the message are acted upon by MQ; properties in any other <mq> folder in the message are ignored.
- If the folder is in UTF-8, only single-byte UTF-8 characters are allowed in the folder. A multi-byte character in the folder, can cause parsing to fail, and the message to be rejected.

- Do not include MQRFH2 groups in the <mq> folder. The presence of Unicode character U+003C in a property value will cause the message to be rejected.
- Do not use escape strings in the folder. An escape string is treated as the actual value of the element.
- Only Unicode character U+0020 is treated as white space within the folder. All other characters are treated as significant and can cause parsing of the folder to fail, and the message to be rejected.

If parsing of the <mq> folder fails, or if the folder does not observe these restrictions, the message is rejected with CompCode **MQCC\_FAILED** and Reason **MQRC\_RFH\_RESTRICTED\_FORMAT\_ERR**.

## MQRFH2 headers that are not valid

At the time an MQPUT, MQPUT1, or MQGET call processes, a partial parsing of any MQRFH2 headers in the message can occur to check what folders are included, and to determine if the folders contain properties. Overview of MQRFH2 headers that are not valid.

If the partial parsing of the message cannot complete successfully because the structure is not valid, for example, the StructLength field is too small, then:

- The MQPUT or MQPUT1 call fails with reason code MQRC\_RFH\_ERROR, if it can be determined that the application includes some IBM WebSphere MQ 7 option, so that existing applications do not fail.
- The MQGET call returns successfully, and the MQRFH2 containing the error is returned in the buffer you provided.

If the partial parsing fails because it cannot be detected whether a particular folder contains properties or not, for example, the folder begins <<jms, so parsing fails before the folder name is determined, then:

- The MQPUT or MQPUT1 call fails with reason code MQRC\_RFH\_FORMAT\_ERROR, if it can be determined that the application includes some IBM WebSphere MQ 7 option, so that existing applications do not fail.
- The MQGET call returns successfully, and the MQRFH2 containing the error is returned in the buffer you provided.
- While internally within the queue manager, the message is not rejected due to the badly formatted folder, but the folder is always treated as if no properties were contained inside it.

A message can flow through the queue manager network with a folder containing such a syntax error, but never being parsed and detected, while one or more folders in the message are:

- Valid
- Successfully parsed
- Used in the processing of the message

Therefore, detection is not guaranteed.

If one of your applications uses “MQSETMP - Set message property” on page 780, or MQINQMP to access a property, and in so doing this causes an MQRFH2 folder to be fully parsed, detecting an error such that parsing cannot complete, this is indicated by an appropriate return code to the API call. No properties in the folder are made available to the application.

If an attempt is made to fully parse an MQRFH2 folder and the parser finds unrecognized element attributes, or an unrecognized data type, parsing continues and complete successfully with no warnings being issued; this does not constitute a parsing error.

## Code page conversion

This section describes codeset names and CCSIDs, national language, z/OS conversion, IBM i conversion, and Unicode conversion support.

Each national language section lists the following information:

- The native CCSIDs supported
- The code page conversions that are not supported

The following terms are used in the information:

**AIX**  
Indicates IBM MQ for AIX.

**Linux**  
Indicates IBM MQ for Linux for Intel and IBM MQ for Linux for zSeries.

**IBM i**  
Indicates IBM MQ for IBM i.

**Windows**  
Indicates IBM MQ for Windows.

**z/OS**  
Indicates IBM MQ for z/OS.

The default for data conversion is for the conversion to be performed at the target (receiving) system.

If the source product supports the conversion a channel can be set up and data exchanged by setting the channel attribute CONVERT to YES at the source.

**Note:**

1. Conversion for IBM MQ MQI client information takes place in the server, so the server must support conversion from the client CCSID to the server CCSID.
2. The conversion might include support added by CSD/PTF to the latest version of IBM MQ. Check the content of the latest service level to see if you need to install a CSD/PTF to enable this conversion.
3. The IBM MQ queue manager CCSID must be Mixed or SBCS.
4. Some CCSIDs, for example 850 on AIX, that are not supported by the operating system can still be used by the application and also can be set as the IBM MQ queue manager CCSID. This is allowed for backward compatibility purpose only and the conversion will fail if the relevant conversion tables are not installed.

See [Table 641 on page 939](#) for a cross-reference between some of the CCSID numbers and some industry codeset names.

**Related reference**

“National languages” on page 940

This information contains languages supported by IBM MQ.

**Codeset names and CCSIDs**

Codeset names and the corresponding CCSIDs for each codeset name.

**z/OS** IBM MQ for z/OS provides more conversion than is listed in the language specific tables. For a complete list of conversions, see [Table 674 on page 966](#).

## US English

Details of CCSIDs and CCSID conversion for US English.

Platform	Native CCSIDs
 IBM i  z/OS	37, 924, 1140
 AIX	819, 923, 5348
 Windows	437, 850, 1252, 5348, 858
 Linux	819, 923
Apple client	1275

All non-client platforms support conversion between their native CCSIDs and the native CCSIDs of the other platforms, with the following exceptions.

## IBM i

Code page:

### 37

Does not convert to code pages 923, 858

### 924

Does not convert to code pages 437, 858, 1051, 1140, 1252, 1275, 5348

### 1140

Does not convert to code pages 924, 1051, 1275

## German

Details of CCSIDs and CCSID conversion for German.

Platform	Native CCSIDs
 IBM i  z/OS	273, 924, 1141

Table 643. Native CCSIDs for German on supported platforms (continued)

Platform	Native CCSIDs
 AIX	819, 923, 5348
 Windows	437, 850, 858, 1252, 5348
 Linux	819, 923
Apple client	1275

All non-client platforms support conversion between their native CCSIDs and the native CCSIDs of the other platforms, with the following exceptions.

## IBM i

Code page:

### 273

Does not convert to code pages 858, 923, 924, 1275

### 924

Does not convert to code pages 273, 437, 858, 1051, 1141, 1252, 1275, 5348

### 1141

Does not convert to code pages 924, 1051, 1275

## Danish and Norwegian

Details of CCSIDs and CCSID conversion for Danish and Norwegian.

Table 644. native CCSIDs for Danish and Norwegian on supported platforms

Platform	Native CCSIDs
 IBM i	277, 924, 1142
 z/OS	
 AIX	819, 923, 5348
 Windows	850, 858, 865, 1252, 5348
 Linux	819, 923
Apple client	1275

All non-client platforms support conversion between their native CCSIDs and the native CCSIDs of the other platforms, with the following exceptions.

## IBM i

Code page:

### 277

Does not convert to code pages 1051, 1275

## Italian

Details of CCSIDs and CCSID conversion for Italian.

*Table 646. Native CCSIDs for Italian on supported platforms*

Platform	Native CCSIDs
 IBM i  z/OS	280, 924, 1144
 AIX	819, 923, 5348
 Windows	437, 850, 858, 1252, 5348
 Linux	819, 923
Apple client	1275

All non-client platforms support conversion between their native CCSIDs and the native CCSIDs of the other platforms, with the following exceptions.

## IBM i

Code page:

### 280

Does not convert to code pages 858, 923, 924, 1275

### 924

Does not convert to code pages 280, 437, 858, 1051, 1144, 1252, 1275, 5348

### 1144

Does not convert to code pages 924, 1051, 1275

## Spanish

Details of CCSIDs and CCSID conversion for Spanish.

Platform	Native CCSIDs
 IBM i  z/OS	284, 924, 1145
 AIX	819, 923, 5348
 Windows	437, 850, 858, 1252, 5348
 Linux	819, 923
Apple client	1275

All non-client platforms support conversion between their native CCSIDs and the native CCSIDs of the other platforms, with the following exceptions.

### IBM i

Code page:

#### 284

Does not convert to code pages 858, 923, 924, 1275

#### 924

Does not convert to code pages 284, 437, 858, 1051, 1145, 1252, 1275, 5348

#### 1145

Does not convert to code pages 924, 1051, 1275

## UK English /Gaelic

Details of CCSIDs and CCSID conversion for UK English/Gaelic.

Platform	Native CCSIDs
 IBM i  z/OS	285, 924, 1146
 AIX	819, 923, 5348
 Windows	437, 850, 858, 1252, 5348
 Linux	819, 923
Apple client	1275

All non-client platforms support conversion between their native CCSIDs and the native CCSIDs of the other platforms, with the following exceptions.

## IBM i

Code page:

### 285

Does not convert to code pages 858, 923, 924, 1275

### 924

Does not convert to code pages 285, 437, 858, 1051, 1146, 1252, 1275, 5348

### 1146

Does not convert to code pages 924, 1051, 1275

## French

Details of CCSIDs and CCSID conversion for French.

Platform	Native CCSIDs
IBM i z/OS	297, 924, 1147
AIX	819, 923, 5348
Windows	437, 850, 858, 1252, 5348
Linux	819, 923
Apple client	1275

All non-client platforms support conversion between their native CCSIDs and the native CCSIDs of the other platforms, with the following exceptions.

## IBM i

Code page:

### 297

Does not convert to code pages 858, 923, 924, 1275, 5348

### 924

Does not convert to code pages 297, 437, 858, 1051, 1147, 1252, 1275, 5348

### 1147

Does not convert to code pages 924, 1051, 1275

## Multilingual

Details of CCSIDs and CCSID conversion for Multilingual.

Platform	Native CCSIDs
IBM i z/OS	500, 924, 1148

Table 650. Native CCSIDs for multilingual conversion on supported platforms (continued)

Platform	Native CCSIDs
 AIX	819, 923, 5348
 Windows	437, 850, 858, 1252, 5348
 Linux	819, 923
Apple client	1275

All non-client platforms support conversion between their native CCSIDs and the native CCSIDs of the other platforms, with the following exceptions.

## IBM i

Code page:

### 500

Does not convert to code pages 858, 923

### 924

Does not convert to code pages 437, 858, 1051, 1148, 1252, 1275, 5348

### 1148

Does not convert to code pages 924, 1051, 1275

## Portuguese

Details of CCSIDs and CCSID conversion for Portuguese.

Table 651. Native CCSIDs for Portuguese on supported platforms

Platform	Native CCSIDs
 IBM i	37, 500, 924, 1140
 z/OS	500, 924, 1140
 AIX	819, 923, 5348
 Windows	850, 858, 860, 1252, 5348
 Linux	819, 923
Apple client	1275

All non-client platforms support conversion between their native CCSIDs and the native CCSIDs of the other platforms, with the following exceptions.

## IBM i

Code page:

### 37

Does not convert to code pages 858, 923, 1275

### Turkish

Details of CCSIDs and CCSID conversion for Turkish.

Table 659. Native CCSIDs for Turkish on supported platforms

Platform	Native CCSIDs
 IBM i  z/OS	1026
 Windows	857, 1254, 5350
 AIX  Linux	920
Apple client	1281

All non-client platforms support conversion between their native CCSIDs and the native CCSIDs of the other platforms, with the following exceptions.

## IBM i

Code page:

### 1026

Does not convert to code page 5350

## Hebrew

Details of CCSIDs and CCSID conversion for Hebrew.

*Table 660. Native CCSIDs for Hebrew on supported platforms*

Platform	Native CCSIDs
z/OS	424, 803, 4899, 12712
IBM i	424
AIX	916, 9048
Windows	1255, 5351
Linux	916

All platforms support conversion between their native CCSIDs and the native CCSIDs of other platforms, with the following exceptions.

## z/OS

Code page:

### 424

Does not convert to code pages 867, 4899, 9048, 12712

### 803

Does not convert to code pages 867, 4899, 5351, 9048, 12712

### 4899

Does not convert to code pages 424, 803, 856, 862, 916, 1255

### 12712

Does not convert to code pages 424, 803, 856, 916, 1255

## IBM i

Code page:

### 424

Does not convert to code pages 803, 867, 4899, 5351, 9048, 12712

Code page 424 also converts to and from CCSID 4952, which is a variant of 856.

## AIX

Code page:

**916**

Does not convert to code pages 867, 4899, 9048, 12712

**9048**

Does not convert to code pages 424, 803, 856, 862, 916, 1255

**Farsi**

Details of CCSIDs and CCSID conversion for Farsi.

Platform	Native CCSIDs
 IBM i  z/OS	1097
 AIX  Linux  Windows	1098 (see note)

**Note:** The native CCSID for these platforms has not been standardized and might change.

All platforms support conversion between their native CCSIDs and the native CCSIDs of other platforms.

**Urdu**

Details of CCSIDs and CCSID conversion for Urdu.

Platform	Native CCSIDs
 IBM i  z/OS	918
 Windows	868
 AIX  Linux	1006

All platforms support conversion between their native CCSIDs and the native CCSIDs of other platforms, with the following exceptions.

**IBM i**

Code page:

**918**

Does not convert to code page 1006

## Thai

Details of CCSIDs and CCSID conversion for Thai.

Platform	Native CCSIDs
 IBM i  z/OS	838
 AIX  Linux  Windows	874 (see note)

**Note:** The native CCSID for these platforms has not been standardized and might change.

All platforms support conversion between their native CCSIDs and the native CCSIDs of other platforms.

## Lao

Details of CCSIDs and CCSID conversion for Lao.

Platform	Native CCSIDs
 IBM i  z/OS	1132
 AIX  Linux  Windows	1133

All platforms support conversion between their native CCSIDs and the native CCSIDs of other platforms.

## Vietnamese

Details of CCSIDs and CCSID conversion for Vietnamese.

Platform	Native CCSIDs
 IBM i  z/OS	1130
 Windows	1258, 5354
 AIX  Linux	1129

All platforms support conversion between their native CCSIDs and the native CCSIDs of other platforms, with the following exceptions.

## IBM i

Code page:

### 1130

Does not convert to code pages 1129, 5354

## Japanese Latin SBCS

Details of CCSIDs and CCSID conversion for Japanese Latin SBCS.

Platform	Native CCSIDs
IBM i z/OS	1027
AIX	932, 5050, 33722 (see Note 1)
Windows	932, 943 (see Note 2)
Linux	943, 5050

### Note:

- 5050 and 33722 are CCSIDs related to base code page 954 on AIX. The CCSID reported by the operating system is 33722.
- Windows NT uses code page 932 but this is best represented by the CCSID of 943. However, not all platforms of IBM MQ support this CCSID.

On IBM MQ for Windows CCSID 932 is used to represent code page 932, but a change to file `./conv/table/ccsid.tbl` can be made which changes the CCSID used to 943.

All platforms support conversion between their native CCSIDs and the native CCSIDs of other platforms, with the following exceptions.

## z/OS

Code page:

### 1027

Does not convert to code pages 932, 942, 943, 954, 5050, 33722

## IBM i

## Japanese Katakana SBCS

Details of CCSIDs and CCSID conversion for Japanese Katakana SBCS.

Platform	Native CCSIDs
IBM i z/OS	290
AIX	932, 5050, 33722 (see Note 1)
Windows	932, 943 (see Note 2)
Linux	943, 5050

### Note:

- 5050 and 33722 are CCSIDs related to base code page 954 on AIX. The CCSID reported by the operating system is 33722.
- Windows NT uses code page 932 but this is best represented by the CCSID of 943. However, not all platforms of IBM MQ support this CCSID.  
On IBM MQ for Windows CCSID 932 is used to represent code page 932, but a change to file . ./ conv/table/ccsid.tbl can be made which changes the CCSID used to 943.
- In addition to the previous conversions, IBM MQ supports conversion from CCSID 897 to CCSIDs 37, 273, 277, 278, 280, 284, 285, 290, 297, 437, 500, 819, 850, 1027, and 1252 on the following platforms:
  - AIX
  - Linux

All platforms support conversion between their native CCSIDs and the native CCSIDs of other platforms, with the following exceptions.

## z/OS

Code page:

### 290

Does not convert to code pages 932, 943, 954, 5050, 33722

### 5050

Does not convert to code pages 290, 897

## Japanese Kanji/ Latin Mixed

Details of CCSIDs and CCSID conversion for Japanese Kanji/Latin Mixed.

Platform	Native CCSIDs
IBM i z/OS	1399, 5035 (see Note 1)
AIX	932, 5050, 33722 (see Note 2)
Windows	932, 943 (see Note 4)
Linux	943, 5050

**Note:**

1.   5035 is a CCSID related to code page 939
2.  5050 and 33722 are CCSIDs related to base code page 954 on AIX. The CCSID reported by the operating system is 33722.
3.  Windows NT uses code page 932 but this is best represented by the CCSID of 943. However, not all platforms of IBM MQ support this CCSID.

On IBM MQ for Windows CCSID 932 is used to represent code page 932, but a change to file `./conv/table/ccsid.tbl` can be made which changes the CCSID used to 943.

All platforms support conversion between their native CCSIDs and the native CCSIDs of other platforms, with the following exceptions.

### z/OS

Does not convert to code page 5039

#### 5035

Does not convert to code page 5039

### Japanese Kanji/ Katakana Mixed

Details of CCSIDs and CCSID conversion for Japanese Kanji/Katakana Mixed.

Platform	Native CCSIDs
 z/OS	1390, 5026 (see Note “1” on page 962)
 IBM i	5026 (see Note “1” on page 962)
 AIX	932, 5050, 33722 (see Note “2” on page 963)
 Windows	932, 943 (see Note “3” on page 963)
 Linux	943, 5050

**Note:**

1.   The single-byte mode of CCSIDs 1390 and 5026 in EBCDIC contain lowercase characters in different locations to the typical or invariant layout for basic Latin. Therefore

you must take care to ensure data is not lost when message data is converted to other CCSIDs. Also, the use of these CCSIDs as a queue manager's default CCSID can cause issues when communicating with other queue managers. For example, channel names using lowercase characters might not be correctly interpreted on the remote system. 5026 is a CCSID related to code page 930. CCSID 5026 is the CCSID reported on IBM i when the Japanese Katakana (DBCS) feature is selected.

2.  5050 and 33722 are CCSIDs related to base code page 954 on AIX. The CCSID reported by the operating system is 33722.
3.  Windows NT uses code page 932 but this is best represented by the CCSID of 943. However, not all platforms of IBM MQ support this CCSID.

On Windows, CCSID 932 is used to represent code page 932, but a change to file `./conv/table/ccsid.tbl` can be made that changes the CCSID used to 943.

All platforms support conversion between their native CCSIDs and the native CCSIDs of other platforms, with the following exceptions.

## z/OS

### z/OS

Code page:

#### 1390

Does not convert to code pages 954, 5026, 5050, 33722

Does not accept lowercase characters.

#### 5026

Does not convert to code pages 954, 1390, 5050, 33722

## IBM i

### IBM i

Code page:

#### 5026

Does not convert to code pages 1390, 5039

## Korean

Details of CCSIDs and CCSID conversion for Korean.

Platform	Native CCSIDs
 IBM i  z/OS	933, 1364
 AIX  Linux	970
 Windows	949, 1363

All platforms support conversion between their native CCSIDs and the native CCSIDs of other platforms, with the following exceptions.

## z/OS

Code page:

### 933

Does not convert to code page 970

### 1364

Does not convert to code page 970

## Simplified Chinese

Details of CCSIDs and CCSID conversion for Simplified Chinese.

Platform	Native CCSIDs
z/OS	935, 1388
IBM i	935, 1388
AIX	1383, 1386
Windows	1381, 1386(see Note 2)
Linux	1383

### Note:

1. Windows uses code page 936 but this is best represented by the CCSID of 1386. However, not all platforms of IBM MQ support this CCSID.

On IBM MQ for Windows CCSID 1381 is used to represent code page 936, but a change to file `./conv/table/ccsid.tbl` can be made which changes the CCSID used to 1386.

2. IBM MQ supports the Chinese GB18030 standard.

On z/OS, Windows and Linux, conversion support is provided between Unicode (UTF-8 and UTF-16) and CCSID 1388 (EBCDIC with GB18030 extensions), Unicode (UTF-8 and UTF-16) and CCSID 5488 (GB18030), and between CCSID 1388 and CCSID 5488.

**Note:** The CCSID must be set to 5488 in order to use GB18030 characters. However, it is not possible to set the CCSID on a queue manager created with the IBM MQ Explorer or the IBM MQ Console. Instead, you must either create the queue manager using the CLI with a CCSID of 5488 or use the CLI command line to change the CCSID after you create the queue manager.

On IBM i, support is provided by the operating system for conversion between Unicode (UTF-8 and UTF-16) and CCSID 1388 (EBCDIC with GB18030 extensions).

All platforms support conversion between their native CCSIDs and the native CCSIDs of other platforms, with the following exceptions.

## z/OS

## IBM i IBM i conversion support

A full list of CCSIDs, and conversions supported by IBM i, can be found in the appropriate IBM i publication.

The supported code pages are listed in [Supported CCSID mappings](#).

## Unicode conversion support

Some platforms support the conversion of user data to or from Unicode encoding. The two forms of Unicode encoding supported are UTF-16 (CCSIDs 1200, 13488, and 17584) and UTF-8 (CCSID 1208). You should use CCSIDs 1200 or 1208, as they represent the most recent Unicode version supported.

UTF-16 surrogate pairs (a pair of 2-byte UTF-16 characters in the range X'D800' through to X'DFFF' that represent a Unicode code point above U+FFFF) are supported. If a target CCSID does not contain a mapping for a code point represented by a UTF-16 surrogate pair, the pair of characters convert to a single substitution character.

Combining character sequences are supported by IBM MQ. This means that, in some cases, a precomposed character in the source CCSID will be converted to a combining character sequence in the target CCSID, or the other way round.

**Note:** IBM MQ does not support UTF-16 queue manager CCSIDs so message header data cannot be encoded in UTF-16.

## IBM MQ AIX support for Unicode

On IBM MQ for AIX conversion to, and from, the supported Unicode CCSIDs (preferably 1200 or 1208) is supported for the non-Unicode CCSIDs in the following list:

037  
273, 278, 280, 284, 285, 297  
423, 437  
500  
813, 819, 850, 852, 856, 857, 858, 860, 861, 865, 867, 869, 875, 878, 880  
901, 902, 912, 915, 916, 920, 923, 924, 932, 933, 935, 937, 938, 939, 942, 943, 948, 949, 950, 954, 964, 970  
1026, 1046, 1089

1200, 1208, 1250, 1251, 1253, 1254, 1258, 1280, 1281, 1282, 1283, 1284, 1285  
1363, 1364, 1381, 1383, 1386, 1388  
4899  
5026, 5035, 5050, 5346, 5347, 5348, 5349, 5350, 5351, 5352, 5353, 5354, 5488  
9044, 9048, 9449  
12712  
13488  
17584  
33722

## IBM MQ for Windows and Linux support for Unicode

On IBM MQ for Windows and IBM MQ for Linux conversion to, and from, the supported Unicode CCSIDs (preferably 1200 or 1208) is supported for the non-Unicode CCSIDs in the following list:

037,  
277, 278, 280, 284, 285, 290, 297  
300, 301  
420, 424, 437  
500  
813, 819, 833, 835, 836, 837, 838, 850, 852, 855, 856, 857, 858, 860, 861, 862, 863, 864, 865, 866, 867, 868, 869, 870, 871, 874, 875, 878, 880, 891, 897

901, 902, 903, 904, 912, 913<sup>"5" on page 991</sup>, 915, 916, 918, 920, 921, 922, 923, 924, 927, 928, 930, 931<sup>"1" on page 991</sup>, 932<sup>"2" on page 991</sup>, 933, 935, 937, 938<sup>"3" on page 991</sup>, 939, 941, 942, 943, 947, 948, 949, 950, 951, 954<sup>"4" on page 991</sup>, 964, 970  
1006, 1025, 1026, 1027, 1040, 1041, 1042, 1043, 1046, 1047, 1051, 1088, 1089, 1097, 1098  
1112, 1114, 1115, 1122, 1123, 1124, 1129, 1130, 1132, 1133, 1140, 1141, 1142, 1143, 1144, 1145, 1146, 1147, 1148, 1149, 1153, 1156, 1157  
1200, 1208, 1250, 1251, 1252, 1253, 1254, 1255, 1256, 1257, 1258, 1275, 1280, 1281, 1282, 1283  
1363, 1364, 1374, 1375, 1376, 1377, 1378, 1379, 1380, 1381, 1383, 1386, 1388  
4899  
5050, 5346, 5347, 5348, 5349, 5350, 5351, 5352, 5353, 5354, 5488<sup>"5" on page 991</sup>  
9044, 9048, 9449  
12712  
13488  
17584  
33722<sup>"4" on page 991</sup>

#### Notes:

1. 931 uses 939 for conversion.
2. 932 uses 942 for conversion.
3. 938 uses 948 for conversion.
4. 954 and 33722 use 5050 for conversion.
5. On Windows and Linux only.

## IBM i support for Unicode

For details on UNICODE support refer to the appropriate IBM i publication relating to your operating system.

## IBM MQ for z/OS support for Unicode

On IBM MQ for z/OS conversion to, and from, the supported Unicode CCSIDs (preferably 1200 or 1208) is supported for the non-Unicode CCSIDs in the following list:

37  
256, 259, 273, 275, 277, 278, 280, 282, 284, 285, 290, 293, 297  
300, 301, 367  
420, 423, 424, 437

## Coding standards on 64-bit platforms

Use this information to learn about coding standards on 64-bit platforms and the preferred data types.

### Preferred data types

These types never change size and are available on both 32-bit and 64-bit IBM MQ platforms:

Table 675. Data type names and lengths

Name	Length
MQLONG	4 bytes
MQULONG	4 bytes
MQINT32	4 bytes
MQUINT32	4 bytes
MQINT64	8 bytes
MQUINT64	8 bytes

## Standard data types on AIX, Linux, and Windows

Learn about standard data types on 32-bit AIX and Linux, and 64-bit AIX, Linux, and Windows applications.

### 32-bit AIX and Linux applications

Table 676. Data type names and lengths for 32-bit AIX and Linux applications

Name	Length
char	1 byte
short	2 bytes
int	4 bytes
long	4 bytes
float	4 bytes
double	8 bytes

Table 676. Data type names and lengths for 32-bit AIX and Linux applications (continued)

Name	Length
long double	8 bytes
pointer	4 bytes
ptrdiff_t	4 bytes
size_t	4 bytes
time_t	4 bytes
clock_t	4 bytes
wchar_t	4 bytes

 Note that on AIX a wchar\_t is 2 bytes.

### 64-bit AIX and Linux applications

Table 677. Data type names and lengths for 64-bit AIX and Linux applications

Name	Length
char	1 byte
short	2 bytes
int	4 bytes
long	8 bytes
float	4 bytes
double	8 bytes
long double	8 bytes
pointer	8 bytes
ptrdiff_t	8 bytes
size_t	8 bytes
time_t	8 bytes
clock_t	4 bytes
wchar_t	4 bytes

 Note that on AIX a wchar\_t is 2 bytes.

### Windows 64-bit applications

Table 678. Data type names and lengths for Windows 64-bit applications

Name	Length
char	1 byte
short	2 bytes
int	4 bytes

Table 678. Data type names and lengths for Windows 64-bit applications (continued)

Name	Length
long	4 bytes
float	4 bytes
double	8 bytes
long double	8 bytes
pointer	8 bytes
	Note that all pointers are 8 bytes.
ptrdiff_t	8 bytes
size_t	8 bytes
time_t	8 bytes
clock_t	4 bytes
wchar_t	2 bytes
WORD	2 bytes
DWORD	4 bytes
HANDLE	8 bytes
HFILE	4 bytes

## Coding considerations on Windows

### Windows

#### HANDLE hf;

Use

```
hf = CreateFile((LPCTSTR) FileName,
               Access,
               ShareMode,
               xihSecAttsNTRestrict,
               Create,
               AttrAndFlags,
               NULL);
```

Do not use

```
HFILE hf;
hf = (HFILE) CreateFile((LPCTSTR) FileName,
                       Access,
                       ShareMode,
                       xihSecAttsNTRestrict,
                       Create,
                       AttrAndFlags,
                       NULL);
```

as this produces an error.

#### size\_t len fgets

Use

```
size_t len
while (fgets(string1, (int) len, fp) != NULL)
len = strlen(buffer);
```

Do not use

```
int len;

while (fgets(string1, len, fp) != NULL)
    len = strlen(buffer);
```

## printf

Use

```
printf("My struc pointer: %p", pMyStruc);
```

Do not use

```
printf("My struc pointer: %x", pMyStruc);
```

If you need hexadecimal output, you have to print the upper and lower 4 bytes separately.

## char \*ptr

Use

```
char * ptr1;
char * ptr2;
size_t bufLen;

bufLen = ptr2 - ptr1;
```

Do not use

```
char *ptr1;
char *ptr2;
UINT32 bufLen;

bufLen = ptr2 - ptr1;
```

## alignBytes

Use

```
alignBytes = (unsigned short) ((size_t) address % 16);
```

Do not use

```
void *address;
unsigned short alignBytes;

alignBytes = (unsigned short) ((UINT32) address % 16);
```

## len

Use

```
len = (UINT32) ((char *) address2 - (char *) address1);
```

Do not use

```
void *address1;
void *address2;
UINT32 len;
```

```
len = (UINT32) ((char *) address2 - (char *) address1);
```

## sscanf

### Use

```
MQLONG SBCSpvt;  
sscanf(line, "%d", &SBCSpvt);
```

### Do not use

```
MQLONG SBCSpvt;  
sscanf(line, "%1d", &SBCSpvt);
```

%1d tries to put an 8-byte type into a 4-byte type; only use %l if you are dealing with an actual long data type. MQLONG, UINT32 and INT32 are defined to be four bytes, the same as an int on all IBM MQ platforms:

Application programming for IBM i.

Use this information to help you develop applications for IBM i.

## Deprecation of compatibility mode for RPG and COBOL applications on IBM i

From IBM MQ for IBM i 9.0, the product no longer provides support for RPG or COBOL applications that use dynamic linkage known as compatibility mode. This mode of operation was needed for applications that are written before MQSeries 5.1, and subsequent versions of the product provided a compatible runtime environment for these applications, even though the copybooks needed for compiling them were removed in IBM WebSphere MQ 6.0. Dynamic linkage (compatibility mode) was provided by the following programs in library QMQM, which are removed at IBM MQ for IBM i 9.0:

- AMQVSTUB
- AMQZSTUB
- QMQM
- MQCLOSE
- MQCONN
- MQDISC
- MQGET
- MQINQ
- MQOPEN

- MQPUT
- MQPUT1
- MQSET

From IBM MQ for IBM i 9.0, applications that use this compatibility mode of operation need to be recompiled to use the static bound MQ calls that are provided by the LIBMQM and LIBMQM\_R service programs. Sample programs, such as AMQ3PUT4 and AMQ3GET4, show you how to use this programming model. For more information about using these MQ calls, see [IBM i Application Programming Reference \(ILE/RPG\)](#).

**Notes:**

- You need to recode applications, currently using the CALL 'QMQM' interface, to use the LIBMQM service program instead.

The program objects and service programs in the preceding list, for example, QMQM, MQCONN, MQPUT, AMQVSTUB, and AMQZSTUB, are removed in IBM MQ for IBM i 9.0, and applications that were coded to use compatibility mode cease to work.

- If applications are bound to the LIBMQM service program at IBM MQ for IBM i 8.0, you should not need to recompile or relink those applications at IBM MQ for IBM i 9.0 or later.
- It is not possible to install more than one version of IBM MQ for IBM i on the same partition.

To find out whether your RPG or COBOL program uses compatibility mode, use the **DSPPGMREF** (Display Program References) command to display the external programs called by the application program. If there are references to the programs listed in this section, the program will not run at IBM MQ for IBM i 9.0 or later. The following example of **DSPPGMREF** output shows three program objects that are deprecated, MQCONN, MQOPEN, MQCLOSE:

```

Program . . . . . : MYAPPPGM
Library . . . . . : MYLIB
Text 'description'. . . . . : ILE/COBOL SAMPLE PUT TO QUEUE (MQPUT)
Number of objects referenced . . . . . : 5
Object . . . . . : MQCONN
Library . . . . . : *LIBL
Object type . . . . . : *PGM
Object . . . . . : MQOPEN
Library . . . . . : *LIBL
Object type . . . . . : *PGM
Object . . . . . : MQCLOSE
Library . . . . . : *LIBL
Object type . . . . . : *PGM

```

Such programs must be recompiled using the Bound Procedural Call method described in [Preparing COBOL programs in IBM i](#).

If you attempt to run an application program at IBM MQ for IBM i 9.0 or later that uses compatibility mode, the most commonly seen first error is an MCH3401 trying to call program MQCONN or QMQM.

**IBM i Data type descriptions on IBM i**

This collection of topics provides descriptions of data types used in IBM i programming.

**Conventions used in the description of data types**

For each elementary data type, this information gives a description of its usage, in a form that is independent of the programming language. This is followed by typical declarations in the ILE version of the RPG programming language. The definitions of elementary data types are included here to provide consistency. RPG uses 'D' specifications where working fields can be declared using whatever attributes you need. You can, however, do this in the calculation specifications where the field is used.

To use the elementary data types, you create:

- A /COPY member containing all the data types, or
- An external data structure (PF) containing all the data types. You then need to specify your working fields with attributes 'LIKE' the appropriate data type field.

The benefits of the second option are that the definitions can be used as a 'FIELD REFERENCE FILE' for other IBM i objects. If an IBM MQ data type definition changes, it is a relatively simple matter to re-create these objects.

## Elementary data types

All of the other data types described in this section equate either directly to these elementary data types, or to aggregates of these elementary data types (arrays or structures).

Data type	Representation
MQBOOL	10-digit signed integer
MQBYTE	1-byte alphanumeric field
MQBYTE16	16-byte alphanumeric field
MQBYTE24	24-byte alphanumeric field
MQBYTE32	32-byte alphanumeric field
MQBYTE64	64-byte alphanumeric field
MQCHAR	1-byte alphanumeric field
MQCHAR4	4-byte alphanumeric field
MQCHAR8	8-byte alphanumeric field
MQCHAR12	12-byte alphanumeric field
MQCHAR16	16-byte alphanumeric field
MQCHAR20	20-byte alphanumeric field
MQCHAR28	28-byte alphanumeric field
MQCHAR32	32-byte alphanumeric field
MQCHAR48	48-byte alphanumeric field
MQCHAR64	64-byte alphanumeric field
MQCHAR128	128-byte alphanumeric field
MQCHAR256	256-byte alphanumeric field
MQFLOAT32	4-byte floating-point number
MQFLOAT64	8-byte floating-point number
MQHCONFIG	Configuration handle
MQHCONN	10-digit signed integer
MQHMSG	Message handle that gives access to a message
MQHOBJ	10-digit signed integer
MQINT8	8-bit signed integer
MQINT16	16-bit signed integer
MQINT32	32-bit signed integer

Table 679. Elementary data types (continued)

<b>Data type</b>	<b>Representation</b>
MQINT64	64-bit signed integer
MQLONG	32-bit signed integer
MQPID	Process identifier
MQPTR	Pointer
MQTID	Thread identifier
MQUINT8	8-bit unsigned integer
MQUINT16	16-bit unsigned integer
MQUINT32	32-bit unsigned integer
MQUINT64	64-bit unsigned integer
MQULONG	32-bit unsigned integer
PMQACH	Pointer to a data structure of type MQACH
PMQAIR	Pointer to a data structure of type MQAIR

PMQINT8	Pointer to data of type MQINT8
PMQINT16	Pointer to data of type MQINT16
PMQINT32	Pointer to data of type MQINT32
PMQINT64	Pointer to data of type MQINT64
PMQLONG	Pointer to data of type MQLONG
PMQMD	Pointer to a data structure of type MQMD
PMQMDE	Pointer to a data structure of type MQMDE
PMQMD1	Pointer to a data structure of type MQMD1
PMQMD2	Pointer to a data structure of type MQMD2
PMQMhBO	Pointer to a data structure of type MQMhBO
PMQOD	Pointer to a data structure of type MQOD
PMQOR	Pointer to a data structure of type MQOR
PMQPD	Pointer to a data structure of type MQPD
PMQPID	Pointer to a process identifier MQPID
PMQPMO	Pointer to a data structure of type MQPMO
PMQPTR	Pointer to data of type MQPTR
PMQRFH	Pointer to a data structure of type MQRFH
PMQRFH2	Pointer to a data structure of type MQRFH2
PMQRMH	Pointer to a data structure of type MQRMH
PMQRR	Pointer to a data structure of type MQRR
PMQSCO	Pointer to a data structure of type MQSCO
PMQSD	Pointer to a data structure of type MQSD
PMQSMPO	Pointer to a data structure of type MQSMPO

Table 679. Elementary data types (continued)

Data type	Representation
PMQSRO	Pointer to a data structure of type MQSRO
PMQSTS	Pointer to a data structure of type MQSTS
PMQTID	Pointer to a thread identifier MQTID
PMQTM	Pointer to a data structure of type MQTM
PMQTMCM2	Pointer to a data structure of type MQTMCM2
PMQUINT8	Pointer to data of type MQUINT8
PMQUINT16	Pointer to data of type MQUINT16
PMQUINT32	Pointer to data of type MQUINT32
PMQUINT64	Pointer to data of type MQUINT64
PMQULONG	Pointer to data of type MQULONG
PMQVOID	Pointer
PMQWIH	Pointer to a data structure of type MQWIH
PMQXQH	Pointer to a data structure of type MQXQH

#### IBM i **MQBOOL on IBM i**

The MQBOOL data type represents a boolean value. The value 0 represents false. Any other value represents true.

An MQBOOL must be aligned as for the MQLONG data type.

#### IBM i **MQBYTE on IBM i**

The MQBYTE data type represents a single byte of data.

No particular interpretation is placed on the byte—it is treated as a string of bits, and not as a binary number or character. No special alignment is required.

An array of MQBYTE is sometimes used to represent an area of main storage with a nature that is not known to the queue manager. For example, the area might contain application message data or a structure. The boundary alignment of this area must be compatible with the nature of the data contained within it.

#### IBM i **MQBYTEN (String of *n* bytes) on IBM i**

Each MQBYTEN data type represents a string of *n* bytes.

Where *n* can take one of the following values:

- 16, 24, 32, or 64.

Each byte is described by the MQBYTE data type. No special alignment is required.

If the data in the string is shorter than the defined length of the string, the data must be padded with nulls to fill the string.

When the queue manager returns byte strings to the application (for example, on the MQGET call), the queue manager always pads with nulls to the defined length of the string.

Constants are available that define the lengths of byte string fields.

### **IBM i MQCHAR (character) on IBM i**

The MQCHAR data type represents a single character.

The coded character set identifier of the character is that of the queue manager (see the **CodedCharSetId** attribute in topic [CodedCharSetId](#)). No special alignment is required.

**Note:** Application message data specified on the MQGET, MQPUT, and MQPUT1 calls is described by the MQBYTE data type, not the MQCHAR data type.

### **IBM i MQCHARn (String of n characters) on IBM i**

Each MQCHARn data type represents a string of *n* characters.

Where *n* can take one of the following values:

- 4, 8, 12, 16, 20, 28, 32, 48, 64, 128, or 256

Each character is described by the MQCHAR data type. No special alignment is required.

If the data in the string is shorter than the defined length of the string, the data must be padded with blanks to fill the string. In some cases a null character can be used to end the string prematurely, instead of padding with blanks; the null character and characters following it are treated as blanks, up to the defined length of the string. The places where a null can be used are identified in the call and data type descriptions.

When the queue manager returns character strings to the application (for example, on the MQGET call), the queue manager always pads with blanks to the defined length of the string; the queue manager does not use the null character to delimit the string.

Constants are available that define the lengths of character string fields.

### **IBM i MQFLOAT32 on IBM i**

The MQFLOAT32 data type is a 32-bit floating-point number represented using the standard IEEE floating-point format.

An MQFLOAT32 must be aligned on a 4-byte boundary.

### **IBM i MQFLOAT64 on IBM i**

The MQFLOAT64 data type is a 64-bit floating-point number represented using the standard IEEE floating-point format.

An MQFLOAT64 must be aligned on an 8-byte boundary.

### **MQHCONFIG - configuration handle**

The MQHCONFIG data type represents a configuration handle, that is, the component that is being configured for a particular installable service. A configuration handle must be aligned on its natural boundary.

**Note:** Applications must test variables of this type for equality only.

### **IBM i MQHCONN (Connection handle) on IBM i**

The MQHCONN data type represents a connection handle, that is, the connection to a particular queue manager.

A connection handle must be aligned on its natural boundary.

**Note:** Applications must test variables of this type for equality only.

### **IBM i MQHMSG (Message handle) on IBM i**

The MQHMSG data type represents a message handle that gives access to a message.

A message handle must be aligned on an 8-byte boundary.

**Note:** Applications must test variables of this type for equality only.

### **IBM i MQHOBJ (Object handle) on IBM i**

The MQHOBJ data type represents an object handle that gives access to an object.

An object handle must be aligned on its natural boundary.

**Note:** Applications must test variables of this type for equality only.

### **IBM i MQINT8 (8-bit signed integer) on IBM i**

The MQINT8 data type is an 8-bit signed integer that can take any value in the range -128 to +127, unless otherwise restricted by the context.

### **IBM i MQINT16 (16-bit signed integer) on IBM i**

The MQINT16 data type is a 16-bit signed integer that can take any value in the range -32 768 to +32 767, unless otherwise restricted by the context.

An MQINT16 must be aligned on a 2-byte boundary.

### **IBM i MQINT32 (32-bit integer) on IBM i**

The MQINT32 data type is a 32-bit signed integer.

It is equivalent to MQLONG.

### **IBM i MQINT64 (64-bit integer) on IBM i**

The MQINT64 data type is a 64-bit signed integer that can take any value in the range -9 223 372 036 854 775 808 through +9 223 372 036 854 775 807, unless otherwise restricted by the context.

For COBOL, the valid range is limited to -999 999 999 999 999 999 through +999 999 999 999 999 999. An MQINT64 should be aligned on an 8-byte boundary.

### **IBM i MQLONG (Long integer) on IBM i**

The MQLONG data type is a 32-bit signed binary integer that can take any value in the range -2 147 483 648 through +2 147 483 647, unless otherwise restricted by the context, aligned on its natural boundary.

### **MQPID - process identifier**

The IBM MQ process identifier.

This is the same identifier used in IBM MQ trace and FFST dumps, but might be different from the operating system process identifier.

### **MQPTR - pointer**

The MQPTR data type is the address of data of any type. A pointer must be aligned on its natural boundary; this is a 16-byte boundary on IBM i.

Some programming languages support typed pointers; the MQI also uses these in a few cases.

### **MQTID - thread identifier**

The MQ thread identifier.

This is the same identifier used in MQ trace and FFST dumps, but might be different from the operating system thread identifier.

***MQUINT8 (8-bit unsigned integer) on IBM i***

The MQUINT8 data type is an 8-bit unsigned integer that can take any value in the range 0 to +255, unless otherwise restricted by the context.

***MQUINT16 - 16-bit unsigned integer***

The MQUINT16 data type is a 16-bit unsigned integer that can take any value in the range 0 through +65 535, unless otherwise restricted by the context.

An MQUINT16 must be aligned on a 2-byte boundary.

***MQUINT32 (32-bit unsigned integer) on IBM i***

The MQUINT32 data type is a 32-bit unsigned integer. It is equivalent to MQULONG.

***MQUINT64 - 64-bit unsigned integer***

The MQUINT64 data type is a 64-bit unsigned integer that can take any value in the range 0 through +18 446 744 073 709 551 615 unless otherwise restricted by the context.

For COBOL, the valid range is limited to 0 through +999 999 999 999 999 999. An MQUINT64 should be aligned on a 8-byte boundary.

***MQULONG - 32-bit unsigned integer***

The MQULONG data type is a 32-bit unsigned binary integer that can take any value in the range 0 through +4 294 967 294, unless otherwise restricted by the context.

An MQULONG must be aligned on a 4-byte boundary.

***PMQACH - pointer to a data structure of type MQACH***

A pointer to a data structure of type MQACH.

***PMQAIR - pointer to a data structure of type MQAIR***

A pointer to a data structure of type MQAIR.

***PMQAXC - pointer to a data structure of type MQAXC***

A pointer to a data structure of type MQAXC.

***PMQAXP - pointer to a data structure of type MQAXP***

A pointer to a data structure of type MQAXP.

***PMQBMHO - pointer to a data structure of type MQBMHO***

A pointer to a data structure of type MQBMHO.

***PMQBO - pointer to a data structure of type MQBO***

A pointer to a data structure of type MQBO.

***PMQBOOL - pointer to data of type MQBOOL***

A pointer to data of type MQBOOL.

A pointer to data of type MQBOOL.

***PMQBYTE - pointer to a data type of MQBYTE***

A pointer to a data type of MQBYTE.

***PMQBYTEn - pointer to a data structure of type MQBYTEn***

A pointer to a data structure of type MQBYTEn, where n can be 8, 12, 16, 24, 32, 40, 48 or 128.

***PMQCBC - pointer to a data structure of type MQCBC***

A pointer to a data structure of type MQCBC.

***PMQCBD - pointer to a data structure of type MQCBD***

A pointer to a data structure of type MQCBD.

***PMQCHAR - pointer to data of type MQCHAR***

A pointer to data of type MQCHAR.

***PMQCHARV - pointer to a data structure of type MQCHARV***

A pointer to a data structure of type MQCHARV.

***PMQCHARn - pointer to a data type of MQCHARn***

A pointer to a data type of MQCHARn, where n can be 4, 8, 12, 20, 28, 32, 64, 128, 256, 264.

***PMQCIH - pointer to a data structure of type of MQCIH***

A pointer to a data structure of type of MQCIH.

***PMQCMHO - pointer to a data structure of type MQCMHO***

A pointer to a data structure of type MQCMHO.

***PMQCNO - pointer to a data structure of type of MQCNO***

A pointer to a data structure of type of MQCNO.

***PMQCSP - pointer to a data structure of type MQCSP***

A pointer to a data structure of type MQCSP.

***PMQCTLO - pointer to a data structure of type MQCTLO***

A pointer to a data structure of type MQCTLO.

***PMQDH - pointer to a data structure of type MQDH***

A pointer to a data structure of type MQDH.

***PMQDHO - pointer to a data structure of type MQDHO***

A pointer to a data structure of type MQDHO.

***PMQDLH - pointer to a data structure of type of MQDLH***

A pointer to a data structure of type of MQDLH.

***PMQDMHO - pointer to a data structure of type MQDMHO***

A pointer to a data structure of type MQDMHO.

***PMQDMPO - pointer to a data structure of type MQDMPO***

A pointer to a data structure of type MQDMPO.

A pointer to a data structure of type MQDMPO.

***PMQEPPH - pointer to a data structure of type MQEPPH***

A pointer to a data structure of type MQEPPH.

***PMQFLOAT32 - pointer to data of type MQFLOAT32***

A pointer to data of type MQFLOAT32.

***PMQFLOAT64 - pointer to data of type MQFLOAT64***

A pointer to data of type MQFLOAT64.

***PMQFUNC - pointer to a function***

A pointer to a function.

***PMQGMPO - pointer to a data structure of type MQGMPO***

A pointer to a data structure of type MQGMPO.

***PMQHCONFIG - pointer to a data type of MQHCONFIG***

A pointer to a data type of MQHCONFIG.

***PMQHCONN - pointer to a data type of MQHCONN***

A pointer to a data type of MQHCONN.

***PMQHMSG - pointer to a data type of MQHMSG***

A pointer to a data type of MQHMSG.

***PMQHOBJ - pointer to data of type MQHOBJ***

A pointer to data of type MQSMPO.

***PMQIIH - pointer to a data structure of type MQIIH***

A pointer to a data structure of type MQIIH.

***PMQIMPO - pointer to a data structure of type MQIMPO***

A pointer to a data structure of type MQIMPO.

***PMQINT8 - pointer to data of type MQINT8***

A pointer to data of type MQINT8.

***PMQINT16 - pointer to data of type MQINT16***

A pointer to data of type MQINT16.

***IBM i PMQINT32 (Pointer to data of type MQINT32) on IBM i***

The PMQINT32 data type is a pointer to data of type MQINT32. It is equivalent to PMQLONG.

***IBM i PMQINT64 (Pointer to data of type MQINT64) on IBM i***

The PMQINT64 data type is a pointer to data of type MQINT64.

***PMQLONG - pointer to data of type MQLONG***

A pointer to data of type MQLONG.

***PMQMD - pointer to structure of type MQMD***

A pointer to structure of type MQMD.

***PMQMDE - pointer to a data structure of type MQMDE***

A pointer to a data structure of type MQMDE.

***PMQM DI - pointer to a data structure of type MQMDI***

A pointer to a data structure of type MQMDI.

***PMQM D2 - pointer to a data structure of type MQMD2***

A pointer to a data structure of type MQMD2.

***PMQM HBO - pointer to a data structure of type MQM HBO***

A pointer to a data structure of type MQM HBO.

***PMQ OD - pointer to a data structure of type MQ OD***

A pointer to a data structure of type MQ OD.

***PMQ OR - pointer to a data structure of type MQ OR***

A pointer to a data structure of type MQ OR.

***PMQ PD - pointer to a data structure of type MQ PD***

A pointer to a data structure of type MQ PD.

***PMQ PID - pointer to a process identifier***

A pointer to a process identifier.

***PMQ PMO - pointer to a data structure of type MQ PMO***

A pointer to a data structure of type MQ PMO.

***PMQ PTR - pointer to data of type MQ PTR***

A pointer to data of type MQ PTR.

***PMQ RFH - pointer to a data structure of type MQ RFH***

A pointer to a data structure of type MQ RFH.

***PMQ RFH2 - pointer to a data structure of type MQ RFH2***

A pointer to a data structure of type MQ RFH2.

.

***PMQ RMH - pointer to a data structure of type MQ RMH***

A pointer to a data structure of type MQ RMH.

***PMQRR - pointer to a data structure of type MQRR***

A pointer to a data structure of type MQRR.

***PMQSCO - pointer to a data structure of type MQSCO***

A pointer to a data structure of type MQSCO.

***PMQSD - pointer to a data structure of type MQSD***

A pointer to a data structure of type MQSD.

***PMQSMPO - pointer to a data structure of type MQSMPO***

A pointer to a data structure of type MQSMPO.

***PMQSRO - pointer to a data structure of type MQSRO***

A pointer to a data structure of type MQSRO.

***PMQSTS - pointer to a data structure of type MQSTS***

A pointer to a data structure of type MQSTS.

***PMQTID - pointer to a data structure of type MQTID***

A pointer to a data structure of type MQTID.

***PMQTM - pointer to a data structure of type MQTM***

A pointer to a data structure of type MQTM.

***PMQTM2 - pointer to a data structure of type MQTM2***

A pointer to a data structure of type MQTM2.

***PMQUINT8 - pointer to data of type MQUINT8***

A pointer to data of type MQUINT8.

***PMQUINT16 - pointer to data of type MQUINT16***

A pointer to data of type MQUINT16.

***IBM i PMQUINT32 (Pointer to data of type MQUINT32) on IBM i***

The PMQUINT32 data type is a pointer to data of type MQUINT32. It is equivalent to PMQLONG.

The PMQUINT64 data type is a pointer to data of type MQUINT64.

**PMQULONG - pointer to data of type MQULONG**

A pointer to data of type MQULONG.

**PMQVOID - pointer**

A pointer.

**PMQWIH - pointer to a data structure of type MQWIH**

A pointer to a data structure of type MQWIH.

**PMQXQH - pointer to a data structure of type MQXQH**

A pointer to a data structure of type MQXQH.

**Language considerations**

This topic contains information to help you use the MQI from the RPG programming language.

Some of these language considerations are:

- [“COPY files” on page 1010](#)
- [“Calls” on page 1012](#)
- [“Call parameters” on page 1012](#)
- [“Structures” on page 1012](#)
- [“Named constants” on page 1013](#)
- [“MQI procedures” on page 1013](#)
- [“Threading considerations” on page 1013](#)
- [“Commitment control” on page 1013](#)
- [“Coding the bound calls” on page 1013](#)
- [“Notational conventions” on page 1015](#)

**COPY files**

Various COPY files are provided to assist with the writing of RPG application programs that use message queuing. There are three sets of COPY files:

- COPY files with names ending with the letter *G* are for use with programs that use static linkage. These files are initialized with the exceptions stated in [“Structures” on page 1012](#).
- COPY files with names ending with the letter *H* are for use with programs that use static linkage, but are **not** initialized.
- COPY files with names ending with the letter *R* are for use with programs that use dynamic linkage. These files are initialized with the exceptions stated in [“Structures” on page 1012](#).

The COPY files reside in QRPGLSRC in the QMQM library.

For each set of COPY files, there are two files containing named constants, and one file for each of the structures. The COPY files are summarized in [Table 680 on page 1011](#).

Table 680. RPG COPY files

File name (static linkage, initialized, CMQ*G)	File name (static linkage, not initialized, CMQ*H)	File name (dynamic linkage, initialized, CMQ*R)	Contents
CMQBOG	CMQBOH	-	Begin options structure
CMQCDG	CMQCDH	CMQCDR	Channel definition structure
CMQCFBFG	CMQCFBFH	-	PCF bit filter parameter
CMQCFG	-	-	Constants for PCF and events
CMQCFBSG	CMQCFBSH	-	PCF byte string
CMQCFGRG	CMQCFGRH	-	PCF group parameter
CMQCFIFG	CMQCFIFH	-	PCF integer filter parameter
CMQCFHG	CMQCFHH	-	PCF header
CMQCFILG	CMQCFILH	-	PCF integer list parameter structure
CMQCFING	CMQCFINH	-	PCF integer parameter structure
CMQCFSG	CMQCFSFH	-	PCF string filter parameter
CMQCFSLG	CMQCFSLH	-	PCF string list parameter structure
CMQCFSTG	CMQCFSTH	-	PCF string parameter structure
CMQCFXLG	CMQCFXLH	-	PCF short name for CFIL64
CMQCFXNG	CMQCFXNH	-	PCF short name for CFIN64
CMQCIHG	CMQCIHH	-	CICS information header structure
CMQCNOG	CMQCNOH	-	Connect options structure
CMQCSPG	CMQCSPH	-	Security parameters
CMQCXPG	CMQCXPH	CMQCXPR	Channel exit parameter structure
CMQDHG	CMQDHH	CMQDHR	Distribution header structure
CMQDLHG	CMQDLHH	CMQDLHR	Dead letter header structure
CMQDXPG	CMQDXPH	CMQDXPR	Data conversion exit parameter structure
CMQEPHG	CMQEPHH	-	Embedded PCF header structure
CMQG	-	CMQR	Named constants for main MQI
CMQGMOG	CMQGMOH	CMQGMOR	Get message options structure
CMQIIHG	CMQIIHH	CMQIIHR	IMS information header structure
CMQMDEG	CMQMDEH	CMQMDER	Message descriptor extension structure
CMQMDG	CMQMDH	CMQMDR	Message descriptor structure
CMQMD1G	CMQMD1H	CMQMD1R	Message descriptor structure version 1
CMQMD2G	CMQMD2H	-	Message descriptor structure version 2
CMQODG	CMQODH	CMQODR	Object descriptor structure
CMQORG	CMQORH	CMQORR	Object record structure

Table 680. RPG COPY files (continued)

File name (static linkage, initialized, CMQ*G)	File name (static linkage, not initialized, CMQ*H)	File name (dynamic linkage, initialized, CMQ*R)	Contents
CMQPMOG	CMQPMOH	CMQPMOR	Put message options structure
CMQPSG	-	-	Constants for publish/subscribe
CMQRFHG	CMQRFHH	-	Rules and formatting header structure
CMQRFH2G	CMQRFH2H	-	Rules and formatting header 2 structure
CMQRMHG	CMQRMHH	CMQRMHR	Reference message header structure
CMQRRG	CMQRRH	CMQRRR	Response record structure
CMQTMCG	CMQTMCH	CMQTMCR	Trigger message structure (character format)
CMQTMCG2G	CMQTMCG2H	CMQTMCG2R	Trigger message structure (character format) version 2
CMQTMG	CMQTMH	CMQTMR	Trigger message structure
CMQWIHG	CMQWIHH	-	Work information header structure
CMQXG	-	CMQXR	Named constants for data conversion exit
CMQXQHG	CMQXQHH	CMQXQHR	Transmission queue header structure

## Calls

Calls are described using their individual names.

## Call parameters

Some parameters passed to the MQI can have more than one concurrent function. This is because the integer value passed is often tested on the setting of individual bits within the field, and not on its total value. This allows you to 'add' several functions together and pass them as a single parameter.

## Structures

All IBM MQ structures are defined with initial values for the fields, with the following exceptions:

- Any structure with a suffix of H.
- MQTMC
- MQTMC2

These initial values are defined in the relevant table for each structure.

The structure declarations do not contain DS statements. This allows the application to declare either a single data structure or a multiple-occurrence data structure, by coding the DS statement and then using the /COPY statement to copy in the remainder of the declaration:

```
D*..1.....2.....3.....4.....5.....6.....7
D* Declare an MQMD data structure with 5 occurrences
DMYMD      DS              5
D/COPY CMQMDR
```

## Named constants

There are many integer and character values that provide data interchange between your application program and the queue manager. To facilitate a more readable and consistent approach to using these values, named constants are defined for them. You can use these named constants and not the values they represent, as this improves the readability of the program source code.

When the COPY file CMQG is included in a program to define the constants, the RPG compiler will issue many severity-zero messages for the constants that are not used by the program; these messages are benign, and can safely be ignored.

## MQI procedures

When using the ILE bound calls, you must bind to the MQI procedures when you create your program. These procedures are exported from the following service programs as appropriate:

### QMQM/LIBMQM

This service program contains the single-threaded bindings for version 5.1 and above. See the following section for special considerations when writing threaded applications.

### QMQM/LIBMQM\_R

This service program contains the multi-threaded bindings for version 5.1 and above. See the following section for special considerations when writing threaded applications.

### QMQM/LIBMQIC

This service program is for binding non-threaded client applications.

### QMQM/LIBMQIC\_R

This service program is for binding threaded client applications.

Use the CRTPGM command to create your programs. For example, the following command creates a single-threaded program that uses the ILE bound calls:

```
CRTPGM PGM(MYPROGRAM) BNDSRVPGM(QMQM/LIBMQM)
```

## Threading considerations

The RPG compiler used for IBM i is part of the WebSphere Development Toolset and WebSphere Development Studio for IBM i and is known as the ILE RPG IV Compiler.

In general, RPG programs should not use the multi-threaded service programs. Exceptions are RPG programs created using the ILE RPG IV Compiler, and containing the THREAD(\*SERIALIZE) keyword in the control specification. However, even though these programs are thread safe, careful consideration must be given to the overall application design, as THREAD(\*SERIALIZE) forces serialization of RPG procedures at the module level, and this might have an adverse affect on overall performance.

Where RPG programs are used as data-conversion exits, they must be made thread-safe, and should be recompiled using the version 4.4 ILE RPG compiler or above, with THREAD(\*SERIALIZE) specified in the control specification.

For further information about threading, see the *IBM i IBM MQ Development Studio: ILE RPG Reference*, and the *IBM i IBM MQ Development Studio: ILE RPG Programmer's Guide*.

## Commitment control

The MQI syncpoint functions MQCMIT and MQBACK are available to ILE RPG programs running in normal mode; these calls allow the program to commit and back out changes to MQ resources.

## Coding the bound calls

MQI ILE procedures are listed in [Table 681 on page 1014](#).

Table 681. ILE RPG bound calls supported by each service program

Name of call	LIBMQM and LIBMQM_R	LIBMQIC and LIBMQIC_R
MQBACK	Y	Y
MQBEGIN	Y	Y
MQCMIT	Y	Y
MQCLOSE	Y	Y
MQCONN	Y	Y
MQCONNX	Y	Y
MQDISC	Y	Y
MQGET	Y	Y
MQINQ	Y	Y
MQOPEN	Y	Y
MQPUT	Y	Y
MQPUT1	Y	Y
MQSET	Y	Y
MQXCNVC	Y	Y

To use these procedures you need to:

1. Define the external procedures in your 'D' specifications. These are all available within the COPY file member CMQG containing the named constants.
2. Use the CALLP operation code to call the procedure along with its parameters.

For example the MQOPEN call requires the inclusion of the following code:

```

D*****
D** MQOPEN Call -- Open Object (From COPY file CMQG) **
D*****
D*
D*.1....:....2....:....3....:....4....:....5....:....6....:....7..
DMQOPEN PR EXTPROC('MQOPEN')
D* Connection handle
D HCONN 10I 0 VALUE
D* Object descriptor
D OBJDSC 224A
D* Options that control the action of MQOPEN
D OPTS 10I 0 VALUE
D* Object handle
D HOBJ 10I 0
D* Completion code
D CMPCOD 10I 0
D* Reason code qualifying CMPCOD
D REASON 10I 0
D*
    
```

To call the procedure, after initializing the various parameters, you need the following code:

```

...+... 1 ...+... 2 ...+... 3 ...+... 4 ...+... 5 ...+... 6 ...+... 7 ...+... 8
C CALLP MQOPEN(HCONN : MQOD : OPTS : HOBJ :
C CMPCOD : REASON)
    
```

Here, the structure MQOD is defined using the COPY member CMQODG which breaks it down into its components.

## Notational conventions

The latter topics in this section show how the:

- Calls should be invoked
- Parameters should be declared
- Various data types should be declared

In a number of cases, parameters are arrays or character strings with a size that is not fixed. For these, a lowercase "n" is used to represent a numeric constant. When the declaration for that parameter is coded, the "n" must be replaced by the numeric value required.

## MQAIR (Authentication information record) on IBM i

The MQAIR structure represents the authentication information record.

### Overview

**Purpose:** The MQAIR structure allows an application running as an IBM MQ client to specify information about an authenticator that is to be used for the client connection. The structure is an input parameter on the MQCONN call.

**Character set and encoding:** Data in MQAIR must be in the character set given by the **CodedCharSetId** queue manager attribute and encoding of the local queue manager given by ENNAT.

- [“Fields” on page 1015](#)
- [“Initial values” on page 1017](#)
- [“RPG declaration” on page 1017](#)

### Fields

The MQAIR structure contains the following fields; the fields are described in **alphabetical order**:

#### AICN (10-digit signed integer)

This is either the host name or the network address of a host on which the LDAP server is running. This can be followed by an optional port number, enclosed in parentheses.

If the value is shorter than the length of the field, terminate the value with a null character, or pad it with blanks to the length of the field. If the value is not valid, the call fails with reason code RC2387.

The default port number is 389.

This is an input field. The length of this field is given by LNAICN. The initial value of this field is blank characters.

#### AITYP (10-digit signed integer)

This is the type of authentication information contained in the record.

The value must be:

##### AITLDP

Certificate revocation using LDAP server.

If the value is not valid, the call fails with reason code RC2386.

This is an input field. The initial value of this field is AITLDP.

#### AIPW (10-digit signed integer)

This is the password needed to access the LDAP CRL server.

If the value is shorter than the length of the field, terminate the value with a null character, or pad it with blanks to the length of the field. If the LDAP server does not require a password, or you omit the

LDAP user name, *AIPW* must be null or blank. If you omit the LDAP user name and *AIPW* is not null or blank, the call fails with reason code RC2390.

This is an input field. The length of this field is given by *LNLDPW*. The initial value of this field blank characters.

#### **AILUL (10-digit signed integer)**

This is the length in bytes of the LDAP user name addressed by the *AILUP* or *AILUO* field. The value must be in the range zero through *LNDISN*. If the value is not valid, the call fails with reason code RC2389.

If the LDAP server involved does not require a user name, set this field to zero.

This is an input field. The initial value of this field is 0.

#### **AILUO (10-digit signed integer)**

This is the offset in bytes of the LDAP user name from the start of the *MQAIR* structure.

The offset can be positive or negative. The field is ignored if *LDAPUserNameLength* is zero.

You can use either *LDAPUserNamePtr* or *LDAPUserNameOffset* to specify the LDAP user name, but not both; see the description of the *LDAPUserNamePtr* field for details.

This is an input field. The initial value of this field is 0.

#### **AILUP (10-digit signed integer)**

This is the LDAP user name.

It consists of the Distinguished Name of the user who is attempting to access the LDAP CRL server. If the value is shorter than the length specified by *AILUL*, terminate the value with a null character, or pad it with blanks to the length *AILUL*. The field is ignored if *AILUL* is zero.

You can supply the LDAP user name in one of two ways:

- By using the pointer field *AILUP*

In this case, the application can declare a string that is separate from the *MQAIR* structure, and set *AILUP* to the address of the string.

Consider using *AILUP* for programming languages that support the pointer data type in a fashion that is portable to different environments (for example, the C programming language).

- By using the offset field *AILUO*

In this case, the application must declare a compound structure containing the *MQSCO* structure followed by the array of *MQAIR* records followed by the LDAP user name strings, and set *AILUO* to the offset of the appropriate name string from the start of the *MQAIR* structure. Ensure that this value is correct, and has a value that can be accommodated within an *MLONG* (the most restrictive programming language is COBOL, for which the valid range is -999 999 999 through +999 999 999).

Consider using *AILUO* for programming languages that do not support the pointer data type, or that implement the pointer data type in a fashion that might not be portable to different environments (for example, the COBOL programming language).

Whichever technique is chosen, use only one of *AILUP* and *AILUO*; the call fails with reason code RC2388.

This is an input field. The initial value of this field is the null pointer in those programming languages that support pointers, and an all-null byte string otherwise.

**Note:** On platforms where the programming language does not support the pointer data type, this field is declared as a byte string of the appropriate length.

#### **AISID (10-digit signed integer)**

The value must be:

### **AISIDV**

Identifier for the authentication information record.

This is always an input field. The initial value of this field is AISIDV.

### **AIVER (10-digit signed integer)**

The value must be:

#### **AIVER1**

Version-1 authentication information record.

The following constant specifies the version number of the current version:

#### **AIVERC**

Current version of authentication information record.

This is always an input field. The initial value of this field is AIVER1.

## **Initial values**

Field name	Name of constant	Value of constant
<i>AISID</i>	AISIDV	'AIR↵'
<i>AIVER</i>	AIVERC	1
<i>AITYP</i>	AITLDP	1
<i>AICN</i>	None	Null string or blanks
<i>AILUP</i>	None	Null pointer or null bytes
<i>AILUO</i>	None	0
<i>AILUL</i>	None	0
<i>AIPW</i>	None	Null string or blanks

### **Notes:**

1. The symbol ↵ represents a single blank character.

## **RPG declaration**

```
D*..1.....2.....3.....4.....5.....6.....7..
D* MQAIR Structure
D*
D* Structure identifier
D AISID          1      4    INZ('AIR ')
D* Structure version number

```

Structure defining the buffer to message handle options.

## Overview

**Purpose:** The MQBMHO structure allows applications to specify options that control how message handles are produced from buffers. The structure is an input parameter on the MQBUFMH call.

**Character set and encoding:** Data in MQBMHO must be in the character set of the application and encoding of the application (ENNAT).

- [“Fields” on page 1018](#)
- [“Initial values” on page 1019](#)
- [“RPG declaration” on page 1019](#)

## Fields

The MQBMHO structure contains the following fields; the fields are described in **alphabetical order**:

### **BMSID (10-digit signed integer)**

Buffer to message handle structure - StrucId field.

This is the structure identifier. The value must be:

#### **BMSIDV**

Identifier for buffer to message handle structure.

This is always an input field. The initial value of this field is BMSIDV.

### **BMVER (10-digit signed integer)**

Buffer to message handle structure - Version field.

This is the structure version number. The value must be:

#### **BMVER1**

Version number for buffer to message handle structure.

The following constant specifies the version number of the current version:

#### **BMVERVC**

Current version of buffer to message handle structure.

This is always an input field. The initial value of this field is BMVER1.

### **BMOPT (10-digit signed integer)**

Buffer to message handle structure - Options field.

The value can be:

#### **BMDLPR**

Properties that are added to the message handle are deleted from the buffer. If the call fails no properties are deleted.

Default options: If you do not need the option described, use the following option:

#### **BMNONE**

No options specified.

This is always an input field. The initial value of this field is BMDLPR.

## Initial values

Field name	Name of constant	Value of constant
<i>BMSID</i>	BMSIDV	'BMHO'
<i>BMVER</i>	BMVER1	1
<i>BMOPT</i>	BMNONE	0

## RPG declaration

```
D* MQBMHO Structure
D*
D*
D* Structure identifier
D  BMSID          1      4    INZ('BMHO')
D*
D* Structure version number
D  BMVER          5      8I 0  INZ(1)
D*
D* Options that control the action of MQBUFMH
D  BMOPT          9      12I 0 INZ(1)
```

## IBM i MQBO (Begin options) on IBM i

The MQBO structure allows the application to specify options relating to the creation of a unit of work.

### Overview

**Purpose:** The structure is an input/output parameter on the MQBEGIN call.

**Character set and encoding:** Data in MQBO must be in the character set given by the **CodedCharSetId** queue manager attribute and encoding of the local queue manager given by ENNAT.

- [“Fields” on page 1019](#)
- [“Initial values” on page 1020](#)
- [“RPG declaration” on page 1020](#)

### Fields

The MQBO structure contains the following fields; the fields are described in **alphabetical order**:

#### **BOOPT (10-digit signed integer)**

Options that control the action of MQBEGIN.

The value must be:

##### **BONONE**

No options specified.

This is always an input field. The initial value of this field is BONONE.

#### **BOSID (4-byte character string)**

Structure identifier.

The value must be:

##### **BOSIDV**

Identifier for begin-options structure.

This is always an input field. The initial value of this field is BOSIDV.

## BOVER (10-digit signed integer)

Structure version number.

The value must be:

### BOVER1

Version number for begin-options structure.

The following constant specifies the version number of the current version:

### BOVERC

Current version of begin-options structure.

This is always an input field. The initial value of this field is BOVER1.

## Initial values

Field name	Name of constant	Value of constant
BOSID	BOSIDV	'B0  ' (with two blank characters)
BOVER	BOVER1	1
BOOPT	BONONE	0

### Notes:

1. The symbol represents a single blank character.

## IBM i MQCBC (Callback context) on IBM i

Structure describing the callback routine.

### Overview

#### Purpose

The MQCBC structure is used to specify context information that is passed to a callback function.

The structure is an input/output parameter on the call to a message consumer routine.

#### Version

The current version of MQCBC is CBCV2.

#### Character set and encoding

Data in MQCBC is in the character set given by the **CodedCharSetId** queue manager attribute and encoding of the local queue manager given by ENNAT. However, if the application is running as an IBM MQ client, the structure is in the character set and encoding of the client.

- [“Fields” on page 1021](#)
- [“Initial values” on page 1026](#)

- [“RPG declaration” on page 1026](#)

## Fields

The MQCBC structure contains the following fields; the fields are described in alphabetical order:

### **CBCBUFFLEN (10 digit signed integer)**

The buffer can be larger than both the MaxMsgLength value defined for the consumer and the ReturnedLength value in the MQGMO.

Callback context structure - BufferLength field.

This is the length in bytes of the message buffer that has been passed to this function.

The actual message length is supplied in [DataLength](#) field.

The application can use the entire buffer for its own purposes for the duration of the callback function.

This is an input field to the message consumer function; it is not relevant to an exception handler function.

### **CBCCALLBA (10 digit signed integer)**

Callback context structure - CallbackArea field.

This is a field that is available for the callback function to use.

The queue manager makes no decisions based on the contents of this field and it is passed unchanged from the [CBDCALLBA](#) field in the MQCBD structure, which is a parameter on the MQCB call used to define the callback function.

Changes to the *CBCCALLBA* are preserved across the invocations of the callback function for an *CBCHOBJ*. This field is not shared with callback functions for other handles.

This is an input/output field to the callback function. The initial value of this field is a null pointer or null bytes.

### **CBCCALLT (10 digit signed integer)**

Callback Context structure - CallType field.

Field containing information about why this function has been called. The following call types are defined.

Message delivery call types: These call types contain information about a message. The **CBCCLEN** and **CBCBUFFLEN** parameters are valid for these call types.

#### **CBCTMR**

The message consumer function has been invoked with a message that has been destructively removed from the object handle.

If the value of *CBCCC* is CCWARN, the value of the *Reason* field is RC2079 or one of the codes indicating a data conversion problem.

#### **CBCTMN**

The message consumer function has been invoked with a message that has not yet been destructively removed from the object handle. The message can be destructively removed from the object handle using the *MsgToken*.

The message might not have been removed because:

- The MQGMO options requested a browse operation, GMBR\*
- The message is larger than the available buffer and the MQGMO options do not specify *gmtm*

If the value of *CBCCC* is CCWARN, the value of the *Reason* field is RC2080 or one of the codes indicating a data conversion problem.

Callback control call types: These call types contain information about the control of the callback and do not contain details about a message. These call types are requested using `CBDLOPT` in the MQCBD structure.

The **CBCLLEN** and **CBCBUFFLEN** parameters are not valid for these call types.

#### **CBCTRC**

The purpose of this call type is to allow the callback function to perform some initial setup.

The callback function is invoked immediately after the callback is registered, that is, upon return from an MQCB call using a value for the *Operation* field of CBREG.

This call type is used both for message consumers and event handlers.

If requested, this is the first invocation of the callback function.

The value of the *CBCREA* field is RCNONE.

#### **CBCTSC**

The purpose of this call type is to allow the callback function to perform some setup when it is started, for example, reinstating resources that were cleaned up when it was previously stopped.

The callback function is invoked when the connection is started using either CTLSR or CTLSW.

If a callback function is registered within another callback function, this call type is invoked when the callback returns.

This call type is used for message consumers only.

The value of the *CBCREA* field is RCNONE.

#### **CBCTTC**

The purpose of this call type is to allow the callback function to perform some cleanup when it is stopped for a while, for example, cleaning up additional resources that have been acquired during the consuming of messages.

The callback function is invoked when an MQCTL call is issued using a value for the *Operation* field of CTLSP.

This call type is used for message consumers only.

The value of the *CBCREA* field is set to indicate the reason for stopping.

#### **CBCTDC**

The purpose of this call type is to allow the callback function to perform final cleanup at the end of the consume process. The callback function is invoked when the:

- Callback function is deregistered using an MQCB call with BCUNR.
- Queue is closed, causing an implicit deregister. In this instance the callback function is passed HOUNUH as the object handle.
- MQDISC call completes - causing an implicit close and, therefore, a deregister. In this case the connection is not disconnected immediately, and any ongoing transaction is not yet committed.

If any of these actions are taken inside the callback function itself, the action is invoked once the callback returns.

This call type is used both for message consumers and event handlers.

If requested, this is the last invocation of the callback function.

The value of the *CBCREA* field is set to indicate the reason for stopping.

#### **CBCTEC**

##### **Event handler function**

The event handler function has been invoked without a message when:

- An MQCTL call is issued with a value for the *Operation* field of CTLSP, or
- The queue manager or connection stops or quiesces.

This call can be used to take appropriate action for all callback functions.

- **Message consumer function**

The message consumer function has been invoked without a message when an error (*CBCCC* = *CCFAIL*) has been detected that is specific to the object handle; for example *CBCREA* code = *RC2016* .

The value of the *CBCREA* field is set to indicate the reason for the call.

This is an input field. *CBCTMR* and *CMCTMN* are applicable only to message consumer functions.

### **CBCCC (10 digit signed integer)**

Callback context structure - *CompCode* field.

This is the completion code. It indicates whether there were any problems consuming the message; it is one of the following:

#### **CCOK**

Successful completion

#### **CCWARN**

Warning (partial completion)

#### **CCFAIL**

Call failed

This is an input field. The initial value of this field is *CCOK*.

### **CBCCONNAREA (10 digit signed integer)**

Callback context structure - *ConnectionArea* field.

This is a field that is available for the callback function to use.

The queue manager makes no decisions based on the contents of this field and it is passed unchanged from the *ConnectionArea* field in the *MQCTLO* structure, which is a parameter on the *MQCTL* call used to control the callback function.

Any changes made to this field by the callback functions are preserved across the invocations of the callback function. This area can be used to pass information that is to be shared by all callback functions. Unlike *CallbackArea*, this area is common across all callbacks for a connection handle.

This is an input and output field. The initial value of this field is a null pointer or null bytes.

### **CBCLLEN (10 digit signed integer)**

This is the length in bytes of the application data in the message. If the value is zero, it means that the message contains no application data.

The *CBCLLEN* field contains the length of the message but not necessarily the length of the message data passed to the consumer. It could be that the message was truncated. Use the *GMRL* field in the *MQGMO* to determine how much data has been passed to the consumer.

If the reason code indicates the message has been truncated, you can use the *CBCLLEN* field to determine how large the actual message is. This allows you to determine the size of the buffer required to accommodate the message data, and then issue an *MQCB* call to update the *CBDMML* in the *MQCBD* with an appropriate value.

If the *GMCONV* option is specified, the converted message could be larger than the value returned for *DataLength*. In such cases, the application probably needs to issue an *MQCB* call to update the *CBDMML* in the *MQCBD* to be greater than the value returned by the queue manager for *DataLength*.

To avoid message truncation problems, specify *MaxMsgLength* as *CBDFM*. This causes the queue manager to allocate a buffer for the full message length after data conversion. Be aware, however, that even if this option is specified, it is still possible that sufficient storage is not available to correctly process the request. Applications should always check the returned reason code. For example, if it

is not possible to allocate sufficient storage to convert the message, the messages is returned to the application unconverted.

This is an input field to the message consumer function; it is not relevant to an event handler function.

### **CBCFLG (10 digit signed integer)**

Flags containing information about this consumer.

The following option is defined:

#### **CBCFBE**

This flag can be returned if a previous MQCLOSE call using the COQSC option failed with a reason code of RC2458.

This code indicated that the last read ahead message is being returned and that the buffer is now empty. If the application issues another MQCLOSE call using the COQSC option, it succeeds.

Note, that an application is not guaranteed to be given a message with this flag set, as there might still be messages in the read-ahead buffer that do not match the current selection criteria. In this instance, the consumer function is invoked with the reason code RC2019 .

If the read ahead buffer is empty, the consumer is invoked with the CBCFBE flag and the reason code RC2518.

This is an input field to the message consumer function; it is not relevant to an event handler function.

### **CBCHOBJ (10 digit signed integer)**

Callback context structure - CBCHOBJ field.

For a call to a message consumer, this is the handle for the object relating to the message consumer.

For an event handler, this value is HONONE

The application can use this handle and the message token in the Get Message Options block to get the message if a message has not been removed from the queue.

This is always an input field. The initial value of this field is HOUNUH

### **CBCRCD (10 digit signed integer)**

**CBCRCD** indicates how long the queue manager waits before trying to reconnect. The field can be modified by an event handler to change the delay or stop reconnection altogether.

Use the **CBCRCD** field only if the value of the **Reason** field in the Callback Context is RC2545.

On entry to the event handler the value of **CBCRCD** is the number of milliseconds the queue manager is going to wait before making a reconnection attempt. [Table 685 on page 1024](#) lists the values that you can set to modify the behavior of the queue manager on return from the event handler.

<i>Table 685. CBCRCD values</i>	
<b>Value</b>	<b>Description</b>
-1	Make no more reconnection attempts. An error is returned to the application.
0	Try to reconnect immediately.
>0	Wait for this many milliseconds before trying the connection again.

### **CBCREA (10 digit signed integer)**

Callback context structure - Reason field.

This is the reason code qualifying the CBCCC

This is an input field. The initial value of this field is RCNONE.

### **CBCSTATE (10 digit signed integer)**

An indication of the state of the current consumer. This field is of most value to an application when a nonzero reason code is passed to the consumer function.

You can use this field to simplify application programming because you do not need to code behavior for each reason code.

This is an input field. The initial value of this field is CSNONE

<b>State</b>	<b>Queue manager action</b>	<b>Value of constant</b>
<i>CSNONE</i> This reason code represents a normal call with no additional reason information	None; this is the normal operation.	0
<i>CSSUST</i> These reason codes represent temporary conditions.	The callback routine is called to report the condition and then suspended. After a period the system might attempt the operation again, which can lead to the same condition being raised again.	1
<i>CSSUSU</i> These reason codes represent conditions where the callback needs to act to resolve the condition.	The consumer is suspended and the callback routine is called to report the condition. The callback routine should resolve the condition if possible and either RESUME or close down the connection.	2
<i>CSSUS</i> These reason codes represent failures that prevent further message callbacks.	The queue manager automatically suspends the callback function. If the callback function is resumed it is likely to receive the same reason code again.	3
<i>CSSTOP</i> These reason codes represent the end of message consumption.	Delivered to the exception handler and to callbacks that specified CBDTC. No further messages can be consumed.	4

### **CBCSID (10 digit signed integer)**

Callback context structure - StrucId field.

This is the structure identifier; the value must be:

#### **CBCSI**

Identifier for callback context structure.

This is always an input field. The initial value of this field is CBCSI.

### **CBCVER (10 digit signed integer)**

Callback context structure - Version field.

This is the structure version number; the value must be:

#### **CBCV1**

Version-1 callback context structure.

The following constant specifies the version number of the current version:

#### **CBCCV**

Current version of the callback context structure.

This is always an input field. The initial value of this field is CBCV1.

## Initial values

Table 687. Fields in MQCBC		
Field name	Name of constant	Value of constant
CBCSID	CBCSI	'CBC↵'
CBCVER	CBCV1	1

## IBM i MQCBD (Callback descriptor) on IBM i

Structure specifying the callback function.

### Overview

**Purpose:** The MQCBD structure is used to specify a callback function and the options controlling its use by the queue manager.

The structure is an input parameter on the MQCB call.

**Version:** The current version of MQCBD is CBDV1.

**Character set and encoding:** Data in MQCBD must be in the character set and encoding of the local queue manager; these are given by the **CodedCharSetId** queue manager attribute and ENNAT. However, if the application is running as an IBM MQ MQI client, the structure must be in the character set and encoding of the client.

- [“Fields” on page 1027](#)
- [“Initial values” on page 1031](#)
- [“RPG declaration” on page 1031](#)

### Fields

The MQCBD structure contains the following fields; the fields are described in **alphabetical order**:

#### **CBDCALLBA (10-digit signed integer)**

This is a field that is available for the callback function to use.

The queue manager makes no decisions based on the contents of this field and it is passed unchanged from the [CBCCALLBA](#) field in the MQCBD structure, which is a parameter on the callback function declaration.

The value is used only on an *Operation* having a value CBREG, with no currently defined callback, it does not replace a previous definition.

This is an input and output field to the callback function. The initial value of this field is a null pointer or null bytes.

#### **CBDCALLBF (10-digit signed integer)**

The callback function is invoked as a function call.

Use this field to specify a pointer to the callback function.

You must specify either *CallbackFunction* or *CallbackName*. If you specify both, the reason code RC2486 is returned.

If neither *CallbackName* nor *CallbackFunction* is not set, the call fails with the reason code RC2486.

This option is not supported in the following environments:

- CICS on z/OS

- Programming languages and compilers that do not support function-pointer references

In such situations, the call fails with the reason code RC2486.

This is an input field. The initial value of this field is a null pointer or null bytes.

### **CBDCALLBN (10-digit signed integer)**

The callback function is invoked as a dynamically linked program.

You must specify either *CallbackFunction* or *CallbackName*. If you specify both, the reason code RC2486 is returned.

If either *CallbackName* or *CallbackFunction* is not true, the call fails with the reason code RC2486.

The module is loaded when the first callback routine to use is registered, and unloaded when the last callback routine to use it deregisters.

Except where noted in the following text, the name is left-aligned within the field, with no embedded blanks; the name itself is padded with blanks to the length of the field. In the descriptions that follow, square brackets ([]) denote optional information:

#### **IBMi**

The callback name can be one of the following formats:

- Library "/" Program
- Library "/" ServiceProgram "("FunctionName")"

For example, MyLibrary/MyProgram(MyFunction).

The library name can be \*LIBL. Both the library and program names are limited to a maximum of 10 characters.

#### **AIX and Linux**

The callback name is the name of a dynamically loadable module or library, suffixed with the name of a function residing in that library. The function name must be enclosed in parentheses.

The library name can optionally be prefixed with a directory path:

```
[path]library(function)
```

If the path is not specified the system search path is used.

The name is limited to a maximum of 128 characters.

#### **Windows**

The callback name is the name of a dynamic-link library, suffixed with the name of a function residing in that library. The function name must be enclosed in parentheses. The library name can optionally be prefixed with a directory path and drive:

```
[d:][path]library(function)
```

If the drive and path are not specified the system search path is used.

The name is limited to a maximum of 128 characters.

#### **z/OS**

The callback name is the name of a load module that is valid for specification on the EP parameter of the LINK or LOAD macro.

The name is limited to a maximum of 8 characters.

#### **z/OS CICS**

The callback name is the name of a load module that is valid for specification on the PROGRAM parameter of the EXEC CICS LINK command macro.

The name is limited to a maximum of 8 characters.

The program can be defined as remote using the REMOTESYTEM option of the installed PROGRAM definition or by the dynamic routing program.

The remote CICS region must be connected to IBM MQ if the program is to use IBM MQ API calls. Note, however, that the CBCHOBJ field in the MQCBC structure is not valid in a remote system.

If a failure occurs trying to load *CallbackName*, one of the following error codes is returned to the application:

- RC2495
- RC2496
- RC2497

A message is also written to the error log containing the name of the module for which the load was attempted, and the failing reason code from the operating system.

This is an input field. The initial value of this field is a null string or blanks.

### **CBDCALLBT (10-digit signed integer)**

This is the type of the callback function. The value must be one of:

#### **CBTMC**

Defines this callback as a message consumer function.

A message consumer callback function is called when a message, meeting the selection criteria specified, is available on an object handle and the connection is started.

#### **CBTEH**

Defines this callback as the asynchronous event routine; it is not driven to consume messages for a handle.

*Hobj* is not required on the MQCB call defining the event handler and is ignored if specified.

The event handler is called for conditions that affect the whole message consumer environment. The consumer function is invoked without a message when an event, for example, a queue manager or connection stopping, or quiescing, occurs. It is not called for conditions that are specific to a single message consumer, for example, RC2016.

Events are delivered to the application, regardless of whether the connection is started or stopped, except in the following environments:

- CICS on z/OS environment
- nonthreaded applications

If the caller does not pass one of these values, the call fails with a reason code of RC2483

This is always an input field. The initial value of this field is CBTMC.

### **CBDMML (10-digit signed integer)**

This is the length in bytes of the longest message that can be read from the handle and given to the callback routine. If a message has a longer length, the callback routine receives *MaxMsgLength* bytes of the message, and reason code:

- RC2080 or
- RC2079 if you specified GMATM.

The actual message length is supplied in the “CBCLEN (10 digit signed integer)” on page 1023 field of the MQCBC structure.

The following special value is defined:

#### **CBDFM**

The buffer length is adjusted by the system to return messages without truncation.

If insufficient memory is available to allocate a buffer to receive the message, the system calls the callback function with an RC2071 reason code.

If, for example, you request data conversion, and there is insufficient memory available to convert the message data, the unconverted message is passed to the callback function.

This is an input field. The initial value of the *MaxMsgLength* field is CBDFM.

### **CBDOPT (10-digit signed integer)**

Callback descriptor structure - Options field.

Any one, or all, of the following can be specified. To specify more than one option, either add the values together (do not add the same constant more than once), or combine the values using the bitwise OR operation (if the programming language supports bit operations). Combinations that are not valid are noted; any other combinations are valid.

#### **CBDFQ**

The MQCB call fails if the queue manager is in the quiescing state.

On z/OS, this option also forces the MQCB call to fail if the connection (for a CICS or IMS application) is in the quiescing state.

Specify GMFIQ, in the MQGMO options passed on the MQCB call, to cause notification to message consumers when they are quiescing.

**Control options:** The following options control whether the callback function is called, without a message, when the state of the consumer changes:

#### **CBDRC**

The callback function is invoked with call type CBCTRC

#### **CBDSC**

The callback function is invoked with call type CBCTSC.

#### **CBDTC**

The callback function is invoked with call type CBCTTC.

#### **CBDDC**

The callback function is invoked with call type CBCTDC.

See [“CBCCALLT \(10 digit signed integer\)”](#) on page 1021 for further details about these call types.

**Default option:** If you do not need any of the options described, use the following option:

#### **CBDNO**

Use this value to indicate that no other options have been specified; all options assume their default values.

CBDNO is defined to aid program documentation; it is not intended that this option is used with any other, but as its value is zero, such use cannot be detected.

This is an input field. The initial value of the *Options* field is CBDNO.

### **CBDSID (10-digit signed integer)**

Callback descriptor structure - StrucId field.

This is the structure identifier; the value must be:

#### **CBDSI**

Identifier for callback descriptor structure.

This is always an input field. The initial value of this field is CBDSI.

### **CBDVER (10-digit signed integer)**

Callback descriptor structure - Version field.

This is the structure version number; the value must be:

#### **CBDV1**

Version-1 callback descriptor structure.

The following constant specifies the version number of the current version:

**CBDCV**

Current version of callback descriptor structure.

This is always an input field. The initial value of this field is CBDV1.

**Initial values**

<i>Table 688. Fields in MQCBD</i>

```

Use the MQCHARV structure to describe a variable length string.

## Overview

**Character set and encoding:** Data in the MQCHARV must be in the encoding of the local queue manager that is given by ENNAT and the character set of the VCHRC field within the structure. If the application is running as an IBM MQ MQI client, the structure must be in the encoding of the client. Some character sets have a representation that depends on the encoding. If VCHRC is one of these character sets, the encoding used is the same encoding as that of the other fields in the MQCHARV. The character set identified by VSCCSID can be a double-byte character set (DBCS).

**Usage:** The MQCHARV structure addresses data that might be discontinuous with the structure containing it. To address this data, fields declared with the pointer data type can be used.

- [“Fields” on page 1032](#)
- [“Initial values” on page 1033](#)
- [“RPG declaration” on page 1033](#)
- [“Redefinition of CSAPL” on page 1034](#)

## Fields

The MQCHARV structure contains the following fields; the fields are described in **alphabetical order**:

### VCHRC (10-digit signed integer)

This is the character set identifier of the variable length string addressed by the VCHRP or VCHRO field.

The initial value of this field is CSAPL. This is defined by IBM MQ to indicate that it should be changed by the queue manager to the true character set identifier of the queue manager. This is in the same way as CSQM behaves. As a result, the value CSAPL is never associated with a variable length string. The initial value of this field can be changed by defining a different value for the constant CSAPL for your compile unit by the appropriate means for your application's programming language.

### VCHRL (10-digit signed integer)

The length in bytes of the variable length string addressed by the VCHRP or VCHRO field.

The initial value of this field is 0. The value must be either greater than or equal to zero or the following special value which is recognized:

#### VSNTL

If VSNTL is not specified, VCHRL bytes are included as part of the string. If null characters are present they do not delimit the string.

If VSNTL is specified, the string is delimited by the first null encountered in the string. The null itself is not included as part of that string.

**Note:** The null character used to terminate a string if VSNTL is specified is a null from the code set specified by VCHRC.

For example, in UTF-16 (CCSIDs 1200, 13488, and 17584), this is the 2-byte Unicode encoding where a null is represented by a 16 bit number of all zeros. In UTF-16 it is common to find single bytes set to all zero which are part of characters (7-bit ASCII characters for example), but the strings will only be null terminated when two 'zero' bytes are found on an even byte boundary. It is possible to get two 'zero' bytes on an odd boundary when they are each part of valid characters. For example, x'01' x'00' x'00' x'30' represents two valid Unicode characters and does not null terminate the string.

### VCHRO (10-digit signed integer)

The offset in bytes of the variable length string from the start of the MQCHARV, or the structure containing it.

When the MQCHARV structure is embedded within another structure, this value is the offset in bytes of the variable length string from the start of the structure that contains this MQCHARV structure. When the MQCHARV structure is not embedded within another structure, for example, if it is specified as a parameter on a function call, the offset is relative to the start of the MQCHARV structure.

The offset can be positive or negative. You can use either the VCHRP or VCHRO field to specify the variable length string, but not both.

The initial value of this field is 0.

### VCHRP (pointer)

This is a pointer to the variable length string.

You can use either the VCHRP or VCHRO field to specify the variable length string, but not both.

The initial value of this field is a null pointer or null bytes.

### VCHRS (10-digit signed integer)

The size in bytes of the buffer addressed by the VCHRP or VCHRO field.

When the MQCHARV structure is used as an output field on a function call, this field must be initialized with the length of the buffer provided. If the value of VCHRL is greater than VCHRS then only VCHRS bytes of data will be returned to the caller in the buffer.

The value must be greater than or equal to zero or the following special value which is recognized:

#### VSUSL

If VSUSL is specified, the length of the buffer is taken from the VCHRL field in the MQCHARV structure. This special value is not appropriate when the structure is used as an output field and a buffer is provided. This is the initial value of this field.

## Initial values

Field name	Name of constant	Value of constant
VCHRP	None	Null pointer or null bytes.
VCHRO	None	0
VCHRS	VSUSL	-1
VCHRL	None	0
VCHRC	CSAPL	-3

## RPG declaration

```
D* .1.....2.....3.....4.....5.....6.....7..
D* MQCHARV Structure
D*
D* Address of variable length string
D VCHRP          1      16*
D* Offset of variable length string
D VCHRO         17      20I 0
D* Size of buffer
D VCHRS         21      24I 0
D* Length of variable length string
D VCHRL         25      28I 0
```

```
D* CCSID of variable length string
D VCHRC                29      32I 0
```

## Redefinition of CSAPL

Unlike the programming languages supported on other platforms, RPG does not have a way of redefining a defined constant, so you must set each VCHRC specifically if you want to use a value other than CSAPL.

## IBM i MQCIH (CICS bridge header) on IBM i

The MQCIH structure describes the information that can be present at the start of a message sent to the CICS bridge through IBM MQ for z/OS.

### Overview

**Format name:** FMCICS.

**Version:** The current version of MQCIH is CIVER2. Fields that exist only in the more-recent version of the structure are identified as such in the descriptions that follow.

The COPY file provided contains the most recent version of MQCIH, with the initial value of the *CIVER* field set to CIVER2.

**Character set and encoding:** Special conditions apply to the character set and encoding used for the MQCIH structure and application message data:

- Applications that connect to the queue manager that owns the CICS bridge queue must provide an MQCIH structure that is in the character set and encoding of the queue manager. This is because data conversion of the MQCIH structure is not performed in this case.
- Applications that connect to other queue managers can provide an MQCIH structure that is in any of the supported character sets and encodings; conversion of the MQCIH is performed by the receiving message channel agent connected to the queue manager that owns the CICS bridge queue.

**Note:** There is one exception to this. If the queue manager that owns the CICS bridge queue is using CICS for distributed queuing, the MQCIH must be in the character set and encoding of the queue manager that owns the CICS bridge queue.

- The application message data following the MQCIH structure must be in the same character set and encoding as the MQCIH structure. The *CICSI* and *CIENC* fields in the MQCIH structure cannot be used to specify the character set and encoding of the application message data.

A data-conversion exit must be provided by the user to convert the application message data if the data is not one of the built-in formats supported by the queue manager.

**Usage:** If the values required by the application are the same as the initial values shown in [Table 691 on page 1043](#), and the bridge is running with AUTH=LOCAL or AUTH=IDENTIFY, the MQCIH structure can be omitted from the message. In all other cases, the structure must be present.

The bridge accepts either a version-1 or a version-2 MQCIH structure, but for 3270 transactions a version-2 structure must be used.

The application must ensure that fields documented as "request" fields have appropriate values in the message sent to the bridge; these fields are input to the bridge.

Fields documented as "response" fields are set by the CICS bridge in the reply message that the bridge sends to the application. Error information is returned in the *CIRET*, *CIFNC*, *CICC*, *CIREA*, and *CIAC* fields, but not all of them are set in all cases. [Table 690 on page 1034](#) shows which fields are set for different values of *CIRET*.

<i>Table 690. Contents of error information fields in MQCIH structure</i>				
<b>CIRET</b>	<b>CIFNC</b>	<b>CICC</b>	<b>CIREA</b>	<b>CIAC</b>
CRC000	-	-	-	-

Table 690. Contents of error information fields in MQCIH structure (continued)

<b>CIRET</b>	<b>CIFNC</b>	<b>CICC</b>	<b>CIREA</b>	<b>CIAC</b>
CRC003	-	-	FBC*	-
CRC002 CRC008	IBM MQ call name	IBM MQ <i>CMPCOD</i>	IBM MQ <i>REASON</i>	-
CRC001 CRC006 CRC007 CRC009	CICS EIBFN	CICS EIBRESP	CICS EIBRESP2	-
CRC004 CRC005	-	-	-	CICS ABCODE

- “Fields” on page 1035
- “Initial values” on page 1043
- “RPG declaration” on page 1044

## Fields

The MQCIH structure contains the following fields; the fields are described in **alphabetical order**:

### CIAC (4-byte character string)

Abend code.

The value returned in this field is significant only if the *CIRET* field has the value CRC005 or CRC004. If it does, *CIAC* contains the CICS ABCODE value.

This is a response field. The length of this field is given by LNABNC. The initial value of this field is 4 blank characters.

This is an indicator specifying whether ADS descriptors should be sent on SEND and RECEIVE BMS requests. The following values are defined:

#### **ADNONE**

Do not send or receive ADS descriptor.

#### **ADSEND**

Send ADS descriptor.

#### **ADRECV**

Receive ADS descriptor.

#### **ADMSGF**

Use message format for the ADS descriptor.

This causes the ADS descriptor to be sent or received using the long form of the ADS descriptor. The long form has fields that are aligned on 4-byte boundaries.

The *CIADS* field should be set as follows:

- If ADS descriptors are not being used, set the field to ADNONE.
- If ADS descriptors *are* being used, and with the *same* CCSID in each environment, set the field to the sum of ADSEND and ADRECV.
- If ADS descriptors *are* being used, but with *different* CCSIDs in each environment, set the field to the sum of ADSEND, ADRECV, and ADMSGF.

This is a request field used only for 3270 transactions. The initial value of this field is ADNONE.

### CIADS (10-digit signed integer)

Send/receive ADS descriptor.

This is an indicator specifying whether ADS descriptors should be sent on SEND and RECEIVE BMS requests. The following values are defined:

**ADNONE**

Do not send or receive ADS descriptor.

**ADSEND**

Send ADS descriptor.

**ADRECV**

Receive ADS descriptor.

**ADMSGF**

Use message format for the ADS descriptor.

This causes the ADS descriptor to be sent or received using the long form of the ADS descriptor. The long form has fields that are aligned on 4-byte boundaries.

The *CIADS* field should be set as follows:

- If ADS descriptors are not being used, set the field to ADNONE.
- If ADS descriptors *are* being used, and with the *same* CCSID in each environment, set the field to the sum of ADSEND and ADRECV.
- If ADS descriptors *are* being used, but with *different* CCSIDs in each environment, set the field to the sum of ADSEND, ADRECV, and ADMSGF.

This is a request field used only for 3270 transactions. The initial value of this field is ADNONE.

**CIAI (4-byte character string)**

AID key.

This is the initial value of the AID key when the transaction is started. It is a 1-byte value, left-aligned.

This is a request field used only for 3270 transactions. The length of this field is given by LNATID. The initial value of this field is 4 blanks.

**CIAUT (8-byte character string)**

Password or passticket.

This is a password or passticket. If user-identifier authentication is active for the CICS bridge, *CIAUT* is used with the user identifier in the MQMD identity context to authenticate the sender of the message.

This is a request field. The length of this field is given by LNAUTH. The initial value of this field is 8 blanks.

**CICC (10-digit signed integer)**

IBM MQ completion code or CICS EIBRESP.

The value returned in this field is dependent on *CIRET*; see [Table 690 on page 1034](#).

This is a response field. The initial value of this field is CCOK.

**CICNC (4-byte character string)**

Abend transaction code.

This is the abend code to be used to terminate the transaction (normally a conversational transaction that is requesting more data). Otherwise this field is set to blanks.

This is a request field used only for 3270 transactions. The length of this field is given by LNCNCL. The initial value of this field is 4 blanks.

**CICP (10-digit signed integer)**

Cursor position.

This is the initial cursor position when the transaction is started. Later, for conversational transactions, the cursor position is in the RECEIVE vector.

This is a request field used only for 3270 transactions. The initial value of this field is 0. This field is not present if *CIVER* is less than *CIVER2*.

**CICSI (10-digit signed integer)**

Reserved.

This is a reserved field; its value is not significant. The initial value of this field is 0.

**CICT (10-digit signed integer)**

Whether task can be conversational.

This is an indicator specifying whether the task should be allowed to issue requests for more information, or should abend. The value must be one of the following:

**CTYES**

Task is conversational.

**CTNO**

Task is not conversational.

This is a request field used only for 3270 transactions. The initial value of this field is CTNO.

**CIENC (10-digit signed integer)**

Reserved.

This is a reserved field; its value is not significant. The initial value of this field is 0.

**CIEO (10-digit signed integer)**

Offset of error in message.

This is the position of invalid data detected by the bridge exit. This field provides the offset from the start of the message to the location of the invalid data.

This is a response field used only for 3270 transactions. The initial value of this field is 0. This field is not present if *CIVER* is less than *CIVER2*.

**CIFAC (8-byte bit string)**

Bridge facility token.

This is an 8-byte bridge facility token. The purpose of a bridge facility token is to allow multiple transactions in a pseudoconversation to use the same bridge facility (virtual 3270 terminal). In the first, or only, message in a pseudoconversation, a value of FCNONE should be set; this tells CICS to allocate a new bridge facility for this message. A bridge facility token is returned in response messages when a nonzero *CIFKT* is specified on the input message. Subsequent input messages can then use the same bridge facility token.

The following special value is defined:

**FCNONE**

No BVT token specified.

This is both a request and a response field used only for 3270 transactions. The length of this field is given by *LNFAC*. The initial value of this field is FCNONE.

**CIFKT (10-digit signed integer)**

Bridge facility release time.

This is the length of time in seconds that the bridge facility will be kept after the user transaction has ended. For nonconversational transactions, the value should be zero.

This is a request field used only for 3270 transactions. The initial value of this field is 0.

**CIFL (4-byte character string)**

Terminal emulated attributes.

This is the name of an installed terminal that is to be used as a model for the bridge facility. A value of blanks means that *CIFL* is taken from the bridge transaction profile definition, or a default value is used.

This is a request field used only for 3270 transactions. The length of this field is given by *LNFACL*. The initial value of this field is 4 blanks.

### **CIFLG (10-digit signed integer)**

Flags.

The value must be:

#### **CIFNON**

No flags.

This is a request field. The initial value of this field is *CIFNON*.

### **CIFMT (8-byte character string)**

IBM MQ format name of data that follows *MQCIH*.

This specifies the IBM MQ format name of the data that follows the *MQCIH* structure.

On the *MQPUT* or *MQPUT1* call, the application must set this field to the value appropriate to the data. The rules for coding this field are the same as those for the *MDFMT* field in *MQMD*.

This format name is also used for the reply message, if the *CIRFM* field has the value *FMNONE*.

- For DPL requests, *CIFMT* must be the format name of the *COMMAREA*.
- For 3270 requests, *CIFMT* must be *CSQCBDCI*, and *CIRFM* must be *CSQCBDCO*.

The data-conversion exits for these formats must be installed on the queue manager where they are to run.

If the request message results in the generation of an error reply message, the error reply message has a format name of *FMSTR*.

This is a request field. The length of this field is given by *LNFMNT*. The initial value of this field is *FMNONE*.

### **CIFNC (4-byte character string)**

IBM MQ call name or CICS *EIBFN* function.

The value returned in this field is dependent on *CIRET*; see [Table 690 on page 1034](#). The following values are possible when *CIFNC* contains an IBM MQ call name:

#### **CFCONN**

*MQCONN* call.

#### **CFGET**

*MQGET* call.

#### **CFINQ**

*MQINQ* call.

#### **CFOPEN**

*MQOPEN* call.

#### **CFPUT**

*MQPUT* call.

#### **CFPUT1**

*MQPUT1* call.

#### **CFNONE**

No call.

This is a response field. The length of this field is given by *LNFUNC*. The initial value of this field is *CFNONE*.

**CIGWI (10-digit signed integer)**

Wait interval for MQGET call issued by bridge task.

This field is applicable only when *CIUOW* has the value CUFIRST. It allows the sending application to specify the approximate time in milliseconds that the MQGET calls issued by the bridge should wait for second and subsequent request messages for the unit of work started by this message. This overrides the default wait interval used by the bridge. The following special values may be used:

**WIDFLT**

Default wait interval.

This causes the CICS bridge to wait for the period specified when the bridge was started.

**WIULIM**

Unlimited wait interval.

This is a request field. The initial value of this field is WIDFLT.

**CIII (10-digit signed integer)**

Reserved.

This is a reserved field. The value must be 0. This field is not present if *CIVER* is less than CIVER2.

**CILEN (10-digit signed integer)**

Length of MQCIH structure.

The value must be one of the following:

**CILEN1**

Length of version-1 CICS information header structure.

**CILEN2**

Length of version-2 CICS information header structure.

The following constant specifies the length of the current version:

**CILENC**

Length of current version of CICS information header structure.

This is a request field. The initial value of this field is CILEN2.

**CILT (10-digit signed integer)**

Link type.

This indicates the type of object that the bridge should try to link. The value must be one of the following:

**LTPROG**

DPL program.

**LTTRAN**

3270 transaction.

This is a request field. The initial value of this field is LTPROG.

**CINTI (4-byte character string)**

Next transaction to attach.

This is the name of the next transaction returned by the user transaction (typically by EXEC CICS RETURN TRANSID). If there is no next transaction, this field is set to blanks.

This is a response field used only for 3270 transactions. The length of this field is given by LNTRID. The initial value of this field is 4 blanks.

**CIODL (10-digit signed integer)**

Output COMMAREA data length.

This is the length of the user data to be returned to the client in a reply message. This length includes the 8-byte program name. The length of the COMMAREA passed to the linked program is the maximum of this field and the length of the user data in the request message, minus 8.

**Note:** The length of the user data in a message is the length of the message *excluding* the MQCIH structure.

If the length of the user data in the request message is smaller than *CIODL*, the *DATALENGTH* option of the *LINK* command is used; this allows the *LINK* to be function-shipped efficiently to another CICS region.

The following special value can be used:

**OLINPT**

Output length is same as input length.

This value might be needed even if no reply is requested, in order to ensure that the COMMAREA passed to the linked program is of sufficient size.

This is a request field used only for DPL programs. The initial value of this field *OLINPT*.

**CIREA (10-digit signed integer)**

IBM MQ reason or feedback code, or CICS EIBRESP2.

The value returned in this field is dependent on *CIRET* ; see [Table 690 on page 1034](#).

This is a response field. The initial value of this field is *RCNONE*.

**CIRET (10-digit signed integer)**

Return code from bridge.

This is the return code from the CICS bridge describing the outcome of the processing performed by the bridge. The *CIFNC*, *CICC*, *CIREA*, and *CIAC* fields may contain additional information (see [Table 690 on page 1034](#) ). The value is one of the following:

**CRC000**

(0, X'000') No error.

**CRC001**

(1, X'001') EXEC CICS statement detected an error.

**CRC002**

(2, X'002') IBM MQ call detected an error.

**CRC003**

(3, X'003') CICS bridge detected an error.

**CRC004**

(4, X'004') CICS bridge ended abnormally.

**CRC005**

(5, X'005') Application ended abnormally.

**CRC006**

(6, X'006') Security error occurred.

**CRC007**

(7, X'007') Program not available.

**CRC008**

(8, X'008') Second or later message within current unit of work not received within specified time.

**CRC009**

(9, X'009') Transaction not available.

This is a response field. The initial value of this field is *CRC000*.

**CIRFM (8-byte character string)**

IBM MQ format name of reply message.

This is the IBM MQ format name of the reply message that will be sent in response to the current message. The rules for coding this are the same as those for the *MDFMT* field in MQMD.

This is a request field used only for DPL programs. The length of this field is given by LNFMT. The initial value of this field is FMNONE.

**CIRSI (4-byte character string)**

Reserved.

This is a reserved field. The value must be 4 blanks. The length of this field is given by LNRSID.

**CIRS1 (8-byte character string)**

Reserved.

This is a reserved field. The value must be 8 blanks.

**CIRS2 (8-byte character string)**

Reserved.

This is a reserved field. The value must be 8 blanks.

**CIRS3 (8-byte character string)**

Reserved.

This is a reserved field. The value must be 8 blanks.

**CIRS4 (10-digit signed integer)**

Reserved.

This is a reserved field. The value must be 0. This field is not present if *CIVER* is less than CIVER2.

**CIRTI (4-byte character string)**

Reserved.

This is a reserved field. The value must be 4 blanks. The length of this field is given by LNTRID.

**CISC (4-byte character string)**

Transaction start code.

This is an indicator specifying whether the bridge emulates a terminal transaction or a START transaction. The value must be one of the following:

**SCSTRT**

Start.

**SCDATA**

Start data.

**SCTERM**

Terminate input.

**SCNONE**

None.

In the response from the bridge, this field is set to the start code appropriate to the next transaction ID contained in the *CINTI* field. The following start codes are possible in the response:

- SCSTRT
- SCDATA
- SCTERM

For CICS Transaction Server 1.2 this field is a request field only; its value in the response is undefined.

For CICS Transaction Server 1.3 and subsequent releases, this is both a request and a response field.

This field is used only for 3270 transactions. The length of this field is given by LNSTCO. The initial value of this field is SCNONE.

#### **CISID (4-byte character string)**

Structure identifier.

The value must be:

##### **CISIDV**

Identifier for CICS information header structure.

This is a request field. The initial value of this field is CISIDV.

#### **CITES (10-digit signed integer)**

Status at end of task.

This field shows the status of the user transaction at end of task. One of the following values is returned:

##### **TENOSY**

Not synchronized.

The user transaction has not yet completed and has not syncpointed. The *MDMT* field in MQMD is MTRQST in this case.

##### **TECMIT**

Commit unit of work.

The user transaction has not yet completed, but has syncpointed the first unit of work. The *MDMT* field in MQMD is MTDGRM in this case.

##### **TEBACK**

Back out unit of work.

The user transaction has not yet completed. The current unit of work will be backed out. The *MDMT* field in MQMD is MTDGRM in this case.

##### **TEENDT**

End task.

The user transaction has ended (or abended). The *MDMT* field in MQMD is MTRPLY in this case.

This is a response field used only for 3270 transactions. The initial value of this field is TENOSY.

#### **CITI (4-byte character string)**

Transaction to attach.

If *CILT* has the value LTRAN, *CITI* is the transaction identifier of the user transaction to be run; a nonblank value must be specified in this case.

If *CILT* has the value LTPROG, *CITI* is the transaction code under which all programs within the unit of work are to be run. If the value specified is blank, the CICS DPL bridge default transaction code (CKBP) is used. If the value is nonblank, it must have been defined to CICS as a local TRANSACTION with an initial program of CSQCBP00. This field is applicable only when *CIUOW* has the value CUFRST or CUONLY.

This is a request field. The length of this field is given by LNTRID. The initial value of this field is 4 blanks.

#### **CIUOW (10-digit signed integer)**

Unit-of-work control.

This controls the unit-of-work processing performed by the CICS bridge. You can request the bridge to run a single transaction, or one or more programs within a unit of work. The field indicates whether the CICS bridge should start a unit of work, perform the requested function within the current unit of

work, or end the unit of work by committing it or backing it out. Various combinations are supported, to optimize the data transmission flows.

The value must be one of the following:

**CUONLY**

Start unit of work, perform function, then commit the unit of work (DPL and 3270).

**CUCONT**

Additional data for the current unit of work (3270 only).

**CUFRST**

Start unit of work and perform function (DPL only).

**CUMIDL**

Perform function within current unit of work (DPL only).

**CULAST**

Perform function, then commit the unit of work (DPL only).

**CUCMIT**

Commit the unit of work (DPL only).

**CUBACK**

Back out the unit of work (DPL only).

This is a request field. The initial value of this field is CUONLY.

**CIVER (10-digit signed integer)**

Structure version number.

The value must be one of the following:

**CIVER1**

Version-1 CICS information header structure.

**CIVER2**

Version-2 CICS information header structure.

Fields that exist only in the more-recent version of the structure are identified as such in the descriptions of the fields. The following constant specifies the version number of the current version:

**CIVERC**

Current version of CICS information header structure.

This is a request field. The initial value of this field is CIVER2.

**Initial values**

<i>Table 691. Fields in MQCIH</i>		
<b>Field name</b>	<b>Name of constant</b>	<b>Value of constant</b>

```

The **MQCMHO** structure allows applications to specify options that control how message handles are created.

## Overview

### Purpose

The structure is an input parameter on the **MQCRTMH** call.

### Character set and encoding

Data in **MQCMHO** must be in the character set of the application and encoding of the application (ENNAT).

- [“Fields” on page 1046](#)
- [“Initial values” on page 1047](#)
- [“RPG declaration” on page 1048](#)

## Fields

The **MQCMHO** structure contains the following fields; the fields are described in alphabetical order:

### CMOPT (10 digit signed integer)

One of the following options can be specified:

#### CMVAL

When **MQSETMP** is called to set a property in this message handle, the property name is validated to ensure that it:

- contains no invalid characters.
- does not begin "JMS" or "usr.JMS" except for the following:
  - JMSCorrelationID
  - JMSReplyTo
  - JMSType
  - JMSXGroupID
  - JMSXGroupSeq

These names are reserved for JMS properties.

- is not one of the following keywords, in any mixture of upper or lowercase:
  - "AND"
  - "BETWEEN"
  - "ESCAPE"
  - "FALSE"
  - "IN"
  - "IS"
  - "LIKE"
  - "NOT"
  - "NULL"
  - "OR"
  - "TRUE"
- does not begin "Body." or "Root." (except for "Root.MQMD.").

If the property is MQ-defined ("mq.\*") and the name is recognized, the property descriptor fields are set to the correct values for the property. If the property is not recognized, the *Support* field of the property descriptor is set to **PDSUPO** (for more information, see [PDSUP](#)).

### **CMDEFV**

This specifies that the default level of validation of property names occurs.

The default level of validation is equivalent to that specified by **CMVAL**.

In a future release an administrative option might be defined which will change the level of validation that will occur when **CMDEFV** is defined.

This is the default value.

### **CMNOVA**

No validation on the property name occurs. See the description of **CMVAL**.

**Default option:** If none of the options previously described in this section is required, the following option can be used:

### **CMNONE**

All options assume their default values. Use this value to indicate that no other options have been specified. **CMNONE** aids program documentation; it is not intended that this option be used with any other, but as its value is zero, such use cannot be detected.

This is always an input field. The initial value of this field is **CMDEFV**.

### **CMSID (10 digit signed integer)**

This is the structure identifier; the value must be:

#### **CMSIDV**

Identifier for create message handle options structure.

This is always an input field. The initial value of this field is **CMSIDV**.

### **CMVER (10 digit signed integer)**

This is the structure version number; the value must be:

#### **CMVER1**

Version-1 create message handle options structure.

The following constant specifies the version number of the current version:

#### **CMVERC**

Current version of create message handle options structure.

This is always an input field. The initial value of this field is **CMVER1**.

## **Initial values**

<i>Table 692. Fields in MQCMHO</i>

## IBM i MQCNO (Connect options) on IBM i

The MQCNO structure allows the application to specify options relating to the connection to the local queue manager.

### Overview

**Purpose:** The structure is an input/output parameter on the MQCONN call.

**Version:** The current version of MQCNO is CNVER6. Fields that exist only in the more-recent versions of the structure are identified as such in the descriptions that follow.

The COPY file provided contains the most recent version of MQCNO that is supported by the environment, but with the initial value of the CNVER field set to CNVER1. To use fields that are not present in the version-1 structure, the application must set the CNVER field to the version number of the version required.

**Character set and encoding:** Data in MQCNO must be in the character set given by the **CodedCharSetId** queue manager attribute and encoding of the local queue manager given by ENNAT.

- [“Fields” on page 1048](#)
- [“Initial values” on page 1053](#)
- [“RPG declaration” on page 1054](#)

### Fields

The MQCNO structure contains the following fields; the fields are described in **alphabetical order**:

#### CCDTUL (10-digit signed integer)

CCDTUL is the length of the string identified by either CCDTUP or CCDTUO which contains a URL that identifies the location of the client connection channel table to use for the connection.

Use CCDTUL only when the application issuing the MQCONN call is running as an IBM MQ MQI client.

This is a programmatic alternative to setting the [MQCHLLIB](#) and [MQCHLTAB](#) environment variables.

If the application is not running as a client, CCDTUL is ignored.

This field is ignored if CNVER is less than CNVER6.

#### CCDTUO (10-digit signed integer)

CCDTUO is the offset in bytes, from the start of the MQCNO structure, to a string which contains a URL that identifies the location of the client connection channel table to use for the connection. The offset can be positive or negative.

Use CCDTUL only when the application issuing the MQCONN call is running as an IBM MQ MQI client.

**Important:** You can use only one of CCDTUP and CCDTUO. The call fails with reason code RC2600 if both fields are nonzero.

This is a programmatic alternative to setting the MQCHLLIB and MQCHLTAB environment variables.

If the application is not running as a client, CCDTUO is ignored.

This field is ignored if CNVER is less than CNVER6.

### **CCDTUP (pointer)**

CCDTUP is an optional pointer to a string which contains a URL, to identify the location of the client connection channel table to use for the connection..

Use CCDTUP only when the application issuing the MQCONN call is running as an IBM MQ MQI client.

**Important:** You can use only one of CCDTUP and CCDTUO. The call fails with reason code RC2600 if both fields are nonzero.

This is a programmatic alternative to setting the MQCHLLIB and MQCHLTAB environment variables.

If the application is not running as a client, CCDTUP is ignored.

This field is ignored if CNVER is less than CNVER6.

### **CNAN (28-byte character string)**

The name set by the application to identify the connection to the queue manager. The initial value of the field is null characters.

This field is ignored if CNVER is less than CNVER7.

### **CNCCO (10-digit signed integer)**

This is the offset in bytes of an MQCD channel definition structure from the start of the MQCNO structure.

### **CNCCP (pointer)**

This is a pointer to an MQCD channel definition structure.

### **CNCONID (24-byte character string)**

Unique connection identifier. This field allows the queue manager to reliably identify an application process by assigning it a unique identifier when it first connects to the queue manager.

Applications use the connection identifier for correlation purposes when making PUT and GET calls. All connections are assigned an identifier by the queue manager, no matter how the connection was established.

It is possible to use the connection identifier to force the end of a long running unit of work. To do this, specifying the connection identifier using the PCF command 'Stop Connection', or the MQSC command STOP CONN. For more information about using these commands, see the related links.

The initial value of the field is 24 null bytes.

### **CNCT (128-byte bit string)**

This is a tag that the queue manager associates with the resources that are affected by the application during this connection.

Queue manager connection tag.

Each application or application instance must use a different value for the tag, so that the queue manager can correctly serialize access to the affected resources. See the descriptions of the CN\*CT\* options for further details. The tag ceases to be valid when the application terminates, or issues the MQDISC call.

Use the following special value if no tag is required:

#### **CTNONE**

No connection tag specified.

The value is binary zero for the length of the field.

This is an input field. The length of this field is given by LNCTAG. The initial value of this field is CTNONE. This field is ignored if CNVER is less than CNVER3.

Use the field ConnTag when connecting to a z/OS queue manager.

### **CNNORES2 (4-byte character string)**

A reserved field to pad the structure out to a 64-bit boundary. The initial value of the field is binary zero for the length of the field.

This field is ignored if CNVER is less than CNVER7.

### **CNOPT (10 digit signed integer)**

Options that control the action of MQCONN.

#### **Binding options**

The binding options control the type of IBM MQ binding that is used; specify only one of these options:

#### **CNSBND**

Standard binding.

The standard binding option causes the application and the local queue manager agent to run in separate units of execution, typically in separate processes. The arrangement maintains the integrity of the queue manager; that is, it protects the queue manager from errant programs.

Use CNSBND in situations where the application might not have been fully tested, or might be unreliable or untrustworthy. CNSBND is the default.

CNSBND is defined to aid program documentation. Do not use this option with any other option controlling the type of binding used; but because its value is zero, such use cannot be detected.

This option is supported in all environments.

#### **CNFBND**

Fast path binding.

The fast path binding option causes the application and the local queue manager agent to be part of the same unit of execution. Fast path is in contrast to the standard binding, where the application and the local queue manager agent run in separate units of execution.

CNFBND is ignored if the queue manager does not support this type of binding; processing continues as though the option had not been specified.

CNFBND can be of advantage in situations where multiple processes consume more resources than the overall resource used by the application. An application that uses the fast path binding is known as a *trusted application*.

Consider the following important points when deciding whether to use the fast path binding:

- **Using the CNFBND option does not prevent an application altering or corrupting messages and other data areas belonging to the queue manager. Use this option only in situations where you have fully evaluated these issues.**
- The application must not use asynchronous signals or timer interrupts (such as sigkill) with CNFBND. There are also restrictions on the use of shared memory segments.
- The application must not have more than one thread connected to the queue manager at any one time.
- The application must use the MQDISC call to disconnect from the queue manager.
- The application must finish before ending the queue manager with the endmqm command.

The following points apply to the use of CNFBND in the environments indicated:

- On IBM i, the job must run under user profile QMQM that belongs to the QMQMADM group. Also, the program must not terminate abnormally, otherwise unpredictable results might occur.

For more information about the implications of using trusted applications, see [Connecting to a queue manager using the MQCONN call](#) and [Restrictions for trusted applications](#).

### **CNSHBD**

Shared Bindings.

The shared bindings option causes the application and the local queue manager agent to run in separate units of execution, typically in separate processes. The arrangement maintains the integrity of the queue manager; that is, it protects the queue manager from errant programs. However some resources are shared between the application and the local queue manager agent. CNSHBD is ignored if the queue manager does not support this type of binding. Processing continues as though the option had not been specified.

### **CNIBND**

Isolated Bindings.

The isolated bindings option causes the application and the local queue manager agent to run in separate units of execution, typically in separate processes. The arrangement maintains the integrity of the queue manager; that is, it protects the queue manager from errant programs. The application process and the local queue manager agent are isolated from each other in that they do not share resources. CNIBND is ignored if the queue manager does not support this type of binding. Processing continues as though the option had not been specified.

### **Handle-sharing options**

The following options control the sharing of handles between different threads (units of parallel processing) within the same process. Only one of these options can be specified.

#### **CNHSN**

No handle sharing between threads.

The no handle sharing between threads option indicates that connection and object handles can be used only by the thread that caused the handle to be allocated; that is, the thread that issued the MQCONN, MQCONNX, or MQOPEN call. The handles cannot be used by other threads belonging to the same process.

#### **CNHSB**

Serial handle sharing between threads, with call blocking.

The serial handle sharing between threads, with call blocking, option indicates that connection and object handles allocated by one thread of a process can be used by other threads belonging to the same process. However, only one thread at a time can use any particular handle, that is, only serial use of a handle is permitted. If a thread tries to use a handle that is already in use by another thread, the call blocks (waits) until the handle becomes available.

#### **CNHSNB**

Serial handle sharing between threads, without call blocking.

The serial handle sharing between threads, without call blocking, option is the same as the "with blocking" option, except that, if the handle is in use by another thread, the call completes immediately with CCFAIL and RC2219 instead of blocking until the handle becomes available.

A thread can have zero or one nonshared handles, plus zero or more shared handles:

- Each MQCONN or MQCONNX call that specifies CNHSN returns a new nonshared handle on the first call, and the same nonshared handle on subsequent calls (assuming no intervening MQDISC call). The reason code is RC2002 for the second and later calls.
- Each MQCONNX call that specifies CNHSB or CNHSNB returns a new shared handle on each call.

Object handles inherit the same sharing properties as the connection handle specified on the MQOPEN call that created the object handle. Also, units of work inherit the same sharing properties as the connection handle used to start the unit of work; if the unit of work is started

in one thread using a shared handle, the unit of work can be updated in another thread using the same handle.

If you do not specify a handle-sharing option, the default is determined by the environment:

- In the Microsoft Transaction Server (MTS) environment, the default is the same as CNHSB.
- In other environments, the default is the same as CNHSN.

### **Reconnection options**

Reconnection options determine if a connection is reconnectable. Only client connections are reconnectable.

#### **CNRCDF**

The reconnection option is resolved to its default value. If no default is set, the value of this option resolves to **DISABLED**. The value of the option is passed to the server, and can be queried by **PCF** and **MQSC**.

#### **CNRC**

The application can be reconnected to any queue manager consistent with the value of the MQCONNX **QMNAME** parameter. Use the CNRC option only if there is no affinity between the client application and the queue manager with which it initially established a connection. The value of the option is passed to the server, and can be queried by **PCF** and **MQSC**.

#### **CNRC D**

The application cannot be reconnected. The value of the option is not passed to the server.

#### **CNRCQM**

The application can only be reconnected to the queue manager with which it originally connected. Use this value if a client can be reconnected, but there is an affinity between the client application, and the queue manager with which it originally established a connection. Choose this value if you want a client to automatically reconnect to the standby instance of a highly available queue manager. The value of the option is passed to the server, and can be queried by **PCF** and **MQSC**.

Use the options CNRC, CNRC D, and CNRCQM only for client connections. If the options are used for a binding connection, MQCONNX fails with completion code, MQCC\_FAILED and reason code, MQRC\_OPTIONS\_ERROR.

**Default option:** If none of the options described is required, the following option can be used:

#### **CNNONE**

No options are specified.

CNNONE is defined to aid program documentation. It is not intended that this option is used with any other CN\* option, but because its value is zero, such use cannot be detected.

### **CNSCO (10-digit signed integer)**

This is the offset in bytes of an MQSCO structure from the start of the MQCNO structure.

This field is ignored if CNVER is less than CNVER4.

### **CNSCP (pointer)**

This is the address of an MQSCO structure.

This field is ignored if CNVER is less than CNVER4.

### **CNSECPO (10-digit signed integer)**

Security parameters offset. The offset of the MQCSP structure used for specifying a user ID and password.

The value may be positive or negative. The initial value of this field is 0.

This field is ignored if CNVER is less than CNVER5.

**CNSECPP (pointer)**

Security parameters pointer. Address of the MQCSP structure used for specifying a user ID and a password.

The initial value of this field is a null pointer or null bytes.

This field is ignored if CNVER is less than CNVER5.

**CNSID (4-byte character string)**

The structure identifier for the MQCNO structure.

The value must be:

**CNSIDV**

Identifier for connect-options structure.

This is always an input field. The initial value of this field is CNSIDV.

**CNVER (10-digit signed integer)**

The structure version number for the MQCNO structure.

The value must be:

**CNVER6**

Version-6 connect-options structure.

This version is supported in all environments.

**CNVER7**

Version-7 connect-options structure.

This version is supported in all environments.

The following constant specifies the version number of the current version:

**CNVERC**

Current version of connect-options structure.

This is always an input field. The initial value of this field is CNVER7.

**Initial values**

<i>Table 693. Fields in MQCNO</i>		
<b>Field name</b>	<b>Name of constant</b>	<b>Value of constant</b>
CNSID	CNSIDV	' CNO↵

## IBM i MQCSP (Security parameters) on IBM i

Summary of the MQCSP structure for IBM i.

### Overview

**Purpose:** The MQCSP structure enables the authorization service to authenticate a user ID and password. You specify the MQCSP connection security parameters structure on an MQCONN call.

**Character set and encoding:** Data in MQCSP must be in the character set given by the **CodedCharSetId** queue manager attribute and encoding of the local queue manager given by ENNAT.

- [“Fields” on page 1055](#)
- [“Initial values” on page 1057](#)
- [“RPG declaration” on page 1058](#)

### Fields

The MQCSP structure contains the following fields; the fields are described in **alphabetical order**:

#### CSAUTHT (10-digit signed integer)

This is the type of authentication to perform.

Valid values are:

##### CSAN

Do not use user ID and password fields.

##### CSAUIAP

Authenticate user ID and password fields.

This is an input field. The initial value of this field is CSAN.

#### CSCPPL (10-digit signed integer)

This is the length of the password to be used in authentication.

The maximum length of the password is not dependent on the platform. If the length of the password is greater than that allowed, the authentication request fails with an RC2035.

This is an input field. The initial value of this field is 0.

**CSCPPO (10-digit signed integer)**

This is the offset in bytes of the password to be used in authentication.

The offset can be positive or negative.

This is an input field. The initial value of this field is 0.

**CSCPPP (pointer)**

This is the address of the password to be used in authentication.

This is an input field. The initial value of this field is the null pointer.

**CSCSPUIL (10-digit signed integer)**

This is the length of the user ID to be used in authentication.

The maximum length of the user ID is not dependent on the platform. If the length of the user ID is greater than that allowed, the authentication request fails with an RC2035.

This is an input field. The initial value of this field is 0.

**CSCSPUIO (10-digit signed integer)**

This is the offset in bytes of the user ID to be used in authentication.

The offset can be positive or negative.

This is an input field. The initial value of this field is 0.

**CSCSPUIP (pointer)**

This is the address of the user ID to be used in authentication.

This is an input field. The initial value of this field is the null pointer. This field is ignored if CSVER is less than CSVER5.

**CSINITKL (10-digit signed integer)**

This is the length of the initial key for the password protection system.

This is an input field. The initial value of this field is 0.

**CSINITKO (10-digit signed integer)**

This is the offset in bytes of the initial key for the password protection system. The offset can be positive or negative.

You can use either *CSINITKO* or *CSINITKP* to specify the initial key, but not both. For more information, see the description of the *CSINITKP* field.

This is an input field. The initial value of this field is 0.

**CSINITKP (pointer)**

This is the address in bytes of the initial key for the password protection system.

This is an input field. The initial value of this field is the null pointer.

IBM MQ MQI clients can supply the value of some fields as values that have been encrypted using the IBM MQ password protection system. The following fields can contain encrypted values:

- The key repository password, in the MQSCO structure.

An initial key is used by the encryption algorithm to encrypt and decrypt these values. If an initial key is supplied when the values of these fields are encrypted using the **runmqicred** utility, then the same initial key must be specified by the client when it connects to the queue manager.

The initial key specified using this field overrides any initial key that is specified using the *MQS\_MQI\_KEYFILE* environment variable, or the *MQIInitialKeyFile* property in the Security stanza of the client configuration file.

You can use either *CSINITKO* or *CSINITKP* to specify the initial key, but not both.

**CSRE1 (4-byte character string)**

A reserved field, required for pointer alignment on IBM i.

This is an input field. The initial value of this field is all null.

**CSRS2 (8-byte character string)**

A reserved field, required for pointer alignment on IBM i.

This is an input field. The initial value of this field is all null.

**CSSID (4-byte character string)**

Structure identifier.

The value must be:

**CSSIDV**

Identifier for the security parameters structure.

**CSVER (10-digit signed integer)**

Structure version number.

The value must be:

**CSVER1**

Version-1 security parameters structure.

**CSVER2**

Version-2 security parameters structure.

The following constant specifies the version number of the current version:

**CSVERC**

Current version of security parameters structure.

This is always an input field. The initial value of this field is CSVER1.

**Initial values**

**IBM i MQCTLO (Control callback options structure) on IBM i**

Structure specifying the control callback function.

**Overview**

**Purpose**

The MQCTLO structure is used to specify options relating to a control callbacks function.

The structure is an input and output parameter on the [MQCTL](#) call.

**Version**

The current version of MQCTLO is CTLV1.

**Character set and encoding**

Data in MQCTLO must be in the character set given by the **CodedCharSetId** queue manager attribute and encoding of the local queue manager given by ENNAT. However, if the application is running as an IBM MQ client, the structure must be in the character set and encoding of the client.

- [“Fields” on page 1059](#)
- [“Initial values” on page 1060](#)
- [“RPG declaration” on page 1060](#)

## Fields

The MQCTLO structure contains the following fields; the fields are described in alphabetical order:

### **COCONNAREA (10 digit signed integer)**

Control options structure - ConnectionArea field.

This is a field that is available for the callback function to use.

The queue manager makes no decisions based on the contents of this field and it is passed unchanged from the CBCCONNAREA field in the MQCBC structure, which is a parameter on the MQCB call.

This field is ignored for all operations other than CTLSR and CTLSW.

This is an input and output field to the callback function. The initial value of this field is a null pointer or null bytes.

### **COOPT (10 digit signed integer)**

Options that control the action of MQCTLO.

#### **CTLFQ**

Force the MQCTLO call to fail if the queue manager or connection is in the quiescing state.

Specify GMFIQ, in the MQGMO options passed on the MQCB call, to cause notification to message consumers when they are quiescing.

#### **CTLTHR**

This option informs the system that the application requires that all message consumers, for the same connection, are called on the same thread.

**Default option:** If you do not need any of the options described, use the following option:

#### **CTLNO**

Use this value to indicate that no other options have been specified; all options assume their default values. CTLNO is defined to aid program documentation; it is not intended that this option is used with any other, but as its value is zero, such use cannot be detected.

This is an input field. The initial value of the *COOPT* field is CTLNO.

### **CORSV (10 digit signed integer)**

This is a reserved field. The initial value of this field is a blank character.

### **COSID (10 digit signed integer)**

Control options structure - StrucId field.

This is the structure identifier; the value must be:

#### **CTLSI**

Identifier for Control Options structure.

This is always an input field. The initial value of this field is CTLSI.

### **COVER (10 digit signed integer)**

Control options structure - Version field.

This is the structure version number; the value must be:

#### **CTLV1**

Version-1 Control options structure.

The following constant specifies the version number of the current version:

#### **CTLCV**

Current version of Control options structure.

This is always an input field. The initial value of this field is CTLV1.

## Initial values

Field name	Name of constant	Value of constant
<i>COSID</i>	CTLSI	'CTLO'
<i>COVER</i>	CTLV1	1
<i>COOPT</i>	CTLNO	Nulls
<i>CORSV</i>	Reserved field

## MQDH (Distribution header) on IBM i

The MQDH structure describes the additional data that is present in a message when that message is a distribution-list message stored on a transmission queue.

### Overview

**Purpose:** A distribution-list message is a message that is sent to multiple destination queues. The additional data consists of the MQDH structure followed by an array of MQOR records and an array of MQPMR records.

This structure is for use by specialized applications that put messages directly on transmission queues, or which remove messages from transmission queues (for example: message channel agents).

This structure should not be used by normal applications which simply want to put messages to distribution lists. Those applications should use the MQOD structure to define the destinations in the distribution list, and the MQPMO structure to specify message properties or receive information about the messages sent to the individual destinations.

**Character set and encoding:** Data in MQDH must be in the character set given by the **CodedCharSetId** queue manager attribute and encoding of the local queue manager given by ENNAT for the C programming language.

The character set and encoding of the MQDH must be set into the *MDCSI* and *MDENC* fields in:

- The MQMD (if the MQDH structure is at the start of the message data), or
- The header structure that precedes the MQDH structure (all other cases).

**Usage:** When an application puts a message to a distribution list, and some or all of the destinations are remote, the queue manager prefixes the application message data with the MQXQH and MQDH

structures, and places the message on the relevant transmission queue. The data therefore occurs in the following sequence when the message is on a transmission queue:

- MQXQH structure
- MQDH structure plus arrays of MQOR and MQPMR records
- Application message data

Depending on the destinations, more than one such message might be generated by the queue manager, and placed on different transmission queues. In this case, the MQDH structures in those messages identify different subsets of the destinations defined by the distribution list opened by the application.

An application that puts a distribution-list message directly on a transmission queue must conform to the sequence described previously, and must ensure that the MQDH structure is correct. If the MQDH structure is not valid, the queue manager may choose to fail the MQPUT or MQPUT1 call with reason code RC2135.

Messages can be stored on a queue in distribution-list form only if the queue is defined as being able to support distribution list messages (see the **DistLists** queue attribute described in “Attributes for queues” on page 1366 ). If an application puts a distribution-list message directly on a queue that does not support distribution lists, the queue manager splits the distribution list message into individual messages, and places those on the queue instead.

- “Fields” on page 1061
- “Initial values” on page 1064
- “RPG declaration” on page 1064

## Fields

The MQDH structure contains the following fields; the fields are described in **alphabetical order**:

### DHCNT (10-digit signed integer)

Number of MQOR records present.

This defines the number of destinations. A distribution list must always contain at least one destination, so *DHCNT* must always be greater than zero.

The initial value of this field is 0.

### DHCSI (10-digit signed integer)

Character set identifier of data that follows the MQOR and MQPMR records.

This specifies the character set identifier of the data that follows the arrays of MQOR and MQPMR records; it does not apply to character data in the MQDH structure itself.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The following special value can be used:

#### CSINHT

Inherit character-set identifier of this structure.

Character data in the data *following* this structure is in the same character set as this structure.

The queue manager changes this value in the structure sent in the message to the actual character-set identifier of the structure. Provided no error occurs, the value CSINHT is not returned by the MQGET call.

CSINHT cannot be used if the value of the *MDPAT* field in MQMD is ATBRKR.

The initial value of this field is CSUNDF.

### DHENC (10-digit signed integer)

Numeric encoding of data that follows the MQOR and MQPMR records.

This specifies the numeric encoding of the data that follows the arrays of MQOR and MQPMR records; it does not apply to numeric data in the MQDH structure itself.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data.

The initial value of this field is 0.

### **DHFLG (10-digit signed integer)**

General flags.

The following flag can be specified:

#### **DHFNEW**

Generate new message identifiers.

This flag indicates that a new message identifier is to be generated for each destination in the distribution list. This can be set only when there are no put-message records present, or when the records are present but they do not contain the *PRMID* field.

Using this flag defers generation of the message identifiers until the last possible moment, namely the moment when the distribution-list message is finally split into individual messages. This minimizes the amount of control information that must flow with the distribution-list message.

When an application puts a message to a distribution list, the queue manager sets DHFNEW in the MQDH it generates when both of the following statements are true:

- There are no put-message records provided by the application, or the records provided do not contain the *PRMID* field.
- The *MDMID* field in MQMD is MINONE, or the *PMOPT* field in MQPMO includes PMNMID

If no flags are needed, the following can be specified:

#### **DHFNON**

No flags.

This constant indicates that no flags have been specified. DHFNON is defined to aid program documentation. It is not intended that this constant is used with any other, but as its value is zero, such use cannot be detected.

The initial value of this field is DHFNON.

### **DHFMT (8-byte character string)**

Format name of data that follows the MQOR and MQPMR records.

This specifies the format name of the data that follows the arrays of MQOD and MQPMR records (whichever occurs last).

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The rules for coding this field are the same as those for the *MDFMT* field in MQMD.

The initial value of this field is FMNONE.

### **DHLEN (10-digit signed integer)**

Length of MQDH structure plus following MQOR and MQPMR records.

This is the number of bytes from the start of the MQDH structure to the start of the message data following the arrays of MQOR and MQPMR records. The data occurs in the following sequence:

- MQDH structure
- Array of MQOR records
- Array of MQPMR records
- Message data

The arrays of MQOR and MQPMR records are addressed by offsets contained within the MQDH structure. If these offsets result in unused bytes between one or more of the MQDH structure, the

arrays of records, and the message data, those unused bytes must be included in the value of *DHLEN*, but the content of those bytes is not preserved by the queue manager. It is valid for the array of MQPMR records to precede the array of MQOR records.

The initial value of this field is 0.

#### **DHORO (10-digit signed integer)**

Offset of first MQOR record from start of MQDH.

This field gives the offset in bytes of the first record in the array of MQOR object records containing the names of the destination queues. There are *DHCNT* records in this array. These records (plus any bytes skipped between the first object record and the previous field) are included in the length given by the *DHLEN* field.

A distribution list must always contain at least one destination, so *DHORO* must always be greater than zero.

The initial value of this field is 0.

#### **DHPRF (10-digit signed integer)**

Flags indicating which MQPMR fields are present.

Zero or more of the following flags can be specified:

##### **PFMID**

Message-identifier field is present.

##### **PFCID**

Correlation-identifier field is present.

##### **PFGID**

Group-identifier field is present.

##### **PFFB**

Feedback field is present.

##### **PFACC**

Accounting-token field is present.

If no MQPMR fields are present, the following can be specified:

##### **PFNONE**

No put-message record fields are present.

PFNONE is defined to aid program documentation. It is not intended that this constant be used with any other, but as its value is zero, such use cannot be detected.

The initial value of this field is PFNONE.

#### **DHPRO (10-digit signed integer)**

Offset of first MQPMR record from start of MQDH.

This field gives the offset in bytes of the first record in the array of MQPMR put message records containing the message properties. If present, there are *DHCNT* records in this array. These records (plus any bytes skipped between the first put message record and the previous field) are included in the length given by the *DHLEN* field.

Put message records are optional; if no records are provided, *DHPRO* is zero, and *DHPRF* has the value PFNONE.

The initial value of this field is 0.

#### **DHSID (4-byte character string)**

Structure identifier.

The value must be:

**DHSIDV**

Identifier for distribution header structure.

The initial value of this field is DHSIDV.

**DHVER (10-digit signed integer)**

Structure version number.

The value must be:

**DHVER1**

Version number for distribution header structure.

The following constant specifies the version number of the current version:

**DHVERC**

Current version of distribution header structure.

The initial value of this field is DHVER1.

**Initial values**

<i>Table 696. Fields in MQDH</i>

## IBM i MQDLH (Dead-letter header) on IBM i

### Overview

#### Purpose

The MQDLH structure describes the information that prefixes the application message data of messages on the dead-letter (undelivered-message) queue. A message can arrive on the dead-letter queue because the queue manager or message channel agent redirected it to the queue. An application might put the message directly on the queue.

#### Format name

FMDLH

#### Character set and encoding

The MQDLH might be at the start of the application message data. If so, the fields in the MQDLH structure are in the character set and encoding given by the MDCSI and MDENC fields. If not, the character set and encoding are set by the MDCSI and MDENC fields in the header structure that precedes the MQDLH.

The character set must be one that has single-byte characters for the characters that are valid in queue names.

#### Usage

Applications that put messages directly on the dead-letter queue must prefix the message data with an MQDLH structure, and initialize the fields with appropriate values. However, the queue manager does not require that an MQDLH structure is present, or that valid values are specified for the fields.

If a message is too long to put on the dead-letter queue, the application must consider doing one of the following things:

- Truncate the message data to fit on the dead-letter queue.
- Record the message on auxiliary storage and place an exception report message on the dead-letter queue indicating the message is too long.
- Discard the message and return an error to its originator. If the message is a critical message. Discard the message only if it is known that the originator still has a copy of the message. For example, a message received by a message channel agent from a communication channel.

Which of the choices is appropriate depends on the design of the application.

The queue manager performs special processing when a message which is a segment is put with an MQDLH structure at the front. See the description of the MQMDE structure for further details.

- [“Putting messages on the dead-letter queue” on page 1066](#)
- [“Getting messages from the dead-letter queue” on page 1066](#)
- [“Fields” on page 1066](#)
- [“Initial values” on page 1070](#)
- [“RPG declaration” on page 1070](#)

## Putting messages on the dead-letter queue

If a message is put on the dead-letter queue, the MQMD structure used for the MQPUT or MQPUT1 call must be identical to the MQMD associated with the message. The MQMD is typically the one returned by the MQGET call, except for the following cases:

- The MDCSI and MDENC fields must be set to whatever character set and encoding are used for fields in the MQDLH structure.
- The MDFMT field must be set to FMDLH to indicate that the data begins with an MQDLH structure.
- The context fields, MDACC, MDAID, MDAOD, MDPAN, MDPAT, MDPD, MDPT, and MDUID must be set by using a context option appropriate to the circumstances:
  - An application putting on the dead-letter queue a message that is not related to any preceding message must use the PMDEFC option. The PMDEFC option causes the queue manager to set all of the context fields in the message descriptor to their default values.
  - A server application putting on the dead-letter queue a message it received must use the PMPASA option, in order to preserve the original context information.
  - A server application putting on the dead-letter queue a reply to message it received must use the PMPASI option. The PMPASI option preserves the identity information but sets the origin information to be that of the server application.
  - A message channel agent putting on the dead-letter queue a message it received from its communication channel must use the PMSETA option. The PMSETA option preserves the original context information.

In the MQDLH structure itself, the fields must be set as follows:

- The DLCSI, DLENC, and *DLFMT* fields must be set to the values that describe the data that follows the MQDLH structure. These values are typically the values from the original message descriptor.
- The context fields DLPAT, DLPAN, DLPD, and DLPT must be set to values appropriate to the application that is putting the message on the dead-letter queue. These values are not related to the original message.
- Other fields must be set as appropriate.

The application must ensure that all fields have valid values, and that character fields are padded with blanks to the defined length of the field. The character data must not be terminated prematurely by using a null character. The queue manager does not convert the null and subsequent characters to blanks in the MQDLH structure.

## Getting messages from the dead-letter queue

Applications that get messages from the dead-letter queue must verify that the messages begin with an MQDLH structure. The application can determine whether an MQDLH structure is present by examining the MDFMT field in the message descriptor MQMD. If the field has the value FMDLH, the message data begins with an MQDLH structure. Messages on the dead-letter queue might be truncated if they were originally too long for the queue they were intended for.

## Fields

The MQDLH structure contains the following fields; the fields are described in alphabetical order:

### **DLCSI (10-digit signed integer)**

Character set identifier of data that follows MQDLH.

DLCSI specifies the character set identifier of the data that follows the MQDLH structure. The data is typically from the original message. It does not apply to character data in the MQDLH structure itself.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The following special value can be used:

**CSINHT**

Inherit character-set identifier of this structure.

Character data in the data following this structure is in the same character set as this structure.

The queue manager changes this value in the structure sent in the message to the actual character-set identifier of the structure. Provided no error occurs, the value CSINHT is not returned by the MQGET call.

CSINHT cannot be used if the value of the MDPAT field in MQMD is ATBRKR.

The initial value of this field is CSUNDF.

**DLDM (48-byte character string)**

Name of original destination queue manager.

This is the name of the queue manager that was the original destination for the message.

The length of this field is given by LNQMN. The initial value of this field is 48 blank characters.

**DLDQ (48-byte character string)**

Name of original destination queue.

This is the name of the message queue that was the original destination for the message.

The length of this field is given by LNQN. The initial value of this field is 48 blank characters.

**DLENC (10-digit signed integer)**

Numeric encoding of data that follows MQDLH.

DLENC specifies the numeric encoding of the data that follows the MQDLH structure. The data is typically from the original message. It does not apply to numeric data in the MQDLH structure itself.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data.

The initial value of this field is 0.

**DLFMT (8-byte character string)**

Format name of data that follows MQDLH.

This specifies the format name of the data that follows the MQDLH structure (typically the data from the original message).

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The rules for coding this field are the same as the rules for the MDFMT field in MQMD.

The length of this field is given by LNFMT. The initial value of this field is FMNONE.

**DLPAN (28-byte character string)**

Name of application that put message on dead-letter (undelivered-message) queue.

The format of the name depends on the DLPAT field. See the description of the MDPAN field in [“MQMD \(Message descriptor\) on IBM i”](#) on page 1110.

If it is the queue manager that redirects the message to the dead-letter queue, DLPAN contains the first 28 characters of the queue manager name. The name is padded with blanks if necessary.

The length of this field is given by LNPAN. The initial value of this field is 28 blank characters.

**DLPAT (10-digit signed integer)**

Type of application that put message on dead-letter (undelivered-message) queue.

This field has the same meaning as the MDPAT field in the message descriptor MQMD (see [“MQMD \(Message descriptor\) on IBM i”](#) on page 1110 for details).

If it is the queue manager that redirects the message to the dead-letter queue, DLPAT has the value ATQM.

The initial value of this field is 0.

### **DLPD (8-byte character string)**

Date when message was put on dead-letter (undelivered-message) queue.

The format used for the date when this field is generated by the queue manager is:

- YYYYMMDD

where the characters represent:

#### **YYYY**

year (four numeric digits)

#### **MM**

month of year (01 through 12)

#### **DD**

day of month (01 through 31)

Greenwich Mean Time (GMT) is used for the DLPD and DLPT fields, subject to the system clock being set accurately to GMT.

The length of this field is given by LNPDAT. The initial value of this field is eight blank characters.

### **DLPT (8-byte character string)**

Time when message was put on the dead-letter (undelivered-message) queue.

The format used for the time when this field is generated by the queue manager is:

- HHMMSSSTH

where the characters represent (in order):

#### **HH**

hours (00 through 23)

#### **MM**

minutes (00 through 59)

#### **SS**

seconds (00 through 59; see note later in this topic)

#### **T**

tenths of a second (0 through 9)

#### **H**

hundredths of a second (0 through 9)

**Note:** If the system clock is synchronized to an accurate time standard, it is possible for 60 or 61 to be returned for the seconds in DLPT. The extra second occurs when leap seconds are inserted into the global time standard.

Greenwich Mean Time (GMT) is used for the DLPD and DLPT fields, subject to the system clock being set accurately to GMT.

The length of this field is given by LNPTIM. The initial value of this field is eight blank characters.

### **DLREA (10-digit signed integer)**

Reason message arrived on dead-letter (undelivered-message) queue.

This identifies the reason why the message was placed on the dead-letter queue instead of on the original destination queue. It must be one of the FB\* or RC\* values (for example, RC2053). See the description of the *MDFB* field in [“MQMD \(Message descriptor\) on IBM i” on page 1110](#) for details of the common FB\* values that can occur.

If the value is in the range FBIFST through FBILST, the actual IMS error code can be determined by subtracting FBIERR from the value of the *DLREA* field.

Some FB\* values occur only in this field. They relate to repository messages, trigger messages, or transmission-queue messages that are transferred to the dead-letter queue. These values are:

**FBABEG**

Application cannot be started.

An application processing a trigger message was unable to start the application named in the TMAI field of the trigger message; see [“MQTM - Trigger message” on page 1235](#).

**FBATYP**

Application type error.

An application processing a trigger message was unable to start the application because the TMAI field of the trigger message is not valid; see [“MQTM - Trigger message” on page 1235](#).

**FBB OCD**

Cluster-receiver channel deleted.

The message was on a cluster transmission queue intended for a cluster queue that was opened with the FBIERR option. The remote cluster-receiver channel to be used to transmit the message to the destination queue was deleted before the message could be sent. Because FBIERR was specified, only the channel selected when the queue was opened can be used to transmit the message. As this channel is not longer available, the message was placed on the dead-letter queue.

**FBNARM**

Message is not a repository message.

**FBSBCX**

Message stopped by channel auto-definition exit.

**FBSBMX**

Message stopped by channel message exit.

**FBTM**

MQTM structure not valid or missing.

The MDFMT field in MQMD specifies FMTM, but the message does not begin with a valid MQTM structure. For example, the *TMSID* mnemonic eye-catcher might not be valid. The *TMVER* might not be recognized. The length of the trigger message might be insufficient to contain the MQTM structure.

**FBXQME**

Message on transmission queue not in correct format.

A message channel agent found that a message on the transmission queue is not in the correct format. The message channel agent puts the message on the dead-letter queue using this feedback code.

The initial value of this field is RCNONE.

**DLSID (4-byte character string)**

Structure identifier.

The value must be:

**DLSIDV**

Identifier for dead-letter header structure.

The initial value of this field is DLSIDV.

**DLVER (10-digit signed integer)**

Structure version number.

The value must be:

**DLVER1**

Version number for dead-letter header structure.

The following constant specifies the version number of the current version:

**DLVERC**

Current version of dead-letter header structure.

The initial value of this field is DLVER1.

**Initial values**

<i>Table 697. Fields in MQDLH</i>		
<b>Field name</b>	<b>Name of constant</b>	<b>Value of constant</b>

## IBM i MQDMHO (Delete message handle options) on IBM i

The **MQDMHO** structure allows applications to specify options that control how message handles are deleted.

### Overview

**Purpose:** The structure is an input parameter on the **MQDLTMH** call.

**Character set and encoding:** Data in **MQDMHO** must be in the character set of the application and encoding of the application (ENNAT).

- [“Fields” on page 1071](#)
- [“Initial values” on page 1071](#)
- [“RPG declaration” on page 1072](#)

### Fields

The **MQDMHO** structure contains the following fields; the fields are described in **alphabetical order**:

#### **DMOPT (10-digit signed integer)**

The value must be:

##### **DMNONE**

No options specified.

This is always an input field. The initial value of this field is **DMNONE**.

#### **DMSID (10-digit signed integer)**

This is the structure identifier; the value must be:

##### **DMSIDV**

Identifier for delete message handle options structure.

This is always an input field. The initial value of this field is **DMSIDV**.

#### **DMVER (10-digit signed integer)**

This is the structure version number; the value must be:

##### **DMVER1**

Version-1 delete message handle options structure.

The following constant specifies the version number of the current version:

##### **DMVERC**

Current version of delete message handle options structure.

This is always an input field. The initial value of this field is **DMVER1**.

### Initial values

## MQDMPO (Delete message property options) on IBM i

Structure defining the delete message property options.

### Overview

**Purpose:** The MQDMPO structure allows applications to specify options that control how properties of messages are deleted. The structure is an input parameter on the MQDLTMP call.

**Character set and encoding:** Data in MQDMPO must be in the character set of the application and encoding of the application (ENNAT).

- [“Fields” on page 1072](#)
- [“Initial values” on page 1073](#)
- [“RPG declaration” on page 1073](#)

### Fields

The MQDMPO structure contains the following fields; the fields are described in alphabetic order:

#### DPOPT (10-digit signed integer)

Delete message property options structure - DPOPT field.

**Location options:** The following options relate to the relative location of the property compared to the property cursor.

#### DPDELF

Deletes the first property that matches the specified name.

#### DPDELC

Deletes the property pointed to by the property cursor; that is the property that was last inquired by using either the IPINQF or the IPINQN option.

The property cursor is reset when the message handle is reused. It is also reset when the message handle is specified in the *HMSG* field of the MQGMO on an MQGET call, or MQPMO structure on an MQPUT call.

The property cursor is reset when the message handle is reused, or when the message handle is specified in the *HMSG* field of the MQGMO structure on an MQGET structure on an MQGET call or MQPMO structure on an MQPUT call.

The call fails with completion code CCFAIL and reason RC2471 if this option is used when the property cursor has not yet been established. It also fails with these codes if the property pointed to by the property cursor has already been deleted..

If neither of these options is required, the following option can be used:

**DPNONE**

No options specified.

The initial value of this input field is DPDELF.

**DPSID (10-digit signed integer)**

Delete message property options structure - DPSID field.

This is the structure identifier. The value must be:

**DPSIDV**

Identifier for delete message property options structure.

This field is always an input field. The initial value of this field is DPSIDV.

**DPVER (10-digit signed integer)**

Delete message property options structure - DPVER field.

This is the structure version number. The value must be:

**DPVER1**

Version number for delete message property options structure.

The following constant specifies the version number of the current version:

**DPVERC**

Current version of delete message property options structure.

This field is always an input field. The initial value of this field is DPVER1.

**Initial values**

## Overview

### Purpose

The MQEPH structure describes the additional data that is present in a message when that message is a programmable command format (PCF) message. The *EPPFH* field defines the PCF parameters that follow this structure and this allows you to follow the PCF message data with other headers.

### Format name

EPFMT

### Character set and encoding

Data in MQEPH must be in the character set and encoding of the local queue manager; this is given by the **CCSID** queue manager attribute.

Set the character set and encoding of the MQEPH into the *MDCSI* and *MDENC* fields in:

- The MQMD (if the MQEPH structure is at the start of the message data), or
- The header structure that precedes the MQEPH structure (all other cases).

### Usage

You cannot use MQEPH structures to send commands to the command server or any other queue manager PCF-accepting server.

Similarly, the command server or any other queue manager PCF-accepting server do not generate responses or events containing MQEPH structures.

- [“Fields” on page 1074](#)
- [“Initial values” on page 1076](#)
- [“RPG declaration” on page 1076](#)

## Fields

The MQEPH structure contains the following fields; the fields are described in **alphabetical order**:

### EPCSI (10-digit signed integer)

This is the character set identifier of the data that follows the MQEPH structure and the associated PCF parameters; it does not apply to character data in the MQEPH structure itself.

The initial value of this field is EPCUND.

### EPENC (10-digit signed integer)

This is the numeric encoding of the data that follows the MQEPH structure and the associated PCF parameters; it does not apply to character data in the MQEPH structure itself.

The initial value of this field is 0.

### EPFLG (10-digit signed integer)

The following values are available:

#### EPNONE

No flags have been specified. *MDCSI* EPNONE is defined to aid program documentation. It is not intended that this constant be used with any other, but as its value is zero, such use cannot be detected.

#### EPCSEM

The character set of the parameters containing character data is specified individually within the *CCSID* field in each structure. The character set of the *EPSID* and *EPFMT* fields are defined by the *CCSID* in the header structure that precedes the MQEPH structure, or by the *MDCSI* field in the MQMD if the MQEPH is at the start of the message.

The initial value of this field is EPNONE.

### **EPFMT (8-byte character string)**

This is the format name of the data that follows the MQEPH structure and the associated PCF parameters.

The initial value of this field is EPFMNO.

### **EPLEN (10-digit signed integer)**

This is the amount of data preceding the next header structure. It includes:

- The length of the MQEPH header
- The length of all PCF parameters following the header
- Any blank padding following those parameters

EPLEN must be a multiple of 4.

The fixed-length part of the structure is defined by EPSTLF.

The initial value of this field is 68.

### **EPPCFH (MQCFH)**

This is the programmable command format (PCF) header, defining the PCF parameters that follow the MQEPH structure. This enables you to follow the PCF message data with other headers.

The PCF header is initially defined with the following values:

<b>Field name</b>	<b>Name of constant</b>	<b>Value of constant</b>
<i>EP3TYP</i>	CFTNON	0
<i>EP3LEN</i>	FHLENV	36
<i>EP3VER</i>	FHVER3	3
<i>EP3CMD</i>	CMNONE	0
<i>EP3SEQ</i>	None	1
<i>EP3CTL</i>	CFCLST	1
<i>EEP3CC</i>	CCOK	0
<i>EP3REA</i>	RCNONE	0
<i>EP3CNT</i>	None	0

The application must change EP3TYP from CFTNON to a valid structure type for the use it is making of the embedded PCF header.

### **EPSID (4-byte character string)**

The value must be:

#### **EPSTID**

Identifier for the Embedded PCF header structure.

The initial value of this field is EPSTID.

### **EPVER (10-digit signed integer)**

The value can be:

#### **EPVER1**

Version number for embedded PCF header structure.

The following constant specifies the version number of the current version:

**EPVER3**

Current version of embedded PCF header structure.

The initial value of this field is EPVER3.

**Initial values**

<i>Table 701. Fields in MQEPH</i>		
<b>Field name</b>	<b>Name of constant</b>	<b>Value of constant</b>

```

The MQGMO structure allows the application to specify options that control how messages are removed from queues.

## Overview

### Purpose

The structure is an input/output parameter on the MQGET call.

### Version

The current version of MQGMO is GMVER4. Fields that exist only in the more-recent versions of the structure are identified as such in the descriptions that follow.

The COPY file provided contains the most recent version of MQGMO that is supported by the environment, but with the initial value of the *GMVER* field set to GMVER1. To use fields that are not present in the version-1 structure, the application must set the *GMVER* field to the version number of the version required.

### Character set and encoding

Data in MQGMO must be in the character set given by the **CodedCharSetId** queue manager attribute and encoding of the local queue manager given by ENNAT. However, if the application is running as an IBM MQ client, the structure must be in the character set and encoding of the client.

- [“Fields” on page 1077](#)
- [“Initial values” on page 1096](#)
- [“RPG declaration” on page 1097](#)

## Fields

The MQGMO structure contains the following fields; the fields are described in alphabetical order:

### GMGST (1 byte character string)

Flag indicating whether message retrieved is in a group.

It has one of the following values:

#### GSNIG

Message is not in a group.

#### GSMIG

Message is in a group, but is not the last in the group.

#### GSLMIG

Message is the last in the group.

This value is also the value returned if the group consists of only one message.

This field is an output field. The initial value of this field is GSNIG. This field is ignored if *GMVER* is less than GMVER2.

### GMMH (10 digit signed integer)

Message Handle

If the GMPRAQ option is specified and the PRPCTL queue attribute is not set to PRPRFH then this is the handle to a message which is populated with the properties of the message being retrieved from the queue. The handle is created by an MQCRTMH call. Any properties already associated with the handle are cleared before retrieving a message.

The following value can also be specified:

MQHM\_NONE

No message handle supplied.

No message descriptor is required on the MQGET call if a valid message handle is supplied and used on output to contain the message properties, the message descriptor associated with the message handle is used for input fields.

If a message descriptor is specified on the MQGET call, it always takes precedence over the message descriptor associated with a message handle.

If GMPRRF is specified, or the GMPRAQ is specified and the PRPCTL queue attribute is PRPRFH then the call fails with reason code RC2026 when no message descriptor parameter is specified.

On return from the MQGET call, the properties and message descriptor associated with this message handle are updated to reflect the state of the message retrieved (as well as the message descriptor if one was supplied on the MQGET call). The properties of the message can then be inquired using the MQINQMP call.

Except for message descriptor extensions, when present, a property that can be inquired with the MQINQMP call is not contained in the message data; if the message on the queue contained properties in the message data these are removed from the message data before the data is returned to the application.

If no message handle is provided or version is less than GMVER4 then you must supply a valid message descriptor on the MQGET call. Any message properties (except those properties contained in the message descriptor) are returned in the message data subject to the value of the property options in the MQGMO structure and the PRPCTL queue attribute.

This field is an always an input field. The initial value of this field is HMNONE. This field is ignored if *GMVER* is less than GMVER4.

### **GMMO (10 digit signed integer)**

Options controlling selection criteria used for MQGET.

These options allow the application to choose which fields in the **MSGDSC** parameter is used to select the message returned by the MQGET call. The application sets the required options in this field, and then sets the corresponding fields in the **MSGDSC** parameter to the values required for those fields. Only messages that have those values in the MQMD for the message are candidates for retrieval using that **MSGDSC** parameter on the MQGET call. Fields for which the corresponding match option is not specified are ignored when selecting the message to be returned. If no selection criteria are to be used on the MQGET call (that is, any message is acceptable), *GMMO* should be set to MONONE.

If GMLOGO is specified, only certain messages are eligible for return by the next MQGET call:

- If there is no current group or logical message, only messages that have *MDSEQ* equal to 1 and *MDOFF* equal to 0 are eligible for return. In this situation, one or more of the following options can be used to select which of the eligible messages is the one returned:
  - MOMSGI
  - MOCORI
  - MOGRPI
- If there is a current group or logical message, only the next message in the group or next segment in the logical message is eligible for return, and this cannot be altered by specifying MO\* options.

In both cases, match options which are not applicable can still be specified, but the value of the relevant field in the **MSGDSC** parameter must match the value of the corresponding field in the message to be returned; the call fails with reason code RC2247 if this condition is not satisfied.

*GMMO* is ignored if either GMMUC or GMBRWC is specified.

One or more of the following options can be specified:

#### **MOMSGI**

Retrieve message with specified message identifier.

This option specifies that the message to be retrieved must have a message identifier that matches the value of the *MDMID* field in the **MSGDSC** parameter of the MQGET call. This match is in addition to any other matches that might apply (for example, the correlation identifier).

If this option is not specified, the *MDMID* field in the **MSGDSC** parameter is ignored, and any message identifier matches.

**Note:** The message identifier MINONE is a special value that matches any message identifier in the MQMD for the message. Therefore, specifying MOMSGI with MINONE is the same as not specifying MOMSGI.

#### **MOCORI**

Retrieve message with specified correlation identifier.

This option specifies that the message to be retrieved must have a correlation identifier that matches the value of the *MDCID* field in the **MSGDSC** parameter of the MQGET call. This match is in addition to any other matches that might apply (for example, the message identifier).

If this option is not specified, the *MDCID* field in the **MSGDSC** parameter is ignored, and any correlation identifier matches.

**Note:** The correlation identifier CINONE is a special value that matches any correlation identifier in the MQMD for the message. Therefore, specifying MOCORI with CINONE is the same as not specifying MOCORI.

#### **MOGRPI**

Retrieve message with specified group identifier.

This option specifies that the message to be retrieved must have a group identifier that matches the value of the *MDGID* field in the **MSGDSC** parameter of the MQGET call. This match is in addition to any other matches that might apply (for example, the correlation identifier).

If this option is not specified, the *MDGID* field in the **MSGDSC** parameter is ignored, and any group identifier matches.

**Note:** The group identifier GINONE is a special value that matches any group identifier in the MQMD for the message. Therefore, specifying MOGRPI with GINONE is the same as not specifying MOGRPI.

#### **MOSEQN**

Retrieve message with specified message sequence number.

This option specifies that the message to be retrieved must have a message sequence number that matches the value of the *MDSEQ* field in the **MSGDSC** parameter of the MQGET call. This match is in addition to any other matches that might apply (for example, the group identifier).

If this option is not specified, the *MDSEQ* field in the **MSGDSC** parameter is ignored, and any message sequence number matches.

#### **MOOFFS**

Retrieve message with specified offset.

This option specifies that the message to be retrieved must have an offset that matches the value of the *MDOFF* field in the **MSGDSC** parameter of the MQGET call. This match is in addition to any other matches that might apply (for example, the message sequence number).

If this option is not specified, the *MDOFF* field in the **MSGDSC** parameter is ignored, and any offset matches.

If none of the options described is specified, the following option can be used:

#### **MONONE**

No matches.

This option specifies that no matches are to be used in selecting the message to be returned; therefore, all messages on the queue are eligible for retrieval (but subject to control by the GMAMSA, GMASGA, and GMCMPM options).

MONONE is defined to aid program documentation. It is not intended that this option is used with any other MO\* option, but as its value is zero, such use cannot be detected.

This field is an input field. The initial value of this field is MOMSGI with MOCORI. This field is ignored if *GMVER* is less than *GMVER2*.

**Note:** The initial value of the *GMMO* field is defined for compatibility with earlier version queue managers. However, when reading a series of messages from a queue without using selection criteria, this initial value requires the application to reset the *MDMID* and *MDCID* fields to MINONE and CINONE before each MQGET call. The need to reset *MDMID* and *MDCID* can be avoided by setting *GMVER* to *GMVER2*, and *GMMO* to MONONE.

### **GMOPT (10 digit signed integer)**

Options that control the action of MQGET.

Zero or more of the following described options can be specified. If more than one is required the values can be added (do not add the same constant more than once). Combinations of options that are not valid are noted; all other combinations are valid.

**Wait options:** The following options relate to waiting for messages to arrive on the queue:

#### **GMWT**

Wait for message to arrive.

The application is to wait until a suitable message arrives. The maximum time the application waits is specified in *GMWI*.

If MQGET requests are inhibited, or MQGET requests become inhibited while waiting, the wait is canceled and the call completes with CCFAIL and reason code RC2016, regardless of whether there are suitable messages on the queue.

This option can be used with the GMBRWF or GMBRWN options.

If several applications are waiting on the same shared queue, the application, or applications, that are activated when a suitable message arrives are described later in this section.

**Note:** In the following description, a browse MQGET call is one which specifies one of the browse options, but not GMLK; an MQGET call specifying the GMLK option is treated as a nonbrowse call.

- If one or more nonbrowse MQGET calls is waiting, but no browse MQGET calls are waiting, one is activated.
- If one or more browse MQGET calls is waiting, but no nonbrowse MQGET calls are waiting, all are activated.
- If one or more nonbrowse MQGET calls, and one or more browse MQGET calls are waiting, one nonbrowse MQGET call is activated, and none, some, or all the browse MQGET calls. (The number of browse MQGET calls activated cannot be predicted, because it depends on the scheduling considerations of the operating system, and other factors.)

If more than one nonbrowse MQGET call is waiting on the same queue, only one is activated; in this situation the queue manager attempts to give priority to waiting nonbrowse calls in the following order:

1. Specific get-wait requests that can be satisfied only by certain messages, for example, ones with a specific *MDMID* or *MDCID* (or both).
2. General get-wait requests that can be satisfied by any message.

The following points must be noted:

- Within the first category, no additional priority is given to more specific get-wait requests, for example those that specify both *MDMID* and *MDCID*.
- Within either category, it cannot be predicted which application is selected. In particular, the application waiting longest is not necessarily the one selected.

- Path length, and priority-scheduling considerations of the operating system, can mean that a waiting application of lower operating system priority than expected retrieves the message.
- It might also happen that an application that is not waiting retrieves the message in preference to one that is.

GMWT is ignored if specified with GMBRWC or GMMUC; no error is raised.

### **GMNWT**

Return immediately if no suitable message.

The application is not to wait if no suitable message is available. This is the opposite of the GMWT option, and is defined to aid program documentation. It is the default if neither is specified.

### **GMFIQ**

Fail if queue manager is quiescing.

This option forces the MQGET call to fail if the queue manager is in the quiescing state.

If this option is specified together with GMWT, and the wait is outstanding at the time the queue manager enters the quiescing state:

- The wait is canceled and the call returns completion code CCFAIL with reason code RC2161 .

If GMFIQ is not specified and the queue manager enters the quiescing state, the wait is not canceled.

**Syncpoint options:** The following options relate to the participation of the MQGET call within a unit of work:

### **GMSYP**

Get message with syncpoint control.

The request is to operate within the normal unit-of-work protocols. The message is marked as being unavailable to other applications, but it is deleted from the queue only when the unit of work is committed. The message is made available again if the unit of work is backed out.

If this option or GMNSYP is not specified, the get request is not within a unit of work.

This option is not valid with any of the following options:

- GMBRWF
- GMBRWC
- GMBRWN
- GMLK
- GMNSYP
- GMPSYP
- GMUNLK

### **GMPSYP**

Get message with syncpoint control if message is persistent.

The request is to operate within the normal unit-of-work protocols, but only if the message retrieved is persistent. A persistent message has the value PEPER in the *MDPER* field in MQMD.

- If the message is persistent, the queue manager processes the call as though the application had specified GMSYP.
- If the message is not persistent, the queue manager processes the call as though the application had specified GMNSYP (see the following section for details).

This option is not valid with any of the following options:

- GMBRWF
- GMBRWC
- GMBRWN

- GCMCPM
- GMNSYP
- GMSYP
- GMUNLK

### **GMNSYP**

Get message without syncpoint control.

The request is to operate outside the normal unit-of-work protocols. The message is deleted from the queue immediately (unless this is a browse request). The message cannot be made available again by backing out the unit of work.

This option is assumed if GMBRWF or GMBRWN is specified.

If this option and GMSYP are not specified, the get request is not within a unit of work.

This option is not valid with any of the following options:

- GMSYP
- GMPSYP

**Browse options:** The following options relate to browsing messages on the queue:

### **GMBRWF**

Browse from start of queue.

When a queue is opened with the OOBROW option, a browse cursor is established, positioned logically before the first message on the queue. Subsequent MQGET calls specifying the GMBRWF, GMBRWN, or GMBRWC option can be used to retrieve messages from the queue nondestructively. The browse cursor marks the position, within the messages on the queue, from which the next MQGET call with GMBRWN searches for a suitable message.

An MQGET call with GMBRWF causes the previous position of the browse cursor to be ignored. The first message on the queue that satisfies the conditions specified in the message descriptor is retrieved. The message remains on the queue, and the browse cursor is positioned on this message.

After this call, the browse cursor is positioned on the message that has been returned. If the message is removed from the queue before the next MQGET call with GMBRWN is issued, the browse cursor remains at the position in the queue that the message occupied, even though that position is now empty.

The GMMUC option can then be used with a nonbrowse MQGET call if required, to remove the message from the queue.

The browse cursor is not moved by a nonbrowse MQGET call using the same *HOBJ* handle. Nor is it moved by a browse MQGET call that returns a completion code of CCFAIL, or a reason code of RC2080 .

The GMLK option can be specified together with this option, to cause the message that is browsed to be locked.

GMBRWF can be specified with any valid combination of the GM\* and MO\* options that control the processing of messages in groups and segments of logical messages.

If GMLOGO is specified, the messages are browsed in logical order. If that option is omitted, the messages are browsed in physical order. When GMBRWF is specified, it is possible to switch between logical order and physical order, but subsequent MQGET calls using GMBRWN must browse the queue in the same order as the most recent call that specified GMBRWF for the queue handle.

The group and segment information that the queue manager retains for MQGET calls that browse messages on the queue, is separate from the group and segment information that the queue manager retains for MQGET calls that remove messages from the queue. When GMBRWF is specified, the queue manager ignores the group and segment information for browsing, and scans

the queue as though there were no current group and no current logical message. If the MQGET call is successful (completion code CCOK or CCWARN), the group and segment information for browsing is set to that of the message returned; if the call fails, the group and segment information remains the same as it was before the call.

This option is not valid with any of the following options:

- GMBRWC
- GMBRWN
- GMMUC
- GMSYP
- GMPSYP
- GMUNLK

It is also an error if the queue was not opened for browse.

### **GMBRWN**

Browse from current position in queue.

The browse cursor is advanced to the next message on the queue that satisfies the selection criteria specified on the MQGET call. The message is returned to the application, but remains on the queue.

After a queue has been opened for browse, the first browse call using the handle has the same effect whether it specifies the GMBRWF or GMBRWN option.

If the message is removed from the queue before the next MQGET call with GMBRWN is issued, the browse cursor logically remains at the position in the queue that the message occupied, even though that position is now empty.

Messages are stored on the queue in one of two ways:

- FIFO within priority (MSPRIO), or
- FIFO regardless of priority (MSFIFO)

The **MsgDeliverySequence** queue attribute indicates which method applies (see [“Attributes for queues”](#) on page 1366 for details).

If the queue has a *MsgDeliverySequence* of MSPRIO, and a message arrives on the queue that is of a higher priority than the one currently pointed to by the browse cursor, that message is not found during the current sweep of the queue using GMBRWN. It can only be found after the browse cursor has been reset with GMBRWF (or by reopening the queue).

The GMMUC option can later be used with a nonbrowse MQGET call if required, to remove the message from the queue.

The browse cursor is not moved by nonbrowse MQGET calls using the same *HOBJ* handle.

The GMLK option can be specified together with this option, to cause the message that is browsed to be locked.

GMBRWN can be specified with any valid combination of the GM\* and MO\* options that control the processing of messages in groups and segments of logical messages.

If GMLOGO is specified, the messages are browsed in logical order. If that option is omitted, the messages are browsed in physical order. When GMBRWF is specified, it is possible to switch between logical order and physical order, but subsequent MQGET calls using GMBRWN must browse the queue in the same order as the most recent call that specified GMBRWF for the queue handle. The call fails with reason code RC2259 if this condition is not satisfied.

**Note:** Special care is needed if an MQGET call is used to browse beyond the end of a message group (or logical message not in a group) when GMLOGO is not specified. For example, if the last message in the group happens to precede the first message in the group on the queue, using GMBRWN to browse beyond the end of the group, specifying MOSEQN with MDSEQ set to

1 (to find the first message of the next group) would return again the first message in the group already browsed. This could happen immediately, or a number of MQGET calls later (if there are intervening groups).

The possibility of an infinite loop can be avoided by opening the queue twice for browse:

- Use the first handle to browse only the first message in each group.
- Use the second handle to browse only the messages within a specific group.
- Use the MO\* options to move the second browse cursor to the position of the first browse cursor, before browsing the messages in the group.
- Do not use GMBRWN to browse beyond the end of a group.

The group and segment information that the queue manager retains for MQGET calls that browse messages on the queue, is separate from the group and segment information that it retains for MQGET calls that remove messages from the queue.

This option is not valid with any of the following options:

- GMBRWF
- GMBRWC
- GMMUC
- GMSYP
- GMPSYP
- GMUNLK

It is also an error if the queue was not opened for browse.

#### **GMBRWC**

Browse message under browse cursor.

This option causes the message pointed to by the browse cursor to be retrieved nondestructively, regardless of the MO\* options specified in the *GMMO* field in MQGMO.

The message pointed to by the browse cursor is the one that was last retrieved using either the GMBRWF or the GMBRWN option. The call fails if neither of these calls has been issued for this queue since it was opened, or if the message that was under the browse cursor has since been retrieved destructively.

The position of the browse cursor is not changed by this call.

The GMMUC option can then be used with a nonbrowse MQGET call if required, to remove the message from the queue.

The browse cursor is not moved by a nonbrowse MQGET call using the same *HOBJ* handle. Nor is it moved by a browse MQGET call that returns a completion code of CCFAIL, or a reason code of RC2080.

If GMBRWC is specified with GMLK:

- If there is already a message locked, it must be the one under the cursor, so that is returned without unlocking and relocking it; the message remains locked.
- If there is no locked message, the message under the browse cursor (if there is one) is locked and returned to the application; if there is no message under the browse cursor the call fails.

If GMBRWC is specified without GMLK:

- If there is already a message locked, it must be the one under the cursor. This message is returned to the application and then unlocked. Because the message is now unlocked, there is no guarantee that it can be browsed again, or retrieved destructively (it might be retrieved destructively by another application getting messages from the queue).
- If there is no locked message, the message under the browse cursor (if there is one) is returned to the application; if there is no message under the browse cursor the call fails.

If GMCMPM is specified with GMBRWC, the browse cursor must identify a message with a *MDOFF* field in MQMD that is zero. If this condition is not satisfied, the call fails with reason code RC2246 .

The group and segment information that the queue manager retains for MQGET calls that browse messages on the queue, is separate from the group and segment information that it retains for MQGET calls that remove messages from the queue.

This option is not valid with any of the following options:

- GMBRWF
- GMBRWN
- GMMUC
- GMSYP
- GMPSYP
- GMUNLK

It is also an error if the queue was not opened for browse.

### **GMMUC**

Get message under browse cursor.

This option causes the message pointed to by the browse cursor to be retrieved, regardless of the MO\* options specified in the *GMMO* field in MQGMO. The message is removed from the queue.

The message pointed to by the browse cursor is the one that was last retrieved using either the GMBRWF or the GMBRWN option.

If GMCMPM is specified with GMMUC, the browse cursor must identify a message with a *MDOFF* field in MQMD that is zero. If this condition is not satisfied, the call fails with reason code RC2246 .

This option is not valid with any of the following options:

- GMBRWF
- GMBRWC
- GMBRWN
- GMUNLK

It is also an error if the queue was not opened both for browse and for input. If the browse cursor is not currently pointing to a retrievable message, an error is returned by the MQGET call.

**Lock options:** The following options relate to locking messages on the queue:

### **GMLK**

Lock message.

This option locks the message that is browsed, so that the message becomes invisible to any other handle open for the queue. The option can be specified only if one of the following options is also specified:

- GMBRWF
- GMBRWN
- GMBRWC

Only one message can be locked per queue handle, but this can be a logical message or a physical message:

- If GMCMPM is specified, all the message segments that make up the logical message are locked to the queue handle (if they are all present on the queue and available for retrieval).
- If GMCMPM is not specified, only a single physical message is locked to the queue handle. If this message happens to be a segment of a logical message, the locked segment prevents other applications using GMCMPM to retrieve or browse the logical message.

The locked message is always the one under the browse cursor, and the message can be removed from the queue by a later MQGET call that specifies the GMMUC option. Other MQGET calls using the queue handle can also remove the message (for example, a call that specifies the message identifier of the locked message).

If the call returns completion code CCFAIL, or CCWARN with reason code RC2080, no message is locked.

If the application decides not to remove the message from the queue, the lock is released by:

- Issuing another MQGET call for this handle, with either GMBRWF or GMBRWN specified (with or without GMLK); the message is unlocked if the call completes with CCOK or CCWARN, but remains locked if the call completes with CCFAIL. However, the following exceptions apply:
  - The message is not unlocked if CCWARN is returned with RC2080.
  - The message is unlocked if CCFAIL is returned with RC2033.

If GMLK is also specified, the message returned is locked. If GMLK is not specified, there is no locked message after the call.

If GMWT is specified, and no message is immediately available, the unlock on the original message occurs before the start of the wait (providing the call is otherwise free from error).

- Issuing another MQGET call for this handle, with GMBRWC (without GMLK); the message is unlocked if the call completes with CCOK or CCWARN, but remains locked if the call completes with CCFAIL. However, the following exception applies:
  - The message is not unlocked if CCWARN is returned with RC2080.
- Issuing another MQGET call for this handle with GMUNLK.
- Issuing an MQCLOSE call for this handle (either explicitly, or implicitly by the application ending).

No special open option is required to specify this option, other than OOBROW, which is needed in order to specify the accompanying browse option.

This option is not valid with any of the following options:

- GMSYP
- GMPSYP
- GMUNLK

#### **GMUNLK**

Unlock message.

The message to be unlocked must have been previously locked by an MQGET call with the GMLK option. If there is no message locked for this handle, the call completes with CCWARN and RC2209.

The **MSGDSC**, **BUFLN**, **BUFFER**, and **DATLEN** parameters are not checked or altered if GMUNLK is specified. No message is returned in *BUFFER*.

No special open option is required to specify this option (although OOBROW is needed to issue the lock request in the first place).

This option is not valid with any options except the following:

- GMNWT
- GMNSYP

Both of these options are assumed whether specified or not.

**Message-data options:** The following options relate to the processing of the message data when the message is read from the queue:

#### **GMATM**

Allow truncation of message data.

If the message buffer is too small to hold the complete message, this option allows the MQGET call to fill the buffer with as much of the message as the buffer can hold, issue a warning completion code, and complete its processing. This means:

- When browsing messages, the browse cursor is advanced to the returned message.
- When removing messages, the returned message is removed from the queue.
- Reason code RC2079 is returned if no other error occurs.

Without this option, the buffer is still filled with as much of the message as it can hold, a warning completion code is issued, but processing is not completed. This means:

- When browsing messages, the browse cursor is not advanced.
- When removing messages, the message is not removed from the queue.
- Reason code RC2080 is returned if no other error occurs.

## **GMCONV**

Convert message data.

This option requests that the application data in the message is converted, to conform to the *MDCSI* and *MDENC* values specified in the **MSGDSC** parameter on the MQGET call, before the data is copied to the **BUFFER** parameter.

The *MDFMT* field specified when the message was put is assumed by the conversion process to identify the nature of the data in the message. Conversion of the message data is by the queue manager for built-in formats, and by a user-written exit for other formats.

- If conversion is performed successfully, the *MDCSI* and *MDENC* fields specified in the **MSGDSC** parameter are unchanged on return from the MQGET call.
- If conversion cannot be performed successfully (but the MQGET call otherwise completes without error), the message data is returned unconverted, and the *MDCSI* and *MDENC* fields in **MSGDSC** are set to the values for the unconverted message. The completion code is CCWARN in this case.

In either case, therefore, these fields describe the character-set identifier and encoding of the message data that is returned in the **BUFFER** parameter.

See the *MDFMT* field described in [“MQMD \(Message descriptor\) on IBM i”](#) on page 1110 for a list of format names for which the queue manager performs the conversion.

**Group and segment options:** The following options relate to the processing of messages in groups and segments of logical messages. These definitions might be of help in understanding the options:

### **Physical message**

This is the smallest unit of information that can be placed on or removed from a queue; it often corresponds to the information specified or retrieved on a single MQPUT, MQPUT1, or MQGET call. Every physical message has its own message descriptor (MQMD). Generally, physical messages are distinguished by differing values for the message identifier (*MDMID* field in MQMD), although this is not enforced by the queue manager.

### **Logical message**

This is a single unit of application information. In the absence of system constraints, a logical message would be the same as a physical message. But where logical messages are large, system constraints might make it advisable or necessary to split a logical message into two or more physical messages, called segments.

A logical message that has been segmented consists of two or more physical messages that have the same nonnull group identifier (*MDGID* field in MQMD), and the same message sequence number (*MDSEQ* field in MQMD). The segments are distinguished by differing values for the segment offset (*MDOFF* field in MQMD), which gives the offset of the data in the physical message from the start of the data in the logical message. Because each segment is a physical message, the segments in a logical message typically have differing message identifiers.

A logical message that has not been segmented, but for which segmentation has been permitted by the sending application, also has a nonnull group identifier, although in this case there is only one physical message with that group identifier if the logical message does not belong to a message group. Logical messages for which segmentation has been inhibited by the sending application have a null group identifier (GINONE), unless the logical message belongs to a message group.

### **Message group**

This is a set of one or more logical messages that have the same nonnull group identifier. The logical messages in the group are distinguished by differing values for the message sequence number, which is an integer in the range 1 through n, where n is the number of logical messages in the group. If one or more of the logical messages is segmented, there are more than n physical messages in the group.

### **GMLOGO**

Messages in groups and segments of logical messages are returned in logical order.

This option controls the order in which messages are returned by successive MQGET calls for the queue handle. The option must be specified on each of those calls in order to have an effect.

If GMLOGO is specified for successive MQGET calls for the queue handle, messages in groups are returned in the order given by their message sequence numbers, and segments of logical messages are returned in the order given by their segment offsets. This order might be different from the order in which those messages and segments occur on the queue.

**Note:** Specifying GMLOGO has no adverse consequences on messages that do not belong to groups and that are not segments. In effect, such messages are treated as though each belonged to a message group consisting of only one message. Thus it is perfectly safe to specify GMLOGO when retrieving messages from queues that might contain a mixture of messages in groups, message segments, and unsegmented messages not in groups.

To return the messages in the required order, the queue manager retains the group and segment information between successive MQGET calls. This information identifies the current message group and current logical message for the queue handle, the current position within the group and logical message, and whether the messages are being retrieved within a unit of work. Because the queue manager retains this information, the application does not need to set the group and segment information before each MQGET call. Specifically, it means that the application does not need to set the *MDGID*, *MDSEQ*, and *MDOFF* fields in MQMD. However, the application does need to set the *GMSYP* or *GMNSYP* option correctly on each call.

When the queue is opened, there is no current message group and no current logical message. A message group becomes the current message group when a message that has the MFMIG flag is returned by the MQGET call. With GMLOGO specified on successive calls, that group remains the current group until a message is returned that has:

- MFLMIG without MFSEG (that is, the last logical message in the group is not segmented), or
- MFLMIG with MFLSEG (that is, the message returned is the last segment of the last logical message in the group).

When such a message is returned, the message group is terminated, and on successful completion of that MQGET call there is no longer a current group. In a similar way, a logical message becomes the current logical message when a message that has the MFSEG flag is returned by the MQGET call, and that logical message is terminated when the message that has the MFLSEG flag is returned.

If no selection criteria are specified, successive MQGET calls return (in the correct order) the messages for the first message group on the queue, then the messages for the second message group, and so on, until there are no more messages available. It is possible to select the particular message groups returned by specifying one or more of the following options in the *GMMO* field:

- MOMSGI
- MOCORI

- MOGRPI

However, these options are effective only when there is no current message group or logical message; see the *GMMO* field described in this topic.

Table 702 on page 1089 shows the values of the *MDMID*, *MDCID*, *MDGID*, *MDSEQ*, and *MDOFF* fields that the queue manager looks for when attempting to find a message to return on the MQGET call. This applies both to removing messages from the queue, and browsing messages on the queue. The columns in the table have the following meanings:

**LOG ORD**

Indicates whether the GMLOGO option is specified on the call.

**Cur grp**

Indicates whether a current message group exists before the call.

**Cur log msg**

Indicates whether a current logical message exists before the call.

**Other columns**

Show the values that the queue manager looks for. "Previous" denotes the value returned for the field in the previous message for the queue handle.

Table 702. MQGET options relating to messages in groups and segments of logical messages							
Options you specify	Group and log-msg status before call		Values the queue manager looks for				
LOG ORD	Cur grp	Cur log msg	<i>MDMID</i>	<i>MDCID</i>	<i>MDGID</i>	<i>MDSEQ</i>	<i>MDOFF</i>
Yes	No	No	Controlled by <i>GMMO</i>	Controlled by <i>GMMO</i>	Controlled by <i>GMMO</i>	1	0
Yes	No	Yes	Any message identifier	Any correlation identifier	Previous group identifier	1	Previous offset + previous segment length
Yes	Yes	No	Any message identifier	Any correlation identifier	Previous group identifier	Previous sequence number + 1	0
Yes	Yes	Yes	Any message identifier	Any correlation identifier	Previous group identifier	Previous sequence number	Previous offset + previous segment length
No	Either	Either	Controlled by <i>GMMO</i>	Controlled by <i>GMMO</i>	Controlled by <i>GMMO</i>	Controlled by <i>GMMO</i>	Controlled by <i>GMMO</i>

When multiple message groups are present on the queue and eligible for return, the groups are returned in the order determined by the position on the queue of the first segment of the first logical message in each group (that is, the physical messages that have message sequence numbers of 1, and offsets of 0, determine the order in which eligible groups are returned).

The GMLOGO option affects units of work as follows:

- If the first logical message or segment in a group is retrieved within a unit of work, all the other logical messages and segments in the group must be retrieved within a unit of work, if the same queue handle is used. However, they need not be retrieved within the same unit of work. This allows a message group consisting of many physical messages to be split across two or more consecutive units of work for the queue handle.

- If the first logical message or segment in a group is not retrieved within a unit of work, none of the other logical messages and segments in the group can be retrieved within a unit of work, if the same queue handle is used.

If these conditions are not satisfied, the MQGET call fails with reason code RC2245 .

When GMLOGO is specified, the MQGMO supplied on the MQGET call must not be less than GMVER2, and the MQMD must not be less than MDVER2. If this condition is not satisfied, the call fails with reason code RC2256 or RC2257 , as appropriate.

If GMLOGO is not specified for successive MQGET calls for the queue handle, messages are returned without regard for whether they belong to message groups, or whether they are segments of logical messages. This means that messages or segments from a particular group or logical message might be returned out of order, or they might be intermingled with messages or segments from other groups or logical messages, or with messages that are not in groups and are not segments. In this situation, the particular messages that are returned by successive MQGET calls is controlled by the MO\* options specified on those calls (see the *GMMO* field described in [“MQGMO \(Get-message options\) on IBM i”](#) on page 1077 for details of these options).

This is the technique that can be used to restart a message group or logical message in the middle, after a system failure has occurred. When the system restarts, the application can set the *MDGID*, *MDSEQ*, *MDOFF*, and *GMMO* fields to the appropriate values, and then issue the MQGET call with *GMSYP* or *GMNSYP* set as needed, but without specifying GMLOGO. If this call is successful, the queue manager retains the group and segment information, and subsequent MQGET calls using that queue handle can specify GMLOGO as normal.

The group and segment information that the queue manager retains for the MQGET call is separate from the group and segment information that it retains for the MQPUT call. In addition, the queue manager retains separate information for:

- MQGET calls that remove messages from the queue.
- MQGET calls that browse messages on the queue.

For any given queue handle, the application is free to mix MQGET calls that specify GMLOGO with MQGET calls that do not, but the following points must be noted:

- If GMLOGO is not specified, each successful MQGET call causes the queue manager to set the saved group and segment information to the values corresponding to the message returned; this replaces the existing group and segment information retained by the queue manager for the queue handle. Only the information appropriate to the action of the call (browse or remove) is modified.
- If GMLOGO is not specified, the call does not fail if there is a current message group or logical message; the call might however succeed with a CCWARN completion code. [Table 703 on page 1090](#) shows the various cases that can arise. In these cases, if the completion code is not CCOK, the reason code is one of the following:
  - RC2241
  - RC2242
  - RC2245

**Note:** The queue manager does not check the group and segment information when browsing a queue, or when closing a queue that was opened for browse but not input; in those cases the completion code is always CCOK (assuming no other errors).

<i>Table 703. Outcome when MQGET or MQCLOSE call is not consistent with group and segment information</i>		
<b>Current call is</b>	<b>Previous call was MQGET with GMLOGO</b>	<b>Previous call was MQGET without GMLOGO</b>
MQGET with GMLOGO	CCFAIL	CCFAIL

Table 703. Outcome when MQGET or MQCLOSE call is not consistent with group and segment information (continued)		
Current call is	Previous call was MQGET with GMLOGO	Previous call was MQGET without GMLOGO
MQGET without GMLOGO	CCWARN	CCOK
MQCLOSE with an unterminated group or logical message	CCWARN	CCOK

Applications that simply want to retrieve messages and segments in logical order are recommended to specify GMLOGO, as this is the simplest option to use. This option relieves the application of the need to manage the group and segment information, because the queue manager manages that information. However, specialized applications might need more control than provided by the GMLOGO option, and this can be achieved by not specifying that option. If this is done, the application must ensure that the *MDMID*, *MDCID*, *MDGID*, *MDSEQ*, and *MDOFF* fields in MQMD, and the MO\* options in GMMO in MQGMO, are set correctly, before each MQGET call.

For example, an application that wants to forward physical messages that it receives, without regard for whether those messages are in groups or segments of logical messages, should not specify GMLOGO. This is because in a complex network with multiple paths between sending and receiving queue managers, the physical messages might arrive out of order. By not specifying GMLOGO and the corresponding PMLOGO on the MQPUT call, the forwarding application can retrieve and forward each physical message as soon as it arrives, without having to wait for the next one in logical order to arrive.

GMLOGO can be specified with any of the other GM\* options, and with various of the MO\* options in appropriate circumstances.

### GMCMPPM

Only complete logical messages are retrievable.

This option specifies that only a complete logical message can be returned by the MQGET call. If the logical message is segmented, the queue manager reassembles the segments and returns the complete logical message to the application; the fact that the logical message was segmented is not apparent to the application retrieving it.

**Note:** This is the only option that causes the queue manager to reassemble message segments. If not specified, segments are returned individually to the application if they are present on the queue (and they satisfy the other selection criteria specified on the MQGET call). Applications that do not want to receive individual segments should therefore always specify GMCMPPM.

To use this option, the application must provide a buffer which is large enough to accommodate the complete message, or specify the GMATM option.

If the queue contains segmented messages with some of the segments missing (perhaps because they have been delayed in the network and have not yet arrived), specifying GMCMPPM prevents the retrieval of segments belonging to incomplete logical messages. However, those message segments still contribute to the value of the **CurrentQDepth** queue attribute; this means that there might be no retrievable logical messages, even though *CurrentQDepth* is greater than zero.

For persistent messages, the queue manager can reassemble the segments only within a unit of work:

- If the MQGET call is operating within a user-defined unit of work, that unit of work is used. If the call fails part way through the reassembly process, the queue manager reinstates on the queue any segments that were removed during reassembly. However, the failure does not prevent the unit of work being committed successfully.
- If the call is operating outside a user-defined unit of work, and there is no user-defined unit of work in existence, the queue manager creates a unit of work just for the duration of the

call. If the call is successful, the queue manager commits the unit of work automatically (the application does not need to do this). If the call fails, the queue manager backs out the unit of work.

- If the call is operating outside a user-defined unit of work, but a user-defined unit of work does exist, the queue manager is unable to perform reassembly. If the message does not require reassembly, the call can still succeed. But if the message does require reassembly, the call fails with reason code RC2255 .

For nonpersistent messages, the queue manager does not require a unit of work to be available in order to perform reassembly.

Each physical message that is a segment has its own message descriptor. For the segments constituting a single logical message, most of the fields in the message descriptor is the same for all segments in the logical message - typically it is only the *MDMID*, *MDOFF*, and *MDMFL* fields that differ between segments in the logical message. However, if a segment is placed on a dead-letter queue at an intermediate queue manager, the DLQ handler retrieves the message specifying the GMCONV option, and this might result in the character set or encoding of the segment being changed. If the DLQ handler successfully sends the segment on its way, the segment might have a character set or encoding that differs from the other segments in the logical message when the segment finally arrives at the destination queue manager.

A logical message consisting of segments in which the *MDCSI*, *MDENC*, or both fields differ cannot be reassembled by the queue manager into a single logical message. Instead, the queue manager reassembles and returns the first few consecutive segments at the start of the logical message that have the same character-set identifiers and encodings, and the MQGET call completes with completion code CCWARN and reason code RC2243 or RC2244 , as appropriate. This happens regardless of whether GMCONV is specified. To retrieve the remaining segments, the application must reissue the MQGET call without the GMCMPM option, retrieving the segments one by one. GMLOGO can be used to retrieve the remaining segments in order.

It is also possible for an application which puts segments to set other fields in the message descriptor to values that differ between segments. However, there is no advantage in doing this if the receiving application uses GMCMPM to retrieve the logical message. When the queue manager reassembles a logical message, it returns in the message descriptor the values from the message descriptor for the first segment; the only exception is the *MDMFL* field, which the queue manager sets to indicate that the reassembled message is the only segment.

If GMCMPM is specified for a report message, the queue manager performs special processing. The queue manager checks the queue to see if all the report messages of that report type relating to the different segments in the logical message are present on the queue. If they are, they can be retrieved as a single message by specifying GMCMPM. For this to be possible, either the report messages must be generated by a queue manager or MCA which supports segmentation, or the originating application must request at least 100 bytes of message data (that is, the appropriate RO\*D or RO\*F options must be specified). If less than the full amount of application data is present for a segment, the missing bytes are replaced by nulls in the report message returned.

If GMCMPM is specified with GMMUC or GMBRWC, the browse cursor must be positioned on a message with a *MDOFF* field in MQMD that has a value of 0. If this condition is not satisfied, the call fails with reason code RC2246 .

GMCMPM implies GMASGA, which need not therefore be specified.

GMCMPM can be specified with any of the other GM\* options apart from GMPSYP, and with any of the MO\* options apart from MOOFFS.

## **GMAMSA**

All messages in group must be available.

This option specifies that messages in a group become available for retrieval only when all messages in the group are available. If the queue contains message groups with some of the messages missing (perhaps because they have been delayed in the network and have not yet arrived), specifying GMAMSA prevents retrieval of messages belonging to incomplete groups.

However, those messages still contribute to the value of the **CurrentQDepth** queue attribute; this means that there might be no retrievable message groups, even though **CurrentQDepth** is greater than zero. If there are no other messages that are retrievable, reason code RC2033 is returned after the specified wait interval (if any) has expired.

The processing of GMAMSA depends on whether GMLOGO is also specified:

- If both options are specified, GMAMSA affects only when there is no current group or logical message. If there is a current group or logical message, GMAMSA is ignored. This means that GMAMSA can remain on when processing messages in logical order.
- If GMAMSA is specified without GMLOGO, GMAMSA always has an effect. This means that the option must be turned off after the first message in the group has been removed from the queue, in order to be able to remove the remaining messages in the group.

Successful completion of an MQGET call specifying GMAMSA means that at the time that the MQGET call was issued, all the messages in the group were on the queue. However, be aware that other applications are still able to remove messages from the group (the group is not locked to the application that retrieves the first message in the group).

If this option is not specified, messages belonging to groups can be retrieved even when the group is incomplete.

GMAMSA implies GMASGA, which need not therefore be specified.

GMAMSA can be specified with any of the other GM\* options, and with any of the MO\* options.

## **GMASGA**

All segments in a logical message must be available.

This option specifies that segments in a logical message become available for retrieval only when all segments in the logical message are available. If the queue contains segmented messages with some of the segments missing (perhaps because they have been delayed in the network and have not yet arrived), specifying GMASGA prevents retrieval of segments belonging to incomplete logical messages. However those segments still contribute to the value of the **CurrentQDepth** queue attribute; this means that there might be no retrievable logical messages, even though **CurrentQDepth** is greater than zero. If there are no other messages that are retrievable, reason code RC2033 is returned after the specified wait interval (if any) has expired.

The processing of GMASGA depends on whether GMLOGO is also specified:

- If both options are specified, GMASGA has an effect only when there is no current logical message. If there is a current logical message, GMASGA is ignored. This means that GMASGA can remain on when processing messages in logical order.
- If GMASGA is specified without GMLOGO, GMASGA always has an effect. This means that the option must be turned off after the first segment in the logical message has been removed from the queue, in order to be able to remove the remaining segments in the logical message.

If this option is not specified, message segments can be retrieved even when the logical message is incomplete.

While both GMCMPM and GMASGA require all segments to be available before any of them can be retrieved, the former returns the complete message, whereas the latter allows the segments to be retrieved one by one.

If GMASGA is specified for a report message, the queue manager performs special processing. The queue manager checks the queue to see if there is at least one report message for each of the segments that make up the complete logical message. If there is, the GMASGA condition is satisfied. However, the queue manager does not check the type of the report messages present, and so there might be a mixture of report types in the report messages relating to the segments of the logical message. As a result, the success of GMASGA does not imply that GMCMPM succeeds. If there is a mixture of report types present for the segments of a particular logical message, those report messages must be retrieved one by one.

GMASGA can be specified with any of the other GM\* options, and with any of the MO\* options.

**Default option:** If none of the options described are required, the following option can be used:

**GMNONE**

No options specified.

This value can be used to indicate that no other options have been specified; all options assume their default values. GMNONE is defined to aid program documentation; it is not intended that this option is used with any other, but as its value is zero, such use cannot be detected.

The initial value of the *GMOPT* field is GMNWT.

**GMRE1 (1 byte character string)**

Reserved.

This is a reserved field. The initial value of this field is a blank character. This field is ignored if *GMVER* is less than GMVER2.

**GMRL (10 digit signed integer)**

Length of message data returned (bytes).

This is an output field that is set by the queue manager to the length in bytes of the message data returned by the MQGET call in the **BUFFER** parameter. If the queue manager does not support this capability, *GMRL* is set to the value RLUNDF.

When messages are converted between encodings or character sets, the message data can sometimes change size. On return from the MQGET call:

- If *GMRL* is not RLUNDF, the number of bytes of message data returned is given by *GMRL*.
- If *GMRL* has the value RLUNDF, the number of bytes of message data returned is typically given by the smaller of *BUFLen* and *DATLEN*, but can be less than this if the MQGET call completes with reason code RC2079 . If this happens, the insignificant bytes in the **BUFFER** parameter are set to nulls.

The following special value is defined:

**RLUNDF**

Length of returned data not defined.

The initial value of this field is RLUNDF. This field is ignored if *GMVER* is less than GMVER3.

**GMRQN (48 byte character string)**

Resolved name of destination queue.

This is an output field which is set by the queue manager to the local name of the queue from which the message was retrieved, as defined to the local queue manager. This is different from the name used to open the queue if:

- An alias queue was opened (in which case, the name of the local queue to which the alias resolved is returned), or
- A model queue was opened (in which case, the name of the dynamic local queue is returned).

The length of this field is given by LNQN. The initial value of this field is 48 blank characters.

**GMRS2 (1 byte character string)**

Reserved.

This is a reserved field. The initial value of this field is a blank character. This field is ignored if *GMVER* is less than GMVER4.

**GMSEG (1 byte character string)**

Flag indicating whether further segmentation is allowed for the message retrieved.

It has one of the following values:

**SEGIHB**

Segmentation not allowed.

**SEGALW**

Segmentation allowed.

This is an output field. The initial value of this field is SEGIHB. This field is ignored if *GMVER* is less than *GMVER2*.

**GMSG1 (10 digit signed integer)**

Signal.

This is a reserved field; its value is not significant. The initial value of this field is 0.

**GMSG2 (10 digit signed integer)**

Signal identifier.

This is a reserved field; its value is not significant.

**GMSID (4 byte character string)**

Structure identifier.

The value must be:

**GMSIDV**

Identifier for get-message options structure.

This field is always an input field. The initial value of this field is GMSIDV.

**GMSST (1 byte character string)**

Flag indicating whether message retrieved is a segment of a logical message.

It has one of the following values:

**SSNSEG**

Message is not a segment.

**SSSEG**

Message is a segment, but is not the last segment of the logical message.

**SSLSEG**

Message is the last segment of the logical message.

This is also the value returned if the logical message consists of only one segment.

This field is an output field. The initial value of this field is SSNSEG. This field is ignored if *GMVER* is less than *GMVER2*.

**GMTOK (16 byte bit string)**

Message token.

This is a reserved field; its value is not significant. The following special value is defined:

**MTKNON**

No message token.

The value is binary zero for the length of the field.

The length of this field is given by *LNMTOK*. The initial value of this field is MTKNON. This field is ignored if *GMVER* is less than *GMVER3*.

**GMVER (10 digit signed integer)**

Structure version number.

The value must be one of the following:

**GMVER1**

Version-1 get-message options structure.

**GMVER2**

Version-2 get-message options structure.

**GMVER3**

Version-3 get-message options structure.

**GMVER4**

Version-4 get-message options structure.

Fields that exist only in the more-recent versions of the structure are identified as such in the descriptions of the fields. The following constant specifies the version number of the current version:

**GMVERC**

Current version of get-message options structure.

This field is always an input field. The initial value of this field is GMVER1.

**GMVER (10 digit signed integer)**

Structure version number.

The value must be one of the following:

**GMVER1**

Version-1 get-message options structure.

**GMVER2**

Version-2 get-message options structure.

**GMVER3**

Version-3 get-message options structure.

**GMVER4**

Version-4 get-message options structure.

Fields that exist only in the more-recent versions of the structure are identified as such in the descriptions of the fields. The following constant specifies the version number of the current version:

**GMVERC**

Current version of get-message options structure.

This field is always an input field. The initial value of this field is GMVER1.

**GMWI (10 digit signed integer)**

Wait interval.

This is the approximate time, expressed in milliseconds, that the MQGET call waits for a suitable message to arrive (that is, a message satisfying the selection criteria specified in the **MSGDSC** parameter of the MQGET call; see the *MDMID* field described in “MQMD (Message descriptor) on IBM i” on page 1110 for more details). If no suitable message has arrived after this time has elapsed, the call completes with CCFAIL and reason code RC2033.

*GMWI* is used with the GMWT option. It is ignored if this option is not specified. If it is specified, *GMWI* must be greater than or equal to zero, or the following special value:

**WIULIM**

Unlimited wait interval.

The initial value of this field is 0.

**Initial values**

Field name	Name of constant	Value of constant
<i>GMSID</i>	GMSIDV	'GMO-'
<i>GMVER</i>	GMVER1	1

## IBM i MQIIH (IMS information header) on IBM i

The MQIIH structure describes the information that must be present at the start of a message sent to the IMS bridge through IBM MQ for z/OS.

### Overview

**Format name:** FMIMS.

**Character set and encoding:** Special conditions apply to the character set and encoding used for the MQIIH structure and application message data:

- Applications that connect to the queue manager that owns the IMS bridge queue must provide an MQIIH structure that is in the character set and encoding of the queue manager. This is because data conversion of the MQIIH structure is not performed in this case.
- Applications that connect to other queue managers can provide an MQIIH structure that is in any of the supported character sets and encodings; conversion of the MQIIH is performed by the receiving message channel agent connected to the queue manager that owns the IMS bridge queue.

**Note:** There is one exception to this. If the queue manager that owns the IMS bridge queue is using CICS for distributed queuing, the MQIIH must be in the character set and encoding of the queue manager that owns the IMS bridge queue.

- The application message data following the MQIIH structure must be in the same character set and encoding as the MQIIH structure. The *IICSI* and *IIENC* fields in the MQIIH structure cannot be used to specify the character set and encoding of the application message data.

A data-conversion exit must be provided by the user to convert the application message data if the data is not one of the built-in formats supported by the queue manager.

- [“Authenticating passtickets for IMS bridge applications” on page 1098](#)
- [“Fields” on page 1098](#)
- [“Initial values” on page 1101](#)
- [“RPG declaration” on page 1102](#)

### Authenticating passtickets for IMS bridge applications

It is now possible for IBM MQ administrators to specify the application name to be used for authenticating passtickets, for IMS bridge applications. To do this, the application name is specified as a new attribute PTKTAPPL for the STGCLASS object definition, as a 1 to 8 character alphanumeric string.

A blank value means that authentication occurs as with previous releases of IBM MQ, that is, no application name flows on the authentication request, and the MVSxxxx value to is used instead.

A value of 1 - 8 alphanumeric characters must follow the rules for passticket application names as described in the RACF publications.

IBM MQ Administrators and RACF administrators must both agree on the valid application names to be used. The RACF administrator must create a profile in the PTKTDATA class giving READ access to the user IDs of all applications that are to be granted access. The IBM MQ administrator must create or alter the required STGCLASS definitions that specify the application name to be used for passticket authentication.

For related information, see the *Script (MQSC) Command Reference*.

### Fields

The MQIIH structure contains the following fields; the fields are described in **alphabetical order**:

**IIAUT (8-byte character string)**

RACF password or passticket.

This is optional; if specified, it is used with the user ID in the MQMD security context to build a UTOKEN that is sent to IMS to provide a security context. If it is not specified, the user ID is used without verification. This depends on the setting of the RACF switches, which may require an authenticator to be present.

This is ignored if the first byte is blank or null. The following special value may be used:

**IAUNON**

No authentication.

The length of this field is given by LNAUTH. The initial value of this field is IAUNON.

**IICMT (1-byte character string)**

Commit mode.

See the *OTMA Reference* for more information about IMS commit modes. The value must be one of the following:

**ICMCTS**

Commit then send.

This mode implies double queuing of output, but shorter region occupancy times. Fast-path and conversational transactions cannot run with this mode.

**ICMSTC**

Send then commit.

The initial value of this field is ICMCTS.

**IICSI (10-digit signed integer)**

Reserved.

This is a reserved field; its value is not significant. The initial value of this field is 0.

**IIENC (10-digit signed integer)**

Reserved.

This is a reserved field; its value is not significant. The initial value of this field is 0.

**IIFLG (10-digit signed integer)**

Flags.

The value must be:

**IINONE**

No flags.

The initial value of this field is IINONE.

**IIFMT (8-byte character string)**

IBM MQ format name of data that follows MQIIH.

This specifies the IBM MQ format name of the data that follows the MQIIH structure.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The rules for coding this field are the same as those for the *MDFMT* field in MQMD.

The length of this field is given by LNFMT. The initial value of this field is FMNONE.

**IILEN (10-digit signed integer)**

Length of MQIIH structure.

The value must be:

**IILEN1**

Length of IMS information header structure.

The initial value of this field is IILEN1.

**IILTO (8-byte character string)**

Logical terminal override.

This is placed in the IO PCB field. It is optional; if it is not specified the TPIPE name is used. It is ignored if the first byte is blank, or null.

The length of this field is given by LNLTOV. The initial value of this field is 8 blank characters.

**IIMMN (8-byte character string)**

Message format services map name.

This is placed in the IO PCB field. It is optional. On input it represents the MID, on output it represents the MOD. It is ignored if the first byte is blank or null.

The length of this field is given by LNMFMN. The initial value of this field is 8 blank characters.

**IIRFM (8-byte character string)**

IBM MQ format name of reply message.

This is the IBM MQ format name of the reply message that will be sent in response to the current message. The rules for coding this are the same as those for the *MDFMT* field in MQMD.

The length of this field is given by LNFMT. The initial value of this field is FMNONE.

**IIRSV (1-byte character string)**

Reserved.

This is a reserved field; it must be blank.

**IISEC (1-byte character string)**

Security scope.

This indicates the required IMS security processing. The following values are defined:

**ISSCHK**

Check security scope.

An ACEE is built in the control region, but not in the dependent region.

**ISSFUL**

Full security scope.

A cached ACEE is built in the control region and a non-cached ACEE is built in the dependent region. If you use ISSFUL, you must ensure that the user ID for which the ACEE is built has access to the resources used in the dependent region.

If ISSCHK and ISSFUL are not specified for this field, ISSCHK is assumed.

The initial value of this field is ISSCHK.

**IISID (4-byte character string)**

Structure identifier.

The value must be:

**IISIDV**

Identifier for IMS information header structure.

The initial value of this field is IISIDV.

**IITID (16-byte bit string)**

Transaction instance identifier.

This field is used by output messages from IMS so is ignored on first input. If *IITST* is set to *ITSIC*, this must be provided in the next input, and all subsequent inputs, to enable IMS to correlate the messages to the correct conversation. The following special value may be used:

**ITINON**

No transaction instance ID.

The length of this field is given by *LNTIID*. The initial value of this field is *ITINON*.

**IITST (1-byte character string)**

Transaction state.

This indicates the IMS conversation state. This is ignored on first input because no conversation exists. On subsequent inputs it indicates whether a conversation is active or not. On output it is set by IMS. The value must be one of the following:

**ITSIC**

In conversation.

**ITSNIC**

Not in conversation.

**ITSARC**

Return transaction state data in architected form.

This value is used only with the *IMS /DISPLAY TRAN* command. It causes the transaction state data to be returned in the IMS architected form instead of character form. See [Writing IMS transaction programs through IBM MQ](#) for further details.

The initial value of this field is *ITSNIC*.

**IIVER (10-digit signed integer)**

Structure version number.

The value must be:

**IIVER1**

Version number for IMS information header structure.

The following constant specifies the version number of the current version:

**IIVERC**

Current version of IMS information header structure.

The initial value of this field is *IIVER1*.

**Initial values**

```

The MQIMPO structure allows applications to specify options that control how properties of messages are inquired.

## Overview

**Purpose:** The structure is an input parameter on the MQINQMP call.

**Character set and encoding:** Data in MQIMPO must be in the character set of the application and encoding of the application (ENNAT).

- [“Fields” on page 1103](#)
- [“Initial values” on page 1109](#)
- [“RPG declaration” on page 1109](#)

## Fields

The MQIMPO structure contains the following fields; the fields are described in **alphabetical order**:

### IPOPT (10-digit signed integer)

The following options control the action of MQINQMP. You can specify one or more of these options. To specify more than one option, either add the values together (do not add the same constant more than once), or combine the values using the bitwise OR operation (if the programming language supports bit operations). Combinations of options that are not valid are noted; all other combinations are valid.

**Value data options:** The following options relate to the processing of the value data when the property is retrieved from the message.

#### IPCVAL

This option requests that the value of the property be converted to conform to the *IPREQCSI* and *IPREQENC* values specified before the MQINQMP call returns the property value in the *Value* area.

- If conversion is successful, the *IPRETCSI* and *IPRETENC* fields are set to the same as *IPREQCSI* and *IPREQENC* on return from the MQINQMP call.
- If conversion fails, but the MQINQMP call otherwise completes without error, the property value is returned unconverted.

If the property is a string, the *IPRETCSI* and *IPRETENC* fields are set to the character set and encoding of the unconverted string.

The completion code is CCWARN in this case, with reason code RC2466. The property cursor is advanced to the returned property.

If the property value expands during conversion, and exceeds the size of the **Value** parameter, the value is returned unconverted, with completion code CCFAIL; the reason code is set to RC2469.

The **DataLength** parameter of the MQINQMP call returns the length that the property value would have converted to, in order to allow the application to determine the size of the buffer required to accommodate the converted property value. The property cursor is unchanged.

This option also requests that:

- If the property name contains a wildcard, and
- The *IPRETNAMECHRP* field is initialized with an address or offset for the returned name, then the returned name is converted to conform to the *IPREQCSI* and *IPREQENC* values.

- If conversion is successful, the *VSCCSID* field of *IPRETNAMECHRP* and the encoding of the returned name are set to the input value of *IPREQCSI* and *IPREQENC*.
- If conversion fails, but the MQINQMP call otherwise completes without error or warning, the returned name is unconverted. The completion code is CCWARN in this case, with reason code RC2492.

The property cursor is advanced to the returned property. RC2466 is returned if both the value and the name are not converted.

If the returned name expands during conversion, and exceeds the size of the *VSBuFSIZE* field of the *RequestedName*, the returned string is left unconverted, with completion code CCFAIL and the reason code is set to RC2465.

The *VSLength* field of the MQCHARV structure returns the length that the property value would have converted to, in order to allow the application to determine the size of the buffer required to accommodate the converted property value. The property cursor is unchanged.

### IPCTYP

This option requests that the value of the property be converted from its current data type, into the data type specified on the **Type** parameter of the MQINQMP call.

- If conversion is successful, the **Type** parameter is unchanged on return of the MQINQMP call.
- If conversion fails, but the MQINQMP call otherwise completes without error, the call fails with reason RC2470. The property cursor is unchanged.

If the conversion of the data type causes the value to expand during conversion, and the converted value exceeds the size of the **Value** parameter, the value is returned unconverted, with completion code CCFAIL and the reason code is set to RC2469.

The **DataLength** parameter of the MQINQMP call returns the length that the property value would have converted to, in order to allow the application to determine the size of the buffer required to accommodate the converted property value. The property cursor is unchanged.

If the value of the **Type** parameter of the MQINQMP call is not valid, the call fails with reason RC2473.

If the requested data type conversion is not supported, the call fails with reason RC2470. The following data type conversions are supported:

<i>Table 706. Supported data type conversions</i>	
Property data type	Supported target data types
TYPBOL	TYPSTR, TYPI8, TYPI16, TYPI32, TYPI64
TYPBST	TYPSTR
TYPI8	TYPSTR, TYPI16, TYPI32, TYPI64
TYPI16	TYPSTR, TYPI32, TYPI64
TYPI32	TYPSTR, TYPI64
TYPI64	TYPSTR
TYPF32	TYPSTR, TYPF64
TYPF64	TYPSTR
TYPSTR	TYPBOL, TYPI8, TYPI16, TYPI32, TYPI64, TYPF32, TYPF64
TYPNUL	None

The general rules governing the supported conversions are as follows:

- Numeric property values can be converted from one data type to another, provided that no data is lost during the conversion.

For example, the value of a property with data type TYPI32 can be converted into a value with data type TYPI64, but cannot be converted into a value with data type TYPI16.

- A property value of any data type can be converted into a string.
- A string property value can be converted to any other data type provided the string is formatted correctly for the conversion. If an application attempts to convert a string property value that is not formatted correctly, IBM MQ returns reason code RC2472.
- If an application attempts a conversion that is not supported, IBM MQ returns reason code RC2470.

The specific rules for converting a property value from one data type to another are as follows:

- When converting a TYPBOL property value to a string, the value TRUE is converted to the string "TRUE", and the value false is converted to the string "FALSE".
- When converting a TYPBOL property value to a numeric data type, the value TRUE is converted to one, and the value FALSE is converted to zero.
- When converting a string property value to a TYPBOL value, the string "TRUE" , or "1" , is converted to TRUE, and the string "FALSE", or "0", is converted to FALSE.

Note that the terms "TRUE" and "FALSE" are not case sensitive.

Any other string cannot be converted; IBM MQ returns reason code RC2472.

- When converting a string property value to a value with data type TYPI8, TYPI16, TYPI32 or TYPI64, the string must have the following format:

```
[blanks][sign]digits
```

The meanings of the components of the string are as follows:

**blanks**

Optional leading blank characters

**sign**

An optional plus sign (+) or minus sign (-) character.

**digits**

A contiguous sequence of digit characters (0-9). At least one digit character must be present.

After the sequence of digit characters, the string can contain other characters that are not digit characters, but the conversion stops as soon as the first of these characters is reached. The string is assumed to represent a decimal integer.

IBM MQ returns reason code RC2472 if the string is not formatted correctly.

- When converting a string property value to a value with data type TYPF32 or TYPF64, the string must have the following format:

```
[blanks][sign]digits[.digits][e_char[e_sign]e_digits]
```

The meanings of the components of the string are as follows:

**blanks**

Optional leading blank characters

**sign**

An optional plus sign (+) or minus sign (-) character.

**digits**

A contiguous sequence of digit characters (0-9). At least one digit character must be present.

**e\_char**

An exponent character, which is either "E" or "e".

**e\_sign**

An optional plus sign (+) or minus sign (-) character for the exponent.

**e\_digits**

A contiguous sequence of digit characters (0-9) for the exponent. At least one digit character must be present if the string contains an exponent character.

After the sequence of digit characters, or the optional characters representing an exponent, the string can contain other characters that are not digit characters, but the conversion stops as soon as the first of these characters is reached. The string is assumed to represent a decimal floating point number with an exponent that is a power of 10.

IBM MQ returns reason code RC2472 if the string is not formatted correctly.

- When converting a numeric property value to a string, the value is converted to the string representation of the value as a decimal number, not the string containing the ASCII character for that value. For example, the integer 65 is converted to the string "65", not the string "A".
- When converting a byte string property value to a string, each byte is converted to the two hexadecimal characters that represent the byte. For example, the byte array {0xF1, 0x12, 0x00, 0xFF} is converted to the string "F11200FF".

**IPQLEN**

Query the type and length of the property value. The length is returned in the **DataLength** parameter of the MQINQMP call. The property value is not returned.

If a *ReturnedName* buffer is specified, the *VSLength* field of the MQCHARV structure is filled in with the length of the property name. The property name is not returned.

**Iteration options:** The following options relate to iterating over properties, using a name with a wildcard character

**IPINQF**

Inquire on the first property that matches the specified name. After this call, a cursor is established on the property that is returned.

This is the default value.

The IPINQF option can subsequently be used with an MQINQMP call, if required, to inquire on the same property again.

Note that there is only one property cursor; therefore, if the property name, specified in the MQINQMP call, changes the cursor is reset.

This option is not valid with either of the following options:

IPINQN

IPINQC

**IPINQN**

Inquires on the next property that matches the specified name, continuing the search from the property cursor. The cursor is advanced to the property that is returned.

If this is the first MQINQMP call for the specified name, then the first property that matches the specified name is returned.

The IPINQN option can subsequently be used with an MQINQMP call if required, to inquire on the same property again.

If the property under the cursor has been deleted, MQINQMP returns the next matching property following the one that has been deleted.

If a property is added that matches the wildcard, while an iteration is in progress, the property might or might not be returned during the completion of the iteration. The property is returned once the iteration restarts using IPINQF.

A property matching the wildcard that was deleted, while the iteration was in progress, is not returned subsequent to its deletion.

This option is not valid with either of the following options:

IPINQF  
IPINQC

#### **IPINQC**

Retrieve the value of the property pointed to by the property cursor. The property pointed to by the property cursor is the one that was last inquired, using either the IPINQF or the IPINQN option.

The property cursor is reset when the message handle is reused, when the message handle is specified in the *MsgHandle* field of the MQGMO on an MQGET call, or when the message handle is specified in *OriginalMsgHandle* or *NewMsgHandle* fields of the MQPMO structure on an MQPUT call.

If this option is used when the property cursor has not yet been established, or if the property pointed to by the property cursor has been deleted, the call fails with completion code CCFAIL and reason RC2471.

This option is not valid with either of the following options:

IPINQF  
IPINQN

If none of the options previously described is required, the following option can be used:

#### **IPNONE**

Use this value to indicate that no other options have been specified; all options assume their default values.

IPNONE aids program documentation; it is not intended that this option be used with any other, but as its value is zero, such use cannot be detected.

This is always an input field. The initial value of this field is IPINQF.

#### **IPREQCSI (10-digit signed integer)**

The character set that the inquired property value is to be converted into if the value is a character string. This is also the character set into which the *ReturnedName* is to be converted when IPCVAL or IPCTYP is specified.

The initial value of this field is CSAPL.

#### **IPREQENC (10-digit signed integer)**

This is the encoding into which the inquired property value is to be converted when IPCVAL or IPCTYP is specified.

The initial value of this field is ENNAT.

#### **IPRE1 (10-digit signed integer)**

This is a reserved field. The initial value of this field is a blank character.

#### **IPRETCSI (10-digit signed integer)**

On output, this is the character set of the value returned if the **Type** parameter of the MQINQMP call is TYPSTR.

If the IPCVAL option is specified and conversion was successful, the *ReturnedCCSID* field, on return, is the same value as the value passed in.

The initial value of this field is zero.

### **IPRETENC (10-digit signed integer)**

On output, this is the encoding of the value returned.

If the IPCVAL option is specified and conversion was successful, the *ReturnedEncoding* field, on return, is the same value as the value passed in.

The initial value of this field is ENNAT.

### **IPRETNAMCHRP (10-digit signed integer)**

The actual name of the inquired property.

On input a string buffer can be passed in using the *VSPtr* or *VSOffset* field of the MQCHARV structure. The length of the string buffer is specified using the *VSBuFSIZE* field of the MQCHARV structure.

On return from the MQINQMP call, the string buffer is completed with the name of the property that was inquired, provided the string buffer was long enough to fully contain the name. The *VSLength* field of the MQCHARV structure is filled in with the length of the property name. The *VSCCSID* field of the MQCHARV structure is filled in to indicate the character set of the returned name, whether or not conversion of the name failed.

This is an input/output field. The initial value of this field is MQCHARV\_DEFAULT.

### **IPSID (10-digit signed integer)**

This is the structure identifier. The value must be:

#### **IPSIDV**

Identifier for inquire message property options structure.

This is always an input field. The initial value of this field is IPSIDV.

### **IPTYP (10-digit signed integer)**

A string representation of the data type of the property.

If the property was specified in an MQRFH2 header and the MQRFH2 dt attribute is not recognized, this field can be used to determine the data type of the property. *TypeString* is returned in coded character set 1208 (UTF-8), and is the first eight bytes of the value of the dt attribute of the property that failed to be recognized

This is always an output field. The initial value of this field is the null string in the C programming language, and 8 blank characters in other programming languages.

### **IPVER (10-digit signed integer)**

This is the structure version number. The value must be:

#### **IPVER1**

Version number for inquire message property options structure.

The following constant specifies the version number of the current version:

#### **IPVERC**

Current version of inquire message property options structure.

This is always an input field. The initial value of this field is IPVER1.

## Initial values

Table 707. Fields in MQIPMO		
Field name	Name of constant	Value of constant
IPSID	IPSIDV	'IMPO'

## Overview

**Purpose:** The MQMD structure contains the control information that accompanies the application data when a message travels between the sending and receiving applications. The structure is an input/output parameter on the MQGET, MQPUT, and MQPUT1 calls.

**Version:** The current version of MQMD is MDVER2. Fields that exist only in the more-recent versions of the structure are identified as such in the descriptions that follow.

The COPY file provided contains the most recent version of MQMD that is supported by the environment, but with the initial value of the MDVER field set to MDVER1. To use fields that are not present in the version-1 structure, the application must set the MDVER field to the version number of the version required.

A declaration for the version-1 structure is available with the name MQMD1.

**Character set and encoding:** Data in MQMD must be in the character set given by the **CodedCharSetId** queue manager attribute and encoding of the local queue manager given by ENNAT. However, if the application is running as an IBM MQ MQI client, the structure must be in the character set and encoding of the client.

If the sending and receiving queue managers use different character sets or encodings, the data in MQMD is converted automatically. It is not necessary for the application to convert the MQMD.

- [“Using different versions of MQMD” on page 1110](#)
- [“Message context” on page 1111](#)
- [“Message expiry” on page 1111](#)
- [“Fields” on page 1111](#)
- [“Initial values” on page 1151](#)
- [“RPG declaration” on page 1152](#)

## Using different versions of MQMD

A version-2 MQMD is generally equivalent to using a version-1 MQMD and prefixing the message data with an MQMDE structure. However, if all of the fields in the MQMDE structure have their default values, the MQMDE can be omitted. A version-1 MQMD plus MQMDE are used as described later in this section.

- On the MQPUT and MQPUT1 calls, if the application provides a version-1 MQMD, the application can optionally prefix the message data with an MQMDE, setting the MDFMT field in MQMD to FMMDE to indicate that an MQMDE is present. If the application does not provide an MQMDE, the queue manager assumes default values for the fields in the MQMDE.

**Note:** Several of the fields that exist in the version-2 MQMD but not the version-1 MQMD are input/output fields on the MQPUT and MQPUT1 calls. However, the queue manager does not return any values in the equivalent fields in the MQMDE on output from the MQPUT and MQPUT1 calls; if the application requires those output values, it must use a version-2 MQMD.

- On the MQGET call, if the application provides a version-1 MQMD, the queue manager prefixes the message returned with an MQMDE, but only if one or more of the fields in the MQMDE has a non-default value. The MDFMT field in MQMD will have the value FMMDE to indicate that an MQMDE is present.

The default values that the queue manager used for the fields in the MQMDE are the same as the initial values of those fields, shown in [Table 709 on page 1151](#).

When a message is on a transmission queue, some of the fields in MQMD are set to particular values; see [“MQXQH \(Transmission-queue header\) on IBM i” on page 1245](#) for details.

## Message context

Certain fields in MQMD contain the message context. Typically:

- *Identity context* relates to the application that originally put the message
- *Origin context* relates to the application that most recently put the message
- *User context* relates to the application that originally put the message.

These two applications can be the same application, but they can also be different applications (for example, when a message is forwarded from one application to another).

Although identity and origin context usually have the meanings described previously, the content of both types of context fields in MQMD actually depends on the PM\* options that are specified when the message is put. As a result, identity context does not necessarily relate to the application that originally put the message, and origin context does not necessarily relate to the application that most recently put the message - it depends on the design of the application suite.

There is one class of application that never alters message context, namely the message channel agent (MCA). MCAs that receive messages from remote queue managers use the context option PMSETA on the MQPUT or MQPUT1 call. This allows the receiving MCA to preserve exactly the message context that travelled with the message from the sending MCA. However, the result is that the origin context does not relate to the application that most recently put the message (the receiving MCA), but instead relates to an earlier application that put the message (possibly the originating application itself).

For more information see [Message context](#).

## Message expiry

Messages that have expired on a loaded queue (a queue that has been opened) are automatically removed from the queue within a reasonable period of time after their expiry. Some other new features of this release of IBM MQ can lead to loaded queues being scanned less frequently than in the previous product version, however expired messages on loaded queues are always removed within a reasonable period of their expiry.

## Fields

The MQMD structure contains the following fields; the fields are described in alphabetical order:

### MDACC (32-byte bit string)

Accounting token.

This is part of the *identity context* of the message. For more information about message context, see [Message context](#) and [Controlling context information](#).

*MDACC* allows an application to cause work done as a result of the message to be appropriately charged. The queue manager treats this information as a string of bits and does not check its content.

When the queue manager generates this information, it is set as follows:

- The first byte of the field is set to the length of the accounting information present in the bytes that follow; this length is in the range zero through 30, and is stored in the first byte as a binary integer.
- The second and subsequent bytes (as specified by the length field) are set to the accounting information appropriate to the environment.

–  On z/OS the accounting information is set to:

- For z/OS batch, the accounting information from the JES JOB card or from a JES ACCT statement in the EXEC card (comma separators are changed to X'FF'). This information is truncated, if necessary, to 31 bytes.
- For TSO, the user's account number.
- For CICS, the LU 6.2 unit of work identifier (UEPUOWDS) (26 bytes).

- For IMS, the 8-character PSB name concatenated with the 16-character IMS recovery token.
  -  On IBM i, the accounting information is set to the accounting code for the job.
  -   On AIX and Linux, the accounting information is set to the numeric user identifier, in ASCII characters.
  -  On Windows, the accounting information is set to a Windows NT security identifier (SID) in a compressed format. The SID uniquely identifies the user identifier stored in the *MDUID* field. When the SID is stored in the *MDACC* field, the 6-byte Identifier Authority (located in the third and subsequent bytes of the SID) is omitted. For example, if the Windows NT SID is 28 bytes long, 22 bytes of SID information are stored in the *MDACC* field.
- The last byte is set to the accounting-token type, one of the following values:

**ATTCIC**

CICS LUOW identifier.

**ATTDOS**

PC DOS default accounting token.

**ATTWNT**

Windows security identifier.

**ATT400**

IBM i accounting token.

**ATTUNX**

AIX and Linux numeric identifier.

**ATTUSR**

User-defined accounting token.

**ATTUNK**

Unknown accounting-token type.

The accounting-token type is set to an explicit value only in the following environments:

-  AIX
-  IBM i
-  Windows

and for IBM MQ MQI clients connected to these systems.

In other environments, the accounting-token type is set to the value ATTUNK. In these environments the MDPAT field can be used to deduce the type of accounting token received.

- All other bytes are set to binary zero.

For the MQPUT and MQPUT1 calls, this is an input/output field if PMSETI or PMSETA is specified in the **PMO** parameter. If neither PMSETI nor PMSETA is specified, this field is ignored on input and is an output-only field. For more information on message context, see [Message context](#) and [Controlling context information](#).

After the successful completion of an MQPUT or MQPUT1 call, this field contains the MDACC that was transmitted with the message if it was put to a queue. This will be the value of MDACC that is kept with the message if it is retained (see description of PMRET in “MQPMO (Put-message options) on IBM i” on page 1173 for more details about retained publications) but is not used as the MDACC when the message is sent as a publication to subscribers since they provide a value to override MDACC in all publications sent to them. If the message has no context, the field is entirely binary zero.

This is an output field for the MQGET call.

This field is not subject to any translation based on the character set of the queue manager-the field is treated as a string of bits, and not as a string of characters.

The queue manager does nothing with the information in this field. The application must interpret the information if it wants to use the information for accounting purposes.

The following special value may be used for the *MDACC* field:

**ACNONE**

No accounting token is specified.

The value is binary zero for the length of the field.

The length of this field is given by *LNACCT*. The initial value of this field is *ACNONE*.

**MDAID (32-byte character string)**

Application data relating to identity.

This is part of the *identity context* of the message. For more information about message context, see [Message context](#) and [Controlling context information](#).

MDAID is information that is defined by the application suite, and can be used to provide additional information about the message or its originator. The queue manager treats this information as character data, but does not define the format of it. When the queue manager generates this information, it is entirely blank.

For the *MQPUT* and *MQPUT1* calls, this is an input/output field if *PMSETI* or *PMSETA* is specified in the **PMO** parameter. If a null character is present, the null and any following characters are converted to blanks by the queue manager. If neither *PMSETI* nor *PMSETA* is specified, this field is ignored on input and is an output-only field. For more information on message context, see [Message context](#) and [Controlling context information](#).

After the successful completion of an *MQPUT* or *MQPUT1* call, this field contains the MDAID that was transmitted with the message if it was put to a queue. This will be the value of MDAID that is kept with the message if it is retained (see description of *PMRET* for more details about retained publications) but is not used as the MDAID when the message is sent as a publication to subscribers since they provide a value to override MDAID in all publications sent to them. If the message has no context, the field is entirely blank.

This is an output field for the *MQGET* call. The length of this field is given by *LNAIDD*. The initial value of this field is 32 blank characters.

**MDAOD (4-byte character string)**

Application data relating to origin.

This is part of the *origin context* of the message. For more information about message context, see [Message context](#) and [Controlling context information](#).

MDAOD is information that is defined by the application suite that can be used to provide additional information about the origin of the message. For example, it could be set by applications running with suitable user authority to indicate whether the identity data is trusted.

The queue manager treats this information as character data, but does not define the format of it. When the queue manager generates this information, it is entirely blank.

For the *MQPUT* and *MQPUT1* calls, this is an input/output field if *PMSETA* is specified in the **PMO** parameter. Any information following a null character within the field is discarded. The null character and any following characters are converted to blanks by the queue manager. If *PMSETA* is not specified, this field is ignored on input and is an output-only field.

After the successful completion of an *MQPUT* or *MQPUT1* call, this field contains the MDAOD that was transmitted with the message if it was put to a queue. This will be the value of MDAOD that is kept with the message if it is retained (see description of *PMRET* for more details about retained publications) but is not used as the MDAOD when the message is sent as a publication to subscribers since they provide a value to override MDAOD in all publications sent to them. If the message has no context, the field is entirely blank.

This is an output field for the MQGET call. The length of this field is given by LNAORD. The initial value of this field is 4 blank characters.

### **MDBOC (10-digit signed integer)**

Backout counter.

This is a count of the number of times the message has been previously returned by the MQGET call as part of a unit of work, and subsequently backed out. It is provided as an aid to the application in detecting processing errors that are based on message content. The count excludes MQGET calls that specified any of the GMBRW\* options.

The accuracy of this count is affected by the **HardenGetBackout** queue attribute; see [“Attributes for queues” on page 1366](#).

This is an output field for the MQGET call. It is ignored for the MQPUT and MQPUT1 calls. The initial value of this field is 0.

### **MDCID (24-byte bit string)**

Correlation identifier.

This is a byte string that the application can use to relate one message to another, or to relate the message to other work that the application is performing. The correlation identifier is a permanent property of the message, and persists across restarts of the queue manager. Because the correlation identifier is a byte string and not a character string, the correlation identifier is not converted between character sets when the message flows from one queue manager to another.

For the MQPUT and MQPUT1 calls, the application can specify any value. The queue manager transmits this value with the message and delivers it to the application that issues the get request for the message.

If the application specifies PMNCID, the queue manager generates a unique correlation identifier which is sent with the message, and also returned to the sending application on output from the MQPUT or MQPUT1 call.

This generated correlation identifier is kept with the message if it is retained and is used as the correlation identifier when the message is sent as a publication to subscribers who specify CINONE in the SDCID field in the MQSD passed on the MQSUB call.

See [“MQPMO \(Put-message options\) on IBM i” on page 1173](#) for more details about retained publications

When the queue manager or a message channel agent generates a report message, it sets the MDCID field in the way specified by the MDREP field of the original message, either ROCMTC or ROPCI. Applications which generate report messages should also do this.

For the MQGET call, MDCID is one of the five fields that can be used to select a particular message to be retrieved from the queue. See the description of the MDMID field for details of how to specify values for this field.

Specifying CINONE as the correlation identifier has the same effect as not specifying MOCORI, that is, any correlation identifier will match.

If the GMMUC option is specified in the **GMO** parameter on the MQGET call, this field is ignored.

On return from an MQGET call, the MDCID field is set to the correlation identifier of the message returned (if any).

The following special values may be used:

#### **CINONE**

No correlation identifier is specified.

The value is binary zero for the length of the field.

#### **CINEWS**

Message is the start of a new session.

This value is recognized by the CICS bridge as indicating the start of a new session, that is, the start of a new sequence of messages.

For the MQGET call, this is an input/output field. For the MQPUT and MQPUT1 calls, this is an input field if PMNCID is not specified, and an output field if PMNCID is specified. The length of this field is given by LNCID. The initial value of this field is CINONE.

### **MDCSI (10-digit signed integer)**

This specifies the character set identifier of character data in the message.

**Note:** Character data in MQMD and the other IBM MQ data structures that are parameters on calls must be in the character set of the queue manager. This is defined by the queue manager's **CodedCharSetId** attribute; see [“Attributes for the queue manager on IBM i” on page 1397](#) for details of this attribute.

The following special values can be used:

#### **CSQM**

Queue manager's character set identifier.

Character data in the message is in the queue manager's character set.

On the MQPUT and MQPUT1 calls, the queue manager changes this value in the MQMD sent with the message to the true character-set identifier of the queue manager. As a result, the value CSQM is never returned by the MQGET call.

#### **CSINHT**

Inherit character-set identifier of this structure.

Character data in the message is in the same character set as this structure; this is the queue manager's character set. (For MQMD only, CSINHT has the same meaning as CSQM).

The queue manager changes this value in the MQMD sent with the message to the actual character-set identifier of MQMD. Provided no error occurs, the value CSINHT is not returned by the MQGET call.

CSINHT cannot be used if the value of the MDPAT field in MQMD is ATBRKR.

#### **CSEMBD**

Embedded character set identifier.

Character data in the message is in a character set with the identifier that is contained within the message data itself. There can be any number of character-set identifiers embedded within the message data, applying to different parts of the data. This value must be used for PCF messages that contain data in a mixture of character sets. PCF messages have a format name of FMPCF.

Specify this value only on the MQPUT and MQPUT1 calls. If it is specified on the MQGET call, it prevents conversion of the message.

On the MQPUT and MQPUT1 calls, the queue manager changes the values CSQM and CSINHT in the MQMD sent with the message as described previously, but does not change the MQMD specified on the MQPUT or MQPUT1 call. No other check is carried out on the value specified.

Applications that retrieve messages should compare this field against the value the application is expecting; if the values differ, the application may need to convert character data in the message.

If the GMCONV option is specified on the MQGET call, this field is an input/output field. The value specified by the application is the coded character-set identifier to which the message data should be converted if necessary. If conversion is successful or unnecessary, the value is unchanged (except that the value CSQM or CSINHT is converted to the actual value). If conversion is unsuccessful, the value after the MQGET call represents the coded character-set identifier of the unconverted message that is returned to the application.

Otherwise, this is an output field for the MQGET call, and an input field for the MQPUT and MQPUT1 calls. The initial value of this field is CSQM.

## **MDENC (10-digit signed integer)**

Numeric encoding of message data.

This specifies the numeric encoding of numeric data in the message; it does not apply to numeric data in the MQMD structure itself. The numeric encoding defines the representation used for binary integers, packed-decimal integers, and floating-point numbers.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The queue manager does not check that the field is valid. The following special value is defined:

### **ENNAT**

Native machine encoding.

The encoding is the default for the programming language and machine on which the application is running.

**Note:** The value of this constant depends on the programming language and environment. For this reason, applications must be compiled using the header, macro, COPY, or INCLUDE files appropriate to the environment in which the application will run.

Applications that put messages should normally specify ENNAT. Applications that retrieve messages should compare this field against the value ENNAT; if the values differ, the application may need to convert numeric data in the message. The GMCONV option can be used to request the queue manager to convert the message as part of the processing of the MQGET call.

If the GMCONV option is specified on the MQGET call, this field is an input/output field. The value specified by the application is the encoding to which the message data should be converted if necessary. If conversion is successful or unnecessary, the value is unchanged. If conversion is unsuccessful, the value after the MQGET call represents the encoding of the unconverted message that is returned to the application.

In other cases, this is an output field for the MQGET call, and an input field for the MQPUT and MQPUT1 calls. The initial value of this field is ENNAT.

## **MDEXP (10-digit signed integer)**

Message lifetime.

This is a period of time expressed in tenths of a second, set by the application that puts the message. The message becomes eligible to be discarded if it has not been removed from the destination queue before this period of time elapses.

The value is decremented to reflect the time the message spends on the destination queue, and also on any intermediate transmission queues if the put is to a remote queue. It may also be decremented by message channel agents to reflect transmission times, if these are significant. Likewise, an application forwarding this message to another queue might decrement the value if necessary, if it has retained the message for a significant time. However, the expiration time is treated as approximate, and the value need not be decremented to reflect small time intervals.

When the message is retrieved by an application using the MQGET call, the MDEXP field represents the amount of the original expiry time that still remains.

After a message's expiry time has elapsed, it becomes eligible to be discarded by the queue manager. In the current implementations, the message is discarded when a browse or nonbrowse MQGET call occurs that would have returned the message had it not already expired. For example, a nonbrowse MQGET call with the GMMO field in MQGMO set to MONONE reading from a FIFO ordered queue will cause all the expired messages to be discarded up to the first unexpired message. With a priority ordered queue, the same call will discard expired messages of higher priority and messages of an equal priority that arrived on the queue before the first unexpired message.

A message that has expired is never returned to an application (either by a browse or a non-browse MQGET call), so the value in the MDEXP field of the message descriptor after a successful MQGET call is either greater than zero, or the special value EIULIM.

If a message is put on a remote queue, the message may expire (and be discarded) while it is on an intermediate transmission queue, before the message reaches the destination queue.

A report is generated when an expired message is discarded, if the message specified one of the ROEXP\* report options. If none of these options is specified, no such report is generated; the message is assumed to be no longer relevant after this time period (perhaps because a later message has superseded it).

Any other program that discards messages based on expiry time must also send an appropriate report message if one was requested.

**Note:**

1. If a message is put with an MDEXP time of zero, the MQPUT or MQPUT1 call fails with reason code RC2013; no report message is generated in this case.
2. Since a message with an expiry time that has elapsed may not actually be discarded until later, there may be messages on a queue that have passed their expiry time, and which are not therefore eligible for retrieval. These messages nevertheless count towards the number of messages on the queue for all purposes, including depth triggering.
3. An expiration report is generated, if requested, when the message is actually discarded, not when it becomes eligible for discarding.
4. Discarding of an expired message, and the generation of an expiration report if requested, are never part of the application's unit of work, even if the message was scheduled for discarding as a result of an MQGET call operating within a unit of work.
5. If a nearly-expired message is retrieved by an MQGET call within a unit of work, and the unit of work is subsequently backed out, the message may become eligible to be discarded before it can be retrieved again.
6. If a nearly-expired message is locked by an MQGET call with GMLK, the message may become eligible to be discarded before it can be retrieved by an MQGET call with GMMUC; reason code RC2034 is returned on this subsequent MQGET call if that happens.
7. When a request message with an expiry time greater than zero is retrieved, the application can take one of the following actions when it sends the reply message:
  - Copy the remaining expiry time from the request message to the reply message.
  - Set the expiry time in the reply message to an explicit value greater than zero.
  - Set the expiry time in the reply message to EIULIM.

The action to take depends on the design of the application suite. However, the default action for putting messages to a dead-letter (undelivered-message) queue should be to preserve the remaining expiry time of the message, and to continue to decrement it.

8. Trigger messages are always generated with EIULIM.
9. A message (normally on a transmission queue) which has a MDFMT name of FMXQH has a second message descriptor within the MQXQH. It therefore has two MDEXP fields associated with it. The following additional points should be noted in this case:
  - When an application puts a message on a remote queue, the queue manager places the message initially on a local transmission queue, and prefixes the application message data with an MQXQH structure. The queue manager sets the values of the two MDEXP fields to be the same as that specified by the application.

If an application puts a message directly on a local transmission queue, the message data must already begin with an MQXQH structure, and the format name must be FMXQH (but the queue manager does not enforce this). In this case the application need not set the values of these two MDEXP fields to be the same. (The queue manager does not check that the MDEXP field within the MQXQH contains a valid value, or even that the message data is long enough to include it.)
  - When a message with a MDFMT name of FMXQH is retrieved from a queue (whether this is a normal or a transmission queue), the queue manager decrements both these MDEXP fields with

the time spent waiting on the queue. No error is raised if the message data is not long enough to include the MDEXP field in the MQXQH.

- The queue manager uses the MDEXP field in the separate message descriptor (that is, not the one in the message descriptor embedded within the MQXQH structure) to test whether the message is eligible for discarding.
- If the initial values of the two MDEXP fields were different, it is therefore possible for the MDEXP time in the separate message descriptor when the message is retrieved to be greater than zero (so the message is not eligible for discarding), while the time according to the MDEXP field in the MQXQH has elapsed. In this case the MDEXP field in the MQXQH is set to zero.

The following special value is recognized:

**EIULIM**

Unlimited lifetime.

The message has an unlimited expiration time.

This is an output field for the MQGET call, and an input field for the MQPUT and MQPUT1 calls. The initial value of this field is EIULIM.

**MDFB (10-digit signed integer)**

Feedback or reason code.

This is used with a message of type MTRPRT to indicate the nature of the report, and is only meaningful with that type of message. The field can contain one of the FB\* values, or one of the RC\* values. Feedback codes are grouped as follows:

**FBNONE**

No feedback provided.

**FBSFST**

Lowest value for system-generated feedback.

**FBSLST**

Highest value for system-generated feedback.

The range of system-generated feedback codes FBSFST through FBSLST includes the general feedback codes listed later in this section (FB\*), and also the reason codes (RC\*) that can occur when the message cannot be put on the destination queue.

**FBAFST**

Lowest value for application-generated feedback.

**FBALST**

Highest value for application-generated feedback.

Applications that generate report messages should not use feedback codes in the system range (other than FBQUIT), unless they want to simulate report messages generated by the queue manager or message channel agent.

On the MQPUT or MQPUT1 calls, the value specified must either be FBNONE, or be within the system range or application range. This is checked whatever the value of MDMT.

**General feedback codes:**

**FBCOA**

Confirmation of arrival on the destination queue (see ROCOA).

**FBCOD**

Confirmation of delivery to the receiving application (see ROCOD).

**FBEXP**

Message expired.

Message was discarded because it had not been removed from the destination queue before its expiry time had elapsed.

**FBPAN**

Positive action notification (see ROPAN).

**FBNAN**

Negative action notification (see RONAN).

**FBQUIT**

Application should end.

This can be used by a workload scheduling program to control the number of instances of an application program that are running. Sending an MTRPRT message with this feedback code to an instance of the application program indicates to that instance that it should stop processing. However, adherence to this convention is a matter for the application; it is not enforced by the queue manager.

**IMS-bridge feedback codes:** When the IMS bridge receives a nonzero IMS-OTMA sense code, the IMS bridge converts the sense code from hexadecimal to decimal, adds the value FBIERR (300), and places the result in the MDFB field of the reply message. This results in the feedback code having a value in the range FBIFST (301) through FBILST (399) when an IMS-OTMA error has occurred.

The following feedback codes can be generated by the IMS bridge:

**FBDLZ**

Data length zero.

A segment length was zero in the application data of the message.

**FBDLN**

Data length negative.

A segment length was negative in the application data of the message.

**FBDLTB**

Data length too big.

A segment length was too big in the application data of the message.

**FBBUFO**

Buffer overflow.

The value of one of the length fields would cause the data to overflow the message buffer.

**FBLOB1**

Length in error by one.

The value of one of the length fields was one byte too short.

**FBIIH**

MQIIH structure not valid or missing.

The MDFMT field in MQMD specifies FMIMS, but the message does not begin with a valid MQIIH structure.

**FBNAFI**

User ID not authorized for use in IMS.

The user ID contained in the message descriptor MQMD, or the password contained in the IIAUT field in the MQIIH structure, failed the validation performed by the IMS bridge. As a result the message was not passed to IMS.

**FBIERR**

Unexpected error returned by IMS.

An unexpected error was returned by IMS. Consult the IBM MQ error log on the system on which the IMS bridge resides for more information about the error.

**FBIFST**

Lowest value for IMS-generated feedback.

IMS-generated feedback codes occupy the range FBIFST (300) through FBILST (399). The IMS-OTMA sense code itself is MDFB minus FBIERR.

**FBILST**

Highest value for IMS-generated feedback.

**CICS-bridge feedback codes:** The following feedback codes can be generated by the CICS bridge:

**FBCAAB**

Application abended.

The application program specified in the message abended. This feedback code occurs only in the DLREA field of the MQDLH structure.

**FBCANS**

Application cannot be started.

The EXEC CICS LINK for the application program specified in the message failed. This feedback code occurs only in the DLREA field of the MQDLH structure.

**FBCBRF**

CICS bridge terminated abnormally without completing normal error processing.

**FBCCSSE**

Character set identifier not valid.

**FBCIHE**

CICS information header structure missing or not valid.

**FBCCAE**

Length of CICS commarea not valid.

**FBCCLIE**

Correlation identifier not valid.

**FBCDLQ**

Dead-letter queue not available.

The CICS bridge task was unable to copy a reply to this request to the dead-letter queue. The request was backed out.

**FBCENE**

Encoding not valid.

**FBCINE**

CICS bridge encountered an unexpected error.

This feedback code occurs only in the DLREA field of the MQDLH structure.

**FBCNTA**

User identifier not authorized or password not valid.

This feedback code occurs only in the DLREA field of the MQDLH structure.

**FBCUBO**

Unit of work backed out.

The unit of work was backed out, for one of the following reasons:

- A failure was detected while processing another request within the same unit of work.
- A CICS abend occurred while the unit of work was in progress.

**FBCUWE**

Unit-of-work control field CIUOW not valid.

**MQ reason codes:** For exception report messages, MDFB contains an MQ reason code. Among possible reason codes are:

**RC2051**

(2051, X'803') Put calls inhibited for the queue.

**RC2053**

(2053, X'805') Queue already contains maximum number of messages.

**RC2035**

(2035, X'7F3') Not authorized for access.

**RC2056**

(2056, X'808') No space available on disk for queue.

**RC2048**

(2048, X'800') Queue does not support persistent messages.

**RC2031**

(2031, X'7EF') Message length greater than maximum for queue manager.

**RC2030**

(2030, X'7EE') Message length greater than maximum for queue.

This is an output field for the MQGET call, and an input field for MQPUT and MQPUT1 calls. The initial value of this field is FBNONE.

**MDFMT (8-byte character string)**

Format name of message data.

This is a name that the sender of the message may use to indicate to the receiver the nature of the data in the message. Any characters that are in the queue manager's character set may be specified for the name, but it is recommended that the name be restricted to the following:

- Uppercase A through Z
- Numeric digits 0 through 9

If other characters are used, it may not be possible to translate the name between the character sets of the sending and receiving queue managers.

The name should be padded with blanks to the length of the field, or a null character used to terminate the name before the end of the field; the null and any subsequent characters are treated as blanks. Do not specify a name with leading or embedded blanks. For the MQGET call, the queue manager returns the name padded with blanks to the length of the field.

The queue manager does not check that the name complies with the recommendations described previously.

Names beginning "MQ" in upper, lower, and mixed case have meanings that are defined by the queue manager; you should not use names beginning with these letters for your own formats. The queue manager built-in formats are:

**FMNONE**

No format name.

The nature of the data is undefined. This means that the data cannot be converted when the message is retrieved from a queue using the GMCONV option.

If GMCONV is specified on the MQGET call, and the character set or encoding of data in the message differs from that specified in the **MSGDSC** parameter, the message is returned with the following completion and reason codes (assuming no other errors):

- Completion code CCWARN and reason code RC2110 if the FMNONE data is at the beginning of the message.
- Completion code CCOK and reason code RCNONE if the FMNONE data is at the end of the message (that is, preceded by one or more MQ header structures). The MQ header structures are converted to the requested character set and encoding in this case.

**FMADMN**

Command server request/reply message.

The message is a command-server request or reply message in programmable command format (PCF). Messages of this format can be converted if the GMCONV option is specified on the MQGET

call. For more information about using programmable command format messages, see [Using Programmable Command Formats](#).

#### **FMCIICS**

CICS information header.

The message data begins with the CICS information header MQCIH, which is followed by the application data. The format name of the application data is given by the CIFMT field in the MQCIH structure.

#### **FMCMND1**

Type 1 command reply message.

The message is an MQSC command-server reply message containing the object count, completion code, and reason code. Messages of this format can be converted if the GMCONV option is specified on the MQGET call.

#### **FMCMND2**

Type 2 command reply message.

The message is an MQSC command-server reply message containing information about the object(s) requested. Messages of this format can be converted if the GMCONV option is specified on the MQGET call.

#### **FMDLH**

Dead-letter header.

The message data begins with the dead-letter header MQDLH. The data from the original message immediately follows the MQDLH structure. The format name of the original message data is given by the DLFMT field in the MQDLH structure; see [“MQDLH \(Dead-letter header\) on IBM i”](#) on page 1065 for details of this structure. Messages of this format can be converted if the GMCONV option is specified on the MQGET call.

COA and COD reports are not generated for messages which have a MDFMT of FMDLH.

#### **FMDH**

Distribution-list header.

The message data begins with the distribution-list header MQDH; this includes the arrays of MQOR and MQPMR records. The distribution-list header may be followed by additional data. The format of the additional data (if any) is given by the DHFMT field in the MQDH structure; see [“MQDH \(Distribution header\) on IBM i”](#) on page 1060 for details of this structure. Messages with format FMDH can be converted if the GMCONV option is specified on the MQGET call.

#### **FMEVNT**

Event message.

The message is an MQ event message that reports an event that occurred. Event messages have the same structure as programmable commands; for more information about this structure, see [Structures for commands and responses](#). For information about events, see [Event monitoring](#).

Version-1 event messages can be converted if the GMCONV option is specified on the MQGET call.

#### **FMIMS**

IMS information header.

The message data begins with the IMS information header MQIIH, which is followed by the application data. The format name of the application data is given by the IIFMT field in the MQIIH structure. Messages of this format can be converted if the GMCONV option is specified on the MQGET call.

#### **FMIMVS**

IMS variable string.

The message is an IMS variable string, which is a string of the form 11zzccc, where:

**11**

is a 2-byte length field specifying the total length of the IMS variable string item. This length is equal to the length of 11 (2 bytes), plus the length of zz (2 bytes), plus the length of the character string itself. 11 is a 2-byte binary integer in the encoding specified by the MDENC field.

**zz**

is a 2-byte field containing flags that are significant to IMS. zz is a byte string consisting of two 1-byte bit string fields, and is transmitted without change from sender to receiver (that is, zz is not subject to any conversion).

**ccc**

is a variable-length character string containing 11-4 characters. ccc is in the character set specified by the MDCSI field.

Messages of this format can be converted if the GMCONV option is specified on the MQGET call.

**FMMDE**

Message-descriptor extension.

The message data begins with the message-descriptor extension MQMDE, and is optionally followed by other data (usually the application message data). The format name, character set, and encoding of the data which follows the MQMDE is given by the MEFMT, MEC SI, and MEENC fields in the MQMDE. See [“MQMDE \(Message descriptor extension\) on IBM i” on page 1153](#) for details of this structure. Messages of this format can be converted if the GMCONV option is specified on the MQGET call.

**FMPCF**

User-defined message in programmable command format (PCF).

The message is a user-defined message that conforms to the structure of a programmable command format (PCF) message. Messages of this format can be converted if the GMCONV option is specified on the MQGET call. See [Using Programmable Command Formats](#) for more information about using programmable command format messages.

**FMRMH**

Reference message header.

The message data begins with the reference message header MQRMH, and is optionally followed by other data. The format name, character set, and encoding of the data is given by the RMFMT, RMC SI, and RMENC fields in the MQRMH. See [“MQRMH \(Reference message header\) on IBM i” on page 1199](#) for details of this structure. Messages of this format can be converted if the GMCONV option is specified on the MQGET call.

**FMRFH**

Rules and formatting header.

The message data begins with the rules and formatting header MQRFH, and is optionally followed by other data. The format name, character set, and encoding of the data (if any) is given by the RFFMT, RFC SI, and RFENC fields in the MQRFH. Messages of this format can be converted if the GMCONV option is specified on the MQGET call.

**FMRFH2**

Rules and formatting header version 2.

The message data begins with the version-2 rules and formatting header MQRFH2, and is optionally followed by other data. The format name, character set, and encoding of the optional data (if any) is given by the RF2FMT, RF2CSI, and RF2ENC fields in the MQRFH2. Messages of this format can be converted if the GMCONV option is specified on the MQGET call.

**FMSTR**

Message consisting entirely of characters.

The application message data can be either an SBCS string (single-byte character set), or a DBCS string (double-byte character set). Messages of this format can be converted if the GMCONV option is specified on the MQGET call.

#### **FMTM**

Trigger message.

The message is a trigger message, described by the MQTM structure; see [“MQTM - Trigger message” on page 1235](#) for details of this structure. Messages of this format can be converted if the GMCONV option is specified on the MQGET call.

#### **FMWIH**

Work information header.

The message data begins with the work information header MQWIH, which is followed by the application data. The format name of the application data is given by the WIFMT field in the MQWIH structure.

#### **FMXQH**

Transmission queue header.

The message data begins with the transmission queue header MQXQH. The data from the original message immediately follows the MQXQH structure. The format name of the original message data is given by the MDFMT field in the MQMD structure which is part of the transmission queue header MQXQH. See [“MQXQH \(Transmission-queue header\) on IBM i” on page 1245](#) for details of this structure.

COA and COD reports are not generated for messages which have a MDFMT of FMXQH.

This is an output field for the MQGET call, and an input field for the MQPUT and MQPUT1 calls. The length of this field is given by LNFMT. The initial value of this field is FMNONE.

#### **MDGID (24-byte bit string)**

Group identifier.

This is a byte string that is used to identify the particular message group or logical message to which the physical message belongs. MDGID is also used if segmentation is allowed for the message. In all of these cases, MDGID has a non-null value, and one or more of the following flags is set in the MDMFL field:

- MFMIG
- MFLMIG
- MFSEG
- MFLSEG
- MFSEGA

If none of these flags is set, MDGID has the special null value GINONE.

This field need not be set by the application on the MQPUT or MQGET call if:

- On the MQPUT call, PMLOGO is specified.
- On the MQGET call, MOGRPI is not specified.

Consider using these calls for messages that are not report messages. However, if the application requires more control, or the call is MQPUT1, the application must ensure that MDGID is set to an appropriate value.

Message groups and segments can be processed correctly only if the group identifier is unique. For this reason, applications should not generate their own group identifiers ; instead, applications should do one of the following:

- If PMLOGO is specified, the queue manager automatically generates a unique group identifier for the first message in the group or segment of the logical message, and uses that group identifier for the

remaining messages in the group or segments of the logical message, so the application does not need to take any special action. Consider using this procedure.

- If PMLOGO is not specified, the application should request the queue manager to generate the group identifier, by setting MDGID to GINONE on the first MQPUT or MQPUT1 call for a message in the group or segment of the logical message. The group identifier returned by the queue manager on output from that call should then be used for the remaining messages in the group or segments of the logical message. If a message group contains segmented messages, the same group identifier must be used for all segments and messages in the group.

When PMLOGO is not specified, messages in groups and segments of logical messages can be put in any order (for example, in reverse order), but the group identifier must be allocated by the first MQPUT or MQPUT1 call that is issued for any of those messages.

On input to the MQPUT and MQPUT1 calls, the queue manager uses the value detailed in [PMOPT](#). On output from the MQPUT and MQPUT1 calls, the queue manager sets this field to the value that was sent with the message if the object opened is a single queue and not a distribution list, but leaves it unchanged if the object opened is a distribution list. In the latter case, if the application needs to know the group identifiers generated, the application must provide MQPMR records containing the PRGID field.

On input to the MQGET call, the queue manager uses the value detailed in [Table 1](#). On output from the MQGET call, the queue manager sets this field to the value for the message retrieved.

The following special value is defined:

#### **GINONE**

No group identifier specified.

The value is binary zero for the length of the field. This is the value that is used for messages that are not in groups, not segments of logical messages, and for which segmentation is not allowed.

The length of this field is given by LNGID. The initial value of this field is GINONE. This field is ignored if MDVER is less than MDVER2.

#### **MDMFL (10-digit signed integer)**

Message flags.

These are flags that specify attributes of the message, or control its processing. The flags are divided into the following categories:

- Segmentation flag
- Status flags

These are described in turn.

**Segmentation flags:** When a message is too big for a queue, an attempt to put the message on the queue usually fails. Segmentation is a technique whereby the queue manager or application splits the message into smaller pieces called segments, and places each segment on the queue as a separate physical message. The application which retrieves the message can either retrieve the segments one by one, or request the queue manager to reassemble the segments into a single message which is returned by the MQGET call. The latter is achieved by specifying the GMCMPM option on the MQGET call, and supplying a buffer that is big enough to accommodate the complete message. (See [“MQGMO \(Get-message options\) on IBM i”](#) on page 1077 for details of the GMCMPM option.) Segmentation of a message can occur at the sending queue manager, at an intermediate queue manager, or at the destination queue manager.

You can specify one of the following to control the segmentation of a message:

#### **MFSEGI**

Segmentation inhibited.

This option prevents the message being broken into segments by the queue manager. If specified for a message that is already a segment, this option prevents the segment being broken into smaller segments.

The value of this flag is binary zero. This is the default.

## **MFSEGA**

Segmentation allowed.

This option allows the message to be broken into segments by the queue manager. If specified for a message that is already a segment, this option allows the segment to be broken into smaller segments. MFSEGA can be set without either MFSEG or MFLSEG being set.

When the queue manager segments a message, the queue manager turns on the MFSEG flag in the copy of the MQMD that is sent with each segment, but does not alter the settings of these flags in the MQMD provided by the application on the MQPUT or MQPUT1 call. For the last segment in the logical message, the queue manager also turns on the MFLSEG flag in the MQMD that is sent with the segment.

**Note:** Care is needed when messages are put with MFSEGA but without PMLOGO. If the message is:

- Not a segment, and
- Not in a group, and
- Not being forwarded,

the application must remember to reset the MDGID field to GINONE before each MQPUT or MQPUT1 call, in order to cause a unique group identifier to be generated by the queue manager for each message. If this is not done, unrelated messages could inadvertently end up with the same group identifier, which might lead to incorrect processing subsequently. See the descriptions of the MDGID field and the PMLOGO option for more information about when the MDGID field must be reset.

The queue manager splits messages into segments as necessary in order to ensure that the segments (plus any header data that may be required) fit on the queue. However, there is a lower limit for the size of a segment generated by the queue manager, and only the last segment created from a message can be smaller than this limit. (The lower limit for the size of an application-generated segment is one byte.) Segments generated by the queue manager may be of unequal length. The queue manager processes the message as follows:

- User-defined formats are split on boundaries which are multiples of 16 bytes. This means that the queue manager will not generate segments that are smaller than 16 bytes (other than the last segment).
- Built-in formats other than FMSTR are split at points appropriate to the nature of the data present. However, the queue manager never splits a message in the middle of an MQ header structure. This means that a segment containing a single MQ header structure cannot be split further by the queue manager, and as a result the minimum possible segment size for that message is greater than 16 bytes.

The second or later segment generated by the queue manager will begin with one of the following:

- An MQ header structure
- The start of the application message data
- Part-way through the application message data
- FMSTR is split without regard for the nature of the data present (SBCS, DBCS, or mixed SBCS/DBCS). When the string is DBCS or mixed SBCS/DBCS, this may result in segments which cannot be converted from one character set to another. The queue manager never splits FMSTR messages into segments that are smaller than 16 bytes (other than the last segment).
- The MDFMT, MDCSI, and MDENC fields in the MQMD of each segment are set by the queue manager to describe correctly the data present at the start of the segment; the format name will be either the name of a built-in format, or the name of a user-defined format.
- The MDREP field in the MQMD of segments with MDOFF greater than zero are modified as follows:

- For each report type, if the report option is RO\*D, but the segment cannot possibly contain any of the first 100 bytes of user data (that is, the data following any MQ header structures that may be present), the report option is changed to RO\*.

The queue manager follows the previously rules, but otherwise splits messages unpredictably; do not make assumptions about where a message is split

For persistent messages, the queue manager can perform segmentation only within a unit of work:

- If the MQPUT or MQPUT1 call is operating within a user-defined unit of work, that unit of work is used. If the call fails partway through the segmentation process, the queue manager removes any segments that were placed on the queue as a result of the failing call. However, the failure does not prevent the unit of work being committed successfully.
- If the call is operating outside a user-defined unit of work, and there is no user-defined unit of work in existence, the queue manager creates a unit of work just for the duration of the call. If the call is successful, the queue manager commits the unit of work automatically (the application does not need to do this). If the call fails, the queue manager backs out the unit of work.
- If the call is operating outside a user-defined unit of work, but a user-defined unit of work does exist, the queue manager is unable to perform segmentation. If the message does not require segmentation, the call can still succeed. But if the message does require segmentation, the call fails with reason code RC2255.

For nonpersistent messages, the queue manager does not require a unit of work to be available in order to perform segmentation.

Special consideration must be given to data conversion of messages which may be segmented:

- If data conversion is performed only by the receiving application on the MQGET call, and the application specifies the GMCMPM option, the data-conversion exit will be passed the complete message for the exit to convert, and the fact that the message was segmented will not be apparent to the exit.
- If the receiving application retrieves one segment at a time, the data-conversion exit will be invoked to convert one segment at a time. The exit must therefore be capable of converting the data in a segment independently of the data in any of the other segments.

If the nature of the data in the message is such that arbitrary segmentation of the data on 16-byte boundaries may result in segments which cannot be converted by the exit, or the format is FMSTR and the character set is DBCS or mixed SBCS/DBCS, the sending application should itself create and put the segments, specifying MFSEGI to suppress further segmentation. In this way, the sending application can ensure that each segment contains sufficient information to allow the data-conversion exit to convert the segment successfully.

- If sender conversion is specified for a sending message channel agent (MCA), the MCA converts only messages which are not segments of logical messages; the MCA never attempts to convert messages which are segments.

This flag is an input flag on the MQPUT and MQPUT1 calls, and an output flag on the MQGET call. On the latter call, the queue manager also echoes the value of the flag to the GMSEG field in MQGMO.

The initial value of this flag is MFSEGI.

**Status flags:** These are flags that indicate whether the physical message belongs to a message group, is a segment of a logical message, both, or neither. One or more of the following can be specified on the MQPUT or MQPUT1 call, or returned by the MQGET call:

**MFMI**

Message is a member of a group.

**MFLMI**

Message is the last logical message in a group.

If this flag is set, the queue manager turns on MFMIG in the copy of MQMD that is sent with the message, but does not alter the settings of these flags in the MQMD provided by the application on the MQPUT or MQPUT1 call.

It is valid for a group to consist of only one logical message. If this is the case, MFLMIG is set, but the MDSEQ field has the value one.

### **MFSEG**

Message is a segment of a logical message.

When MFSEG is specified without MFLSEG, the length of the application message data in the segment (excluding the lengths of any MQ header structures that may be present) must be at least one. If the length is zero, the MQPUT or MQPUT1 call fails with reason code RC2253.

### **MFLSEG**

Message is the last segment of a logical message.

If this flag is set, the queue manager turns on MFSEG in the copy of MQMD that is sent with the message, but does not alter the settings of these flags in the MQMD provided by the application on the MQPUT or MQPUT1 call.

It is valid for a logical message to consist of only one segment. If this is the case, MFLSEG is set, but the MDOFF field has the value zero.

When MFLSEG is specified, it is permissible for the length of the application message data in the segment (excluding the lengths of any header structures that may be present) to be zero.

The application must ensure that these flags are set correctly when putting messages. If PMLOGO is specified, or was specified on the preceding MQPUT call for the queue handle, the settings of the flags must be consistent with the group and segment information retained by the queue manager for the queue handle. The following conditions apply to successive MQPUT calls for the queue handle when PMLOGO is specified:

- If there is no current group or logical message, all of these flags (and combinations of them) are valid.
- Once MFMIG has been specified, it must remain on until MFLMIG is specified. The call fails with reason code RC2241 if this condition is not satisfied.
- Once MFSEG has been specified, it must remain on until MFLSEG is specified. The call fails with reason code RC2242 if this condition is not satisfied.
- Once MFSEG has been specified without MFMIG, MFMIG must remain off until after MFLSEG has been specified. The call fails with reason code RC2242 if this condition is not satisfied.

Table 1 shows the valid combinations of the flags, and the values used for various fields.

These flags are input flags on the MQPUT and MQPUT1 calls, and output flags on the MQGET call. On the latter call, the queue manager also echoes the values of the flags to the GMGST and GMSST fields in MQGMO.

**Default flags:** The following can be specified to indicate that the message has default attributes:

### **MFNONE**

No message flags (default message attributes).

This inhibits segmentation, and indicates that the message is not in a group and is not a segment of a logical message. MFNONE is defined to aid program documentation. It is not intended that this flag be used with any other, but as its value is zero, such use cannot be detected.

The MDMFL field is partitioned into subfields; for details see [“Report options and message flags on IBM i” on page 1431](#).

The initial value of this field is MFNONE. This field is ignored if MDVER is less than MDVER2.

### **MDMID (24-byte bit string)**

Message identifier.

This is a byte string that is used to distinguish one message from another. Generally, no two messages should have the same message identifier, although this is not disallowed by the queue manager. The message identifier is a permanent property of the message, and persists across restarts of the queue manager. Because the message identifier is a byte string and not a character string, the message identifier is not converted between character sets when the message flows from one queue manager to another.

For the MQPUT and MQPUT1 calls, if MINONE or PMNMID is specified by the application, the queue manager generates a unique message identifier when the message is put, and places it in the message descriptor sent with the message. The queue manager also returns this message identifier in the message descriptor belonging to the sending application. The application can use this value to record information about particular messages, and to respond to queries from other parts of the application.

An MDMID generated by the queue manager consists of a 4-byte product identifier ( AMQ– or CSQ– in either ASCII or EBCDIC, where – represents a single blank character), followed by a product-specific implementation of a unique string. In IBM MQ this contains the first 12 characters of the queue manager name, and a value derived from the system clock. All queue managers that can intercommunicate must therefore have names that differ in the first 12 characters, to ensure that message identifiers are unique. The ability to generate a unique string also depends upon the system clock not being changed backward. To eliminate the possibility of a message identifier generated by the queue manager duplicating one generated by the application, the application should avoid generating identifiers with initial characters in the range A through I in ASCII or EBCDIC (X'41' through X'49' and X'C1' through X'C9'). However, the application is not prevented from generating identifiers with initial characters in these ranges.

If the message is being put to a topic, the queue manager generates unique message identifiers as necessary for each message published. If PMNMID is specified by the application, the queue manager generates a unique message identifier to return on output. If MINONE is specified by the application, the value of the MDMID field in the MQMD is unchanged on return from the call.

See the description of PMRET in [PMOPT](#) for more details about retained publications.

If the message is being put to a distribution list, the queue manager generates unique message identifiers as necessary, but the value of the MDMID field in MQMD is unchanged on return from the call, even if MINONE or PMNMID was specified. If the application needs to know the message identifiers generated by the queue manager, the application must provide MQPMR records containing the PRMID field.

The sending application can also specify a particular value for the message identifier, other than MINONE; this stops the queue manager generating a unique message identifier. An application that is forwarding a message can use this facility to propagate the message identifier of the original message.

The queue manager does not itself make any use of this field except to:

- Generate a unique value if requested, as described previously
- Deliver the value to the application that issues the get request for the message
- Copy the value to the MDCID field of any report message that it generates about this message (depending on the MDREP options)

When the queue manager or a message channel agent generates a report message, it sets the MDMID field in the way specified by the MDREP field of the original message, either RONMI or ROPMI. Applications that generate report messages should also do this.

For the MQGET call, MDMID is one of the five fields that can be used to select a particular message to be retrieved from the queue. Normally the MQGET call returns the next message on the queue, but if a particular message is required, this can be obtained by specifying one or more of the five selection criteria, in any combination; these fields are:

- MDMID
- MDCID
- MDGID

- MDSEQ
- MDOFF

The application sets one or more of these field to the values required, and then sets the corresponding MO\* match options in the GMMO field in MQGMO to indicate that those fields should be used as selection criteria. Only messages that have the specified values in those fields are candidates for retrieval. The default for the GMMO field (if not altered by the application) is to match both the message identifier and the correlation identifier.

Normally, the message returned is the first message on the queue that satisfies the selection criteria. But if GMBRWN is specified, the message returned is the next message that satisfies the selection criteria; the scan for this message starts with the message following the current cursor position.

**Note:** The queue is scanned sequentially for a message that satisfies the selection criteria, so retrieval times will be slower than if no selection criteria are specified, especially if many messages have to be scanned before a suitable one is found.

See [Table 1](#) for more information about how selection criteria are used in various situations.

Specifying MINONE as the message identifier has the same effect as not specifying MOMSGI, that is, any message identifier will match.

This field is ignored if the GMMUC option is specified in the **GMO** parameter on the MQGET call.

On return from an MQGET call, the MDMID field is set to the message identifier of the message returned (if any).

The following special value may be used:

**MINONE**

No message identifier is specified.

The value is binary zero for the length of the field.

This is an input/output field for the MQGET, MQPUT, and MQPUT1 calls. The length of this field is given by LNMIID. The initial value of this field is MINONE.

**MDMT (10-digit signed integer)**

Message type.

This indicates the type of the message. Message types are grouped as follows:

**MTSFST**

Lowest value for system-defined message types.

**MTSLST**

Highest value for system-defined message types.

The following values are currently defined within the system range:

**MTDGRM**

Message not requiring a reply.

The message is one that does not require a reply.

**MTRQST**

Message requiring a reply.

The message is one that requires a reply.

The name of the queue to which the reply should be sent must be specified in the MDRQ field. The MDREP field indicates how the MDMID and MDCID of the reply are to be set.

**MTRPLY**

Reply to an earlier request message.

The message is the reply to an earlier request message (MTRQST). The message should be sent to the queue indicated by the MDRQ field of the request message. The MDREP field of the request should be used to control how the MDMID and MDCID of the reply are set.

**Note:** The queue manager does not enforce the request-reply relationship; this is an application responsibility.

#### **MTRPRT**

Report message.

The message is reporting on some expected or unexpected occurrence, usually related to some other message (for example, a request message was received which contained data that was not valid). The message should be sent to the queue indicated by the MDRQ field of the message descriptor of the original message. The MDFB field should be set to indicate the nature of the report. The MDREP field of the original message can be used to control how the MDMID and MDCID of the report message should be set.

Report messages generated by the queue manager or message channel agent are always sent to the MDRQ queue, with the MDFB and MDCID fields set as described previously.

Other values within the system range may be defined in future versions of the MQI, and are accepted by the MQPUT and MQPUT1 calls without error.

Application-defined values can also be used. They must be within the following range:

#### **MTAFST**

Lowest value for application-defined message types.

#### **MTALST**

Highest value for application-defined message types.

For the MQPUT and MQPUT1 calls, the MDMT value must be within either the system-defined range or the application-defined range; if it is not, the call fails with reason code RC2029.

This is an output field for the MQGET call, and an input field for MQPUT and MQPUT1 calls. The initial value of this field is MTDGRM.

#### **MDOFF (10-digit signed integer)**

Offset of data in physical message from start of logical message.

This is the offset in bytes of the data in the physical message from the start of the logical message of which the data forms part. This data is called a *segment*. The offset is in the range 0 through 999 999 999. A physical message which is not a segment of a logical message has an offset of zero.

This field need not be set by the application on the MQPUT or MQGET call if:

- On the MQPUT call, PMLOGO is specified.
- On the MQGET call, MOOFFS is not specified.

These are the recommended ways of using these calls for messages that are not report messages. However, if the application does not comply with these conditions, or the call is MQPUT1, the application must ensure that MDOFF is set to an appropriate value.

On input to the MQPUT and MQPUT1 calls, the queue manager uses the value detailed in [Table 1](#). On output from the MQPUT and MQPUT1 calls, the queue manager sets this field to the value that was sent with the message.

For a report message reporting on a segment of a logical message, the MDOLN field (provided it is not OLUNDF) is used to update the offset in the segment information retained by the queue manager.

On input to the MQGET call, the queue manager uses the value detailed in [Table 1](#). On output from the MQGET call, the queue manager sets this field to the value for the message retrieved.

The initial value of this field is zero. This field is ignored if MDVER is less than MDVER2.

#### **MDOLN (10-digit signed integer)**

Length of original message.

This field is of relevance only for report messages that are segments. It specifies the length of the message segment to which the report message relates; it does not specify the length of the logical message of which the segment forms part, nor the length of the data in the report message.

**Note:** When generating a report message for a message that is a segment, the queue manager and message channel agent copy into the MQMD for the report message the MDGID, MDSEQ, MDOFF, and MDMFL, fields from the original message. As a result, the report message is also a segment. Applications that generate report messages are recommended to do the same, and to ensure that the MDOLN field is set correctly.

The following special value is defined:

**OLUNDF**

Original length of message not defined.

MDOLN is an input field on the MQPUT and MQPUT1 calls, but the value provided by the application is accepted only in particular circumstances:

- If the message being put is a segment and is also a report message, the queue manager accepts the value specified. The value must be:
  - Greater than zero if the segment is not the last segment
  - Not less than zero if the segment is the last segment
  - Not less than the length of data present in the message

If these conditions are not satisfied, the call fails with reason code RC2252.

- If the message being put is a segment but not a report message, the queue manager ignores the field and uses the length of the application message data instead.
- In all other cases, the queue manager ignores the field and uses the value OLUNDF instead.

This is an output field on the MQGET call.

The initial value of this field is OLUNDF. This field is ignored if MDVER is less than MDVER2.

**MDPAN (28-byte character string)**

Name of application that put the message.

This is part of the *origin context* of the message. For more information about message context, see [Message context](#) and [Controlling context information](#).

The format of the MDPAN depends on the value of MDPAT.

When this field is set by the queue manager (that is, for all options except PMSETA), it is set to value which is determined by the environment:

-  On z/OS, the queue manager uses:
  - For z/OS batch, the 8-character job name from the JES JOB card
  - For TSO, the 7-character TSO user identifier
  - For CICS, the 8-character applid, followed by the 4-character tranid
  - For IMS, the 8-character IMS system identifier, followed by the 8-character PSB name
  - For XCF, the 8-character XCF group name, followed by the 16-character XCF member name
  - For a message generated by a queue manager, the first 28 characters of the queue manager name
  - For distributed queuing without CICS, the 8-character jobname of the channel initiator followed by the 8-character name of the module putting to the dead-letter queue followed by an 8-character task identifier.
  - For MQSeries Java language bindings processing with IBM MQ for z/OS the 8-character jobname of the address space created for the z/OS UNIX System Services environment. Typically, this will be a TSO user identifier with a single numeric character appended.

The name or names are each padded to the right with blanks, as is any space in the remainder of the field. Where there is more than one name, there is no separator between them.

- **Windows** On PC DOS, and Windows systems, the queue manager uses:
  - For a CICS application, the CICS transaction name
  - For a non-CICS application, the rightmost 28 characters of the fully-qualified name of the executable
- **IBM i** On IBM i, the queue manager uses the fully-qualified job name.
- **Linux** **AIX** On AIX and Linux, the queue manager uses:
  - For a CICS application, the CICS transaction name
  - For a non-CICS application, the rightmost 14 characters of the fully-qualified name of the executable if this is available to the queue manager, and blanks otherwise (for example, on AIX)
- On VSE/ESA, the queue manager uses the 8-character applid, followed by the 4-character tranid.

For the MQPUT and MQPUT1 calls, this is an input/output field if PMSETA is specified in the **PMO** parameter. Any information following a null character within the field is discarded. The null character and any following characters are converted to blanks by the queue manager. If PMSETA is not specified, this field is ignored on input and is an output-only field.

This is an output field for the MQGET call. The length of this field is given by LNPAN. The initial value of this field is 28 blank characters.

### **MDPAT (10-digit signed integer)**

Type of application that put the message.

This is part of the **origin context** of the message. For more information about message context, see [Message context](#) and [Controlling context information](#).

*MDPAT* may have one of the following standard types. User-defined types can also be used but should be restricted to values in the range ATUFST through ATULST.

#### **ATAIX**

AIX application (same value as ATUNIX).

#### **ATBRKR**

Broker.

#### **ATCICS**

CICS transaction.

#### **ATCICB**

CICS bridge.

#### **ATVSE**

CICS/VSE transaction.

#### **ATDOS**

IBM MQ MQI client application on PC DOS.

#### **ATDQM**

Distributed queue manager agent.

#### **ATGUAR**

Tandem Guardian application (same value as ATNSK).

#### **ATIMS**

IMS application.

#### **ATIMSB**

IMS bridge.

#### **ATJAVA**

Java.

**ATMVS**

MVS or TSO application (same value as ATZOS).

**ATNOTE**

Lotus Notes Agent application.

**ATNSK**

Tandem NonStop Kernel application.

**AT390**

OS/390 application (same value as ATZOS).

**AT400**

IBM i application.

**ATQM**

Queue manager.

**ATUNIX**

UNIX application.

**ATVOS**

Stratus VOS application.

**ATWIN**

16-bit Windows application.

**ATWINT**

32-bit Windows application.

**ATXCF**

XCF.

**ATZOS**

z/OS application.

**ATDEF**

Default application type.

This is the default application type for the platform on which the application is running.

**Note:** The value of this constant is environment-specific.

**ATUNK**

Unknown application type.

This value can be used to indicate that the application type is unknown, even though other context information is present.

**ATUFST**

Lowest value for user-defined application type.

**ATULST**

Highest value for user-defined application type.

The following special value can also occur:

**ATNCON**

No context information present in message.

This value is set by the queue manager when a message is put with no context (that is, the PMNOC context option is specified).

When a message is retrieved, MDPAT can be tested for this value to decide whether the message has context (it is recommended that MDPAT is never set to ATNCON, by an application using PMSETA, if any of the other context fields are nonblank).

**ATSIB**

Indicates a message originated in another IBM MQ messaging product and arrived via the SIB (Service Integration Bus) bridge.

When the queue manager generates this information as a result of an application put, the field is set to a value that is determined by the environment.

**IBM i** Note that on IBM i, the field is set to AT400; the queue manager never uses ATCICS on IBM i.

For the MQPUT and MQPUT1 calls, this is an input/output field if PMSETA is specified in the **PMO** parameter. If PMSETA is not specified, this field is ignored on input and is an output-only field.

After the successful completion of an MQPUT or MQPUT1 call, this field contains the MDPAT that was transmitted with the message if it was put to a queue. This will be the value of MDPAT that is kept with the message if it is retained (see description of PMRET for more details about retained publications) but is not used as the MDPAT when the message is sent as a publication to subscribers since they provide a value to override MDPAT in all publications sent to them. If the message has no context, the field is set to ATNCON.

This is an output field for the MQGET call. The initial value of this field is ATNCON.

### **MDPD (8-byte character string)**

Date when message was put.

This is part of the *origin context* of the message. For more information about message context, see [Message context](#) and [Controlling context information](#).

The format used for the date when this field is generated by the queue manager is:

- YYYYMMDD

where the characters represent:

#### **YYYY**

year (four numeric digits)

#### **MM**

month of year (01 through 12)

#### **DD**

day of month (01 through 31)

Greenwich Mean Time (GMT) is used for the MDPD and MDPT fields, subject to the system clock being set accurately to GMT.

If the message was put as part of a unit of work, the date is that when the message was put, and not the date when the unit of work was committed.

For the MQPUT and MQPUT1 calls, this is an input/output field if PMSETA is specified in the **PMO** parameter. The contents of the field are not checked by the queue manager, except that any information following a null character within the field is discarded. The null character and any following characters are converted to blanks by the queue manager. If PMSETA is not specified, this field is ignored on input and is an output-only field.

After the successful completion of an MQPUT or MQPUT1 call, this field contains the MDPD that was transmitted with the message if it was put to a queue. This will be the value of MDPD that is kept with the message if it is retained (see description of PMRET for more details about retained publications) but is not used as the MDPD when the message is sent as a publication to subscribers since they provide a value to override MDPD in all publications sent to them. If the message has no context, the field is entirely blank.

This is an output field for the MQGET call. The length of this field is given by LNPDAT. The initial value of this field is 8 blank characters.

### **MDPER (10-digit signed integer)**

Message persistence.

This indicates whether the message survives system failures and restarts of the queue manager. For the MQPUT and MQPUT1 calls, the value must be one of the following:

## PEPER

Message is persistent.

This means that the message survives system failures and restarts of the queue manager. Once the message has been put, and the putter's unit of work committed (if the message is put as part of a unit of work), the message is preserved on auxiliary storage. It remains there until the message is removed from the queue, and the getter's unit of work committed (if the message is retrieved as part of a unit of work).

When a persistent message is sent to a remote queue, a store-and-forward mechanism is used to hold the message at each queue manager along the route to the destination, until the message is known to have arrived at the next queue manager.

Persistent messages cannot be placed on:

- Temporary dynamic queues
- Shared queues where the coupling facility structure level is less than three, or the coupling facility structure is not recoverable.

Persistent messages can be placed on permanent dynamic queues, predefined queues, and shared queues where the coupling facility structure level is 3, and the coupling facility is recoverable.

## PENPER

Message is not persistent.

This means that the message does not normally survive system failures or restarts of the queue manager. This applies even if an intact copy of the message is found on auxiliary storage during restart of the queue manager.

In the special case of shared queues, nonpersistent messages *do* survive restarts of queue managers in the queue sharing group, but do not survive failures of the coupling facility used to store messages on the shared queues.

## PEQDEF

Message has default persistence.

- If the queue is a cluster queue, the persistence of the message is taken from the **DefPersistence** attribute defined at the destination queue manager that owns the particular instance of the queue on which the message is placed. Usually, all of the instances of a cluster queue have the same value for the **DefPersistence** attribute, although this is not mandated.

The value of **DefPersistence** is copied into the *MDPER* field when the message is placed on the destination queue. If **DefPersistence** is changed subsequently, messages that have already been placed on the queue are not affected.

- If the queue is not a cluster queue, the persistence of the message is taken from the **DefPersistence** attribute defined at the local queue manager, even if the destination queue manager is remote.

If there is more than one definition in the queue-name resolution path, the default persistence is taken from the value of this attribute in the first definition in the path. This could be:

- An alias queue
- A local queue
- A local definition of a remote queue
- A queue manager alias
- A transmission queue (for example, the *DefXmitQName* queue)

The value of **DefPersistence** is copied into the *MDPER* field when the message is put. If **DefPersistence** is changed subsequently, messages that have already been put are not affected.

Both persistent and nonpersistent messages can exist on the same queue.

When replying to a message, applications should normally use for the reply message the persistence of the request message.

For an MQGET call, the value returned is either PEPER or PENPER.

This is an output field for the MQGET call, and an input field for the MQPUT and MQPUT1 calls. The initial value of this field is PEQDEF.

### **MDPRI (10-digit signed integer)**

Message priority.

For the MQPUT and MQPUT1 calls, the value must be greater than or equal to zero; zero is the lowest priority. The following special value can also be used:

#### **PRQDEF**

Default priority for queue.

- If the queue is a cluster queue, the priority for the message is taken from the **DefPriority** attribute as defined at the destination queue manager that owns the particular instance of the queue on which the message is placed. Usually, all of the instances of a cluster queue have the same value for the **DefPriority** attribute, although this is not mandated.

The value of **DefPriority** is copied into the MDPRI field when the message is placed on the destination queue. If **DefPriority** is changed subsequently, messages that have already been placed on the queue are not affected.

- If the queue is not a cluster queue, the priority for the message is taken from the **DefPriority** attribute as defined at the local queue manager, even if the destination queue manager is remote.

If there is more than one definition in the queue-name resolution path, the default priority is taken from the value of this attribute in the first definition in the path. This could be:

- An alias queue
- A local queue
- A local definition of a remote queue
- A queue manager alias
- A transmission queue (for example, the DefXmitQName queue)

The value of **DefPriority** is copied into the MDPRI field when the message is put. If **DefPriority** is changed subsequently, messages that have already been put are not affected.

The value returned by the MQGET call is always greater than or equal to zero; the value PRQDEF is never returned.

If a message is put with a priority greater than the maximum supported by the local queue manager (this maximum is given by the **MaxPriority** queue manager attribute), the message is accepted by the queue manager, but placed on the queue at the queue manager's maximum priority; the MQPUT or MQPUT1 call completes with CCWARN and reason code RC2049. However, the MDPRI field retains the value specified by the application which put the message.

When replying to a message, applications should normally use for the reply message the priority of the request message. In other situations, specifying PRQDEF allows priority tuning to be carried out without changing the application.

This is an output field for the MQGET call, and an input field for the MQPUT and MQPUT1 calls. The initial value of this field is PRQDEF.

### **MDPT (8-byte character string)**

Time when message was put.

This is part of the **origin context** of the message. For more information about message context, see [Message context](#) and [Controlling context information](#).

The format used for the time when this field is generated by the queue manager is:

- HHMMSSSTH

where the characters represent (in order):

**HH**

hours (00 through 23)

**MM**

minutes (00 through 59)

**SS**

seconds (00 through 59; see [note](#))

**T**

tenths of a second (0 through 9)

**H**

hundredths of a second (0 through 9)

**Note:** If the system clock is synchronized to a very accurate time standard, it is possible on rare occasions for 60 or 61 to be returned for the seconds in MDPT. This happens when leap seconds are inserted into the global time standard.

Greenwich Mean Time (GMT) is used for the MDPD and MDPT fields, subject to the system clock being set accurately to GMT.

If the message was put as part of a unit of work, the time is that when the message was put, and not the time when the unit of work was committed.

For the MQPUT and MQPUT1 calls, this is an input/output field if PMSETA is specified in the **PMO** parameter. The contents of the field are not checked by the queue manager, except that any information following a null character within the field is discarded. The null character and any following characters are converted to blanks by the queue manager. If PMSETA is not specified, this field is ignored on input and is an output-only field.

After the successful completion of an MQPUT or MQPUT1 call, this field contains the MDPT value that was transmitted with the message if it was put to a queue. This will be the value of MDPT that is kept with the message if it is retained (see description of PMRET for more details about retained publications) but is not used as the MDPT when the message is sent as a publication to subscribers since they provide a value to override MDPT in all publications sent to them. If the message has no context, the field is entirely blank.

This is an output field for the MQGET call. The length of this field is given by LNPTIM. The initial value of this field is 8 blank characters.

### **MDREP (10-digit signed integer)**

Options for report messages.

A report message is a message about another message, used to inform an application about expected or unexpected events that relate to the original message. The MDREP field enables the application sending the original message to specify which report messages are required, whether the application message data is to be included in them, and also (for both reports and replies) how the message and correlation identifiers in the report or reply message are to be set. Any or all (or none) of the following types of report message can be requested:

- Exception
- Expiration
- Confirm on arrival (COA)
- Confirm on delivery (COD)
- Positive action notification (PAN)
- Negative action notification (NAN)

If more than one type of report message is required, or other report options are needed, the values can be added together (do not add the same constant more than once).

The application that receives the report message can determine the reason the report was generated by examining the MDFB field in the MQMD; see the MDFB field for more details.

The use of report options when putting a message to a topic can cause zero, one or many report messages to be generated and sent to the application. This is because the publication message may be sent to zero, one or many subscribing applications.

**Exception options:** You can specify one of the following options to request an exception report message.

## **ROACTIVITY**

Activity reports required

This report option enables an activity report to be generated, whenever a message with this report option set is processed by supporting applications.

Messages with this report option set must be accepted by any queue manager, even if they do not 'understand' the option. This allows the report option to be set on any user message, even if they are processed by previous queue managers. To achieve this, the report option is placed in the ROAUM subfield.

If a process (either a queue manager or a user process) performs an Activity on a message with ROACT set, it can choose to generate and put an activity report.

The activity report option allows the route of any message to be traced throughout a queue manager network. The report option can be specified on any current user message and instantly they can begin to calculate the route of the message through the network. If the application generating the message cannot enable activity report generation, it can be enabled by using an API crossing exit supplied by queue manager administrators.

Several conditions are applicable to activity reports:

1. The route will be less detailed if there are fewer queue managers in the network which are able to generate activity reports.
2. The activity reports may not be easily 'orderable' in order to determine the route taken.
3. The activity reports may not be able to find a route to their requested destination.

## **ROEXC**

Exception reports required.

This type of report can be generated by a message channel agent when a message is sent to another queue manager and the message cannot be delivered to the specified destination queue. For example, the destination queue or an intermediate transmission queue might be full, or the message might be too big for the queue.

Generation of the exception report message depends on the persistence of the original message, and the speed of the message channel (normal or fast) through which the original message travels:

- For all persistent messages, and for nonpersistent messages traveling through normal message channels, the exception report is generated only if the action specified by the sending application for the error condition can be completed successfully. The sending application can specify one of the following actions to control the disposition of the original message when the error condition arises:
  - RODLQ (this causes the original message to be placed on the dead-letter queue).
  - RODISC (this causes the original message to be discarded).

If the action specified by the sending application cannot be completed successfully, the original message is left on the transmission queue, and no exception report message is generated.

- For nonpersistent messages traveling through fast message channels, the original message is removed from the transmission queue and the exception report generated even if the specified action for the error condition cannot be completed successfully. For example, if RODLQ is specified, but the original message cannot be placed on the dead-letter queue because (say) that queue is full, the exception report message is generated and the original message discarded.

See [Message persistence](#) for more information about normal and fast message channels.

An exception report is not generated if the application that put the original message can be notified synchronously of the problem by means of the reason code returned by the MQPUT or MQPUT1 call.

Applications can also send exception reports, to indicate that a message that it has received cannot be processed (for example, because it is a debit transaction that would cause the account to exceed its credit limit).

Message data from the original message is not included with the report message.

Do not specify more than one of ROEXC, ROEXCD, and ROEXCF.

#### **ROEXCD**

Exception reports with data required.

This is the same as ROEXC, except that the first 100 bytes of the application message data from the original message are included in the report message. If the original message contains one or more MQ header structures, they are included in the report message, in addition to the 100 bytes of application data.

Do not specify more than one of ROEXC, ROEXCD, and ROEXCF.

#### **ROEXCF**

Exception reports with full data required.

This is the same as ROEXC, except that all of the application message data from the original message is included in the report message.

Do not specify more than one of ROEXC, ROEXCD, and ROEXCF.

**Expiration options:** You can specify one of the following options to request an expiration report message.

#### **ROEXP**

Expiration reports required.

This type of report is generated by the queue manager if the message is discarded before delivery to an application because its expiry time has passed (see the MDEXP field). If this option is not set, no report message is generated if a message is discarded for this reason (even if one of the ROEXC\* options is specified).

Message data from the original message is not included with the report message.

Do not specify more than one of ROEXP, ROEXPD, and ROEXPF.

#### **ROEXPD**

Expiration reports with data required.

This is the same as ROEXP, except that the first 100 bytes of the application message data from the original message are included in the report message. If the original message contains one or more MQ header structures, they are included in the report message, in addition to the 100 bytes of application data.

Do not specify more than one of ROEXP, ROEXPD, and ROEXPF.

#### **ROEXPF**

Expiration reports with full data required.

This is the same as ROEXP, except that all of the application message data from the original message is included in the report message.

Do not specify more than one of ROEXP, ROEXPD, and ROEXPF.

**Confirm-on-arrival options:** You can specify one of the following options to request a confirm-on-arrival report message.

#### **ROCOA**

Confirm-on-arrival reports required.

This type of report is generated by the queue manager that owns the destination queue, when the message is placed on the destination queue. Message data from the original message is not included with the report message.

If the message is put as part of a unit of work, and the destination queue is a local queue, the COA report message generated by the queue manager becomes available for retrieval only if and when the unit of work is committed.

A COA report is not generated if the MDFMT field in the message descriptor is FMXQH or FMDLH. This prevents a COA report being generated if the message is put on a transmission queue, or is undeliverable and put on a dead-letter queue.

Do not specify more than one of ROCOA, ROCOAD, and ROCOAF.

#### **ROCOAD**

Confirm-on-arrival reports with data required.

This is the same as ROCOA, except that the first 100 bytes of the application message data from the original message are included in the report message. If the original message contains one or more MQ header structures, they are included in the report message, in addition to the 100 bytes of application data.

Do not specify more than one of ROCOA, ROCOAD, and ROCOAF.

#### **ROCOAF**

Confirm-on-arrival reports with full data required.

This is the same as ROCOA, except that all of the application message data from the original message is included in the report message.

Do not specify more than one of ROCOA, ROCOAD, and ROCOAF.

**Discard and expiry options:** You can specify the following option to set the expiry time and discard flag for report messages.

#### **ROPDAE**

Set report message expiry time and discard flag.

This option ensures that report messages and reply messages inherit the expiry time and discard flag (whether to discard or not), from their original messages. With this option set, report and reply messages:

1. Inherit the RODISC flag (if it was set).
2. Inherit the remaining expiry time of the message, if the message is not an expiry report. If the message is an expiry report, the expiry time is set to 60 seconds.

With this option set, the following applies:

#### **Note:**

1. Report and reply messages are generated with a discard flag and an expiry value, and cannot remain within the system.
2. Trace route messages are prevented from reaching destination queues on non-trace route enabled queue managers.
3. Queues are prevented from being filled with reports that cannot be delivered, if communications links are broken.

4. Command server responses inherit the remaining expiry of the request.

**Confirm-on-delivery options:** You can specify one of the following options to request a confirm-on-delivery report message.

#### **ROCOD**

Confirm-on-delivery reports required.

This type of report is generated by the queue manager when an application retrieves the message from the destination queue in a way that causes the message to be deleted from the queue. Message data from the original message is not included with the report message.

If the message is retrieved as part of a unit of work, the report message is generated within the same unit of work, so that the report is not available until the unit of work is committed. If the unit of work is backed out, the report is not sent.

A COD report is not generated if the MDFMT field in the message descriptor is FMDLH. This prevents a COD report being generated if the message is undeliverable and put on a dead-letter queue.

ROCOD is not valid if the destination queue is an XCF queue.

Do not specify more than one of ROCOD, ROCODD, and ROCODF.

#### **ROCODD**

Confirm-on-delivery reports with data required.

This is the same as ROCOD, except that the first 100 bytes of the application message data from the original message are included in the report message. If the original message contains one or more MQ header structures, they are included in the report message, in addition to the 100 bytes of application data.

If GMATM is specified on the MQGET call for the original message, and the message retrieved is truncated, the amount of application message data placed in the report message is the minimum of:

- The length of the original message
- 100 bytes.

ROCODD is not valid if the destination queue is an XCF queue.

Do not specify more than one of ROCOD, ROCODD, and ROCODF.

#### **ROCODF**

Confirm-on-delivery reports with full data required.

This is the same as ROCOD, except that all of the application message data from the original message is included in the report message.

ROCODF is not valid if the destination queue is an XCF queue.

Do not specify more than one of ROCOD, ROCODD, and ROCODF.

**Action-notification options:** You can specify one or both of the following options to request that the receiving application send a positive-action or negative-action report message.

#### **ROPAN**

Positive action notification reports required.

This type of report is generated by the application that retrieves the message and acts upon it. It indicates that the action requested in the message has been performed successfully. The application generating the report determines whether any data is to be included with the report.

Other than conveying this request to the application retrieving the message, the queue manager takes no action based upon this option. It is the responsibility of the retrieving application to generate the report if appropriate.

## **RONAN**

Negative action notification reports required.

This type of report is generated by the application that retrieves the message and acts upon it. It indicates that the action requested in the message has not been performed successfully. The application generating the report determines whether any data is to be included with the report. For example, it may be desirable to include some data indicating why the request could not be performed.

Other than conveying this request to the application retrieving the message, the queue manager takes no action based upon this option. It is the responsibility of the retrieving application to generate the report if appropriate.

Determination of which conditions correspond to a positive action and which correspond to a negative action is the responsibility of the application. However, it is recommended that if the request has been only partially performed, a NAN report rather than a PAN report should be generated if requested. It is also recommended that every possible condition should correspond to either a positive action, or a negative action, but not both.

**Message-identifier options:** You can specify one of the following options to control how the MDMID of the report message (or of the reply message) is to be set.

## **RONMI**

New message identifier.

This is the default action, and indicates that if a report or reply is generated as a result of this message, a new MDMID is to be generated for the report or reply message.

## **ROPMI**

Pass message identifier.

If a report or reply is generated as a result of this message, the MDMID of this message is to be copied to the MDMID of the report or reply message.

The MsgId of a publication message will be different for each subscriber that receives a copy of the publication and therefore the MsgId copied into the report or reply message will be different for each one.

If this option is not specified, RONMI is assumed.

**Correlation-identifier options:** You can specify one of the following options to control how the MDCID of the report message (or of the reply message) is to be set.

## **ROCMTC**

Copy message identifier to correlation identifier.

This is the default action, and indicates that if a report or reply is generated as a result of this message, the MDMID of this message is to be copied to the MDCID of the report or reply message.

The MsgId of a publication message will be different for each subscriber that receives a copy of the publication and therefore the MsgId copied into the CorrelId of the report or reply message will be different for each one.

## **ROPCI**

Pass correlation identifier.

If a report or reply is generated as a result of this message, the MDCID of this message is to be copied to the MDCID of the report or reply message.

The MDCID of a publication message will be specific to a subscriber unless it uses the SOSCID option and sets the SCDIC field in the MQSD to CINONE. Therefore it is possible that the MDCID copied into the MDCID of the report or reply message will be different for each one.

If this option is not specified, ROCMTC is assumed.

Servers replying to requests or generating report messages are recommended to check whether the ROPMI or ROPCI options were set in the original message. If they were, the servers should take the

action described for those options. If neither is set, the servers should take the corresponding default action.

: You can specify one of the following options to control the disposition of the original message when it cannot be delivered to the destination queue. These options apply only to those situations that would result in an exception report message being generated if one had been requested by the sending application. The application can set the disposition options independently of requesting exception reports.

### **RODLQ**

Place message on dead-letter queue.

This is the default action, and indicates that the message should be placed on the dead-letter queue, if the message cannot be delivered to the destination queue. This happens in the following situations:

- When the application that put the original message cannot be notified synchronously of the problem by means of the reason code returned by the MQPUT or MQPUT1 call. An exception report message is generated, if one was requested by the sender.
- When the application that put the original message was putting to a topic

An exception report message will be generated, if one was requested by the sender.

### **RODISC**

Discard message.

This indicates that the message should be discarded if it cannot be delivered to the destination queue. This happens in the following situations:

- When the application that put the original message cannot be notified synchronously of the problem by means of the reason code returned by the MQPUT or MQPUT1 call. An exception report message is generated, if one was requested by the sender.
- When the application that put the original message was putting to a topic

An exception report message will be generated, if one was requested by the sender.

If it is required to return the original message to the sender, without the original message being placed on the dead-letter queue, the sender should specify RODISC with ROEXCF.

**Default option:** You can specify the following if no report options are required:

### **RONONE**

No reports required.

This value can be used to indicate that no other options have been specified. RONONE is defined to aid program documentation. It is not intended that this option be used with any other, but as its value is zero, such use cannot be detected.

### **General information:**

1. All report types required must be specifically requested by the application sending the original message. For example, if a COA report is requested but an exception report is not, a COA report is generated when the message is placed on the destination queue, but no exception report is generated if the destination queue is full when the message arrives there. If no MDREP options are set, no report messages are generated by the queue manager or message channel agent (MCA).

Some report options can be specified even though the local queue manager does not recognize them; this is useful when the option is to be processed by the destination queue manager. See [“Report options and message flags on IBM i” on page 1431](#) for more details.

If a report message is requested, the name of the queue to which the report should be sent must be specified in the MDRQ field. When a report message is received, the nature of the report can be determined by examining the MDFB field in the message descriptor.

2. If the queue manager or MCA that generates a report message is unable to put the report message on the reply queue (for example, because the reply queue or transmission queue is full), the report

message is placed instead on the dead-letter queue. If that also fails, or there is no dead-letter queue, the action taken depends on the type of the report message:

- If the report message is an exception report, the message which caused the exception report to be generated is left on its transmission queue; this ensures that the message is not lost.
- For all other report types, the report message is discarded and processing continues normally. This is done because either the original message has already been delivered safely (for COA or COD report messages), or is no longer of any interest (for an expiration report message).

Once a report message has been placed successfully on a queue (either the destination queue or an intermediate transmission queue), the message is no longer subject to special processing; it is treated just like any other message.

3. When the report is generated, the MDRQ queue is opened and the report message put using the authority of the MDUID in the MQMD of the message causing the report, except in the following cases:

- Exception reports generated by a receiving MCA are put with whatever authority the MCA used when it tried to put the message causing the report. The CDPA channel attribute determines the user identifier used.
- COA reports generated by the queue manager are put with whatever authority was used when the message causing the report was put on the queue manager generating the report. For example, if the message was put by a receiving MCA using the MCA's user identifier, the queue manager puts the COA report using the MCA's user identifier.

Applications generating reports should normally use the same authority as they would have used to generate a reply; this should normally be the authority of the user identifier in the original message.

If the report has to travel to a remote destination, senders and receivers can decide whether to accept it, in the same way as they do for other messages.

4. If a report message with data is requested:

- The report message is always generated with the amount of data requested by the sender of the original message. If the report message is too big for the reply queue, the processing described previously occurs; the report message is never truncated in order to fit on the reply queue.
- If the MDFMT of the original message is FMXQH, the data included in the report does not include the MQXQH. The report data starts with the first byte of the data beyond the MQXQH in the original message. This occurs whether the queue is a transmission queue.

5. If a COA, COD, or expiration report message is received at the reply queue, it is guaranteed that the original message arrived, was delivered, or expired, as appropriate. However, if one or more of these report messages is requested and is not received, the reverse cannot be assumed, since one of the following may have occurred:

- a. The report message is held up because a link is down.
- b. The report message is held up because a blocking condition exists at an intermediate transmission queue or at the reply queue (for example, the queue is full or inhibited for puts).
- c. The report message is on a dead-letter queue.
- d. When the queue manager was attempting to generate the report message, it was unable to put it on the appropriate queue, and was also unable to put it on the dead-letter queue, so the report message could not be generated.
- e. A failure of the queue manager occurred between the action being reported (arrival, delivery or expiry), and generation of the corresponding report message. (This does not happen for COD report messages if the application retrieves the original message within a unit of work, as the COD report message is generated within the same unit of work.)

Exception report messages may be held up in the same way for reasons 1, 2, and 3 previously. However, when an MCA is unable to generate an exception report message (the report message cannot be put either on the reply queue or the dead-letter queue), the original message remains

on the transmission queue at the sender, and the channel is closed. This occurs irrespective of whether the report message was to be generated at the sending or the receiving end of the channel.

6. If the original message is temporarily blocked (resulting in an exception report message being generated and the original message being put on a dead-letter queue), but the blockage clears and an application then reads the original message from the dead-letter queue and puts it again to its destination, the following may occur:
  - Even though an exception report message has been generated, the original message eventually arrives successfully at its destination.
  - More than one exception report message is generated in respect of a single original message, since the original message may encounter another blockage later.

#### **Report messages when putting to a topic:**

1. Reports can be generated when putting a message to a topic. This message will be sent to all subscribers to the topic, which could be zero, one or many. This should be taken into account when choosing to use report options as many report messages could be generated as a result.
2. When putting a message to a topic, there may be many destination queues that are to be given a copy of the message. If some of these destination queues have a problem, such as queue full, then the successful completion of the MQPUT depends on the setting of NPMSGDLV or PMSGDLV (depending on the persistence of the message). If the setting is such that message delivery to the destination queue must be successful (for example, it is a persistent message to a durable subscriber and PMSGDLV is set to ALL or ALLDUR), then success is defined as one of the following criteria being met:
  - Successful put to the subscriber queue
  - Use of RODLQ and a successful put to the Dead-letter queue if the subscriber queue cannot take the message
  - Use of RODISC if the subscriber queue cannot take the message.

#### **Report messages for message segments:**

1. Report messages can be requested for messages that have segmentation allowed (see the description of the MFSEGA flag). If the queue manager finds it necessary to segment the message, a report message can be generated for each of the segments that subsequently encounters the relevant condition. Applications should therefore be prepared to receive multiple report messages for each type of report message requested. The MDGID field in the report message can be used to correlate the multiple reports with the group identifier of the original message, and the MDFB field used to identify the type of each report message.
2. If GMLOGO is used to retrieve report messages for segments, be aware that reports of different types may be returned by the successive MQGET calls. For example, if both COA and COD reports are requested for a message that is segmented by the queue manager, the MQGET calls for the report messages may return the COA and COD report messages interleaved in an unpredictable fashion. This can be avoided by using the GMCMPM option (optionally with GMATM). GMCMPM causes the queue manager to reassemble report messages that have the same report type. For example, the first MQGET call might reassemble all of the COA messages relating to the original message, and the second MQGET call might reassemble all of the COD messages. Which is reassembled first depends on which type of report message happens to occur first on the queue.
3. Applications that themselves put segments can specify different report options for each segment. However, the following points should be noted:
  - If the segments are retrieved using the GMCMPM option, only the report options in the first segment are honored by the queue manager.
  - If the segments are retrieved one by one, and most of them have one of the ROCOD\* options, but at least one segment does not, it will not be possible to use the GMCMPM option to retrieve the report messages with a single MQGET call, or use the GMASGA option to detect when all of the report messages have arrived.

4. In an MQ network, it is possible for the queue managers to have differing capabilities. If a report message for a segment is generated by a queue manager or MCA that does not support segmentation, the queue manager or MCA will not by default include the necessary segment information in the report message, and this may make it difficult to identify the original message that caused the report to be generated. This difficulty can be avoided by requesting data with the report message, that is, by specifying the appropriate RO\*D or RO\*F options. However, be aware that if RO\*D is specified, less than 100 bytes of application message data may be returned to the application which retrieves the report message, if the report message is generated by a queue manager or MCA that does not support segmentation.

**Contents of the message descriptor for a report message:** When the queue manager or message channel agent (MCA) generates a report message, it sets the fields in the message descriptor to the following values, and then puts the message in the normal way.

*Table 708. Values used for MQMD fields when a report message is system-generated*

<b>Field in MQMD</b>	<b>Value used</b>
MDSID	MDSIDV
MDVER	MDVER2
MDREP	RONONE
MDMT	MTRPRT
MDEXP	EIULIM
MDFB	As appropriate for the nature of the report (FBCOA, FBCOD, FBEXP, or an RC* value)
MDENC	Copied from the original message descriptor
MDCSI	Copied from the original message descriptor
MDFMT	Copied from the original message descriptor
MDPRI	Copied from the original message descriptor
MDPER	Copied from the original message descriptor
MDMID	As specified by the report options in the original message descriptor
MDCID	As specified by the report options in the original message descriptor
MDBOC	0
MDRQ	Blanks
MDRM	Name of queue manager
MDUID	As set by the PMPASI option
MDACC	As set by the PMPASI option
MDAID	As set by the PMPASI option
MDPAT	ATQM, or as appropriate for the message channel agent
MDPAN	First 28 bytes of the queue manager name or message channel agent name. For report messages generated by the IMS bridge, this field contains the XCF group name and XCF member name of the IMS system to which the message relates.
MDPD	Date when report message is sent
MDPT	Time when report message is sent
MDAOD	Blanks
MDGID	Copied from the original message descriptor

Table 708. Values used for MQMD fields when a report message is system-generated (continued)

Field in MQMD	Value used
MDSEQ	Copied from the original message descriptor
MDOFF	Copied from the original message descriptor
MDMFL	Copied from the original message descriptor
MDOLN	Copied from the original message descriptor if not OLUNDF, and set to the length of the original message data otherwise

An application generating a report is recommended to set similar values, except for the following:

- The MDRM field can be set to blanks (the queue manager will change this to the name of the local queue manager when the message is put).
- The context fields should be set using the option that would have been used for a reply, normally PMPASI.

**Analyzing the report field:** The MDREP field contains subfields; because of this, applications that need to check whether the sender of the message requested a particular report should use one of the techniques described in [“Analyzing the report field on IBM i”](#) on page 1433.

This is an output field for the MQGET call, and an input field for the MQPUT and MQPUT1 calls. The initial value of this field is RONONE.

#### **MDRM (48-byte character string)**

Name of reply queue manager.

This is the name of the queue manager to which the reply message or report message should be sent. MDRQ is the local name of a queue that is defined on this queue manager.

If the MDRM field is blank, the local queue manager looks up the **MDRQ** name in its queue definitions. If a local definition of a remote queue exists with this name, the **MDRM** value in the transmitted message is replaced by the value of the **RemoteQMGrName** attribute from the definition of the remote queue, and this value will be returned in the message descriptor when the receiving application issues an MQGET call for the message. If a local definition of a remote queue does not exist, the MDRM that is transmitted with the message is the name of the local queue manager.

If the name is specified, it may contain trailing blanks; the first null character and characters following it are treated as blanks. Otherwise, however, no check is made that the name satisfies the naming rules for queue managers, or that this name is known to the sending queue manager; this is also true for the name transmitted, if the **MDRM** is replaced in the transmitted message.

If a reply-to queue is not required, it is recommended (although this is not checked) that the MDRM field should be set to blanks; the field should not be left uninitialized.

For the MQGET call, the queue manager always returns the name padded with blanks to the length of the field.

This is an output field for the MQGET call, and an input field for the MQPUT and MQPUT1 calls. The length of this field is given by LNQMN. The initial value of this field is 48 blank characters.

#### **MDRQ (48-byte character string)**

Name of reply queue.

This is the name of the message queue to which the application that issued the get request for the message should send MTRPLY and MTRPRT messages. The name is the local name of a queue that is defined on the queue manager identified by MDRM. This queue should not be a model queue, although the sending queue manager does not verify this when the message is put.

For the MQPUT and MQPUT1 calls, this field must not be blank if the MDMT field has the value MTRQST, or if any report messages are requested by the MDREP field. However, the value specified (or

substituted) is passed on to the application that issues the get request for the message, whatever the message type.

If the MDRM field is blank, the local queue manager looks up the MDRQ name in its own queue definitions. If a local definition of a remote queue exists with this name, the MDRQ value in the transmitted message is replaced by the value of the **RemoteQName** attribute from the definition of the remote queue, and this value will be returned in the message descriptor when the receiving application issues an MQGET call for the message. If a local definition of a remote queue does not exist, MDRQ is unchanged.

If the name is specified, it may contain trailing blanks; the first null character and characters following it are treated as blanks. Otherwise, however, no check is made that the name satisfies the naming rules for queues; this is also true for the name transmitted, if the MDRQ is replaced in the transmitted message. The only check made is that a name has been specified, if the circumstances require it.

If a reply-to queue is not required, it is recommended (although this is not checked) that the MDRQ field should be set to blanks; the field should not be left uninitialized.

For the MQGET call, the queue manager always returns the name padded with blanks to the length of the field.

If a message that requires a report message cannot be delivered, and the report message also cannot be delivered to the queue specified, both the original message and the report message go to the dead-letter (undelivered-message) queue. See the **DeadLetterQName** attribute described in [“Attributes for the queue manager on IBM i” on page 1397](#).

This is an output field for the MQGET call, and an input field for the MQPUT and MQPUT1 calls. The length of this field is given by LNQN. The initial value of this field is 48 blank characters.

### **MDSEQ (10-digit signed integer)**

Sequence number of logical message within group.

Sequence numbers start at 1, and increase by 1 for each new logical message in the group, up to a maximum of 999 999 999. A physical message which is not in a group has a sequence number of 1.

This field need not be set by the application on the MQPUT or MQGET call if:

- On the MQPUT call, PMLOGO is specified.
- On the MQGET call, MOSEQN is not specified.

These are the recommended ways of using these calls for messages that are not report messages. However, if the application requires more control, or the call is MQPUT1, the application must ensure that MDSEQ is set to an appropriate value.

On input to the MQPUT and MQPUT1 calls, the queue manager uses the value detailed in [Table 1](#). On output from the MQPUT and MQPUT1 calls, the queue manager sets this field to the value that was sent with the message.

On input to the MQGET call, the queue manager uses the value detailed in [Table 1](#). On output from the MQGET call, the queue manager sets this field to the value for the message retrieved.

The initial value of this field is one. This field is ignored if MDVER is less than MDVER2.

### **MDSID (4-byte character string)**

Structure identifier.

The value must be:

#### **MDSIDV**

Identifier for message descriptor structure.

This is always an input field. The initial value of this field is MDSIDV.

### **MDUID (12-byte character string)**

User identifier.

This is part of the *identity context* of the message. For more information about message context, see [Message context](#) and [Controlling context information](#).

MDUID specifies the user identifier of the application that originated the message. The queue manager treats this information as character data, but does not define the format of it.

After a message has been received, MDUID can be used in the ODAU field of the **OBJDSC** parameter of a subsequent MQOPEN or MQPUT1 call, so that the authorization check is performed for the MDUID user instead of the application performing the open.

When the queue manager generates this information for an MQPUT or MQPUT1 call, the queue manager uses a user identifier determined from the environment.

When the user identifier is determined from the environment:

-  **z/OS** On z/OS, the queue manager uses:
  - For batch, the user identifier from the JES JOB card or started task
  - For TSO, the log on user identifier
  - For CICS, the user identifier associated with the task
  - For IMS, the user identifier depends on the type of application:
    - For:
      - Nonmessage BMP regions
      - Nonmessage IFP regions
      - Message BMP and message IFP regions that have not issued a successful GU callthe queue manager uses the user identifier from the region JES JOB card or the TSO user identifier. If these are blank or null, it uses the name of the program specification block (PSB).
    - For:
      - Message BMP and message IFP regions that have issued a successful GU call
      - MPP regionsthe queue manager uses one of:
      - The signed-on user identifier associated with the message
      - The logical terminal (LTERM) name
      - The user identifier from the region JES JOB card
      - The TSO user identifier
      - The PSB name
-  **IBM i** On IBM i, the queue manager uses the name of the user profile associated with the application job.
-  **Linux**  **AIX** On AIX and Linux, the queue manager uses:
  - The application's logon name
  - The effective user identifier of the process if no logon is available
  - The user identifier associated with the transaction, if the application is a CICS transaction
- On VSE/ESA, this is a reserved field.
-  **Windows** On Windows, the queue manager uses the first 12 characters of the logged-on user name.

For the MQPUT and MQPUT1 calls, this is an input/output field if PMSETI or PMSETA is specified in the **PMO** parameter. Any information following a null character within the field is discarded. The null character and any following characters are converted to blanks by the queue manager. If PMSETI or PMSETA is not specified, this field is ignored on input and is an output-only field.

After the successful completion of an MQPUT or MQPUT1 call, this field contains the MDUID that was transmitted with the message if it was put to a queue. This will be the value of MDUID that is kept with the message if it is retained (see description of PMRET for more details about retained publications) but is not used as the MDUID when the message is sent as a publication to subscribers since they provide a value to override MDUID in all publications sent to them. If the message has no context, the field is entirely blank.

This is an output field for the MQGET call. The length of this field is given by LNUID. The initial value of this field is 12 blank characters.

### MDVER (10-digit signed integer)

Structure version number.

The value must be one of the following:

#### MDVER1

Version-1 message descriptor structure.

#### MDVER2

Version-2 message descriptor structure.

**Note:** When a version-2 MQMD is used, the queue manager performs additional checks on any MQ header structures that may be present at the beginning of the application message data; for further details see the usage notes for the MQPUT call.

Fields that exist only in the more-recent version of the structure are identified as such in the descriptions of the fields. The following constant specifies the version number of the current version:

#### MDVERC

Current version of message descriptor structure.

This is always an input field. The initial value of this field is MDVER1.

### Initial values

## IBM i MQMDE (Message descriptor extension) on IBM i

### Overview

**Purpose:** The MQMDE structure describes the data that sometimes occurs preceding the application message data. The structure contains those MQMD fields that exist in the version-2 MQMD, but not in the version-1 MQMD.

**Format name:** FMMDE.

**Character set and encoding:** Data in MQMDE must be in the character set given by the **CodedCharSetId** queue manager attribute and encoding of the local queue manager given by ENNAT for the C programming language.

The character set and encoding of the MQMDE must be set into the *MDCSI* and *MDENC* fields in:

- The MQMD (if the MQMDE structure is at the start of the message data), or
- The header structure that precedes the MQMDE structure (all other cases).

If the MQMDE is not in the queue manager's character set and encoding, the MQMDE is accepted but not honored, that is, the MQMDE is treated as message data.

**Usage:** Normal applications should use a version-2 MQMD, in which case they will not encounter an MQMDE structure. However, specialized applications, and applications that continue to use a version-1 MQMD, may encounter an MQMDE in some situations. The MQMDE structure can occur in the following circumstances:

- Specified on the MQPUT and MQPUT1 calls
- Returned by the MQGET call
- In messages on transmission queues
- [“MQMDE specified on MQPUT and MQPUT1 calls” on page 1154](#)

- “MQMDE returned by MQGET call” on page 1154
- “MQMDE in messages on transmission queues” on page 1155
- “Fields” on page 1155
- “Initial values” on page 1157
- “RPG declaration” on page 1157

## MQMDE specified on MQPUT and MQPUT1 calls

On the MQPUT and MQPUT1 calls, if the application provides a version-1 MQMD, the application can optionally prefix the message data with an MQMDE, setting the *MDFMT* field in MQMD to FMMDE to indicate that an MQMDE is present. If the application does not provide an MQMDE, the queue manager assumes default values for the fields in the MQMDE. The default values that the queue manager uses are the same as the initial values for the structure - see [Table 711 on page 1157](#).

If the application provides a version-2 MQMD *and* prefixes the application message data with an MQMDE, the structures are processed as shown in [Table 710 on page 1154](#).

MQMD version	Values of version-2 fields	Values of corresponding fields in MQMDE	Action taken by queue manager
1	-	Valid	MQMDE is honored
2	Default	Valid	MQMDE is honored
2	Not default	Valid	MQMDE is treated as message data
1 or 2	Any	Not valid	Call fails with an appropriate reason code
1 or 2	Any	MQMDE is in the wrong character set or encoding, or is an unsupported version	MQMDE is treated as message data

There is one special case. If the application uses a version-2 MQMD to put a message that is a segment (that is, the MFSEG or MFLSEG flag is set), and the format name in the MQMD is FMDLH, the queue manager generates an MQMDE structure and inserts it *between* the MQDLH structure and the data that follows it. In the MQMD that the queue manager retains with the message, the version-2 fields are set to their default values.

Several of the fields that exist in the version-2 MQMD but not the version-1 MQMD are input/output fields on MQPUT and MQPUT1. However, the queue manager does not return any values in the equivalent fields in the MQMDE on output from the MQPUT and MQPUT1 calls; if the application requires those output values, it must use a version-2 MQMD.

## MQMDE returned by MQGET call

On the MQGET call, if the application provides a version-1 MQMD, the queue manager prefixes the message returned with an MQMDE, but only if one or more of the fields in the MQMDE has a nondefault value. The queue manager sets the *MDFMT* field in MQMD to the value FMMDE to indicate that an MQMDE is present.

If the application provides an MQMDE at the start of the **BUFFER** parameter, the MQMDE is ignored. On return from the MQGET call, it is replaced by the MQMDE for the message (if one is needed), or overwritten by the application message data (if the MQMDE is not needed).

If an MQMDE is returned by the MQGET call, the data in the MQMDE is typically in the queue manager's character set and encoding. However the MQMDE may be in some other character set and encoding if:

- The MQMDE was treated as data on the MQPUT or MQPUT1 call (see [Table 710 on page 1154](#) for the circumstances that can cause this).
- The message was received from a remote queue manager connected by a TCP connection, and the receiving message channel agent (MCA) was not set up correctly (see [Security of IBM MQ for IBM i objects](#) for further information).

## MQMDE in messages on transmission queues

Messages on transmission queues are prefixed with the MQXQH structure, which contains within it a version-1 MQMD. An MQMDE may also be present, positioned between the MQXQH structure and application message data, but it will typically be present only if one or more of the fields in the MQMDE has a nondefault value.

Other IBM MQ header structures can also occur between the MQXQH structure and the application message data. For example, when the dead-letter header MQDLH is present, and the message is not a segment, the order is:

- MQXQH (containing a version-1 MQMD)
- MQMDE
- MQDLH
- Application message data

## Fields

The MQMDE structure contains the following fields; the fields are described in **alphabetical order**:

### MECSI (10-digit signed integer)

Character-set identifier of data that follows MQMDE.

This specifies the character set identifier of the data that follows the MQMDE structure; it does not apply to character data in the MQMDE structure itself.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The queue manager does not check that this field is valid. The following special value can be used:

#### CSINHT

Inherit character-set identifier of this structure.

Character data in the data *following* this structure is in the same character set as this structure.

The queue manager changes this value in the structure sent in the message to the actual character-set identifier of the structure. Provided no error occurs, the value CSINHT is not returned by the MQGET call.

CSINHT cannot be used if the value of the *MDPAT* field in MQMD is ATBRKR.

The initial value of this field is CSUNDF.

### MEENC (10-digit signed integer)

MEENC (10-digit signed integer)

This specifies the numeric encoding of the data that follows the MQMDE structure; it does not apply to numeric data in the MQMDE structure itself.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The queue manager does not check that the field is valid. See the *MDENC* field described in [“MQMD \(Message descriptor\) on IBM i” on page 1110](#) for more information about data encodings.

The initial value of this field is ENNAT.

### MEFLG (10-digit signed integer)

General flags.

The following flag can be specified:

**MEFNON**

No flags.

The initial value of this field is MEFNON.

**MEFMT (8-byte character string)**

Format name of data that follows MQMDE.

This specifies the format name of the data that follows the MQMDE structure.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The queue manager does not check that this field is valid. See the *MDFMT* field described in [“MQMD \(Message descriptor\) on IBM i” on page 1110](#) for more information about format names.

The initial value of this field is FMNONE.

**MEGID (24-byte bit string)**

Group identifier.

See the *MDGID* field described in [“MQMD \(Message descriptor\) on IBM i” on page 1110](#). The initial value of this field is GINONE.

**MELEN (10-digit signed integer)**

Length of MQMDE structure.

The following value is defined:

**MELEN2**

Length of version-2 message descriptor extension structure.

The initial value of this field is MELEN2.

**MEMFL (10-digit signed integer)**

Message flags.

See the *MDMFL* field described in [“MQMD \(Message descriptor\) on IBM i” on page 1110](#). The initial value of this field is MFNONE.

**MEOFF (10-digit signed integer)**

Offset of data in physical message from start of logical message.

See the *MDOFF* field described in [“MQMD \(Message descriptor\) on IBM i” on page 1110](#). The initial value of this field is 0.

**MEOLN (10-digit signed integer)**

Length of original message.

See the *MDOLN* field described in [“MQMD \(Message descriptor\) on IBM i” on page 1110](#). The initial value of this field is OLUNDF.

**MESEQ (10-digit signed integer)**

Sequence number of logical message within group.

See the *MDSEQ* field described in [“MQMD \(Message descriptor\) on IBM i” on page 1110](#). The initial value of this field is 1.

**MESID (4-byte character string)**

Structure identifier.

The value must be:

**MESIDV**

Identifier for message descriptor extension structure.

The initial value of this field is MESIDV.

### MEVER (10-digit signed integer)

Structure version number.

The value must be:

#### MEVER2

Version-2 message descriptor extension structure.

The following constant specifies the version number of the current version:

#### MEVERC

Current version of message descriptor extension structure.

The initial value of this field is MEVER2.

## Initial values

Field name	Name of constant	Value of constant
MESID	MESIDV	'MDE↵'

## IBM i MQMHBO (Message handle to buffer options) on IBM i

Structure defining the message handle to buffer options

### Overview

**Purpose:** The MQMHBO structure allows applications to specify options that control how buffers are produced from message handles. The structure is an input parameter on the MQMHBUF call.

**Character set and encoding:** Data in MQMHBO must be in the character set of the application and encoding of the application (ENNAT).

- [“Fields” on page 1158](#)
- [“Initial values” on page 1159](#)
- [“RPG declaration” on page 1159](#)

### Fields

The MQMHBO structure contains the following fields; the fields are described in **alphabetical order**:

#### MBOPT (10-digit signed integer)

Message handle to buffer options structure - MBOPT field.

These options control the action of MQMHBUF.

You must specify the following option:

##### MBPRRF

When converting properties from a message handle into a buffer, convert them into the MQRFH2 format.

Optionally, you can also specify the following option. To specify more than one option, either add the values together (do not add the same constant more than once), or combine the values using the bitwise OR operation (if the programming language supports bit operations).

##### MBDLPR

Properties that are added to the buffer are deleted from the message handle. If the call fails no properties are deleted.

This is always an input field. The initial value of this field is MBPRRF.

#### MBSID (10-digit signed integer)

Message handle to buffer options structure - MBSID field.

This is the structure identifier. The value must be:

##### MBSIDV

Identifier for message handle to buffer options structure.

This is always an input field. The initial value of this field is MBSIDV.

## MBVER (10-digit signed integer)

This is the structure version number. The value must be:

### MBVER1

Version number for message handle to buffer options structure.

The following constant specifies the version number of the current version:

### MBVERC

Current version of message handle to buffer options structure.

This is always an input field. The initial value of this field is MBVER1.

## Initial values

Field name	Name of constant	Value of constant
MVSID	MBSIDV	'MHBO'
MBVER	MBVER1	1
MBOPT	MBPRRF	

### Notes:

1. The value Null string or blanks denotes a blank character.

## IBM i MQOD (Object descriptor) on IBM i

The MQOD structure is used to specify an object by name.

## Overview

**Purpose:** The following types of object are valid:

- Queue or distribution list
- Namelist
- Process definition
- Queue manager
- Topic

The structure is an input/output parameter on the MQOPEN and MQPUT1 calls.

**Version:** The current version of MQOD is ODVER4. Fields that exist only in the more-recent versions of the structure are identified as such in the descriptions that follow.

The COPY file provided contains the most recent version of MQOD that is supported by the environment, but with the initial value of the *ODVER* field set to ODVER1. To use fields that are not present in the version-1 structure, the application must set the *ODVER* field to the version number of the version required.

To open a distribution list, *ODVER* must be ODVER2 or greater.

**Character set and encoding:** Data in MQOD must be in the character set given by the **CodedCharSetId** queue manager attribute and encoding of the local queue manager given by ENNAT. However, if the application is running as an IBM MQ client, the structure must be in the character set and encoding of the client.

- [“Fields” on page 1160](#)
- [“Initial values” on page 1167](#)
- [“RPG declaration” on page 1168](#)

## Fields

The MQOD structure contains the following fields; the fields are described in **alphabetical order**:

### **ODASI (40-byte bit string)**

Alternate security identifier.

This is a security identifier that is passed with the *ODAU* to the authorization service to allow appropriate authorization checks to be performed. *ODASI* is used only if:

- OOALTU is specified on the MQOPEN call, or
- PMALTU is specified on the MQPUT1 call,

and the *ODAU* field is not entirely blank up to the first null character or the end of the field.

The *ODASI* field has the following structure:

- The first byte is a binary integer containing the length of the significant data that follows; the value excludes the length byte itself. If no security identifier is present, the length is zero.
- The second byte indicates the type of security identifier that is present; the following values are possible:

#### **SITWNT**

Windows security identifier.

#### **SITNON**

No security identifier.

- The third and subsequent bytes up to the length defined by the first byte contain the security identifier itself.
- Remaining bytes in the field are set to binary zero.

The following special value may be used:

#### **SINONE**

No security identifier specified.

The value is binary zero for the length of the field.

This is an input field. The length of this field is given by LNSCID. The initial value of this field is SINONE. This field is ignored if *ODVER* is less than ODVER3.

### **ODAU (12-byte character string)**

Alternate user identifier.

If OOALTU is specified for the MQOPEN call, or PMALTU for the MQPUT1 call, this field contains an alternate user identifier that is to be used to check the authorization for the open, in place of the user

identifier that the application is currently running under. Some checks, however, are still carried out with the current user identifier (for example, context checks).

If OOALTU and PMALTU are not specified and this field is entirely blank up to the first null character or the end of the field, the open can succeed only if no user authorization is needed to open this object with the options specified.

If neither OOALTU nor PMALTU is specified, this field is ignored.

This is an input field. The length of this field is given by LNUID. The initial value of this field is 12 blank characters.

### **ODDN (48-byte character string)**

Dynamic queue name.

This is the name of a dynamic queue that is to be created by the MQOPEN call. This is of relevance only when *ODON* specifies the name of a model queue; in all other cases *ODDN* is ignored.

The characters that are valid in the name are the same as those for *ODON*, except that an asterisk is also valid. A name that is blank (or one in which only blanks are shown before the first null character) is not valid if *ODON* is the name of a model queue.

If the last non-blank character in the name is an asterisk (\*), the queue manager replaces the asterisk with a string of characters that guarantees that the name generated for the queue is unique at the local queue manager. To allow a sufficient number of characters for this, the asterisk is valid only in positions 1 through 33. There must be no characters other than blanks or a null character following the asterisk.

It is valid for the asterisk to occur in the first character position, in which case the name consists solely of the characters generated by the queue manager.

This is an input field. The length of this field is given by LNQN. The initial value of this field is 'AMQ.\*', padded with blanks.

### **ODIDC (10-digit signed integer)**

Number of queues that failed to open.

This is the number of queues in the distribution list that failed to open successfully. If present, this field is also set when opening a single queue which is not in a distribution list.

**Note:** If present, this field is set only if the **CMPCOD** parameter on the MQOPEN or MQPUT1 call is CCOK or CCWARN; it is not set if the **CMPCOD** parameter is CCFail.

This is an output field. The initial value of this field is 0. This field is ignored if *ODVER* is less than *ODVER2*.

### **ODKDC (10-digit signed integer)**

Number of local queues opened successfully.

This is the number of queues in the distribution list that resolve to local queues and that were opened successfully. The count does not include queues that resolve to remote queues (even though a local transmission queue is used initially to store the message). If present, this field is also set when opening a single queue which is not in a distribution list.

This is an output field. The initial value of this field is 0. This field is ignored if *ODVER* is less than *ODVER2*.

### **ODMN (48-byte character string)**

Object queue manager name.

This is the name of the queue manager on which the *ODON* object is defined. The characters that are valid in the name are the same as those for *ODON* (see previously). A name that is entirely blank up to the first null character or the end of the field denotes the queue manager to which the application is connected (the local queue manager).

The following points apply to the types of object indicated:

- If *ODOT* is OTTOP, OTNLST, OTPRO, or OTQM, *ODMN* must be blank or the name of the local queue manager.
- If *ODON* is the name of a model queue, the queue manager creates a dynamic queue with the attributes of the model queue, and returns in the *ODMN* field the name of the queue manager on which the queue is created; this is the name of the local queue manager. A model queue can be specified only on the MQOPEN call; a model queue is not valid on the MQPUT1 call.
- If *ODON* is the name of a cluster queue, and *ODMN* is blank, the actual destination of messages sent using the queue handle returned by the MQOPEN call is chosen by the queue manager (or cluster workload exit, if one is installed) as follows:
  - If OOBND0 is specified, the queue manager selects an instance of the cluster queue during the processing of the MQOPEN call, and all messages put using this queue handle are sent to that instance.
  - If OOBNDN is specified, the queue manager may choose a different instance of the destination queue (residing on a different queue manager in the cluster) for each successive MQPUT call that uses this queue handle.

If the application needs to send a message to a *specific* instance of a cluster queue (that is, a queue instance that resides on a particular queue manager in the cluster), the application should specify the name of that queue manager in the *ODMN* field. This forces the local queue manager to send the message to the specified destination queue manager.

- If the object being opened is a distribution list (that is, *ODREC* is greater than zero), *ODMN* must be blank or the null string. If this condition is not satisfied, the call fails with reason code RC2153.

This is an input/output field for the MQOPEN call when *ODON* is the name of a model queue, and an input-only field in all other cases. The length of this field is given by LNQMN. The initial value of this field is 48 blank characters.

### **ODON (48-byte character string)**

Object name.

This is the local name of the object as defined on the queue manager identified by *ODMN*. The name can contain the following characters:

- Uppercase alphabetic characters (A - Z)
- Lowercase alphabetic characters (a - z)
- Numeric digits (0 - 9)
- Period (.), forward slash (/), underscore (\_), percent (%)

The name must not contain leading or embedded blanks, but may contain trailing blanks. A null character can be used to indicate the end of significant data in the name; the null and any characters following it are treated as blanks. The following restrictions apply in the environments indicated:

- On systems that use EBCDIC Katakana, lowercase characters cannot be used.
- On IBM i, names containing lowercase characters, forward slash, or percent, must be enclosed in quotation marks when specified on commands. These quotation marks must not be specified for names that occur as fields in structures or as parameters on calls.

The following points apply to the types of object indicated:

- If *ODON* is the name of a model queue, the queue manager creates a dynamic queue with the attributes of the model queue, and returns in the *ODON* field the name of the queue created. A model queue can be specified only on the MQOPEN call; a model queue is not valid on the MQPUT1 call.
- If the object being opened is a distribution list (that is, *ODREC* is present and greater than zero), *ODON* must be blank or the null string. If this condition is not satisfied, the call fails with reason code RC2152.

- If *ODOT* is OTQM, special rules apply; in this case the name must be entirely blank up to the first null character or the end of the field.
- If *ODON* is the name of an alias queue with TARGTYPE(TOPIC), a security check is first made on the named alias queue, as is normal for the use of alias queues. If this security check is successful, this MQOPEN call will continue and behaves like an MQOPEN of an OTTOP, including making a security check against the administrative topic object.

This is an input/output field for the MQOPEN call when *ODON* is the name of a model queue, and an input-only field in all other cases. The length of this field is given by LNQN. The initial value of this field is 48 blank characters.

The full topic name can be built from two different fields: *ODON* and *ODOS*. For details of how these two fields are used, see [Combining topic strings](#).

### **ODORO (10-digit signed integer)**

Offset of first object record from start of MQOD.

This is the offset in bytes of the first MQOR object record from the start of the MQOD structure. The offset can be positive or negative. *ODORO* is used only when a distribution list is being opened. The field is ignored if *ODREC* is zero.

When a distribution list is being opened, an array of one or more MQOR object records must be provided in order to specify the names of the destination queues in the distribution list. This can be done in one of two ways:

- By using the offset field *ODORO*

In this case, the application should declare its own structure containing an MQOD followed by the array of MQOR records (with as many array elements as are needed), and set *ODORO* to the offset of the first element in the array from the start of the MQOD. Care must be taken to ensure that this offset is correct.

- By using the pointer field *ODORP*

In this case, the application can declare the array of MQOR structures separately from the MQOD structure, and set *ODORP* to the address of the array.

Whichever technique is chosen, one of *ODORO* and *ODORP* must be used; the call fails with reason code RC2155 if both are zero, or both are nonzero.

This is an input field. The initial value of this field is 0. This field is ignored if *ODVER* is less than ODVER2.

### **ODORP (pointer)**

Address of first object record.

This is the address of the first MQOR object record. *ODORP* is used only when a distribution list is being opened. The field is ignored if *ODREC* is zero.

This is an input field. The initial value of this field is the null pointer. Either *ODORP* or *ODORO* can be used to specify the object records, but not both; see the description of the *ODORO* field previously for details. If *ODORP* is not used, it must be set to the null pointer or null bytes. This field is ignored if *ODVER* is less than ODVER2.

### **ODOS (MQCHARV)**

ODOS specifies the long object name to be used.

This field is referenced only for certain values of *ODOT*. See the description of [ODOT](#) for details of which values indicate that this field is used.

If *ODOS* is specified incorrectly, according to the description of how to use the [MQCHARV](#) structure, or if it exceeds the maximum length, the call fails with reason code RC2441.

This is an input field. The initial values of the fields in this structure are the same as those in the MQCHARV structure.

The full topic name can be built from two different fields: *ODON* and *ODOS*. For details of how these two fields are used, see [Combining topic strings](#). This field is ignored if *ODVER* is less than *ODVER4*.

### **ODOT (10-digit signed integer)**

Object type.

Type of object being named in *ODON*. Possible values are:

#### **OTQ**

Queue. The name of the object is found in *ODON*.

#### **OTNLST**

Namelist. The name of the object is found in *ODON*.

#### **OTPRO**

Process definition. The name of the object is found in *ODON*.

#### **OTQM**

Queue manager. The name of the object is found in *ODON*.

#### **OTTOP**

Topic. The full topic name can be built from two different fields: *ODON* and *ODOS*.

For details of how those two fields are used, see [Combining topic strings](#).

If the object identified by the *ODON* field cannot be found, the call will fail with reason code RC2425 even if there is a string specified in *ODOS*.

This is always an input field. The initial value of this field is OTQ.

### **ODREC (10-digit signed integer)**

Number of object records present.

This is the number of MQOR object records that have been provided by the application. If this number is greater than zero, it indicates that a distribution list is being opened, with *ODREC* being the number of destination queues in the list. It is valid for a distribution list to contain only one destination.

The value of *ODREC* must not be less than zero, and if it is greater than zero *ODOT* must be OTQ; the call fails with reason code RC2154 if these conditions are not satisfied.

This is an input field. The initial value of this field is 0. This field is ignored if *ODVER* is less than *ODVER2*.

### **ODRMN (48-byte character string)**

Resolved queue manager name.

This is the name of the destination queue manager after name resolution has been performed by the local queue manager. The name returned is the name of the queue manager that owns the queue identified by *ODRQN*. *ODRMN* can be the name of the local queue manager.

If *ODRQN* is a shared queue that is owned by the queue sharing group to which the local queue manager belongs, *ODRMN* is the name of the queue sharing group. If the queue is owned by some other queue sharing group, *ODRQN* can be the name of the queue sharing group or the name of a queue manager that is a member of the queue sharing group (the nature of the value returned is determined by the queue definitions that exist at the local queue manager).

A nonblank value is returned only if the object is a single queue opened for browse, input, or output (or any combination). If the object opened is any of the following, *ODRMN* is set to blanks:

- Not a queue
- A queue, but not opened for browse, input, or output
- A cluster queue with OOBNDN specified (or with OOBNDQ in effect when the **DefBind** queue attribute has the value BNDNOT)
- A distribution list

This is an output field. The length of this field is given by LNQN. The initial value of this field is the null string in C, and 48 blank characters in other programming languages. This field is ignored if *ODVER* is less than *ODVER3*.

### **ODRO (MQCHARV)**

ODRO is the long object name after the queue manager resolves the name provided in *ODON*.

This field is returned only for certain types of objects, topics, and queue aliases which reference a topic object.

If the long object name is provided in *ODOS* and nothing is provided in *ODON*, the value returned in this field is the same as provided in *ODOS*.

If this field is omitted (that is *ODRO.VSBufSize* is zero), the *ODRO* is not returned, but the length is returned in *ODRO.VSLength*. If the length is shorter than the full *ODRO* then it is truncated and returns as many of the rightmost characters as can fit in the provided length.

If *ODRO* is specified incorrectly, according to the description of how to use the *MQCHARV* structure, or if it exceeds the maximum length, the call fails with reason code RC2520. This field is ignored if *ODVER* is less than *ODVER4*.

### **ODRQN (48-byte character string)**

Resolved queue name.

This is the name of the destination queue after name resolution has been performed by the local queue manager. The name returned is the name of a queue that exists on the queue manager identified by *ODRMN*.

A nonblank value is returned only if the object is a single queue opened for browse, input, or output (or any combination). If the object opened is any of the following, *ODRQN* is set to blanks:

- Not a queue
- A queue, but not opened for browse, input, or output
- A distribution list
- An alias queue that references a topic object (refer to [“ODRO \(MQCHARV\)”](#) on page 1165 instead)

This is an output field. The length of this field is given by LNQN. The initial value of this field is the null string in C, and 48 blank characters in other programming languages. This field is ignored if *ODVER* is less than *ODVER3*.

### **ODRRO (10-digit signed integer)**

Offset of first response record from start of MQOD.

This is the offset in bytes of the first MQRR response record from the start of the MQOD structure. The offset can be positive or negative. *ODRRO* is used only when a distribution list is being opened. The field is ignored if *ODREC* is zero.

When a distribution list is being opened, an array of one or more MQRR response records can be provided in order to identify the queues that failed to open (*RRCC* field in MQRR), and the reason for each failure (*RRREA* field in MQRR). The data is returned in the array of response records in the same order as the queue names occur in the array of object records. The queue manager sets the response records only when the outcome of the call is mixed (that is, some queues were opened successfully while others failed, or all failed but for differing reasons); reason code RC2136 from the call indicates this case. If the same reason code applies to all queues, that reason is returned in the **REASON** parameter of the MQOPEN or MQPUT1 call, and the response records are not set. Response records are optional, but if they are supplied there must be *ODREC* of them.

The response records can be provided in the same way as the object records, either by specifying an offset in *ODRRO*, or by specifying an address in *ODRRP*; see the description of *ODORO* previously for details of how to do this. However, no more than one of *ODRRO* and *ODRRP* can be used; the call fails with reason code RC2156 if both are nonzero.

For the MQPUT1 call, these response records are used to return information about errors that occur when the message is sent to the queues in the distribution list, as well as errors that occur when the queues are opened. The completion code and reason code from the put operation for a queue replace those from the open operation for that queue only if the completion code from the latter was CCOK or CCWARN.

This is an input field. The initial value of this field is 0. This field is ignored if *ODVER* is less than *ODVER2*.

### **ODRRP (pointer)**

Address of first response record.

This is the address of the first MQRR response record. *ODRRP* is used only when a distribution list is being opened. The field is ignored if *ODREC* is zero.

Either *ODRRP* or *ODRRO* can be used to specify the response records, but not both; see the previous description of the *ODRRO* field for details. If *ODRRP* is not used, it must be set to the null pointer or null bytes.

This is an input field. The initial value of this field is the null pointer. This field is ignored if *ODVER* is less than *ODVER2*.

### **ODSID (4-byte character string)**

Structure identifier.

The value must be:

#### **ODSIDV**

Identifier for object descriptor structure.

This is always an input field. The initial value of this field is *ODSIDV*.

### **ODSS (MQCHARV)**

*ODSS* contains the string used to provide the selection criteria used when retrieving messages off a queue.

*ODSS* must not be provided in the following cases:

- If *ODOT* is not OTQ
- If the queue being opened is not being opened using one of the input options, OOINP\*

If *ODSS* is provided in these cases, the call fails with reason code RC2516.

If *ODSS* is specified incorrectly, according to the description of how to use the *MQCHARV* structure, or if it exceeds the maximum length, the call fails with reason code RC2519. This field is ignored if *ODVER* is less than *ODVER4*.

### **ODUDC (10-digit signed integer)**

Number of remote queues opened successfully

This is the number of queues in the distribution list that resolve to remote queues and that were opened successfully. If present, this field is also set when opening a single queue which is not in a distribution list.

This is an output field. The initial value of this field is 0. This field is ignored if *ODVER* is less than *ODVER2*.

### **ODVER (10-digit signed integer)**

Structure version number.

The value must be one of the following:

#### **ODVER1**

Version-1 object descriptor structure.

**ODVER2**

Version-2 object descriptor structure.

**ODVER3**

Version-3 object descriptor structure.

**ODVER4**

Version-4 object descriptor structure.

Fields that exist only in the more-recent versions of the structure are identified as such in the descriptions of the fields. The following constant specifies the version number of the current version:

**ODVERC**

Current version of object descriptor structure.

This is always an input field. The initial value of this field is ODVER1.

**Initial values**

<i>Table 713. Fields in MQOD</i>		
<b>Field name</b>	<b>Name of constant</b>	<b>Value of constant</b>

## IBM i MQOR (Object record) on IBM i

The MQOR structure is used to specify the queue name and queue manager name of a single destination queue.

### Overview

**Purpose:** MQOR is an input structure for the MQOPEN and MQPUT1 calls.

**Character set and encoding:** Data in MQOR must be in the character set given by the **CodedCharSetId** queue manager attribute and encoding of the local queue manager given by ENNAT. However, if the application is running as an IBM MQ client, the structure must be in the character set and encoding of the client.

**Usage:** By providing an array of these structures on the MQOPEN call, it is possible to open a list of queues; this list is called a *distribution list*. Each message put using the queue handle returned by that MQOPEN call is placed on each of the queues in the list, if the queue was opened successfully.

- [“Fields” on page 1169](#)
- [“Initial values” on page 1170](#)
- [“RPG declaration” on page 1170](#)

### Fields

The MQOR structure contains the following fields; the fields are described in **alphabetical order**:

#### ORMN (48-byte character string)

Object queue manager name.

This is the same as the *ODMN* field in the MQOD structure (see MQOD for details).

This is always an input field. The initial value of this field is 48 blank characters.

## ORON (48-byte character string)

Object name.

This is the same as the *ODON* field in the MQOD structure (see MQOD for details), except that:

- It must be the name of a queue.
- It must not be the name of a model queue.

This is always an input field. The initial value of this field is 48 blank characters.

## Initial values

Field name	Name of constant	Value of constant
<i>ORON</i>	None	Blanks
<i>ORMN</i>	None	Blanks

## RPG declaration

```

## MQPD - Property descriptor

The **MQPD** is used to define the attributes of a property.

### Overview

**Purpose:** The structure is an input/output parameter on the MQSETMP call and an output parameter on the MQINQMP call.

**Character set and encoding:** Data in MQPD must be in the character set of the application and encoding of the application (ENNAT).

- [“Fields” on page 1170](#)
- [“Initial values” on page 1173](#)
- [“RPG declaration” on page 1173](#)

### Fields

The MQPD structure contains the following fields; the fields are described in **alphabetical order**:

#### PDCT (10-digit signed integer)

This describes what message context the property belongs to.

When a queue manager receives a message containing an IBM MQ-defined property that the queue manager recognizes as being incorrect, the queue manager corrects the value of the *PDCT* field.

The following option can be specified:

#### PDUSC

The property is associated with the user context.

No special authorization is required to be able to set a property associated with the user context using the MQSETMP call.

If the option previously described is not required, the following option can be used:

**PDNOC**

The property is not associated with a message context.

An unrecognized value is rejected with a *PDREA* code of RC2482.

This is an input/output field to the MQSETMP call and an output field from the MQINQMP call. The initial value of this field is PDNOC.

**PDCPYOPT (10-digit signed integer)**

This describes which type of messages the property should be copied into.

This is an output only field for recognized IBM MQ-defined properties; IBM MQ sets the appropriate value.

When a queue manager receives a message containing an IBM MQ-defined property that the queue manager recognizes as being incorrect, the queue manager corrects the value of the *CopyOptions* field.

You can specify one or more of these options. To specify more than one option, either add the values together (do not add the same constant more than once), or combine the values using the bitwise OR operation (if the programming language supports bit operations).

**COPFOR**

This property is copied into a message being forwarded.

**COPPUB**

This property is copied into the message received by a subscriber when a message is being published.

**COPREP**

This property is copied into a reply message.

**COPRP**

This property is copied into a report message.

**COPALL**

This property is copied into all types of subsequent messages.

**COPNON**

This property is not copied into a message.

**Default option:** The following option can be specified to supply the default set of copy options:

**COPDEF**

This property is copied into a message being forwarded, into a report message, or into a message received by a subscriber when a message is being published.

This is equivalent to specifying the combination of options COPFOR, plus COPRP, plus COPPUB.

If none of the options described previously are required, use the following option:

**COPNON**

Use this value to indicate that no other copy options have been specified; programmatically no relationship exists between this property and subsequent messages. This is always returned for message descriptor properties.

This is an input/output field to the MQSETMP call and an output field from the MQINQMP call. The initial value of this field is COPDEF.

**PDOPT (10-digit signed integer)**

The value must be:

**PDNONE**

No options specified

This is always an input field. The initial value of this field is PDNONE.

### **PDSID (10-digit signed integer)**

This is the structure identifier; the value must be:

#### **PSIDV**

Identifier for property descriptor structure.

This is always an input field. The initial value of this field is **PSIDV**.

### **PDSUP (10-digit signed integer)**

This field describes what level of support for the message property is required of the queue manager, in order for the message containing this property to be put to a queue. This applies only to IBM MQ-defined properties; support for all other properties is optional.

The field is automatically set to the correct value when the IBM MQ-defined property is known by the queue manager. If the property is not recognized, PDSUPO is assigned. When a queue manager receives a message containing an IBM MQ-defined property that the queue manager recognizes as being incorrect, the queue manager corrects the value of the *PDSUP* field.

When setting an IBM MQ-defined property using the MQSETMP call on a message handle where the CMNOVA option was set, *PDSUP* becomes an input field. This allows an application to put an IBM MQ-defined property, with the correct value, where the property is unsupported by the connected queue manager, but where the message is intended to be processed on another queue manager.

The value PDSUPO is always assigned to properties that are not IBM MQ-defined properties.

One of the following values is returned by the MQINQMP call, or one of the values can be specified, when using the MQSETMP call on a message handle where the CMNOVA option is set:

#### **PDSUPO**

The property is accepted by a queue manager even if it is not supported. The property can be discarded in order for the message to flow to a queue manager that does not support message properties. This value is also assigned to properties that are not IBM MQ-defined.

#### **PDSUPR**

Support for the property is required. The message is rejected by a queue manager that does not support the IBM MQ-defined property. The MQPUT or MQPUT1 call fails with completion code CCFAIL and reason code RC2490.

#### **PDSUPL**

The message is rejected by a queue manager that does not support the IBM MQ-defined property if the message is destined for a local queue. The MQPUT or MQPUT1 call fails with completion code CCFAIL and reason code RC2490.

The MQPUT or MQPUT1 call succeeds if the message is destined for a remote queue manager.

This is an output field on the MQINQMP call and an input field on the MQSETMP call if the message handle was created with the CMNOVA option set. The initial value of this field is PDSUPO.

### **PDVER (10-digit signed integer)**

This is the structure version number; the value must be:

#### **PDVER1**

Version-1 property descriptor structure.

The following constant specifies the version number of the current version:

#### **PDVERC**

Current version of property descriptor structure.

This is always an input field. The initial value of this field is **PDVER1**.

## Initial values

Field name	Name of constant	Value of constant
PDSID	PDSIDV	'PD'
PDVER	PDVER1	1
PDOPT	PDNONE	0
PDSUP	PDSUPO	0
PDCT	PDNOC	0
PDCPYOPT	COPDEF	0

## MQPMO (Put-message options) on IBM i

The MQPMO structure allows the application to specify options that control how messages are placed on queues or published to topics.

### Overview

#### Purpose

The structure is an input/output parameter on the MQPUT and MQPUT1 calls.

#### Version

The current version of MQPMO is PMVER2. Fields that exist only in the more-recent versions of the structure are identified as such in the descriptions that follow.

The COPY file provided contains the most recent version of MQPMO that is supported by the environment, but with the initial value of the *PMVER* field set to PMVER1. To use fields that are not present in the version-1 structure, the application must set the *PMVER* field to the version number of the version required.

#### Character set and encoding

Data in MQPMO must be in the character set given by the **CodedCharSetId** queue manager attribute and encoding of the local queue manager given by ENNAT. However, if the application is running as an IBM MQ client, the structure must be in the character set and encoding of the client.

- [“Fields” on page 1173](#)
- [“Initial values” on page 1187](#)
- [“RPG declaration” on page 1187](#)

### Fields

The MQPMO structure contains the following fields; the fields are described in alphabetical order:

**PMCT (10 digit signed integer)**

Object handle of input queue.

If PMPASI or PMPASA is specified, this field must contain the input queue handle from which context information to be associated with the message being put is taken.

If PMPASI and PMPASA are not specified, this field is ignored.

This is an input field. The initial value of this field is 0.

**PMIDC (10 digit signed integer)**

Number of messages that could not be sent.

This is the number of messages that could not be sent to queues in the distribution list. The count includes queues that failed to open, and queues that were opened successfully but for which the put operation failed. This field is also set when putting a message to a single queue which is not in a distribution list.

**Note:** This field is set only if the **CMPCOD** parameter on the MQPUT or MQPUT1 call is CCOK or CCWARN; it is not set if the **CMPCOD** parameter is CCFAIL.

This is an output field. The initial value of this field is 0. This field is not set if *PMVER* is less than *PMVER2*.

**PMKDC (10 digit signed integer)**

Number of messages sent successfully to local queues.

This is the number of messages that the current MQPUT or MQPUT1 call has sent successfully to queues in the distribution list that are local queues. The count does not include messages sent to queues that resolve to remote queues (even though a local transmission queue is used initially to store the message). This field is also set when putting a message to a single queue which is not in a distribution list.

This is an output field. The initial value of this field is 0. This field is not set if *PMVER* is less than *PMVER2*.

**PMOPT (10 digit signed integer)**

Options that control the action of MQPUT and MQPUT1.

Any or none of the following can be specified. If more than one is required the values can be added (do not add the same constant more than once). Combinations that are not valid are noted; any other combinations are valid.

**Publishing options:** The following options control the way messages are published to a topic.

**PMSRTO**

Any information filled into the MDRQ and MDRM fields of the MQMD of this publication is not passed on to subscribers. If this option is used with a report option that requires a ReplyToQ, the call fails with RC2027 .

**PMRET**

The publication being sent is to be retained by the queue manager. This allows a subscriber to request a copy of this publication after the time it was published, by using the MQSUBRQ call. It also allows a publication to be sent to applications which make their subscription after the time this publication was made, unless they choose not to be sent it by using the option SONEWP. If an application is sent a publication which was retained, it is indicated by the mq.IsRetained message property of that publication.

Only one publication can be retained at each node of the topic tree. That means if there already is a retained publication for this topic, published by any other application, it is replaced with this publication. It is therefore better to avoid having more than one publisher retaining messages on the same topic.

When retained publications are requested by a subscriber, the subscription used may contain a wildcard in the topic, in which case a number of retained publications might match (at various nodes in the topic tree) and several publications may be sent to the requesting application. See the description of the “MQSUBRQ - Subscription request” on page 795 call for more details.

If this option is used and the publication cannot be retained, the message is not published and the call fails with RC2479 .

**Syncpoint options:** The following options relate to the participation of the MQPUT or MQPUT1 call within a unit of work:

#### **PMSYP**

Put message with syncpoint control.

The request is to operate within the normal unit-of-work protocols. The message is not visible outside the unit of work until the unit of work is committed. If the unit of work is backed out, the message is deleted.

If this option and PMNSYP are not specified, the put request is not within a unit of work.

PMSYP must not be specified with PMNSYP.

#### **PMNSYP**

Put message without syncpoint control.

The request is to operate outside the normal unit-of-work protocols. The message is available immediately, and it cannot be deleted by backing out a unit of work.

If this option and PMSYP are not specified, the put request is not within a unit of work.

PMNSYP must not be specified with PMSYP.

**Message-identifier and correlation-identifier options:** The following options request the queue manager to generate a new message identifier or correlation identifier:

#### **PMNMID**

Generate a new message identifier.

This option causes the queue manager to replace the contents of the *MDMID* field in MQMD with a new message identifier. This message identifier is sent with the message, and returned to the application on output from the MQPUT or MQPUT1 call.

This option can also be specified when the message is being put to a distribution list; see the description of the *PRMID* field in the MQPMR structure for details.

Using this option relieves the application of the need to reset the *MDMID* field to MINONE before each MQPUT or MQPUT1 call.

#### **PMNCID**

Generate a new correlation identifier.

This option causes the queue manager to replace the contents of the *MDCID* field in MQMD with a new correlation identifier. This correlation identifier is sent with the message, and returned to the application on output from the MQPUT or MQPUT1 call.

This option can also be specified when the message is being put to a distribution list; see the description of the *PRCID* field in the MQPMR structure for details.

PMNCID is useful in situations where the application requires a unique correlation identifier.

**Group and segment options:** The following option relates to the processing of messages in groups and segments of logical messages. These definitions might be of help in understanding the option:

#### **Physical message**

This is the smallest unit of information that can be placed on or removed from a queue; it often corresponds to the information specified or retrieved on a single MQPUT, MQPUT1, or MQGET call. Every physical message has its own message descriptor (MQMD). Generally, physical messages

are distinguished by differing values for the message identifier (*MDMID* field in MQMD), although this is not enforced by the queue manager.

### Logical message

This is a single unit of application information. In the absence of system constraints, a logical message would be the same as a physical message. But where logical messages are large, system constraints may make it advisable or necessary to split a logical message into two or more physical messages, called *segments*.

A logical message that has been segmented consists of two or more physical messages that have the same nonnull group identifier (*MDGID* field in MQMD), and the same message sequence number (*MDSEQ* field in MQMD). The segments are distinguished by differing values for the segment offset (*MDOFF* field in MQMD), which gives the offset of the data in the physical message from the start of the data in the logical message. Because each segment is a physical message, the segments in a logical message typically have differing message identifiers.

A logical message that has not been segmented, but for which segmentation has been permitted by the sending application, also has a nonnull group identifier, although in this case there is only one physical message with that group identifier if the logical message does not belong to a message group. Logical messages for which segmentation has been inhibited by the sending application have a null group identifier (GINONE), unless the logical message belongs to a message group.

### Message group

This is a set of one or more logical messages that have the same nonnull group identifier. The logical messages in the group are distinguished by differing values for the message sequence number, which is an integer in the range 1 through n, where n is the number of logical messages in the group. If one or more of the logical messages is segmented, there are more than n physical messages in the group.

### PMLOGO

Messages in groups and segments of logical messages are put in logical order.

This option tells the queue manager how the application puts messages in groups and segments of logical messages. It can be specified only on the MQPUT call; it is not valid on the MQPUT1 call.

If PMLOGO is specified, it indicates that the application uses successive MQPUT calls to:

- Put the segments in each logical message in the order of increasing segment offset, starting from 0, with no gaps.
- Put all of the segments in one logical message before putting the segments in the next logical message.
- Put the logical messages in each message group in the order of increasing message sequence number, starting from 1, with no gaps.
- Put all of the logical messages in one message group before putting logical messages in the next message group.

This order is called "logical order".

Because the application has told the queue manager how it puts messages in groups and segments of logical messages, the application does not have to maintain and update the group and segment information about each MQPUT call, as the queue manager does this. Specifically, it means that the application does not need to set the *MDGID*, *MDSEQ*, and *MDOFF* fields in MQMD, as the queue manager sets these to the appropriate values. The application need set only the *MDMFL* field in MQMD, to indicate when messages belong to groups or are segments of logical messages, and to indicate the last message in a group or last segment of a logical message.

Once a message group or logical message has been started, subsequent MQPUT calls must specify the appropriate MF\* flags in *MDMFL* in MQMD. If the application tries to put a message not in a group when there is an unterminated message group, or put a message which is not a segment when there is an unterminated logical message, the call fails with reason code RC2241 or RC2242, as appropriate. However, the queue manager retains the information about the

current message group or current logical message, and the application can terminate them by sending a message (possibly with no application message data) specifying MFLMIG or MFLSEG as appropriate, before reissuing the MQPUT call to put the message that is not in the group or not a segment.

Table 716 on page 1177 shows the combinations of options and flags that are valid, and the values of the *MDGID*, *MDSEQ*, and *MDOFF* fields that the queue manager uses in each case. Combinations of options and flags that are not shown in the table are not valid. The columns in the table have the following meanings:

**LOG ORD**

Indicates whether the PMLOGO option is specified on the call.

**MIG**

Indicates whether the MFMIG or MFLMIG option is specified on the call.

**SEG**

Indicates whether the MFSEG or MFLSEG option is specified on the call.

**SEG OK**

Indicates whether the MFSEGA option is specified on the call.

**Cur grp**

Indicates whether a current message group exists before the call.

**Cur log msg**

Indicates whether a current logical message exists before the call.

**Other columns**

Show the values that the queue manager uses. "Previous" denotes the value used for the field in the previous message for the queue handle.

**PMRLOC**

Specifies that the PMRQN in the MQPMO structure must be completed with the name of the local queue which the message actually gets put to. The ResolvedQMGrName is similarly completed with the name of the local queue manager hosting the local queue. See OORLOQ for what this means. If a user is authorized for a put to a queue then they have the required authority to specify this flag on the MQPUT call. No special authority is needed.

Options you specify				Group and log-msg status before call		Values the queue manager uses		
LOG ORD	MIG	SEG	SEG OK	Cur grp	Cur log msg	MDGID	MDSEQ	MDOFF
Yes	No	No	No	No	No	GINONE	1	0
Yes	No	No	Yes	No	No	New group id	1	0
Yes	No	Yes	Yes or No	No	No	New group id	1	0
Yes	No	Yes	Yes or No	No	Yes	Previous group id	1	Previous offset + previous segment length
Yes	Yes	Yes or No	Yes or No	No	No	New group id	1	0
Yes	Yes	Yes or No	Yes or No	Yes	No	Previous group id	Previous sequence number + 1	0

Table 716. MQPUT options relating to messages in groups and segments of logical messages (continued)

Options you specify				Group and log-msg status before call		Values the queue manager uses		
Yes	Yes	Yes	Yes or No	Yes	Yes	Previous group id	Previous sequence number	Previous offset + previous segment length
No	No	No	No	Yes or No	Yes or No	GINONE	1	0
No	No	No	Yes	Yes or No	Yes or No	New group ID if GINONE, else value in field	1	0
No	No	Yes	Yes or No	Yes or No	Yes or No	New group ID if GINONE, else value in field	1	Value in field
No	Yes	No	Yes or No	Yes or No	Yes or No	New group ID if GINONE, else value in field	Value in field	0
No	Yes	Yes	Yes or No	Yes or No	Yes or No	New group ID if GINONE, else value in field	Value in field	Value in field

**Note:**

- PMLOGO is not valid on the MQPUT1 call.
- For the *MDMID* field, the queue manager generates a new message identifier if PMNMID or MINONE is specified, and uses the value in the field otherwise.
- For the *MDCID* field, the queue manager generates a new correlation identifier if PMNCID is specified, and uses the value in the field otherwise.

When PMLOGO is specified, the queue manager requires that all messages in a group and segments in a logical message be put with the same value in the *MDPER* field in MQMD, that is, all must be persistent, or all must be nonpersistent. If this condition is not satisfied, the MQPUT call fails with reason code RC2185 .

The PMLOGO option affects units of work as follows:

- If the first physical message in a group or logical message is put within a unit of work, all of the other physical messages in the group or logical message must be put within a unit of work, if the same queue handle is used. However, they need not be put within the same unit of work. This allows a message group or logical message consisting of many physical messages to be split across two or more consecutive units of work for the queue handle.
- If the first physical message in a group or logical message is not put within a unit of work, none of the other physical messages in the group or logical message can be put within a unit of work, if the same queue handle is used.

If these conditions are not satisfied, the MQPUT call fails with reason code RC2245 .

When PMLOGO is specified, the MQMD supplied on the MQPUT call must not be less than MDVER2. If this condition is not satisfied, the call fails with reason code RC2257 .

If PMLOGO is not specified, messages in groups and segments of logical messages can be put in any order, and it is not necessary to put complete message groups or complete logical messages.

It is the responsibility of the application to ensure that the *MDGID*, *MDSEQ*, *MDOFF*, and *MDMFL* fields have appropriate values.

This is the technique that can be used to restart a message group or logical message in the middle, after a system failure has occurred. When the system restarts, the application can set the *MDGID*, *MDSEQ*, *MDOFF*, *MDMFL*, and *MDPER* fields to the appropriate values, and then issue the MQPUT call with PMSYP or PMNSYP set as *necessary*, but without specifying PMLOGO. If this call is successful, the queue manager retains the group and segment information, and subsequent MQPUT calls using that queue handle can specify PMLOGO as normal.

The group and segment information that the queue manager retains for the MQPUT call is separate from the group and segment information that it retains for the MQGET call.

For any given queue handle, the application is free to mix MQPUT calls that specify PMLOGO with MQPUT calls that do not, but the following points should be noted:

- If PMLOGO is not specified, each successful MQPUT call causes the queue manager to set the group and segment information for the queue handle to the values specified by the application; this replaces the existing group and segment information retained by the queue manager for the queue handle.
- If PMLOGO is not specified, the call does not fail if there is a current message group or logical message; the call might however succeed with a CCWARN completion code. [Table 717 on page 1179](#) shows the various cases that can arise. In these cases, if the completion code is not CCOK, the reason code is one of the following (as appropriate):
  - RC2241
  - RC2242
  - RC2185
  - RC2245

**Note:** The queue manager does not check the group and segment information for the MQPUT1 call.

<i>Table 717. Outcome when MQPUT or MQCLOSE call is not consistent with group and segment information</i>		
<b>Current call is</b>	<b>Previous call was MQPUT with PMLOGO</b>	<b>Previous call was MQPUT without PMLOGO</b>
MQPUT with PMLOGO	CCFAIL	CCFAIL
MQPUT without PMLOGO	CCWARN	CCOK
MQCLOSE with an unterminated group or logical message	CCWARN	CCOK

Applications that simply want to put messages and segments in logical order are recommended to specify PMLOGO, as this is the simplest option to use. This option relieves the application of the need to manage the group and segment information, because the queue manager manages that information. However, specialized applications may need more control than provided by the PMLOGO option, and this can be achieved by not specifying that option. If this is done, the application must ensure that the *MDGID*, *MDSEQ*, *MDOFF*, and *MDMFL* fields in MQMD are set correctly, before each MQPUT or MQPUT1 call.

For example, an application that wants to forward physical messages that it receives, without regard for whether those messages are in groups or segments of logical messages, must not specify PMLOGO. There are two reasons for this:

- If the messages are retrieved and put in order, specifying PMLOGO causes a new group identifier to be assigned to the messages, and this might make it difficult or impossible for the originator of the messages to correlate any reply or report messages that result from the message group.

- In a complex network with multiple paths between sending and receiving queue managers, the physical messages might arrive out of order. By not specifying PMLOGO and the corresponding GMLOGO on the MQGET call, the forwarding application can retrieve and forward each physical message as soon as it arrives, without needing to wait for the next one in logical order to arrive.

Applications that generate report messages for messages in groups or segments of logical messages must also not specify PMLOGO when putting the report message.

PMLOGO can be specified with any of the other PM\* options.

**Context options:** The following options control the processing of message context:

**PMNOC**

No context is to be associated with the message.

Both identity and origin context are set to indicate no context. This means that the context fields in MQMD are set to:

- Blanks for character fields
- Nulls for byte fields
- Zeros for numeric fields

**PMDEFC**

Use default context.

The message is to have default context information associated with it, for both identity and origin. The queue manager sets the context fields in the message descriptor as follows:

*Table 718. Default context information values for MQMD fields*

<b>Field in MQMD</b>	<b>Value used</b>
<i>MDUID</i>	Determined from the environment if possible; set to blanks otherwise.
<i>MDACC</i>	Determined from the environment if possible; set to ACNONE otherwise.
<i>MDAID</i>	Set to blanks.
<i>MDPAT</i>	Determined from the environment.
<i>MDPAN</i>	Determined from the environment if possible; set to blanks otherwise.
<i>MDPD</i>	Set to date when message is put.
<i>MDPT</i>	Set to time when message is put.
<i>MDAOD</i>	Set to blanks.

For more information about message context, see [Message context](#) and [Controlling context information](#).

This is the default action if no context options are specified.

**PMPASI**

Pass identity context from an input queue handle.

The message is to have context information associated with it. Identity context is taken from the queue handle specified in the *PMCT* field. Origin context information is generated by the queue manager in the same way that it is for PMDEFC (see the previous table for values). For more information about message context, see [Message context](#) and [Controlling context information](#).

For the MQPUT call, the queue must have been opened with the OOPASI option (or an option that implies it). For the MQPUT1 call, the same authorization check is carried out as for the MQOPEN call with the OOPASI option.

**PMPASA**

Pass all context from an input queue handle.

The message is to have context information associated with it. Both identity and origin context are taken from the queue handle specified in the *PMCT* field. For more information about message context, see [Message context](#) and [Controlling context information](#).

For the MQPUT call, the queue must have been opened with the OOPASA option (or an option that implies it). For the MQPUT1 call, the same authorization check is carried out as for the MQOPEN call with the OOPASA option.

#### **PMSETI**

Set identity context from the application.

The message is to have context information associated with it. The application specifies the identity context in the MQMD structure. Origin context information is generated by the queue manager in the same way that it is for PMDEFC (see the previous table for values). For more information about message context, see [Message context](#) and [Controlling context information](#).

For the MQPUT call, the queue must have been opened with the OOSETI option (or an option that implies it). For the MQPUT1 call, the same authorization check is carried out as for the MQOPEN call with the OOSETI option.

#### **PMSETA**

Set all context from the application.

The message is to have context information associated with it. The application specifies the identity and origin context in the MQMD structure. For more information about message context, see [Message context](#) and [Controlling context information](#).

For the MQPUT call, the queue must have been opened with the OOSETA option. For the MQPUT1 call, the same authorization check is carried out as for the MQOPEN call with the OOSETA option.

Only one of the PM\* context options can be specified. If none of these options is specified, PMDEFC is assumed.

**Put response types.** The following options control the response returned to an MQPUT or MQPUT1 call. You can only specify one of these options. If PMARES and PMSRES are not specified, PMRASQ or PMRAST is assumed.

#### **PMARES**

The PMARES option requests that an MQPUT or MQPUT1 operation is completed without the application waiting for the queue manager to complete the call. Using this option can improve messaging performance, particularly for applications using client bindings. An application can periodically check, using the MQSTAT verb, whether an error has occurred during any previous asynchronous calls.

With this option, only the following fields are guaranteed to be completed in the MQMD;

- MDAID
- MDPAT
- MDPAN
- MDAOD

Additionally, if either or both of PMNMID or PMNCID are specified as options, the MDMID and MDCID returned are also completed. (PMNMID can be implicitly specified by specifying a blank MDMID field).

Only the fields previously specified are completed. Other information that would normally be returned in the MQMD or MQPMO structure is undefined.

When requesting asynchronous put response for MQPUT or MQPUT1, a CMPCOD and REASON of CCOK and RCNONE does not necessarily mean that the message was successfully put to a queue. When developing an MQI application that uses asynchronous put response and require confirmation that messages have been put to a queue you should check both CMPCOD and REASON codes from the put operations and also use MQSTAT to query asynchronous error information.

Although the success or failure of each individual MQPUT/MQPUT1 call might not be returned immediately, the first error that occurred under an asynchronous call can be determined at a later juncture through a call to MQSTAT.

If a persistent message under syncpoint fails to be delivered using asynchronous put response, and you attempt to commit the transaction, the commit fails and the transaction is backed out with a completion code of CCFAIL and a reason of RC2003 . The application can make a call to MQSTAT to determine the cause of a previous MQPUT or MQPUT1 failure

#### **PMSRES**

Specifying this value for a put option in the MQPMO structure ensures that the MQPUT or MQPUT1 operation is always issued synchronously. If the operation is successful, all fields in the MQMD and MQPMO are completed. It is provided to ensure a synchronous response irrespective of the default put response value defined on the queue or topic object.

#### **PMRASQ**

If this value is specified for an MQPUT call, the put response type used is taken from the DEFPRESP value specified on the queue when it was opened by the application. If a client application is connected to a queue manager at a level earlier than IBM WebSphere MQ 7.0, it behaves as if PMSRES was specified.

If this option is specified for an MQPUT1 call, the DEFPRESP value from the queue definition is not used. If the MQPUT1 call is using PMSYP it behaves as for PMARES, and if it is using PMNSYP it behaves as for PMSRES.

#### **PMRAST**

This is a synonym for PMRASQ for use with topic objects.

**Other options:** The following options control authorization checking, and what happens when the queue manager is quiescing:

#### **PMALTU**

Validate with specified user identifier.

This indicates that the *ODAU* field in the **OBJDSC** parameter of the MQPUT1 call contains a user identifier that is to be used to validate authority to put messages on the queue. The call can succeed only if this *ODAU* is authorized to open the queue with the specified options, regardless of whether the user identifier under which the application is running is authorized to do so. (This does not apply to the context options specified, however, which are always checked against the user identifier under which the application is running.)

This option is valid only with the MQPUT1 call.

#### **PMFIQ**

Fail if queue manager is quiescing.

This option forces the MQPUT or MQPUT1 call to fail if the queue manager is in the quiescing state.

The call returns completion code CCFAIL with reason code RC2161 .

**Default option:** If none of the options described previously are required, the following option can be used:

#### **PMNONE**

No options specified.

This value can be used to indicate that no other options have been specified; all options assume their default values. PMNONE is defined to aid program documentation; it is not intended that this option is used with any other, but as its value is zero, such use cannot be detected.

This is an input field. The initial value of the *PMOPT* field is PMNONE.

#### **MPRF (10 digit signed integer)**

Flags indicating which MQPMR fields are present.

This field contains flags that must be set to indicate which MQPMR fields are present in the put message records provided by the application. *PMPRF* is used only when the message is being put to a distribution list. The field is ignored if *PMREC* is zero, or both *PMPRO* and *PMPRP* are zero.

For fields that are present, the queue manager uses for each destination the values from the fields in the corresponding put message record. For fields that are absent, the queue manager uses the values from the MQMD structure.

One or more of the following flags can be specified to indicate which fields are present in the put message records:

**PFMID**

Message-identifier field is present.

**PFCID**

Correlation-identifier field is present.

**PFGID**

Group-identifier field is present.

**PFFB**

Feedback field is present.

**PFACC**

Accounting-token field is present.

If this flag is specified, either *PMSETI* or *PMSETA* must be specified in the *PMOPT* field; if this condition is not satisfied, the call fails with reason code RC2158 .

If no MQPMR fields are present, the following can be specified:

**PFNONE**

No put-message record fields are present.

If this value is specified, either *PMREC* must be zero, or both *PMPRO* and *PMPRP* must be zero.

PFNONE is defined to aid program documentation. It is not intended that this constant is used with any other, but as its value is zero, such use cannot be detected.

If *PMPRF* contains flags which are not valid, or put message records are provided but *PMPRF* has the value PFNONE, the call fails with reason code RC2158 .

This is an input field. The initial value of this field is PFNONE. This field is ignored if *PMVER* is less than *PMVER2*.

**PMPRO (10 digit signed integer)**

Offset of first put message record from start of MQPMO.

This is the offset in bytes of the first MQPMR put message record from the start of the MQPMO structure. The offset can be positive or negative. *PMPRO* is used only when the message is being put to a distribution list. The field is ignored if *PMREC* is zero.

When the message is being put to a distribution list, an array of one or more MQPMR put message records can be provided in order to specify certain properties of the message for each destination individually; these properties are:

- message identifier
- correlation identifier
- group identifier
- feedback value
- accounting token

It is not necessary to specify all of these properties, but whatever subset is chosen, the fields must be specified in the correct order. See the description of the MQPMR structure for further details.

Usually, there should be as many put message records as there are object records specified by MQOD when the distribution list is opened; each put message record supplies the message properties for

the queue identified by the corresponding object record. Queues in the distribution list which fail to open must still have put message records allocated for them at the appropriate positions in the array, although the message properties are ignored in this case.

It is possible for the number of put message records to differ from the number of object records. If there are fewer put message records than object records, the message properties for the destinations which do not have put message records are taken from the corresponding fields in the message descriptor MQMD. If there are more put message records than object records, the excess are not used (although it must still be possible to access them). Put message records are optional, but if they are supplied there must be *PMREC* of them.

The put message records can be provided in a similar way to the object records in MQOD, either by specifying an offset in *PMPRO*, or by specifying an address in *PMPRP* ; for details of how to do this, see the *ODORO* field described in [“MQOD \(Object descriptor\) on IBM i” on page 1159](#).

No more than one of *PMPRO* and *PMPRP* can be used; the call fails with reason code RC2159 if both are nonzero.

This is an input field. The initial value of this field is 0. This field is ignored if *PMVER* is less than *PMVER2*.

### **PMPRP (pointer)**

Address of first put message record.

This is the address of the first MQPMR put message record. *PMPRP* is used only when the message is being put to a distribution list. The field is ignored if *PMREC* is zero.

Either *PMPRP* or *PMPRO* can be used to specify the put message records, but not both; see the description of the [PMRRO](#) field for details. If *PMPRP* is not used, it must be set to the null pointer or null bytes.

This is an input field. The initial value of this field is the null pointer. This field is ignored if *PMVER* is less than *PMVER2*.

### **PMREC (10 digit signed integer)**

Number of put message records or response records present.

This is the number of MQPMR put message records or MQRR response records that have been provided by the application. This number can be greater than zero only if the message is being put to a distribution list. Put message records and response records are optional - the application need not provide any records, or it can choose to provide records of only one type. However, if the application provides records of both types, it must provide *PMREC* records of each type.

The value of *PMREC* need not be the same as the number of destinations in the distribution list. If too many records are provided, the excess are not used; if too few records are provided, default values are used for the message properties for those destinations that do not have put message records (see *PMPRO* later in this topic).

If *PMREC* is less than zero, or is greater than zero but the message is not being put to a distribution list, the call fails with reason code RC2154 .

This is an input field. The initial value of this field is 0. This field is ignored if *PMVER* is less than *PMVER2*.

### **PMRMN (48 byte character string)**

Resolved name of destination queue manager.

This is the name of the destination queue manager after name resolution has been performed by the local queue manager. The name returned is the name of the queue manager that owns the queue identified by *PMRQN*, and can be the name of the local queue manager.

If *PMRQN* is a shared queue that is owned by the queue sharing group to which the local queue manager belongs, *PMRMN* is the name of the queue sharing group. If the queue is owned by some other queue sharing group, *PMRQN* can be the name of the queue sharing group or the name of a

queue manager that is a member of the queue sharing group (the nature of the value returned is determined by the queue definitions that exist at the local queue manager).

A nonblank value is returned only if the object is a single queue; if the object is a distribution list or topic, the value returned is undefined.

This is an output field. The length of this field is given by LNQM. The initial value of this field is 48 blank characters.

### **PMRQN (48 byte character string)**

Resolved name of destination queue.

This is the name of the destination queue after name resolution has been performed by the local queue manager. The name returned is the name of a queue that exists on the queue manager identified by *PMRMN*.

A nonblank value is returned only if the object is a single queue; if the object is a distribution list or topic, the value returned is undefined.

This is an output field. The length of this field is given by LNQN. The initial value of this field is 48 blank characters.

### **PMRRO (10 digit signed integer)**

Offset of first response record from start of MQPMO.

This is the offset in bytes of the first MQRR response record from the start of the MQPMO structure. The offset can be positive or negative. *PMRRO* is used only when the message is being put to a distribution list. The field is ignored if *PMREC* is zero.

When the message is being put to a distribution list, an array of one or more MQRR response records can be provided in order to identify the queues to which the message was not sent successfully (*RRCC* field in MQRR), and the reason for each failure (*RRREA* field in MQRR). The message might not have been sent either because the queue failed to open, or because the put operation failed. The queue manager sets the response records only when the outcome of the call is mixed (that is, some messages were sent successfully while others failed, or all failed but for differing reasons); reason code RC2136 from the call indicates this case. If the same reason code applies to all queues, that reason is returned in the **REASON** parameter of the MQPUT or MQPUT1 call, and the response records are not set.

Usually, there should be as many response records as there are object records specified by MQOD when the distribution list is opened; when necessary, each response record is set to the completion code and reason code for the put to the queue identified by the corresponding object record. Queues in the distribution list which fail to open must still have response records allocated for them at the appropriate positions in the array, although they are set to the completion code and reason code resulting from the open operation, rather than the put operation.

It is possible for the number of response records to differ from the number of object records. If there are fewer response records than object records, it may not be possible for the application to identify all of the destinations for which the put operation failed, or the reasons for the failures. If there are more response records than object records, the excess are not used (although it must still be possible to access them). Response records are optional, but if they are supplied there must be *PMREC* of them.

The response records can be provided in a similar way to the object records in MQOD, either by specifying an offset in *PMRRO*, or by specifying an address in *PMRRP*; for details of how to do this, see the *ODORO* field described in "[MQOD \(Object descriptor\) on IBM i](#)" on page 1159. However, no more than one of *PMRRO* and *PMRRP* can be used; the call fails with reason code RC2156 if both are nonzero.

For the MQPUT1 call, this field must be zero. This is because the response information (if requested) is returned in the response records specified by the object descriptor MQOD.

This is an input field. The initial value of this field is 0. This field is ignored if *PMVER* is less than *PMVER2*.

**PMRRP (pointer)**

Address of first response record.

This is the address of the first MQRR response record. *PMRRP* is used only when the message is being put to a distribution list. The field is ignored if *PMREC* is zero.

Either *PMRRP* or *PMRRO* can be used to specify the response records, but not both; see the description of the *PMRRO* field for details. If *PMRRP* is not used, it must be set to the null pointer or null bytes.

For the MQPUT1 call, this field must be the null pointer or null bytes. This is because the response information (if requested) is returned in the response records specified by the object descriptor MQOD.

This is an input field. The initial value of this field is the null pointer. This field is ignored if *PMVER* is less than *PMVER2*.

**PMSID (4 byte character string)**

Structure identifier.

The value must be:

**PMSIDV**

Identifier for put-message options structure.

This is always an input field. The initial value of this field is *PMSIDV*.

**PMSL (MQLONG)**

The level of subscription targeted by this publication.

Only those subscriptions with the highest *PMSL* less than or equal to this value receives this publication. This value must be in the range zero to 9; zero is the lowest level.

The initial value of this field is 9.

**PMTO (10 digit signed integer)**

Reserved.

This is a reserved field; its value is not significant. The initial value of this field is -1.

**PMUDC (10 digit signed integer)**

Number of messages sent successfully to remote queues.

This is the number of messages that the current MQPUT or MQPUT1 call has sent successfully to queues in the distribution list that resolve to remote queues. Messages that the queue manager retains temporarily in distribution-list form count as the number of individual destinations that those distribution lists contain. This field is also set when putting a message to a single queue which is not in a distribution list.

This is an output field. The initial value of this field is 0. This field is not set if *PMVER* is less than *PMVER2*.

**PMVER (10 digit signed integer)**

Structure version number.

The value must be one of the following:

**PMVER1**

Version-1 put-message options structure.

**PMVER2**

Version-2 put-message options structure.

Fields that exist only in the more-recent version of the structure are identified as such in the descriptions of the fields. The following constant specifies the version number of the current version:

## PMVERC

Current version of put-message options structure.

This is always an input field. The initial value of this field is PMVER1.

## Initial values

Field name	Name of constant	Value of constant
PMSID	PMSIDV	'PMO~'
PMVER	PMVER1	1
PMOPT	PMNONE	0
PMTO	None	-1
PMCT	None	0
PMKDC	None	0
PMUDC	None	0
PMIDC	None	0
PMRQN	None	Blanks
PMRMN	None	Blanks
PMREC	None	0
PMPRF	PFNONE	0
PMPRO	None	0
PMRRO	None	0
PMPRP	None	Null pointer or null bytes
PMRRP	None	Null pointer or null bytes

**Note:**

1. The symbol ~ represents a single blank character.

## IBM i MQPMR (Put-message record) on IBM i

The MQPMR structure is used to specify various message properties for a single destination when a message is being put to a distribution list.

### Overview

**Purpose:** MQPMR is an input/output structure for the MQPUT and MQPUT1 calls.

**Character set and encoding:** Data in MQPMR must be in the character set given by the **CodedCharSetId** queue manager attribute and encoding of the local queue manager given by ENNAT. However, if the application is running as an IBM MQ client, the structure must be in the character set and encoding of the client.

**Usage:** By providing an array of these structures on the MQPUT or MQPUT1 call, it is possible to specify different values for each destination queue in a distribution list. Some of the fields are input only, others are input/output.

**Note:** This structure is unusual in that it does not have a fixed layout. The fields in this structure are optional, and the presence or absence of each field is indicated by the flags in the *PMPRF* field in MQPMO. Fields that are present **must occur in the following order** :

- *PRMID*
- *PRCID*
- *PRGID*
- *PRFB*
- *PRACC*

Fields that are absent occupy no space in the record.

Because MQPMR does not have a fixed layout, no definition of it is provided in the COPY file. The application programmer should create a declaration containing the fields that are required by the application, and set the flags in *PMPRF* to indicate the fields that are present.

- [“Fields” on page 1188](#)
- [“Initial values” on page 1190](#)
- [“RPG declaration” on page 1190](#)

### Fields

The MQPMR structure contains the following fields; the fields are described in **alphabetical order**:

**PRACC (32-byte bit string)**

Accounting token.

This is the accounting token to be used for the message sent to the queue with a name that was specified by the corresponding element in the array of MQOR structures provided on the MQOPEN or MQPUT1 call. It is processed in the same way as the *MDACC* field in MQMD for a put to a single queue. See the description of *MDACC* in [“MQMD \(Message descriptor\) on IBM i” on page 1110](#) for information about the content of this field.

If this field is not present, the value in MQMD is used.

This is an input field.

**PRCID (24-byte bit string)**

Correlation identifier.

This is the correlation identifier to be used for the message sent to the queue with the name that was specified by the corresponding element in the array of MQOR structures provided on the MQOPEN or MQPUT1 call. It is processed in the same way as the *MDCID* field in MQMD for a put to a single queue.

If this field is not present in the MQPMR record, or there are fewer MQPMR records than destinations, the value in MQMD is used for those destinations that do not have an MQPMR record containing a *PRCID* field.

If PMNCID is specified, a *single* new correlation identifier is generated and used for all of the destinations in the distribution list, regardless of whether they have MQPMR records. This is different from the way that PMNMID is processed (see *PRMID* field).

This is an input/output field.

**PRFB (10-digit signed integer)**

Feedback or reason code.

This is the feedback code to be used for the message sent to the queue with the name that was specified by the corresponding element in the array of MQOR structures provided on the MQOPEN or MQPUT1 call. It is processed in the same way as the *MDFB* field in MQMD for a put to a single queue.

If this field is not present, the value in MQMD is used.

This is an input field.

**PRGID (24-byte bit string)**

Group identifier.

This is the group identifier to be used for the message sent to the queue with the name that was specified by the corresponding element in the array of MQOR structures provided on the MQOPEN or MQPUT1 call. It is processed in the same way as the *MDGID* field in MQMD for a put to a single queue.

If this field is not present in the MQPMR record, or there are fewer MQPMR records than destinations, the value in MQMD is used for those destinations that do not have an MQPMR record containing a *PRGID* field. The value is processed as documented in [Table 716 on page 1177](#), but with the following differences:

- In those cases where a new group identifier would be used, the queue manager generates a different group identifier for each destination (that is, no two destinations have the same group identifier).
- In those cases where the value in the field would be used, the call fails with reason code RC2258.

This is an input/output field.

**PRMID (24-byte bit string)**

Message identifier.

This is the message identifier to be used for the message sent to the queue with the name that was specified by the corresponding element in the array of MQOR structures provided on the MQOPEN or MQPUT1 call. It is processed in the same way as the *MDMID* field in MQMD for a put to a single queue.

If this field is not present in the MQPMR record, or there are fewer MQPMR records than destinations, the value in MQMD is used for those destinations that do not have an MQPMR record containing a *PRMID* field. If that value is MINONE, a new message identifier is generated for *each* of those destinations (that is, no two of those destinations have the same message identifier).

If PMNMID is specified, new message identifiers are generated for all of the destinations in the distribution list, regardless of whether they have MQPMR records. This is different from the way that PMNCID is processed (see *PRCID* field).

This is an input/output field.

## Initial values

There are no initial values defined for this structure, as no structure declaration is provided. The following sample declaration shows how the structure should be declared by the application programmer if all of the fields are required.

## RPG declaration

```
D*..1....:....2....:....3....:....4....:....5....:....6....:....7..  
D* MQPMR Structure

```

## IBM i MQRFH (Rules and formatting header) on IBM i

The MQRFH structure defines the layout of the rules and formatting header.

### Overview

**Purpose:** This header can be used to send string data in the form of name-value pairs.

**Format name:** FMRFH.

**Character set and encoding:** The fields in the MQRFH structure (including *RFNVS*) are in the character set and encoding given by the *MDCSI* and *MDENC* fields in the header structure that precedes the MQRFH, or by those fields in the MQMD structure if the MQRFH is at the start of the application message data.

The character set must be one that has single-byte characters for the characters that are valid in queue names.

- [“Fields” on page 1190](#)
- [“Initial values” on page 1193](#)
- [“RPG declaration” on page 1193](#)

### Fields

The MQRFH structure contains the following fields; the fields are described in **alphabetical order**:

### **RFCSI (10-digit signed integer)**

Character set identifier of data that follows *RFNVS*.

This specifies the character set identifier of the data that follows *RFNVS* ; it does not apply to character data in the MQRFH structure itself.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The following special value can be used:

#### **CSINHT**

Inherit character-set identifier of this structure.

Character data in the data *following* this structure is in the same character set as this structure.

The queue manager changes this value in the structure sent in the message to the actual character-set identifier of the structure. Provided no error occurs, the value CSINHT is not returned by the MQGET call.

CSINHT cannot be used if the value of the *MDPAT* field in MQMD is ATBRKR.

The initial value of this field is CSUNDF.

Numeric encoding of data that follows *RFNVS*.

This specifies the numeric encoding of the data that follows *RFNVS* ; it does not apply to numeric data in the MQRFH structure itself.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data.

The initial value of this field is ENNAT.

### **RFFLG (10-digit signed integer)**

Flags.

The following can be specified:

#### **RFNONE**

No flags.

The initial value of this field is RFNONE.

### **RFFMT (8-byte character string)**

Format name of data that follows *RFNVS*.

This specifies the format name of the data that follows *RFNVS*.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The rules for coding this field are the same as those for the *MDFMT* field in MQMD.

The initial value of this field is FMNONE.

### **RFLEN (10-digit signed integer)**

Total length of MQRFH including *RFNVS*.

This is the length in bytes of the MQRFH structure, including the *RFNVS* field at the end of the structure. The length does not include any user data that follows the *RFNVS* field.

To avoid problems with data conversion of the user data in some environments, consider using *RFLEN* as a multiple of four.

The following constant gives the length of the *fixed* part of the structure, that is, the length excluding the *RFNVS* field:

#### **RFLENV**

Length of fixed part of MQRFH structure.

The initial value of this field is RFLENV.

### **RFNVS (n-byte character string)**

String containing name-value pairs.

This is a variable-length character string containing name-value pairs in the form:

```
name1 value1 name2 value2 name3 value3 ...
```

Each name or value must be separated from the adjacent name or value by one or more blank characters; these blanks are not significant. A name or value can contain significant blanks by prefixing and suffixing the name or value with the quotation mark character; all characters between the opening quotation mark and the matching closing quotation mark are treated as significant. In the following example, the name is FAMOUS\_WORDS, and the value is Hello World:

```
FAMOUS_WORDS "Hello World"
```

A name or value can contain any characters other than the null character (which acts as a delimiter for *RFNVS*). However, to assist interoperability an application might prefer to restrict names to the following characters:

- First character: uppercase or lowercase alphabetic (A through Z, or a through z), or underscore.
- Subsequent characters: upper or lowercase alphabetic, decimal digit (0 through 9), underscore, hyphen, or dot.

If a name or value contains one or more quotation marks, the name or value must be enclosed in quotation marks, and each quotation mark within the string must be doubled:

```
Famous_Words "The program displayed ""Hello World"""
```

Names and values are case sensitive, that is, lowercase letters are not considered to be the same as uppercase letters. For example, FAMOUS\_WORDS and Famous\_Words are two different names.

The length in bytes of *RFNVS* is equal to *RFLEN* minus *RFLENV*. To avoid problems with data conversion of the user data in some environments, it is recommended that this length should be a multiple of four. *RFNVS* must be padded with blanks to this length, or terminated earlier by placing a null character following the last significant character in the string. The null character and the bytes following it, up to the specified length of *RFNVS*, are ignored.

**Note:** Because the length of this field is not fixed, the field is omitted from the declarations of the structure that are provided for the supported programming languages.

### **RFSID (4-byte character string)**

Structure identifier.

The value must be:

#### **RFSIDV**

Identifier for rules and formatting header structure.

The initial value of this field is RFSIDV.

### **RFVER (10-digit signed integer)**

Structure version number.

The value must be:

#### **RFVER1**

Version-1 rules and formatting header structure.

The initial value of this field is RFVER1.

## Initial values

Table 720. Fields in MQRFH		
Field name	Name of constant	Value of constant
RFSID	RFSIDV	'RFH↵'
RFVER	RFVER1	1
RFLEN	RFLENV	32
RFENC	ENNAT	Depends on environment
RFCSI	CSUNDF	0
RFFMT	FMNONE	Blanks
RFFLG	RFNONE	0

**Notes:**

- The symbol ↵ represents a single blank character.

## IBM i MQRFH2 (Rules and formatting header 2) on IBM i

The MQRFH2 structure defines the format of the version-2 rules and formatting header.

### Overview

**Purpose:** This header can be used to send data that has been encoded using an XML-like syntax. A message can contain two or more MQRFH2 structures in series, with user data optionally following the last MQRFH2 structure in the series.

**Format name:** FMRFH2.

**Character set and encoding:** Special rules apply to the character set and encoding used for the MQRFH2 structure:

- Fields other than *RF2NVD* are in the character set and encoding that are given by the *MDCSI* and *MDENC* fields in the header structure that precedes MQRFH2, or by those fields in the MQMD structure if the MQRFH2 is at the start of the application message data.

The character set must be one that has single-byte characters for the characters that are valid in queue names.

When GMCONV is specified on the MQGET call, the queue manager converts these fields to the requested character set and encoding.

- *RF2NVD* is in the character set given by the *RF2NVC* field. Only certain Unicode character sets are valid for *RF2NVC* (see the description of *RF2NVC* for details).

Some character sets have a representation that is dependent on the encoding. If *RF2NVC* is one of these character sets, *RF2NVD* must be in the same encoding as the other fields in the MQRFH2.

When GMCONV is specified on the MQGET call, the queue manager converts *RF2NVD* to the requested encoding, but does not change its character set.

- [“Fields” on page 1194](#)
- [“Initial values” on page 1199](#)
- [“RPG declaration” on page 1199](#)

## Fields

The MQRFH2 structure contains the following fields; the fields are described in alphabetical order:

### **RF2CSI (10-digit signed integer)**

Character set identifier of data that follows last *RF2NVD* field.

This specifies the character set identifier of the data that follows the last *RF2NVD* field. It does not apply to character data in the MQRFH2 structure itself

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The following special value can be used:

#### **CSINHT**

Inherit character-set identifier of this structure.

Character data in the data *following* this structure is in the same character set as this structure.

The queue manager changes this value in the structure sent in the message to the actual character-set identifier of the structure. Provided no error occurs, the value CSINHT is not returned by the MQGET call.

CSINHT cannot be used if the value of the *MDPAT* field in MQMD is ATBRKR.

The initial value of this field is CSINHT.

### **RF2ENC (10-digit signed integer)**

Numeric encoding of data that follows last *RF2NVD* field.

This specifies the numeric encoding of the data that follows the last *RF2NVD* field; it does not apply to numeric data in the MQRFH2 structure itself.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data.

The initial value of this field is ENNAT.

### **RF2FLG (10-digit signed integer)**

Flags.

The following value must be specified:

#### **RFNONE**

No flags.

The initial value of this field is RFNONE.

### **RF2FMT (8-byte character string)**

Format name of data that follows last *RF2NVD* field.

This specifies the format name of the data that follows the last *RF2NVD* field.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The rules for coding this field are the same as those for the *MDFMT* field in MQMD.

The initial value of this field is FMNONE.

### **RF2LEN (10-digit signed integer)**

Total length of MQRFH2 including all *RF2NVL* and *RF2NVD* fields.

This is the length in bytes of the MQRFH2 structure, including the *RF2NVL* and *RF2NVD* fields at the end of the structure. It is valid for there to be multiple pairs of *RF2NVL* and *RF2NVD* fields at the end of the structure, in the sequence:

```
length1, data1, length2, data2, ...
```

*RF2LEN* does not include any user data that may follow the last *RF2NVD* field at the end of the structure.

To avoid problems with data conversion of the user data in some environments, consider using *RF2LEN* as a multiple of four.

The following constant gives the length of the *fixed* part of the structure, that is, the length excluding the *RF2NVL* and *RF2NVD* fields:

### **RFLEN2**

Length of fixed part of MQRFH2 structure.

The initial value of this field is RFLEN2.

### **RF2NVC (10-digit signed integer)**

Character set identifier of *RF2NVD*.

This specifies the coded character set identifier of the data in the *RF2NVD* field. This is different from the character set of the other strings in the MQRFH2 structure, and can be different from the character set of the data (if any) that follows the last *RF2NVD* field at the end of the structure.

*RF2NVC* must have one of the following CCSID values:

#### **1200**

UTF-16, most recent Unicode version supported

#### **13488**

UTF-16, Unicode version 2.0 subset

#### **17584**

UTF-16, Unicode version 3.0 subset (includes the Euro symbol)

#### **1208**

UTF-8, most recent Unicode version supported

For the UTF-16 character sets, the encoding (byte order) of the *RF2NVD* must be the same as the encoding of the other fields in the MQRFH2 structure. Surrogate characters (X'D800' through X'DFFF') are not supported.

**Note:** If *RF2NVC* does not have one of the values listed previously, and the MQRFH2 structure requires conversion on the MQGET call, the call completes with reason code RC2111 and the message is returned unconverted.

The initial value of this field is 1208.

### **RF2NVD (n-byte character string)**

Name/value data.

This is a variable-length character string containing data encoded using an XML-like syntax. The length in bytes of this string is provided by the *RF2NVL* field that precedes the *RF2NVD* field; this length should be a multiple of four.

The *RF2NVL* and *RF2NVD* fields are optional, but if present they must occur as a pair and be adjacent. The pair of fields can be repeated as many times as required, for example:

```
length1 data1 length2 data2 length3 data3
```

Because these fields are optional, they are omitted from the declarations of the structure that are provided for the various programming languages supported.

*RF2NVD* is unusual because it is not converted to the character set specified on the MQGET call when the message is retrieved with the GMCONV option in effect; *RF2NVD* remains in its original character set. However, *RF2NVD* is converted to the encoding specified on the MQGET call.

**Syntax of name/value data:** The string consists of a single "folder" that contains zero or more properties. The folder is delimited by XML start and end tags with the same name as the folder:

```
<folder> property1 property2 ... </folder>
```

Characters following the folder end tag, up to the length defined by *RF2NVL*, must be blank. Within the folder, each property is composed of a name and a value, and optionally a data type:

```
<name dt="datatype">value</name>
```

In these examples:

- The delimiter characters (<, =, ", /, and >) must be specified exactly as shown.
- name is the user-specified name of the property; see the following example for more information about names.
- datatype is an optional user-specified data type of the property; see the following example for valid data types.
- value is the user-specified value of the property; see the following paragraphs for more information about values.
- Blanks are significant between the > character which precedes a value, and the < character which follows the value, and at least one blank must precede dt=. Elsewhere blanks can be coded freely between tags, or preceding or following tags (for example, in order to improve readability); these blanks are not significant.

If properties are related to each other, they can be grouped together by enclosing them within XML start and end tags with the same name as the group:

```
<folder> <group> property1 property2 ... </group> </folder>
```

Groups can be nested within other groups, without limit, and a group can occur more than once within a folder. It is also valid for a folder to contain some properties in groups and other properties not in groups.

**Names of properties, groups, and folders:** Names of properties, groups, and folders must be valid XML tag names, with the exception of the colon character, which is not permitted in a property, group, or folder name. In particular:

- Names must start with a letter or an underscore. Valid letters are defined in the W3C XML specification, and consist essentially of Unicode categories Ll, Lu, Lo, Lt, and Nl.
- The remaining characters in a name can be letters, decimal digits, underscores, hyphens, or dots. These correspond to Unicode categories Ll, Lu, Lo, Lt, Nl, Mc, Mn, Lm, and Nd.
- The Unicode compatibility characters (X'F900' and above) are not permitted in any part of a name.
- Names must not start with the string XML in any mixture of upper or lowercase.

In addition:

- Names are case-sensitive. For example, ABC, abc, and Abc are three different names.
- Each folder has a separate namespace. As a result, a group or property in one folder does not conflict with a group or property of the same name in another folder.
- Groups and properties occupy the same namespace within a folder. As a result, a property cannot have the same name as a group within the folder containing that property.

Generally, programs that analyze the *RF2NVD* field should ignore properties or groups that have names that the program does not recognize, provided that those properties or groups are correctly formed.

**Data types of properties:** Each property can have an optional data type. If specified, the data type must be one of the following values, in upper, lower, or mixed case:

<i>Table 721. Data types and their usage</i>	
<b>Data type</b>	<b>Used for</b>
string	Any sequence of characters. Certain characters must be specified using escape sequences.
boolean	The character 0 or 1 (1 denotes TRUE).
bin.hex	Hexadecimal digits representing octets.
i1	Integer number in the range -128 through +127, expressed using only decimal digits and optional sign.
i2	Integer number in the range -32 768 through +32 767, expressed using only decimal digits and optional sign.
i4	Integer number in the range -2 147 483 648 through +2 147 483 647, expressed using only decimal digits and optional sign.
i8	Integer number in the range -9 223 372 036 854 775 808 through +9 223 372 036 854 775 807, expressed using only decimal digits and optional sign.
int	Integer number in the range -9 223 372 036 854 775 808 through +9 223 372 036 854 775 807, expressed using only decimal digits and optional sign. This can be used in place of i1, i2, i4, or i8 if the sender does not want to imply a particular precision.
r4	Floating-point number with magnitude in the range 1.175E-37 through 3.402 823 47E+38, expressed using decimal digits, optional sign, optional fractional digits, and optional exponent.
r8	Floating-point number with magnitude in the range 2.225E-307 through 1.797 693 134 862 3E+308 expressed using decimal digits, optional sign, optional fractional digits, and optional exponent.

**Values of properties:** The value of a property can consist of any characters, except for special characters that have a mandatory associated escape sequence. Each occurrence in the value of a character marked as "mandatory" in the following table must be replaced by the corresponding escape sequence. The table also shows characters that have an optional associated escape

sequence. Each occurrence in the value of a character marked as "optional" can be replaced by the corresponding escape sequence, but this is not required.

<i>Table 722. Escaped characters and their usage</i>		
<b>Character</b>	<b>Escape sequence</b>	<b>Usage</b>
&	&amp;	Mandatory
<	<	Mandatory
>	&gt;	Optional
"	&quot;	Optional
'	&apos;	Optional

**Note:** The & character at the start of an escape sequence must not be replaced by &amp; ;.

In the following example, the blanks in the value are significant; however, no escape sequences are needed:

```
<Famous_Words>The program displayed "Hello World"</Famous_Words>
```

### **RF2NVL (10-digit signed integer)**

Length of *RF2NVD*.

This specifies the length in bytes of the data in the *RF2NVD* field. To avoid problems with data conversion of the data (if any) that follows the *RF2NVD* field, *RF2NVL* should be a multiple of four.

**Note:** The *RF2NVL* and *RF2NVD* fields are optional, but if present they must occur as a pair and be adjacent. The pair of fields can be repeated as many times as required, for example:

```
length1 data1 length2 data2 length3 data3
```

Because these fields are optional, they are omitted from the declarations of the structure that are provided for the various programming languages supported.

### **RF2SID (4-byte character string)**

Structure identifier.

The value must be:

#### **RFSIDV**

Identifier for rules and formatting header structure.

The initial value of this field is RFSIDV.

### **RF2VER (10-digit signed integer)**

Structure version number.

The value must be:

#### **RFVER2**

Version-2 rules and formatting header structure.

The initial value of this field is RFVER2.

## Initial values

Table 723. Fields in MQRFH2		
Field name	Name of constant	Value of constant

```

## IBM i MQRMH (Reference message header) on IBM i

The MQRMH structure defines the format of a reference message header.

### Overview

**Purpose:** This header is used with user-written message channel exits to send large amounts of data (called "bulk data") from one queue manager to another. The difference compared to normal messaging is that the bulk data is not stored on a queue; instead, only a *reference* to the bulk data is stored on the queue. This reduces the possibility of IBM MQ resources being exhausted by a few large messages.

**Format name:** FMRMH.

**Character set and encoding:** Character data in MQRMH, and the strings addressed by the offset fields, must be in the character set of the local queue manager; this is given by the **CodedCharSetId** queue manager attribute. Numeric data in MQRMH must be in the native machine encoding; this is given by the value of ENNAT for the C programming language.

The character set and encoding of the MQRMH must be set into the *MDCSI* and *MDENC* fields in:

- The MQMD (if the MQRMH structure is at the start of the message data), or
- The header structure that precedes the MQRMH structure (all other cases).

**Usage:** An application puts a message consisting of an MQRMH, but omitting the bulk data. When the message is read from the transmission queue by a message channel agent (MCA), a user-supplied message exit is invoked to process the reference message header. The exit can append to the reference message the bulk data identified by the MQRMH structure, before the MCA sends the message through the channel to the next queue manager.

At the receiving end, a message exit that waits for reference messages should exist. When a reference message is received, the exit should create the object from the bulk data that follows the MQRMH in the message, and then pass on the reference message without the bulk data. The reference message can later be retrieved by an application reading the reference message (without the bulk data) from a queue.

Normally, the MQRMH structure is all that is in the message. However, if the message is on a transmission queue, one or more additional headers will precede the MQRMH structure.

A reference message can also be sent to a distribution list. In this case, the MQDH structure and its related records precede the MQRMH structure when the message is on a transmission queue.

**Note:** A reference message should not be sent as a segmented message, because the message exit cannot process it correctly.

- [“Data conversion” on page 1200](#)
- [“Fields” on page 1200](#)
- [“Initial values” on page 1204](#)
- [“RPG declaration” on page 1206](#)

## Data conversion

For data conversion purposes, conversion of the MQRMH structure includes conversion of the source environment data, source object name, destination environment data, and destination object name. Any other bytes within *RMLLEN* bytes of the start of the structure are either discarded or have undefined values after data conversion. The bulk data will be converted provided that all of the following statements are true:

- The bulk data is present in the message when the data conversion is performed.
- The *RMFMT* field in MQRMH has a value other than FMNONE.
- A user-written data-conversion exit exists with the format name specified.

Be aware, however, that typically the bulk data is not present in the message when the message is on a queue, and that as a result the bulk data will not be converted by the GMCONV option.

## Fields

The MQRMH structure contains the following fields; the fields are described in **alphabetical order**:

### RMCSI (10-digit signed integer)

Character set identifier of bulk data.

This specifies the character set identifier of the bulk data; it does not apply to character data in the MQRMH structure itself.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The following special value can be used:

### CSINHT

Inherit character-set identifier of this structure.

Character data in the data *following* this structure is in the same character set as this structure.

The queue manager changes this value in the structure sent in the message to the actual character-set identifier of the structure. Provided no error occurs, the value CSINHT is not returned by the MQGET call.

CSINHT cannot be used if the value of the *MDPAT* field in MQMD is ATBRKR.

The initial value of this field is CSUNDF.

#### **RMDEL (10-digit signed integer)**

Length of destination environment data.

If this field is zero, there is no destination environment data, and *RMDEO* is ignored.

#### **RMDEO (10-digit signed integer)**

Offset of destination environment data.

This field specifies the offset of the destination environment data from the start of the MQRMH structure. Destination environment data can be specified by the creator of the reference message, if that data is known to the creator. For example, the destination environment data might be the directory path of the object where the bulk data is to be stored. However, if the creator does not know the destination environment data, it is the responsibility of the user-supplied message exit to determine any environment information needed.

The length of the destination environment data is given by *RMDEL* ; if this length is zero, there is no destination environment data, and *RMDEO* is ignored. If present, the destination environment data must reside completely within *RMLEN* bytes from the start of the structure.

Applications should not assume that the destination environment data is contiguous with any of the data addressed by the *RMSEO*, *RMSNO*, and *RMDNO* fields.

The initial value of this field is 0.

#### **RMDL (10-digit signed integer)**

Length of bulk data.

The *RMDL* field specifies the length of the bulk data referenced by the MQRMH structure.

If the bulk data is present in the message, the data begins at an offset of *RMLEN* bytes from the start of the MQRMH structure. The length of the entire message minus *RMLEN* gives the length of the bulk data present.

If data is present in the message, *RMDL* specifies the amount of that data that is relevant. The normal case is for *RMDL* to have the same value as the length of data present in the message.

If the MQRMH structure represents the remaining data in the object (starting from the specified logical offset), the value zero can be used for *RMDL*, if the bulk data is not present in the message.

If no data is present, the end of MQRMH coincides with the end of the message.

The initial value of this field is 0.

#### **RMDNL (10-digit signed integer)**

Length of destination object name.

If this field is zero, there is no destination object name, and *RMDNO* is ignored.

#### **RMDNO (10-digit signed integer)**

Offset of destination object name.

This field specifies the offset of the destination object name from the start of the MQRMH structure. The destination object name can be specified by the creator of the reference message, if that data is known to the creator. However, if the creator does not know the destination object name, it is the responsibility of the user-supplied message exit to identify the object to be created or modified.

The length of the destination object name is given by *RMDNL* ; if this length is zero, there is no destination object name, and *RMDNO* is ignored. If present, the destination object name must reside completely within *RMLLEN* bytes from the start of the structure.

Applications should not assume that the destination object name is contiguous with any of the data addressed by the *RMSEO*, *RMSNO*, and *RMDEO* fields.

The initial value of this field is 0.

### **RMDO (10-digit signed integer)**

Low offset of bulk data.

This field specifies the low offset of the bulk data from the start of the object of which the bulk data forms part. The offset of the bulk data from the start of the object is called the *logical offset*. This is not the physical offset of the bulk data from the start of the MQRMH structure - that offset is given by *RMLLEN*.

To allow large objects to be sent using reference messages, the logical offset is divided into two fields, and the actual logical offset is given by the sum of these two fields:

- *RMDO* represents the remainder obtained when the logical offset is divided by 1 000 000 000. It is thus a value in the range 0 through 999 999 999.
- *RMDO2* represents the result obtained when the logical offset is divided by 1 000 000 000. It is thus the number of complete multiples of 1 000 000 000 that exist in the logical offset. The number of multiples is in the range 0 through 999 999 999.

The initial value of this field is 0.

### **RMDO2 (10-digit signed integer)**

High offset of bulk data.

This field specifies the high offset of the bulk data from the start of the object of which the bulk data forms part. It is a value in the range 0 through 999 999 999. See *RMDO* for details.

The initial value of this field is 0.

### **RMENC (10-digit signed integer)**

Numeric encoding of bulk data.

This specifies the numeric encoding of the bulk data; it does not apply to numeric data in the MQRMH structure itself.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data.

The initial value of this field is ENNAT.

### **RMFLG (10-digit signed integer)**

Reference message flags.

The following flags are defined:

#### **RMLAST**

Reference message contains or represents last part of object.

This flag indicates that the reference message represents or contains the last part of the referenced object.

#### **RMNLST**

Reference message does not contain or represent last part of object.

RMNLST is defined to aid program documentation. It is not intended that this option be used with any other, but as its value is zero, such use cannot be detected.

The initial value of this field is RMNLST.

**RMFMT (8-byte character string)**

Format name of bulk data.

This specifies the format name of the bulk data.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The rules for coding this field are the same as those for the *MDFMT* field in MQMD.

The initial value of this field is FMNONE.

**RMLen (10-digit signed integer)**

Total length of MQRMH, including strings at end of fixed fields, but not the bulk data.

The initial value of this field is zero.

**RMOII (24-byte bit string)**

Object instance identifier.

This field can be used to identify a specific instance of an object. If it is not needed, it should be set to the following value:

**OIINON**

No object instance identifier specified.

The value is binary zero for the length of the field.

The length of this field is given by LNOIID. The initial value of this field is OIINON.

**RMOT (8-byte character string)**

Object type.

This is a name that can be used by the message exit to recognize types of reference message that it supports. Consider making the name conform to the same rules as the *RMFMT* field.

The initial value of this field is 8 blanks.

**RMSEL (10-digit signed integer)**

Length of source environment data.

If this field is zero, there is no source environment data, and *RMSEO* is ignored.

The initial value of this field is 0.

**RMSEO (10-digit signed integer)**

Offset of source environment data.

This field specifies the offset of the source environment data from the start of the MQRMH structure. Source environment data can be specified by the creator of the reference message, if that data is known to the creator. For example, the source environment data might be the directory path of the object containing the bulk data. However, if the creator does not know the source environment data, it is the responsibility of the user-supplied message exit to determine any environment information needed.

The length of the source environment data is given by *RMSEL* ; if this length is zero, there is no source environment data, and *RMSEO* is ignored. If present, the source environment data must reside completely within *RMLen* bytes from the start of the structure.

Applications should not assume that the environment data starts immediately after the last fixed field in the structure or that it is contiguous with any of the data addressed by the *RMSNO*, *RMDEO*, and *RMDNO* fields.

The initial value of this field is 0.

**RMSID (4-byte character string)**

Structure identifier.

The value must be:

**RMSIDV**

Identifier for reference message header structure.

The initial value of this field is RMSIDV.

**RMSNL (10-digit signed integer)**

Length of source object name.

If this field is zero, there is no source object name, and *RMSNO* is ignored.

The initial value of this field is 0.

**RMSNO (10-digit signed integer)**

Offset of source object name.

This field specifies the offset of the source object name from the start of the MQRMH structure. The source object name can be specified by the creator of the reference message, if that data is known to the creator. However, if the creator does not know the source object name, it is the responsibility of the user-supplied message exit to identify the object to be accessed.

The length of the source object name is given by *RMSNL* ; if this length is zero, there is no source object name, and *RMSNO* is ignored. If present, the source object name must reside completely within *RMLLEN* bytes from the start of the structure.

Applications should not assume that the source object name is contiguous with any of the data addressed by the *RMSEO*, *RMDEO*, and *RMDNO* fields.

The initial value of this field is 0.

**RMVER (10-digit signed integer)**

Structure version number.

The value must be:

**RMVER1**

Version-1 reference message header structure.

The following constant specifies the version number of the current version:

**RMVERC**

Current version of reference message header structure.

The initial value of this field is RMVER1.

**Initial values**

Field name	Name of constant	Value of constant
<i>RMSID</i>	RMSIDV	'RMH↵'
<i>RMVER</i>	RMVER1	1
<i>RMLLEN</i>	None	0
<i>RMENC</i>	ENNAT	Depends on environment
<i>RMCSI</i>	CSUNDF	0

## RPG declaration

### IBM i MQRR (Response record) on IBM i

The MQRR structure is used to receive the completion code and reason code resulting from the open or put operation for a single destination queue, when the destination is a distribution list.

## Overview

**Purpose:** MQRR is an output structure for the MQOPEN, MQPUT, and MQPUT1 calls.

**Character set and encoding:** Data in MQRR must be in the character set given by the **CodedCharSetId** queue manager attribute and encoding of the local queue manager given by ENNAT. However, if the application is running as an IBM MQ client, the structure must be in the character set and encoding of the client.

**Usage:** By providing an array of these structures on the MQOPEN and MQPUT calls, or on the MQPUT1 call, it is possible to determine the completion codes and reason codes for all of the queues in a distribution list when the outcome of the call is mixed, that is, when the call succeeds for some queues in the list but fails for others. Reason code RC2136 from the call indicates that the response records (if provided by the application) have been set by the queue manager.

- [“Fields” on page 1206](#)
- [“Initial values” on page 1206](#)
- [“RPG declaration” on page 1207](#)

## Fields

The MQRR structure contains the following fields; the fields are described in **alphabetical order**:

### RRCC (10-digit signed integer)

Completion code for queue.

This is the completion code resulting from the open or put operation for the queue with the name that was specified by the corresponding element in the array of MQOR structures provided on the MQOPEN or MQPUT1 call.

This is always an output field. The initial value of this field is CCOK.

### RRREA (10-digit signed integer)

Reason code for queue.

This is the reason code resulting from the open or put operation for the queue with the name that was specified by the corresponding element in the array of MQOR structures provided on the MQOPEN or MQPUT1 call.

This is always an output field. The initial value of this field is RCNONE.

## Initial values

Field name	Name of constant	Value of constant
RRCC	CCOK	0

Table 725. Fields in MQRR (continued)

Field name	Name of constant	Value of constant
RRREA	RCNONE	0

## IBM i MQSCO (TLS configuration options) on IBM i

The MQSCO structure (with the TLS fields in the MQCD structure) allows an application running as an IBM MQ MQI client to specify configuration options that control the use of TLS for the client connection when the channel protocol is TCP/IP.

### Overview

**Purpose:** The structure is an input parameter on the MQCONN call.

If the channel protocol for the client channel is not TCP/IP, the MQSCO structure is ignored.

**Character set and encoding:** Data in MQSCO must be in the character set given by the **CodedCharSetId** queue manager attribute and encoding of the local queue manager given by ENNAT.

- [“Fields” on page 1207](#)
- [“Initial values” on page 1211](#)
- [“RPG declaration” on page 1212](#)

### Fields

The MQSCO structure contains the following fields; the fields are described in **alphabetical order**:

#### SCAIC (10-digit signed integer)

This is the number of authentication information (MQAIR) records addressed by the *SCAIP* or *SCAIO* fields. For more information, see [“MQAIR \(Authentication information record\) on IBM i” on page 1015](#). The value must be zero or greater. If the value is not valid, the call fails with reason code RC2383.

This is an input field. The initial value of this field is 0.

#### SCAIO (10-digit signed integer)

This is the offset in bytes of the first authentication information record from the start of the MQSCO structure. The offset can be positive or negative. The field is ignored if *SCAIC* is zero.

You can use either *SCAIO* or *SCAIP* to specify the MQAIR records, but not both; see the description of the *SCAIP* field for details.

This is an input field. The initial value of this field is 0.

#### SCAIP (10-digit signed integer)

This is the address of the first authentication information record. The field is ignored if *SCAIC* is zero.

You can provide the array of MQAIR records in one of two ways:

- By using the pointer field *SCAIP*

In this case, the application can declare an array of MQAIR records that is separate from the MQSCO structure, and set *SCAIP* to the address of the array.

Consider using *SCAIP* for programming languages that support the pointer data type in a fashion that is portable to different environments (for example, the C programming language).

- By using the offset field *SCAIO*

In this case, the application must declare a compound structure containing an MQSCO followed by the array of MQAIR records, and set *SCAIO* to the offset of the first record in the array from the start of the MQSCO structure. Ensure that this value is correct, and has a value that can be accommodated within an MQLONG (the most restrictive programming language is COBOL, for which the valid range is -999 999 999 through +999 999 999).

Consider using *SCAIO* for programming languages that do not support the pointer data type, or that implement the pointer data type in a fashion that is not portable to different environments (for example, the COBOL programming language).

Whatever technique you choose, only one of *SCAIP* and *SCAIO* can be used; the call fails with reason code RC2384 if both are nonzero.

This is an input field. The initial value of this field is the null pointer in those programming languages that support pointers, and an all-null byte string otherwise.

**Note:** On platforms where the programming language does not support the pointer data type, this field is declared as a byte string of the appropriate length.

### **SCCERLBL (10-digit signed integer)**

This field gives details of the certificate label being used.

IBM MQ initializes the value for the SCCERLBL field as blanks. Either enter the required value, or accept the default value.

*ibmwebspheremquser\_id* is a valid value for this field for all versions of the product, and for MQSCO versions less than 5.0 it is the only valid value. Therefore the value of this field is interpreted at run time, and changed if necessary. If you specify an MQSCO version less than 5.0, or accept the default value of blanks for the SCCERLBL field, the system uses the value *ibmwebspheremquser\_id*.

This is an input field.

### **SCCERTVPOL (10-digit signed integer)**

This field specifies what type of certificate validation policy is used. The field can be set to one of the following values:

#### **MQ\_CERT\_VAL\_POLICY\_ANY**

Apply each of the certificate validation policies supported by the secure sockets library. Accept the certificate chain if any of the policies considers the certificate chain valid.

#### **MQ\_CERT\_VAL\_POLICY\_RFC5280**

Apply only the RFC5280 compliant certificate validation policy. This setting provides stricter validation than the ANY setting, but rejects some older digital certificates.

The initial value of this field is MQ\_CERT\_VAL\_POLICY\_ANY

### **SCCH (10-digit signed integer)**

This field gives configuration details for cryptographic hardware connected to the client system.

Set the field to a string in the following format, or leave it blank or null:

```
GSK_PKCS11=the PKCS #11 driver path and file name;the PKCS #11
token label;the PKCS #11 token password;symmetric cipher setting>;
```

To use cryptographic hardware which conforms to the PKCS11 interface, for example, the IBM 4960 or IBM 4963, specify the PKCS11 driver path, PKCS11 token label, and PKCS11 token password strings, each terminated by a semi-colon.

The PKCS #11 driver path is an absolute path to the shared library providing support for the PKCS #11 card. The PKCS #11 driver file name is the name of the shared library. An example of the value required for the PKCS #11 path and file name is:

```
/usr/lib/pkcs11/PKCS11_API.so
```

The PKCS #11 token label must be entirely in lowercase. If you have configured your hardware with a mixed case or uppercase token label, reconfigure it with this lowercase label.

If no cryptographic hardware configuration is required, set the field to blank or null.

If the value is shorter than the length of the field, terminate the value with a null character, or pad it with blanks to the length of the field. If the value is not valid, or leads to a failure when used to configure the cryptographic hardware, the call fails with reason code RC2382.

This is an input field. The length of this field is given by LNSSCH. The initial value of this field is blank characters.

### **SCEPSUITEB (10-digit signed integer)**

This field Specifies whether Suite B compliant cryptography is used and what level of strength is employed. The value can be one or more of:

- SCEPSUITEB0  
Suite B compliant cryptography is not used.
- SCEPSUITEB1  
Suite B 128-bit strength security is used.
- SCEPSUITEB2  
Suite B 192-bit strength security is used.

**Note:** Using SCEPSUITEB0 with any other value in this field is invalid.

### **SCFR (10-digit signed integer)**

IBM MQ can be configured with cryptographic hardware so that the cryptography modules used are those provided by the hardware product; these can be FIPS-certified to a particular level depending on the cryptographic hardware product in use.

Use this field to specify that only FIPS-certified algorithms are used if the cryptography is provided in IBM MQ-provided software.

When IBM MQ is installed an implementation of TLS cryptography is also installed which provides some FIPS-certified modules.

The values can be:

#### **MQSSL\_FIPS\_NO**

This is the default value. When set to this value:

- Any CipherSpec supported on a particular platform can be used.
- If run without use of cryptographic hardware, the following CipherSpecs run using FIPS 140-2 certified cryptography on the IBM MQ platforms:
  - TLS\_RSA\_WITH\_3DES\_EDE\_CBC\_SHA
  - TLS\_RSA\_WITH\_AES\_128\_CBC\_SHA
  - TLS\_RSA\_WITH\_AES\_256\_CBC\_SHA

#### **MQSSL\_FIPS\_YES**

When set to this value, unless you are using cryptographic hardware to perform the cryptography, you can be sure that

- Only FIPS-certified cryptographic algorithms can be used in the CipherSpec applying to this client connection.

- Inbound and outbound TLS channel connections only succeed if one of the following Cipher Specs are used:
  - TLS\_RSA\_WITH\_3DES\_EDE\_CBC\_SHA
  - TLS\_RSA\_WITH\_AES\_128\_CBC\_SHA
  - TLS\_RSA\_WITH\_AES\_256\_CBC\_SHA

**Notes:**

1.  CipherSpec TLS\_RSA\_WITH\_3DES\_EDE\_CBC\_SHA is deprecated.
2. Where possible, if FIPS-only CipherSpecs is configured then the MQI client rejects connections which specify a non-FIPS CipherSpec with RC2393. IBM MQ does not guarantee to reject all such connections and it is your responsibility to determine whether your IBM MQ configuration is FIPS-compliant.

**SCKEYPWL (10-digit signed integer)**

This is the length of the TLS key repository passphrase.

The maximum length of the key repository passphrase is 128 characters. If the key repository passphrase is greater than the maximum length permitted, the connection fails with RC2381.

This is an input field. The initial value of this field is 0.

**SCKEYPWO (10-digit signed integer)**

This is the offset in bytes of the TLS key repository passphrase. The offset can be positive or negative.

You can use either SCKEYPWO or SCKEYPWP to specify the key repository passphrase, but not both. For more information, see the description of the SCKEYPWP field.

This is an input field. The initial value of this field is 0.

**SCKEYPWP (pointer)**

This is the address of the TLS key repository passphrase.

This is an input field. The initial value of this field is the null pointer.

The key repository passphrase can be specified as a plain text string, or a passphrase that has been encrypted using the **runmqicred** utility.

The key repository passphrase specified using this field overrides any key repository passphrase that is specified using the *MQKEYRPWD* environment variable, or the *SSLKeyRepositoryPassword* property in the SSL stanza of the client configuration file.

You can use either SCKEYPWO or SCKEYPWP to specify the key repository passphrase, but not both.

**SCKR (10-digit signed integer)**

This field specifies the location of the key database file in which keys and certificates are stored. If the file suffix is not specified, a suffix of *.kdb* is added automatically.

Each key database file can have an associated *password stash file*. This holds encrypted passwords that are used to allow programmatic access to the key database. The password stash file must reside in the same directory and have the same file stem as the key database, and must end with the suffix *.sth*.

For example, if the key database file is */xxx/yyy/key.kdb*, then the password stash file must be */xxx/yyy/key.sth*, where *xxx* and *yyy* represent directory names.

The key database password can also be specified using the *SCKEYPWP* or *SCKEYPWO* fields.

If the value is shorter than the length of the field, terminate the value with a null character, or pad it with blanks to the length of the field. The value is not checked; if there is an error in accessing the key repository, the call fails with reason code RC2381.

To run a TLS connection from an IBM MQ MQI client, set *SCKR* to a valid key database file name.

This is an input field. The length of this field is given by LNSSKR. The initial value of this field is a blank character.

### **SCSID (10-digit signed integer)**

This is the structure identifier; the value must be:

#### **SCSIDV**

Identifier for TLS configuration options structure.

This is always an input field. The initial value of this field is SCSIDV.

### **SCVER (10-digit signed integer)**

This is the structure version number; the value must be:

#### **SCVER1**

Version-1 TLS configuration options structure.

#### **SCVER2**

Version-2 TLS configuration options structure.

#### **SCVER3**

Version-3 TLS configuration options structure.

#### **SCVER4**

Version-4 TLS configuration options structure.

#### **SCVER5**

Version-5 TLS configuration options structure.

#### **SCVER6**

Version-6 TLS configuration options structure.

The following constant specifies the version number of the current version:

#### **SCVERC**

Current version of TLS configuration options structure.

This is always an input field. The initial value of this field is SCVER1.

## **Initial values**

<b>Field name</b>	<b>Name of constant</b>	<b>Value of constant</b>
<i>SCSID</i>	SCSIDV	' SC0↵ '
<i>SCVER</i>	SCVER1	1
<i>SCKR</i>	None	Null string or blanks
<i>SCCH</i>	None	Null string or blanks
<i>SCAIC</i>	None	0
<i>SCAIO</i>	None	0
<i>SCAIP</i>	None	Null pointer or null bytes
<i>SCKRC</i>	None	Null pointer or null bytes

## IBM i MQSD (Subscription descriptor) on IBM i

The MQSD structure is used to specify details about the subscription being made.

### Overview

#### Purpose

The structure is an input/output parameter on the MQSUB call.

#### Managed subscriptions

If an application has no specific need to use a particular queue as the destination for those publications that match its subscription, it can use the managed subscription feature. If an application elects to use a managed subscription, the queue manager informs the subscriber about the destination where published messages are sent, by providing an object handle as an output from the MQSUB call. For more information, see [HOBJ \(10-digit signed integer\) - input/output](#).

When the subscription is removed, the queue manager also undertakes to clean up messages that have not been retrieved from the managed destination, in the following situations:

- When the subscription is removed - by use of MQCLOSE with CORMSB - and the managed Hobj is closed.
- By implicit means when the connection is lost to an application using a non-durable subscription (SONDUR)
- By expiration when a subscription is removed because it has expired and the managed Hobj is closed.

You must use managed subscriptions with non-durable subscriptions, so that the clean up can occur, and so that messages for closed non-durable subscriptions do not take up space in your queue manager. Durable subscriptions can also use managed destinations.

### Character set and encoding

Data in MQSD must be in the character set given by the **CodedCharSetId** queue manager attribute and encoding of the local queue manager given by ENNAT. However, if the application is running as an IBM MQ client, the structure must be in the character set and encoding of the client.

- [“Fields” on page 1213](#)
- [“Initial values” on page 1225](#)
- [“RPG declaration” on page 1226](#)

### Fields

The MQSD structure contains the following fields; the fields are described in alphabetical order:

#### SDAID (32 byte character string)

This value is in the *MDAID* field of the Message Descriptor (MQMD) of all publication messages matching this subscription. *SDAID* is part of the identity context of the message. For more information about message context, see [Message context](#).

For more information about *MDAID* see [MDAID](#).

If the SOSETI option is not specified, the *MDAID* which is set in each message published for this subscription is blanks, as default context information.

If the SOSETI option is specified, the *SDAID* is being generated by the user and this field is an input field which contains the *MDAID* to be set in each publication for this subscription.

The length of this field is given by LNAIDD. The initial value of this field is 32 blank characters.

If altering an existing subscription using the SOALT option, the *SDAID* of any future publication messages can be changed.

On return from an MQSUB call using SORES, this field is set to the current *MDAID* being used for the subscription.

#### SDACC (32 byte character string)

This value is in the *MDACC* field of the Message Descriptor (MQMD) of all publication messages matching this subscription. *MDACC* is part of the identity context of the message. For more information about message context, see [Message context](#).

For more information about *MDACC* see [MDACC](#).

You can use the following special value for the *SDACC* field:

#### ACNONE

No accounting token is specified.

The value is binary zero for the length of the field.

If the `S0SETI` option is not specified, the accounting token is generated by the queue manager as default context information and this field is an output field which contains the `MDACC` which is set in each message published for this subscription.

If the `S0SETI` option is specified, the accounting token is being generated by the user and this field is an input field which contains the `MDACC` to be set in each publication for this subscription.

The length of this field is given by `LNACCT`. The initial value of this field is `ACNONE`.

If altering an existing subscription using the `SOALT` option, the value of `MDACC` in any future publication messages can be changed.

On return from an `MQSUB` call using `S0RES`, this field is set to the current `MDACC` being used for the subscription.

### **SDASI (40 byte bit string)**

This is a security identifier that is passed with the `SDAU` to the authorization service to allow appropriate authorization checks to be performed.

`SDASI` is used only if `SOALTU` is specified, and the `SDAU` field is not entirely blank up to the first null character or the end of the field.

On return from an `MQSUB` call using `S0RES`, this field is unchanged.

See the description of `ODASI` in the `MQOD` data type for more information.

### **SDAU (12 byte character string)**

If you specify `SOALTU`, this field contains an alternate user identifier that is used to check the authorization for the subscription and for output to the destination queue (specified in the **Hobj** parameter of the `MQSUB` call), in place of the user identifier that the application is currently running under.

If successful, the user identifier specified in this field is recorded as the subscription owning user identifier in place of the user identifier that the application is currently running under.

If `SOALTU` is specified and this field is entirely blank up to the first null character or the end of the field, the subscription can succeed only if no user authorization is needed to subscribe to this topic with the options specified or the destination queue for output.

If `SOALTU` is not specified, this field is ignored.

On return from an `MQSUB` call using `S0RES`, this field is unchanged.

This is an input field. The length of this field is given by `LNUID`. The initial value of this field is 12 blank characters.

### **SDCID (24 byte bit string)**

All publications sent to match this subscription contain this correlation identifier in the message descriptor. If multiple subscriptions use the same queue to get their publications from, using `MQGET` by correlation ID allows only publications for a specific subscription to be obtained. This correlation identifier can either be generated by the queue manager or by the user.

If the `S0SCID` option is not specified, the correlation identifier is generated by the queue manager and this field is an output field which contains the correlation identifier which is set in each message published for this subscription.

If the `S0SCID` option is specified, the correlation identifier is being generated by the user and this field is an input field which contains the correlation identifier to be set in each publication for this subscription. In this case, if the field contains `CINONE`, the correlation identifier which is set in each message published for this subscription is the correlation identifier that was created by the original put of the message.

If the `S0GRP` option is specified and the correlation identifier specified is the same as an existing grouped subscription using the same queue and an overlapping topic string, only the most significant subscription in the group is provided with a copy of the publication.

The length of this field is given by LNCID. The initial value of this field is CINONE.

If altering an existing subscription using the SOALT option, and this field is an input field, then the subscription correlation ID can be changed, unless the subscription has been created using the SOGRP option.

On return from an MQSUB call using SORES, this field is set to the current correlation ID for the subscription.

### **SDEXP (10 digit signed integer)**

This is the time expressed in tenths of a second after which the subscription expires. No more publications will match this subscription after this interval has passed. This is also used as the value in the *MDEXP* field in the MQMD of the publications sent to this subscriber.

The following special value is recognized:

#### **EIULIM**

The subscription has an unlimited expiration time.

If altering an existing subscription using the SOALT option, the expiry of the subscription can be changed.

On return from an MQSUB call using the SORES option this field is set to the original expiry of the subscription and not the remaining expiry time.

### **SDON (48 byte character string)**

This is the name of the topic object as defined on the local queue manager.

The name can contain the following characters:

- Uppercase alphabetic characters (A through Z)
- Lowercase alphabetic characters (a through z)
- Numeric digits (0 through 9)
- Period (.), forward slash (/), underscore (\_), percent (%)

The name must not contain leading or embedded blanks, but can contain trailing blanks. Use a null character to indicate the end of significant data in the name; the null and any characters following it are treated as blanks. The following restrictions apply:

- On systems that use EBCDIC Katakana, lowercase characters cannot be used.
- Names containing lowercase characters, forward slash, or percent, must be enclosed in quotation marks when specified on commands. These quotation marks must not be specified for names that occur as fields in structures or as parameters on calls.

The *SDON* is used to form the Full topic name.

The full topic name can be built from two different fields: *SDON* and *SDOS*. For details of how these two fields are used, see [Combining topic strings](#).

On return from an MQSUB call using the SORES option this field is unchanged.

The length of this field is given by LNTOPN. The initial value of this field is 48 blank characters.

If altering an existing subscription using the SDALT option, the name of the topic object subscribed to cannot be changed. This field and *SDOS* can be omitted. If they are provided they must resolve to the same full topic name or the call fails with RC2510 .

### **SDOPT (10 digit signed integer)**

You must specify at least one of the following options:

- SOALT
- SORES
- SOCRT

The values can be added. Do not add the same constant more than once. The table shows how you can combine these options: Combinations that are not valid are noted; any other combinations are valid.

### Access or creation options

Access and creation options control whether a subscription is created, or whether an existing subscription is returned or altered. You must specify at least one of these options. The table displays valid combinations of access or creation options.

<i>Table 727. Valid combinations of access and creation options</i>	
<b>Combination of options</b>	<b>Notes</b>
SOCRT	Creates a subscription if one does not exist; fails if the subscription exists.
SORES	Resumes an existing subscription, fails if no subscription exists.
SOCRT + SORES	Creates a subscription if one does not exist and resumes a matching one, if it does exist. Useful combination if used in an application that might be run a number of times.
SORES + SOALT (see note)	Resumes an existing subscription, altering any fields to match those specified in the MQSD, fails if no subscription exists.
SOCRT + SOALT (see note)	Creates a subscription if one does not exist and resumes a matching one, if it does exist, altering any fields to match those specified in the MQSD. Useful combination if used in an application that wants to ensure that its subscription is in a certain state before proceeding.

#### Note:

Options specifying SOALT can also specify SORES, but this combination has no additional effect to specifying SOALT alone. SOALT implies SORES, because calling MQSUB to alter a subscription implies that the subscriptions are also resumed. The opposite is not true, however: resuming a subscription does not imply it is to be altered.

### SOCRT

Create a subscription for the topic specified. If a subscription using the same *SDSN* exists, the call fails with RC2432. This failure can be avoided by combining the SOCRT option with SORES. The *SDSN* is not always necessary. For more details, see the description of that field.

Combining SOCRT with SORES first checks whether there is an existing subscription for the specified *SDSN*, and if there is returns a handle to that preexisting subscription; but if there is no existing subscription, a new one is created using all the fields provided in the MQSD.

SOCRT can also be combined with SOALT to similar effect (see details about SOALT later in this topic).

### SORES

Return a handle to a preexisting subscription which matches those specified by *SDSN*. No changes are made to the matching subscription attributes, and they are returned on output in the MQSD structure. Most of the contents of the MQSD are not used: The fields used are *SDSID*, *SDVER*, *SDOPT*, *SDAID* and *SDASI*, and *SDSN*.

The call fails with reason code RC2428 if a subscription does not exist matching the full subscription name. This failure can be avoided by combining the SOCRT option with SORES. For details about SOCRT, see [SOCRT](#).

The user ID of the subscription is the user ID that created the subscription, or if it has been later altered by a different user ID, it is the user ID of the most recent, successful alteration. If an *SDAID* is used, and use of alternate user IDs is allowed for that user, *SDAID* is recorded as the user ID that created the subscription instead of the user ID under which the subscription was made.

The user ID that created the subscription is recorded as *SDAU* if that field is used, and the use of alternate user IDs is allowed for that user.

If a matching subscription exists which was created without the *SOAUID* option and the user ID of the subscription is different from that of the application requesting a handle to the subscription, the call fails with reason code *RC2434* .

If a matching subscription exists and is currently in use by another application, the call fails with reason code *RC2429* . If it is currently in use by the same connection, the call does not fail and a handle to the subscription is returned.

If the subscription named in *SubName* is not a valid subscription to resume or alter from an application, the call fails with *RC2523* .

*SORES* is implied by *SOALT* and so is not required to be combined with that option, however, it is not an error if those two options are combined.

## SOALT

Return a handle to a preexisting subscription with the full subscription name matching those specified in *SDSN*. Any attributes of the subscription that are different from those specified in the *MQSD* is altered in the subscription unless alteration is disallowed for that attribute. Details are noted in the description of each attribute and are summarized in the following table. If you try to alter an attribute that cannot be changed, the call fails with the reason code shown in the following table.

The call fails with reason code *RC2428* if a subscription does not exist matching the full subscription name. This failure can be avoided by combining the *SOCRT* option with *SOALT*.

Combining *SOCRT* with *SOALT* first checks whether there is an existing subscription for the specified full subscription name, and if there is returns a handle to that preexisting subscription with alterations made as previously detailed; but if there is no existing subscription, a new one is created using all the fields provided in the *MQSD*.

The user ID of the subscription is the user ID that created the subscription, or if it has been later altered by a different user ID, it is the user ID of the most recent successful alteration. If *SDAU* is used (and use of alternate user IDs is allowed for that user), then the alternate user ID is recorded as the user ID that created the subscription instead of the user ID under which the subscription was made.

If a matching subscription exists that was created without the option *SOAUID* and the user ID of the subscription is different from that of the application requesting a handle to the subscription, the call fails with reason code *RC2434* .

If a matching subscription exists and is currently in use by another application, the call fails with *RC2429* . If it is currently in use by the same connection the call does not fail and a handle to the subscription is returned.

If the subscription named in *SubName* is not a valid subscription to resume or alter from an application, the call fails with *RC2523* .

The following tables show the subscription attributes that can be altered by *SOALT*.

<i>Table 728. Attributes in MQSD and MQSUB that can be altered</i>			
Data type descriptor or function call	Field name	Can this attribute be altered using SOALT?	Reason code
MQSD	Durability options	No	RC2509

Table 728. Attributes in MQSD and MQSUB that can be altered (continued)

Data type descriptor or function call	Field name	Can this attribute be altered using SOALT?	Reason code
MQSD	Destination Options	Yes	None
MQSD	Registration options	Yes (see note 1 )	RC2515 if you try to alter SOGRP
MQSD	Publication options	Yes (see note 2 )	None
MQSD	Wildcard options	No	RC2510
MQSD	Other options	No (see note 3 )	None
MQSD	ObjectName	No	RC2510
MQSD	SDAU	No (see note 4 )	None
MQSD	SDASI	No (see note 4 )	None
MQSD	SDEXP	Yes	None
MQSD	SDOS	No	RC2510
MQSD	SDSN	No (see note 5 )	None
MQSD	SDSUD	Yes	None
MQSD	SDCID	Yes (see note 6 )	RC2515 when in a grouped subscription
MQSD	SDPRI	Yes	None
MQSD	SDACC	Yes	None
MQSD	SDAID	Yes	None
MQSD	SDSL	No	RC2512
MQSUB	Hobj	Yes (see note 6 )	RC2515 when in a grouped subscription

**Notes:**

1. SOGRP cannot be altered.
2. SONEWP cannot be altered because it is not part of the subscription
3. These options are not part of the subscription
4. This attribute is not part of the subscription
5. This attribute is the identity of the subscription being altered
6. Alterable except when part of a grouped sub ( SOGRP )

**Durability options:** The following options control how durable the subscription is. You can specify only one of these options. If you are altering an existing subscription using the SOALT option, you cannot change the durability of the subscription. On return from an MQSUB call using SORES, the appropriate durability option is set.

**SODUR**

Request that the subscription to this topic remains until it is explicitly removed using MQCLOSE with the CORMSB option. If this subscription is not explicitly removed it will remain even after this application connects to the queue manager is closed.

If a durable subscription is requested to a topic that is defined as not allowing durable subscriptions, the call fails with RC2436 .

## SONDUR

Request that the subscription to this topic is removed when the application connection to the queue manager is closed, if it has not already been explicitly removed. SONDUR is the opposite of the SODUR option, and is defined to aid program documentation. It is the default if neither is specified.

**Destination options:** The following options control the destination that publications for a topic that has been subscribed to are sent to. If altering an existing subscription using the SOALT option, the destination used for publications for the subscription can be changed. On return from an MQSUB call using SORES, this option is set if appropriate.

## SOMAN

Request that the destination that the publications are sent to is managed by the queue manager.

The object handle returned in *HOBJ* represents a queue manager managed queue, and is for use with subsequent MQGET, MQCB, MQINQ, or MQCLOSE calls.

An object handle returned from a previous MQSUB call cannot be provided in the **Hobj** parameter when SOMAN is not specified.

**Registration options:** The following options control the details of the registration that is made to the queue manager for this subscription. If altering an existing subscription using the SOALT option, these registration options can be changed. On return from an MQSUB call using SORES the appropriate registration options is set.

## SOGRP

This subscription is grouped with other subscriptions of the same *SDSL* using the same queue and specifying the same correlation ID so that any publications to topics that would cause more than one publication message to be provided to the group of subscriptions, due to an overlapping set of topic strings being used, only causes one message to be delivered to the queue. If this option is not used, then each unique subscription (identified by *SDSN*) that matches is provided with a copy of the publication which might mean that more than one copy of the publication might be placed on the queue shared by a number of subscriptions.

Only the most significant subscription in the group is provided with a copy of the publication. The most significant subscription is based on the Full topic name up to the point where a wildcard is found. If a mixture of wildcard schemes is used within the group, only the position of the wildcard is important. You are advised not to combine different wildcard schemes within a group of subscriptions that share the same queue.

When creating a new grouped subscription it must still have a unique *SDSN*, but if it matches the full topic name of an existing subscription in the group, the call fails with RC2514 .

If the most significant subscription in group also specifies SONOLC and this is a publication from the same application, then no publication is delivered to the queue.

When altering a subscription made with this option, the fields which imply the grouping, *Hobj* on the MQSUB call (representing the queue and queue manager name), and the *SDCID* cannot be changed. Attempting to alter them causes the call to fail with RC2515 .

This option must be combined with SOSCID with a *SDCID* that is not set to CINONE, and cannot be combined with SOMAN.

## SOAUID

When SOAUID is specified, the identity of the subscriber is not restricted to a single user ID. This allows any user to alter or resume the subscription when they have suitable authority. Only a single user can have the subscription at any one time. An attempt to resume use of a subscription currently in use by another application causes the call to fail with RC2429 .

To add this option to an existing subscription, the MQSUB call, using SOALT, must come from the same user ID as the original subscription itself.

If an MQSUB call references an existing subscription with SOAUID set, and the user ID differs from the original subscription, the call succeeds only if the new user ID has authority to subscribe to the topic. On successful completion, future publications to this subscriber are put to the subscriber's queue with the new user ID set in the publication message.

Do not specify both SOAUID and SOFUID. If neither is specified, the default is SOFUID.

### **SOAUID**

When SOAUID is specified, the subscription can be altered or resumed by only the last user ID to alter the subscription. If the subscription has not been altered, it is the user ID that created the subscription.

If an MQSUB verb references an existing subscription with SOAUID set and alters the subscription using SOALT to use the SOFUID, the user ID of the subscription is now fixed at this new user ID. The call succeeds only if the new user ID has authority to subscribe to the topic.

If a user ID other than the one recorded as owning a subscription tries to resume or alter an SOFUID subscription, the call fails with RC2434 . The owning user ID of a subscription can be viewed using the **DISPLAY SBSTATUS** command.

Do not specify both SOAUID and SOFUID. If neither is specified, the default is SOFUID.

**Publication options:** The following options control the way publications are sent to this subscriber. If altering an existing subscription using the SOALT option, these publication options can be changed.

### **SONOLC**

Tells the broker that the application does not want to see any of its own publications. Publications are considered to have originated from the same application if the connection handles are the same. On return from an MQSUB call using SORES this option is set if appropriate.

### **SONEWP**

No currently retained publications are to be sent, when this subscription is created, only new publications. This option only applies when SOCRE is specified. Any subsequent changes to a subscription do not alter the flow of publications and so any publications that have been retained on a topic, has already been sent to the subscriber as new publications.

If this option is specified without SOCRE it causes the call to fail with RC2046 . On return from an MQSUB call using SORES this option is not set even if the subscription was created using this option.

If this option is not used, previously retained messages are sent to the destination queue provided. If this action fails due to an error, either RC2525 or RC2526 , the creation of the subscription fails.

This option is not valid in combination with SOPUBR.

### **SOPUBR**

Setting this option indicates that the subscriber requests information specifically when required. The queue manager does not send unsolicited messages to the subscriber. The retained publication (or possibly multiple publications if a wildcard is specified in the topic) is sent to the subscriber each time an MQSUBRQ call is made using the Hsub handle from a previous MQSUB call. No publications are sent as a result of the MQSUB call using this option. On return from an MQSUB call using SORES this option is set if appropriate.

This option is not valid in combination with SONEWP.

**Wildcard options:** The following options control how wildcards are interpreted in the string provided in the *SDOS* field of the MQSD. You can specify only one of these options. If altering an existing subscription using the SOALT option, these wildcard options cannot be changed. On return from an MQSUB call using SORES the appropriate wildcard option is set.

### **SOWCHR**

Wildcards only operate on characters within the topic string. The SOWCHR field treats forward slash (/) as just another character with no special significance.

The behavior defined by SOWCHR is shown in the following table:

<i>Table 729. How wildcards are interpreted</i>	
<b>Special Character</b>	<b>Behavior</b>
*	Wildcard, zero or more characters
?	Wildcard, one character
%	Escape character to allow the characters '*', '?', or '%' to be used in a string and not be interpreted as a special character, for example, '%*', '%?' or '%%'.

For example, publishing on the following topic:

```
/level0/level1/level2/level3/level4
```

matches subscribers using the following topics:

```
*
/*
/ level0/level1/level2/level3/*
/ level0/level1/*/level3/level4
/ level0/level1/le?e12/level3/level4
```

**Note:** This use of wildcards supplies exactly the meaning provided in IBM MQ V6 and WebSphere MB V6 when using MQRFH1 formatted messages for Publish/Subscribe. It is recommended that this is not used for newly written applications and is only used for applications that were previously running against that version and have not been changed to use the default wildcard behavior as described in SOWTOP.

### **SOWTOP**

Wildcards only operate on topic elements within the topic string. This is the default behavior if none is chosen.

The behavior required by SOWTOP is shown in the following table:

<i>Table 730. How wildcards are interpreted</i>	
<b>Special Character</b>	<b>Behavior</b>
/	Topic level separator
#	Wildcard: multiple topic level
+	Wildcard: single topic level

### **Note:**

The '+' and '#' are not treated as wildcards if they are mixed in with other characters (including themselves) within a topic level. In the following string, the '#' and '+' characters are treated as ordinary characters.

```
level0/level1/#+/level3/level1#
```

For example, publishing on the following topic:

```
/level0/level1/level2/level3/level4
```

matches subscribers using the following topics:

```
#
/##
```

```
/ level0/level1/level2/level3/#  
/ level0/level1/+/level3/level4
```

**Note:** This use of wildcards supplies the meaning provided in WebSphere Message Broker 6 when using MQRFH2 formatted messages for Publish/Subscribe.

**Other options:** The following options control the way the API call is issued rather than the subscription. On return from an MQSUB call using SORES these options are unchanged.

#### SOALTU

The SDAU field contains a user identifier to use to validate this MQSUB call. The call can succeed only if this SDAU is authorized to open the object with the specified access options, regardless of whether the user identifier under which the application is running is authorized to do so.

#### SOSCID

The subscription is to use the correlation identifier supplied in the *SDCID* field. If this option is not specified, a correlation identifier is automatically created by the queue manager at subscription time and is returned to the application in the *SDCID* field. See [SDCID \(24-byte bit string\)](#)SDCID for more information.

#### SOSETI

The subscription is to use the accounting token and application identity data supplied in the *SDACC* and *SDAID* fields.

If this option is specified, the same authorization check is carried out as if the destination queue was accessed using an MQOPEN call with 00SETI, except in the case where the SOMAN option is also used in which case there is no authorization check on the destination queue.

If this option is not specified, the publications sent to this subscriber has default context information associated with them as follows:

Field in MQMD	Value used
<i>MDUID</i>	The user ID associated with the subscription at the time the subscription was made.
<i>MDACC</i>	Determined from the environment if possible; Set to ACNONE if not.
<i>MDAID</i>	Set to blanks

This option is only valid with SOCRE and SOALT. If used with SORES, the *SDACC* and *SDAID* fields are ignored, so this option has no effect.

If a subscription is altered without using this option where previously the subscription had supplied identity context information, default context information is generated for the altered subscription.

If a subscription allowing different user IDs to use it with option SOAUID, is resumed by a different user ID, default identity context is generated for the new user ID now owning the subscription and any subsequent publications are delivered containing the new identity context.

#### SOFIQ

The MQSUB call fails if the queue manager is in quiescing state. On z/OS, for a CICS or IMS application, this option also forces the MQSUB call to fail if the connection is in quiescing state.

#### SDAU (12 byte character string)

If you specify SOALTU, this field contains an alternate user identifier that is used to check the authorization for the subscription and for output to the destination queue (specified in the **Hobj**

parameter of the MQSUB call), in place of the user identifier that the application is currently running under.

If successful, the user identifier specified in this field is recorded as the subscription owning user identifier in place of the user identifier that the application is currently running under.

If SOALTU is specified and this field is entirely blank up to the first null character or the end of the field, the subscription can succeed only if no user authorization is must subscribe to this topic with the options specified or the destination queue for output.

If SOALTU is not specified, this field is ignored.

On return from an MQSUB call using SORES, this field is unchanged.

This is an input field. The length of this field is given by LNUID. The initial value of this field is 12 blank characters.

### **SDPRI (10 digit signed integer)**

This is the value that is in the *MQPRI* field of the Message Descriptor (MQMD) of all publication messages matching this subscription. For more information about the *MQPRI* field in the MQMD, see [MDPRI](#).

The value must be greater than or equal to zero; zero is the lowest priority. The following special values can also be used:

#### **PRQDEF**

When a subscription queue is provided in the *Hobj* field in the MQSUB call, and is not a managed handle, then the priority for the message is taken from the **DefPriority** attribute of this queue. If the queue so identified is a cluster queue or there is more than one definition in the queue-name resolution path then the priority is determined when the publication message is put to the queue as described for [MDPRI](#).

If the MQSUB call uses a managed handle, the priority for the message is taken from the **DefPriority** attribute of the model queue associated with the topic subscribed to.

#### **PRPUB**

The priority for the message is the priority of the original publication. This is the initial value of the field.

If altering an existing subscription using the SOALT option, the *MQPRI* of any future publication messages can be changed.

On return from an MQSUB call using SORES, this field is set to the current priority being used for the subscription.

### **SDRO (MQCHARV)**

SDRO is the long object name after the queue manager resolves the name provided in *SDON*.

If the long object name is provided in *SDOS* and nothing is provided in *SDON*, the value returned in this field is the same as provided in *SDOS*.

If this field is omitted (that is *SDRO.VSBufSize* is zero), the *SDRO* is not returned, but the length is returned in *SDRO.VSLength*. If the length is shorter than the full *SDRO*, it is truncated and returns as many of the rightmost characters as can fit in the provided length.

If *SDRO* is specified incorrectly, according to the description of how to use the [MQCHARV](#) structure, or if it exceeds the maximum length, the call fails with reason code RC2520 .

### **SDSID (4 byte character string)**

This is the structure identifier; the value must be:

#### **SDSIDV**

Identifier for Subscription Descriptor structure.

This is always an input field. The initial value of this field is SDSIDV

### **SDSL (10 digit signed integer)**

This is the level associated with the subscription. Publications are only delivered to this subscription if it is in the set of subscriptions with the highest *SDSL* value less than or equal to the *PubLevel* used at publication time.

The value must be in the range zero to 9. Zero is the lowest level.

The initial value of this field is 1.

If altering an existing subscription using the *SOALT* option, then *SDSL* cannot be changed.

### **SDSN (MQCHARV)**

*SDSN* specifies the subscription name.

This field is required only if *SDOPT* specifies the *SODUR* option, but if it is provided it is used by the queue manager for *SONDUR* as well. If specified, *SDSN* must be unique within the queue manager, because it is the field used to identify subscriptions.

The maximum length of *SDSN* is 10240.

This field serves two purposes. For a *SODUR* subscription, it is the means by which you identify a subscription to resume it after it has been created, if you have either closed the handle to the subscription (using the *COKPSB* option) or have been disconnected from the queue manager. Identifying a subscription to remove it after it has been created is done using the *MQSUB* call with the *SORES* option. The *SDSN* field is also displayed in the administration view of subscriptions in the *SDSN* field in *DISPLAY SBSTATUS*.

If *SDSN* is specified incorrectly, according to the description of how to use the *MQCHARV* structure, or if it exceeds the maximum length, or if it is omitted when it is required (that is *SDSN.VCHRL* is zero), or if it exceeds the maximum length, the call fails with reason code *RC2440*.

This is an input field. The initial values of the fields in this structure are the same as those in the *MQCHARV* structure.

If altering an existing subscription using the *SOALT* option, the subscription name cannot be changed, because it is the field used to identify the subscription. It is not changed on output from an *MQSUB* call with the *SORES* option.

### **SDSS (MQCHARV)**

*SDSS* is the string that provides the selection criteria used when subscribing for messages from a topic.

This variable length field is returned on output from an *MQSUB* call using the *SORES* option, if a buffer is provided, and if there is also a positive buffer length in *VSBufSize*. If no buffer is provided on the call, only the length of the selection string is returned in the *VSLength* field of the *MQCHARV*. If the buffer provided is smaller than the space required to return the field, only *VSBufSize* bytes are returned in the provided buffer.

If *SDSS* is specified incorrectly, according to the description of how to use the *MQCHARV* structure, or if it exceeds the maximum length, the call fails with reason code *RC2519*.

### **SDSUD (MQCHARV)**

The data provided on the subscription in this field is included as the *mq.SubUserData* message property of every publication sent to this subscription.

The maximum length of *SDSUD* is 10240.

If *SDSUD* is specified incorrectly, according to the description of how to use the *MQCHARV* structure, or if it exceeds the maximum length, the call fails with reason code *RC2431*.

This is an input field. The initial values of the fields in this structure are the same as those in the *MQCHARV* structure.

If altering an existing subscription using the *SOALT* option, the subscription user data can be changed.

This variable length field is returned on output from an MQSUB call using the SORES option, if a buffer is provided and there is a positive buffer length in *VSBuflen*. If no buffer is provided on the call, only the length of the subscription user data is returned in the *VCHRL* field of the MQCHARV. If the buffer provided is smaller than the space required to return the field, only *VSBuflen* bytes are returned in the provided buffer.

**SDVER (10 digit signed integer)**

This is the structure version number; the value must be:

**SDVER1**

Version-1 Subscription Descriptor structure.

The following constant specifies the version number of the current version:

**SDVERC**

Current version of Subscription Descriptor structure.

This is always an input field. The initial value of the field is SDVER1.

**Initial values**

<i>Table 732. Fields in MQSD</i>		
<b>Field name</b>	<b>Name of constant</b>	<b>Value of constant</b>
<i>SDSID</i>	SDSIDV	'SD↵↵'
<i>SDVER</i>	SDVER1	1
<i>SDOPT</i>	SONDUR	0
<i>SDON</i>	None	Blanks
<i>SDAU</i>	None	Blanks
<i>SDASI</i>	SINONE	Nulls
<i>SDEXP</i>	EIULIM	-1
<i>SDOS</i>	Names and values as defined for MQCHARV

## MQSMPO (Set message property options) on IBM i

The **MQSMPO** structure allows applications to specify options that control how properties of messages are set.

### Overview

**Purpose:** The structure is an input parameter on the **MQSETMP** call.

**Character set and encoding:** Data in **MQSMPO** must be in the character set of the application and encoding of the application (ENNAT).

- [“Fields” on page 1227](#)
- [“Initial values” on page 1228](#)

- [“RPG declaration” on page 1228](#)

## Fields

The MQSMPO structure contains the following fields; the fields are described in **alphabetical order**:

### **SPOPT (10-digit signed integer)**

**Location options:** The following options relate to the relative location of the property compared to the property cursor:

#### **SPSETF**

Sets the value of the first property that matches the specified name, or if it does not exist, adds a new property after all other properties with a matching hierarchy.

#### **SPSETC**

Sets the value of the property pointed to by the property cursor. The property pointed to by the property cursor is the one that was last inquired using either the IPINQF or the IPINQN option.

The property cursor is reset when the message handle is reused, or when the message handle is specified in the *HMSG* field of the MQGMO structure on an MQGET call or the MQPMO structure on an MQPUT call.

If this option is used when the property cursor has not yet been established or if the property pointed to by the property cursor has been deleted, the call fails with completion code CCFAIL and reason code RC2471.

#### **SPSETA**

Sets a new property after the property pointed to by the property cursor. The property pointed to by the property cursor is the one that was last inquired using either the IPINQF or the IPINQO option.

The property cursor is reset when the message handle is reused, or when the message handle is specified in the *HMSG* field of the MQGMO structure on an MQGET call or the MQPMO structure on an MQPUT call.

If this option is used when the property cursor has not yet been established or if the property pointed to by the property cursor has been deleted, the call fails with completion code CCFAIL and reason code RC2471.

If you need none of the options described, use the following option:

#### **SPNONE**

No options specified.

This is always an input field. The initial value of this field is SPSETF.

### **SPSID (10-digit signed integer)**

This is the structure identifier; the value must be:

#### **SPSIDV**

Identifier for set message property options structure.

This is always an input field. The initial value of this field is **SPSIDV**.

### **SPVAKCSI (10-digit signed integer)**

The character set of the property value to be set if the value is a character string.

This is always an input field. The initial value of this field is **CSAPL**.

### **SPVALENC (10-digit signed integer)**

The encoding of the property value to be set if the value is numeric.

This is always an input field. The initial value of this field is **ENNAT**.

## SPVER (10-digit signed integer)

This is the structure version number; the value must be:

### SPVER1

Version-1 set message property options structure.

The following constant specifies the version number of the current version:

### SPVERC

Current version of set message property options structure.

This is always an input field. The initial value of this field is **SPVER1**.

## Initial values

Field name	Name of constant	Value of constant
SPSID	SPSIDV	'SMPO'
SPVER	SPVER1	1
SPOPT	SPNONE	0
SPVALENC	ENNAT	Depends on environment
SPVALCSI	CSAPL	-3

## IBM i MQSRO (Subscription Request Options) on IBM i

The MQSRO structure allows the application to specify options that control how a subscription request is made.

### Overview

**Purpose:** The structure is an input/output parameter on the MQSUBRQ call.

**Version:** The current version of MQSRO is SRVER1.

- [“Fields” on page 1229](#)
- [“Initial values” on page 1229](#)
- [“RPG declaration” on page 1230](#)

## Fields

The MQSRO structure contains the following fields; the fields are described in **alphabetical order**:

### SRNMP (10-digit signed integer)

This is an output field, returned to the application to indicate the number of publications sent to the subscription queue as a result of this call. Although this number of publications have been sent as a result of this call, there is no guarantee that this many messages will be available for the application to get, especially if they are non-persistent messages.

There may be more than one publication if the topic subscribed to, contained a wildcard. If no wildcards were present in the topic string when the subscription represented by *HSUB* was created, then at most one publication is sent as a result of this call.

### SROPT (10-digit signed integer)

One of the following options must be specified. Only one option can be specified.

**Other options:** The following option controls what happens when the queue manager is quiescing:

#### SRFIQ

The MQSUBRQ call fails if the queue manager is in the quiescing state.

**Default option:** If the option described previously is not required, the following option must be used:

#### SRNONE

Use this value to indicate that no other options have been specified; all options assume their default values.

SRNONE helps program documentation. Although it is not intended that this option be used with any other, because its value is zero, this use cannot be detected.

### SRSID (4-byte character string)

This is the structure identifier; the value must be:

#### SRSIDV

Identifier for Subscription Request SROPT structure.

This is always an input field. The initial value of this field is SRSIDV.

### SRVER (10-digit signed integer)

This is the structure version number; the value must be:

#### SRVER1

Version-1 Subscription Request Options structure.

The following constant specifies the version number of the current version:

#### SRVERC

Current version of Subscription Request Options structure.

This is always an input field. The initial value of this field is SRVER1.

## Initial values

Field name	Name of constant	Value of constant
SRSID	SRSIDV	'SRO~'
SRVER	SRVER1	1
SROPT	SRNONE	0
SRNMP	None	0

Table 734. Fields in MQSRO (continued)

Field name	Name of constant	Value of constant
<b>Notes:</b>		
1. The symbol ~ represents a single blank character.		
2. The value Null string or blanks denotes the null string in C, and blank characters in other programming languages.

```

## MQSTS (Status reporting structure) on IBM i

The MQSTS structure describes the data in the status structure returned by the MQSTAT command.

### Overview

**Character set and encoding:** Character data in MQSTS is in the character set of the local queue manager; this is given by the *CodedCharSetId* queue manager attribute. Numeric data in MQSTS is in the native machine encoding; this is given by *ENNAT*.

**Usage:** The MQSTAT command is used to retrieve status information. This information is returned in an MQSTS structure. For information about MQSTAT, see [“MQSTAT \(Retrieve status information\) on IBM i” on page 1356](#).

- [“Fields” on page 1230](#)
- [“Initial values” on page 1233](#)
- [“RPG declaration” on page 1234](#)

### Fields

The MQSTS structure contains the following fields; the fields are described in **alphabetical order**:

#### STSCC (10-digit signed integer)

This is the completion code resulting from the first error reported in the MQSTS structure.

This is always an output field. The initial value of this field is CCOK.

#### STSFC (10-digit signed integer)

This is the number of asynchronous put calls that failed.

This is an output field. The initial value of this field is 0.

#### STSOBJN (48-byte character string)

This is the local name of the object involved in the first failure.

This is an output field. The initial value of this field is 48 blank characters.

### **STSOQMGR (48-byte character string)**

This is the name of the queue manager on which the *STSOBJN* object is defined. A name that is entirely blank up to the first null character or the end of the field denotes the queue manager to which the application is connected (the local queue manager).

This is an output field. The initial value of this field is 48 blank characters.

### **STS00 (10-digit signed integer)**

The STS00 used to open the object being reported upon. Present only in version 2 of MQSTS or higher.

The value of STS00 depends on the value of the MQSTAT **STYPE** parameter.

#### **STATAPT**

Zero.

#### **STATREC**

Zero.

#### **STATRER**

The STS00 used when the failure occurred. The reason for the failure is reported in the *STSCC* and *STSRC* fields in the MQSTS structure.

STS00 is an output field. Its initial value is zero.

### **STSOS (MQCHARV)**

Long object name of failing object being reported on. Present only in version 2 of MQSTS or higher.

STSOS is a MQCHARV field with a maximum length of 10240. See [MQCHARV](#) for a description of how to use the MQCHARV structure.

The interpretation of STSOS depends on the value of the MQSTAT **STYPE** parameter.

#### **STATAPT**

This is the long object name of the queue or topic used in the MQPUT operation, which failed.

#### **STATREC**

Zero length string

#### **STATRER**

This is the long object name of the object that caused the reconnection to fail.

STSOS is an output field. Its initial value is a zero length string.

### **STSOT (10-digit signed integer)**

The type of object being named in *ObjectName*. Possible values are:

#### **OTALSQ**

Alias queue.

#### **OTLOCQ**

Local queue.

#### **OTMODQ**

Model queue.

#### **OTQ**

Queue.

#### **OTREMQ**

Remote queue.

#### **OTTOP**

Topic.

This is always an output field. The initial value of this field is OTQ.

### **STSRC (10-digit signed integer)**

This is the reason code resulting from the first error reported in the MQSTS structure

This is always an output field. The initial value of this field is RCNONE.

### **STSRBJN (48-byte character string)**

This is the name of the destination queue named in *STSRBJN* after the local queue manager resolves the name. The name returned is the name of a queue that exists on the queue manager identified by *STSRQMGR*.

A nonblank value is returned only if the object is a single queue opened for browse, input, or output (or any combination). If the object opened is any of the following, *STSRBJN* is set to blanks:

- A topic
- A queue, but not opened for browse, input, or output

This is an output field. The initial value of this field is 48 blank characters.

### **STSRQMGR (48-byte character string)**

This is the name of the destination queue manager after the local queue manager resolves the name. The name returned is the name of the queue manager that owns the queue identified by *STSRBJN*. *STSRQMGR* can be the name of the local queue manager.

If *STSRBJN* is a shared queue that is owned by the queue sharing group to which the local queue manager belongs, *STSRQMGR* is the name of the queue sharing group. If the queue is owned by some other queue sharing group, *STSRBJN* can be the name of the queue sharing group or the name of a queue manager that is a member of the queue sharing group (the nature of the value returned is determined by the queue definitions that exist at the local queue manager).

A nonblank value is returned only if the object is a single queue opened for browse, input, or output (or any combination). If the object opened is any of the following, *STSRQMGR* is set to blanks:

- A topic
- A queue, but not opened for browse, input, or output
- A cluster queue with OOBNDN specified (or with OOBNDQ in effect when the **DefBind** queue attribute has the value OOBNDN)

This is an output field. The initial value of this field is 48 blank characters.

### **STSSC (10-digit signed integer)**

This is the number of asynchronous put calls that succeeded.

This is an output field. The initial value of this field is 0.

### **STSSID (4-byte character string)**

This is the structure identifier. The value must be:

#### **STSSID**

Identifier for status reporting structure.

The initial value of this field is STSSID.

### **STSSO (10 digit signed integer)**

The STSSO used to open the failing subscription. Present only in version 2 of MQSTS or higher.

The interpretation of STSSO depends on the value of the MQSTAT **STYPE** parameter.

#### **STATAPT**

Zero.

#### **STATREC**

Zero.

## STATRER

The STSS0 used when the failure occurred. The reason for the failure is reported in the STSCC and STSRC fields in the MQSTS structure. If the failure is not related to subscribing to a topic, the value returned is zero.

STSS0 is an output field. Its initial value is zero.

## STSSUN (MQCHARV)

The name of the failing subscription. Present only in version 2 of MQSTS or higher.

STSSUN is a MQCHARV field with a maximum length of 10240. See [MQCHARV](#) for a description of how to use the MQCHARV structure.

The interpretation of STSSUN depends on the value of the MQSTAT **STYPE** parameter.

## STATAPT

Zero length string.

## STATREC

Zero length string.

## STATRER

The name of the subscription that caused reconnection to fail. If no subscription name is available, or the failure is not related to a subscription, this is a zero-length string.

STSSUN is an output field. Its initial value is a zero length string.

## STSVR (10-digit signed integer)

This is the structure version number. The value must be:

### STSVR1

Version number for status reporting structure.

The following constant specifies the version number of the current version:

### STSVRC

Current version of status reporting structure.

The initial value of this field is STSVR1.

## STSWC (10-digit signed integer)

This is the number of asynchronous put calls that completed with a warning.

This is an output field. The initial value of this field is 0.

## Initial values

Field name	Name of constant	Value of constant
STSSID	STSID	
STSVR	STSVRC	STSVR1
STSCC	CCOK	0
STSRC	RCNONE	0

## MQTM - Trigger message

The MQTM structure describes the data in the trigger message that is sent by the queue manager to a trigger-monitor application when a trigger event occurs for a queue.

### Overview

**Purpose:** This structure is part of the IBM MQ Trigger Monitor Interface (TMI), which is one of the IBM MQ framework interfaces.

**Format name:** FMTM.

**Character set and encoding:** Character data in MQTM is in the character set of the queue manager that generates the MQTM. Numeric data in MQTM is in the machine encoding of the queue manager that generates the MQTM.

The character set and encoding of the MQTM are given by the *MDCSI* and *MDENC* fields in:

- The MQMD (if the MQTM structure is at the start of the message data), or
- The header structure that precedes the MQTM structure (all other cases).

**Usage:** A trigger-monitor application may need to pass some or all of the information in the trigger message to the application which is started by the trigger-monitor application. Information which may be needed by the started application includes *TMQN*, *TMTD*, and *TMUD*. The trigger-monitor application can pass the MQTM structure directly to the started application, or pass an MQTMC2 structure instead, depending on what is permitted by the environment and convenient for the started application. For information about MQTMC2, see [“MQTMC2 \(Trigger message 2 - character format\) on IBM i” on page 1239](#).

- On IBM i, the trigger-monitor application provided with IBM MQ passes an MQTMC2 structure to the started application.

For information about triggers, see [Prerequisites for triggering](#).

- [“MQMD for a trigger message” on page 1235](#)
- [“Fields” on page 1236](#)
- [“Initial values” on page 1238](#)
- [“RPG declaration” on page 1239](#)

### MQMD for a trigger message

Table 736. Settings for the fields in the MQMD of a trigger message generated by the queue manager

Field in MQMD	Value used
<i>MDSID</i>	MDSIDV
<i>MDVER</i>	MDVER1
<i>MDREP</i>	RONONE
<i>MDMT</i>	MTDGRM
<i>MDEXP</i>	EIULIM
<i>MDFB</i>	FBNONE
<i>MDENC</i>	ENNAT
<i>MDCSI</i>	Queue manager's <b>CodedCharSetId</b> attribute

Table 736. Settings for the fields in the MQMD of a trigger message generated by the queue manager (continued)

Field in MQMD	Value used
<i>MDFMT</i>	FMTM
<i>MDPRI</i>	Initiation queue's <b>DefPriority</b> attribute
<i>MDPER</i>	PENPER
<i>MDMID</i>	A unique value
<i>MDCID</i>	CINONE
<i>MDBOC</i>	0
<i>MDRQ</i>	Blanks
<i>MDRM</i>	Name of queue manager
<i>MDUID</i>	Blanks
<i>MDACC</i>	ACNONE
<i>MDAID</i>	Blanks
<i>MDPAT</i>	ATQM, or as appropriate for the message channel agent
<i>MDPAN</i>	First 28 bytes of the queue manager name
<i>MDPD</i>	Date when trigger message is sent
<i>MDPT</i>	Time when trigger message is sent
<i>MDAOD</i>	Blanks

An application that generates a trigger message is recommended to set similar values, except for the following:

- The *MDPRI* field can be set to PRQDEF (the queue manager will change this to the default priority for the initiation queue when the message is put).
- The *MDRM* field can be set to blanks (the queue manager will change this to the name of the local queue manager when the message is put).
- The context fields should be set as appropriate for the application.

## Fields

The MQTM structure contains the following fields; the fields are described in **alphabetical order**:

### TMAI (256-byte character string)

Application identifier.

This is a character string that identifies the application to be started, and is used by the trigger-monitor application that receives the trigger message. The queue manager initializes this field with the value of the **AppId** attribute of the process object identified by the *TMPN* field; see [“Attributes for process definitions on IBM i” on page 1395](#) for details of this attribute. The content of this data is of no significance to the queue manager.

The meaning of *TMAI* is determined by the trigger-monitor application. The trigger monitor provided by IBM MQ requires *TMAI* to be the name of an executable program.

The length of this field is given by LNPROA. The initial value of this field is 256 blank characters.

### TMAT (10-digit signed integer)

Application type.

This identifies the nature of the program to be started, and is used by the trigger-monitor application that receives the trigger message. The queue manager initializes this field with the value of the **App1Type** attribute of the process object identified by the *TMPN* field; see [“Attributes for process definitions on IBM i” on page 1395](#) for details of this attribute. The content of this data is of no significance to the queue manager.

*TMAT* can have one of the following standard values. User-defined types can also be used, but should be restricted to values in the range ATUFST through ATULST:

**ATCICS**

CICS transaction.

**ATVSE**

CICS/VSE transaction.

**AT400**

IBM i application.

**ATUFST**

Lowest value for user-defined application type.

**ATULST**

Highest value for user-defined application type.

The initial value of this field is 0.

**TMED (128-byte character string)**

Environment data.

This is a character string that contains environment-related information pertaining to the application to be started, and is used by the trigger-monitor application that receives the trigger message. The queue manager initializes this field with the value of the **EnvData** attribute of the process object identified by the *TMPN* field; see [“Attributes for process definitions on IBM i” on page 1395](#) for details of this attribute. The content of this data is of no significance to the queue manager.

The length of this field is given by LNPROE. The initial value of this field is 128 blank characters.

**TMPN (48-byte character string)**

Name of process object.

This is the name of the queue manager process object specified for the triggered queue, and can be used by the trigger-monitor application that receives the trigger message. The queue manager initializes this field with the value of the **ProcessName** attribute of the queue identified by the *TMQN* field; see [“Attributes for queues” on page 1366](#) for details of this attribute.

Names that are shorter than the defined length of the field are always padded to the right with blanks; they are not ended prematurely by a null character.

The length of this field is given by LNPRON. The initial value of this field is 48 blank characters.

**TMQN (48-byte character string)**

Name of triggered queue.

This is the name of the queue for which a trigger event occurred, and is used by the application started by the trigger-monitor application. The queue manager initializes this field with the value of the **QName** attribute of the triggered queue; see [“Attributes for queues” on page 1366](#) for details of this attribute.

Names that are shorter than the defined length of the field are padded to the right with blanks; they are not ended prematurely by a null character.

The length of this field is given by LNQN. The initial value of this field is 48 blank characters.

### TMSID (4-byte character string)

Structure identifier.

The value must be:

#### TMSIDV

Identifier for trigger message structure.

The initial value of this field is TMSIDV.

### TMTD (64-byte character string)

Trigger data.

This is free-format data for use by the trigger-monitor application that receives the trigger message. The queue manager initializes this field with the value of the **TriggerData** attribute of the queue identified by the *TMQN* field; see “Attributes for queues” on page 1366 for details of this attribute. The content of this data is of no significance to the queue manager.

The length of this field is given by LNTRGD. The initial value of this field is 64 blank characters.

### TMUD (128-byte character string)

User data.

This is a character string that contains user information relevant to the application to be started, and is used by the trigger-monitor application that receives the trigger message. The queue manager initializes this field with the value of the **UserData** attribute of the process object identified by the *TMPN* field; see “Attributes for process definitions on IBM i” on page 1395 for details of this attribute. The content of this data is of no significance to the queue manager.

The length of this field is given by LNPROU. The initial value of this field is 128 blank characters.

### TMVER (10-digit signed integer)

Structure version number.

The value must be:

#### TMVER1

Version number for trigger message structure.

The following constant specifies the version number of the current version:

#### TMVERC

Current version of trigger message structure.

The initial value of this field is TMVER1.

## Initial values

Field name	Name of constant	Value of constant
<i>TMSID</i>	TMSIDV	'TMSIDV'
<i>TMVER</i>	TMVER1	1

## MQTMC2 (Trigger message 2 - character format) on IBM i

When a trigger-monitor application retrieves a trigger message (MQTM) from an initiation queue, the trigger monitor might need to pass some or all of the information in the trigger message to the application that is started by the trigger monitor.

### Overview

**Purpose:** Information that may be needed by the started application includes *TC2QN*, *TC2TD*, and *TC2UD*. The trigger monitor application can pass the MQTM structure directly to the started application, or pass an MQTMC2 structure instead, depending on what is permitted by the environment and convenient for the started application.

This structure is part of the IBM MQ Trigger Monitor Interface (TMI), which is one of the IBM MQ framework interfaces.

**Character set and encoding:** Character data in MQTMC2 is in the character set of the local queue manager; this is given by the **CodedCharSetId** queue manager attribute.

**Usage:** The MQTMC2 structure is like the format of the MQTM structure. The difference is that the non-character fields in MQTM are changed in MQTMC2 to character fields of the same length, and the queue manager name is added at the end of the structure.

- On IBM i, the trigger monitor application provided with IBM MQ passes an MQTMC2 structure to the started application.
- [“Fields” on page 1240](#)
- [“Initial values” on page 1241](#)
- [“RPG declaration” on page 1241](#)

## Fields

The MQTMC2 structure contains the following fields; the fields are described in **alphabetical order**:

### **TC2AI (256-byte character string)**

Application identifier.

See the *TMAI* field in the MQTM structure.

### **TC2AT (4-byte character string)**

Application type.

This field always contains blanks, whatever the value in the *TMAT* field in the MQTM structure of the original trigger message.

### **TC2ED (128-byte character string)**

Environment data.

See the *TMED* field in the MQTM structure.

### **TC2PN (48-byte character string)**

Name of process object.

See the *TMPN* field in the MQTM structure.

### **TC2QMN (48-byte character string)**

Queue manager name.

This is the name of the queue manager at which the trigger event occurred.

### **TC2QN (48-byte character string)**

Name of triggered queue.

See the *TMQN* field in the MQTM structure.

### **TC2SID (4-byte character string)**

Structure identifier.

The value must be:

#### **TCSIDV**

Identifier for trigger message (character format) structure.

### **TC2TD (64-byte character string)**

Trigger data.

See the *TMTD* field in the MQTM structure.

### **TC2UD (128-byte character string)**

User data.

See the *TMUD* field in the MQTM structure.

### **TC2VER (4-byte character string)**

Structure version number.

The value must be:

#### **TCVER2**

Version 2 trigger message (character format) structure.

The following constant specifies the version number of the current version:

#### **TCVERC**

Current version of trigger message (character format) structure.

## Initial values

## IBM i MQWIH (Work information header) on IBM i

The MQWIH structure describes the information that must be present at the start of a message that is to be handled by the z/OS workload manager.

### Overview

**Format name:** FMWIH.

**Character set and encoding:** The fields in the MQWIH structure are in the character set and encoding given by the *MDCSI* and *MDENC* fields in the header structure that precedes MQWIH, or by those fields in the MQMD structure if the MQWIH is at the start of the application message data.

The character set must be one that has single-byte characters for the characters that are valid in queue names.

**Usage:** If a message is to be processed by the z/OS workload manager, the message must begin with an MQWIH structure.

- [“Fields” on page 1242](#)
- [“Initial values” on page 1244](#)
- [“RPG declaration” on page 1244](#)

## Fields

The MQWIH structure contains the following fields; the fields are described in **alphabetical order**:

### WICSI (10-digit signed integer)

Character-set identifier of data that follows MQWIH.

This specifies the character set identifier of the data that follows the MQWIH structure; it does not apply to character data in the MQWIH structure itself.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The following special value can be used:

#### CSINHT

Inherit character-set identifier of this structure.

Character data in the data *following* this structure is in the same character set as this structure.

The queue manager changes this value in the structure sent in the message to the actual character-set identifier of the structure. Provided no error occurs, the value CSINHT is not returned by the MQGET call.

CSINHT cannot be used if the value of the *MDPAT* field in MQMD is ATBRKR.

The initial value of this field is CSUNDF.

### WIENC (10-digit signed integer)

Numeric encoding of data that follows MQWIH.

This specifies the numeric encoding of the data that follows the MQWIH structure; it does not apply to numeric data in the MQWIH structure itself.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data.

The initial value of this field is 0.

### WIFLG (10-digit signed integer)

Flags

The value must be:

#### WINONE

No flags.

The initial value of this field is WINONE.

### WIFMT (8-byte character string)

Format name of data that follows MQWIH.

This specifies the format name of the data that follows the MQWIH structure.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The rules for coding this field are the same as those for the *MDFMT* field in MQMD.

The length of this field is given by LNFMT. The initial value of this field is FMNONE.

**WILEN (10-digit signed integer)**

Length of MQWIH structure.

The value must be:

**WILEN1**

Length of version-1 work information header structure.

The following constant specifies the length of the current version:

**WILENC**

Length of current version of work information header structure.

The initial value of this field is WILEN1.

**WIRSV (32-byte character string)**

Reserved.

This is a reserved field; it must be blank.

**WISID (4-byte character string)**

Structure identifier.

The value must be:

**WISIDV**

Identifier for work information header structure.

The initial value of this field is WISIDV.

**WISNM (32-byte character string)**

Service name.

This is the name of the service that is to process the message.

The length of this field is given by LNSVNM. The initial value of this field is 32 blank characters.

**WISST (8-byte character string)**

Service step name.

This is the name of the step of *WISNM* to which the message relates.

The length of this field is given by LNSVST. The initial value of this field is 8 blank characters.

**WITOK (16-byte bit string)**

Message token.

This is a message token that uniquely identifies the message.

For the MQPUT and MQPUT1 calls, this field is ignored. The length of this field is given by LNMTOK.

The initial value of this field is MTKNON.

**WIVER (10-digit signed integer)**

Structure version number.

The value must be:

**WIVER1**

Version-1 work information header structure.

The following constant specifies the version number of the current version:

**WIVERC**

Current version of work information header structure.

The initial value of this field is WIVER1.

## Initial values

```

The MQXQH structure describes the information that is prefixed to the application message data of messages when they are on transmission queues.

## Overview

**Purpose:** A transmission queue is a special type of local queue that temporarily holds messages destined for remote queues (that is, destined for queues that do not belong to the local queue manager). A transmission queue is denoted by the **Usage** queue attribute having the value USTRAN.

**Format name:** FMXQH.

**Character set and encoding:** Data in MQXQH must be in the character set given by the **CodedCharSetId** queue manager attribute and encoding of the local queue manager given by ENNAT for the C programming language.

The character set and encoding of the MQXQH must be set into the *MDCSI* and *MDENC* fields in:

- The separate MQMD (if the MQXQH structure is at the start of the message data), or
- The header structure that precedes the MQXQH structure (all other cases).

**Usage:** A message that is on a transmission queue has *two* message descriptors:

- One message descriptor is stored separately from the message data; this is called the *separate message descriptor*, and is generated by the queue manager when the message is placed on the transmission queue. Some of the fields in the separate message descriptor are copied from the message descriptor provided by the application on the MQPUT or MQPUT1 call.

The separate message descriptor is the one that is returned to the application in the **MSGDSC** parameter of the MQGET call when the message is removed from the transmission queue.

- A second message descriptor is stored within the MQXQH structure as part of the message data; this is called the *embedded message descriptor*, and is a copy of the message descriptor that was provided by the application on the MQPUT or MQPUT1 call (with minor variations).

The embedded message descriptor is always a version-1 MQMD. If the message put by the application has nondefault values for one or more of the version-2 fields in the MQMD, an MQMDE structure follows the MQXQH, and is in turn followed by the application message data (if any). The MQMDE is either:

- Generated by the queue manager (if the application uses a version-2 MQMD to put the message), or
- Already present at the start of the application message data (if the application uses a version-1 MQMD to put the message).

The embedded message descriptor is the one that is returned to the application in the **MSGDSC** parameter of the MQGET call when the message is removed from the final destination queue.

- [“RPG declaration” on page 1249](#)

## Fields in the separate message descriptor

The fields in the separate message descriptor are set by the queue manager as shown in the following list. If the queue manager does not support the version-2 MQMD, a version-1 MQMD is used without loss of function.

Table 740. Fields in the separate message descriptor and values used

Field in separate MQMD	Value used
<i>MDSID</i>	MDSIDV
<i>MDVER</i>	MDVER2
<i>MDREP</i>	Copied from the embedded message descriptor, but with the bits identified by ROAUXM set to zero. (This prevents a COA or COD report message being generated when a message is placed on or removed from a transmission queue.)
<i>MDMT</i>	Copied from the embedded message descriptor.
<i>MDEXP</i>	Copied from the embedded message descriptor.
<i>MDFB</i>	Copied from the embedded message descriptor.
<i>MDENC</i>	ENNAT
<i>MDCSI</i>	Queue manager's <b>CodedCharSetId</b> attribute.
<i>MDFMT</i>	FMXQH
<i>MDPRI</i>	Copied from the embedded message descriptor.
<i>MDPER</i>	Copied from the embedded message descriptor.
<i>MDMID</i>	A new value is generated by the queue manager. This message identifier is different from the <i>MDMID</i> that the queue manager may have generated for the embedded message descriptor (see described previously).
<i>MDCID</i>	The <i>MDMID</i> from the embedded message descriptor.
<i>MDBOC</i>	0
<i>MDRQ</i>	Copied from the embedded message descriptor.
<i>MDRM</i>	Copied from the embedded message descriptor.
<i>MDUID</i>	Copied from the embedded message descriptor.
<i>MDACC</i>	Copied from the embedded message descriptor.
<i>MDAID</i>	Copied from the embedded message descriptor.
<i>MDPAT</i>	ATQM
<i>MDPAN</i>	First 28 bytes of the queue manager name.
<i>MDPD</i>	Date when message was put on transmission queue.
<i>MDPT</i>	Time when message was put on transmission queue.
<i>MDAOD</i>	Blanks
<i>MDGID</i>	GINONE
<i>MDSEQ</i>	1
<i>MDOFF</i>	0
<i>MDMFL</i>	MFNONE
<i>MDOLN</i>	OLUNDF

### Fields in the embedded message descriptor

The fields in the embedded message descriptor have the same values as those in the **MSGDSC** parameter of the MQPUT or MQPUT1 call, except for the following:

- The *MDVER* field always has the value MDVER1.
- If the *MDPRI* field has the value PRQDEF, it is replaced by the value of the queue's **DefPriority** attribute.
- If the *MDPER* field has the value PEQDEF, it is replaced by the value of the queue's **DefPersistence** attribute.
- If the *MDMID* field has the value MINONE, or the PMNMID option was specified, or the message is a distribution-list message, *MDMID* is replaced by a new message identifier generated by the queue manager.

When a distribution-list message is split into smaller distribution-list messages placed on different transmission queues, the *MDMID* field in each of the new embedded message descriptors is the same as that in the original distribution-list message.

- If the PMNCID option was specified, *MDCID* is replaced by a new correlation identifier generated by the queue manager.
- The context fields are set as indicated by the PM\* options specified in the **PMO** parameter; the context fields are:
  - *MDACC*
  - *MDAID*
  - *MDAOD*
  - *MDPAN*
  - *MDPAT*
  - *MDPD*
  - *MDPT*
  - *MDUID*
- The version-2 fields (if they were present) are removed from the MQMD, and moved into an MQMDE structure, if one or more of the version-2 fields has a nondefault value.

## Putting messages on remote queues

: When an application puts a message on a remote queue (either by specifying the name of the remote queue directly, or by using a local definition of the remote queue), the local queue manager:

- Creates an MQXQH structure containing the embedded message descriptor
- Appends an MQMDE if one is needed and is not already present
- Appends the application message data
- Places the message on an appropriate transmission queue

## Putting messages directly on transmission queues

It is also possible for an application to put a message directly on a transmission queue. In this case the application must prefix the application message data with an MQXQH structure, and initialize the fields with appropriate values. In addition, the *MDFMT* field in the **MSGDSC** parameter of the MQPUT or MQPUT1 call must have the value FMXQH.

Character data in the MQXQH structure created by the application must be in the character set of the local queue manager (defined by the **CodedCharSetId** queue manager attribute), and integer data must be in the native machine encoding. In addition, character data in the MQXQH structure must be padded with blanks to the defined length of the field; the data must not be ended prematurely by using a null character, because the queue manager does not convert the null and subsequent characters to blanks in the MQXQH structure.

Note however that the queue manager does not check that an MQXQH structure is present, or that valid values have been specified for the fields.

## Getting messages from transmission queues

Applications that get messages from a transmission queue must process the information in the MQXQH structure in an appropriate fashion. The presence of the MQXQH structure at the beginning of the application message data is indicated by the value FMXQH being returned in the *MDFMT* field in the **MSGDSC** parameter of the MQGET call. The values returned in the *MDCSI* and *MDENC* fields in the **MSGDSC** parameter, indicates the character set and encoding of the character and integer data in the MQXQH structure. The character set and encoding of the application message data are defined by the *MDCSI* and *MDENC* fields in the embedded message descriptor.

### Fields

The MQXQH structure contains the following fields; the fields are described in **alphabetical order**:

#### **XQMD (MQMD1)**

Original message descriptor.

This is the embedded message descriptor, and is a close copy of the message descriptor MQMD that was specified as the **MSGDSC** parameter on the MQPUT or MQPUT1 call when the message was originally put to the remote queue.

**Note:** This is a version-1 MQMD.

The initial values of the fields in this structure are the same as those in the MQMD structure.

#### **XQRQ (48-byte character string)**

Name of destination queue.

This is the name of the message queue that is the apparent eventual destination for the message (this may prove not to be the actual eventual destination if, for example, this queue is defined at *XQRQM* to be a local definition of another remote queue).

If the message is a distribution-list message (that is, the *MDFMT* field in the embedded message descriptor is FMDH), *XQRQ* is blank.

The length of this field is given by LNQN. The initial value of this field is 48 blank characters.

#### **XQRQM (48-byte character string)**

Name of destination queue manager.

This is the name of the queue manager or queue sharing group that owns the queue that is the apparent eventual destination for the message.

If the message is a distribution-list message, *XQRQM* is blank.

The length of this field is given by LNQM. The initial value of this field is 48 blank characters.

#### **XQSID (4-byte character string)**

Structure identifier.

The value must be:

##### **XQSIDV**

Identifier for transmission-queue header structure.

The initial value of this field is XQSIDV.

#### **XQVER (10-digit signed integer)**

Structure version number.

The value must be:

##### **XQVER1**

Version number for transmission-queue header structure.

The following constant specifies the version number of the current version:

## XQVERC

Current version of transmission-queue header structure.

The initial value of this field is XQVER1.

## Initial values

Field name	Name of constant	Value of constant
XQSID	XQSIDV	'XQH~'
XQVER	XQVER1	1
XQRQ	None	Blanks
XQRQM	None	Blanks
XQMD	Same names and values as MQMD; see Table 709 on page 1151	-

**Notes:**

1. The symbol ~ represents a single blank character.

## IBM i **Function calls on IBM i**

Use this information to learn about the function calls available in IBM i programming.

### **Conventions used in the call descriptions on IBM i**

For each call, this collection of topics gives a description of the parameters and usage of the call. This is followed by typical invocations of the call, and typical declarations of its parameters, in the RPG programming language.

**Important:** When coding IBM MQ API calls you must ensure that all relevant parameters (as described in the following sections) are provided. Failure to do so can produce unpredictable results.

The description of each call contains the following sections:

#### **Call name**

The call name, followed by a brief description of the purpose of the call.

#### **Parameters**

For each parameter, the name is followed by its data type in parentheses ( ) and its direction; for example:

*CMPCOD* (9-digit decimal integer) - output

There is more information about the structure data types in [“Elementary data types” on page 998](#).

The direction of the parameter can be:

#### **Input**

You (the programmer) must provide this parameter.

#### **Output**

The call returns this parameter.

#### **Input/output**

You must provide this parameter, but it is modified by the call.

There is also a brief description of the purpose of the parameter, together with a list of any values that the parameter can take.

The last two parameters in each call are a completion code and a reason code. The completion code indicates whether the call completed successfully, partially, or not at all. Further information about the partial success or the failure of the call is given in the reason code.

#### **Usage notes**

Additional information about the call, describing how to use it and any restrictions on its use.

#### **RPG invocation**

Typical invocation of the call, and declaration of its parameters, in RPG.

Other notational conventions are:

#### **Constants**

Names of constants are shown in uppercase; for example, OOOUT.

#### **Arrays**

In some calls, parameters are arrays of character strings with a size that is not fixed. In the descriptions of these parameters, a lowercase *n* represents a numeric constant. When you code the declaration for that parameter, replace the *n* with the numeric value you require.

## IBM i **MQBACK (Back out changes) on IBM i**

The MQBACK call indicates to the queue manager that all of the message gets and puts that have occurred since the last syncpoint are to be backed out. Messages put as part of a unit of work are deleted; messages retrieved as part of a unit of work are reinstated on the queue.

- This call is supported in the following environments:

-  AIX
-  IBM i
-  Windows

- [“Syntax” on page 1251](#)
- [“Usage notes” on page 1251](#)
- [“Parameters” on page 1252](#)
- [“RPG Declaration” on page 1253](#)

## Syntax

MQBACK (*Hconn*, *CompCode*, *Reason*)

## Usage notes

Consider these usage notes when using MQBACK.

1. This call can be used only when the queue manager itself coordinates the unit of work. This is a local unit of work, where the changes affect only IBM MQ resources.
2. In environments where the queue manager does not coordinate the unit of work, the appropriate back-out call must be used instead of MQBACK. The environment may also support an implicit back out caused by the application terminating abnormally.
  - On IBM i, this call can be used for local units of work coordinated by the queue manager. This means that a commitment definition must not exist at job level, that is, the STRCMTCTL command with the **CMTSCOPE(\*JOB)** parameter must not have been issued for the job.
3. If an application ends with uncommitted changes in a unit of work, the disposition of those changes depends on whether the application ends normally or abnormally. See the usage notes in [“MQDISC \(Disconnect queue manager\) on IBM i” on page 1289](#) for further details.
4. When an application puts or gets messages in groups or segments of logical messages, the queue manager retains information relating to the message group and logical message for the last successful MQPUT and MQGET calls. This information is associated with the queue handle, and includes such things as:
  - The values of the *MDGID*, *MDSEQ*, *MDOFF*, and *MDMFL* fields in MQMD.
  - Whether the message is part of a unit of work.
  - For the MQPUT call: whether the message is persistent or nonpersistent.

The queue manager keeps *three* sets of group and segment information, one set for each of the following:

- The last successful MQPUT call (this can be part of a unit of work).
- The last successful MQGET call that removed a message from the queue (this can be part of a unit of work).
- The last successful MQGET call that browsed a message on the queue (this cannot be part of a unit of work).

If the application puts or gets the messages as part of a unit of work, and the application then decides to back out the unit of work, the group and segment information is restored to the value that it had previously:

- The information associated with the MQPUT call is restored to the value that it had before the first successful MQPUT call for that queue handle in the current unit of work.

- The information associated with the MQGET call is restored to the value that it had before the first successful MQGET call for that queue handle in the current unit of work.

Queues which were updated by the application after the unit of work had started, but outside the scope of the unit of work, do not have their group and segment information restored if the unit of work is backed out.

Restoring the group and segment information to its previous value when a unit of work is backed out allows the application to spread a large message group or large logical message consisting of many segments across several units of work, and to restart at the correct point in the message group or logical message if one of the units of work fails. Using several units of work might be advantageous if the local queue manager has only limited queue storage. However, the application must maintain sufficient information to be able to restart putting or getting messages at the correct point if a system failure occurs. For details of how to restart at the correct point after a system failure, see the PMLOGO option described in [“MQPMO \(Put-message options\) on IBM i” on page 1173](#), and the GMLOGO option described in [“MQGMO \(Get-message options\) on IBM i” on page 1077](#).

The remaining usage notes apply only when the queue manager coordinates the units of work:

1. A unit of work has the same scope as a connection handle. This means that all IBM MQ calls which affect a particular unit of work must be performed using the same connection handle. Calls issued using a different connection handle (for example, calls issued by another application) affect a different unit of work. See the **HCONN** parameter described in [“MQCONN \(Connect queue manager\) on IBM i” on page 1276](#) for information about the scope of connection handles.
2. Only messages that were put or retrieved as part of the current unit of work are affected by this call.
3. A long-running application that issues MQGET, MQPUT, or MQPUT1 calls within a unit of work, but which never issues a commit or backout call, can cause queues to fill up with messages that are not available to other applications. To guard against this possibility, the administrator should set the **MaxUncommittedMsgs** queue manager attribute to a value that is low enough to prevent runaway applications filling the queues, but high enough to allow the expected messaging applications to work correctly.

## Parameters

The MQBACK call has the following parameters:

### **HCONN (10-digit signed integer) - input**

Connection handle.

This handle represents the connection to the queue manager. The value of *HCONN* was returned by a previous MQCONN or MQCONNX call.

### **CMPCOD (10-digit signed integer) - output**

Completion code.

It is one of the following:

#### **CCOK**

Successful completion.

#### **CCFAIL**

Call failed.

### **REASON (10-digit signed integer) - output**

Reason code qualifying *COMCOD*.

If *COMCOD* is CCOK:

#### **RCNONE**

(0, X'000') No reason to report.

If *COMCOD* is CCFAIL:

**RC2219**

(2219, X'8AB') MQI call reentered before previous call complete.

**RC2009**

(2009, X'7D9') Connection to queue manager lost.

**RC2018**

(2018, X'7E2') Connection handle not valid.

**RC2101**

(2101, X'835') Object damaged.

**RC2123**

(2123, X'84B') Result of commit or back-out operation is mixed.

**RC2162**

(2162, X'872') Queue manager shutting down.

**RC2102**

(2102, X'836') Insufficient system resources available.

**RC2071**

(2071, X'817') Insufficient storage available.

**RC2195**

(2195, X'893') Unexpected error occurred.

**RPG Declaration**

```

C*..1.....2.....3.....4.....5.....6.....7..
C                               CALLP      MQBACK(HCONN : COMCOD : REASON)

```

D* Reason code qualifying COMCOD
D REASON          10I 0

```

**IBM i MQBEGIN (Begin unit of work) on IBM i**

The MQBEGIN call begins a unit of work that is coordinated by the queue manager, and that may involve external resource managers.

- This call is supported in the following environments:

-  AIX
-  IBM i
-  Windows

- [“Syntax” on page 1254](#)
- [“Usage notes” on page 1254](#)
- [“Parameters” on page 1255](#)
- [“RPG Declaration” on page 1256](#)

## Syntax

MQBEGIN (*HCONN, BEGOP, CMPCOD, REASON*)

## Usage notes

1. The MQBEGIN call can be used to start a unit of work that is coordinated by the queue manager and that might involve changes to resources owned by other resource managers. The queue manager supports three types of unit-of-work:

### Queue manager-coordinated local unit of work

This is a unit of work in which the queue manager is the only resource manager participating, and so the queue manager acts as the unit-of-work coordinator.

- To start this type of unit of work, the PMSYP or GMSYP option should be specified on the first MQPUT, MQPUT1, or MQGET call in the unit of work.

It is not necessary for the application to issue the MQBEGIN call to start the unit of work, but if MQBEGIN is used, the call completes with CCWARN and reason code RC2121.

- To commit or back out this type of unit of work, the MQCMIT or MQBACK call must be used.

### Queue manager-coordinated global unit of work

This is a unit of work in which the queue manager acts as the unit-of-work coordinator, both for IBM MQ resources *and* for resources belonging to other resource managers. Those resource managers cooperate with the queue manager to ensure that all changes to resources in the unit of work are committed or backed out together.

- To start this type of unit of work, the MQBEGIN call must be used.
- To commit or back out this type of unit of work, the MQCMIT and MQBACK calls must be used.

### Externally-coordinated global unit of work

This is a unit of work in which the queue manager is a participant, but the queue manager does not act as the unit-of-work coordinator. Instead, there is an external unit-of-work coordinator with whom the queue manager cooperates.

- To start this type of unit of work, the relevant call provided by the external unit-of-work coordinator must be used.

If the MQBEGIN call is used to try to start the unit of work, the call fails with reason code RC2012.

- To commit or back out this type of unit of work, the commit and back-out calls provided by the external unit-of-work coordinator must be used.

If the MQCMIT or MQBACK call is used to try to commit or back out the unit of work, the call fails with reason code RC2012.

2. If the application ends with uncommitted changes in a unit of work, the disposition of those changes depends on whether the application ends normally or abnormally. See the usage notes in [“MQDISC \(Disconnect queue manager\) on IBM i” on page 1289](#) for further details.
3. An application can participate in only one unit of work at a time. The MQBEGIN call fails with reason code RC2128 if there is already a unit of work in existence for the application, regardless of which type of unit of work it is.
4. The MQBEGIN call is not valid in an IBM MQ client environment. An attempt to use the call fails with reason code RC2012.
5. When the queue manager is acting as the unit-of-work coordinator for global units of work, the resource managers that can participate in the unit of work are defined in the queue manager's configuration file.
6. On IBM i, the three types of unit of work are supported as follows:

- **Queue manager-coordinated local units of work** can be used only when a commitment definition does not exist at the job level, that is, the STRCMTCTL command with the **CMTSCOPE(\*JOB)** parameter must not have been issued for the job.
- **Queue manager-coordinated global units of work** are not supported.
- **Externally-coordinated global units of work** can be used only when a commitment definition exists at job level, that is, the STRCMTCTL command with the **CMTSCOPE(\*JOB)** parameter must have been issued for the job. If this has been done, the IBM i COMMIT and ROLLBACK operations apply to IBM MQ resources as well as to resources belonging to other participating resource managers.

## Parameters

The MQBEGIN call has the following parameters:

### HCONN (10-digit signed integer) - input

Connection handle.

This handle represents the connection to the queue manager. The value of *HCONN* was returned by a previous MQCONN or MQCONNX call.

### BEGOP (MQBO) - input/output

Options that control the action of MQBEGIN.

See [“MQBO \(Begin options\) on IBM i” on page 1019](#) for details.

If no options are required, programs written in C or S/390 assembler can specify a null parameter address, instead of specifying the address of an MQBO structure.

### CMPCOD (10-digit signed integer) - output

Completion code.

It is one of the following:

#### CCOK

Successful completion.

#### CCWARN

Warning (partial completion).

#### CCFAIL

Call failed.

### REASON (10-digit signed integer) - output

Reason code qualifying *CMPCOD*.

If *CMPCOD* is CCOK:

#### RCNONE

(0, X'000') No reason to report.

If *CMPCOD* is CCWARN:

#### RC2121

(2121, X'849') No participating resource managers registered.

#### RC2122

(2122, X'84A') Participating resource manager not available.

If *CMPCOD* is CCFAIL:

#### RC2134

(2134, X'856') Begin-options structure not valid.

#### RC2219

(2219, X'8AB') MQI call reentered before previous call complete.

**RC2009**

(2009, X'7D9') Connection to queue manager lost.

**RC2012**

(2012, X'7DC') Call not valid in environment.

**RC2018**

(2018, X'7E2') Connection handle not valid.

**RC2046**

(2046, X'7FE') Options not valid or not consistent.

**RC2162**

(2162, X'872') Queue manager shutting down.

**RC2102**

(2102, X'836') Insufficient system resources available.

**RC2071**

(2071, X'817') Insufficient storage available.

**RC2195**

(2195, X'893') Unexpected error occurred.

**RC2128**

(2128, X'850') Unit of work already started.

**RPG Declaration**

```

C*..1.....2.....3.....4.....5.....6.....7..
C          CALLP      MQBEGIN(HCONN : BEGOP : CMPCOD :
C                                REASON)

```

The prototype definition for the call is:

```

D*..1.....2.....3.....4.....5.....6.....7..
DMQBEGIN      PR          EXTPROC('MQBEGIN')
D* Connection handle
D HCONN              10I 0 VALUE

D BEGOP              12A
D* Completion code
D CMPCOD              10I 0
D* Reason code qualifying CMPCOD
D REASON              10I 0

```

**IBM i MQBUFMH (Convert buffer into message handle) on IBM i**

The MQBUFMH function call converts a buffer into a message handle and is the inverse of the MQMHBUF call.

This call takes a message descriptor and MQRFH2 properties in the buffer and makes them available through a message handle. The MQRFH2 properties in the message data are, optionally, removed. The *Encoding*, *CodedCharSetId*, and *Format* fields of the message descriptor are updated, if necessary, to correctly describe the contents of the buffer after the properties have been removed.

- [“Syntax” on page 1256](#)
- [“Usage notes” on page 1257](#)
- [“Parameters” on page 1257](#)
- [“RPG Declaration” on page 1258](#)

**Syntax**

MQBUFMH (*Hconn*, *Hmsg*, *BufMsgHOpts*, *MsgDesc*, *Buffer*, *BufferLength*, *DataLength*, *CompCode*, *Reason*)

## Usage notes

MQBUFMH calls cannot be intercepted by API exits - a buffer is converted into a message handle in the application space; the call does not reach the queue manager.

## Parameters

The MQBUFMH call has the following parameters:

### HCONN (10-digit signed integer) - input

This handle represents the connection to the queue manager. The value of *HCONN* must match the connection handle that was used to create the message handle specified in the **Hmsg** parameter.

If the message handle was created by using HCUNAS, a valid connection must be established on the thread converting a buffer into a message handle. If a valid connection is not established, the call fails with RC2009.

### HMSG (20-digit signed integer) - input

This handle is the message handle for which a buffer is required. The value was returned by a previous MQCRTMH call.

### BMHOPT (MQBMHO) - input

The MQBMHO structure allows applications to specify options that control how message handles are produced from buffers.

See [“MQBMHO \(Buffer to message handle options\) on IBM i” on page 1018](#) for details.

### MSGDSC (MQMD) - input/output

The *MSGDSC* structure contains the message descriptor properties and describes the contents of the buffer area.

On output from the call, the properties are optionally removed from the buffer area and, in this case, the message descriptor is updated to correctly describe the buffer area.

Data in this structure must be in the character set and encoding of the application.

### BUFLEN (10-digit signed integer) - input

*BUFLEN* is the length of the Buffer area, in bytes.

A *BUFLEN* of zero bytes is valid, and indicates that the buffer area contains no data.

### BUFFER (1-byte bit string x BUFLEN) - input/output

*BUFFER* defines the area containing the message buffer. For most data, you must align the buffer on a 4-byte boundary.

If *BUFFER* contains character or numeric data, set the *CodedCharSetId* and *Encoding* fields in the **MSGDSC** parameter to the values appropriate to the data; this enables the data to be converted, if necessary.

If properties are found in the message buffer they are optionally removed; they later become available from the message handle on return from the call.

In the C programming language, the parameter is declared as a pointer-to-void, which means the address of any type of data can be specified as the parameter.

If the **BUFLEN** parameter is zero, *BUFFER* is not referred to. In this case, the parameter address passed by programs written in C or System/390 assembler can be null.

### DATLEN (10-digit signed integer) - output

*DATLEN* is the length, in bytes, of the buffer which might have the properties removed.

## CMPCOD (10-digit signed integer) - output

### CCOK

Successful completion.

### CCFAIL

Call failed.

## REASON (10-digit signed integer) - output

The reason code qualifying *CMPCOD*.

If *CMPCOD* is CCOK:

### RCNONE

(0, X'000') No reason to report.

If *CMPCOD* is CCFAIL:

### RC2204

(2204, X'089C') Adapter not available.

### RC2130

(2130, X'852') Unable to load adapter service module.

### RC2157

(2157, X'86D') Primary and home ASIDs differ.

### RC2489

(2489, X'09B9') Buffer to message handle options structure not valid.

### RC2004

(2004, X'07D4') Buffer parameter not valid.

### RC2005

(2005, X'07D5') Buffer length parameter not valid.

### RC2219

(2219, X'08AB') MQI call entered before previous call completed.

### RC2009

(2009, X'07D9') Connection to queue manager lost.

### RC2460

(2460, X'099C') Message handle not valid.

### RC2026

(2026, X'07EA') Message descriptor not valid.

### RC2499

(2499, X'09C3') Message handle already in use.

### RC2046

(2046, X'07FE') Options not valid or not consistent.

### RC2334

(2334, X'091E') MQRFH2 structure not valid.

### RC2421

(2421, X'0975') An MQRFH2 folder containing properties could not be parsed.

### RC2195

(2195, X'893') Unexpected error occurred.

## RPG Declaration

```
C*..1.....2.....3.....4.....5.....6.....7..
C                                CALLP      MQBUFMH(HCONN : HMSG : BMHOPT :
                                MSGDSC : BUFLen : BUFFER :
                                DATLEN : CMPCOD : REASON)
```

The prototype definition for the call is:

```

D* Reason code qualifying CompCode
D REASON         10I 0
```

## IBM i MQCB (Manage callback) on IBM i

The MQCB call reregisters a callback for the specified object handle and controls activation and changes to the callback.

A callback is a piece of code (specified as either the name of a function that can be dynamically linked or as a function pointer) that is called by IBM MQ when certain events occur.

To use MQCB and MQCTL on a V7 client you must be connected to a V7 server and the **SHARECNV** parameter of the channel must have a non-zero value.

The types of callback that can be defined are:

### Message consumer

A message consumer callback function is called when a message, meeting the selection criteria specified, is available on an object handle.

Only one callback function can be registered against each object handle. If a single queue is to be read with multiple selection criteria then the queue must be opened multiple times and a consumer function registered on each handle.

### Event handler

The event handler is called for conditions that affect the whole callback environment.

The function is called when an event condition occurs, for example, a queue manager or connection stopping or quiescing.

The function is not called for conditions that are specific to a single message consumer, for example RC2016; it is called however if a callback function does not end normally.

- [“Syntax” on page 1259](#)
- [“Usage notes for MQCB” on page 1259](#)
- [“Parameters for MQCB” on page 1261](#)
- [“RPG Declaration” on page 1267](#)

## Syntax

MQCB (*HCONN*, *OPERATN*, *HOBJ*, *CBDSC*, *MSGDSC*, *GMO*, *CMPCOD*, *REASON*)

## Usage notes for MQCB

1. MQCB is used to define the action to be invoked for each message, matching the specified criteria, available on the queue. When the action is processed, either the message is removed from the queue

and passed to the defined message consumer, or a message token is provided, which is used to retrieve the message.

2. MQCB can be used to define callback routines before starting consumption with MQCTL or it can be used from within a callback routine.
3. To use MQCB from outside of a callback routine, you must first suspend message consumption by using MQCTL and resume consumption afterward.

### Message consumer callback sequence

You can configure a consumer to invoke callback at key points during the lifecycle of the consumer. For example:

- when the consumer is first registered,
- when the connection is started,
- when the connection is stopped and
- when the consumer is deregistered, either explicitly, or implicitly by an MQCLOSE.

Verb	Meaning
MQCTL(START)	MQCTL call by using the CTLSR Operation
MQCTL(STOP)	MQCTL call by using the CTLSP Operation
MQCTL(WAIT)	MQCTL call by using the CTLSW Operation

Allows the consumer to maintain state associated with the consumer. When a callback is requested by an application, the rules for consumer invocation are as follows:

#### REGISTER

Is always the first type of invocation of the callback.

Is always called on the same thread as the MQCB(CBREG) call.

#### START

Is always called synchronously with the MQCTL(START) verb.

- All START callbacks are completed before the MQCTL(START) verb returns.

Is on the same thread as the message delivery if CTLTHR is requested.

The call with start is not guaranteed if, for example, a previous callback issues MQCTL(STOP) during the MQCTL(START).

#### STOP

No further messages or events are delivered after this call until the connection is restarted.

A STOP is guaranteed if the application was previously called for START, or a message, or an event.

#### DEREGISTER

Is always the last type of invocation of the callback.

Ensure that your application performs thread-based initialization and cleanup in the START and STOP callbacks. You can do non thread-based initialization and cleanup with REGISTER and DEREGISTER callbacks.

Do not make any assumptions about the life and availability of the thread other than what is stated. For example, do not rely on a thread staying alive beyond the last call to DEREGISTER. Similarly, when you have chosen not to use CTLTHR, do not assume that the thread exists whenever the connection is started.

If your application has particular requirements for thread characteristics, it can always create a thread accordingly, then use MQCTL(WAIT). This step *donates* the thread to IBM MQ for asynchronous message delivery.

## Message consumer connection usage

Normally, when an application issues another MQI call while one is outstanding, the call fails with reason code RC2219.

There are special cases, however, when the application must issue a further MQI call before the previous call has completed. For example, the consumer can be invoked during an MQCB call with CBRE.

In such an instance, when as a result of the application issuing either an MQCB or MQCTL verb, the application is called back, the application is allowed to issue a further MQI call. This instance means you can issue, for example, an MQOPEN call, in the consumer function when called with a CBCCALLT type of CBCTRC. Any MQI call, except for MQDISC, is allowed.

## Parameters for MQCB

The MQCB call has the following parameters:

### HCONN (10-digit signed integer) - input

Manage callback function - HCONN parameter.

This handle represents the connection to the queue manager. The value of *HCONN* was returned by a previous MQCONN or MQCONNX call.

### OPERATN (10-digit signed integer) - input

Manage callback function - OPERATN parameter.

The operation being processed on the callback defined for the specified object handle. You must specify one of the following options; if more than one option is required, the values can be added (do not add the same constant more than once) or combined by using the bitwise OR operation (if the programming language supports bit operations).

Combinations that are not valid are noted; all other combinations are valid.

### CBREG

Define the callback function for the specified object handle. This operation defines the function to be called and the selection criteria to be used.

If a callback function is already defined for the object handle the definition is replaced. If an error is detected while replacing the callback, the function is deregistered.

If a callback is registered in the same callback function in which it was previously deregistered, this is treated as a replace operation; any initial or final calls are not invoked.

You can use CBREG with CTLSU or CTLRE.

### CBUNR

Stop the consuming of messages for the object handle and removes the handle from those eligible for a callback.

A callback is automatically deregistered if the associated handle is closed.

If CBUNR is called from within a consumer, and the callback has a stop call defined, it is invoked upon return from the consumer.

If this operation is issued against an *Hobj* with no registered consumer, the call returns with RC2448.

### CTLSU

Suspends the consuming of messages for the object handle.

If this operation is applied to an event handler, the event handler does not get events while suspended, and any events missed while in the suspended state are not provided to the operation when it is resumed.

While suspended, the consumer function continues to get the control type callbacks.

## **CTLRE**

Resume the consuming of messages for the object handle.

If this operation is applied to an event handler, the event handler does not get events while suspended, and any events missed while in the suspended state are not provided to the operation when it is resumed.

## **CBDSC (MQCBD) - input**

Manage callback function - CBDSC parameter.

This is a structure that identifies the callback function that is being registered by the application and the options used when registering it.

See “MQCBD - Callback descriptor” on page 289 for details of the structure.

Callback descriptor is required only for the CBREG option; if the descriptor is not required, the parameter address passed can be null.

## **HOBJ (10-digit signed integer) - input**

Manage callback function - HOBJ parameter.

This handle represents the access that has been established to the object from which a message is to be consumed. This is a handle that has been returned from a previous [MQOPEN](#) or [MQSUB](#) call (in the **HOBj** parameter).

*HOBj* is not required when defining an event handler routine (CBTEH) and must be specified as HONONE.

If this *Hobj* has been returned from an [MQOPEN](#) call, the queue must have been opened with one or more of the following options:

- OOINPS
- OOINPX
- OOINPQ
- OOBROW

## **MSGDSC (MQMD) - input**

Manage callback function -MSGDSC parameter.

This structure describes the attributes of the message required, and the attributes of the message retrieved.

The **MsgDesc** parameter defines the attributes of the messages required by the consumer, and the version of the MQMD to be passed to the message consumer.

The *MsgId*, *CorrelId*, *GroupId*, *MsgSeqNumber*, and *Offset* in the MQMD are used for message selection, depending on the options specified in the **GetMsgOpts** parameter.

The *Encoding* and *CodedCharSetId* are used for message conversion if you specify the GMCONV option.

See [MQMD](#) for details.

*MsgDesc* is used only for CBREG and, if you require values other than the default for any fields. *MsgDesc* is not used for an event handler.

If the descriptor is not required the parameter address passed can be null.

Note, that if multiple consumers are registered against the same queue with overlapping selectors, the chosen consumer for each message is undefined.

## **GMO (MQGMO) - input**

Manage callback function - GMO parameter.

Options that control how the message consumer gets messages.

All options have the meaning as described in [“MQGMO \(Get-message options\) on IBM i”](#) on page 1077, when used on an MQGET call, except:

**GMSSIG**

This option is not permitted.

**GMBRWF, GMBRWN, GMMBH, GMMBC**

The order of messages delivered to a browsing consumer is dictated by the combinations of these options. Significant combinations are:

**GMBRWF**

The first message on the queue is delivered repeatedly to the consumer. This is useful when the consumer destructively consumes the message in the callback. Use this option with care.

**GMBRWN**

The consumer is given each message on the queue, from the current cursor position until the end of the queue is reached.

**GMBRWF + GMBRWN**

The cursor is reset to the start of the queue. The consumer is then given each message until the cursor reaches the end of the queue.

**GMBRWF + GMMBH or GMMBC**

Starting at the beginning of the queue, the consumer is given the first nonmarked message on the queue, which is then marked for this consumer. This combination ensures that the consumer can receive new messages added behind the current cursor point.

**GMBRWN + GMMBH or GMMBC**

Starting at the cursor position the consumer is given the next nonmarked message on the queue, which is then marked for this consumer. Use this combination with care because messages can be added to the queue behind the current cursor position.

**GMBRWF + GMBRWN + GMMBH or GMMBC**

This combination is not permitted, if used the call returns RC2046.

**GMNWT, GMWT and GMWI**

These options control how the consumer is invoked.

**GMNWT**

The consumer is never called with RC2033. The consumer is only invoked for messages and events

**GMWT with a zero GMWI**

The RC2033 code is only passed to the consumer when there are no messages and

- the consumer has been started
- the consumer has been delivered at least one message since the last no messages reason code.

This prevents the consumer from polling in a busy loop when a zero wait interval is specified.

**GMWT and a positive GMWI**

The user is invoked after the specified wait interval with reason code RC2033. This call is made regardless of whether any messages have been delivered to the consumer. This allows the user to perform heartbeat or batch type processing.

**GMWT and GMWI of WIULIM**

This specifies an infinite wait before returning RC2033. The consumer is never called with RC2033.

*GMO* is used only for CBREG and, if you require values other than the default for any fields. *GMO* is not used for an event handler.

If the options are not required the parameter address passed can be null.

If a message properties handle is provided in the MQGMO structure, a copy is provided in the MQGMO structure that is passed into the consumer callback. On return from the MQCB call, the application can delete the message properties handle.

### **CMPCOD (10-digit signed integer) - output**

Manage callback function - CMPCOD parameter.

The completion code; it is one of the following:

#### **CCOK**

Successful completion.

#### **CCWARN**

Warning (partial completion).

#### **CCFAIL**

Call failed.

### **REASON (10-digit signed integer) - output**

Manage callback function - REASON parameter.

The following reason codes are the codes that the queue manager can return for the **REASON** parameter.

If *CMPCOD* is CCOK:

#### **RCNONE**

(0, X'000') No reason to report.

If *CompCode* is CCFAIL:

#### **RC2204**

(2204, X'89C') Adapter not available.

#### **RC2133**

(2133, X'855') Unable to load data conversion services modules.

#### **RC2130**

(2130, X'852') Unable to load adapter service module.

#### **RC2374**

(2374, X'946') API exit failed.

#### **RC2183**

(2183, X'887') Unable to load API exit.

#### **RC2157**

(2157, X'86D') Primary and home ASIDs differ.

#### **RC2005**

(2005, X'7D5') Buffer length parameter not valid.

#### **RC2219**

(2219, X'8AB') MQI call entered before previous call complete.

#### **RC2487**

(2487, X'9B7') Incorrect callback type field.

#### **RC2448**

(2448, X'990') Unable to deregister, suspend, or resume because there is no registered callback.

#### **RC2486**

(2486, X'9B6') Either *CallbackFunction* or *CallbackName* must be specified but not both.

#### **RC2483**

(2483, X'9B3') Incorrect callback type field.

#### **RC2484**

(2484, X'9B4') Incorrect MQCBD options field.

#### **RC2140**

(2140, X'85C') Wait request rejected by CICS.

#### **RC2009**

(2009, X'7D9') Connection to queue manager lost.

- RC2217**  
(2217, X'8A9') Not authorized for connection.
- RC2202**  
(2202, X'89A') Connection quiescing.
- RC2203**  
(2203, X'89B') Connection shutting down.
- RC2207**  
(2207, X'89F') Correlation-identifier error.
- RC2010**  
(2010, X'7DA') Data length parameter not valid.
- RC2016**  
(2016, X'7E0') Gets inhibited for the queue.
- RC2351**  
(2351, X'92F') Global units of work conflict.
- RC2186**  
(2186, X'88A') Get-message options structure not valid.
- RC2353**  
(2353, X'931') Handle in use for global unit of work.
- RC2018**  
(2018, X'7E2') Connection handle not valid.
- RC2019**  
(2019, X'7E3') Object handle not valid.
- RC2259**  
(2259, X'8D3') Inconsistent browse specification.
- RC2245**  
(2245, X'8C5') Inconsistent unit-of-work specification.
- RC2246**  
(2246, X'8C6') Message under cursor not valid for retrieval.
- RC2352**  
(2352, X'930') Global unit of work conflicts with local unit of work.
- RC2247**  
(2247, X'8C7') Match options not valid.
- RC2485**  
(2485, X'9B4') Incorrect *MaxMsgLength* field.
- RC2026**  
(2026, X'7EA') Message descriptor not valid.
- RC2497**  
(2497, X'9C1') The specified function entry point could not be found in the module.
- RC2496**  
(2496, X'9C0') Module found, however it is of the wrong type; not 32 bit, 64 bit, or a valid dynamic link library.
- RC2495**  
(2495, X'9BF') Module not found in the search path or not authorized to load.
- RC2250**  
(2250, X'8CA') Message sequence number not valid.
- RC2331**  
(2331, X'91B') Use of message token not valid.
- RC2033**  
(2033, X'7F1') No message available.

- RC2034**  
(2034, X'7F2') Browse cursor not positioned on message.
- RC2036**  
(2036, X'7F4') Queue not open for browse.
- RC2037**  
(2037, X'7F5') Queue not open for input.
- RC2041**  
(2041, X'7F9') Object definition changed since opened.
- RC2101**  
(2101, X'835') Object damaged.
- RC2206**  
(2206, X'89E') Incorrect operation code on API Call.
- RC2046**  
(2046, X'7FE') Options not valid or not consistent.
- RC2193**  
(2193, X'891') Error accessing page-set data set.
- RC2052**  
(2052, X'804') Queue has been deleted.
- RC2394**  
(2394, X'95A') Queue has wrong index type.
- RC2058**  
(2058, X'80A') Queue manager name not valid or not known.
- RC2059**  
(2059, X'80B') Queue manager not available for connection.
- RC2161**  
(2161, X'871') Queue manager quiescing.
- RC2162**  
(2162, X'872') Queue manager shutting down.
- RC2102**  
(2102, X'836') Insufficient system resources available.
- RC2069**  
(2069, X'815') Signal outstanding for this handle.
- RC2071**  
(2071, X'817') Insufficient storage available.
- RC2109**  
(2109, X'83D') Call suppressed by exit program.
- RC2024**  
(2024, X'7E8') No more messages can be handled within current unit of work.
- RC2072**  
(2072, X'818') Syncpoint support not available.
- RC2195**  
(2195, X'893') Unexpected error occurred.
- RC2354**  
(2354, X'932') Enlistment in global unit of work failed.
- RC2355**  
(2355, X'933') Mixture of unit-of-work calls not supported.
- RC2255**  
(2255, X'8CF') Unit of work not available for the queue manager to use.
- RC2090**  
(2090, X'82A') Wait interval in MQGMO not valid.

**RC2256**

(2256, X'8D0') Wrong version of MQGMO supplied.

**RC2257**

(2257, X'8D1') Wrong version of MQMD supplied.

**RC2298**

(2298, X'8FA') The function requested is not available in the current environment.

**RPG Declaration**

```

C*..1.....2.....3.....4.....5.....6.....7..
C          CALLP      MQCB(HCONN : OPERATN : CBDSC :

```

**IBM i MQCLOSE (Close object) on IBM i**

The MQCLOSE call relinquishes access to an object, and is the inverse of the MQOPEN call.

- [“Syntax” on page 1267](#)
- [“Usage notes” on page 1267](#)
- [“Parameters” on page 1268](#)
- [“RPG Declaration” on page 1273](#)

**Syntax**

MQCLOSE (*HCONN*, *HOBJ*, *OPTS*, *CMPCOD*, *REASON*)

**Usage notes**

1. When an application issues the MQDISC call, or ends either normally or abnormally, any objects that were opened by the application and are still open are closed automatically with the CONONE option.
2. The following points apply if the object being closed is a *queue*:
  - If operations on the queue are performed as part of a unit of work, the queue can be closed before or after the syncpoint occurs without affecting the outcome of the syncpoint.
  - If the queue was opened with the OOBROW option, the browse cursor is destroyed. If the queue is later reopened with the OOBROW option, a new browse cursor is created (see the OOBROW option described in MQOPEN).

- If a message is currently locked for this handle at the time of the MQCLOSE call, the lock is released (see the GMLK option described in “MQGMO (Get-message options) on IBM i” on page 1077).

3. The following points apply if the object being closed is a *dynamic queue* (either permanent or temporary):

- For a dynamic queue, the options CODEL or COPURG can be specified regardless of the options specified on the corresponding MQOPEN call.
- When a dynamic queue is deleted, all MQGET calls with the GMWT option that are outstanding against the queue are canceled and reason code RC2052 is returned. See the GMWT option described in “MQGMO (Get-message options) on IBM i” on page 1077.

After a dynamic queue has been deleted, any call (other than MQCLOSE) that attempts to reference the queue using a previously acquired *HOBJ* handle fails with reason code RC2052.

Be aware that although a deleted queue cannot be accessed by applications, the queue is not removed from the system, and associated resources are not freed, until all handles that reference the queue have been closed, and all units of work that affect the queue have been either committed or backed out.

- When a permanent dynamic queue is deleted, if the *HOBJ* handle specified on the MQCLOSE call is not the one that was returned by the MQOPEN call that created the queue, a check is made that the user identifier which was used to validate the MQOPEN call is authorized to delete the queue. If the OOALTU option was specified on the MQOPEN call, the user identifier checked is the *ODAU*.

This check is not performed if:

- The handle specified is the one returned by the MQOPEN call that created the queue.
- The queue being deleted is a temporary dynamic queue.
- When a temporary dynamic queue is closed, if the *HOBJ* handle specified on the MQCLOSE call is the one that was returned by the MQOPEN call that created the queue, the queue is deleted. This occurs regardless of the close options specified on the MQCLOSE call. If there are messages on the queue, they are discarded; no report messages are generated.

If there are uncommitted units of work that affect the queue, the queue and its messages are still deleted, but this does not cause the units of work to fail. However, as described previously, the resources associated with the units of work are not freed until each of the units of work has been either committed or backed out.

4. The following points apply if the object being closed is a *distribution list*:

- The only valid close option for a distribution list is CONONE; the call fails with reason code RC2046 or RC2045 if any other options are specified.
- When a distribution list is closed, individual completion codes and reason codes are not returned for the queues in the list - only the **CMPCOD** and **REASON** parameters of the call are available for diagnostic purposes.

If a failure occurs closing one of the queues, the queue manager continues processing and attempts to close the remaining queues in the distribution list. The **CMPCOD** and **REASON** parameters of the call are then set to return information describing the failure. Thus it is possible for the completion code to be CCFAIL, even though most of the queues were closed successfully. The queue that encountered the error is not identified.

If there is a failure on more than one queue, it is not defined which failure is reported in the **CMPCOD** and **REASON** parameters.

## Parameters

The MQCLOSE call has the following parameters:

### **HCONN (10-digit signed integer) - input**

Connection handle.

This handle represents the connection to the queue manager. The value of *HCONN* was returned by a previous *MQCONN* or *MQCONNX* call.

### **HOBJ (10-digit signed integer) - input/output**

Object handle.

This handle represents the object that is being closed. The object can be of any type. The value of *HOBJ* was returned by a previous *MQOPEN* call.

On successful completion of the call, the queue manager sets this parameter to a value that is not a valid handle for the environment. This value is:

#### **HOUNUH**

Unusable object handle.

### **OPTS (10-digit signed integer) - input**

Options that control the action of *MQCLOSE*.

The **OPTS** parameter controls how the object is closed. Only permanent dynamic queues and subscriptions can be closed in more than one way. Permanent dynamic queues can either be retained or deleted; these are queues with a **DefinitionType** attribute that has the value *QDPERM* (see the **DefinitionType** attribute described in [“Attributes for queues” on page 1366](#)). The close options are summarized in a table later in this topic.

Durable subscriptions can either be kept or removed; these are created using the *MQSUB* call with the *SODUR* option.

When closing the handle to a managed destination (that is the **Hobj** parameter returned on an *MQSUB* call which used the *SOMAN* option) the queue manager will clean up any unretrieved publications when the associated subscription has also been removed. That is done using the *CORMSB* option on the **Hsub** parameter returned on an *MQSUB* call. Note that *CORMSB* is the default behavior on *MQCLOSE* for a non-durable subscription.

When closing a handle to a non-managed destination you are responsible for cleaning up the queue where publications are sent. You are recommended to close the subscription using *CORMSB* first and then process messages off the queue until there are none remaining.

One (and only one) of the following must be specified:

#### **Dynamic queue closure options**

These options control how permanent dynamic queues are closed:

#### **CODEL**

Delete the queue.

The queue is deleted if either of the following is true:

- It is a permanent dynamic queue, created by a previous *MQOPEN* call, and there are no messages on the queue and no uncommitted get or put requests outstanding for the queue (either for the current task or any other task).
- It is the temporary dynamic queue that was created by the *MQOPEN* call that returned *HOBJ*. In this case, all the messages on the queue are purged.

In all other cases, including the case where the *Hobj* was returned on an *MQSUB* call, the call fails with reason code *RC2045*, and the object is not deleted.

#### **COPURG**

Delete the queue, purging any messages on it.

The queue is deleted if either of the following is true:

- It is a permanent dynamic queue, created by a previous *MQOPEN* call, and there are no uncommitted get or put requests outstanding for the queue (either for the current task or any other task).
- It is the temporary dynamic queue that was created by the *MQOPEN* call that returned *HOBJ*.

In all other cases, including the case where the *Hobj* was returned on an MQSUB call, the call fails with reason code RC2045, and the object is not deleted.

The next table shows which close options are valid, and whether the object is retained or deleted.

<i>Table 743. Valid close options for use with retained or deleted objects</i>			
<b>Type of object or queue</b>	<b>CONONE</b>	<b>CODEL</b>	<b>COPURG</b>
Object other than a queue	Retained	Not valid	Not valid
Predefined queue	Retained	Not valid	Not valid
Permanent dynamic queue	Retained	Deleted if empty and no pending updates	Messages deleted; queue deleted if no pending updates
Temporary dynamic queue (call issued by creator of queue)	Deleted	Deleted	Deleted
Temporary dynamic queue (call not issued by creator of queue)	Retained	Not valid	Not valid
Distribution list	Retained	Not valid	Not valid
Managed subscription destination	Retained	Not valid	Not valid
Distribution list (subscription has been removed)	Messages deleted; queue deleted	Not valid	Not valid

### **Subscription closure options**

These options control whether durable subscriptions are removed when the handle is closed, and whether publications still waiting to be read by the application are cleaned up. These options are only valid for use with an object handle returned in the **HSUB** parameter of an MQSUB call.

#### **COKPSB**

The handle to the subscription is closed but the subscription made is kept. Publications will continue to be sent to the destination specified in the subscription. This option is only valid if the subscription was made with the option SODUR. COKPSB is the default if the subscription is durable

#### **CORMSB**

The subscription is removed and the handle to the subscription is closed.

The **Hobj** parameter of the MQSUB call is not invalidated by closure of the **Hsub** parameter and may continue to be used for MQGET or MQCB to receive the remaining publications. When the **Hobj** parameter of the MQSUB call is also closed, if it was a managed destination any unretrieved publications will be removed.

CORMSB is the default if the subscription is non-durable.

These subscription closure options are summarized in the following tables:

To close a durable subscription handle but leave the subscription around, use the following subscription closure options:

<i>Table 744. Task options for closing a durable subscription handle and leaving the subscription around</i>	
<b>Task</b>	<b>Subscription closure option</b>
Keep publications on an MQOPENed handle	COKPSB

Table 744. Task options for closing a durable subscription handle and leaving the subscription around (continued)

Task	Subscription closure option
Remove publications on an MQOPENed handle	Action not allowed
Keep publications on a handle with SOMAN	COKPSB
Remove publications on a handle with SOMAN	Action not allowed

To unsubscribe, either by closing a durable subscription handle and unsubscribing it or closing a non-durable subscription handle, use the following subscription closure options:

Table 745. Task options for unsubscribing

Task	Subscription closure option
Keep publications on an MQOPENed handle	CORMSB
Remove publications on an MQOPENed handle	Action not allowed
Keep publications on a handle with SOMAN	CORMSB
Remove publications on a handle with SOMAN	COPGSB

### Read ahead options

The following options control what happens to non-persistent messages which have been sent to the client before an application requested them and have not yet been consumed by the application. These messages are stored in the client read ahead buffer waiting to be requested by the application and can either be discarded or consumed from the queue before the MQCLOSE is completed.

#### COIMM

The object is closed immediately and any messages which have been sent to the client before an application requested them are discarded and are not available to be consumed by any application. This is the default value.

#### COQSC

A request to close the object is made, but if any messages which have been sent to the client before an application requested them, still reside in the client read ahead buffer, the MQCLOSE call will return with a warning code of RC2458, and the object handle will remain valid.

The application can then continue to use the object handle to retrieve messages until no more are available, and then close the object again. No more messages will be sent to the client ahead of an application requesting them, read ahead is now turned off.

Applications are advised to use COQSC rather than trying to reach a point where there are no more messages in the client read ahead buffer, since a message could arrive between the last MQGET call and the following MQCLOSE which would be discarded if COIMM was used.

If an MQCLOSE with COQSC is issued from within an asynchronous callback function, the same behavior of reading ahead messages applies. If the warning code RC2458 is returned, then the callback function will be called at least one more time. When the last remaining message that was read ahead has been passed to the callback function the CBCFLG field is set to CBCFBE.

### Default option

If you require none of the options described previously, you can use the following option:

#### CONONE

No optional close processing required.

This must be specified for:

- Objects other than queues
- Predefined queues

- Temporary dynamic queues (but only in those cases where *HOBJ* is not the handle returned by the MQOPEN call that created the queue).
- Distribution lists

In all of the previous cases, the object is retained and not deleted.

If this option is specified for a temporary dynamic queue:

- The queue is deleted, if it was created by the MQOPEN call that returned *HOBJ* ; any messages that are on the queue are purged.
- In all other cases the queue (and any messages on it) are retained.

If this option is specified for a permanent dynamic queue, the queue is retained and not deleted.

### **CMPCOD (10-digit signed integer) - output**

Completion code.

It is one of the following:

#### **CCOK**

Successful completion.

#### **CCWARN**

Warning (partial completion).

#### **CCFAIL**

Call failed.

### **REASON (10-digit signed integer) - output**

Reason code qualifying *CMPCOD*.

If *CMPCOD* is CCOK:

#### **RCNONE**

(0, X'000') No reason to report.

If *CMPCOD* is CCWARN:

#### **RC2241**

(2241, X'8C1') Message group not complete.

#### **RC2242**

(2242, X'8C2') Logical message not complete.

If *CMPCOD* is CCFAIL:

#### **RC2219**

(2219, X'8AB') MQI call reentered before previous call complete.

#### **RC2009**

(2009, X'7D9') Connection to queue manager lost.

#### **RC2018**

(2018, X'7E2') Connection handle not valid.

#### **RC2019**

(2019, X'7E3') Object handle not valid.

#### **RC2035**

(2035, X'7F3') Not authorized for access.

#### **RC2101**

(2101, X'835') Object damaged.

**IBM i MQCMIT (Commit changes) on IBM i**

The MQCMIT call indicates to the queue manager that the application has reached a syncpoint, and that all of the message gets and puts that have occurred since the last syncpoint are to be made permanent. Messages put as part of a unit of work are made available to other applications; messages retrieved as part of a unit of work are deleted.

- [“Syntax” on page 1273](#)
- [“Usage notes” on page 1274](#)
- [“Parameters” on page 1274](#)
- [“RPG Declaration” on page 1275](#)

**Syntax**

MQCMIT (HCONN, COMCOD, REASON)

## Usage notes

Consider these usage notes when using MQCMIT.

1. This call can be used only when the queue manager itself coordinates the unit of work. This is a local unit of work, where the changes affect only IBM MQ resources.
2. In environments where the queue manager does not coordinate the unit of work, the appropriate commit call must be used instead of MQCMIT. The environment may also support an implicit commit caused by the application terminating normally.
  - On IBM i, this call can be used for local units of work coordinated by the queue manager. This means that a commitment definition must not exist at job level, that is, the STRCMTCTL command with the **CMTSCOPE(\*JOB)** parameter must not have been issued for the job.
3. If an application ends with uncommitted changes in a unit of work, the disposition of those changes depends on whether the application ends normally or abnormally. See the usage notes in [“MQDISC \(Disconnect queue manager\) on IBM i” on page 1289](#) for further details.
4. When an application puts or gets messages in groups or segments of logical messages, the queue manager retains information relating to the message group and logical message for the last successful MQPUT and MQGET calls. This information is associated with the queue handle, and includes such things as:
  - The values of the *MDGID*, *MDSEQ*, *MDOFF*, and *MDMFL* fields in MQMD.
  - Whether the message is part of a unit of work.
  - For the MQPUT call: whether the message is persistent or nonpersistent.

When a unit of work is committed, the queue manager retains the group and segment information, and the application can continue putting or getting messages in the current message group or logical message.

Retaining the group and segment information when a unit of work is committed allows the application to spread a large message group or large logical message consisting of many segments across several units of work. Using several units of work might be advantageous if the local queue manager has only limited queue storage. However, the application must maintain sufficient information to be able to restart putting or getting messages at the correct point if a system failure occurs. For details of how to restart at the correct point after a system failure, see the PMLOGO option described in [“MQPMO \(Put-message options\) on IBM i” on page 1173](#), and the GMLOGO option described in [“MQGMO \(Get-message options\) on IBM i” on page 1077](#).

The remaining usage notes apply only when the queue manager coordinates the units of work:

1. A unit of work has the same scope as a connection handle. This means that all IBM MQ calls which affect a particular unit of work must be performed using the same connection handle. Calls issued using a different connection handle (for example, calls issued by another application) affect a different unit of work. See the **HCONN** parameter described in MQCONN for information about the scope of connection handles.
2. Only messages that were put or retrieved as part of the current unit of work are affected by this call.
3. A long-running application that issues MQGET, MQPUT, or MQPUT1 calls within a unit of work, but which never issues a commit or back-out call, can cause queues to fill up with messages that are not available to other applications. To guard against this possibility, the administrator should set the **MaxUncommittedMsgs** queue manager attribute to a value that is low enough to prevent runaway applications filling the queues, but high enough to allow the expected messaging applications to work correctly.

## Parameters

The MQCMIT call has the following parameters:

### **HCONN (10-digit signed integer) - input**

Connection handle.

This handle represents the connection to the queue manager. The value of *HCONN* was returned by a previous *MQCONN* or *MQCONNX* call.

### **COMCOD (10-digit signed integer) - output**

Completion code.

It is one of the following:

#### **CCOK**

Successful completion.

#### **CCWARN**

Warning (partial completion).

#### **CCFAIL**

Call failed.

### **REASON (10-digit signed integer) - output**

Reason code qualifying *COMCOD*.

If *COMCOD* is **CCOK**:

#### **RCNONE**

(0, X'000') No reason to report.

If *COMCOD* is **CCWARN**:

#### **RC2003**

(2003, X'7D3') Unit of work backed out.

#### **RC2124**

(2124, X'84C') Result of commit operation is pending.

If *COMCOD* is **CCFAIL**:

#### **RC2219**

(2219, X'8AB') MQI call reentered before previous call complete.

#### **RC2009**

(2009, X'7D9') Connection to queue manager lost.

#### **RC2018**

(2018, X'7E2') Connection handle not valid.

#### **RC2101**

(2101, X'835') Object damaged.

#### **RC2123**

(2123, X'84B') Result of commit or back-out operation is mixed.

#### **RC2162**

(2162, X'872') Queue manager shutting down.

#### **RC2102**

(2102, X'836') Insufficient system resources available.

#### **RC2071**

(2071, X'817') Insufficient storage available.

#### **RC2195**

(2195, X'893') Unexpected error occurred.

```

## IBM i MQCONN (Connect queue manager) on IBM i

The MQCONN call connects an application program to a queue manager. It provides a queue manager connection handle, which is used by the application on subsequent message queuing calls.

- Applications must use the MQCONN or MQCONNX call to connect to the queue manager, and the MQDISC call to disconnect from the queue manager.

On IBM MQ for Multiplatforms, each thread in an application can connect to different queue managers. On other systems, all concurrent connections within a process must be to the same queue manager.

- [“Syntax” on page 1276](#)
- [“Usage notes” on page 1276](#)
- [“Parameters” on page 1277](#)
- [“RPG Declaration” on page 1279](#)

### Syntax

MQCONN (QMNAME, HCONN, CMPCOD, REASON)

### Usage notes

1. The queue manager to which connection is made using the MQCONN call is called the *local queue manager*.
2. Queues that are owned by the local queue manager appear to the application as local queues. It is possible to put messages on and get messages from these queues.  
  
Shared queues that are owned by the queue sharing group to which the local queue manager belongs appear to the application as local queues. It is possible to put messages on and get messages from these queues.  
  
Queues that are owned by remote queue managers appear as remote queues. It is possible to put messages on these queues, but not possible to get messages from these queues.
3. If the queue manager fails while an application is running, the application must issue the MQCONN call again in order to obtain a new connection handle to use on subsequent IBM MQ calls. The application can issue the MQCONN call periodically until the call succeeds.  
  
If an application is not sure whether it is connected to the queue manager, the application can safely issue an MQCONN call in order to obtain a connection handle. If the application is already connected, the handle returned is the same as that returned by the previous MQCONN call, but with completion code CCWARN and reason code RC2002.
4. When the application has finished using IBM MQ calls, the application should use the MQDISC call to disconnect from the queue manager.
5. On IBM i, programs that end abnormally are not automatically disconnected from the queue manager. Therefore applications should be written to allow for the possibility of the MQCONN or MQCONNX call returning completion code CCWARN and reason code RC2002. The connection handle returned in this situation can be used as normal.

## Parameters

The MQCONN call has the following parameters:

### **QMNAME (48-byte character string) - input**

Name of queue manager.

This is the name of the queue manager to which the application wants to connect. The name can contain the following characters:

- Uppercase alphabetic characters (A through Z)
- Lowercase alphabetic characters (a through z)
- Numeric digits (0 through 9)
- Period (.), forward slash (/), underscore (\_), percent (%)

The name must not contain leading or embedded blanks, but might contain trailing blanks. A null character can be used to indicate the end of significant data in the name; the null and any characters following it are treated as blanks. The following restrictions apply in the environments indicated:

- On IBM i, names containing lowercase characters, forward slash, or percent must be enclosed in quotation marks when specified on commands. These quotation marks must not be specified in the **QMNAME** parameter.

If the name consists entirely of blanks, the name of the *default* queue manager is used.

The name specified for *QMNAME* must be the name of a *connectable* queue manager.

**Queue sharing groups:** On systems where several queue managers exist and are configured to form a queue sharing group, the name of the queue sharing group can be specified for *QMNAME* in place of the name of a queue manager. This allows the application to connect to *any* queue manager that is available in the queue sharing group. The system can also be configured so that a blank *QMNAME* causes connection to the queue sharing group instead of to the default queue manager.

If *QMNAME* specifies the name of the queue sharing group, but there is also a queue manager with that name on the system, connection is made to the latter in preference to the former. Only if that connection fails is connection to one of the queue managers in the queue sharing group attempted.

If the connection is successful, the handle returned by the MQCONN or MQCONNX call can be used to access *all* of the resources (both shared and nonshared) that belong to the particular queue manager to which connection has been made. Access to these resources is subject to the typical authorization controls.

If the application issues two MQCONN or MQCONNX calls in order to establish concurrent connections, and one or both calls specifies the name of the queue sharing group, the second call may return completion code CCWARN and reason code RC2002. This occurs when the second call connects to the same queue manager as the first call.

Queue sharing groups are supported only on z/OS. Connection to a queue sharing group is supported only in the batch, RRS batch, and TSO environments.

**IBM MQ client applications:** For IBM MQ MQI client applications, a connection is attempted for each client-connection channel definition with the specified queue manager name, until one is successful. The queue manager, however, must have the same name as the specified name. If an all-blank name is specified, each client-connection channel with an all-blank queue manager name is tried until one is successful; in this case there is no check against the actual name of the queue manager.

**IBM MQ client queue manager groups:** If the specified name starts with an asterisk (\*), the actual queue manager to which connection is made may have a name that is different from that specified by the application. The specified name (without the asterisk) defines a *group* of queue managers that are eligible for connection. The implementation selects one from the group by trying each one in turn, in alphabetic order, until one is found to which a connection can be made. If none of the queue managers in the group is available for connection, the call fails. Each queue manager is tried once

only. If an asterisk alone is specified for the name, an implementation-defined default queue manager group is used.

Queue manager groups are supported only for applications running in an MQ-client environment; the call fails if a non-client application specifies a queue manager name beginning with an asterisk. A group is defined by providing several client connection channel definitions with the same queue manager name (the specified name without the asterisk), to communicate with each of the queue managers in the group. The default group is defined by providing one or more client connection channel definitions, each with a blank queue manager name (specifying an all-blank name therefore has the same effect as specifying a single asterisk for the name for a client application).

After connecting to one queue manager of a group, an application can specify blanks in the typical way in the queue manager name fields in the message and object descriptors to mean the name of the queue manager to which the application has actually connected (the *local queue manager*). If the application needs to know this name, the MQINQ call can be issued to inquire the **QMGrName** queue manager attribute.

Prefixing an asterisk to the connection name implies that the application is not dependent on connecting to a particular queue manager in the group. Suitable applications would be:

- Applications that put messages but do not get messages.
- Applications that put request messages and then get the reply messages from a *temporary dynamic* queue.

Unsuitable applications would be those that need to get messages from a particular queue at a particular queue manager; such applications should not prefix the name with an asterisk.

Note that if an asterisk is specified, the maximum length of the remainder of the name is 47 characters.

The length of this parameter is given by LNQMNL.

#### **HCONN (10-digit signed integer) - output**

Connection handle.

This handle represents the connection to the queue manager. It must be specified on all subsequent message queuing calls issued by the application. It ceases to be valid when the MQDISC call is issued, or when the unit of processing that defines the scope of the handle terminates.

The scope of the handle is restricted to the smallest unit of parallel processing supported by the platform on which the application is running; the handle is not valid outside the unit of parallel processing from which the MQCONN call was issued.

- On IBM i, the scope of the handle is the job issuing the call.

#### **CMPCOD (10-digit signed integer) - output**

Completion code.

It is one of the following:

##### **CCOK**

Successful completion.

##### **CCWARN**

Warning (partial completion).

##### **CCFAIL**

Call failed.

#### **REASON (10-digit signed integer) - output**

Reason code qualifying *CMPCOD*.

If *CMPCOD* is CCOK:

##### **RCNONE**

(0, X'000') No reason to report.

If *CMPCOD* is CCWARN:

**RC2002**

(2002, X'7D2') Application already connected.

If *CMPCOD* is CCFAIL:

**RC2219**

(2219, X'8AB') MQI call reentered before previous call complete.

**RC2267**

(2267, X'8DB') Unable to load cluster workload exit.

**RC2009**

## MQCONN (Connect queue manager (extended)) on IBM i

The MQCONN call connects an application program to a queue manager. It provides a queue manager connection handle, which is used by the application on subsequent IBM MQ calls.

The MQCONN call is like the MQCONN call, except that MQCONN allows options to be specified to control the way that the call works.

On IBM MQ for Multiplatforms, each thread in an application can connect to different queue managers. On other systems, all concurrent connections within a process must be to the same queue manager.

- [“Syntax” on page 1280](#)
- [“Parameters” on page 1280](#)
- [“RPG Declaration” on page 1281](#)

### Syntax

MQCONN (*QMNAME*, *CNOPT*, *HCONN*, *CMPCOD*, *REASON*)

### Parameters

The MQCONN call has the following parameters:

#### QMNAME (48-byte character string) - input

Name of queue manager.

See the **QMNAME** parameter described in [“MQCONN \(Connect queue manager\) on IBM i” on page 1276](#) for details.

#### CNOPT (MQCNO) - input/output

Options that control the action of MQCONN.

See [“MQCNO \(Connect options\) on IBM i” on page 1048](#) for details.

#### HCONN (10-digit signed integer) - output

Connection handle.

See the **HCONN** parameter described in [“MQCONN \(Connect queue manager\) on IBM i” on page 1276](#) for details.

#### CMPCOD (10-digit signed integer) - output

Completion code.

See the **CMPCOD** parameter described in [“MQCONN \(Connect queue manager\) on IBM i” on page 1276](#) for details.

#### REASON (10-digit signed integer) - output

Reason code qualifying *CMPCOD*.

See the **REASON** parameter described in [“MQCONN \(Connect queue manager\) on IBM i” on page 1276](#) for details of possible reason codes.

The following additional reason codes can be returned by the MQCONN call:

If *CMPCOD* is CCFAIL:

##### RC2278

(2278, X'8E6') Client connection fields not valid.

##### RC2139

(2139, X'85B') Connect-options structure not valid.

## RC2046

(2046, X'7FE') Options not valid or not consistent.

## RPG Declaration

```

IBM i

## MQCRTMH (Create message handle) on IBM i

The MQCRTMH call returns a message handle.

An application can use it on subsequent message queuing calls:

- Use the [MQSETMP](#) call to set a property of the message handle.
- Use the [MQINQMP](#) call to inquire on the value of a property of the message handle.
- Use the [MQDLTMP](#) call to delete a property of the message handle.

The message handle can be used on the MQPUT and MQPUT1 calls to associate the properties of the message handle with the properties of the message being put. Similarly, by specifying a message handle on the MQGET call, the properties of the message being retrieved can be accessed by using the message handle when the MQGET call completes.

Use [MQDLTMH](#) to delete the message handle.

- [“Syntax” on page 1281](#)
- [“Parameters” on page 1281](#)
- [“RPG Declaration” on page 1283](#)

## Syntax

MQCRTMH (*Hconn*, *CrtMsgHOpts*, *Hmsg*, *CompCode*, *Reason*)

## Parameters

The MQCRTMH call has the following parameters:

### HCONN (10-digit signed integer) - input

This handle represents the connection to the queue manager. The value of *HCONN* was returned by a previous MQCONN or MQCONNX call. If the connection to the queue manager ceases to be valid and no IBM MQ call is operating on the message handle, [MQDLTMH](#) is implicitly called to delete the message.

Alternatively, you can specify the following value:

## **HCUNAS**

The connection handle does not represent a connection to any particular queue manager.

When this value is used, the message handle must be deleted with an explicit call to `MQDLTMH` in order to release any storage allocated to it; IBM MQ never implicitly deletes the message handle.

There must be at least one valid connection to a queue manager established on the thread creating the message handle, otherwise the call fails with RC2018.

## **CRTOPT (MQCMHO) - input**

The options that control the action of `MQCRTMH`. See `MQCMHO` for details.

## **HMSG (20-digit signed integer) - output**

On output a message handle is returned that can be used to set, inquire, and delete properties of the message handle. Initially the message handle contains no properties.

A message handle also has an associated message descriptor. Initially this message descriptor contains the default values. The values of the associated message descriptor fields can be set and inquired by using the `MQSETMP` and `MQINQMP` calls. The `MQDLTMP` call resets a field of the message descriptor back to its default value.

If the `HCONN` parameter is specified as the value `HCUNAS` then the returned message handle can be used on `MQGET`, `MQPUT`, or `MQPUT1` calls with any connection within the unit of processing, but can be in use by only one IBM MQ call at a time. If the handle is in use when a second IBM MQ call attempts to use the same message handle, the second IBM MQ call fails with reason code RC2499.

If the `HCONN` parameter is not `HCUNAS` then the returned message handle can be used only on the specified connection.

The same `HCONN` parameter value must be used on the subsequent `MQI` calls where this message handle is used:

- `MQDLTMH`
- `MQSETMP`
- `MQINQMP`
- `MQDLTMP`
- `MQMHBUF`
- `MQBUFMH`

The returned message handle ceases to be valid when the `MQDLTMH` call is issued for the message handle, or when the unit of processing that defines the scope of the handle terminates. `MQDLTMH` is called implicitly if a specific connection is supplied when the message handle is created and the connection to the queue manager ceases to be valid, for example, if `MQDBC` is called.

## **CMPCOD (10-digit signed integer) - output**

The completion code; it is one of the following:

### **CCOK**

Successful completion.

### **CCFAIL**

Call failed.

## **REASON (10-digit signed integer) - output**

The reason code qualifying `CMPCOD`.

If `CMPCOD` is `CCOK`:

### **RCNONE**

(0, X'000') No reason to report.

If `CMPCOD` is `CCFAIL`:

**RC2204**

(2204, X'089C') Adapter not available.

**RC2130**

(2130, X'852') Unable to load adapter service module.

**RC2157**

(2157, X'86D') Primary and home ASIDs differ.

**RC2219**

(2219, X'08AB') MQI call entered before previous call completed.

**RC2461**

(2461, X'099D') Create message handle options structure not valid.

**RC2273**

(2273, X'7D9') Connection to queue manager lost.

**RC2017**

(2017, X'07E1') No more handles available.

**RC2018**

(2018, X'7E2') Connection handle not valid.

**RC2460**

(2460, X'099C') Message handle pointer not valid.

**RC2046**

(2046, X'07FE') Options not valid or not consistent.

**RC2071**

(2071, X'817') Insufficient storage available.

**RC2195**

(2195, X'893') Unexpected error occurred.

See [“Return codes for IBM i \(ILE RPG\)”](#) on page 1424 for more details.

**RPG Declaration**

**IBM i MQCTL (Control callback) on IBM i**

The MQCTL call performs controlling actions on the object handles opened for a connection.

- [“Syntax” on page 1284](#)
- [“Usage notes” on page 1284](#)
- [“Parameters” on page 1284](#)
- [“RPG Declaration” on page 1288](#)

## Syntax

MQCTL (*Hconn, Operation, ControlOpts, CompCode, Reason*)

## Usage notes

1. Callback routines must check the responses from all services they invoke, and if the routine detects a condition that cannot be resolved, it must issue an MQCB(CBREG) command to prevent repeated calls to the callback routine.

## Parameters

The MQCTL call has the following parameters:

### HCONN (10-digit signed integer) - input

This handle represents the connection to the queue manager. The value of *HCONN* was returned by a previous MQCONN or MQCONNX call.

### OPERATN (10-digit signed integer) - input

The operation being processed on the callback defined for the specified object handle. You must specify one, and one only, of the following options:

#### CTLSR

Start the consuming of messages for all defined message consumer functions for the specified connection handle.

Callbacks run on a thread started by the system, which is different from any of the application threads.

This operation gives control of the provided connection handle to system. The only MQI calls which can be issued by a thread other than the consumer thread are:

- MQCTL with Operation CTLSP
- MQCTL with Operation CTLSU
- MQDISC - This performs MQCTL with Operation CTLSP before disconnection the HConn.

RC2500 is returned if an IBM MQ API call is issued while the connection handle is started, and the call does not originate from a message consumer function.

If a connection fails, this stops the conversation as soon as possible. It is possible, therefore, for an IBM MQ API call being issued on the main thread to receive the return code RC2500 for a while, followed by the return code RC2009 when the connection reverts to the stopped state.

This can be issued in a consumer function. For the same connection as the callback routine, its only purpose is to cancel a previously issued CTLSP operation.

This option is not supported if the application is bound with a nonthreaded IBM MQ library.

#### CTLSW

Start the consuming of messages for all defined message consumer functions for the specified connection handle.

Message consumers run on the same thread and control is not returned to the caller of MQCTL until:

- Released by the use of the MQCTL CTLSP or CTLSU operations, or
- All consumer routines have been deregistered or suspended.

If all consumers are deregistered or suspended, an implicit CTLSP operation is issued.

This option cannot be used from within a callback routine, either for the current connection handle or any other connection handle. If the call is attempted it returns with RC2012.

If, at any time during a CTLSW operation there are no registered, non-suspended consumers the call fails with a reason code of RC2446.

If, during a CTLSW operation, the connection is suspended, the MQCTL call returns a warning reason code of RC2521; the connection remains 'started'.

The application can choose to issue CTLSP or CTLRE. In this instance, the CTLRE operation blocks.

This option is not supported in a single threaded client.

### **CTLSP**

Stop the consuming of messages, and wait for all consumers to complete their operations before this option completes. This operation releases the connection handle.

If issued from within a callback routine, this option does not take effect until the routine exits. No more message consumer routines are called after the consumer routines for messages already read have completed, and after stop calls (if requested) to callback routines have been made.

If issued outside a callback routine, control does not return to the caller until the consumer routines for messages already read have completed, and after stop calls (if requested) to callbacks have been made. The callbacks themselves, however, remain registered.

This function has no effect on read ahead messages. You must ensure that consumers run MQCLOSE(COQSC), from within the callback function, to determine whether there are any further messages available to be delivered.

### **CTLSU**

Pause the consuming of messages. This operation releases the connection handle.

This does not affect the reading ahead of messages for the application. If you intend to stop consuming messages for a long period, consider closing the queue and reopening it when consumption must continue.

If issued from within a callback routine, it does not take effect until the routine exits. No more message consumer routines will be called after the current routine exits.

If issued outside a callback, control does not return to the caller until the current consumer routine has completed and no more are called.

### **CTLRE**

Resume the consuming of messages.

This option is normally issued from the main application thread, but it can also be used from within a callback routine to cancel an earlier suspension request issued in the same routine.

If CTLRE is used to resume a CTLSW, then the operation blocks.

### **PCTLOP (MQCTLO) - input**

Options that control the action of MQCTL

See [MQCTLO](#) for details of the structure.

### **CMPCOD (10-digit signed integer) - output**

The completion code; it is one of the following:

#### **CCOK**

Successful completion.

#### **CCWARN**

Warning (partial completion).

#### **CCFAIL**

Call failed.

### **REASON (10-digit signed integer) - output**

The following reason codes are the ones that the queue manager can return for the **Reason** parameter.

If *CMPCOD* is CCOK:

**RCNONE**

(0, X'000') No reason to report.

If *CMPCOD* is CCFAIL:

**RC2133**

(2133, X'855') Unable to load data conversion services modules.

**RC2204**

(2204, X'89C') Adapter not available.

**RC2130**

(2130, X'852') Unable to load adapter service module.

**RC2374**

(2374, X'946') API exit failed.

**RC2183**

(2183, X'887') Unable to load API exit.

**RC2157**

(2157, X'86D') Primary and home ASIDs differ.

**RC2005**

(2005, X'7D5') Buffer length parameter not valid.

**RC2487**

(2487, X'9B7') Unable to call the callback routine

**RC2448**

(2448, X'990') Unable to Deregister, Suspend, or Resume because there is no registered callback

**RC2486**

(2486, X'9B6') Either, both CallbackFunction and CallbackName have been specified on a CBREG call, or either one of CallbackFunction or CallbackName has been specified but does not match the currently registered callback function.

**RC2483**

(2483, X'9B3') Incorrect CallBackType field.

**RC2219**

(2219, X'8AB') MQI call entered before previous call complete.

**RC2444**

(2444, X'98C') Option block is incorrect.

**RC2484**

(2484, X'9B4') Incorrect MQCBD options field.

**RC2140**

(2140, X'85C') Wait request rejected by CICS.

**RC2009**

(2009, X'7D9') Connection to queue manager lost.

**RC2217**

(2217, X'8A9') Not authorized for connection.

**RC2202**

(2202, X'89A') Connection quiescing.

**RC2203**

(2203, X'89B') Connection shutting down.

**RC2207**

(2207, X'89F') Correlation-identifier error.

**RC2016**

(2016, X'7E0') Gets inhibited for the queue.

**RC2351**  
(2351, X'92F') Global units of work conflict.

**RC2186**  
(2186, X'88A') Get-message options structure not valid.

**RC2353**  
(2353, X'931') Handle in use for global unit of work.

**RC2018**  
(2018, X'7E2') Connection handle not valid.

**RC2019**  
(2019, X'7E3') Object handle not valid.

**RC2259**  
(2259, X'8D3') Inconsistent browse specification.

**RC2245**  
(2245, X'8C5') Inconsistent unit-of-work specification.

**RC2246**  
(2246, X'8C6') Message under cursor not valid for retrieval.

**RC2352**  
(2352, X'930') Global unit of work conflicts with local unit of work.

**RC2247**  
(2247, X'8C7') Match options not valid.

**RC2485**  
(2485, X'9B5') Incorrect MaxMsgLength field

**RC2026**  
(2026, X'7EA') Message descriptor not valid.

**RC2497**  
(2497, X'9C1')The specified function entry point was not be found in the module.

**RC2496**  
(2496, X'9C0') Module is found but is of the wrong type (32-bit or 64-bit) or is not a valid dll.

**RC2495**  
(2495, X'9BF') Module not found in the search path or not authorized to load.

**RC2206**  
(2206, X'89E') Message-identifier error.

**RC2250**  
(2250, X'8CA') Message sequence number not valid.

**RC2331**  
(2331, X'91B') Use of message token not valid.

**RC2036**  
(2036, X'7F4') Queue not open for browse.

**RC2037**  
(2037, X'7F5') Queue not open for input.

**RC2041**  
(2041, X'7F9') Object definition changed since opened.

**RC2101**  
(2101, X'835') Object damaged.

**RC2488**  
(2488, X'9B8') Incorrect Operation code on API Call

**RC2046**  
(2046, X'7FE') Options not valid or not consistent.

**RC2193**  
(2193, X'891') Error accessing page-set data set.

**RC2052**

(2052, X'804') Queue has been deleted.

**RC2394**

(2394, X'95A') Queue has wrong index type.

**RC2058**

(2058, X'80A') Queue manager name not valid or not known.

**RC2059**

(2059, X'80B') Queue manager not available for connection.

**RC2161**

(2161, X'871') Queue manager quiescing.

**RC2162**

(2162, X'872') Queue manager shutting down.

**RC2102**

(2102, X'836') Insufficient system resources available.

**RC2069**

(2069, X'815') Signal outstanding for this handle.

**RC2071**

(2071, X'817') Insufficient storage available.

**RC2109**

(2109, X'83D') Call suppressed by exit program.

**RC2072**

(2072, X'818') Syncpoint support not available.

**RC2195**

(2195, X'893') Unexpected error occurred.

**RC2354**

(2354, X'932') Enlistment in global unit of work failed.

**RC2355**

(2355, X'933') Mixture of unit-of-work calls not supported.

**RC2255**

(2255, X'8CF') Unit of work not available for the queue manager to use.

**RC2090**

(2090, X'82A') Wait interval in MQGMO not valid.

**RC2256**

(2256, X'8D0') Wrong version of MQGMO supplied.

**RC2257**

(2257, X'8D1') Wrong version of MQMD supplied.

**RC2298**

(2298, X'8FA') The function requested is not available in the current environment.

**RPG Declaration**

```

## IBM i MQDISC (Disconnect queue manager) on IBM i

The MQDISC call breaks the connection between the queue manager and the application program, and is the inverse of the MQCONN or MQCONNX call.

- [“Syntax” on page 1289](#)
- [“Usage notes” on page 1289](#)
- [“Parameters” on page 1289](#)
- [“RPG Declaration” on page 1290](#)

### Syntax

MQDISC (*HCONN*, *CMPCOD*, *REASON*)

### Usage notes

1. If an MQDISC call is issued when the application still has objects open, those objects are closed by the queue manager, with the close options set to CONONE.
2. If the application ends with uncommitted changes in a unit of work, the disposition of those changes depends on how the application ends:
  - a. If the application issues the MQDISC call before ending:
    - For a queue manager coordinated unit of work, the queue manager issues the MQCMIT call on behalf of the application. The unit of work is committed if possible, and backed out if not.
    - For an externally coordinated unit of work, there is no change in the status of the unit of work; however, the queue manager will indicate that the unit of work should be committed, when asked by the unit-of-work coordinator.
  - b. If the application ends normally but without issuing the MQDISC call, the unit of work is backed out.
  - c. If the application ends *abnormally* without issuing the MQDISC call, the unit of work is backed out.

### Parameters

The MQDISC call has the following parameters:

#### **HCONN (10-digit signed integer) - input/output**

Connection handle.

This handle represents the connection to the queue manager. The value of *HCONN* was returned by a previous MQCONN or MQCONNX call.

On successful completion of the call, the queue manager sets *HCONN* to a value that is not a valid handle for the environment. This value is:

#### **HCUNUH**

Unusable connection handle.

#### **CMPCOD (10-digit signed integer) - output**

Completion code.

It is one of the following:

**CCOK**

Successful completion.

**CCWARN**

Warning (partial completion).

**CCFAIL**

Call failed.

**REASON (10-digit signed integer) - output**Reason code qualifying *CMPCOD*.If *CMPCOD* is CCOK:**RCNONE**

(0, X'000') No reason to report.

If *CMPCOD* is CCFAIL:**RC2219**

(2219, X'8AB') MQI call reentered before previous call complete.

**RC2009**

(2009, X'7D9') Connection to queue manager lost.

**RC2018**

(2018, X'7E2') Connection handle not valid.

**RC2058**

(2058, X'80A') Queue manager name not valid or not known.

**RC2059**

(2059, X'80B') Queue manager not available for connection.

**RC2162**

(2162, X'872') Queue manager shutting down.

**RC2102**

(2102, X'836') Insufficient system resources available.

**RC2071**

(2071, X'817') Insufficient storage available.

**RC2195**

(2195, X'893') Unexpected error occurred.

**RPG Declaration**

```

**IBM i MQDLTMH (Delete message handle) on IBM i**

The MQDLTMH call deletes a message handle and is the inverse of the MQCRTMH call.

- [“Syntax” on page 1291](#)

- [“Usage notes” on page 1291](#)
- [“Parameters” on page 1292](#)
- [“RPG Declaration” on page 1293](#)

## Syntax

MQDLTMH ((*Hconn*, *Hmsg*, *DltMsgHOpts*, *CompCode*, *Reason*))

## Usage notes

1. You can use this call only when the queue manager itself coordinates the unit of work. This can be:
  - A local unit of work, where the changes affect only IBM MQ resources.
  - A global unit of work, where the changes can affect resources belonging to other resource managers, as well as affecting IBM MQ resources.

For further details about local and global units of work, see [“MQBEGIN \(Begin unit of work\) on IBM i” on page 1253](#).
2. In environments where the queue manager does not coordinate the unit of work, use the appropriate back-out call instead of MQBACK. The environment might also support an implicit back out caused by the application terminating abnormally.
  - On z/OS, use the following calls:
    - Batch programs (including IMS batch DL/I programs) can use the MQBACK call if the unit of work affects only IBM MQ resources. However, if the unit of work affects both IBM MQ resources and resources belonging to other resource managers (for example, Db2 ), use the SRRBACK call provided by the z/OS Recoverable Resource Service (RRS). The SRRBACK call backs out changes to resources belonging to the resource managers that have been enabled for RRS coordination.
    - CICS applications must use the EXEC CICS SYNCPOINT ROLLBACK command to back out the unit of work. Do not use the MQBACK call for CICS applications.
    - IMS applications (other than batch DL/I programs) must use IMS calls such as ROLB to back out the unit of work. Do not use the MQBACK call for IMS applications (other than batch DL/I programs).
  - On IBM i, use this call for local units of work coordinated by the queue manager. This means that a commitment definition must not exist at job level, that is, the STRCMTCTL command with the **CMTSCOPE(\*JOB)** parameter must not have been issued for the job.
3. If an application ends with uncommitted changes in a unit of work, the disposition of those changes depends on whether the application ends normally or abnormally. See the usage notes in [“MQDISC \(Disconnect queue manager\) on IBM i” on page 1289](#) for further details.
4. When an application puts or gets messages in groups or segments of logical messages, the queue manager retains information relating to the message group and logical message for the last successful MQPUT and MQGET calls. This information is associated with the queue handle, and includes such things as:
  - The values of the *GroupId*, *MsgSeqNumber*, *Offset*, and *MsgFlags* fields in MQMD.
  - Whether the message is part of a unit of work.
  - For the MQPUT call: whether the message is persistent or nonpersistent.

The queue manager keeps three sets of group and segment information, one set for each of the following:

- The last successful MQPUT call (this can be part of a unit of work).
- The last successful MQGET call that removed a message from the queue (this can be part of a unit of work).
- The last successful MQGET call that browsed a message on the queue (this cannot be part of a unit of work).

If the application puts or gets the messages as part of a unit of work, and the application then backs out the unit of work, the group and segment information is restored to the value that it had previously:

- The information associated with the MQPUT call is restored to the value that it had before the first successful MQPUT call for that queue handle in the current unit of work.
- The information associated with the MQGET call is restored to the value that it had before the first successful MQGET call for that queue handle in the current unit of work.

Queues that were updated by the application after the unit of work started, but outside the scope of the unit of work, do not have their group and segment information restored if the unit of work is backed out.

Restoring the group and segment information to its previous value when a unit of work is backed out allows the application to spread a large message group or large logical message consisting of many segments across several units of work, and to restart at the correct point in the message group or logical message if one of the units of work fails. Using several units of work might be advantageous if the local queue manager has only limited queue storage. However, the application must maintain sufficient information to be able to restart putting or getting messages at the correct point if that a system failure occurs.

For details of how to restart at the correct point after a system failure, see the PMLOGO option described in [PMOPT \(10 digit signed integer\)](#), and the GMLOGO option described in [GMOPT \(10 digit signed integer\)](#).

The remaining usage notes apply only when the queue manager coordinates the units of work:

5. A unit of work has the same scope as a connection handle. All IBM MQ calls that affect a particular unit of work must be performed using the same connection handle. Calls issued using a different connection handle (for example, calls issued by another application) affect a different unit of work. See [HCONN \(10 digit signed integer\) - output](#) for information about the scope of connection handles.
6. Only messages that were put or retrieved as part of the current unit of work are affected by this call.
7. A long-running application that issues MQGET, MQPUT, or MQPUT1 calls within a unit of work, but that never issues a commit or backout call, can fill queues with messages that are not available to other applications. To guard against this possibility, the administrator must set the **MaxUncommittedMsgs** queue manager attribute to a value that is low enough to prevent runaway applications filling the queues, but high enough to allow the expected messaging applications to work correctly.

## Parameters

The MQDLTMH call has the following parameters:

### **HCONN (10-digit signed integer) - input**

This handle represents the connection to the queue manager.

The value must match the connection handle that was used to create the message handle specified in the **HMSG** parameter.

If the message handle was created using HCUNAS then a valid connection must be established on the thread deleting the message handle, otherwise the call fails with RC2009 .

### **HMSG (20-digit signed integer) - input/output**

This is the message handle to be deleted. The value was returned by a previous MQCRTMH call.

On successful completion of the call, the handle is set to an invalid value for the environment. This value is:

#### **HMUNUH**

Unusable message handle.

The message handle cannot be deleted if another IBM MQ call is in progress that was passed the same message handle.

## DLTOPT (MQDMHO) - input

See [MQDMHO](#) for details.

## CMPCOD (10-digit signed integer) - output

The completion code; it is one of the following:

### CCOK

Successful completion.

### CCFAIL

Call failed.

## REASON (10-digit signed integer) - output

The reason code qualifying *CMPCOD*.

If *CMPCOD* is CCOK:

### RCNONE

(0, X'000') No reason to report.

If *CMPCOD* is CCFAIL:

### RC2204

(2204, X'089C') Adapter not available.

### RC2130

(2130, X'852') Unable to load adapter service module.

### RC2157

(2157, X'86D') Primary and home ASIDs differ.

### RC2219

(2219, X'08AB') MQI call entered before previous call completed.

### RC2009

(2009, X'07D9') Connection to queue manager lost.

### RC2462

(2462, X'099E') Delete message handle options structure not valid.

### RC2460

(2460, X'099C') Message handle pointer not valid.

### RC2499

(2499, X'09C3') Message handle already in use.

### RC2046

(2046, X'07FE') Options not valid or not consistent.

### RC2071

(2071, X'817') Insufficient storage available.

### RC2195

(2195, X'893') Unexpected error occurred.

See [“Return codes for IBM i \(ILE RPG\)”](#) on page 1424 for more details.

## MQDLTMP - Delete message property

The MQDLTMP call deletes a property from a message handle and is the inverse of the MQSETMP call.

- [“Syntax” on page 1294](#)
- [“Parameters” on page 1294](#)
- [“RPG Declaration” on page 1295](#)

### Syntax

MQDLTMP (*Hconn, Hmsg, DltPropOpts, Name, CompCode, Reason*)

### Parameters

The MQDLTMP call has the following parameters:

#### HCONN (10-digit signed integer) - Input

This handle represents the connection to the queue manager. The value must match the connection handle that was used to create the message handle specified in the **HMSG** parameter.

If the message handle was created using HCUNAS then a valid connection must be established on the thread deleting the message handle otherwise the call fails with RC2009.

#### HMSG (20-digit signed integer) - input

This is the message handle containing the property to be deleted. The value was returned by a previous MQCRTMH call.

#### DLTOPT (MQDMPO) - Input

See the [MQDMPO](#) data type for details.

#### PRNAME (MQCHARV) - input

The name of the property to delete. See [Property names](#) for further information about property names.

Wildcards are not allowed in the property name.

#### CMPCOD (10-digit signed integer) - output

The completion code; it is one of the following:

##### CCOK

Successful completion.

##### CCWARN

Warning (partial completion).

##### CCFAIL

Call failed.

#### REASON (10-digit signed integer) - output

The reason code qualifying *CMPCOD*.

If *CMPCOD* is CCOK:

##### RCNONE

(0, X'000') No reason to report.

If *CMPCOD* is CCWARN:

**RC2471**

(2471, X'09A7') Property not available.

**RC2421**

(2421, X'0975') An MQRFH2 folder containing properties could not be parsed.

If *CMPCOD* is CCFAIL:

**RC2204**

(2204, X'089C') Adapter not available.

**RC2130**

(2130, X'0852') Unable to load adapter service module.

**RC2157**

(2157, X'086D') Primary and home ASIDs differ.

**RC2219**

(2219, X'08AB') MQI call entered before previous call completed.

**RC2009**

(2009, X'07D9') Connection to queue manager lost.

**RC2481**

(2481, X'09B1') Delete message property options structure not valid.

**RC2460**

(2460, X'099C') Message handle not valid.

**RC2499**

(2499, X'09C3') Message handle already in use.

**RC2046**

(2046, X'07FE') Options not valid or not consistent.

**RC2442**

(2442, X'098A') Invalid property name.

**RC2111**

(2111, X'083F') Property name coded character set identifier not valid.

**RC2195**

(2195, X'0893') Unexpected error occurred.

For more information about these codes, see [API completion and reason codes](#).

## RPG Declaration

```
C*..1.....2.....3.....4.....5.....6.....7..
C          CALLP      MQDLTMP(HCONN : HMSG : DLTOPT :
                        PRNAME : CMPCOD : REASON)
```

The prototype definition for the call is:

```
DMQDLTMP          PR          EXTPROC('MQDLTMP')
D* Connection handle
D HCONN          10I 0 VALUE

D REASON          10I 0
```

The MQGET call retrieves a message from a local queue that has been opened by using the MQOPEN call.

- [“Syntax” on page 1296](#)
- [“Usage notes” on page 1296](#)
- [“Parameters” on page 1299](#)
- [“RPG Declaration” on page 1303](#)

## Syntax

MQGET (*HCONN, HOBJ, MSGDSC, GMO, BUFLN, BUFFER, DATLEN, CMPCOD, REASON*)

## Usage notes

1. The message retrieved is normally deleted from the queue. This deletion can occur as part of the MQGET call itself, or as part of a syncpoint. Message deletion does not occur if a GMBRWF or GMBRWN option is specified on the **GMO** parameter (see the *GMOPT* field described in [“MQGMO \(Get-message options\) on IBM i” on page 1077](#)).
2. If the GMLK option is specified with one of the browse options, the browsed message is locked so that it is visible only to this handle.

If the GMUNLK option is specified, a previously locked message is unlocked. No message is retrieved in this case, and the **MSGDSC, BUFLN, BUFFER** and **DATLEN** parameters are not checked or altered.

3. If the application issuing the MQGET call is running as an IBM MQ MQI client, it is possible for the message retrieved to be lost if during the processing of the MQGET call the IBM MQ MQI client terminates abnormally or the client connection is severed. This arises because the surrogate that is running on the platform of the queue manager and which issues the MQGET call on the behalf of the client cannot detect the loss of the client until the surrogate is about to return the message to the client; this is after the message has been removed from the queue. This can occur for both persistent messages and nonpersistent messages.

The risk of losing messages in this way can be eliminated by always retrieving messages within units of work (that is, by specifying the GMSYP option on the MQGET call, and using the MQCMIT or MQBACK calls to commit or back out the unit of work when processing of the message is complete). If GMSYP is specified, and the client terminates abnormally or the connection is severed, the surrogate backs out the unit of work on the queue manager and the message is reinstated on the queue.

In principle, the same situation can arise with applications that are running on the platform of the queue manager, but in this case the window during which a message can be lost is small. However, as with IBM MQ MQI clients the risk can be eliminated by retrieving the message within a unit of work.

4. If an application puts a sequence of messages on a particular queue within a single unit of work, and then commits that unit of work successfully, the messages become available for retrieval as follows:
  - If the queue is a *nonshared queue* (that is, a local queue), all messages within the unit of work become available at the same time.
  - If the queue is a *shared queue*, messages within the unit of work become available in the order in which they were put, but not all at the same time. When the system is heavily laden, it is possible for the first message in the unit of work to be retrieved successfully, but for the MQGET call for the second or subsequent message in the unit of work to fail with RC2033. If this occurs, the application must wait a short while and then try the operation again.
5. If an application puts a sequence of messages on the same queue without using message groups, the order of those messages is preserved if certain conditions are satisfied. See the usage notes in the description of the MQPUT call for details. If the conditions are satisfied, the messages are presented to the receiving application in the order in which they were sent, if:

- Only one receiver is getting messages from the queue.

If there are two or more applications getting messages from the queue, they must agree with the sender the mechanism to be used to identify messages that belong to a sequence. For example, the sender might set all of the MDCID fields in the messages in a sequence to a value that was unique to that sequence of messages.

- The receiver does not deliberately change the order of retrieval, for example by specifying a particular MDMID or MDCID.

If the sending application put the messages as a message group, the messages are presented to the receiving application in the correct order if the receiving application specifies the GMLOGO option on the MQGET call. For more information about message groups, see:

- MDMFL field in MQMD
- PMLOGO option in MQPMO
- GMLOGO option in MQGMO

6. Applications test for the feedback code FBQUIT in the MDFB field of the **MSGDSC** parameter. If this value is found, the application ends. See the MDFB field described in [“MQMD \(Message descriptor\) on IBM i” on page 1110](#) for more information.
7. If the queue identified by HOBJ was opened with the OOSAVA option, and the completion code from the MQGET call is CCOK or CCWARN, the context associated with the queue handle HOBJ is set to the context of the message that has been retrieved (unless the GMBRWF or GMBRWN option is set, in which case the context is marked as not available). This context can be used on a subsequent MQPUT or MQPUT1 call by specifying the PMPASI or PMPASA options. This enables the context of the message received to be transferred in whole or in part to another message (for example, when the message is forwarded to another queue). For more information about message context, see [Message context](#) and [Controlling context information](#).
8. If the GMCONV option is included in the **GMO** parameter, the application message data is converted to the representation requested by the receiving application, before the data is placed in the **BUFFER** parameter:
  - The MDFMT field in the control information in the message identifies the structure of the application data, and the MDCSI and MDENC fields in the control information in the message specify its character-set identifier and encoding.
  - The application issuing the MQGET call specifies in the MDCSI and MDENC fields in the **MSGDSC** parameter the character-set identifier and encoding to which the application message data must be converted.

When conversion of the message data is necessary, the conversion is performed either by the queue manager itself or by a user-written exit, depending on the value of the MDFMT field in the control information in the message:

- The following formats are converted automatically by the queue manager; these formats are called "built-in" formats:

FMADMN	FMMDE
FMCICS	FMPCF
FMCMD1	FMRMH
FMCMD2	FMRFH
FMDLH	FMRFH2
FMDH	FMSTR
FMEVNT	FMTM
FMIMS	FMXQH
FMIMVS	

- The format name FMNONE is a special value that indicates that the nature of the data in the message is undefined. As a consequence, the queue manager does not attempt conversion when the message is retrieved from the queue.

**Note:** If GMCONV is specified on the MQGET call for a message that has a format name of FMNONE, and the character set or encoding of the message differs from that specified in the **MSGDSC** parameter, the message is still returned in the **BUFFER** parameter (assuming no other errors), but the call completes with completion code CCWARN and reason code RC2110.

FMNONE can be used either when the nature of the message data means that it does not require conversion, or when the sending and receiving applications have agreed between themselves the form in which the message data should be sent.

- All other format names cause the message to be passed to a user-written exit for conversion. The exit has the same name as the format, apart from environment-specific additions. User-specified format names must not begin with the letters "MQ", as such names might conflict with format names supported in the future.

User data in the message can be converted between any supported character sets and encodings. However, be aware that if the message contains one or more IBM MQ header structures, the message cannot be converted from or to a character set that has double-byte or multi-byte characters for any of the characters that are valid in queue names. Reason code RC2111 or RC2115 results if this is attempted, and the message is returned unconverted. Unicode character set UTF-16 is an example of such a character set.

On return from MQGET, the following reason code indicates that the message was converted successfully:

- RCNONE

The following reason code indicates that the message might have been converted successfully; the application must check the MDCSI and MDENC fields in the **MSGDSC** parameter to find out:

- RC2079

All other reason codes indicate that the message was not converted.

**Note:** The interpretation of the reason code described in this example is true for conversions performed by user-written exits only if the exit conforms to the processing guidelines.

9. For the built-in formats listed previously, the queue manager might perform default conversion of character strings in the message when the GMCONV option is specified. Default conversion allows the queue manager to use an installation-specified default character set that approximates the actual character set, when converting string data. As a result, the MQGET call can succeed with completion code CCOK, instead of completing with CCWARN and reason code RC2111 or RC2115.

**Note:** The result of using an approximate character set to convert string data is that some characters might be converted incorrectly. This can be avoided by using in the string only characters which are common to both the actual character set and the default character set.

Default conversion applies both to the application message data and to character fields in the MQMD and MQMDE structures:

- Default conversion of the application message data occurs only when all of the following statements are true:
  - The application specifies GMCONV.
  - The message contains data that must be converted either from or to a character set which is not supported.
  - Default conversion was enabled when the queue manager was installed or restarted.
- Default conversion of the character fields in the MQMD and MQMDE structures occurs as necessary, if default conversion is enabled for the queue manager. The conversion is performed even if the GMCONV option is not specified by the application on the MQGET call.

10. The **BUFFER** parameter shown in the RPG programming example is declared as a string; this restricts the maximum length of the parameter to 256 bytes. If a larger buffer is required, the parameter must be declared instead as a structure, or as a field in a physical file.

Declaring the parameter as a structure increases the maximum length possible to 9999 bytes, while declaring the parameter as a field in a physical file increases the maximum length possible to approximately 32 KB.

## Parameters

The MQGET call has the following parameters:

### HCONN (10-digit signed integer) - input

Connection handle.

This handle represents the connection to the queue manager. The value of HCONN was returned by a previous MQCONN or MQCONNX call.

### HOBJ (10-digit signed integer) - input

Object handle.

This handle represents the queue from which a message is to be retrieved. The value of HOBJ was returned by a previous MQOPEN call. The queue must have been opened with one or more of the following options (see [“MQOPEN \(Open object\) on IBM i”](#) on page 1320 for details):

- OOINPS
- OOINPX
- OOINPQ
- OOBROW

### MSGDSC (MQMD) - input/output

Message descriptor.

This structure describes the attributes of the message required, and the attributes of the message retrieved. See [“MQMD \(Message descriptor\) on IBM i”](#) on page 1110 for details.

If BUFLLEN is less than the message length, MSGDSC is still entered by the queue manager, whether GMATM is specified on the **GMO** parameter (see the GMOPT field described in [“MQGMO \(Get-message options\) on IBM i”](#) on page 1077).

If the application provides a version-1 MQMD, the message returned has an MQMDE prefixed to the application message data, but only if one or more of the fields in the MQMDE has a nondefault value. If all of the fields in the MQMDE have default values, the MQMDE is omitted. A format name of FMMDE in the MDFMT field in MQMD indicates that an MQMDE is present.

### GMO (MQGMO) - input/output

Options that control the action of MQGET.

See [“MQGMO \(Get-message options\) on IBM i”](#) on page 1077 for details.

### BUFLLEN (10-digit signed integer) - input

Length in bytes of the BUFFER area.

Zero can be specified for messages that have no data, or if the message is to be removed from the queue and the data discarded (GMATM must be specified in this case).

**Note:** The length of the longest message that it is possible to read from the queue is given by the **MaxMsgLength** queue attribute; see [“Attributes for queues”](#) on page 1366.

### BUFFER (1-byte bit string x BUFLLEN) - output

Area to contain the message data.

The buffer must be aligned on a boundary appropriate to the nature of the data in the message. 4-byte alignment must be suitable for most messages (including messages containing IBM MQ header structures), but some messages might require more stringent alignment. For example, a message containing a 64-bit binary integer might require 8-byte alignment.

If BUFLLEN is less than the message length, as much of the message as possible is moved into BUFFER ; this happens whether GMATM is specified on the **GMO** parameter (see the GMOPT field described in [“MQGMO \(Get-message options\) on IBM i”](#) on page 1077 for more information).

The character set and encoding of the data in **BUFFER** are given by the MDCSI and MDENC fields returned in the **MSGDSC** parameter. If these values are different from the values required by the receiver, the receiver must convert the application message data to the character set and encoding required. The GMCONV option can be used with a user-written exit to perform the conversion of the message data (see [“MQGMO \(Get-message options\) on IBM i”](#) on page 1077 for details of this option).

**Note:** All of the other parameters on the MQGET call are in the character set and encoding of the local queue manager (given by the **CodedCharSetId** queue manager attribute and ENNAT).

If the call fails, the contents of the buffer might still have changed.

### **DATLEN (10-digit signed integer) - output**

Length of the message.

This is the length in bytes of the application data in the message. If this message length is greater than BUFLLEN, only BUFLLEN bytes are returned in the **BUFFER** parameter (that is, the message is truncated). If the value is zero, it means that the message contains no application data.

If BUFLLEN is less than the message length, DATLEN is still entered by the queue manager, whether GMATM is specified on the **GMO** parameter (see the GMOPT field described in [“MQGMO \(Get-message options\) on IBM i”](#) on page 1077 for more information). This allows the application to determine the size of the buffer required to accommodate the message data, and then reissue the call with a buffer of the appropriate size.

However, if the GMCONV option is specified, and the converted message data is too long to fit in BUFFER, the value returned for DATLEN is:

- The length of the unconverted data, for queue manager defined formats.

In this case, if the nature of the data causes it to expand during conversion, the application must allocate a buffer bigger than the value returned by the queue manager for DATLEN.

- The value returned by the data-conversion exit, for application-defined formats.

### **CMPCOD (10-digit signed integer) - output**

Completion code.

It is one of the following:

#### **CCOK**

Successful completion.

#### **CCWARN**

Warning (partial completion).

#### **CCFAIL**

Call failed.

### **REASON (10-digit signed integer) - output**

Reason code qualifying CMPCOD.

The following reason codes are the ones that the queue manager can return for the **REASON** parameter. If the application specifies the GMCONV option, and a user-written exit is invoked to convert some or all of the message data, it is the exit that decides what value is returned for the **REASON** parameter. As a result, values other than the values documented later in this section are possible.

If CMPCOD is CCOK:

**RCNONE**

(0, X'000') No reason to report.

If CMPCOD is CCWARN:

**RC2120**

(2120, X'848') Converted data too large for buffer.

**RC2190**

(2190, X'88E') Converted string too large for field.

**RC2150**

(2150, X'866') DBCS string not valid.

**RC2110**

(2110, X'83E') Message format not valid.

**RC2243**

(2243, X'8C3') Message segments have differing CCSIDs.

**RC2244**

(2244, X'8C4') Message segments have differing encodings.

**RC2209**

(2209, X'8A1') No message locked.

**RC2119**

(2119, X'847') Message data not converted.

**RC2272**

(2272, X'8E0') Message data partially converted.

**RC2145**

(2145, X'861') Source buffer parameter not valid.

**RC2111**

(2111, X'83F') Source coded character set identifier not valid.

**RC2113**

(2113, X'841') Packed-decimal encoding in message not recognized.

**RC2114**

(2114, X'842') Floating-point encoding in message not recognized.

**RC2112**

(2112, X'840') Source integer encoding not recognized.

**RC2143**

(2143, X'85F') Source length parameter not valid.

**RC2146**

(2146, X'862') Target buffer parameter not valid.

**RC2115**

(2115, X'843') Target coded character set identifier not valid.

**RC2117**

(2117, X'845') Packed-decimal encoding specified by receiver not recognized.

**RC2118**

(2118, X'846') Floating-point encoding specified by receiver not recognized.

**RC2116**

(2116, X'844') Target integer encoding not recognized.

**RC2079**

(2079, X'81F') Truncated message returned (processing completed).

**RC2080**

(2080, X'820') Truncated message returned (processing not completed).

If CMPCOD is CCFAIL:

- RC2004**  
(2004, X'7D4') Buffer parameter not valid.
- RC2005**  
(2005, X'7D5') Buffer length parameter not valid.
- RC2219**  
(2219, X'8AB') MQI call reentered before previous call complete.
- RC2009**  
(2009, X'7D9') Connection to queue manager lost.
- RC2010**  
(2010, X'7DA') Data length parameter not valid.
- RC2016**  
(2016, X'7E0') Gets inhibited for the queue.
- RC2186**  
(2186, X'88A') Get-message options structure not valid.
- RC2018**  
(2018, X'7E2') Connection handle not valid.
- RC2019**  
(2019, X'7E3') Object handle not valid.
- RC2241**  
(2241, X'8C1') Message group not complete.
- RC2242**  
(2242, X'8C2') Logical message not complete.
- RC2259**  
(2259, X'8D3') Inconsistent browse specification.
- RC2245**  
(2245, X'8C5') Inconsistent unit-of-work specification.
- RC2246**  
(2246, X'8C6') Message under cursor not valid for retrieval.
- RC2247**  
(2247, X'8C7') Match options not valid.
- RC2026**  
(2026, X'7EA') Message descriptor not valid.
- RC2250**  
(2250, X'8CA') Message sequence number not valid.
- RC2033**  
(2033, X'7F1') No message available.
- RC2034**  
(2034, X'7F2') Browse cursor not positioned on message.
- RC2036**  
(2036, X'7F4') Queue not open for browse.
- RC2037**  
(2037, X'7F5') Queue not open for input.
- RC2041**  
(2041, X'7F9') Object definition changed since opened.
- RC2101**  
(2101, X'835') Object damaged.
- RC2046**  
(2046, X'7FE') Options not valid or not consistent.
- RC2052**  
(2052, X'804') Queue has been deleted.

**RC2058**

(2058, X'80A') Queue manager name not valid or not known.

**RC2059**

(2059, X'80B') Queue manager not available for connection.

**RC2161**

(2161, X'871') Queue manager quiescing.

**RC2162**

(2162, X'872') Queue manager shutting down.

**RC2102**

(2102, X'836') Insufficient system resources available.

**RC2071**

(2071, X'817') Insufficient storage available.

**RC2024**

(2024, X'7E8') No more messages can be handled within current unit of work.

**RC2072**

(2072, X'818') Syncpoint support not available.

**RC2195**

(2195, X'893') Unexpected error occurred.

**RC2255**

(2255, X'8CF') Unit of work not available for the queue manager to use.

**RC2090**

(2090, X'82A') Wait interval in MQGMO not valid.

**RC2256**

(2256, X'8D0') Wrong version of MQGMO supplied.

**RC2257**

(2257, X'8D1') Wrong version of MQMD supplied.

**RPG Declaration**

```

The MQINQ call returns an array of integers and a set of character strings containing the attributes of an object.

The following types of object are valid:

- Queue
- Namelist
- Process definition
- Queue manager
- [“Syntax” on page 1304](#)
- [“Usage notes” on page 1304](#)
- [“Parameters” on page 1305](#)
- [“RPG Declaration” on page 1312](#)

## Syntax

MQINQ (*HCONN, HOBJ, SELCNT, SELS, IACNT, INTATR, CALEN, CHRATR, CMPCOD, REASON*)

## Usage notes

1. The values returned are a snapshot of the selected attributes. There is no guarantee that the attributes are not changed before the application can act upon the returned values.
2. When you open a model queue, a dynamic local queue is created. This is true even if you open the model queue to inquire about its attributes.

The attributes of the dynamic queue (with certain exceptions) are the same as those of the model queue at the time the dynamic queue is created. If you then use the MQINQ call on this queue, the queue manager returns the attributes of the dynamic queue, and not those of the model queue. See [Table 1](#) for details of which attributes of the model queue are inherited by the dynamic queue.

3. If the object being inquired is an alias queue, the attribute values returned by the MQINQ call are those of the alias queue, and not those of the base queue to which the alias resolves.
4. If the object being inquired is a cluster queue, the attributes that can be inquired depend on how the queue is opened:
  - If the cluster queue is opened for inquire plus one or more of input, browse, or set, there must be a local instance of the cluster queue in order for the open to succeed. In this case the attributes that can be inquired are those valid for local queues.
  - If the cluster queue is opened for inquire alone, or inquire and output, only the following attributes can be inquired; the **QType** attribute has the value QTCLUS in this case:
    - CAQD
    - CAQN
    - IADBND
    - IADPER
    - IADPRI
    - IAIPUT
    - IAQTYP

If the cluster queue is opened with no fixed binding (that is, OOBNDN specified on the MQOPEN call, or OOBNDQ specified when the **DefBind** attribute has the value BNDNOT), successive MQINQ calls for the queue might inquire different instances of the cluster queue, although typically all of the instances have the same attribute values.

For more information about cluster queues, see [Configuring a queue manager cluster](#).

5. If a number of attributes are to be inquired, and then some of them are to be set using the MQSET call, it might be convenient to position at the beginning of the selector arrays the attributes that are to be set, so that the same arrays (with reduced counts) can be used for MQSET.
6. If more than one of the warning situations arise (see the **CMPCOD** parameter), the reason code returned is the *first* one in the following list that applies:
  - a. RC2068
  - b. RC2022
  - c. RC2008
7. For more information about object attributes, see:
  - [“Attributes for queues” on page 1366](#)
  - [“Attributes for namelists” on page 1394](#)
  - [“Attributes for process definitions on IBM i” on page 1395](#)
  - [“Attributes for the queue manager on IBM i” on page 1397](#)
8. A new local queue SYSTEM.ADMIN.COMMAND.EVENT is used for queuing messages that are generated whenever commands are issued. Messages are put onto this queue for most commands, depending on how the CMDEV queue manager attribute is set:
  - **ENABLED** - command event messages are generated and put onto the queue for all successful commands.
  - **NODISPLAY** - command event messages are generated and put onto the queue for all successful commands other than the DISPLAY (MQSC) command, and the Inquire (PCF) command.
  - **DISABLED** - command event messages are not generated (this is the queue manager's initial default value).

## Parameters

The MQINQ call has the following parameters:

### **HCONN (10 digit signed integer) - input**

Connection handle.

This handle represents the connection to the queue manager. The value of *HCONN* was returned by a previous MQCONN or MQCONNX call.

### **HOBJ (10 digit signed integer) - input**

Object handle.

This handle represents the object (of any type) with attributes that are required. The handle must have been returned by a previous MQOPEN call that specified the OOINQ option.

### **SELCNT (10 digit signed integer) - input**

Count of selectors.

This is the count of selectors that are supplied in the *SELS* array. It is the number of attributes that are to be returned. Zero is a valid value. The maximum number allowed is 256.

### **SELS (10 digit signed integer x SELCNT) - input**

Array of attribute selectors.

This is an array of **SELCNT** attribute selectors; each selector identifies an attribute (integer or character) with a value that is required.

Each selector must be valid for the type of object that *HOBJ* represents, otherwise the call fails with completion code CCFAIL and reason code RC2067.

In the special case of queues:

- If the selector is not valid for queues of *any* type, the call fails with completion code CCFAIL and reason code RC2067.
- If the selector is applicable only to queues of type or types other than that of the object, the call succeeds with completion code CCWARN and reason code RC2068.
- If the queue being inquired is a cluster queue, the selectors that are valid depend on how the queue was resolved; see usage note 4 for further details.

Selectors can be specified in any order. Attribute values that correspond to integer attribute selectors (IA\* selectors) are returned in *INTATR* in the same order in which these selectors occur in *SELS*. Attribute values that correspond to character attribute selectors (CA\* selectors) are returned in *CHRATR* in the same order in which those selectors occur. IA\* selectors can be interleaved with the CA\* selectors; only the relative order within each type is important.

**Note:**

1. The integer and character attribute selectors are allocated within two different ranges; the IA\* selectors reside within the range IAFRST through IALAST, and the CA\* selectors within the range CAFRST through CALAST.

For each range, the constants IALSTU and CALSTU define the highest value that the queue manager accepts.

2. If all the IA\* selectors occur first, the same element numbers can be used to address corresponding elements in the *SELS* and *INTATR* arrays.

The attributes that can be inquired are listed in the following tables. For the CA\* selectors, the constant that defines the length in bytes of the resulting string in *CHRATR* is given in parentheses.

Selector	Description	Note
CAALTD	Date of most recent alteration (LNDATE).	1
CAALTT	Time of most recent alteration (LNTIME).	1
CABRQN	Excessive backout-requeue name (LNQN).	5
CABASQ	Name of queue that alias resolves to (LNQN).	
CACFSN	Coupling-facility structure name (LNCFSN).	3
CACLN	Cluster name (LNCLUN).	1
CACLNL	Cluster namelist (LNNLN).	1
CACRTD	Queue creation date (LNCRTD).	
CACRTT	Queue creation time (LNCRTT).	
CAINIQ	Initiation queue name (LNQN).	
CAPRON	Name of process definition (LNPRON).	
CAQD	Queue description (LNQD).	
CAQN	Queue name (LNQN).	
CARQMN	Name of remote queue manager (LNQMN).	
CARQN	Name of remote queue as known on remote queue manager (LNQN).	
CATRGD	Trigger data (LNTRGD).	5
CAXQN	Transmission queue name (LNQN).	

Table 746. MQINQ attribute selectors for queues (continued)

<b>Selector</b>	<b>Description</b>	<b>Note</b>
IABTHR	Backout threshold.	5
IACDEP	Number of messages on queue.	
IADBND	Default binding.	1
IADINP	Default open-for-input option.	5
IADPER	Default message persistence.	
IADPRI	Default message priority.	5
IADEFT	Queue definition type.	
IADIST	Distribution list support.	2
IAHGB	Whether to harden backout count.	5
IAIGET	Whether get operations are allowed.	
IAIPUT	Whether put operations are allowed.	
IAMLEN	Maximum message length.	
IAMDEP	Maximum number of messages allowed on queue.	
IAMDS	Whether message priority is relevant.	5
IAOIC	Number of MQOPEN calls that have the queue open for input.	
IAOOC	Number of MQOPEN calls that have the queue open for output.	
IAQDHE	Control attribute for queue depth high events.	4, 5
IAQDHL	High limit for queue depth.	4, 5
IAQDLE	Control attribute for queue depth low events.	4, 5
IAQDLL	Low limit for queue depth.	4, 5
IAQDME	Control attribute for queue depth max events.	4, 5
IAQSI	Limit for queue service interval.	4, 5
IAQSIE	Control attribute for queue service interval events.	4, 5
IAQTYP	Queue type.	
IAQSGD	Queue sharing group disposition.	3
IARINT	Queue retention interval.	5
IASCOP	Queue definition scope.	4, 5
IASHAR	Whether queue can be shared for input.	
IATRGC	Trigger control.	
IATRGD	Trigger depth.	5
IATRGP	Threshold message priority for triggers.	5
IATRGT	Trigger type.	
IAUSAG	Usage.	
CLWLUSEQ	Use remote queues.	

**Note:**

1. Supported on the following platforms:

-  AIX
-  IBM i
-  Windows
-  z/OS

and for IBM MQ MQI clients connected to these systems.

2. Supported on the following platforms:

-  AIX
-  IBM i
-  Windows

and for IBM MQ clients connected to these systems.

3.  Supported on z/OS.

4.  Not supported on z/OS.

5. Not supported on VSE/ESA.

Selector	Description	Note
CAALTD	Date of most recent alteration (LNDATE)	1
CAALTT	Time of most recent alteration (LNTIME)	1
CALSTD	Namelist description (LNNLD)	1
CALSTN	Name of namelist object (LNNLN)	1

IASYNC	Sync point availability	5
IATRLFT	Lifetime of unused non-administrative topics	
IATRGI	Trigger interval	5

#### **IACNT (10 digit signed integer) - input**

Count of integer attributes.

This is the number of elements in the INTATR array. Zero is a valid value.

If this is at least the number of IA\* selectors in the **SELS** parameter, all integer attributes requested are returned.

#### **INTATR (10 digit signed integer x IACNT) - output**

Array of integer attributes.

This is an array of *IACNT* integer attribute values.

Integer attribute values are returned in the same order as the IA\* selectors in the **SELS** parameter. If the array contains more elements than the number of IA\* selectors, the excess elements are unchanged.

If HOBJ represents a queue, but an attribute selector is not applicable to that type of queue, the specific value IAVNA is returned for the corresponding element in the INTATR array.

#### **CALEN (10 digit signed integer) - input**

Length of character attributes buffer.

This is the length in bytes of the **CHRATR** parameter.

This must be at least the sum of the lengths of the requested character attributes (see SELS). Zero is a valid value.

#### **CHRATR (1 byte character string x CALEN) - output**

Character attributes.

This is the buffer in which the character attributes are returned, concatenated together. The length of the buffer is given by the **CALEN** parameter.

Character attributes are returned in the same order as the CA\* selectors in the **SELS** parameter. The length of each attribute string is fixed for each attribute (see SELS), and the value in it is padded to the right with blanks if necessary. If the buffer is larger than that needed to contain all of the requested character attributes (including padding), the bytes beyond the last attribute value returned are unchanged.

If HOBJ represents a queue, but an attribute selector is not applicable to that type of queue, a character string consisting entirely of asterisks (\*) is returned as the value of that attribute in CHRATR.

#### **CMPCOD (10 digit signed integer) - output**

Completion code.

It is one of the following:

##### **CCOK**

Successful completion.

**CCWARN**

Warning (partial completion).

**CCFAIL**

Call failed.

**REASON (10 digit signed integer) - output**

Reason code qualifying CMPCOD.

If CMPCOD is CCOK:

**RCNONE**

(0, X'000') No reason to report.

If *CMPCOD* is CCWARN:

**RC2008**

(2008, X'7D8') Not enough space allowed for character attributes.

**RC2022**

(2022, X'7E6') Not enough space allowed for integer attributes.

**RC2068**

(2068, X'814') Selector not applicable to queue type.

If *CMPCOD* is CCFAIL:

**RC2219**

(2219, X'8AB') MQI call reentered before previous call complete.

**RC2006**

(2006, X'7D6') Length of character attributes not valid.

**RC2007**

(2007, X'7D7') Character attributes string not valid.

**RC2009**

(2009, X'7D9') Connection to queue manager lost.

**RC2018**

(2018, X'7E2') Connection handle not valid.

**RC2019**

(2019, X'7E3') Object handle not valid.

**RC2021**

(2021, X'7E5') Count of integer attributes not valid.

**RC2023**

(2023, X'7E7') Integer attributes array not valid.

**RC2038**

(2038, X'7F6') Queue not open for inquire.

**RC2041**

(2041, X'7F9') Object definition changed since opened.

**RC2101**

(2101, X'835') Object damaged.

**RC2052**

(2052, X'804') Queue has been deleted.

**RC2058**

(2058, X'80A') Queue manager name not valid or not known.

**RC2059**

(2059, X'80B') Queue manager not available for connection.

**RC2162**

(2162, X'872') Queue manager shutting down.

**RC2102**

(2102, X'836') Insufficient system resources available.

**RC2065**

(2065, X'811') Count of selectors not valid.

**RC2067**

(2067, X'813') Attribute selector not valid.

**RC2066**

(2066, X'812') Count of selectors too large.

**RC2071**

(2071, X'817') Insufficient storage available.

**RC2195**

(2195, X'893') Unexpected error occurred.

**RPG Declaration**

**IBM i MQINQMP (Inquire message property) on IBM i**

The MQINQMP call returns the value of a property of a message.

- [“Syntax” on page 1312](#)
- [“Parameters” on page 1312](#)
- [“RPG Declaration” on page 1316](#)

**Syntax**

MQINQMP (*Hconn*, *Hmsg*, *InqPropOpts*, *Name*, *PropDesc*, *Type*, *ValueLength*, *Value*, *DataLength*, *CompCode*, *Reason*)

**Parameters**

The MQINQMP call has the following parameters:

### **HCONN (10-digit signed integer) - input**

This handle represents the connection to the queue manager. The value of *Hconn* must match the connection handle that was used to create the message handle specified in the **Hmsg** parameter.

If the message handle was created using HCUNAS then a valid connection must be established on the thread inquiring a property of the message handle, otherwise the call fails with RC2009.

### **HMSG (20-digit signed integer) - input**

This is the message handle to be inquired. The value was returned by a previous **MQCRTMH** call.

### **INQOPT (MQIMPO) - input**

See the [MQIMPO](#) data type for details.

### **PRNAME (MQCHARV) - input**

This describes the name of the property to inquire.

If no property with this name can be found, the call fails with reason RC2471.

You can use the percent sign (%) character at the end of the property name. The wildcard matches zero or more characters, including the period (.) character. This allows an application to inquire the value of many properties. Call MQINQMP with option IPINQF to get the first matching property and again with the option IPINQN to get the next matching property. When no more matching properties are available, the call fails with RC2471. If the *ReturnedName* field of the InqPropOpts structure is initialized with an address or offset for the returned name of the property, this is completed on return from MQINQMP with the name of the property that has been matched. If the *VSBufSize* field of the *ReturnedName* in the InqPropOpts structure is less than the length of the returned property name the completion code is set CCFAIL with reason RC2465.

Properties that have known synonyms are returned as follows:

1. Properties with the prefix "mqps." are returned with the IBM MQ property name. For example, "MQTopicString" is the returned name rather than "mqps.Top".
2. Properties with the prefix "jms." or "mcd." are returned as the JMS header field name. For example, "JMSExpiration" is the returned name rather than "jms.Exp".
3. Properties with the prefix "usr." are returned without that prefix. For example, "Color" is returned rather than "usr.Color".

Properties with synonyms are only returned once.

In the RPG programming language, the following macro variables are defined for inquiring on all properties and all properties that begin "usr.":

#### **INQALL**

Inquire on all properties of the message.

#### **INQUSR**

Inquire on all properties of the message that start "usr.". The returned name is returned without the "usr." prefix.

If IPINQN is specified but Name has changed since the previous call or this is the first call, then IPINQF is implied.

See [Property names](#) and [Property name restrictions](#) for further information about the use of property names.

### **PRPDSC (MQPD) - output**

This structure is used to define the attributes of a property, including what happens if the property is not supported, what message context the property belongs to, and what messages the property should be copied into. See [MQPD](#) for details of this structure.

## **TYPE (10-digit signed integer) - input/output**

On return from the MQINQMP call this parameter is set to the data type of *Value*. The data type can be any of the following:

### **TYPBOL**

A boolean.

### **TYPBST**

a byte string.

### **TYPI8**

An 8-bit signed integer.

### **TYPI16**

A 16-bit signed integer.

### **TYPI32**

A 32-bit signed integer.

### **TYPI64**

A 64-bit signed integer.

### **TYPF32**

A 32-bit floating-point number.

### **TYPF64**

A 64-bit floating-point number.

### **TYPSTR**

A character string.

### **TYPNUL**

The property exists but has a null value.

If the data type of the property value is not recognized then TYPSTR is returned and a string representation of the value is placed into the *Value* area. A string representation of the data type can be found in the *IPITYP* field of the *IPOPT* parameter. A warning completion code is returned with reason RC2467.

Additionally, if the option IPCTYP is specified, conversion of the property value is requested. Use *Type* as an input to specify the data type that you want the property to be returned as. See the description of the IPCTYP option of the [“MQIMPO \(Inquire message property options\) on IBM i”](#) on page 1103 for details of data type conversion.

If you do not request type conversion, you can use the following value on input:

### **TYPAST**

The value of the property is returned without converting its data type.

## **VALLEN (10-digit signed integer) - input**

The length in bytes of the *Value* area.

Specify zero for properties that you do not require the value returned for. These could be properties which are designed by an application to have a null value or an empty string. Also specify zero if the IPQLLEN option has been specified; in this case no value is returned.

## **VALUE (1-byte bit stringxVALLEN) - output**

This is the area to contain the inquired property value. The buffer should be aligned on a boundary appropriate for the value being returned. Failure to do so might result in an error when the value is later accessed.

If *VALLEN* is less than the length of the property value, as much of the property value as possible is moved into *VALUE* and the call fails with completion code CCFAIL and reason RC2469.

The character set of the data in *VALUE* is given by the IPRETCSI field in the INQOPT parameter. The encoding of the data in *VALUE* is given by the IPRETENC field in the INQOPT parameter.

If the *VALLEN* parameter is zero, *VALUE* is not referred to.

### **DATLEN (10-digit signed integer) - output**

This is the length in bytes of the actual property value as returned in the *Value* area.

If *DataLength* is less than the property value length, *DataLength* is still entered on return from the MQINQMP call. This allows the application to determine the size of the buffer required to accommodate the property value, and then reissue the call with a buffer of the appropriate size.

The following values may also be returned.

If the *Type* parameter is set to TYPSTR or TYPBST:

#### **VLEMP**

The property exists but contains no characters or bytes.

### **CMPCOD (10-digit signed integer) - output**

The completion code; it is one of the following:

#### **CCOK**

Successful completion.

#### **CCWARN**

Warning (partial completion).

#### **CCFAIL**

Call failed.

### **REASON (10-digit signed integer) - output**

The reason code qualifying *CompCode*.

If *CMPCOD* is CCOK:

#### **RCNONE**

(0, X'000') No reason to report.

If *CompCode* is CCWARN:

#### **RC2492**

(2492, X'09BC') Returned property name not converted.

#### **RC2466**

(2466, X'09A2') Property value not converted.

#### **RC2467**

(2467, X'09A3') Property data type is not supported.

#### **RC2421**

(2421, X'0975') An MQRFH2 folder containing properties could not be parsed.

If *CMPCOD* is CCFAIL:

#### **RC2204**

(2204, X'089C') Adapter not available.

#### **RC2130**

(2130, X'0852') Unable to load adapter service module.

#### **RC2157**

(2157, X'086D') Primary and home ASIDs differ.

#### **RC2004**

(2004, X'07D4') Value parameter not valid.

#### **RC2005**

(2005, X'07D5') Value length parameter not valid.

#### **RC2219**

(2219, X'08AB') MQI call entered before previous call completed.

#### **RC2009**

(2009, X'07D9') Connection to queue manager lost.

**RC2010**

(2010, X'07DA') Data length parameter not valid.

**RC2464**

(2464, X'09A0') Inquire message property options structure not valid.

**RC2460**

(2460, X'099C') Message handle not valid.

**RC2499**

(2499, X'09C3') Message handle already in use.

**RC2064**

(2046, X'07F8') Options not valid or not consistent.

**RC2482**

(2482, X'09B2') Property descriptor structure not valid.

**RC2470**

(2470, X'09A6') Conversion from the actual to requested data type not supported.

**RC2442**

(2442, X'098A') Invalid property name.

**RC2465**

(2465, X'09A1') Property name too large for returned name buffer.

**RC2471**

(2471, X'09A7) Property not available.

**RC2469**

(2469, X'09A5') Property value too large for the Value area.

**RC2472**

(2472, X'09A8') Number format error encountered in value data.

**RC2473**

(2473, X'09A9') Invalid requested property type.

**RC2111**

(2111, X'083F') Property name coded character set identifier not valid.

**RC2071**

(2071, X'0871') Insufficient storage available.

**RC2195**

(2195, X'0893') Unexpected error occurred.

For detailed information about these codes, see:

IBM i

## MQMHBUF (Convert message handle into buffer) on IBM i

The MQMHBUF converts a message handle into a buffer and is the inverse of the MQBUFMH call.

- [“Syntax” on page 1317](#)
- [“Usage notes” on page 1317](#)
- [“Parameters” on page 1317](#)
- [“RPG Declaration” on page 1319](#)

### Syntax

MQMHBUF (*Hconn, Hmsg, MsgHBufOpts, Name, MsgDesc, BufferLength, Buffer, DataLength, CompCode, Reason*)

### Usage notes

MQMHBUF converts a message handle into a buffer.

You can use it with an MQGET API exit to access certain properties, by using the message property APIs, and then pass these properties in a buffer back to an application designed to use MQRFH2 headers rather than message handles.

This call is the inverse of the MQBUFMH call, which you can use to parse message properties from a buffer into a message handle.

### Parameters

The MQMHBUF call has the following parameters:

#### HCONN (10-digit signed integer) - input

This handle represents the connection to the queue manager.

The value of *HCONN* must match the connection handle that was used to create the message handle specified in the **HMSG** parameter.

If the message handle was created by using HCUNAS, a valid connection must be established on the thread deleting the message handle. If a valid connection is not established, the call fails with RC2009.

#### HMSG (20-digit signed integer) - input

This handle is the message handle for which a buffer is required.

The value was returned by a previous MQCRTMH call.

#### MHBOPT (MQMHBO) - input

The MQMHBO structure allows applications to specify options that control how buffers are produced from message handles.

See “MQBMHO (Buffer to message handle options) on IBM i” on page 1018 for details.

### **PRNAME (MQCHARV) - input**

The name of the property or properties to put into the buffer.

If no property matching the name can be found, the call fails with RC2471.

#### **Wildcards**

You can use a wildcard to put more than one property into the buffer. To do so, use the percent sign (%) at the end of the property name. This wildcard matches zero or more characters, including the period (.) character.

See [Property names](#) and [Property name restrictions](#) for further information about the use of property names.

### **MSGDSC (MQMD) - input/output**

The *MSGDSC* structure describes the contents of the buffer area.

On output, the *Encoding*, *CodedCharSetId* and *Format* fields are set to correctly describe the encoding, character set identifier, and format of the data in the buffer area as written by the call.

Data in this structure is in the character set and encoding of the application.

### **BUFLEN (10-digit signed integer) - input**

*BUFLEN* is the length of the Buffer area, in bytes.

### **BUFFER (1-byte bit string x BUFLEN) - input/output**

*BUFFER* defines the area containing the message buffer. For most data, you must align the buffer on a 4-byte boundary.

If *BUFFER* contains character or numeric data, set the *CodedCharSetId* and *Encoding* fields in the **MSGDSC** parameter to the values appropriate to the data; this enables the data to be converted, if necessary.

If properties are found in the message buffer they are optionally removed; they later become available from the message handle on return from the call.

In the C programming language, the parameter is declared as a pointer-to-void, which means the address of any type of data can be specified as the parameter.

If the **BUFLEN** parameter is zero, *BUFFER* is not referred to. In this case, the parameter address passed by programs written in C or System/390 assembler can be null.

### **DATLEN (10-digit signed integer) - output**

*DATLEN* is the length, in bytes, of the returned properties in the buffer. If the value is zero, no properties matched the value given in *PRNAME* and the call fails with reason code RC2471.

If *BUFLEN* is less than the length required to store the properties in the buffer, the MQMHBUF call fails with RC2469, but a value is still entered into *DATLEN*. This allows the application to determine the size of the buffer required to accommodate the properties, and then reissue the call with the required *BUFLEN*.

### **CMPCOD (10-digit signed integer) - output**

The completion code; it is one of the following:

#### **CCOK**

Successful completion.

#### **CCFAIL**

Call failed.

### **REASON (10-digit signed integer) - output**

The reason code qualifying *CMPCOD*.

If *CMPCOD* is CCOK:

**RCNONE**

(0, X'000') No reason to report.

If *CMPCOD* is CCFAIL:

**RC2204**

(2204, X'089C') Adapter not available.

**RC2130**

(2130, X'852') Unable to load adapter service module.

**RC2157**

(2157, X'86D') Primary and home ASIDs differ.

**RC2501**

(2501, X'095C') Message handle to buffer options structure not valid.

**RC2004**

(2004, X'07D4') Buffer parameter not valid.

**RC2005**

(2005, X'07D5') Buffer length parameter not valid.

**RC2219**

(2219, X'08AB') MQI call entered before previous call completed.

**RC2009**

(2009, X'07D9') Connection to queue manager lost.

**RC2010**

(2010, X'07DA') Data length parameter not valid.

**RC2460**

(2460, X'099C') Message handle not valid.

**RC2026**

(2026, X'07EA') Message descriptor not valid.

**RC2499**

(2499, X'09C3') Message handle already in use.

**RC2046**

(2046, X'07FE') Options not valid or not consistent.

**RC2442**

(2442, X'098A') Property name is not valid.

**RC2471**

(2471, X'09A7') Property not available.

**RC2469**

(2469, X'09A5') BufferLength value is too small to contain specified properties.

**RC2195**

(2195, X'893') Unexpected error occurred.

## RPG Declaration

```
C*..1.....2.....3.....4.....5.....6.....7..
C          CALLP      MQMHBUF(HCONN : HMSG : MHBOPT :
                        PRNAME : MSGDSC : BUFLen :
                        BUFFER : DATLEN :
                        CMPCOD : REASON)
```

The prototype definition for the call is:

```

## IBM i MQOPEN (Open object) on IBM i

The MQOPEN call establishes access to an object.

The following types of object are valid:

- Queue (including distribution lists)
- Namelist
- Process definition
- Queue manager
- Topic

### Index

- [“Syntax” on page 1320](#)
- [“Usage notes” on page 1320](#)
- [“Parameters” on page 1324](#)
- [“RPG Declaration” on page 1330](#)

### Syntax

MQOPEN (*HCONN*, *OBJDSC*, *OPTS*, *HOBJ*, *CMPCOD*, *REASON*)

### Usage notes

1. The object opened is one of the following:

- A queue, in order to:
  - Get or browse messages (using the MQGET call)
  - Put messages (using the MQPUT call)
  - Inquire about the attributes of the queue (using the MQINQ call)
  - Set the attributes of the queue (using the MQSET call)

If the queue named is a model queue, a dynamic local queue is created.

A distribution list is a special type of queue object that contains a list of queues. It can be opened to put messages, but not to get or browse messages, or to inquire or set attributes. See usage note 8 for further details.

A queue that has QSGDISP(GROUP) is a special type of queue definition that cannot be used with the MQOPEN or MQPUT1 calls.

- A namelist, in order to:

- Inquire about the names of the queues in the list (using the MQINQ call).
  - A process definition, in order to:
    - Inquire about the process attributes (using the MQINQ call).
  - The queue manager, in order to:
    - Inquire about the attributes of the local queue manager (using the MQINQ call).
2. It is valid for an application to open the same object more than once. A different object handle is returned for each open. Each handle that is returned can be used for the functions for which the corresponding open was performed.
3. If the object being opened is a queue but not a cluster queue, all name resolution within the local queue manager takes place at the time of the MQOPEN call. This might include one or more of the following for a particular MQOPEN call:
- Alias resolution to the name of a base queue
  - Resolution of the name of a local definition of a remote queue to the name of the remote queue manager, and the name by which the queue is known at the remote queue manager
  - Resolution of the remote queue manager name to the name of a local transmission queue

However, be aware that subsequent MQINQ or MQSET calls for the handle relate solely to the name that has been opened, and not to the object resulting after name resolution has occurred. For example, if the object opened is an alias, the attributes returned by the MQINQ call are the attributes of the alias, not the attributes of the base queue to which the alias resolves. Name resolution checking is still carried out, however, regardless of what is specified for the **OPTS** parameter on the corresponding MQOPEN.

If the object being opened is a cluster queue, name resolution can occur at the time of the MQOPEN call, or be deferred until later. The point at which resolution occurs is controlled by the OOBND\* options specified on the MQOPEN call:

- OOBND0
- OOBNDN
- OOBNDQ

See [Name resolution](#) for more information about name resolution for cluster queues.

4. The attributes of an object can change while an application has the object open. In many cases, the application does not notice this, but for certain attributes the queue manager marks the handle as no longer valid. These are:
- Any attribute that affects the name resolution of the object. This applies regardless of the open options used, and includes the following:
    - A change to the **BaseQName** attribute of an alias queue that is open.
    - A change to the **RemoteQName** or **RemoteQMgrName** queue attributes, for any handle that is open for this queue, or for a queue which resolves through this definition as a queue manager alias.
    - Any change that causes a currently open handle for a remote queue to resolve to a different *transmission* queue, or to fail to resolve to one at all. For example, this can include:
      - A change to the **XmitQName** attribute of the local definition of a remote queue, whether the definition is being used for a queue, or for a queue manager alias.
- There is one exception to this, namely the creation of a new transmission queue. A handle that would have resolved to this queue had it been present when the handle was opened, but instead resolved to the default transmission queue, is not made invalid.
- A change to the **DefXmitQName** queue manager attribute. In this case all open handles that resolved to the previously named queue (that resolved to it only because it was the default transmission queue) are marked as invalid. Handles that resolved to this queue for other reasons are not affected.

- The **Shareability** queue attribute, if there are two or more handles that are currently providing OOINPS access for this queue, or for a queue that resolves to this queue. If so, *all* handles that are open for this queue, or for a queue that resolves to this queue, are marked as invalid, regardless of the open options.
- The **Usage** queue attribute, for all handles that are open for this queue, or for a queue that resolves to this queue, regardless of the open options.

When a handle is marked as invalid, all subsequent calls (other than MQCLOSE) using this handle fail with reason code RC2041; the application should issue an MQCLOSE call (using the original handle) and then reopen the queue. Any uncommitted updates against the old handle from previous successful calls can still be committed or backed out, as required by the application logic.

If changing an attribute will cause this to happen, a special "force" version of the command must be used.

5. The queue manager performs security checks when an MQOPEN call is issued, to verify that the user identifier under which the application is running has the appropriate level of authority before access is permitted. The authority check is made on the name of the object being opened, and not on the name, or names, resulting after a name has been resolved.

If the object being opened is a model queue, the queue manager performs a full security check against both the name of the model queue and the name of the dynamic queue that is created. If the resulting dynamic queue is then opened explicitly, a further resource security check is performed against the name of the dynamic queue.

6. A remote queue can be specified in one of two ways in the **OBJDSC** parameter of this call (see the *ODON* and *ODMN* fields described in [“MQOD \(Object descriptor\) on IBM i”](#) on page 1159):

- By specifying for *ODON* the name of a local definition of the remote queue. In this case, *ODMN* refers to the local queue manager, and can be specified as blanks.

The security validation performed by the local queue manager verifies that the user is authorized to open the local definition of the remote queue.

- By specifying for *ODON* the name of the remote queue as known to the remote queue manager. In this case, *ODMN* is the name of the remote queue manager.

The security validation performed by the local queue manager verifies that the user is authorized to send messages to the transmission queue resulting from the name resolution process.

In either case:

- No messages are sent by the local queue manager to the remote queue manager in order to check that the user is authorized to put messages on the queue.
- When a message arrives at the remote queue manager, the remote queue manager might reject it because the user originating the message is not authorized.

7. An MQOPEN call with the OOBROW option establishes a browse cursor, for use with MQGET calls that specify the object handle and one of the browse options. This allows the queue to be scanned without altering its contents. A message that has been found by browsing can later be removed from the queue by using the GMMUC option.

Multiple browse cursors can be active for a single application by issuing several MQOPEN requests for the same queue.

8. The following notes apply to the use of distribution lists.

- Fields in the MQOD structure must be set as follows when opening a distribution list:
  - *ODVER* must be ODVER2 or greater.
  - *ODOT* must be OTQ.
  - *ODON* must be blank or the null string.
  - *ODMN* must be blank or the null string.
  - *ODREC* must be greater than zero.

- One of *ODORO* and *ODORP* must be zero and the other nonzero.
- No more than one of *ODRRO* and *ODRRP* can be nonzero.
- There must be *ODREC* object records, addressed by either *ODORO* or *ODORP*. The object records must be set to the names of the destination queues to be opened.
- If one of *ODRRO* and *ODRRP* is nonzero, there must be *ODREC* response records present. They are set by the queue manager if the call completes with reason code RC2136.

A version-2 MQOD can also be used to open a single queue that is not in a distribution list, by ensuring that *ODREC* is zero.

- Only the following open options are valid in the **OPTS** parameter:
  - OOOOUT
  - OOPAS\*
  - OOSSET\*
  - OOALTU
  - OOFIQ
- The destination queues in the distribution list can be local, alias, or remote queues, but they cannot be model queues. If a model queue is specified, that queue fails to open, with reason code RC2057. However, this does not prevent other queues in the list being opened successfully.
- The completion code and reason code parameters are set as follows:
  - If the open operations for the queues in the distribution list all succeed or fail in the same way, the completion code and reason code parameters are set to describe the common result. The MQRR response records (if provided by the application) are not set in this case.
 

For example, if every open succeeds, the completion code is set to CCOK and the reason code is RCNONE; if every open fails because none of the queues exists, the parameters are set to CCFAIL and RC2085.
  - If the open operations for the queues in the distribution list do not all succeed or fail in the same way:
    - The completion code parameter is set to CCWARN if at least one open succeeded, and to CCFAIL if all failed.
    - The reason code parameter is set to RC2136.
    - The response records (if provided by the application) are set to the individual completion codes and reason codes for the queues in the distribution list.
- When a distribution list has been opened successfully, the handle *HOBJ* returned by the call can be used on subsequent MQPUT calls to put messages to queues in the distribution list, and on an MQCLOSE call to relinquish access to the distribution list. The only valid close option for a distribution list is CONONE.

The MQPUT1 call can also be used to put a message to a distribution list; the MQOD structure defining the queues in the list is specified as a parameter on that call.

- Each successfully opened destination in the distribution list counts as a *separate* handle when checking whether the application has exceeded the permitted maximum number of handles (see the **MaxHandles** queue manager attribute). This is true even when two or more of the destinations in the distribution list actually resolve to the same physical queue. If the MQOPEN or MQPUT1 call for a distribution list would cause the number of handles in use by the application to exceed *MaxHandles*, the call fails with reason code RC2017.
- Each destination that is opened successfully has the value of its **OpenOutputCount** attribute incremented by one. If two or more of the destinations in the distribution list actually resolve to the same physical queue, that queue has its **OpenOutputCount** attribute incremented by the number of destinations in the distribution list that resolve to that queue.
- Any change to the queue definitions that would have caused a handle to become invalid had the queues been opened individually (for example, a change in the resolution path), does not cause

the distribution-list handle to become invalid. However, it does result in a failure for that particular queue when the distribution-list handle is used on a subsequent MQPUT call.

- It is valid for a distribution list to contain only one destination.

9. The following notes apply to the use of cluster queues.

- When a cluster queue is opened for the first time, and the local queue manager is not a full repository queue manager, the local queue manager obtains information about the cluster queue from a full repository queue manager. When the network is busy, it may take several seconds for the local queue manager to receive the needed information from the repository queue manager. As a result, the application issuing the MQOPEN call might have to wait for up to 10 seconds before control returns from the MQOPEN call. If the local queue manager does not receive the needed information about the cluster queue within this time, the call fails with reason code RC2189.
- When a cluster queue is opened and there are multiple instances of the queue in the cluster, the instance actually opened depends on the options specified on the MQOPEN call:

- If the options specified include any of the following:

- OOBROW
- OOINPQ
- OOINPX
- OOINPS
- OOSSET

the instance of the cluster queue opened is required to be the local instance. If there is no local instance of the queue, the MQOPEN call fails.

- If the options specified include none of the above, but do include one or both of the following:

- OOINQ
- OOOOUT

the instance opened is the local instance if there is one, and a remote instance otherwise. The instance chosen by the queue manager can, however, be altered by a cluster workload exit (if there is one).

For more information about cluster queues, see [Cluster queues](#).

10. Applications started by a trigger monitor are passed the name of the queue that is associated with the application when the application is started. This queue name can be specified in the **OBJDSC** parameter to open the queue. See the description of the MQTMC structure for further details.
11. When using the OORLOQ option, the local queue is already returned when either a local, alias, or model queue is opened, but this is not the case when, for example, a remote queue or a non-local cluster queue is opened; the ResolvedQName and ResolvedQMgrName are entered with the RemoteQName and RemoteQMgrName found in the remote queue definition, or similarly with the chosen remote cluster queue. If OORLOQ is specified when opening, for example, a remote queue, ResolvedQName will now be the transmission queue which messages will be put to. The ResolvedQMgrName will be entered with the name of the local queue manager hosting the transmission queue. If a user is authorized for browse, input or output on a queue, they have the required authority to specify this flag on the MQOPEN call. No special authority is needed.

## Parameters

The MQOPEN call has the following parameters:

### **HCONN (10-digit signed integer) - input**

Connection handle.

This handle represents the connection to the queue manager. The value of *HCONN* was returned by a previous MQCONN or MQCONNX call.

## **OBJDSC (MQOD) - input/output**

Object descriptor.

This is a structure that identifies the object to be opened; see [“MQOD \(Object descriptor\) on IBM i” on page 1159](#) for details.

If the *ODON* field in the **OBJDSC** parameter is the name of a model queue, a dynamic local queue is created with the attributes of the model queue; this happens irrespective of the open options specified by the **OPTS** parameter. Subsequent operations using the *HOBJ* returned by the MQOPEN call are performed on the new dynamic queue, and not on the model queue. This is true even for the MQINQ and MQSET calls. The name of the model queue in the **OBJDSC** parameter is replaced with the name of the dynamic queue created. The type of the dynamic queue is determined by the value of the **DefinitionType** attribute of the model queue (see [“Attributes for queues” on page 1366](#)). For information about the close options applicable to dynamic queues, see the description of the MQCLOSE call.

## **OPTS (10-digit signed integer) - input**

Options that control the action of MQOPEN.

At least one of the following options must be specified:

- OOB<sub>RW</sub>
- OOINP\* (only one of these)
- OOINQ
- OOO<sub>UT</sub>
- OOSET
- OORLQ

Other options can be specified as required. If more than one option is required, the values can be added (do not add the same constant more than once). Combinations that are not valid are noted; all other combinations are valid. Only options that are applicable to the type of object specified by *OBJDSC* are allowed (see [Valid MQOPEN options for each queue type](#)).

**Access options:** The following options control the type of operations that can be performed on the object:

### **OOINPQ**

Open queue to get messages using queue-defined default.

The queue is opened for use with subsequent MQGET calls. The type of access is either shared or exclusive, depending on the value of the **DefInputOpenOption** queue attribute; see [“Attributes for queues” on page 1366](#) for details.

This option is valid only for local, alias, and model queues; it is not valid for remote queues, distribution lists, and objects that are not queues.

### **OOINPS**

Open queue to get messages with shared access.

The queue is opened for use with subsequent MQGET calls. The call can succeed if the queue is currently open by this or another application with OOI<sub>NP</sub>S, but fails with reason code RC2042 if the queue is currently open with OOIN<sub>PX</sub>.

This option is valid only for local, alias, and model queues; it is not valid for remote queues, distribution lists, and objects that are not queues.

### **OOINPX**

Open queue to get messages with exclusive access.

The queue is opened for use with subsequent MQGET calls. The call fails with reason code RC2042 if the queue is currently open by this or another application for input of any type (OOIN<sub>PS</sub> or OOIN<sub>PX</sub>).

This option is valid only for local, alias, and model queues; it is not valid for remote queues, distribution lists, and objects that are not queues.

The following notes apply to these options:

- Only one of these options can be specified.
- An MQOPEN call with one of these options can succeed even if the **InhibitGet** queue attribute is set to QAGETI (although subsequent MQGET calls will fail while the attribute is set to this value).
- If the queue is defined as not being shareable (that is, the **Shareability** queue attribute has the value QANSHR), attempts to open the queue for shared access are treated as attempts to open the queue with exclusive access.
- If an alias queue is opened with one of these options, the test for exclusive use (or for whether another application has exclusive use) is against the base queue to which the alias resolves.
- These options are not valid if *ODMN* is the name of a queue manager alias; this is true even if the value of the **RemoteQMgrName** attribute in the local definition of a remote queue used for queue manager aliasing is the name of the local queue manager.

### **OOBRW**

Open queue to browse messages.

The queue is opened for use with subsequent MQGET calls with one of the following options:

- GMBRWF
- GMBRWN
- GMBRWC

This is allowed even if the queue is currently open for OOINPX. An MQOPEN call with the OOBRW option establishes a browse cursor, and positions it logically before the first message on the queue; see the *GMOPT* field described in [“MQGMO \(Get-message options\) on IBM i” on page 1077](#) for further information.

This option is valid only for local, alias, and model queues; it is not valid for remote queues, distribution lists, and objects which are not queues. It is also not valid if *ODMN* is the name of a queue manager alias; this is true even if the value of the **RemoteQMgrName** attribute in the local definition of a remote queue used for queue manager aliasing is the name of the local queue manager.

### **OOOUT**

Open queue to put messages, or a topic or topic string to publish messages.

The queue is opened for use with subsequent MQPUT calls.

An MQOPEN call with this option can succeed even if the **InhibitPut** queue attribute is set to QAPUTI (although subsequent MQPUT calls will fail while the attribute is set to this value).

This option is valid for all types of queue, including distribution lists and topics.

### **OOINQ**

Open object to inquire attributes.

The queue, namelist, process definition, or queue manager is opened for use with subsequent MQINQ calls.

This option is valid for all types of object other than distribution lists. It is not valid if *ODMN* is the name of a queue manager alias; this is true even if the value of the **RemoteQMgrName** attribute in the local definition of a remote queue used for queue manager aliasing is the name of the local queue manager.

### **OASET**

Open queue to set attributes.

The queue is opened for use with subsequent MQSET calls.

This option is valid for all types of queue other than distribution lists. It is not valid if *ODMN* is the name of a local definition of a remote queue; this is true even if the value of the **RemoteQMgrName** attribute in the local definition of a remote queue used for queue manager aliasing is the name of the local queue manager.

**Binding options:** The following options apply when the object being opened is a cluster queue; these options control the binding of the queue handle to an instance of the cluster queue:

#### **OOBNDQ**

Bind handle to destination when queue is opened.

This causes the local queue manager to bind the queue handle to an instance of the destination queue when the queue is opened. As a result, all messages put using this handle are sent to the same instance of the destination queue, and by the same route.

This option is valid only for queues, and affects only cluster queues. If specified for a queue that is not a cluster queue, the option is ignored.

#### **OOBNDN**

Do not bind to a specific destination.

This stops the local queue manager binding the queue handle to an instance of the destination queue. As a result, successive MQPUT calls using this handle may result in the messages being sent to *different* instances of the destination queue, or being sent to the same instance but by different routes. It also allows the instance selected to be changed later by the local queue manager, by a remote queue manager, or by a message channel agent (MCA), according to network conditions.

**Note:** Client and server applications which need to exchange a *series* of messages in order to complete a transaction should not use OOBNDN (or OOBNDQ when *DefBind* has the value BNDNOT), because successive messages in the series may be sent to different instances of the server application.

If OOBROW or one of the OOINP\* options is specified for a cluster queue, the queue manager is forced to select the local instance of the cluster queue. As a result, the binding of the queue handle is fixed, even if OOBNDN is specified.

If OOINQ is specified with OOBNDN, successive MQINQ calls using that handle may inquire different instances of the cluster queue, although typically all of the instances have the same attribute values.

OOBNDN is valid only for queues, and affects only cluster queues. If specified for a queue that is not a cluster queue, the option is ignored.

#### **OOBNDQ**

Use default binding for queue.

This causes the local queue manager to bind the queue handle in the way defined by the **DefBind** queue attribute. The value of this attribute is either BNDOPN or BNDNOT.

OOBNDQ is the default if OOBNDQ and OOBNDN are not specified.

OOBNDQ is defined to aid program documentation. It is not intended that this option is used with either of the other two bind options, but because its value is zero such use cannot be detected.

**Context options:** The following options control the processing of message context:

#### **OOSAVA**

Save context when message retrieved.

Context information is associated with this queue handle. This information is set from the context of any message retrieved using this handle. For more information about message context, see [Message context](#) and [Controlling context information](#).

This context information can be passed to a message that is later put on a queue using the MQPUT or MQPUT1 calls. See the PMPASI and PMPASA options described in "[MQPMO \(Put-message options\) on IBM i](#)" on page 1173.

Until a message has been successfully retrieved, context cannot be passed to a message being put on a queue.

A message retrieved using one of the GMBRW\* browse options does not have its context information saved (although the context fields in the **MSGDSC** parameter are set after a browse).

This option is valid only for local, alias, and model queues; it is not valid for remote queues, distribution lists, and objects which are not queues. One of the OOINP\* options must be specified.

#### **OOPASI**

Allow identity context to be passed.

This allows the PMPASI option to be specified in the **PMO** parameter when a message is put on a queue; this gives the message the identity context information from an input queue that was opened with the OOSAVA option. For more information about message context, see [Message context](#) and [Controlling context information](#).

The OOOUT option must be specified.

This option is valid for all types of queue, including distribution lists.

#### **OOPASA**

Allow all context to be passed.

This allows the PMPASA option to be specified in the **PMO** parameter when a message is put on a queue; this gives the message the identity and origin context information from an input queue that was opened with the OOSAVA option. For more information about message context, see [Message context](#) and [Controlling context information](#).

This option implies OOPASI, which need not therefore be specified. The OOOUT option must be specified.

This option is valid for all types of queue, including distribution lists.

#### **OOSSETI**

Allow identity context to be set.

This allows the PMSETI option to be specified in the **PMO** parameter when a message is put on a queue; this gives the message the identity context information contained in the **MSGDSC** parameter specified on the MQPUT or MQPUT1 call. For more information about message context, see [Message context](#) and [Controlling context information](#).

This option implies OOPASI, which need not therefore be specified. The OOOUT option must be specified.

This option is valid for all types of queue, including distribution lists.

#### **OOSSETA**

Allow all context to be set.

This allows the PMSETA option to be specified in the **PMO** parameter when a message is put on a queue; this gives the message the identity and origin context information contained in the **MSGDSC** parameter specified on the MQPUT or MQPUT1 call. For more information about message context, see [Message context](#) and [Controlling context information](#).

This option implies the following options, which need not therefore be specified:

- OOPASI
- OOPASA
- OOSSETI

The OOOUT option must be specified.

This option is valid for all types of queue, including distribution lists.

**Other options:** The following options control authorization checking, and what happens when the queue manager is quiescing:

**OOALTU**

Validate with specified user identifier.

This indicates that the *ODAU* field in the **OBJDSC** parameter contains a user identifier that is to be used to validate this MQOPEN call. The call can succeed only if this *ODAU* is authorized to open the object with the specified access options, regardless of whether the user identifier under which the application is running is authorized to do so. This does not apply to any context options specified, however, which are always checked against the user identifier under which the application is running.

This option is valid for all types of object.

**OOFIQ**

Fail if queue manager is quiescing.

This option forces the MQOPEN call to fail if the queue manager is in quiescing state.

This option is valid for all types of object.

**OORLQ**

Enter the name of local queue that was opened.

This option specifies that the ResolvedQName in the MQOD structure (if available) should be entered with the name of the local queue which was opened. The ResolvedQMGrName will similarly be entered with the name of the local queue manager hosting the local queue.

Option	Alias ( "1" on page 1330 )	Local and Model	Remote	Nonlocal Cluster	Distribution list	Topic

OORLQ	✓	✓	✓	✓	-	-

**Notes:**

1. The validity of options for aliases depends on the validity of the option for the queue to which the alias resolves.
2. This option is valid only for the local definition of a remote queue.
3. This option can be specified for any queue type, but is ignored if the queue is not a cluster queue.
4. This attribute is ignored for a topic.
5. These attributes can be used with a topic, but only affect the context set for the retained message, not the context fields sent to any subscriber.

**HOBJS (10-digit signed integer) - output**

Object handle.

This handle represents the access that has been established to the object. It must be specified on subsequent message queuing calls that operate on the object. It ceases to be valid when the MQCLOSE call is issued, or when the unit of processing that defines the scope of the handle terminates.

The scope of the handle is restricted to the smallest unit of parallel processing supported by the platform on which the application is running; the handle is not valid outside the unit of parallel processing from which the MQOPEN call was issued:

- On IBM i, the scope of the handle is the job issuing the call.

**CMPCOD (10-digit signed integer) - output**

Completion code.

It is one of the following:

**CCOK**

Successful completion.

**CCWARN**

Warning (partial completion).

**CCFAIL**

Call failed.

**RPG Declaration**

```
C*..1.....2.....3.....4.....5.....6.....7..
C          CALLP      MQOPEN(HCONN : OBJDSC : OPTS :
C                               HOBJ : CMPCOD : REASON)
```

The prototype definition for the call is:

```
D*..1.....2.....:.....3.....4.....5.....6.....7..
MQOPEN          PR          EXTPROC('MQOPEN')
D* Connection handle
D HCONN          10I 0 VALUE
D* Object descriptor
D OBJDSC          468A
D* Options that control the action of MQOPEN
D OPTS           10I 0 VALUE
D* Object handle
D HOBJ           10I 0
D* Completion code
D CMPCOD         10I 0
D* Reason code qualifying CMPCOD
D REASON         10I 0
```

## IBM i MQPUT (Put message) on IBM i

The MQPUT call puts a message on a queue, distribution list or to a topic. The queue, distribution list, or topic must already be open.

### Syntax

MQPUT (*HCONN*, *HOBJ*, *MSGDSC*, *PMO*, *BUFLEN*, *BUFFER*, *CMPCOD*, *REASON*)

### Usage notes

### Topics

The following notes apply to the use of topics:

1. When using MQPUT to publish messages on a topic, where one or more subscribers to that topic cannot be given the publication due to a problem with their subscriber queue (for example it is full), the Reason code returned to the MQPUT call and the delivery behavior is dependent on the setting of the PMSGDLV or NPMSGDLV attributes on the TOPIC. Note that delivery of a publication to the dead letter queue when RODLQ is specified, or discarding the message when RODISC is specified, is considered a successful delivery of the message. If none of the publications are delivered, the MQPUT will return with RC2502. This can happen in the following cases:
  - A message is published to a TOPIC with PMSGDLV or NPMSGDLV (depending on the persistence of the message) set to ALL and any subscription (durable or not) has a queue which cannot receive the publication.
  - A message is published to a TOPIC with PMSGDLV or NPMSGDLV (depending on the persistence of the message) set to ALLDUR and a durable subscription has a queue which cannot receive the publication.

The MQPUT can return with RCNONE even though publications could not be delivered to some subscribers in the following cases:

- A message is published to a TOPIC with PMSGDLV or NPMSGDLV (depending on the persistence of the message) set to ALLAVAIL and any subscription, durable or not, has a queue which cannot receive the publication.
  - A message is published to a TOPIC with PMSGDLV or NPMSGDLV (depending on the persistence of the message) set to ALLDUR and a non-durable subscription has a queue which cannot receive the publication.
2. If there are no subscribers to the topic being used, the message published is not sent to any queue and is discarded. It does not make any difference whether this message is persistent or non-persistent, or whether it has unlimited expiry or some small expiry time, it is still discarded if there are no subscribers. The exception to this is if the message is to be retained, in which case, although it is not sent to any subscribers' queues, it is stored against the topic to be delivered to any new subscriptions or to any subscribers that ask for retained publications using MQSUBRQ.

## MQPUT and MQPUT1

Both the MQPUT and MQPUT1 calls can be used to put messages on a queue; which call to use depends on the circumstances

- The MQPUT call should be used when multiple messages are to be placed on the *same* queue.

An MQOPEN call specifying the OOOOUT option is issued first, followed by one or more MQPUT requests to add messages to the queue; finally the queue is closed with an MQCLOSE call. This gives better performance than repeated use of the MQPUT1 call.

- The MQPUT1 call should be used when only *one* message is to be put on a queue.

This call encapsulates the MQOPEN, MQPUT, and MQCLOSE calls into a single call, minimizing the number of calls that must be issued.

## Destination queues

If an application puts a sequence of messages on the same queue without using message groups, the order of those messages is preserved if the following conditions are satisfied. Some conditions apply to both local and remote destination queues; other conditions apply only to remote destination queues.

### Conditions for local and remote destination queues

- All of the MQPUT calls are within the same unit of work, or none of them is within a unit of work.

When messages are put onto a particular queue within a single unit of work, messages from other applications might be interspersed with the sequence of messages on the queue.

- All of the MQPUT calls are made using the same object handle *HOBJ*.

In some environments, message sequence is also preserved when different object handles are used, provided the calls are made from the same application. The meaning of "same application" is determined by the environment:

– On IBM i, the application is the job.

- The messages all have the same priority.

### Additional conditions for remote destination queues

- There is only one path from the sending queue manager to the destination queue manager.

If there is a possibility that some messages in the sequence may go on a different path (for example, because of reconfiguration, traffic balancing, or path selection based on message size), the order of the messages at the destination queue manager cannot be guaranteed.

- Messages are not placed temporarily on dead-letter queues at the sending, intermediate, or destination queue managers.

If one or more of the messages is put temporarily on a dead-letter queue (for example, because a transmission queue or the destination queue is temporarily full), the messages can arrive on the destination queue out of sequence.

- The messages are either all persistent or all nonpersistent.

If a channel on the route between the sending and destination queue managers has its **CDNPM** attribute set to **NPFAST**, nonpersistent messages can jump ahead of persistent messages, resulting in the order of persistent messages relative to nonpersistent messages not being preserved. However, the order of persistent messages relative to each other, and of nonpersistent messages relative to each other, is preserved.

If these conditions are not satisfied, message groups can be used to preserve message order, but note that this requires both the sending and receiving applications to use the message-grouping support. For more information about message groups, see:

- *MDMFL* field in MQMD
- *PMLOGO* option in MQPMO
- *GMLOGO* option in MQGMO

## Distribution lists

The following notes apply to the use of distribution lists.

1. Messages can be put to a distribution list using either a version-1 or a version-2 MQPMO. If a version-1 MQPMO is used (or a version-2 MQPMO with *PMREC* equal to zero), no put message records or response records can be provided by the application. This means that it will not be possible to identify the queues which encounter errors, if the message is sent successfully to some queues in the distribution list and not others.

If put message records or response records are provided by the application, the *PMVER* field must be set to *PMVER2*.

A version-2 MQPMO can also be used to send messages to a single queue that is not in a distribution list, by ensuring that *PMREC* is zero.

2. The completion code and reason code parameters are set as follows:

- If the puts to the queues in the distribution list all succeed or fail in the same way, the completion code and reason code parameters are set to describe the common result. The MQRR response records (if provided by the application) are not set in this case.

For example, if every put succeeds, the completion code is set to *CCOK* and the reason code is *RCNONE*; if every put fails because all of the queues are inhibited for puts, the parameters are set to *CCFAIL* and *RC2051*.

- If the puts to the queues in the distribution list do not all succeed or fail in the same way:
  - The completion code parameter is set to *CCWARN* if at least one put succeeded, and to *CCFAIL* if all failed.
  - The reason code parameter is set to *RC2136*.
  - The response records (if provided by the application) are set to the individual completion codes and reason codes for the queues in the distribution list.

If the put to a destination fails because the open for that destination failed, the fields in the response record are set to *CCFAIL* and *RC2137*; that destination is included in *PMIDC*.

3. If a destination in the distribution list resolves to a local queue, the message is placed on that queue in normal form (that is, not as a distribution-list message). If more than one destination resolves to the same local queue, one message is placed on the queue for each such destination.

If a destination in the distribution list resolves to a remote queue, a message is placed on the appropriate transmission queue. Where several destinations resolve to the same transmission queue, a single distribution-list message containing those destinations may be placed on the transmission

queue, even if those destinations were not adjacent in the list of destinations provided by the application. However, this can be done only if the transmission queue supports distribution-list messages (see the **DistLists** queue attribute described in [“Attributes for queues” on page 1366](#) ).

If the transmission queue does not support distribution lists, one copy of the message in normal form is placed on the transmission queue for each destination that uses that transmission queue.

If a distribution list with the application message data is too large for a transmission queue, the distribution list message is split up into smaller distribution-list messages, each containing fewer destinations. If the application message data only just fits on the queue, distribution-list messages cannot be used at all, and the queue manager generates one copy of the message in normal form for each destination that uses that transmission queue.

If different destinations have different message priority or message persistence (this can occur when the application specifies PRQDEF or PEQDEF), the messages are not held in the same distribution-list message. Instead, the queue manager generates as many distribution-list messages as are necessary to accommodate the differing priority and persistence values.

4. A put to a distribution list might result in:

- A single distribution-list message, or
- A number of smaller distribution-list messages, or
- A mixture of distribution list messages and normal messages, or
- Normal messages only.

Which of the previous occurs depends on whether:

- The destinations in the list are local, remote, or a mixture.
- The destinations have the same message priority and message persistence.
- The transmission queues can hold distribution-list messages.
- The transmission queues' maximum message lengths are large enough to accommodate the message in distribution-list form.

However, regardless of which of the above occurs, each *physical* message resulting (that is, each normal message or distribution-list message resulting from the put) counts as only *one* message when:

- Checking whether the application has exceeded the permitted maximum number of messages in a unit of work (see the **MaxUncommittedMsgs** queue manager attribute).
- Checking whether the triggering conditions are satisfied.
- Incrementing queue depths and checking whether the queues' maximum queue depth would be exceeded.

5. Any change to the queue definitions that would have caused a handle to become invalid had the queues been opened individually (for example, a change in the resolution path), does not cause the distribution-list handle to become invalid. However, it does result in a failure for that particular queue when the distribution-list handle is used on a subsequent MQPUT call.

## Headers

If a message is put with one or more IBM MQ header structures at the beginning of the application message data, the queue manager performs certain checks on the header structures to verify that they are valid. If the queue manager detects an error, the call fails with an appropriate reason code. The checks performed vary according to the particular structures that are present. In addition, the checks are performed only if a version-2 or later MQMD is used on the MQPUT or MQPUT1 call; the checks are not performed if a version-1 MQMD is used, even if an MQMDE is present at the start of the application message data.

The following IBM MQ header structures are validated completely by the queue manager: MQDH, MQMDE.

For other IBM MQ header structures, the queue manager performs some validation, but does not check every field. Structures that are not supported by the local queue manager, and structures following the first MQDLH in the message, are not validated.

In addition to general checks on the fields in IBM MQ structures, the following conditions must be satisfied:

- An IBM MQ structure must not be split over two or more segments - the structure must be entirely contained within one segment.
- The sum of the lengths of the structures in a PCF message must equal the length specified by the **BUFLEN** parameter on the MQPUT or MQPUT1 call. A PCF message is a message that has one of the following format names:
  - FMADMN
  - FMEVNT
  - FMPCF
- IBM MQ structures must not be truncated, except in the following situations where truncated structures are permitted:
  - Messages which are report messages.
  - PCF messages.
  - Messages containing an MQDLH structure. (Structures *following* the first MQDLH can be truncated; structures preceding the MQDLH cannot.)

## Buffer

The **BUFFER** parameter shown in the RPG programming example is declared as a string; this restricts the maximum length of the parameter to 256 bytes. If a larger buffer is required, the parameter should be declared instead as a structure, or as a field in a physical file. This will increase the maximum length possible to approximately 32 KB.

## Parameters

The MQPUT call has the following parameters:

### **HCONN (10-digit signed integer) - input**

Connection handle.

This handle represents the connection to the queue manager. The value of *HCONN* was returned by a previous MQCONN or MQCONNX call.

### **HOBJ (10-digit signed integer) - input**

Object handle.

This handle represents the queue to which the message is added, or the topic to which the message is published. The value of *HOBJ* was returned by a previous MQOPEN call that specified the OOOUT option.

### **MSGDSC (MQMD) - input/output**

Message descriptor.

This structure describes the attributes of the message being sent, and receives information about the message after the put request is complete. See [“MQMD \(Message descriptor\) on IBM i” on page 1110](#) for details.

If the application provides a version-1 MQMD, the message data can be prefixed with an MQMDE structure in order to specify values for the fields that exist in the version-2 MQMD but not the version-1. The *MDFMT* field in the MQMD must be set to FMMDE to indicate that an MQMDE is present. See [“MQMDE \(Message descriptor extension\) on IBM i” on page 1153](#) for more details.

## PMO (MQPMO) - input/output

Options that control the action of MQPUT.

See “MQPMO (Put-message options) on IBM i” on page 1173 for details.

## BUFLEN (10-digit signed integer) - input

Length of the message in *BUFFER*.

Zero is valid, and indicates that the message contains no application data. The upper limit for *BUFLEN* depends on various factors:

- If the destination queue is a shared queue, the upper limit is 63 KB (64 512 bytes).
- If the destination is a local queue or resolves to a local queue (but is not a shared queue), the upper limit depends on whether:
  - The local queue manager supports segmentation.
  - The sending application specifies the flag that allows the queue manager to segment the message. This flag is MFSEGA, and can be specified either in a version-2 MQMD, or in an MQMDE used with a version-1 MQMD.

If both of these conditions are satisfied, *BUFLEN* cannot exceed 999 999 999 minus the value of the *MDOFF* field in MQMD. The longest logical message that can be put is therefore 999 999 999 bytes (when *MDOFF* is zero). However, resource constraints imposed by the operating system or environment in which the application is running may result in a lower limit.

If one or both of the previously described conditions are not satisfied, *BUFLEN* cannot exceed the smaller of the queue's **MaxMsgLength** attribute and queue manager's **MaxMsgLength** attribute.

- If the destination is a remote queue or resolves to a remote queue, the conditions for local queues apply, *but at each queue manager through which the message must pass in order to reach the destination queue* ; in particular:
  1. The local transmission queue used to store the message temporarily at the local queue manager
  2. Intermediate transmission queues (if any) used to store the message at queue managers on the route between the local and destination queue managers
  3. The destination queue at the destination queue manager

The longest message that can be put is therefore governed by the most restrictive of these queues and queue managers.

When a message is on a transmission queue, additional information resides with the message data, and this reduces the amount of application data that can be carried. In this situation it is recommended that LNMHD bytes be subtracted from the *MaxMsgLength* values of the transmission queues when determining the limit for *BUFLEN*.

**Note:** Only failure to comply with condition 1 can be diagnosed synchronously (with reason code RC2030 or RC2031) when the message is put. If conditions 2 or 3 are not satisfied, the message is redirected to a dead-letter (undelivered-message) queue, either at an intermediate queue manager or at the destination queue manager. If this happens, a report message is generated if one was requested by the sender.

## BUFFER (1-byte bit string x BUFLEN) - input

Message data.

This is a buffer containing the application data to be sent. The buffer should be aligned on a boundary appropriate to the nature of the data in the message. 4-byte alignment should be suitable for most messages (including messages containing MQ header structures), but some messages may require more stringent alignment. For example, a message containing a 64-bit binary integer might require 8-byte alignment.

If *BUFFER* contains character data, numeric data, or both, the *MDCSI* and *MDENC* fields in the **MSGDSC** parameter should be set to the values appropriate to the data; this will enable the receiver of the message to convert the data (if necessary) to the character set and encoding used by the receiver.

**Note:** All of the other parameters on the MQPUT call must be in the character set given by the **CodedCharSetId** queue manager attribute, and encoding of the local queue manager given by the ENNAT.

### **CMPCOD (10-digit signed integer) - output**

Completion code.

It is one of the following:

#### **CCOK**

Successful completion.

#### **CCWARN**

Warning (partial completion).

#### **CCFAIL**

Call failed.

### **REASON (10-digit signed integer) - output**

Reason code qualifying *CMPCOD*.

If *CMPCOD* is CCOK:

#### **RCNONE**

(0, X'000') No reason to report.

If *CMPCOD* is CCWARN:

#### **RC2104**

(2104, X'838') Report option in message descriptor not recognized.

#### **RC2136**

(2136, X'858') Multiple reason codes returned.

If *CMPCOD* is CCFAIL:

#### **RC2004**

(2004, X'7D4') Buffer parameter not valid.

#### **RC2005**

(2005, X'7D5') Buffer length parameter not valid.

#### **RC2009**

(2009, X'7D9') Connection to queue manager lost.

#### **RC2013**

(2013, X'7DD') Expiry time not valid.

#### **RC2014**

(2014, X'7DE') Feedback code not valid.

#### **RC2018**

(2018, X'7E2') Connection handle not valid.

#### **RC2019**

(2019, X'7E3') Object handle not valid.

#### **RC2024**

(2024, X'7E8') No more messages can be handled within current unit of work.

#### **RC2026**

(2026, X'7EA') Message descriptor not valid.

#### **RC2027**

(2027, X'7EB') Missing reply-to queue.

- RC2029**  
(2029, X'7ED') Message type in message descriptor not valid.
- RC2030**  
(2030, X'7EE') Message length greater than maximum for queue.
- RC2031**  
(2031, X'7EF') Message length greater than maximum for queue manager.
- RC2039**  
(2039, X'7F7') Queue not open for output.
- RC2041**  
(2041, X'7F9') Object definition changed since opened.
- RC2046**  
(2046, X'7FE') Options not valid or not consistent.
- RC2047**  
(2047, X'7FF') Persistence not valid.
- RC2048**  
(2048, X'800') Queue does not support persistent messages.
- RC2050**  
(2050, X'802') Message priority not valid.
- RC2051**  
(2051, X'803') Put calls inhibited for the queue.
- RC2052**  
(2052, X'804') Queue has been deleted.
- RC2053**  
(2053, X'805') Queue already contains maximum number of messages.
- RC2056**  
(2056, X'808') No space available on disk for queue.
- RC2058**  
(2058, X'80A') Queue manager name not valid or not known.
- RC2059**  
(2059, X'80B') Queue manager not available for connection.
- RC2061**  
(2061, X'80D') Report options in message descriptor not valid.
- RC2071**  
(2071, X'817') Insufficient storage available.
- RC2072**  
(2072, X'818') Syncpoint support not available.
- RC2093**  
(2093, X'82D') Queue not open for pass all context.
- RC2094**  
(2094, X'82E') Queue not open for pass identity context.
- RC2095**  
(2095, X'82F') Queue not open for set all context.
- RC2096**  
(2096, X'830') Queue not open for set identity context.
- RC2097**  
(2097, X'831') Queue handle referred to does not save context.
- RC2098**  
(2098, X'832') Context not available for queue handle referred to.
- RC2101**  
(2101, X'835') Object damaged.

**RC2102**  
(2102, X'836') Insufficient system resources available.

**RC2135**  
(2135, X'857') Distribution header structure not valid.

**RC2136**  
(2136, X'858') Multiple reason codes returned.

**RC2137**  
(2137, X'859') Object not opened successfully.

**RC2149**  
(2149, X'865') PCF structures not valid.

**RC2154**  
(2154, X'86A') Number of records present not valid.

**RC2156**  
(2156, X'86C') Response records not valid.

**RC2158**  
(2158, X'86E') Put message record flags not valid.

**RC2159**  
(2159, X'86F') Put message records not valid.

**RC2161**  
(2161, X'871') Queue manager quiescing.

**RC2162**  
(2162, X'872') Queue manager shutting down.

**RC2173**  
(2173, X'87D') Put-message options structure not valid.

**RC2185**  
(2185, X'889') Inconsistent persistence specification.

**RC2188**  
(2188, X'88C') Call rejected by cluster workload exit.

**RC2189**  
(2189, X'88D') Cluster name resolution failed.

**RC2195**  
(2195, X'893') Unexpected error occurred.

**RC2219**  
(2219, X'8AB') MQI call reentered before previous call complete.

**RC2241**  
(2241, X'8C1') Message group not complete.

**RC2242**  
(2242, X'8C2') Logical message not complete.

**RC2245**  
(2245, X'8C5') Inconsistent unit-of-work specification.

**RC2248**  
(2248, X'8C8') Message descriptor extension not valid.

**RC2249**  
(2249, X'8C9') Message flags not valid.

**RC2250**  
(2250, X'8CA') Message sequence number not valid.

**RC2251**  
(2251, X'8CB') Message segment offset not valid.

**RC2252**  
(2252, X'8CC') Original length not valid.

**RC2253**

(2253, X'8CD') Length of data in message segment is zero.

**RC2255**

(2255, X'8CF') Unit of work not available for the queue manager to use.

**RC2257**

(2257, X'8D1') Wrong version of MQMD supplied.

**RC2258**

(2258, X'8D2') Group identifier not valid.

**RC2266**

(2266, X'8DA') Cluster workload exit failed.

**RC2269**

(2269, X'8DD') Cluster resource error.

**RC2270**

(2270, X'8DE') No destination queues available.

**RC2420**

(2420) An MQPUT call was issued, but the message data contains an MQEPH structure that is not valid.

**RC2479**

(2479, X'9AF') Publication could not be retained.

**RC2480**

(2480, X'9B0') Target type has changed: the alias queue referred to a queue but now refers to a topic.

**RC2502**

(2502, X'9C6') Publication failed, and publication has not been delivered to any subscribers

**RC2551**

(2551, X'9F7') Specified selection string is not available.

**RC2554**

(2554, X'9FA') Message content could not be parsed to determine whether the message should be delivered to a subscriber with an extended message selector.

**RPG Declaration**

```

C*.1.....2.....3.....4.....5.....6.....7..
C          CALLP      MQPUT(HCONN : HOBJ : MSGDSC : PMO :
C                      BUFLLEN : BUFFER : CMPCOD :
C                      REASON)

```

The prototype definition for the call is:

```

```

The MQPUT1 call puts one message on a queue or distribution list, or to a topic. The queue, distribution list, or topic does not need to be open.

- [“Syntax” on page 1341](#)
- [“Usage notes” on page 1341](#)
- [“Parameters” on page 1342](#)
- [“RPG Declaration” on page 1346](#)

## Syntax

MQPUT1 (*HCONN, OBJDSC, MSGDSC, PMO, BUFLen, BUFFER, CMPCOD, REASON*)

## Usage notes

1. Both the MQPUT and MQPUT1 calls can be used to put messages on a queue; which call to use depends on the circumstances:
  - The MQPUT call should be used when multiple messages are to be placed on the *same* queue.  
An MQOPEN call specifying the OOOUT option is issued first, followed by one or more MQPUT requests to add messages to the queue; finally the queue is closed with an MQCLOSE call. This gives better performance than repeated use of the MQPUT1 call.
  - The MQPUT1 call should be used when only *one* message is to be put on a queue.  
This call encapsulates the MQOPEN, MQPUT, and MQCLOSE calls into a single call, minimizing the number of calls that must be issued.
2. If an application puts a sequence of messages on the same queue without using message groups, the order of those messages is preserved if certain conditions are satisfied. However, in most environments the MQPUT1 call does not satisfy these conditions, and so does not preserve message order. The MQPUT call must be used instead in these environments. See the usage notes in the description of the MQPUT call for details.
3. The MQPUT1 call can be used to put messages to distribution lists. For general information about this, see the usage notes for the MQOPEN and MQPUT calls.

The following differences apply when using the MQPUT1 call:

- a. If MQRr response records are provided by the application, they must be provided using the MQOD structure; they cannot be provided using the MQPMO structure.
- b. The reason code RC2137 is never returned by MQPUT1 in the response records; if a queue fails to open, the response record for that queue contains the actual reason code resulting from the open operation.

If an open operation for a queue succeeds with a completion code of CCWARN, the completion code and reason code in the response record for that queue are replaced by the completion and reason codes resulting from the put operation.

As with the MQOPEN and MQPUT calls, the queue manager sets the response records (if provided) only when the outcome of the call is not the same for all queues in the distribution list; this is indicated by the call completing with reason code RC2136.

4. If the MQPUT1 call is used to put a message on a cluster queue, the call behaves as though OOBNDN had been specified on the MQOPEN call.
5. If a message is put with one or more IBM MQ header structures at the beginning of the application message data, the queue manager performs certain checks on the header structures to verify that they are valid. For more information about this, see the usage notes for the MQPUT call.

6. If more than one of the warning situations arise (see the **CMPCOD** parameter), the reason code returned is the *first* one in the following list that applies:
  - a. RC2136
  - b. RC2242
  - c. RC2241
  - d. RC2049 or RC2104
7. The **BUFFER** parameter shown in the RPG programming example is declared as a string; this restricts the maximum length of the parameter to 256 bytes. If a larger buffer is required, the parameter should be declared instead as a structure, or as a field in a physical file. This will increase the maximum length possible to approximately 32 KB.

## Parameters

The MQPUT1 call has the following parameters:

### **HCONN (10-digit signed integer) - input**

Connection handle.

This handle represents the connection to the queue manager. The value of *HCONN* was returned by a previous MQCONN or MQCONNX call.

### **OBJDSC (MQOD) - input/output**

Object descriptor.

This is a structure which identifies the queue to which the message is added. See [“MQOD \(Object descriptor\) on IBM i” on page 1159](#) for details.

The user must be authorized to open the queue for output. The queue must **not** be a model queue.

### **MSGDSC (MQMD) - input/output**

Message descriptor.

This structure describes the attributes of the message being sent, and receives feedback information after the put request is complete. See [“MQMD \(Message descriptor\) on IBM i” on page 1110](#) for details.

If the application provides a version-1 MQMD, the message data can be prefixed with an MQMDE structure in order to specify values for the fields that exist in the version-2 MQMD but not the version-1. The *MDFMT* field in the MQMD must be set to FMMDE to indicate that an MQMDE is present. See [“MQMDE \(Message descriptor extension\) on IBM i” on page 1153](#) for more details.

### **PMO (MQPMO) - input/output**

Options that control the action of MQPUT1.

See [“MQPMO \(Put-message options\) on IBM i” on page 1173](#) for details.

### **BUFLEN (10-digit signed integer) - input**

Length of the message in *BUFFER*.

Zero is valid, and indicates that the message contains no application data. The upper limit depends on various factors; see the description of the **BUFLEN** parameter of the MQPUT call for further details.

### **BUFFER (1-byte bit string x BUFLEN) - input**

Message data.

This is a buffer containing the application message data to be sent. The buffer should be aligned on a boundary appropriate to the nature of the data in the message. 4-byte alignment should be suitable for most messages (including messages containing IBM MQ header structures), but some messages may require more stringent alignment. For example, a message containing a 64-bit binary integer might require 8-byte alignment.

If *BUFFER* contains character data, numeric data, or both, the *MDCSI* and *MDENC* fields in the **MSGDSC** parameter should be set to the values appropriate to the data; this will enable the receiver of the message to convert the data (if necessary) to the character set and encoding used by the receiver.

**Note:** All of the other parameters on the MQPUT1 call must be in the character set given by the **CodedCharSetId** queue manager attribute and encoding of the local queue manager given by ENNAT.

### **CMPCOD (10-digit signed integer) - output**

Completion code.

It is one of the following:

#### **CCOK**

Successful completion.

#### **CCWARN**

Warning (partial completion).

#### **CCFAIL**

Call failed.

### **REASON (10-digit signed integer) - output**

Reason code qualifying *CMPCOD*.

If *CMPCOD* is CCOK:

#### **RCNONE**

(0, X'000') No reason to report.

If *CMPCOD* is CCWARN:

#### **RC2104**

(2104, X'838') Report option in message descriptor not recognized.

#### **RC2136**

(2136, X'858') Multiple reason codes returned.

#### **RC2049**

(2049, X'801') Message Priority exceeds maximum value supported.

#### **RC2241**

(2241, X'8C1') Message group not complete.

#### **RC2242**

(2242, X'8C2') Logical message not complete.

If *CMPCOD* is CCFAIL:

#### **RC2001**

(2001, X'7D1') Alias base queue not a valid type.

#### **RC2004**

(2004, X'7D4') Buffer parameter not valid.

#### **RC2005**

(2005, X'7D5') Buffer length parameter not valid.

#### **RC2009**

(2009, X'7D9') Connection to queue manager lost.

#### **RC2013**

(2013, X'7DD') Expiry time not valid.

#### **RC2014**

(2014, X'7DE') Feedback code not valid.

#### **RC2017**

(2017, X'7E1') No more handles available.

- RC2018**  
(2018, X'7E2') Connection handle not valid.
- RC2024**  
(2024, X'7E8') No more messages can be handled within current unit of work.
- RC2026**  
(2026, X'7EA') Message descriptor not valid.
- RC2027**  
(2027, X'7EB') Missing reply-to queue.
- RC2029**  
(2029, X'7ED') Message type in message descriptor not valid.
- RC2030**  
(2030, X'7EE') Message length greater than maximum for queue.
- RC2031**  
(2031, X'7EF') Message length greater than maximum for queue manager.
- RC2035**  
(2035, X'7F3') Not authorized for access.
- RC2042**  
(2042, X'7FA') Object already open with conflicting options.
- RC2043**  
(2043, X'7FB') Object type not valid.
- RC2044**  
(2044, X'7FC') Object descriptor structure not valid.
- RC2046**  
(2046, X'7FE') Options not valid or not consistent.
- RC2047**  
(2047, X'7FF') Persistence not valid.
- RC2048**  
(2048, X'800') Queue does not support persistent messages.
- RC2050**  
(2050, X'802') Message priority not valid.
- RC2051**  
(2051, X'803') Put calls inhibited for the queue.
- RC2052**  
(2052, X'804') Queue has been deleted.
- RC2053**  
(2053, X'805') Queue already contains maximum number of messages.
- RC2056**  
(2056, X'808') No space available on disk for queue.
- RC2057**  
(2057, X'809') Queue type not valid.
- RC2058**  
(2058, X'80A') Queue manager name not valid or not known.
- RC2059**  
(2059, X'80B') Queue manager not available for connection.
- RC2061**  
(2061, X'80D') Report options in message descriptor not valid.
- RC2063**  
(2063, X'80F') Security error occurred.
- RC2071**  
(2071, X'817') Insufficient storage available.

**RC2072**  
(2072, X'818') Syncpoint support not available.

**RC2082**  
(2082, X'822') Unknown alias base queue.

**RC2085**  
(2085, X'825') Unknown object name.

**RC2086**  
(2086, X'826') Unknown object queue manager.

**RC2087**  
(2087, X'827') Unknown remote queue manager.

**RC2091**  
(2091, X'82B') Transmission queue not local.

**RC2092**  
(2092, X'82C') Transmission queue with wrong usage.

**RC2097**  
(2097, X'831') Queue handle referred to does not save context.

**RC2098**  
(2098, X'832') Context not available for queue handle referred to.

**RC2101**  
(2101, X'835') Object damaged.

**RC2102**  
(2102, X'836') Insufficient system resources available.

**RC2135**  
(2135, X'857') Distribution header structure not valid.

**RC2136**  
(2136, X'858') Multiple reason codes returned.

**RC2149**  
(2149, X'865') PCF structures not valid.

**RC2154**  
(2154, X'86A') Number of records present not valid.

**RC2155**  
(2155, X'86B') Object records not valid.

**RC2156**  
(2156, X'86C') Response records not valid.

**RC2158**  
(2158, X'86E') Put message record flags not valid.

**RC2159**  
(2159, X'86F') Put message records not valid.

**RC2161**  
(2161, X'871') Queue manager quiescing.

**RC2162**  
(2162, X'872') Queue manager shutting down.

**RC2173**  
(2173, X'87D') Put-message options structure not valid.

**RC2184**  
(2184, X'888') Remote queue name not valid.

**RC2188**  
(2188, X'88C') Call rejected by cluster workload exit.

**RC2189**  
(2189, X'88D') Cluster name resolution failed.

- RC2195**  
(2195, X'893') Unexpected error occurred.
- RC2196**  
(2196, X'894') Unknown transmission queue.
- RC2197**  
(2197, X'895') Unknown default transmission queue.
- RC2198**  
(2198, X'896') Default transmission queue not local.
- RC2199**  
(2199, X'897') Default transmission queue usage error.
- RC2258**  
(2258, X'8D2') Group identifier not valid.
- RC2248**  
(2248, X'8C8') Message descriptor extension not valid.
- RC2219**  
(2219, X'8AB') MQI call reentered before previous call complete.
- RC2249**  
(2249, X'8C9') Message flags not valid.
- RC2250**  
(2250, X'8CA') Message sequence number not valid.
- RC2251**  
(2251, X'8CB') Message segment offset not valid.
- RC2252**  
(2252, X'8CC') Original length not valid.
- RC2253**  
(2253, X'8CD') Length of data in message segment is zero.
- RC2255**  
(2255, X'8CF') Unit of work not available for the queue manager to use.
- RC2257**  
(2257, X'8D1') Wrong version of MQMD supplied.
- RC2266**  
(2266, X'8DA') Cluster workload exit failed.
- RC2269**  
(2269, X'8DD') Cluster resource error.
- RC2270**  
(2270, X'8DE') No destination queues available.
- RC2420**  
(2420) An MQPUT1 call was issued, but the message data contains an MQEPH structure that is not valid.
- RC2551**  
(2551, X'9F7') Specified selection string is not available.
- RC2554**  
(2554, X'9FA') Message content could not be parsed to determine whether the message should be delivered to a subscriber with an extended message selector.

## RPG Declaration

```

C*..1.....2.....3.....4.....5.....6.....7..

```

## MQSET (Set object attributes) on IBM i

The MQSET call is used to change the attributes of an object represented by a handle. The object must be a queue.

- [“Syntax” on page 1347](#)
- [“Usage notes” on page 1347](#)
- [“Parameters” on page 1348](#)
- [“RPG Declaration” on page 1351](#)

### Syntax

MQSET (*HCONN*, *HOBJ*, *SELCNT*, *SELS*, *IACNT*, *INTATR*, *CALEN*, *CHRATR*, *CMPCOD*, *REASON*)

### Usage notes

1. Using this call, the application can specify an array of integer attributes, or a collection of character attribute strings, or both. If no errors occur, the attributes specified are all set simultaneously. If an error occurs (for example, if a selector is not valid, or an attempt is made to set an attribute to a value that is not valid), the call fails and no attributes are set.
2. The values of attributes can be determined using the MQINQ call ; see [“MQINQ \(Inquire about object attributes\) on IBM i” on page 1304](#) for details.
 

**Note:** Not all attributes with values that can be inquired upon using the MQINQ call can have their values changed using the MQSET call. For example, no process-object or queue manager attributes can be set with this call.
3. Attribute changes are preserved across restarts of the queue manager (other than alterations to temporary dynamic queues, which do not survive restarts of the queue manager).
4. You cannot change the attributes of a model queue using the MQSET call. However, if you open a model queue using the MQOPEN call with the MQOO\_SET option, you can use the MQSET call to set the attributes of the dynamic local queue that is created by the MQOPEN call.
5. If the object being set is a cluster queue, there must be a local instance of the cluster queue for the open to succeed.

For more information about object attributes, see:

- [“Attributes for queues” on page 1366](#)

- [“Attributes for namelists” on page 1394](#)
- [“Attributes for process definitions on IBM i” on page 1395](#)
- [“Attributes for the queue manager on IBM i” on page 1397](#)

## Parameters

The MQSET call has the following parameters:

### **HCONN (10-digit signed integer) - input**

Connection handle.

This handle represents the connection to the queue manager. The value of HCONN was returned by a previous MQCONN or MQCONNX call.

### **HOBJ (10-digit signed integer) - input**

Object handle.

This handle represents the queue object with attributes that are to be set. The handle was returned by a previous MQOPEN call that specified the OOSSET option.

### **SELCNT (10-digit signed integer) - input**

Count of selectors.

This is the count of selectors that are supplied in the SELS array. It is the number of attributes that are to be set. Zero is a valid value. The maximum number allowed is 256.

### **SELS (10-digit signed integer x SELCNT) - input**

Array of attribute selectors.

This is an array of **SELCNT** attribute selectors; each selector identifies an attribute (integer or character) with a value that is to be set.

Each selector must be valid for the type of queue that HOBJ represents. Only certain IA\* and CA\* values are allowed; these values are listed later in this section.

Selectors can be specified in any order. Attribute values that correspond to integer attribute selectors (IA\* selectors) must be specified in INTATR in the same order in which these selectors occur in SELS. Attribute values that correspond to character attribute selectors (CA\* selectors) must be specified in CHRATR in the same order in which those selectors occur. IA\* selectors can be interleaved with the CA\* selectors; only the relative order within each type is important.

It is not an error to specify the same selector more than once; if this is done, the last value specified for a particular selector is the one that takes effect.

#### **Note:**

1. The integer and character attribute selectors are allocated within two different ranges; the IA\* selectors reside within the range IAFRST through IALAST, and the CA\* selectors within the range CAFRST through CALAST.

For each range, the constants IALSTU and CALSTU define the highest value that the queue manager will accept.

2. If all the IA\* selectors occur first, the same element numbers can be used to address corresponding elements in the SELS and INTATR arrays.

The attributes that can be set are listed in the following table. No other attributes can be set using this call. For the CA\* attribute selectors, the constant that defines the length in bytes of the string that is required in CHRATR is provided in parentheses.

<i>Table 751. MQSET attribute selectors for queues</i>		
<b>Selector</b>	<b>Description</b>	<b>Note</b>
CATRGD	Trigger data (LNTRGD).	<a href="#">“2” on page 1349</a>
IADIST	Distribution list support.	<a href="#">“1” on page 1349</a>
IAIGET	Whether get operations are allowed.	
IAIPUT	Whether put operations are allowed.	
IATRGC	Trigger control.	<a href="#">“2” on page 1349</a>
IATRGD	Trigger depth.	<a href="#">“2” on page 1349</a>
IATRGP	Threshold message priority for triggers.	<a href="#">“2” on page 1349</a>
IATRGT	Trigger type.	<a href="#">“2” on page 1349</a>

**Notes:**

1. Supported only on the following platforms:

-  AIX
-  IBM i
-  Windows

and for IBM MQ clients connected to these systems.

2. Not supported on VSE/ESA.

**IACNT (10-digit signed integer) - input**

Count of integer attributes.

This is the number of elements in the INTATR array, and must be at least the number of IA\* selectors in the **SELS** parameter. Zero is a valid value if there are none.

**INTATR (10-digit signed integ x rxIACNT) - input**

Array of integer attributes.

This is an array of IACNT integer attribute values. These attribute values must be in the same order as the IA\* selectors in the SELS array.

**CALEN (10-digit signed integer) - input**

Length of character attributes buffer.

This is the length in bytes of the **CHRATR** parameter, and must be at least the sum of the lengths of the character attributes specified in the SELS array. Zero is a valid value if there are no CA\* selectors in SELS.

**CHRATR (1-byte character string x CALEN) - input**

Character attributes.

This is the buffer containing the character attribute values, concatenated together. The length of the buffer is given by the **CALEN** parameter.

The characters attributes must be specified in the same order as the CA\* selectors in the SELS array. The length of each character attribute is fixed (see SELS). If the value to be set for an attribute contains fewer non-blank characters than the defined length of the attribute, the value in CHRATR must be padded to the right with blanks to make the attribute value match the defined length of the attribute.

### **CMPCOD (10-digit signed integer) - output**

Completion code.

It is one of the following:

#### **CCOK**

Successful completion.

#### **CCFAIL**

Call failed.

### **REASON (10-digit signed integer) - output**

Reason code qualifying CMPCOD.

If CMPCOD is CCOK:

#### **RCNONE**

(0, X'000') No reason to report.

If CMPCOD is CCFail:

#### **RC2219**

(2219, X'8AB') MQI call reentered before previous call complete.

#### **RC2006**

(2006, X'7D6') Length of character attributes not valid.

#### **RC2007**

(2007, X'7D7') Character attributes string not valid.

#### **RC2009**

(2009, X'7D9') Connection to queue manager lost.

#### **RC2018**

(2018, X'7E2') Connection handle not valid.

#### **RC2019**

(2019, X'7E3') Object handle not valid.

#### **RC2020**

(2020, X'7E4') Value for inhibit-get or inhibit-put queue attribute not valid.

#### **RC2021**

(2021, X'7E5') Count of integer attributes not valid.

#### **RC2023**

(2023, X'7E7') Integer attributes array not valid.

#### **RC2040**

(2040, X'7F8') Queue not open for set.

#### **RC2041**

(2041, X'7F9') Object definition changed since opened.

#### **RC2101**

(2101, X'835') Object damaged.

#### **RC2052**

(2052, X'804') Queue has been deleted.

#### **RC2058**

(2058, X'80A') Queue manager name not valid or not known.

**RC2059**

(2059, X'80B') Queue manager not available for connection.

**RC2162**

(2162, X'872') Queue manager shutting down.

**RC2102**

(2102, X'836') Insufficient system resources available.

**RC2065**

(2065, X'811') Count of selectors not valid.

**RC2067**

(2067, X'813') Attribute selector not valid.

**RC2066**

(2066, X'812') Count of selectors too large.

**RC2071**

(2071, X'817') Insufficient storage available.

**RC2075**

(2075, X'81B') Value for trigger-control attribute not valid.

**RC2076**

(2076, X'81C') Value for trigger-depth attribute not valid.

**RC2077**

(2077, X'81D') Value for trigger-message-priority attribute not valid.

**RC2078**

(2078, X'81E') Value for trigger-type attribute not valid.

**RC2195**

(2195, X'893') Unexpected error occurred.

**RPG Declaration**

```

```

The MQSETMP call sets or modifies a property of a message handle.

- [“Syntax” on page 1352](#)
- [“Usage notes” on page 1352](#)
- [“Parameters” on page 1353](#)
- [“RPG Declaration” on page 1356](#)

## Syntax

MQSETMP (*Hconn*, *Hmsg*, *SetPropOpts*, *Name*, *PropDesc*, *Type*, *ValueLength*, *Value*, *CompCode*, *Reason*)

## Usage notes

- You can use this call only when the queue manager itself coordinates the unit of work. This can be:
  - A local unit of work, where the changes affect only IBM MQ resources.
  - A global unit of work, where the changes can affect resources belonging to other resource managers, as well as affecting IBM MQ resources.

For further details about local and global units of work, see [“MQBEGIN \(Begin unit of work\) on IBM i” on page 1253](#).

- In environments where the queue manager does not coordinate the unit of work, use the appropriate back-out call instead of MQBACK. The environment might also support an implicit back out caused by the application terminating abnormally.
  - On z/OS, use the following calls:
    - Batch programs (including IMS batch DL/I programs) can use the MQBACK call if the unit of work affects only IBM MQ resources. However, if the unit of work affects both IBM MQ resources and resources belonging to other resource managers (for example, Db2), use the SRRBACK call provided by the z/OS Recoverable Resource Service (RRS). The SRRBACK call backs out changes to resources belonging to the resource managers that have been enabled for RRS coordination.
    - CICS applications must use the EXEC CICS SYNCPOINT ROLLBACK command to back out the unit of work. Do not use the MQBACK call for CICS applications.
    - IMS applications (other than batch DL/I programs) must use IMS calls such as ROLB to back out the unit of work. Do not use the MQBACK call for IMS applications (other than batch DL/I programs).
  - On IBM i, use this call for local units of work coordinated by the queue manager. This means that a commitment definition must not exist at job level, that is, the STRCMTCTL command with the **CMTSCOPE (\*JOB)** parameter must not have been issued for the job.
- If an application ends with uncommitted changes in a unit of work, the disposition of those changes depends on whether the application ends normally or abnormally. See the usage notes in [“MQDISC \(Disconnect queue manager\) on IBM i” on page 1289](#) for further details.
- When an application puts or gets messages in groups or segments of logical messages, the queue manager retains information relating to the message group and logical message for the last successful MQPUT and MQGET calls. This information is associated with the queue handle, and includes such things as:
  - The values of the *GroupId*, *MsgSeqNumber*, *Offset*, and *MsgFlags* fields in MQMD.
  - Whether the message is part of a unit of work.
  - For the MQPUT call: whether the message is persistent or nonpersistent.

The queue manager keeps three sets of group and segment information, one set for each of the following:

  - The last successful MQPUT call (this can be part of a unit of work).

- The last successful MQGET call that removed a message from the queue (this can be part of a unit of work).
- The last successful MQGET call that browsed a message on the queue (this cannot be part of a unit of work).

If the application puts or gets the messages as part of a unit of work, and the application then decides to back out the unit of work, the group and segment information is restored to the value that it had previously:

- The information associated with the MQPUT call is restored to the value that it had before the first successful MQPUT call for that queue handle in the current unit of work.
- The information associated with the MQGET call is restored to the value that it had before the first successful MQGET call for that queue handle in the current unit of work.

Queues that were updated by the application after the unit of work started, but outside the scope of the unit of work, do not have their group and segment information restored if the unit of work is backed out.

Restoring the group and segment information to its previous value when a unit of work is backed out allows the application to spread a large message group or large logical message consisting of many segments across several units of work, and to restart at the correct point in the message group or logical message if one of the units of work fails.

Using several units of work might be advantageous if the local queue manager has only limited queue storage. However, the application must maintain sufficient information to be able to restart putting or getting messages at the correct point if a system failure occurs.

For details of how to restart at the correct point after a system failure, see the PMLOGO option described in [PMOPT \(10 digit signed integer\)](#), and the GMLOGO option described in [GMOPT \(10 digit signed integer\)](#).

The remaining usage notes apply only when the queue manager coordinates the units of work:

- A unit of work has the same scope as a connection handle. All IBM MQ calls that affect a particular unit of work must be performed using the same connection handle. Calls issued using a different connection handle (for example, calls issued by another application) affect a different unit of work. See [HCONN \(10-digit signed integer\)](#) - output for information about the scope of connection handles.
- Only messages that were put or retrieved as part of the current unit of work are affected by this call.
- A long-running application that issues MQGET, MQPUT, or MQPUT1 calls within a unit of work, but that never issues a commit or backout call, can fill queues with messages that are not available to other applications. To guard against this possibility, the administrator must set the **MaxUncommittedMsgs** queue manager attribute to a value that is low enough to prevent runaway applications filling the queues, but high enough to allow the expected messaging applications to work correctly.

## Parameters

The MQSETMP call has the following parameters:

### **HCONN (10-digit signed integer) - input**

This handle represents the connection to the queue manager.

The value must match the connection handle that was used to create the message handle specified in the **HMSG** parameter.

If the message handle was created using HCUNAS, a valid connection must be established on the thread setting a property of the message handle, otherwise the call fails with reason code RC2009.

### **HMSG (20-digit signed integer) - input**

This is the message handle to be modified. The value was returned by a previous MQCRTMH call.

### **SETOPT (MQSMPO) - input**

Control how message properties are set.

This structure allows applications to specify options that control how message properties are set. The structure is an input parameter on the MQSETMP call. See [MQSMPO](#) for further information.

### **PRNAME (MQCHARV) - input**

This is the name of the property to set.

See [Property names](#) and [Property name restrictions](#) for further information about the use of property names.

### **PRPDSC (MQPD) - input/output**

This structure is used to define the attributes of a property, including:

- what happens if the property is not supported
- what message context the property belongs to
- what messages the property is copied into as it flows

See [MQPD](#) for further information about this structure.

### **TYPE (10 digit signed integer) - input**

The data type of the property being set. It can be one of the following:

#### **TYPBOL**

A boolean. *ValueLength* must be 4.

#### **TYPBST**

A byte string. *ValueLength* must be zero or greater.

#### **TYPI8**

An 8 bit signed integer. *ValueLength* must be 1.

#### **TYPI16**

A 16 bit signed integer. *ValueLength* must be 2.

#### **TYPI32**

A 32 bit signed integer. *ValueLength* must be 4.

#### **TYPI64**

A 64 bit signed integer. *ValueLength* must be 8.

#### **TYPF32**

A 32 bit floating-point number. *ValueLength* must be 4.

#### **TYPF64**

A 64 bit floating-point number. *ValueLength* must be 8.

#### **TYPSTR**

A character string. *ValueLength* must be zero or greater, or the special value VLNULL.

#### **TYPNUL**

The property exists but has a null value. *ValueLength* must be zero.

### **VALLEN (10-digit signed integer) - input**

The length in bytes of the property value in the *Value* parameter.

Zero is valid only for null values or for strings or byte strings. Zero indicates that the property exists but that the value contains no characters or bytes.

The value must be greater than or equal to zero or the following special value if the *Type* parameter has TYPSTR set:

#### **VLNULL**

The value is delimited by the first null encountered in the string. The null is not included as part of the string. This value is invalid if TYPSTR is not also set.

Note: The null character used to terminate a string if VLNULL is set is a null from the character set of the Value.

### **VALUE (1-byte bit string x VALLEN) - input**

The value of the property to be set. The buffer must be aligned on a boundary appropriate to the nature of the data in the value.

In the C programming language, the parameter is declared as a pointer-to-void; the address of any type of data can be specified as the parameter.

If *ValueLength* is zero, *Value* is not referred to. In this case, the parameter address passed by programs written in C or System/390 assembler can be null.

### **CMPCOD (10-digit signed integer) - output**

The completion code; it is one of the following:

#### **CCOK**

Successful completion.

#### **CCFAIL**

Call failed.

### **REASON (10-digit signed integer) - output**

The reason code qualifying *CMPCOD*.

If *CMPCOD* is CCOK:

#### **RCNONE**

(0, X'000') No reason to report.

If *CMPCOD* is CCWARN:

#### **RC2421**

(2421, X'0975') An MQRFH2 folder containing properties could not be parsed.

If *CMPCOD* is CCFAIL:

#### **RC2204**

(2204, X'089C') Adapter not available.

#### **RC2130**

(2130, X'852') Unable to load adapter service module.

#### **RC2157**

(2157, X'86D') Primary and home ASIDs differ.

#### **RC2004**

(2004, X'07D4') Value parameter not valid.

#### **RC2005**

(2005, X'07D5') Value length parameter not valid.

#### **RC2219**

(2219, X'08AB') MQI call entered before previous call completed.

#### **RC2460**

(2460, X'099C') Message handle pointer not valid.

#### **RC2499**

(2499, X'09C3') Message handle already in use.

#### **RC2046**

(2046, X'07FE') Options not valid or not consistent.

#### **RC2482**

(2482, X'09B2') Property descriptor structure not valid.

#### **RC2442**

(2442, X'098A') Invalid property name.

#### **RC2473**

(2473, X'09A9') Invalid property data type.

**RC2472**

(2472, X'09A8') Number format error encountered in value data.

**RC2463**

(2463, X'099F') Set message property options structure not valid.

**RC2111**

(2111, X'083F') Property name coded character set identifier not valid.

**RC2071**

(2071, X'817') Insufficient storage available.

**RC2195**

(2195, X'893') Unexpected error occurred.

See [“Return codes for IBM i \(ILE RPG\)” on page 1424](#) for more details.

**MQSTAT (Retrieve status information) on IBM i**

Use the MQSTAT call to retrieve status information. The type of status information returned is determined by the STYPE value specified on the call.

- [“Syntax” on page 1356](#)
- [“Usage notes” on page 1357](#)
- [“Parameters” on page 1357](#)
- [“RPG Declaration” on page 1358](#)

**Syntax**

MQSTAT (HCONN, STYPE, STAT, CMPCOD, REASON)

## Usage notes

1. A call to MQSTAT specifying a type of STATAPT returns information about previous asynchronous MQPUT and MQPUT1 operations. The MQSTAT structure passed on the call is completed with the first recorded asynchronous warning or error information for that connection. If further errors or warnings follow the first, they do not normally alter these values. However, if an error occurs with a completion code of CCWARN, a subsequent failure with a completion code of CCFAIL is returned instead.
2. If no errors have occurred since the connection was established or since the last call to MQSTAT then a CMPCOD of CCOK and REASON of RCNONE are returned.
3. Counts of the number of asynchronous calls that have been processed under the connection handle are returned by using three counters; STSPSC, STSPWC, and STSPFC. These counters are incremented by the queue manager each time an asynchronous operation is processed successfully, has a warning, or fails (note that for accounting purposes a put to a distribution list counts once per destination queue rather than once per distribution list).
4. A successful call to MQSTAT results in any previous error information or counts being reset.

## Parameters

The MQSTAT call has the following parameters:

### Hconn (MQHCONN) - input

This handle represents the connection to the queue manager. The value of *Hconn* was returned by a previous MQCONN or MQCONNX call.

### STYPE (10-digit signed integer) - input

Type of status information being requested. The only valid value is:

#### STATAPT

Return information about previous asynchronous put operations.

### STS (MQSTS) - input/output

Status information structure. See [“MQSTS \(Status reporting structure\) on IBM i” on page 1230](#) for details.

### CMPCOD (10-digit signed integer) - output

The completion code; it is one of the following:

#### CCOK

Successful completion.

#### CCFAIL

Call failed.

### REASON (10-digit signed integer) - output

The reason code qualifying *CMPCOD*.

If *CMPCOD* is CCOK:

#### RCNONE

(0, X'000') No reason to report.

If *CMPCOD* is CCFAIL:

#### RC2374

(2374, X'946') API exit failed

#### RC2183

(2183, X'887') Unable to load API exit.

#### RC2219

(2219, X'8AB') MQI call entered before previous call complete.

**RC2009**

(2009, X'7D9') Connection to queue manager lost.

**RC2203**

(2203, X'89B') Connection shutting down.

**RC2018**

(2018, X'7E2') Connection handle not valid.

**RC2162**

(2162, X'872') Queue manager stopping

**RC2102**

(2102, X'836') Insufficient system resources available.

**RC2430**

(2430, X'97E') Error with MQSTAT type.

**RC2071**

(2071, X'817') Insufficient storage available.

**RC2424**

(2424, X'978') Error with MQSTS structure

**RC2195**

(2195, X'893') Unexpected error occurred.

**RC2298**

(2298, X'8FA') The function requested is not available in the current environment.

**IBM i MQSUB (Register Subscription) on IBM i**

The MQSUB call registers the applications subscription to a particular topic.

- [“Syntax” on page 1359](#)
- [“Usage notes” on page 1359](#)
- [“Parameters” on page 1360](#)
- [“RPG Declaration” on page 1363](#)

## Syntax

MQSUB (*HCONN, SUBDSC, HOBJ, HSUB, CMPCOD, REASON*)

## Usage notes

- The subscription is made to a topic, named either using the short name of a pre-defined topic object, the full name of the topic string, or it is formed by the concatenation of two parts, as described in [Combining topic strings](#).
- The queue manager performs security checks when an MQSUB call is issued, to verify that the user identifier under which the application is running has the appropriate level of authority before access is permitted. The appropriate topic object is located either by a short name being provided in the call, or the nearest short name object in the topic hierarchy being found if a long name is provided. An authority check is made on this topic object to ensure authority to subscribe is set and on the destination queue to ensure that authority for output is set. If the SDMAN option is used, this means that an authority check is made on the managed queue name associated with this topic object, and if a non-managed queue is provided, this means that an authority check is made on the queue represented by the **HOBJ** parameter.
- The *HOBJ* returned on the MQSUB call when the SOMAN option is used, can be inquired in order to find out attributes such as the Backout threshold and the Excessive backout requeue name. You can also inquire the name of the managed queue, but you should not attempt to directly open this queue.
- Subscriptions can be grouped allowing only a single publication to be delivered to the group of subscriptions even where more than one of the group matched the publication. Subscriptions are grouped using the SOGRP option and in order to group subscriptions they must:
  - be using the same named queue (that is not using the SOMAN option) on the same queue manager - represented by the **HOBJ** parameter on the MQSUB call
  - share the same *SDCID*
  - be of the same *SDSL*

These attributes define the set of subscriptions considered to be in the group, and are also the attributes that cannot be altered if a subscription is grouped. Alteration of *SDSL* results in RC2512, and alteration of any of the others (which can be changed if a subscription is not grouped) results in RC2515.

- Fields in the MQSD are completed on return from an MQSUB call which uses the SORES option. The MQSD returned can be passed directly into an MQSUB call which uses the SOALT option with any changes you need to make to the subscription applied to the MQSD. Some fields have special considerations as noted in the table.

<i>Table 752. MQSD output from MQSUB</i>	
Field name in MQSD	Special considerations
Access or creation options	None of these options are set on return from the MQSUB call. If you later reuse the MQSD in an MQSUB call the option you require must be explicitly set.
Durability options, Destination options, Registration Options & Wildcard options	These options will be set as appropriate
Publication options	These options will be set as appropriate, except for SONEWP which is only applicable to SOCRE.
Other options	These options are unchanged on return from an MQSUB call. They control how the API call is issued and are not stored with the subscription. They must be set as required on any subsequent MQSUB call reusing the MQSD.
ObjectName	This input only field is unchanged on return from an MQSUB call.
ObjectString	This input only field is unchanged on return from an MQSUB call. The Full topic name used is returned in the <i>SDRO</i> field, if a buffer is provided.

Table 752. MQSD output from MQSUB (continued)	
Field name in MQSD	Special considerations
AlternateUserId and AlternateSecurityId	These input only fields are unchanged on return from an MQSUB call. They control how the API call is issued and are not stored with the subscription. They must set as required on any subsequent MQSUB call reusing the MQSD.
SubExpiry	On return from an MQSUB call using the SORES option this field will be set to the original expiry of the subscription and not the remaining expiry time. If you then reuse the MQSD in an MQSUB call using the SOALT option you will reset the expiry of the subscription to start counting down again.
SubName	This field is an input field on an MQSUB call and is not changed on output.
SubUserData and SelectionString	These variable length fields will be returned on output from an MQSUB call using the SORES option, if a buffer is provided, and also a positive buffer length in VCHRP. If no buffer is provided only the length will be returned in the VCHRL field of the MQCHARV. If the buffer provided is smaller than the space required to return the field, only VCHRP bytes are returned in the provided buffer.  If you later reuse the MQSD in an MQSUB call using the SOALT option and a buffer is not provided but a non-zero VCHRL is provided, if that length matches the existing length of the field, no alteration will be made to the field.
SubCorrelId and PubAccountingToken	If you do not use SOSCID, then the SDCID will be generated by the queue manager. If you do not use SOSETI, then the SDACC will be generated by the queue manager.  These fields will be returned in the MQSD from an MQSUB call using the SORES option. If they are generated by the queue manager, the generated value will be returned on an MQSUB call using the SOCRE or SOALT option.
PubPriority, SubLevel & PubApplIdentityData	These fields will be returned in the MQSD.
ResObjectString	This output only field will be returned in the MQSD if a buffer is provided.

## Parameters

The MQSUB call has the following parameters:

### HCONN (10-digit signed integer) - input

This handle represents the connection to the queue manager. The value of HCONN was returned by a previous MQCONN or MQCONNX call.

### SUBDSC (MQSD) - input/output

This is a structure that identifies the object with use that is being registered by the application. See ["MQSD \(Subscription descriptor\) on IBM i"](#) on page 1212 for more information.

### HOBJ (10-digit signed integer) - input/output

This handle represents the access that has been established to obtain the messages sent to this subscription. These messages can either be stored on a specific queue or the queue manager can be asked to manage their storage without the need for a specific queue.

Object handle.

If a specific queue is to be used it must be associated with the subscription at creation time. This can be done in two ways:

- By providing this handle when calling MQSUB with the SDCRT option. If this handle is provided as an input parameter on the call, it must be a valid object handle returned from a previous MQOPEN call of a queue using at least one of OOINP\*, OOOUT (if a remote queue for example), or OOBW option.

If this is not the case, the call fails with RC2019. It cannot be an object handle to an alias queue which resolves to a topic object. If so, the call fails with RC2019

- By using the DEFINE SUB MQSC command and provided that command with the name of a queue object.

If the queue manager is to manage the storage of messages sent to this subscription, you should indicate this when the subscription is created, by using the SOMAN option and setting the parameter value to HONONE. The queue manager returns the handle as an output parameter on the call, and the handle that is returned is known as a managed handle. If HONONE is specified and SOMAN is not also specified, the call fails with RC2019.

A managed handle that is returned by the queue manager can be used on an MQGET or MQCB call, with or without browse options, on an MQINQ call, or on MQCLOSE. It cannot be used on MQPUT, MQSET, or on a subsequent MQSUB; attempting to do so fails with RC2039 for MQPUT, RC2040 for MQSET, or RC2038 for MQSUB.

If the SORES option in the *OPTS* field in the MQSD structure is used to resume this subscription, the handle can be returned to the application in this parameter if HONONE is specified. You can use this whether the subscription is using a managed handle or not. It can be useful for subscriptions created using DEFINE SUB if you want the handle to the subscription queue defined on the DEFINE SUB command. In the case where an administratively created subscription is being resumed, the queue is opened with OOINPQ and OOBROW. If other options are needed, the application must open the subscription queue explicitly and provide the object handle on the call. If there is a problem opening the queue the call will fail with RC2522. If the *HOBJ* is provided, it must be equivalent to the *HOBJ* in the original MQSUB call. This means if an object handle returned from an MQOPEN call is being provided, the handle must be to the same queue as previously used or the call fails with RC2019.

If this subscription is being altered, by using the SOALT option in the *OPTS* field in the MQSD structure, then a different *HOBJ* can be provided. Any publications that have been delivered to the queue previously identified through this parameter remain on that queue and it is the responsibility of the application to retrieve those messages if the **HOBJ** parameter now represents a different queue.

The use of this parameter with various subscription options is summarized in the following table:

Options	Hobj	Description
SOCRT + SOMAN	Ignored on input	Creates a subscription with queue manager managed storage of messages.
SOCRT	Valid object handle	Creates a subscription providing a specific queue as the destination for messages.
SORES	HONONE	Resumes a previously created subscription (managed or not) and have the queue manager return the object handle for use by the application.
SORES	Valid, matching, object handle	Resumes a previously created subscription which uses a specific queue as the destination for messages and use an object handle with specific open options.
SOALT + SOMAN	HONONE	Alters an existing subscription which was previously using a specific queue, to now be managed.
SOALT	Valid object handle	Alters an existing subscription to use a specific queue (either from managed, or from a different specific queue).

Whether it was provided or returned, *HOBJ* must be specified on subsequent MQGET calls that you need to receive the publications.

The *HOBJ* handle ceases to be valid when the MQCLOSE call is issued on it, or when the unit of processing that defines the scope of the handle terminates. The scope of the object handle returned

is the same as that of the connection handle specified on the call. See [HCONN](#) for information about handle scope. An MQCLOSE of the *HOBJ* handle has no effect on the *HSUB* handle.

### **HSUB (10-digit signed integer) - output**

This handle represents the subscription that has been made. It can be used for two further operations:

- It can be used on a subsequent MQSUBRQ call to request that publications be sent when the SOPUBR option has been used when making the subscription.
- It can be used on a subsequent MQCLOSE call to remove the subscription that has been made. The *HSUB* handle ceases to be valid when the MQCLOSE call is issued, or when the unit of processing that defines the scope of the handle terminates. The scope of the object handle returned is the same as that of the connection handle specified on the call. An MQCLOSE of the *HSUB* handle has no effect on the *HOBJ* handle.

This handle cannot be passed to an MQGET or MQCB call. You must use the **HOBJ** parameter. Passing this handle to any other IBM MQ call results in RC2019.

### **CMPCOD (10-digit signed integer) - output**

The completion code; it is one of the following:

#### **CCOK**

Successful completion

#### **CCWARN**

Warning (partial completion)

#### **CCFAIL**

Call failed

### **REASON (10-digit signed integer) - output**

The reason code qualifying *CMPCOD*.

If *CMPCOD* is CCOK:

#### **RCNONE**

(0, X'000') No reason to report.

If *CMPCOD* is CCFAIL:

#### **RC2019**

(2019 X'07E3') Object handle not valid

#### **RC2046**

(2046 X'07FE') Options not valid or not consistent

#### **RC2085**

D* Reason code qualifying CompCode
D REASON          10I 0

```

**IBM i MQSUBRQ (Subscription Request) on IBM i**

The MQSUBRQ call makes a request on a subscription.

- [“Syntax” on page 1364](#)
- [“Usage notes” on page 1364](#)
- [“Parameters” on page 1364](#)
- [“RPG Declaration” on page 1365](#)

## Syntax

MQSUBRQ (*HCONN*, *HSUB*, *ACTION*, *SUBROPT*, *CMPCOD*, *REASON*)

## Usage notes

The following usage notes apply to the use of SRAPUB:

1. If this verb completes successfully, the retained publications matching the subscription specified have been sent to the subscription and can be received by using MQGET or MQCB using the HOBJ returned on the original MQSUB verb that created the subscription.
2. If the topic subscribed to by the original MQSUB verb that created the subscription contained a wildcard, more than one retained publication might be sent. The number of publications sent as a result of this call is recorded in the *SRNMP* field in the SBROPT structure.
3. If this verb completes with a reason code of RC2437 then there were no currently retained publications for the topic specified.
4. If this verb completes with a reason code of RC2525 or RC2526 then there are currently retained publications for the topic specified but an error has occurred that meant they were unable to be delivered.
5. The application must have a current subscription to the topic before it can make this call. If the subscription was made in a previous instance of the application and a valid handle to the subscription is not available, the application must first call MQSUB with the SORES option to obtain a handle to it for use in this call.
6. The publications are sent to the destination that is registered for use with the current subscription of this application. If the publications should be sent somewhere else, the subscription must first be altered using the MQSUB call with the SOALT option.

## Parameters

The MQSUBRQ call has the following parameters:

### **HCONN (10-digit signed integer) - input**

This handle represents the connection to the queue manager. The value of *HCONN* was returned by a previous MQCONN or MQCONNX call.

On z/OS for CICS applications the MQCONN call can be omitted, and the following value specified for *HCONN*:

#### **HCDEFH**

Default connection handle.

### **HSUB (10-digit signed integer) - input**

This handle represents the subscription for which an update is to be requested. The value of *HSUB* was returned from a previous MQSUB call.

### **ACTION (10-digit signed integer) - input**

This parameter controls the particular action that is being requested on the subscription. One (and only one) of the following must be specified:

#### **SRAPUB**

This action requests that an update publication be sent for the specified topic. This is normally used if the subscriber specified the option SOPUBR on the MQSUB call when it made the subscription. If the queue manager has a retained publication for the topic, this is sent to the subscriber. If not, the call fails. If an application is sent a publication which was retained, this is indicated by the MQIsRetained message property of that publication.

Since the topic in the existing subscription represented by the **HSUB** parameter can contain wildcards, the subscriber might receive multiple retained publications.

## SBROPT (MQSRO) - input/output

These options control the action of MQSUBRQ, see [“MQSRO - Subscription request options”](#) on page 590 for details.

## CMPCOD (10-digit signed integer) - output

The completion code; it is one of the following:

### CCOK

Successful completion

### CCWARN

Warning (partial completion)

### CCFAIL

Call failed

## Reason (10-digit signed integer) - output

The reason code qualifying *CMPCOD*.

If *CMPCOD* is CCOK:

### RCNONE

(0, X'000') No reason to report.

If *CMPCOD* is CCFAIL:

### RC2298

2298 (X'08FA') The function requested is not available in the current environment.

### RC2437

2437 (X'0985') There are no retained publications currently stored for this topic.

### RC2046

2046 (X'07FE') Options parameter or field contains options that are not valid, or a combination of options that is not valid.

### RC2161

2161 (X'0871') Queue manager quiescing

### RC2438

2438 (X'0986') On the MQSUBRQ call, the Subscription Request Options MQSRO is not valid.

## RPG Declaration

```
C*.1.....2.....3.....4.....5.....6.....7..
C          CALLP      MQSUBRQ(HCONN : HSUB : ACTION :
C          SBROPT : CMPCOD : REASON)
```

The prototype definition for the call is:

```
D*.1.....2.....3.....4.....5.....6.....7..
DMQSUBRQ      PR          EXTPROC('MQSUBRQ')
D* Connection handle
D HCONN          10I 0 VALUE
D* Subscription handle
D HSUB          10I 0 VALUE
D* Action requested on the subscription
D ACTION        10I 0 VALUE
D* Subscription Request Options
D SBROPT          16A
D* Completion code
D CMPCOD          10I 0
D* Reason code qualifying CompCode
D REASON        10I 0
```

This collection of topics lists only those IBM MQ objects that can be the subject of an MQINQ function call, and gives details of the attributes that can be inquired on and the selectors to be used.

## Attributes for queues

Use this information to learn about the different types of queue definitions and the attributes supported by each.

**Types of queue:** The queue manager supports the following types of queue definition:

### Local queue

This is a physical queue that stores messages. The queue exists on the local queue manager.

Applications connected to the local queue manager can place messages on and remove messages from queues of this type. The value of the **QType** queue attribute is QTLOC.

### Shared queue

This is a physical queue that stores messages. The queue exists in a shared repository that is accessible to all of the queue managers that belong to the queue sharing group that owns the shared repository.

Applications connected to any queue manager in the queue sharing group can place messages on and remove messages from queues of this type. Such queues are effectively the same as local queues. The value of the **QType** queue attribute is QTLOC.

- Shared queues are supported only on z/OS.

### Cluster queue

This is a physical queue that stores messages. The queue exists either on the local queue manager, or on one or more of the queue managers that belong to the same cluster as the local queue manager.

Applications connected to the local queue manager can place messages on queues of this type, regardless of the location of the queue. If an instance of the queue exists on the local queue manager, the queue behaves in the same way as a local queue, and applications connected to the local queue manager can remove messages from the queue. The value of the **QType** queue attribute is QTCLUS.

### Alias queue

This is not a physical queue - it is an alternative name for a local queue. The name of the local queue to which the alias resolves is part of the definition of the alias queue.

Applications connected to the local queue manager can place messages on and remove messages from alias queues - the messages are placed on and removed from the local queue to which the alias resolves. The value of the **QType** queue attribute is QTALS.

### Remote queue

This is not a physical queue - it is the local definition of a queue that exists on a remote queue manager. The local definition of the remote queue contains information that tells the local queue manager how to route messages to the remote queue manager.

Applications connected to the local queue manager can place messages on remote queues - the messages are placed on the local transmission queue used to route messages to the remote queue manager. Applications cannot remove messages from remote queues. The value of the **QType** queue attribute is QTREM.

A remote queue definition can also be used for:

- Reply-queue aliasing

In this case the name of the definition is the name of a reply-to queue. For more information, see [Reply-to queue alias definitions](#).

- Queue manager aliasing

In this case the name of the definition is an alias for a queue manager, and not the name of a queue. For more information, see [Queue manager alias definitions](#).

## Model queue

This is not a physical queue - it is a set of queue attributes from which a local queue can be created.

Messages cannot be stored on queues of this type.

Some queue attributes apply to all types of queue; other queue attributes apply only to certain types of queue. The types of queue to which an attribute applies are indicated by an "X" in [Table 754 on page 1367](#) and subsequent tables.

[Table 754 on page 1367](#) summarizes the attributes that are specific to queues. The attributes are described in alphabetical order.

The names of the attributes shown in the table are the names used with the MQINQ and MQSET calls. When MQSC commands are used to define, alter, or display attributes, alternative short names are used; see [MQSC commands](#) for details.

In the following table, the columns apply as follows:

- The column for local queues applies also to shared queues.
- The column for model queues indicates which attributes are inherited by the local queue created from the model queue.
- The column for cluster queues indicates the attributes that can be inquired when the cluster queue is opened for inquire alone, or for inquire and output. If the cluster queue is opened for inquire plus one or more of input, browse, or set, the column for local queues applies instead.

<b>Attribute</b>	<b>Description</b>	<b>Local</b>	<b>Model</b>	<b>Alias</b>	<b>Remote</b>	<b>Cluster</b>

**IBM i** **AlterationDate (12-byte character string) on IBM i**

Date when definition was last changed.

Table 755. Queue types to which this attribute applies

Local	Model	Alias	Remote	Cluster
X		X	X	

This is the date when the definition was last changed. The format of the date is YYYY-MM-DD, padded with two trailing blanks to make the length 12 bytes (for example, 1992-09-23--), where -- represents two blank characters).

The values of certain attributes (for example, *CurrentQDepth*) change as the queue manager operates. Changes to these attributes do not affect *AlterationDate*.

To determine the value of this attribute, use the CAALTD selector with the MQINQ call. The length of this attribute is given by LNDATE.

### IBM i **AlterationTime (8-byte character string) on IBM i**

Time when definition was last changed.

Table 756. Queue types to which this attribute applies

Local	Model	Alias	Remote	Cluster
X		X	X	

This is the time when the definition was last changed. The format of the time is HH.MM.SS using the 24-hour clock, with a leading zero if the hour is less than 10 (for example 09.10.20). The time is local time.

The values of certain attributes (for example, *CurrentQDepth*) change as the queue manager operates. Changes to these attributes do not affect *AlterationTime*.

To determine the value of this attribute, use the CAALTT selector with the MQINQ call. The length of this attribute is given by LNTIME.

### IBM i **BackoutRequeueQName (48-byte character string) on IBM i**

Excessive backout requeue queue name.

Table 757. Queue types to which this attribute applies

Local	Model	Alias	Remote	Cluster
X	X			

Applications running inside WebSphere Application Server and those that use the IBM MQ Application Server Facilities use this attribute to determine where messages that have been backed out should go. For all other applications, apart from allowing its value to be queried, the queue manager takes no action based on the value of the attribute.

To determine the value of this attribute, use the CABRQN selector with the MQINQ call. The length of this attribute is given by LNQN.

### IBM i **BackoutThreshold (10-digit signed integer) on IBM i**

Backout threshold.

Table 758. Queue types to which this attribute applies

Local	Model	Alias	Remote	Cluster
X	X			

Applications running inside WebSphere Application Server and those that use the IBM MQ Application Server Facilities use this attribute to determine if a message should be backed out. For all other applications, apart from allowing its value to be queried, the queue manager takes no action based on the value of the attribute.

To determine the value of this attribute, use the IABTHR selector with the MQINQ call.

**IBM i BaseQName (48-byte character string) on IBM i**

The queue name to which the alias resolves.

Table 759. Queue types to which this attribute applies

Local	Model	Alias	Remote	Cluster
		X		

This is the name of a queue that is defined to the local queue manager. (For more information about queue names, see the description of the *ODON* field in MQOD. The queue is one of the following types:

**QTLOC**

Local queue.

**QTREM**

Local definition of a remote queue.

**QTCLUS**

Cluster queue.

To determine the value of this attribute, use the CABASQ selector with the MQINQ call. The length of this attribute is given by LNQN.

**IBM i BaseType (integer parameter structure) on IBM i**

The type of object to which the alias resolves.

Table 760. Queue types to which this attribute applies

Local	Model	Alias	Remote	Cluster
		X		

This attribute can have one of the following values:

**OTQ**

Base object type is a queue

**OTTOP**

Base object type is a topic

**IBM i CFStrucName (12-byte character string) on IBM i**

Coupling-facility structure name.

Table 761. Queue types to which this attribute applies				
Local	Model	Alias	Remote	Cluster
X	X			

This is the name of the coupling-facility structure where the messages on the queue are stored. The first character of the name is in the range A through Z, and the remaining characters are in the range A through Z, 0 through 9, or blank.

The full name of the structure in the coupling facility is obtained by suffixing the value of the **QSGName** queue manager attribute with the value of the **CFStrucName** queue attribute.

This attribute applies only to shared queues; it is ignored if *QSGDisp* does not have the value QSGDSH.

To determine the value of this attribute, use the CACFSN selector with the MQINQ call. The length of this attribute is given by LNCFSN.

 This attribute is supported only on z/OS.

### **ClusterChannelName (20-byte character string)**

ClusterChannelName is the generic name of the cluster-sender channels that use this queue as a transmission queue. The attribute specifies which cluster-sender channels send messages to a cluster-receiver channel from this cluster transmission queue.

Table 762. Queue types to which this attribute applies				
Local	Model	Alias	Remote	Cluster
X	X			

The default queue manager configuration is for all cluster-sender channels to send messages from a single transmission queue, SYSTEM.CLUSTER.TRANSMIT.QUEUE. The default configuration can be changed by modified by changing the queue manager attribute, **DefClusterXmitQueueType**. The default value of the attribute is SCTQ. You can change the value to CHANNEL. If you set the **DefClusterXmitQueueType** attribute to CHANNEL, each cluster-sender channel defaults to using a specific cluster transmission queue, SYSTEM.CLUSTER.TRANSMIT.ChannelName.

You can also set the transmission queue attribute ClusterChannelName attribute to a cluster-sender channel manually. Messages that are destined for the queue manager connected by the cluster-sender channel are stored in the transmission queue that identifies the cluster-sender channel. They are not stored in the default cluster transmission queue. If you set the ClusterChannelName attribute to blanks, the channel switches to the default cluster transmission queue when the channel restarts. The default queue is either SYSTEM.CLUSTER.TRANSMIT.ChannelName or SYSTEM.CLUSTER.TRANSMIT.QUEUE, depending on the value of the queue manager DefClusterXmitQueueType attribute.

By specifying asterisks, "\*", in **ClusterChannelName**, you can associate a transmission queue with a set of cluster-sender channels. The asterisks can be at the beginning, end, or any number of places in the middle of the channel name string. **ClusterChannelName** is limited to a length of 20 characters: MQ\_CHANNEL\_NAME\_LENGTH.

### **ClusterName (48-byte character string) on IBM i**

Name of cluster to which queue belongs.

Table 763. Queue types to which this attribute applies				
Local	Model	Alias	Remote	Cluster
X		X	X	

This is the name of the cluster to which the queue belongs. If the queue belongs to more than one cluster, *ClusterNameList* specifies the name of a namelist object that identifies the clusters, and *ClusterName* is blank. At least one of *ClusterName* and *ClusterNameList* must be blank.

To determine the value of this attribute, use the CACLN selector with the MQINQ call. The length of this attribute is given by LNCLUN.

**IBM i ClusterNameList (48-byte character string) on IBM i**

Name of namelist object containing names of clusters to which queue belongs.

Table 764. Queue types to which this attribute applies				
Local	Model	Alias	Remote	Cluster
X		X	X	

This is the name of a namelist object that contains the names of clusters to which this queue belongs. If the queue belongs to only one cluster, the namelist object contains only one name. Alternatively, *ClusterName* can be used to specify the name of the cluster, in which case *ClusterNameList* is blank. At least one of *ClusterName* and *ClusterNameList* must be blank.

To determine the value of this attribute, use the CACLNL selector with the MQINQ call. The length of this attribute is given by LNNLN.

**IBM i CreationDate (12-byte character string) on IBM i**

Date when queue was created.

Table 765. Queue types to which this attribute applies				
Local	Model	Alias	Remote	Cluster
X				

This is the date when the queue was created. The format of the date is YYYY-MM-DD, padded with two trailing blanks to make the length 12 bytes (for example, 1992-09-23-- , where -- represents two blank characters).

- On IBM i, the creation date of a queue might differ from that of the underlying operating system entity (file or userspace) that represents the queue.

To determine the value of this attribute, use the CACRTD selector with the MQINQ call. The length of this attribute is given by LNCRTD.

**IBM i CreationTime (8-byte character string) on IBM i**

Time when queue was created.

Table 766. Queue types to which this attribute applies				
Local	Model	Alias	Remote	Cluster
X				

This is the time when the queue was created. The format of the time is HH.MM.SS using the 24-hour clock, with a leading zero if the hour is less than 10 (for example 09.10.20). The time is local time.

- On IBM i, the creation time of a queue might differ from that of the underlying operating system entity (file or user space) that represents the queue.

To determine the value of this attribute, use the CACRTT selector with the MQINQ call. The length of this attribute is given by LNCRTT.

**IBM i** **CurrentQDepth (10-digit signed integer) on IBM i**

Current queue depth.

Table 767. Queue types to which this attribute applies

Local	Model	Alias	Remote	Cluster
X				

This is the number of messages currently on the queue. It is incremented during an MQPUT call, and during backout of an MQGET call. It is decremented during a nonbrowse MQGET call, and during backout of an MQPUT call. The effect of this is that the count includes messages that have been put on the queue within a unit of work, but which have not yet been committed, even though they are not eligible to be retrieved by the MQGET call. Similarly, it excludes messages that have been retrieved within a unit of work using the MQGET call, but which have yet to be committed.

The count also includes messages which have passed their expiry time but have not yet been discarded, although these messages are not eligible to be retrieved. See the *MDEXP* field described in “MQMD (Message descriptor) on IBM i” on page 1110.

Unit-of-work processing and the segmentation of messages can both cause *CurrentQDepth* to exceed *MaxQDepth*. However, this does not affect the retrievability of the messages - *all* messages on the queue can be retrieved using the MQGET call in the normal way.

The value of this attribute fluctuates as the queue manager operates.

To determine the value of this attribute, use the IACDEP selector with the MQINQ call.

**IBM i** **DefBind (10-digit signed integer) on IBM i**

Default binding.

Table 768. Queue types to which this attribute applies

Local	Model	Alias	Remote	Cluster
X		X	X	X

This attribute is the default binding that is used when OOBNDQ is specified on the MQOPEN call and the queue is a cluster queue. DefBind can have one of the following values:

**BNDOPN**

Binding fixed by MQOPEN call.

**BNDNOT**

Binding not fixed.

**BNDGRP**

Binding is not fixed by the MQOPEN call, but is fixed on MQPUT for all messages in a logical group.

To determine the value of this attribute, use the IADBND selector with the MQINQ call.

**IBM i** **DefinitionType (10-digit signed integer) on IBM i**

Queue definition type.

Table 769. Queue types to which this attribute applies

Local	Model	Alias	Remote	Cluster
X	X			

This indicates how the queue was defined. The value is one of the following:

#### QDPRE

Predefined permanent queue.

The queue is a permanent queue created by the system administrator; only the system administrator can delete it.

Predefined queues are created using the DEFINE MQSC command, and can be deleted only by using the DELETE MQSC command. Predefined queues cannot be created from model queues.

Commands can be issued either by an operator, or by an authorized user sending a command message to the command input queue (see the **CommandInputQName** attribute described in [“Attributes for the queue manager on IBM i” on page 1397](#)).

#### QDPERM

Dynamically defined permanent queue.

The queue is a permanent queue that was created by an application issuing an MQOPEN call with the name of a model queue specified in the object descriptor MQOD. The model queue definition had the value QDPERM for the **DefinitionType** attribute.

This type of queue can be deleted using the MQCLOSE call. See [“MQCLOSE \(Close object\) on IBM i” on page 1267](#) for more details.

The value of the **QSGDisp** attribute for a permanent dynamic queue is QSGDQM.

#### QDTEMP

Dynamically defined temporary queue.

The queue is a temporary queue that was created by an application issuing an MQOPEN call with the name of a model queue specified in the object descriptor MQOD. The model queue definition had the value QDTEMP for the **DefinitionType** attribute.

This type of queue is deleted automatically by the MQCLOSE call when it is closed by the application that created it.

The value of the **QSGDisp** attribute for a temporary dynamic queue is QSGDQM.

#### QDSHAR

Dynamically defined shared queue.

The queue is a shared permanent queue that was created by an application issuing an MQOPEN call with the name of a model queue specified in the object descriptor MQOD. The model queue definition had the value QDSHAR for the **DefinitionType** attribute.

This type of queue can be deleted using the MQCLOSE call. See [“MQCLOSE \(Close object\) on IBM i” on page 1267](#) for more details.

The value of the **QSGDisp** attribute for a shared dynamic queue is QSGDSH.

This attribute in a model queue definition does not indicate how the model queue was defined, because model queues are always predefined. Instead, the value of this attribute in the model queue is used to determine the *DefinitionType* of each of the dynamic queues created from the model queue definition using the MQOPEN call.

To determine the value of this attribute, use the IADEFT selector with the MQINQ call.

## IBM i **DefInputOpenOption (10-digit signed integer) on IBM i**

Default input open option.

Table 770. Queue types to which this attribute applies				
Local	Model	Alias	Remote	Cluster
X	X			

This is the default way in which the queue should be opened for input. It applies if the OOINPQ option is specified on the MQOPEN call when the queue is opened. This can have one of the following values:

### **OOINPX**

Open queue to get messages with exclusive access.

The queue is opened for use with subsequent MQGET calls. The call fails with reason code RC2042 if the queue is currently open by this or another application for input of any type (OOINPS or OOINPX).

### **OOINPS**

Open queue to get messages with shared access.

The queue is opened for use with subsequent MQGET calls. The call can succeed if the queue is currently open by this or another application with OOINPS, but fails with reason code RC2042 if the queue is currently open with OOINPX.

To determine the value of this attribute, use the IADINP selector with the MQINQ call.

## IBM i **DefPersistence (10-digit signed integer) on IBM i**

Default message persistence.

Table 771. Queue types to which this attribute applies				
Local	Model	Alias	Remote	Cluster
X	X	X	X	X

This is the default persistence of messages on the queue. It applies if PEQDEF is specified in the message descriptor when the message is put.

If there is more than one definition in the queue-name resolution path, the default persistence is taken from the value of this attribute in the *first* definition in the path at the time of the MQPUT or MQPUT1 call. This could be:

- An alias queue
- A local queue
- A local definition of a remote queue
- A queue manager alias
- A transmission queue (for example, the *DefXmitQName* queue)

This can have one of the following values:

### **PEPER**

Message is persistent.

This means that the message survives system failures and restarts of the queue manager. Persistent messages cannot be placed on:

- Temporary dynamic queues
- Shared queues

Persistent messages can be placed on permanent dynamic queues, and predefined queues.

#### **PENPER**

Message is not persistent.

This means that the message does not normally survive system failures or restarts of the queue manager. This applies even if an intact copy of the message is found on auxiliary storage during restart of the queue manager.

In the special case of shared queues, nonpersistent messages *do* survive restarts of queue managers in the queue sharing group, but do not survive failures of the coupling facility used to store messages on the shared queues.

Both persistent and nonpersistent messages can exist on the same queue.

To determine the value of this attribute, use the IADPER selector with the MQINQ call.

#### **IBM i** *DefPriority (10-digit signed integer) on IBM i* Default message priority.

Local	Model	Alias	Remote	Cluster
X	X	X	X	X

This is the default priority for messages on the queue. This applies if PRQDEF is specified in the message descriptor when the message is put on the queue.

If there is more than one definition in the queue-name resolution path, the default priority for the message is taken from the value of this attribute in the *first* definition in the path at the time of the put operation. This could be:

- An alias queue
- A local queue
- A local definition of a remote queue
- A queue manager alias
- A transmission queue (for example, the *DefXmitQName* queue)

The way in which a message is placed on a queue depends on the value of the queue's **MsgDeliverySequence** attribute:

- If the **MsgDeliverySequence** attribute is MSPRIO, the logical position at which a message is placed on the queue is dependent on the value of the *MDPRI* field in the message descriptor.
- If the **MsgDeliverySequence** attribute is MSFIFO, messages are placed on the queue as though they had a priority equal to the *DefPriority* of the resolved queue, regardless of the value of the *MDPRI* field in the message descriptor. However, the *MDPRI* field retains the value specified by the application that put the message. See the **MsgDeliverySequence** attribute described in [“Attributes for queues” on page 1366](#) for more information.

Priorities are in the range zero (lowest) through *MaxPriority* (highest); see the **MaxPriority** attribute described in [“Attributes for the queue manager on IBM i” on page 1397](#).

To determine the value of this attribute, use the IADPRI selector with the MQINQ call.

### ▶ IBM i **DefReadAhead (10-digit signed integer) on IBM i**

Specifies the default read ahead behavior for non-persistent messages delivered to the client.

Table 773. Queue types to which this attribute applies

Local	Model	Alias	Remote	Cluster
X	X	X		

DefReadAhead can be set to one of the following values:

#### **RAHNO**

Non-persistent messages are not sent ahead to the client before an application requests them. A maximum of one non-persistent message can be lost if the client ends abnormally.

#### **RAHYES**

Non-persistent messages are sent ahead to the client before an application requests them. Non-persistent messages can be lost if the client ends abnormally or if the client does not consume all the messages it is sent.

#### **RAHDIS**

Read ahead of non-persistent messages is not enabled for this queue. Messages are not sent ahead to the client regardless of whether read ahead is requested by the client application.

To determine the value of this attribute, use the IADRAH selector with the MQINQ call.

### ▶ IBM i **DefPResp (10-digit signed integer) on IBM i**

The default put response type (DEFPRESP) attribute defines the value used by applications when the PutResponseType within MQPMO has been set to PMRASQ. This attribute is valid for all queue types.

Table 774. Queue types to which this attribute applies

Local	Model	Alias	Remote	Cluster
X	X	X	X	X

This can have one of the following values:

#### **SYNC**

The put operation is issued synchronously returning a response.

#### **ASYNC**

The put operation is issued asynchronously, returning a subset of MQMD fields.

To determine the value of this attribute, use the IADPRT selector with the MQINQ call.

### ▶ IBM i **DistLists (10-digit signed integer) on IBM i**

Distribution list support.

Table 775. Queue types to which this attribute applies

Local	Model	Alias	Remote	Cluster
X	X			

This indicates whether distribution-list messages can be placed on the queue. The attribute is set by a message channel agent (MCA) to inform the local queue manager whether the queue manager at the other end of the channel supports distribution lists. This latter queue manager (called the "partnering queue manager") is the one which next receives the message, after it has been removed from the local transmission queue by a sending MCA.

The attribute is set by the sending MCA whenever it establishes a connection to the receiving MCA on the partnering queue manager. In this way, the sending MCA can cause the local queue manager to place on the transmission queue only messages which the partnering queue manager can process correctly.

This attribute is primarily for use with transmission queues, but the processing described is performed regardless of the usage defined for the queue (see the **Usage** attribute).

This can have one of the following values:

**DLSUPP**

Distribution lists supported.

This indicates that distribution-list messages can be stored on the queue, and transmitted to the partnering queue manager in that form. This reduces the amount of processing required to send the message to multiple destinations.

**DLNSUP**

Distribution lists not supported.

This indicates that distribution-list messages cannot be stored on the queue, because the partnering queue manager does not support distribution lists. If an application puts a distribution-list message, and that message is to be placed on this queue, the queue manager splits the distribution-list message and places the individual messages on the queue instead. This increases the amount of processing required to send the message to multiple destinations, but ensures that the messages will be processed correctly by the partnering queue manager.

To determine the value of this attribute, use the IADIST selector with the MQINQ call. To change the value of this attribute, use the MQSET call.

 **HardenGetBackout (10-digit signed integer) on IBM i**

Whether to maintain an accurate backout count.

*Table 776. Queue types to which this attribute applies*

Local	Model	Alias	Remote	Cluster
X	X			

For each message, a count is kept of the number of times that the message is retrieved by an MQGET call within a unit of work, and that unit of work later backed out. This count is available in the *MDBOC* field in the message descriptor after the MQGET call has completed.

The message backout count survives when the queue manager restarts. However, to ensure that the count is accurate, information has to be "hardened" (recorded on disk or other permanent storage device) each time a message is retrieved by an MQGET call within a unit of work for this queue. If this is not done, and a failure of the queue manager occurs together with backout of the MQGET call, the count might not be incremented.

Hardening information for each MQGET call within a unit of work, however, imposes a performance cost, and the **HardenGetBackout** attribute should be set to QABH only if the count has to be accurate.

- On IBM i, the message backout count is always hardened, regardless of the setting of this attribute.

The following values are possible:

**QABH**

Backout count remembered.

Hardening is used to ensure that the backout count for messages on this queue is accurate.

**QABNH**

Backout count might not be remembered.

Hardening is not used to ensure that the backout count for messages on this queue is accurate. The count might therefore be lower than it should be.

To determine the value of this attribute, use the IAHGB selector with the MQINQ call.

**IBM i** **InhibitGet (10-digit signed integer) on IBM i**

Controls whether get operations for this queue are allowed.

Table 777. Queue types to which this attribute applies				
Local	Model	Alias	Remote	Cluster
X	X	X		

If the queue is an alias queue, get operations must be allowed for both the alias and the base queue at the time of the get operation, in order for the MQGET call to succeed. The value is one of the following:

**QAGETI**

Get operations are inhibited.

MQGET calls fail with reason code RC2016. This includes MQGET calls that specify GMBRWF or GMBRWN.

**Note:** If an MQGET call operating within a unit of work completes successfully, changing the value of the **InhibitGet** attribute after to QAGETI does not prevent the unit of work being committed.

**QAGETA**

Get operations are allowed.

To determine the value of this attribute, use the IAIGET selector with the MQINQ call. To change the value of this attribute, use the MQSET call.

**IBM i** **InhibitPut (10-digit signed integer) on IBM i**

Controls whether put operations for this queue are allowed.

Table 778. Queue types to which this attribute applies				
Local	Model	Alias	Remote	Cluster
X	X	X	X	X

If there is more than one definition in the queue-name resolution path, put operations must be allowed for every definition in the path (including any queue manager alias definitions) at the time of the put operation, in order for the MQPUT or MQPUT1 call to succeed. This can have one of the following values:

**QAPUTI**

Put operations are inhibited.

MQPUT and MQPUT1 calls fail with reason code RC2051.

**Note:** If an MQPUT call operating within a unit of work completes successfully, changing the value of the **InhibitPut** attribute later to QAPUTI does not prevent the unit of work being committed.

**QAPUTA**

Put operations are allowed.

To determine the value of this attribute, use the IAIPUT selector with the MQINQ call. To change the value of this attribute, use the MQSET call.

## IBM i **InitiationQName (48-byte character string) on IBM i**

Name of initiation queue.

Table 779. Queue types to which this attribute applies				
Local	Model	Alias	Remote	Cluster
X	X			

This is the name of a queue defined on the local queue manager; the queue must be of type QTLOC. The queue manager sends a trigger message to the initiation queue when application startup is required as a result of a message arriving on the queue to which this attribute belongs. The initiation queue must be monitored by a trigger monitor application which will start the appropriate application after receipt of the trigger message.

To determine the value of this attribute, use the CAINIQ selector with the MQINQ call. The length of this attribute is given by LNQN.

## IBM i **MaxMsgLength (10-digit signed integer) on IBM i**

Maximum message length in bytes.

Table 780. Queue types to which this attribute applies				
Local	Model	Alias	Remote	Cluster
X	X			

This is an upper limit for the length of the longest *physical* message that can be placed on the queue. However, because the **MaxMsgLength** queue attribute can be set independently of the **MaxMsgLength** queue manager attribute, the actual upper limit for the length of the longest physical message that can be placed on the queue is the lesser of those two values.

If the queue manager supports segmentation, it is possible for an application to put a *logical* message that is longer than the lesser of the two **MaxMsgLength** attributes, but only if the application specifies the MFSEGA flag in MQMD. If that flag is specified, the upper limit for the length of a logical message is 999 999 999 bytes, but typically, resource constraints imposed by the operating system or by the environment in which the application is running, results in a lower limit.

An attempt to place on the queue a message that is too long fails with reason code:

- RC2030 if the message is too large for the queue
- RC2031 if the message is too large for the queue manager, but not too large for the queue

The lower limit for the **MaxMsgLength** attribute is zero. The upper limit is determined by the environment:

- On IBM i, the maximum message length is 100 MB (104 857 600 bytes).

For more information, see the **BUFLEN** parameter described in [“MQPUT \(Put message\) on IBM i” on page 1331](#).

To determine the value of this attribute, use the IAMLEN selector with the MQINQ call.

## IBM i **MaxQDepth (10-digit signed integer) on IBM i**

Maximum queue depth.

Table 781. Queue types to which this attribute applies

Local	Model	Alias	Remote	Cluster
X	X			

This is the defined upper limit for the number of physical messages that can exist on the queue at any one time. An attempt to put a message on a queue that already contains *MaxQDepth* messages, fails with reason code RC2053.

Unit-of-work processing and the segmentation of messages can both cause the actual number of physical messages on the queue to exceed *MaxQDepth*. However, this does not affect the retrievability of the messages - *all* messages on the queue can be retrieved using the MQGET call in the normal way.

The value of this attribute is zero or greater. The upper limit is determined by the environment.

**Note:** It is possible for the storage space available to the queue to be exhausted even if there are fewer than *MaxQDepth* messages on the queue.

To determine the value of this attribute, use the IAMDEP selector with the MQINQ call.

### **MediaLog (10-digit signed integer) on IBM i**

Identity of the log extent (or journal receiver on IBM i) needed for media recovery of a particular queue.

Table 782. Queue types to which this attribute applies

Local	Model	Alias	Remote	Cluster
X	X			

On queue managers where circular logging is in use, the value is returned as a null string.

### **MsgDeliverySequence (10-digit signed integer) on IBM i**

Message delivery sequence.

Table 783. Queue types to which this attribute applies

Local	Model	Alias	Remote	Cluster
X	X			

This determines the order in which messages are returned to the application by the MQGET call:

#### **MSFIFO**

Messages are returned in FIFO order (first in, first out).

This means that an MQGET call will return the *first* message that satisfies the selection criteria specified on the call, regardless of the priority of the message.

#### **MSPRIO**

Messages are returned in priority order.

This means that an MQGET call will return the *highest-priority* message that satisfies the selection criteria specified on the call. Within each priority level, messages are returned in FIFO order (first in, first out).

If the relevant attributes are changed while there are messages on the queue, the delivery sequence is as follows:

- The order in which messages are returned by the MQGET call is determined by the values of the **MsgDeliverySequence** and **DefPriority** attributes in force for the queue at the time the message arrives on the queue:
  - If *MsgDeliverySequence* is MSFIFO when the message arrives, the message is placed on the queue as though its priority were *DefPriority*. This does not affect the value of the *MDPRI* field in the message descriptor of the message; that field retains the value it had when the message was first put.
  - If *MsgDeliverySequence* is MSPRIO when the message arrives, the message is placed on the queue at the place appropriate to the priority given by the *MDPRI* field in the message descriptor.

If the value of the **MsgDeliverySequence** attribute is changed while there are messages on the queue, the order of the messages on the queue is not changed.

If the value of the **DefPriority** attribute is changed while there are messages on the queue, the messages will not necessarily be delivered in FIFO order, even though the **MsgDeliverySequence** attribute is set to MSFIFO; those that were placed on the queue at the higher priority are delivered first.

To determine the value of this attribute, use the IAMDS selector with the MQINQ call.

**IBM i** **OpenInputCount (10-digit signed integer) on IBM i**

Number of opens for input.

Table 784. Queue types to which this attribute applies

Local	Model	Alias	Remote	Cluster
X				

This is the number of handles that are currently valid for removing messages from the queue with the MQGET call. It is the total number of such handles known to the *local* queue manager. If the queue is a shared queue, the count does not include opens for input that were performed for the queue at other queue managers in the queue sharing group to which the local queue manager belongs.

The count includes handles where an alias queue which resolves to this queue was opened for input. The count does not include handles where the queue was opened for actions which did not include input (for example, a queue opened only for browse).

The value of this attribute fluctuates as the queue manager operates.

To determine the value of this attribute, use the IAOIC selector with the MQINQ call.

**IBM i** **OpenOutputCount (10-digit signed integer) on IBM i**

Number of opens for output.

Table 785. Queue types to which this attribute applies

Local	Model	Alias	Remote	Cluster
X				

This is the number of handles that are currently valid for adding messages to the queue with the MQPUT call. It is the total number of such handles known to the *local* queue manager; it does not include opens for output that were performed for this queue at remote queue managers. If the queue is a shared queue, the count does not include opens for output that were performed for the queue at other queue managers in the queue sharing group to which the local queue manager belongs.

The count includes handles where an alias queue which resolves to this queue was opened for output. The count does not include handles where the queue was opened for actions which did not include output (for example, a queue opened only for inquire).

The value of this attribute fluctuates as the queue manager operates.

To determine the value of this attribute, use the IAQOC selector with the MQINQ call.

**IBM i** **ProcessName (48-byte character string) on IBM i**

Process name.

<i>Table 786. Queue types to which this attribute applies</i>				
Local	Model	Alias	Remote	Cluster
X	X			

This is the name of a process object that is defined on the local queue manager. The process object identifies a program that can service the queue.

To determine the value of this attribute, use the CAPRON selector with the MQINQ call. The length of this attribute is given by LNPRON.

**IBM i** **QDepthHighEvent (10-digit signed integer) on IBM i**

Controls whether Queue Depth High events are generated.

<i>Table 787. Queue types to which this attribute applies</i>				
Local	Model	Alias	Remote	Cluster
X	X			

A Queue Depth High event indicates that an application has put a message on a queue, which has caused the number of messages on the queue to become greater than or equal to the queue depth high threshold (see the **QDepthHighLimit** attribute).

**Note:** The value of this attribute can change dynamically.

QDepthHighEvent can have one of two values:

**EVRDIS**

Event reporting disabled.

**EVRENA**

Event reporting enabled.

For more information about events, see [Event monitoring](#).

To determine the value of this attribute, use the IAQDHE selector with the MQINQ call.

**IBM i** **QDepthHighLimit (10-digit signed integer) on IBM i**

High limit for queue depth.

<i>Table 788. Queue types to which this attribute applies</i>				
Local	Model	Alias	Remote	Cluster
X	X			

This is the threshold against which the queue depth is compared to generate a Queue Depth High event. This event indicates that an application has put a message on a queue, and this has caused the number of messages on the queue to become greater than or equal to the queue depth high threshold. See the **QDepthHighEvent** attribute.

The value is expressed as a percentage of the maximum queue depth (**MaxQDepth** attribute), and is in the range zero through 100. The default value is 80.

To determine the value of this attribute, use the IAQDHL selector with the MQINQ call.

**IBM i** **QDepthLowEvent (10-digit signed integer) on IBM i**

Controls whether Queue Depth Low events are generated.

*Table 789. Queue types to which this attribute applies*

Local	Model	Alias	Remote	Cluster
X	X			

A Queue Depth Low event indicates that an application has retrieved a message from a queue, which has caused the number of messages on the queue to become less than or equal to the queue depth low threshold (see the **QDepthLowLimit** attribute).

**Note:** The value of this attribute can change dynamically.

QDepthLowEvent can have one of the following values:

**EVRDIS**

Event reporting disabled.

**EVRENA**

Event reporting enabled.

For more information about events, see [Event monitoring](#).

To determine the value of this attribute, use the IAQDLE selector with the MQINQ call.

**IBM i** **QDepthLowLimit (10-digit signed integer) on IBM i**

Low limit for queue depth.

*Table 790. Queue types to which this attribute applies*

Local	Model	Alias	Remote	Cluster
X	X			

This is the threshold against which the queue depth is compared to generate a Queue Depth Low event. This event indicates that an application has retrieved a message from a queue, and this has caused the number of messages on the queue to become less than or equal to the queue depth low threshold. See the **QDepthLowEvent** attribute.

The value is expressed as a percentage of the maximum queue depth (**MaxQDepth** attribute), and is in the range zero through 100. The default value is 20.

To determine the value of this attribute, use the IAQDLL selector with the MQINQ call.

**IBM i** **QDepthMaxEvent (10-digit signed integer) on IBM i**

Controls whether Queue Full events are generated.

<i>Table 791. Queue types to which this attribute applies</i>				
<b>Local</b>	<b>Model</b>	<b>Alias</b>	<b>Remote</b>	<b>Cluster</b>
X	X			

A Queue Full event indicates that a put to a queue has been rejected because the queue is full, that is, the queue depth has already reached its maximum value.

**Note:** The value of this attribute can change dynamically.

This can have one of the following values:

**EVRDIS**

Event reporting disabled.

**EVRENA**

Event reporting enabled.

For more information about events, see [Event monitoring](#).

To determine the value of this attribute, use the IAQDME selector with the MQINQ call.

**IBM i QDesc (64-byte character string) on IBM i**

Queue description.

<i>Table 792. Queue types to which this attribute applies</i>				
<b>Local</b>	<b>Model</b>	<b>Alias</b>	<b>Remote</b>	<b>Cluster</b>
X	X	X	X	X

This is a field that can be used for descriptive commentary. The content of the field is of no significance to the queue manager, but the queue manager might require that the field contains only characters that can be displayed. It cannot contain any null characters; if necessary, it is padded to the right with blanks. In a DBCS installation, the field can contain DBCS characters (subject to a maximum field length of 64 bytes).

**Note:** If this field contains characters that are not in the queue manager's character set (as defined by the **CodedCharSetId** queue manager attribute), those characters might be translated incorrectly if this field is sent to another queue manager.

To determine the value of this attribute, use the CAQD selector with the MQINQ call. The length of this attribute is given by LNQD.

**IBM i QName (48-byte character string) on IBM i**

Queue name.

<i>Table 793. Queue types to which this attribute applies</i>				
<b>Local</b>	<b>Model</b>	<b>Alias</b>	<b>Remote</b>	<b>Cluster</b>
X		X	X	X

This is the name of a queue defined on the local queue manager. For more information about queue names, see [Rules for naming IBM MQ objects](#). All queues defined on a queue manager share the same queue namespace. Therefore, a QTLOC queue and a QTALS queue cannot have the same name.

To determine the value of this attribute, use the CAQN selector with the MQINQ call. The length of this attribute is given by LNQN.

**IBM i** **QServiceInterval (10-digit signed integer) on IBM i**

Target for queue service interval.

Table 794. Queue types to which this attribute applies				
Local	Model	Alias	Remote	Cluster
X	X			

This is the service interval used for comparison to generate Service Interval High and Service Interval OK events. See the **QServiceIntervalEvent** attribute.

The value is in units of milliseconds, and is in the range zero through 999 999 999.

To determine the value of this attribute, use the IAQSI selector with the MQINQ call.

**IBM i** **QServiceIntervalEvent (10-digit signed integer) on IBM i**

Controls whether Service Interval High or Service Interval OK events are generated.

Table 795. Queue types to which this attribute applies				
Local	Model	Alias	Remote	Cluster
X	X			

- A Service Interval High event is generated when a check indicates that no messages have been retrieved from the queue for at least the time indicated by the **QServiceInterval** attribute.
- A Service Interval OK event is generated when a check indicates that messages have been retrieved from the queue within the time indicated by the **QServiceInterval** attribute.

**Note:** The value of this attribute can change dynamically.

This attribute can have one of the following values:

**QSIEHI**

Queue Service Interval High events enabled.

- Queue Service Interval High events are **enabled** and
- Queue Service Interval OK events are **disabled**.

**QSIEOK**

Queue Service Interval OK events enabled.

- Queue Service Interval High events are **disabled** and
- Queue Service Interval OK events are **enabled**.

**QSIENO**

No queue service interval events enabled.

- Queue Service Interval High events are **disabled** and
- Queue Service Interval OK events are also **disabled**.

For shared queues, the value of this attribute is ignored; the value QSIENO is assumed.

For more information about events, see [Event monitoring](#).

To determine the value of this attribute, use the IAQSIE selector with the MQINQ call.

**IBM i** **QSGDisp (10-digit signed integer) on IBM i**

Queue sharing group disposition.

Local	Model	Alias	Remote	Cluster
X		X	X	

This specifies the disposition of the queue. The value is one of the following:

**QSGDQM**

Queue manager disposition.

The object has queue manager disposition. This means that the object definition is known only to the local queue manager; the definition is not known to other queue managers in the queue sharing group.

It is possible for each queue manager in the queue sharing group to have an object with the same name and type as the current object, but these are separate objects and there is no correlation between them. Their attributes are not constrained to be the same as each other.

**QSGDCP**

Copied-object disposition.

The object is a local copy of a master object definition that exists in the shared repository. Each queue manager in the queue sharing group can have its own copy of the object. Initially, all copies have the same attributes, but by using MQSC commands each copy can be altered so that its attributes differ from those of the other copies. The attributes of the copies are resynchronized when the master definition in the shared repository is altered.

**QSGDSH**

Shared disposition.

The object has shared disposition. This means that there exists in the shared repository a single instance of the object that is known to all queue managers in the queue sharing group. When a queue manager in the group accesses the object, it accesses the single shared instance of the object.

To determine the value of this attribute, use the IAQSGD selector with the MQINQ call.

**z/OS** This attribute is supported only on z/OS.

**IBM i** **QType (10-digit signed integer) on IBM i**

Queue type.

Local	Model	Alias	Remote	Cluster
X		X	X	X

This attribute has one of the following values:

**QTALS**

Alias queue definition.

**QTCLUS**

Cluster queue.

**QTLOC**

Local queue.

## QTREM

Local definition of a remote queue.

To determine the value of this attribute, use the IAQTYP selector with the MQINQ call.

### **RemoteQMgrName (48-byte character string) on IBM i**

Name of remote queue manager.

Table 798. Queue types to which this attribute applies				
Local	Model	Alias	Remote	Cluster
			X	

This is the name of the remote queue manager on which the queue *RemoteQName* is defined. If the *RemoteQName* queue has a *QSGDisp* value of QSGDCP or QSGDSH, *RemoteQMgrName* can be the name of the queue sharing group that owns *RemoteQName*.

If an application opens the local definition of a remote queue, *RemoteQMgrName* must not be blank and must not be the name of the local queue manager. If *XmitQName* is blank, the local queue with same name as *RemoteQMgrName* is used as the transmission queue. If there is no queue with the name *RemoteQMgrName*, the queue identified by the **DefXmitQName** queue manager attribute is used.

If this definition is used for a queue manager alias, *RemoteQMgrName* is the name of the queue manager that is being aliased. It can be the name of the local queue manager. Otherwise, if *XmitQName* is blank when the open occurs, there must be a local queue with the same name as *RemoteQMgrName*; this queue is used as the transmission queue.

If this definition is used for a reply-to alias, this name is the name of the queue manager which is to be the *MDRM*.

**Note:** No validation is performed on the value specified for this attribute when the queue definition is created or modified.

To determine the value of this attribute, use the CARQMN selector with the MQINQ call. The length of this attribute is given by LNQMNM.

### **RemoteQName (48-byte character string) on IBM i**

Name of remote queue.

Table 799. Queue types to which this attribute applies				
Local	Model	Alias	Remote	Cluster
			X	

This is the name of the queue as it is known on the remote queue manager *RemoteQMgrName*.

If an application opens the local definition of a remote queue, when the open occurs *RemoteQName* must not be blank.

If this definition is used for a queue manager alias definition, when the open occurs *RemoteQName* must be blank.

If the definition is used for a reply-to alias, this name is the name of the queue that is to be the *MDRQ*.

**Note:** No validation is performed on the value specified for this attribute when the queue definition is created or modified.

To determine the value of this attribute, use the CARQN selector with the MQINQ call. The length of this attribute is given by LNQN.

## IBM i **RetentionInterval (10-digit signed integer) on IBM i**

Retention interval.

Table 800. Queue types to which this attribute applies				
Local	Model	Alias	Remote	Cluster
X	X			

This is the time which the queue should be retained. After this time has elapsed, the queue is eligible for deletion.

The time is measured in hours, counting from the date and time when the queue was created. The creation date of the queue is recorded in the *CreationDate* and the create time of the queue is recorded in the **CreationTime** attribute.

This information is provided to enable a housekeeping application or the operator to identify and delete queues that are no longer required.

**Note:** The queue manager never tries to delete queues based on this attribute, or to prevent the deletion of queues with a retention interval that has not expired; it is the user's responsibility to cause any required action to be taken.

A realistic retention interval should be used to prevent the accumulation of permanent dynamic queues (see *DefinitionType*). However, this attribute can also be used with predefined queues.

To determine the value of this attribute, use the IARINT selector with the MQINQ call.

## IBM i **Scope (10-digit signed integer) on IBM i**

Controls whether an entry for this queue also exists in a cell directory.

Table 801. Queue types to which this attribute applies				
Local	Model	Alias	Remote	Cluster
X		X	X	

A cell directory is provided by an installable Name service. This can have one of the following values:

### **SCOQM**

Queue manager scope.

The queue definition has queue manager scope. This means that the definition of the queue does not extend beyond the queue manager which owns it. To open the queue for output from some other queue manager, either the name of the owning queue manager must be specified, or the other queue manager must have a local definition of the queue.

### **SCOCEL**

Cell scope.

The queue definition has cell scope. This means that the queue definition is also placed in a cell directory available to all of the queue managers in the cell. The queue can be opened for output from any of the queue managers in the cell merely by specifying the name of the queue; the name of the queue manager which owns the queue need not be specified. However, the queue definition is not available to any queue manager in the cell which also has a local definition of a queue with that name, as the local definition takes precedence.

A cell directory is provided by an installable name service such as LDAP (Lightweight Directory Access Protocol). Note that IBM MQ no longer supports the DCE (Distributed Computing Environment) name service that was formerly used for inserting queue definitions into a DCE directory (also no longer supported).

Model and dynamic queues cannot have cell scope.

This value is only valid if a name service supporting a cell directory has been configured.

To determine the value of this attribute, use the IASCOPI selector with the MQINQ call.

Support for this attribute is subject to the following restrictions:

- On IBM i, the attribute is supported, but only SCOQM is valid.

### **IBM i** *Shareability (10-digit signed integer) on IBM i*

Whether queue can be shared for input.

Table 802. Queue types to which this attribute applies				
Local	Model	Alias	Remote	Cluster
X	X			

This indicates whether the queue can be opened for input multiple times concurrently. This can have one of the following values:

#### **QASHR**

Queue is shareable.

Multiple opens with the OOINPS option are allowed.

#### **QANSHR**

Queue is not shareable.

An MQOPEN call with the OOINPS option is treated as OOINPX.

To determine the value of this attribute, use the IASHAR selector with the MQINQ call.

### **IBM i** *TriggerControl (10-digit signed integer) on IBM i*

Trigger control.

Table 803. Queue types to which this attribute applies				
Local	Model	Alias	Remote	Cluster
X	X			

This controls whether trigger messages are written to an initiation queue, in order to cause an application to be started to service the queue. This is one of the following:

#### **TCOFF**

Trigger messages not required.

No trigger messages are to be written for this queue. The value of *TriggerType* is irrelevant in this case.

#### **TCON**

Trigger messages required.

Trigger messages are to be written for this queue, when the appropriate trigger events occur.

To determine the value of this attribute, use the IATRGC selector with the MQINQ call. To change the value of this attribute, use the MQSET call.

**IBM i** **TriggerData (64-byte character string) on IBM i**

Trigger data.

Table 804. Queue types to which this attribute applies				
Local	Model	Alias	Remote	Cluster
X	X			

This is free-format data that the queue manager inserts into the trigger message when a message arriving on this queue causes a trigger message to be written to the initiation queue.

The content of this data is of no significance to the queue manager. It is meaningful either to the trigger-monitor application which processes the initiation queue, or to the application which is started by the trigger monitor.

The character string cannot contain any nulls. It is padded to the right with blanks if necessary.

To determine the value of this attribute, use the CATRGD selector with the MQINQ call. To change the value of this attribute, use the MQSET call. The length of this attribute is given by LNTRGD.

**IBM i** **TriggerDepth (10-digit signed integer) on IBM i**

Trigger depth.

Table 805. Queue types to which this attribute applies				
Local	Model	Alias	Remote	Cluster
X	X			

This is the number of messages of priority *TriggerMsgPriority* or greater that must be on the queue before a trigger message is written. This applies when *TriggerType* is set to TTDPTH. The value of *TriggerDepth* is one or greater. This attribute is not used otherwise.

To determine the value of this attribute, use the IATRGD selector with the MQINQ call. To change the value of this attribute, use the MQSET call.

**IBM i** **TriggerMsgPriority (10-digit signed integer) on IBM i**

Threshold message priority for triggers on IBM MQ for IBM i.

Table 806. Queue types to which this attribute applies				
Local	Model	Alias	Remote	Cluster
X	X			

This is the message priority below which messages do not contribute to the generation of trigger messages (that is, the queue manager ignores these messages when determining whether a trigger message should be generated). *TriggerMsgPriority* can be in the range zero (lowest) through *MaxPriority* (highest; see “Attributes for the queue manager on IBM i” on page 1397); a value of zero causes all messages to contribute to the generation of trigger messages.

To determine the value of this attribute, use the IATRGP selector with the MQINQ call. To change the value of this attribute, use the MQSET call.

**IBM i** *TriggerType (10-digit signed integer) on IBM i*

Trigger type.

Table 807. Queue types to which this attribute applies				
Local	Model	Alias	Remote	Cluster
X	X			

This controls the conditions under which trigger messages are written as a result of messages arriving on this queue. The value is one of the following:

**TTNONE**

No trigger messages.

No trigger messages are written as a result of messages on this queue. This has the same effect as setting *TriggerControl* to TCOFF.

**TTFRST**

Trigger message when queue depth goes from 0 to 1.

A trigger message is written whenever the number of messages of priority *TriggerMsgPriority* or greater on the queue changes from 0 to 1.

**TTEVRY**

Trigger message for every message.

A trigger message is written whenever a message of priority *TriggerMsgPriority* or greater arrives on the queue.

**TTDPTH**

Trigger message when depth threshold exceeded.

A trigger message is written whenever the number of messages of priority *TriggerMsgPriority* or greater on the queue equals or exceeds *TriggerDepth*. After the trigger message has been written, *TriggerControl* is set to TCOFF to prevent further triggering until it is explicitly turned on again.

To determine the value of this attribute, use the IATRGT selector with the MQINQ call. To change the value of this attribute, use the MQSET call.

**IBM i** *Usage (10-digit signed integer) on IBM i*

Queue usage.

Table 808. Queue types to which this attribute applies				
Local	Model	Alias	Remote	Cluster
X	X			

This indicates what the queue is used for. The value is one of the following:

**USNORM**

Normal usage.

This is a queue that normal applications use when putting and getting messages; the queue is not a transmission queue.

**USTRAN**

Transmission queue.

This is a queue used to hold messages destined for remote queue managers. When a normal application sends a message to a remote queue, the local queue manager stores the message

temporarily on the appropriate transmission queue in a special format. A message channel agent then reads the message from the transmission queue, and transports the message to the remote queue manager. For more information about transmission queues, see [Transmission queues](#).

Only privileged applications can open a transmission queue for OOOOUT to put messages on it directly. Only utility applications would normally be expected to do this. Care must be taken that the message data format is correct (see “MQXQH (Transmission-queue header) on IBM i” on page 1245), otherwise errors might occur during the transmission process. Context is not passed or set unless one of the PM\* context options is specified.

To determine the value of this attribute, use the IAUSAG selector with the MQINQ call.

### **IBM i** *XmitQName (48-byte character string) on IBM i*

Transmission queue name.

<i>Table 809. Queue types to which this attribute applies</i>				
<b>Local</b>	<b>Model</b>	<b>Alias</b>	<b>Remote</b>	<b>Cluster</b>
			X	

If this attribute is nonblank when an open occurs, either for a remote queue or for a queue manager alias definition, it specifies the name of the local transmission queue to be used for forwarding the message.

If *XmitQName* is blank, the local queue with the same name as *RemoteQMGrName* is used as the transmission queue. If there is no queue with the name *RemoteQMGrName*, the queue identified by the **DefXmitQName** queue manager attribute is used.

This attribute is ignored if the definition is being used as a queue manager alias and *RemoteQMGrName* is the name of the local queue manager. It is also ignored if the definition is used as a reply-to queue alias definition.

To determine the value of this attribute, use the CAXQN selector with the MQINQ call. The length of this attribute is given by LNQN.

## **Attributes for namelists**

This topic summarizes the attributes that are specific to namelists. The attributes are described in alphabetical order.

**Note:** The names of the attributes shown are the names used with the MQINQ and MQSET calls.

### **Attribute descriptions**

A namelist object has the following attributes:

#### **AlterationDate (12-byte character string)**

Date when definition was last changed.

This is the date when the definition was last changed. The format of the date is YYYY-MM-DD, padded with two trailing blanks to make the length 12 bytes.

To determine the value of this attribute, use the CAALTD selector with the MQINQ call. The length of this attribute is given by LNDATE.

#### **AlterationTime (8-byte character string)**

Time when definition was last changed.

This is the time when the definition was last changed. The format of the time is HH.MM.SS.

To determine the value of this attribute, use the CAALTT selector with the MQINQ call. The length of this attribute is given by LNTIME.

### **NameCount (10-digit signed integer)**

Number of names in namelist.

This is greater than or equal to zero. The following value is defined:

#### **NCMXNL**

Maximum number of names in a namelist.

To determine the value of this attribute, use the IANAMC selector with the MQINQ call.

### **NamelistDesc (64-byte character string)**

Namelist description.

This is a field that might be used for descriptive commentary; its value is established by the definition process. The content of the field is of no significance to the queue manager, but the queue manager might require that the field contains only characters that can be displayed. It cannot contain any null characters; if necessary, it is padded to the right with blanks. In a DBCS installation, this field can contain DBCS characters (subject to a maximum field length of 64 bytes).

**Note:** If this field contains characters that are not in the queue manager's character set (as defined by the **CodedCharSetId** queue manager attribute), those characters might be translated incorrectly if this field is sent to another queue manager.

To determine the value of this attribute, use the CALSTD selector with the MQINQ call.

The length of this attribute is given by LNNLD.

### **NamelistName (48-byte character string)**

Namelist name.

This is the name of a namelist that is defined on the local queue manager.

Each namelist has a name that is different from the names of other namelists belonging to the queue manager, but might duplicate the names of other queue manager objects of different types (for example, queues).

To determine the value of this attribute, use the CALSTN selector with the MQINQ call.

The length of this attribute is given by LNNLN.

### **Names (48-byte character string x NameCount)**

A list of *NameCount* names.

Each name is the name of an object that is defined to the local queue manager. For more information about object names, see [Naming IBM MQ objects](#).

To determine the value of this attribute, use the CANAMS selector with the MQINQ call.

The length of each name in the list is given by LNOBJN.

## **Attributes for process definitions on IBM i**

This topic summarizes the attributes that are specific to process definitions. The attributes are described in alphabetical order.

**Note:** The names of the attributes shown are the names used with the MQINQ and MQSET calls. When MQSC commands are used to define, alter, or display attributes, alternative short names are used; see [MQSC commands](#) for details.

### **Attribute descriptions**

A process-definition object has the following attributes:

#### **AlterationDate (12-byte character string)**

Date when definition was last changed.

This is the date when the definition was last changed. The format of the date is YYYY-MM-DD, padded with two trailing blanks to make the length 12 bytes.

To determine the value of this attribute, use the CAALTD selector with the MQINQ call. The length of this attribute is given by LNDATE.

#### **AlterationTime (8-byte character string)**

Time when definition was last changed.

This is the time when the definition was last changed. The format of the time is HH.MM.SS.

To determine the value of this attribute, use the CAALTT selector with the MQINQ call. The length of this attribute is given by LNTIME.

#### **ApplId (256-byte character string)**

Application identifier.

This is a character string that identifies the application to be started. This information is for use by a trigger-monitor application that processes messages on the initiation queue; the information is sent to the initiation queue as part of the trigger message.

The meaning of *ApplId* is determined by the trigger-monitor application. The trigger monitor provided by IBM MQ requires *ApplId* to be the name of an executable program.

The character string cannot contain any nulls. It is padded to the right with blanks if necessary.

To determine the value of this attribute, use the CAAPPI selector with the MQINQ call. The length of this attribute is given by LNPROA.

#### **ApplType (10-digit signed integer)**

Application type.

This identifies the nature of the program to be started in response to the receipt of a trigger message. This information is for use by a trigger-monitor application that processes messages on the initiation queue; the information is sent to the initiation queue as part of the trigger message.

*ApplType* can have any value. You can use the following values for standard types; user-defined application types are restricted to values in the range ATUFST through ATULST:

##### **ATCICS**

CICS transaction.

##### **AT400**

IBM i application.

##### **ATUFST**

Lowest value for user-defined application type.

##### **ATULST**

Highest value for user-defined application type.

To determine the value of this attribute, use the IAAPPT selector with the MQINQ call.

#### **EnvData (128-byte character string)**

Environment data.

This is a character string that contains environment-related information pertaining to the application to be started. This information is for use by a trigger-monitor application that processes messages on the initiation queue; the information is sent to the initiation queue as part of the trigger message.

The meaning of *EnvData* is determined by the trigger-monitor application. The trigger monitor provided by IBM MQ appends *EnvData* to the parameter list passed to the started application. The parameter list consists of the MQTMC2 structure, followed by one blank, followed by *EnvData* with trailing blanks removed.

The character string cannot contain any nulls. It is padded to the right with blanks if necessary.

To determine the value of this attribute, use the CAENV D selector with the MQINQ call. The length of this attribute is given by LNPROE.

### **ProcessDesc (64-byte character string)**

Process description.

This is a field that can be used for descriptive commentary. The content of the field is of no significance to the queue manager, but the queue manager might require that the field contain only characters that can be displayed. It cannot contain any null characters; if necessary, it is padded to the right with blanks. In a DBCS installation, the field can contain DBCS characters (subject to a maximum field length of 64 bytes).

**Note:** If this field contains characters that are not in the queue manager's character set (as defined by the **CodedCharSetId** queue manager attribute), those characters might be translated incorrectly if this field is sent to another queue manager.

To determine the value of this attribute, use the CAPROD selector with the MQINQ call.

The length of this attribute is given by LNPROD.

### **ProcessName (48-byte character string)**

Process name.

This is the name of a process definition that is defined on the local queue manager.

Each process definition has a name that is different from the names of other process definitions belonging to the queue manager. But the name of the process definition can be the same as the names of other queue manager objects of different types (for example, queues).

To determine the value of this attribute, use the CAPRON selector with the MQINQ call.

The length of this attribute is given by LNPRON.

### **UserData (128-byte character string)**

User data.

This is a character string that contains user information pertaining to the application to be started. This information is for use by a trigger-monitor application that processes messages on the initiation queue, or the application which is started by the trigger monitor. The information is sent to the initiation queue as part of the trigger message.

The meaning of *UserData* is determined by the trigger-monitor application. The trigger monitor provided by IBM MQ passes *UserData* to the started application as part of the parameter list. The parameter list consists of the MQTMC2 structure (containing *UserData*), followed by one blank, followed by *EnvData* with trailing blanks removed.

The character string cannot contain any nulls. It is padded to the right with blanks if necessary.

To determine the value of this attribute, use the CAUSR D selector with the MQINQ call. The length of this attribute is given by LNPROU.

## **Attributes for the queue manager on IBM i**

A summary of queue manager attributes.

Some queue manager attributes are fixed for particular implementations, while others can be changed by using the MQSC command ALTER QMGR. The attributes can also be displayed by using the command DISPLAY QMGR. Most queue manager attributes can be inquired by opening a special OTQM object, and using the MQINQ call with the handle returned.

The following table summarizes the attributes that are specific to the queue manager. The attributes are described in alphabetical order.

**Note:** The names of the attributes shown in this section are the names used with the MQINQ and MQSET calls. When MQSC commands are used to define, alter, or display attributes, alternative short names are used; see [MQSC commands](#) for more information.

<i>Table 810. Attributes for the queue manager</i>	
<b>Attribute</b>	<b>Description</b>
<a href="#">AlterationDate</a>	Date when definition was last changed
<a href="#">AlterationTime</a>	Time when definition was last changed
<a href="#">AuthorityEvent</a>	Controls whether authorization (Not Authorized) events are generated
<a href="#">BridgeEvent</a>	Controls whether IMS bridge events are generated
<a href="#">ChannelAutoDef</a>	Controls whether automatic channel definition is permitted
<a href="#">ChannelAutoDefEvent</a>	Controls whether channel automatic-definition events are generated
<a href="#">ChannelAutoDefExit</a>	Name of user exit for automatic channel definition
<a href="#">ChannelEvent</a>	Controls whether channel events are generated
<a href="#">ClusterCacheType</a>	Controls whether the cluster cache is fixed in size or dynamically sized
<a href="#">ClusterWorkloadData</a>	User data for cluster workload exit
<a href="#">ClusterWorkloadExit</a>	Name of user exit for cluster workload management
<a href="#">ClusterWorkloadLength</a>	Maximum length of message data passed to cluster workload exit
<a href="#">CodedCharSetId</a>	Coded character set identifier
<a href="#">CommandEvent</a>	Controls whether command event messages are queued
<a href="#">CommandInputQName</a>	Command input queue name
<a href="#">CommandLevel</a>	Command level
<a href="#">ConfigurationEvent</a>	Configuration event
<a href="#">DeadLetterQName</a>	Name of dead-letter queue
<a href="#">DefClusterXmitQueueType</a>	Default cluster transmission queue type
<a href="#">DefXmitQName</a>	Default transmission queue name
<a href="#">DistLists</a>	Distribution list support
<a href="#">InhibitEvent</a>	Controls whether inhibit (Inhibit Get and Inhibit Put) events are generated
<a href="#">LocalEvent</a>	Controls whether local error events are generated
<a href="#">LoggerEvent</a>	Controls whether recovery log events are generated
<a href="#">MaxHandles</a>	Maximum number of handles
<a href="#">MaxMsgLength</a>	Maximum message length in bytes
<a href="#">MaxPriority</a>	Maximum priority
<a href="#">MaxUncommittedMsgs</a>	Maximum number of uncommitted messages within a unit of work
<a href="#">PerformanceEvent</a>	Controls whether performance-related events are generated
<a href="#">Platform</a>	Platform on which the queue manager is running

<i>Table 810. Attributes for the queue manager (continued)</i>	
<b>Attribute</b>	<b>Description</b>
<u>PubSubMode</u>	Whether the publish/subscribe engine and queued publish/subscribe interface are running
<u>QMgrDesc</u>	Queue manager description
<u>QMgrIdentifier</u>	Unique internally-generated identifier of queue manager
<u>QMgrName</u>	Queue manager name
<u>RemoteEvent</u>	Controls whether remote error events are generated
<u>RepositoryName</u>	Name of cluster for which this queue manager provides repository services
<u>RepositoryNamelist</u>	Name of namelist object containing names of clusters for which this queue manager provides repository services
<u>SSLCRLNamelist</u>	Name of namelist object containing names of authentication information objects (See Note 1)
<u>SSLEvent</u>	Controls whether TLS events are generated
<u>SSLKeyRepository</u>	Location of TLS key repository (See Note 1)
<u>SSLKeyResetCount</u>	Determines the number of non-encrypted bytes sent and received within a TLS conversation before the encryption key is renegotiated
<u>StartStopEvent</u>	Controls whether start and stop events are generated
<u>SyncPoint</u>	Syncpoint availability
<u>TraceRouteRecording</u>	Controls the recording of trace route information for messages
<u>TreeLifeTime</u>	The lifetime, in seconds, of non-administrative topics
<u>TriggerInterval</u>	Trigger-message interval
<b>Notes:</b>	
1. This attribute cannot be inquired using the MQINQ call, and is not described in this section. For more information about this attribute, see <a href="#">Change Queue Manager</a> .	

**IBM i** ***AlterationDate (12-byte character string) on IBM i***

Date when definition was last changed.

This is the date when the definition was last changed. The format of the date is YYYY-MM-DD, padded with two trailing blanks to make the length 12 bytes.

To determine the value of this attribute, use the CAALTD selector with the MQINQ call. The length of this attribute is given by LNDATE.

**IBM i** ***AlterationTime (8-byte character string) on IBM i***

Time when definition was last changed.

This is the time when the definition was last changed. The format of the time is HH.MM.SS.

To determine the value of this attribute, use the CAALTT selector with the MQINQ call. The length of this attribute is given by LNTIME.

**IBM i AuthorityEvent (10-digit signed integer) on IBM i**

Controls whether authorization (Not Authorized) events are generated.

The AuthorityEvent attribute must be set to one of the following values:

**EVRDIS**

Event reporting disabled.

**EVRENA**

Event reporting enabled.

For more information about events, see [Event monitoring](#).

To determine the value of this attribute, use the IAAUTE selector with the MQINQ call.

**IBM i BridgeEvent (character string) on IBM i**

This attribute determines whether IMS bridge event messages are put onto the SYSTEM.ADMIN.CHANNEL.EVENT queue. It is only supported on z/OS.

**IBM i ChannelAutoDef (10-digit signed integer) on IBM i**

Controls whether automatic channel definition is permitted.

This attribute controls the automatic definition of channels of type CTCRCVR and CTSVCN. Note that the automatic definition of CTCLSD channels is always enabled. This can have one of the following values:

**CHADDI**

Channel auto-definition disabled.

**CHADEN**

Channel auto-definition enabled.

To determine the value of this attribute, use the IACAD selector with the MQINQ call.

**IBM i ChannelAutoDefEvent (10-digit signed integer) on IBM i**

Controls whether channel automatic-definition events are generated.

This applies to channels of type CTCRCVR, CTSVCN, and CTCLSD. This can have one of the following values:

**EVRDIS**

Event reporting disabled.

**EVRENA**

Event reporting enabled.

For more information about events, see [Monitoring and performance](#).

To determine the value of this attribute, use the IACADE selector with the MQINQ call.

**IBM i ChannelAutoDefExit (20-byte character string) on IBM i**

Name of user exit for automatic channel definition.

If this name is nonblank, and *ChannelAutoDef* has the value CHADEN, the exit is called each time that the queue manager is about to create a channel definition. This applies to channels of type CTCRCVR, CTSVCN, and CTCLSD. The exit can then do one of the following:

- Allow the creation of the channel definition to proceed without change.
- Modify the attributes of the channel definition that is created.
- Suppress creation of the channel entirely.

To determine the value of this attribute, use the CACADX selector with the MQINQ call. The length of this attribute is given by LNEXTN.

### **IBM i** ***ChannelEvent (character string) on IBM i***

Determines whether channel event messages are generated.

This attribute determines whether channel event messages are put onto the SYSTEM.ADMIN.CHANNEL.EVENT queue, and if so, what type of messages are queued (for example 'channel started', 'channel stopped', 'channel not activated'). Before the implementation of this attribute, the only way of preventing channel event messages from being queued was to delete the target queue.

This attribute also allows you to collect IMS bridge events only (because you can now switch off channel events, they do not get put onto the same queue). The same applies to TLS events which can also be collected without having to collect channel events as well.

This attribute also allows you to collect significant events only (for example when channels have errors, not when they start and stop normally).

The value for the ChannelEvent attribute can be one of the following:

- EVREXP (only the following channel events are generated: RC2279, RC2283, RC2284, RC2295, RC2296).
- EVRENA (all channel events are generated; that is, in addition to the events generated by EVREXP, the RC2282, and RC2283 events are also generated).
- EVRDIS (no channel events are generated; this is the queue manager initial default value).

To determine the value of this attribute, use the IACHNE selector with the MQINQ call.

### **IBM i** ***ClusterCacheType (32-byte character string) on IBM i***

Controls whether cluster cache is fixed size, or is dynamically sized.

This is a user-defined 32-byte character string that is passed to the cluster workload exit when it is called. If there is no data to pass to the exit, the string is blank.

To determine the value of this attribute, use the CACLWD selector with the MQINQ call.

### **IBM i** ***ClusterWorkloadData (32-byte character string) on IBM i***

User data for cluster workload exit.

This is a user-defined 32-byte character string that is passed to the cluster workload exit when it is called. If there is no data to pass to the exit, the string is blank.

To determine the value of this attribute, use the CACLWD selector with the MQINQ call.

### **IBM i** ***ClusterWorkloadExit (20-byte character string) on IBM i***

Name of user exit for cluster workload management.

If this name is not blank, the exit is called each time that a message is put to a cluster queue or moved from one cluster-sender queue to another. The exit can then either accept the queue instance selected by the queue manager as the destination for the message, or select another queue instance.

To determine the value of this attribute, use the CACLWX selector with the MQINQ call. The length of this attribute is given by LNEXTN.

### **IBM i** ***ClusterWorkloadLength (10-digit signed integer) on IBM i***

Maximum length of message data passed to cluster workload exit.

This is the maximum length of message data that is passed to the cluster workload exit. The actual length of data passed to the exit is the minimum of the following:

- The length of the message.
- The queue manager's **MaxMsgLength** attribute.
- The **ClusterWorkloadLength** attribute.

To determine the value of this attribute, use the IACLWL selector with the MQINQ call.

***CodedCharSetId (10-digit signed integer) on IBM i***

Coded character set identifier.

This defines the character set used by the queue manager for all character string fields defined in the MQI such as the names of objects, and queue creation date and time. The character set must be one that has single-byte characters for the characters that are valid in object names. It does not apply to application data carried in the message. The value depends on the environment:

- On IBM i, the value is that which is set in the environment when the queue manager is first created.

To determine the value of this attribute, use the IACCSI selector with the MQINQ call.

***CommandEvent (integer) on IBM i***

Controls whether messages are put onto a local queue when commands are issued.

This controls whether messages are written to a new event queue, SYSTEM.ADMIN.COMMAND.EVENT, whenever commands are issued. This feature is useful for command tracking notification, and for problem diagnosis. To inquire about the CommandEvent queue manager attribute, use the new attribute selector iacev with one of the following values:

- EVRENA - command event messages are generated and put onto the queue for all successful commands.
- EVND - command event messages are generated and put onto the queue for all successful commands other than the DISPLAY (MQSC) command, and the Inquire (PCF) command.
- EVRDIS - command event messages are not generated or put onto the queue (this is the queue manager's initial default value).

To determine the value of this attribute, use the CMDEV selector with the MQINQ call.

***CommandInputQName (48-byte character string) on IBM i***

Command input queue name.

CommandInputQName is the name of the command input queue defined on the local queue manager. It is a queue to which users can send commands, if authorized to do so. The name of the queue depends on the environment:

- On IBM i, the name of the queue is SYSTEM.ADMIN.COMMAND.QUEUE, and only PCF commands can be sent to it. However, an MQSC command can be sent to this queue if the MQSC command is enclosed within a PCF command of type CMESC. For more information about the Escape command, see [Escape](#).

To determine the value of this attribute, use the CACMDQ selector with the MQINQ call. The length of this attribute is given by LNQN.

***CommandLevel (10-digit signed integer) on IBM i***

Command Level. This indicates the level of system control commands supported by the queue manager.

The level is one of the following values:

**CML800**

Level 800 of system control commands.

This value is returned by the following applications:

- IBM MQ for IBM i
  - Version 8.0

**CML900**

Level 900 of system control commands.

This value is returned by the following applications:

- IBM MQ for IBM i

- Version 9.0

#### **CML910**

Level 910 of system control commands.

This value is returned by the following applications:

- IBM MQ for IBM i
  - Version 9.1

#### **CML920**

Level 920 of system control commands.

This value is returned by the following applications:

- IBM MQ for IBM i
  - Version 9.2

#### **CML930**

Level 930 of system control commands.

This value is returned by the following applications:

- IBM MQ for IBM i
  - Version 9.3

The set of system control commands that corresponds to a particular value of the **CommandLevel** attribute varies according to the value of the **Platform** attribute; both must be used to decide which system control commands are supported.

To determine the value of this attribute, use the IACMDL selector with the MQINQ call.

### **IBM i ConfigurationEvent on IBM i**

Controls whether configuration events are generated and sent to the SYSTEM.ADMIN.CONFIG.EVENT queue default object.

The ConfigurationEvent attribute can be one of the following values:

- EVRENA
- EVRDIS

If the ConfigurationEvent attribute is set to EVRENA, and certain commands are successfully issued by runmqsc or PCF, configuration events are generated and sent to the SYSTEM.ADMIN.CONFIG.EVENT queue. Events for the following commands are issued, even if an alter command does not change the object involved. The commands for which configuration events are generated and sent are:

- DEFINE/ALTER AUTHINFO
- DEFINE/ALTER CHANNEL
- DEFINE/ALTER NAMELIST
- DEFINE/ALTER PROCESS
- DEFINE/ALTER QLOCAL (unless it is a temporary dynamic queue)
- DEFINE/ALTER QMODEL/QALIAS/QREMOTE
- DELETE AUTHINFO
- DELETE CHANNEL
- DELETE NAMELIST
- DELETE PROCESS
- DELETE QLOCAL (unless it is a temporary dynamic queue)
- DELETE QMODEL/QALIAS/QREMOTE
- ALTER QMGR (unless the CONFIGEV attribute is disabled and is not changed to enabled)

- REFRESH QMGR
- An MQSET call, other than for a temporary dynamic queue.

Events are not generated (if enabled) in the following circumstances:

- The command or MQSET call fails.
- The queue manager cannot put the event message on the event queue. The command should still complete successfully.
- Temporary dynamic queues.
- Internal attribute changes done directly or implicitly (not by MQSET or command); this affects TRIGGER, CURDEPTH, IPPROCS, OPPROCS, QDPHIEV, QDPLOEV, QDPMAXEV, QSVCI EV.
- When the configuration event queue is changed, although it an event message will be generated for that change when a Refresh is requested.
- Clustering changes by the commands REFRESH/RESET CLUSTER and RESUME/SUSPEND QMGR.
- Creating or deleting a queue manager.

### **DeadLetterQName (48-byte character string) on IBM i**

Name of dead-letter (undelivered-message) queue.

This is the name of a queue defined on the local queue manager. Messages are sent to this queue if they cannot be routed to their correct destination.

For example, messages are put on this queue when:

- A message arrives at a queue manager, destined for a queue that is not yet defined on that queue manager
- A message arrives at a queue manager, but the queue for which it is destined cannot receive it because, possibly:
  - The queue is full
  - Put requests are inhibited
  - The sending node does not have authority to put messages on the queue

Applications can also put messages on the dead-letter queue.

Report messages are treated in the same way as ordinary messages; if the report message cannot be delivered to its destination queue (typically the queue specified by the *MDRQ* field in the message descriptor of the original message), the report message is placed on the dead-letter (undelivered-message) queue.

**Note:** Messages that have passed their expiry time (see the *MDEXP* field described in [“MQMD \(Message descriptor\) on IBM i” on page 1110](#) ) are **not** transferred to this queue when they are discarded. However, an expiration report message (ROEXP) is still generated and sent to the *MDRQ* queue, if requested by the sending application.

Messages are not put on the dead-letter (undelivered-message) queue when the application that issued the put request has been notified synchronously of the problem with the reason code returned by the MQPUT or MQPUT1 call (for example, a message put on a local queue for which put requests are inhibited).

Messages on the dead-letter (undelivered-message) queue sometimes have their application message data prefixed with an MQDLH structure. This structure contains extra information that indicates why the message was placed on the dead-letter (undelivered-message) queue. See [“MQDLH \(Dead-letter header\) on IBM i” on page 1065](#) for more details of this structure.

This queue must be a local queue, with a **Usage** attribute of USNORM.

If a dead-letter (undelivered-message) queue is not supported by a queue manager, or one has not been defined, the name is all blanks. All IBM MQ queue managers support a dead-letter (undelivered-message) queue, but by default it is not defined.

If the dead-letter (undelivered-message) queue is not defined, or it is full, or unusable for some other reason, a message which would have been transferred to it by a message channel agent is retained instead on the transmission queue.

To determine the value of this attribute, use the CADLQ selector with the MQINQ call. The length of this attribute is given by LNQN.

### ***DefClusterXmitQueueType (10-digit signed integer)***

The DefClusterXmitQueueType attribute controls which transmission queue is selected by default by cluster-sender channels to get messages from, to send the messages to cluster-receiver channels.

The values of **DefClusterXmitQueueType** are MQCLXQ\_SCTQ or MQCLXQ\_CHANNEL.

#### **MQCLXQ\_SCTQ**

All cluster-sender channels send messages from SYSTEM.CLUSTER.TRANSMIT.QUEUE. The correlID of messages placed on the transmission queue identifies which cluster-sender channel the message is destined for.

SCTQ is set when a queue manager is defined.

#### **MQCLXQ\_CHANNEL**

Each cluster-sender channel sends messages from a different transmission queue. Each transmission queue is created as a permanent dynamic queue from the model queue SYSTEM.CLUSTER.TRANSMIT.MODEL.QUEUE.

If the queue manager attribute, DefClusterXmitQueueType, is set to CHANNEL, the default configuration is changed to cluster-sender channels being associated with individual cluster transmission queues. The transmission queues are permanent-dynamic queues created from the model queue SYSTEM.CLUSTER.TRANSMIT.MODEL.QUEUE. Each transmission queue is associated with one cluster-sender channel. As one cluster-sender channel services a cluster transmission queue, the transmission queue contains messages for only one queue manager in one cluster. You can configure clusters so that each queue manager in a cluster contains only one cluster queue. In this case, the message traffic from a queue manager to each cluster queue is transferred separately from messages to other queues.

To query the value, call MQINQ, or send an Inquire Queue Manager (MQCMD\_INQUIRE\_Q\_MGR) PCF command, setting the MQIA\_DEF\_CLUSTER\_XMIT\_Q\_TYPE selector. To change the value, send a Change Queue Manager (MQCMD\_CHANGE\_Q\_MGR) PCF command, setting the MQIA\_DEF\_CLUSTER\_XMIT\_Q\_TYPE selector.

#### **Related reference**

[Change Queue Manager](#)

[Inquire Queue Manager](#)

[“MQINQ \(Inquire about object attributes\) on IBM i” on page 1304](#)

The MQINQ call returns an array of integers and a set of character strings containing the attributes of an object.

### ***IBM i DefXmitQName (48-byte character string) on IBM i***

Default transmission queue name.

This is the name of the transmission queue that is used for the transmission of messages to remote queue managers, if there is no other indication of which transmission queue to use.

If there is no default transmission queue, the name is entirely blank. The initial value of this attribute is blank.

To determine the value of this attribute, use the CADXQN selector with the MQINQ call. The length of this attribute is given by LNQN.

### **IBM i** ***DistLists (10-digit signed integer) on IBM i***

Distribution list support.

This indicates whether the local queue manager supports distribution lists on the MQPUT and MQPUT1 calls. This can have one of the following values:

#### **DLSUPP**

Distribution lists supported.

#### **DLNSUP**

Distribution lists not supported.

To determine the value of this attribute, use the IADIST selector with the MQINQ call.

### **IBM i** ***InhibitEvent (10-digit signed integer) on IBM i***

Controls whether inhibit (Inhibit Get and Inhibit Put) events are generated.

This can have one of the following values:

#### **EVRDIS**

Event reporting disabled.

#### **EVRENA**

Event reporting enabled.

For more information about events, see [Monitoring and performance](#).

To determine the value of this attribute, use the IAINHE selector with the MQINQ call.

### **IBM i** ***LocalEvent (10-digit signed integer) on IBM i***

Controls whether local error events are generated.

The value is one of the following:

#### **EVRDIS**

Event reporting disabled.

#### **EVRENA**

Event reporting enabled.

For more information about events, see [Event monitoring](#)

To determine the value of this attribute, use the IALCLE selector with the MQINQ call.

### **IBM i** ***LoggerEvent (10-digit signed integer) on IBM i***

Controls whether recovery logger events are generated.

This can have one of the following values:

#### **ENABLED**

Logger events are generated.

#### **DISABLED**

Logger events are not generated. This is the queue managers initial default value.

For more information about events, see [Monitoring and performance](#).

### **IBM i** ***MaxHandles (10-digit signed integer) on IBM i***

Maximum number of handles.

This is the maximum number of open handles that any one task can use concurrently. Each successful MQOPEN call for a single queue (or for an object that is not a queue) uses one handle. That handle becomes available for reuse when the object is closed. However, when a distribution list is opened, each queue in the distribution list is allocated a separate handle, and so that MQOPEN call uses as many handles as there are queues in the distribution list. This must be taken into account when deciding on a suitable value for *MaxHandles*.

The MQPUT1 call performs an MQOPEN call as part of its processing; as a result, MQPUT1 uses as many handles as MQOPEN would, but the handles are used only for the duration of the MQPUT1 call itself.

The value is in the range 1 through 999 999 999. On IBM i, the default value is 256.

To determine the value of this attribute, use the IAMHND selector with the MQINQ call.

### **IBM i** **MaxMsgLength (10-digit signed integer) on IBM i**

Maximum message length in bytes.

This is the length of the longest *physical* message that can be handled by the queue manager. However, because the **MaxMsgLength** queue manager attribute can be set independently of the **MaxMsgLength** queue attribute, the longest physical message that can be placed on a queue is the lesser of those two values.

If the queue manager supports segmentation, it is possible for an application to put a *logical* message that is longer than the lesser of the two **MaxMsgLength** attributes, but only if the application specifies the MFSEGA flag in MQMD. If that flag is specified, the upper limit for the length of a logical message is 999 999 999 bytes, but typically, resource constraints imposed by the operating system or by the environment in which the application is running, will result in a lower limit.

The lower limit for the **MaxMsgLength** attribute is 32 KB (32 768 bytes). On IBM i, the maximum message length is 100 MB (104 857 600 bytes).

To determine the value of this attribute, use the IAMLEN selector with the MQINQ call.

### **IBM i** **MaxPriority (10-digit signed integer) on IBM i**

Maximum priority.

This is the maximum message priority supported by the queue manager. Priorities range from zero (lowest) to *MaxPriority* (highest).

To determine the value of this attribute, use the IAMPRI selector with the MQINQ call.

### **IBM i** **MaxUncommittedMsgs (10-digit signed integer) on IBM i**

Maximum number of uncommitted messages within a unit of work.

This is the maximum number of uncommitted messages that can exist within a unit of work. The number of uncommitted messages is the sum of the following since the start of the current unit of work:

- Messages put by the application with the PMSYP option
- Messages retrieved by the application with the GMSYP option
- Trigger messages and COA report messages generated by the queue manager for messages put with the PMSYP option
- COD report messages generated by the queue manager for messages retrieved with the GMSYP option

The following messages are not counted as uncommitted:

- Messages put or retrieved by the application outside a unit of work
- Trigger messages or COA/COD report messages generated by the queue manager as a result of messages put or retrieved outside a unit of work
- Expiration report messages generated by the queue manager (even if the call causing the expiration report message specified GMSYP)
- Event messages generated by the queue manager (even if the call causing the event message specified PMSYP or GMSYP)

#### **Note:**

1. Exception report messages are generated by the Message Channel Agent (MCA), or by the application, and so are treated in the same way as ordinary messages put or retrieved by the application.

2. When a message or segment is put with the PMSYP option, the number of uncommitted messages is incremented by one regardless of how many physical messages actually result from the put. (More than one physical message might result if the queue manager needs to subdivide the message or segment.)
3. When a distribution list is put with the PMSYP option, the number of uncommitted messages is incremented by one *for each physical message that is generated*. This can be as small as one, or as great as the number of destinations in the distribution list.

The lower limit for this attribute is 1; the upper limit is 999 999 999.

To determine the value of this attribute, use the IAMUNC selector with the MQINQ call.

### **PerformanceEvent (10-digit signed integer) on IBM i**

Controls whether performance-related events are generated.

PerformanceEvent can have one of the following values:

#### **EVRDIS**

Event reporting disabled.

#### **EVRENA**

Event reporting enabled.

For more information about events, see [Event monitoring](#).

To determine the value of this attribute, use the IAPFME selector with the MQINQ call.

### **Platform (10-digit signed integer) on IBM i**

Platform on which the queue manager is running.

This indicates the operating system on which the queue manager is running. The value is:

#### **PL400**

IBM i.

### **PubSubMode (10-digit signed integer) on IBM i**

Whether the publish/subscribe engine and the queued publish/subscribe interface are running, therefore allowing applications to publish/subscribe by using the application programming interface and the queues that are being monitored by the queued publish/subscribe interface.

This can have one of the following values:

#### **PSMCP**

The publish/subscribe engine is running. It is therefore possible to publish/subscribe by using the application programming interface. The queued publish/subscribe interface is not running, therefore any message that is put to the queues that are monitored by the queued publish/subscribe interface is not acted on. This setting is used for compatibility with WebSphere Message Broker V6 or earlier versions using this queue manager, because it must read the same queues from which the queued publish/subscribe interface normally reads.

#### **PSMDS**

The publish/subscribe engine and the queued publish/subscribe interface are not running. It is therefore not possible to publish/subscribe by using the application programming interface. Any publish/subscribe messages that are put to the queues that are monitored by the queued publish/subscribe interface are not acted on.

#### **PSMEN**

The publish/subscribe engine and the queued publish/subscribe interface are running. It is therefore possible to publish/subscribe by using the application programming interface and the queues that are being monitored by the queued publish/subscribe interface. This is the queue manager's initial default value.

To determine the value of this attribute, use the PSMODE selector with the MQINQ call.

### ▶ IBM i **QMGrDesc (64-byte character string) on IBM i**

Queue manager description.

This is a field that can be used for descriptive commentary. The content of the field is of no significance to the queue manager, but the queue manager might require that the field contain only characters that can be displayed. It cannot contain any null characters; if necessary, it is padded to the right with blanks. In a DBCS installation, this field can contain DBCS characters (subject to a maximum field length of 64 bytes).

**Note:** If this field contains characters that are not in the queue manager's character set (as defined by the **CodedCharSetId** queue manager attribute), those characters might be translated incorrectly if this field is sent to another queue manager.

On IBM i, the default value is blanks.

To determine the value of this attribute, use the CAQMD selector with the MQINQ call. The length of this attribute is given by LNQMD.

### ▶ IBM i **QMGrIdentifier (48-byte character string) on IBM i**

Unique internally-generated identifier of queue manager.

This is an internally-generated unique name for the queue manager.

To determine the value of this attribute, use the CAQMID selector with the MQINQ call. The length of this attribute is given by LNQMID.

### ▶ IBM i **QMGrName (48-byte character string) on IBM i**

Queue manager name.

This is the name of the local queue manager, that is, the name of the queue manager to which the application is connected.

The first 12 characters of the name are used to construct a unique message identifier (see the *MDMID* field described in “MQMD (Message descriptor) on IBM i” on page 1110). Queue managers that can intercommunicate must therefore have names that differ in the first 12 characters, in order for message identifiers to be unique in the queue manager network.

To determine the value of this attribute, use the CAQMN selector with the MQINQ call. The length of this attribute is given by LNQMN.

### ▶ IBM i **RemoteEvent (10-digit signed integer) on IBM i**

Controls whether remote error events are generated.

The value is one of the following:

#### **EVRDIS**

Event reporting disabled.

#### **EVRENA**

Event reporting enabled.

For more information about events, see [Event monitoring](#).

To determine the value of this attribute, use the IARMTE selector with the MQINQ call.

### ▶ IBM i **RepositoryName (48-byte character string) on IBM i**

Name of cluster for which this queue manager provides repository services.

This is the name of a cluster for which this queue manager provides a repository-manager service. If the queue manager provides this service for more than one cluster, *RepositoryNameList* specifies the name of a namelist object that identifies the clusters, and *RepositoryName* is blank. At least one of *RepositoryName* and *RepositoryNameList* must be blank.

To determine the value of this attribute, use the CARPN selector with the MQINQ call. The length of this attribute is given by LNQMN.

### **IBM i** *RepositoryNameList (48-byte character string) on IBM i*

Name of namelist object containing names of clusters for which this queue manager provides repository services.

This is the name of a namelist object that contains the names of clusters for which this queue manager provides a repository-manager service. If the queue manager provides this service for only one cluster, the namelist object contains only one name. Alternatively, *RepositoryName* can be used to specify the name of the cluster, in which case *RepositoryNameList* is blank. At least one of *RepositoryName* and *RepositoryNameList* must be blank.

To determine the value of this attribute, use the CARPNL selector with the MQINQ call. The length of this attribute is given by LNNLN.

### **IBM i** *SSLEvent (character string) on IBM i*

Determines whether TLS events are generated.

The value is one of the following:

- EVRENA (MQINQ/PCF/config event) ENABLED (MQSC): TLS events are generated (that is, the RC2371 event is generated).
- EVRDIS (MQINQ/PCF/config event) DISABLED (MQSC): TLS events are not generated. This is the queue manager's initial default value.

To determine the value of this attribute, use the IASSLE selector with the MQINQ call.

### **IBM i** *SSLKeyResetCount (integer) on IBM i*

Determines the total number of non-encrypted bytes that are sent and received within a TLS conversation, before the secret key is renegotiated. The number of bytes includes control information sent by the message channel agent (MCA).

This value is only used by TLS channel MCAs which initiate communication from this queue manager (that is, the sender channel MCA in a sender and receiver channel pairing).

If the value of this attribute is greater than 0, and channel heartbeats are enabled for a channel, the secret key is also renegotiated before data is sent or received following a channel heartbeat. The count of bytes until the next secret key renegotiation is reset after each successful renegotiation occurs.

The value can be in the range 0 through 999 999 999. A value of 0 for this attribute indicates that the secret key is never renegotiated. If you specify a TLS secret key reset count in the range 1 byte through 32 KB, TLS channels will use a secret key reset count of 32 KB. This is to avoid the processing cost of excessive key resets which would occur for small TLS secret key reset values.

When the SSL server is an IBM MQ queue manager, and both secret key reset and channel heartbeats are enabled, renegotiation occurs immediately after each channel heartbeat.

To determine the value of this attribute, use the IASSRC selector with the MQINQ call.

### **IBM i** *StartStopEvent (10-digit signed integer) on IBM i*

Controls whether start and stop events are generated.

This attribute can have one of the following values:

#### **EVRDIS**

Event reporting disabled.

#### **EVRENA**

Event reporting enabled.

For more information about events, see [Event monitoring](#).

To determine the value of this attribute, use the IASSE selector with the MQINQ call.

### **IBM i** *SyncPoint (10-digit signed integer) on IBM i*

Syncpoint availability.

This indicates whether the local queue manager supports units of work and syncpointing with the MQGET, MQPUT, and MQPUT1 calls.

#### **SPAVL**

Units of work and syncpointing available.

#### **SPNAVL**

Units of work and syncpointing not available.

To determine the value of this attribute, use the IASYNC selector with the MQINQ call.

### **IBM i** *TraceRouteRecording (10-digit signed integer) on IBM i*

This controls whether information about messages is recorded as they flow through a queue manager.

The value is one of the following:

- RECD: no appending to trace route messages is allowed
- RECDQ: messages are put onto a fixed named queue
- RECDM: determine using message (this is the initial default setting)

To prevent the trace route message from remaining in the system, set an expiry value on it that is greater than zero, and specify the RODISC report option. To prevent report or reply messages remaining in the system, set the report option ROPDAE. For more information, see [“Report options and message flags on IBM i” on page 1431](#).

To determine the value of this attribute, use the IATRGI selector with the MQINQ call.

### **IBM i** *TreeLifeTime (10-digit signed integer) on IBM i*

The lifetime, in seconds, of non-administrative topics.

Non-administrative topics are those created when an application publishes to, or subscribes as, a topic string that does not exist as an administrative node. When this non-administrative node no longer has any active subscriptions, this parameter determines how long the queue manager will wait before removing that node. Only non-administrative topics that are in use by a durable subscription remain after the queue manager is recycled.

Specify a value in the range 0 through 604 000. A value of 0 means that non-administrative topics are not removed by the queue manager. The queue manager's initial default value is 1800.

To determine the value of this attribute, use the IATRLFT selector with the MQINQ call.

### **IBM i** *TriggerInterval (10-digit signed integer) on IBM i*

Trigger-message interval.

This is a time interval (in milliseconds) used to restrict the number of trigger messages. This is relevant only when the *TriggerType* is TFRST. In this case, trigger messages are normally generated only when a suitable message arrives on the queue, and the queue was previously empty. Under certain circumstances, however, an additional trigger message can be generated with TFRST triggering even if the queue was not empty. These additional trigger messages are not generated more often than every *TriggerInterval* milliseconds.

For more information about triggering, see [Triggering channels](#).

The value is in the range zero through 999 999 999. The default value is 999 999 999.

To determine the value of this attribute, use the IATRGI selector with the MQINQ call.

## Applications

This information describes the sample programs delivered with IBM MQ for IBM i for RPG. Also, learn how to build executable applications from the programs you write.

### Building your application

The IBM i publications describe how to build executable applications from the programs you write. This topic describes the additional tasks, and the changes to the standard tasks, you must perform when building IBM MQ for IBM i applications to run under IBM i.

In addition to coding the MQI calls in your source code, you must add the appropriate language statements to include the IBM MQ for IBM i copy files for the RPG language. You should make yourself familiar with the contents of these files; their names, and a brief description of their contents are given in the following text.

#### **IBM MQ copy files on IBM i**

IBM MQ for IBM i provides copy files to assist you with writing your applications in the RPG programming language. They are suitable for use with the WebSphere Development toolset (5722 WDS) ILE RPG 4 Compiler.

The copy files that IBM MQ for IBM i provides to assist with the writing of channel exits are described in [Channel-exit programs for messaging channels](#).

The names of the IBM MQ for IBM i copy files for RPG have the prefix CMQ. They have a suffix of G or H. There are separate copy files containing the named constants, and one file for each of the structures. The copy files are listed in [“Language considerations”](#) on page 1010.

**Note:** For ILE RPG/400, they are supplied as members of file QRPGLSRC in library QMQM.

The structure declarations do not contain DS statements. This allows the application to declare a data structure (or a multiple-occurrence data structure) by coding the DS statement and using the /COPY statement to copy in the remainder of the declaration:

For ILE RPG/400 the statement is:

```
D*..1.....2.....3.....4.....5.....6.....7
D* Declare an MQMD data structure
D MQMD          DS
D/COPY CMQMDG
```

### Preparing your programs to run

To create an executable IBM MQ for IBM i application, you have to compile the source code you have written.

To do this for ILE RPG/400, you can use the typical IBM i commands, CRTRPGMOD and CRTPGM.

After creating your \*MODULE, you need to specify BNDSRVPGM (QMOM/LIBMOM) in the CRTPGM command. This includes the various IBM MQ procedures in your program.

Make sure that the library containing the copy files (QMOM) is in the library list when you perform the compilation.

For further information concerning programming considerations, including client modes, see [“Language considerations”](#) on page 1010.

### Interfaces to the IBM i external syncpoint manager

IBM MQ for IBM i uses native IBM i commitment control as an external syncpoint coordinator.

See the *IBM i Programming: Backup and Recovery Guide* for more information about the commitment control capabilities of IBM i.

To start the IBM i commitment control facilities, use the STRCMTCTL system command. To end commitment control, use the ENDCMTCTL system command.

**Note:** The default value of *Commitment definition scope* is \*ACTGRP. This must be defined as \*JOB for IBM MQ for IBM i. For example:

```
STRCMTCTL LCKLVL(*ALL) CMTSCOPE(*JOB)
```

If you call MQPUT, MQPUT1, or MQGET, specifying PMSYP or GMSYP, after starting commitment control, IBM MQ for IBM i adds itself as an API commitment resource to the commitment definition. This is typically the first such call in a job. While there are any API commitment resources registered under a particular commitment definition, you cannot end commitment control for that definition.

IBM MQ for IBM i removes its registration as an API commitment resource when you disconnect from the queue manager, provided there are no pending MQI operations in the current unit of work.

If you disconnect from the queue manager while there are pending MQPUT, MQPUT1, or MQGET operations in the current unit of work, IBM MQ for IBM i remains registered as an API commitment resource so that it is notified of the next commit or rollback. When the next syncpoint is reached, IBM MQ commits or rolls back the changes as required. It is possible for an application to disconnect and reconnect to a queue manager during an active unit of work and perform further MQGET and MQPUT operations inside the same unit of work (this is a pending disconnect).

If you attempt to issue an ENDCMTCTL system command for that commitment definition, message CPF8355 is issued, indicating that pending changes were active. This message also appears in the job log when the job ends. To avoid this, ensure that you commit or roll back all pending IBM MQ operations, and that you disconnect from the queue manager. Thus, using COMMIT or ROLLBACK commands before ENDCMTCTL should enable end-commitment control to complete successfully.

When IBM i commitment control is used as an external syncpoint coordinator, MQCMIT, MQBACK, and MQBEGIN calls might not be issued. Calls to these functions fail with the reason code RC2012.

To commit or roll back (that is, to back out) your unit of work, use one of the programming languages that supports the commitment control. For example:

- CL commands: COMMIT and ROLLBACK
- ILE C Programming Functions: \_Rcommit and \_Rrollback
- RPG/400: COMMIT and ROLBK
- COBOL/400®: COMMIT and ROLLBACK

### ***Syncpoints in CICS for IBM i applications***

IBM MQ for IBM i participates in units of work with CICS. You can use the MQI within a CICS application to put and get messages inside the current unit of work.

You can use the EXEC CICS SYNCPOINT command to establish a syncpoint that includes the IBM MQ for IBM i operations. To back out all changes up to the previous syncpoint, you can use the EXEC CICS SYNCPOINT ROLLBACK command.

If you use MQPUT, MQPUT1, or MQGET with the PMSYP, or GMSYP, option set in a CICS application, you cannot log off CICS until IBM MQ for IBM i has removed its registration as an API commitment resource. Therefore, you should commit or back out any pending put or get operations before you disconnect from the queue manager. This will allow you to log off CICS.

## **Sample programs on IBM i**

This topic describes the sample programs delivered with IBM MQ for IBM i for RPG. The samples demonstrate typical uses of the Message Queue Interface (MQI).

The samples are not intended to demonstrate general programming techniques, so some error checking that you may want to include in a production program has been omitted. However, these samples are suitable for use as a base for your own message queuing programs.

The source code for all the samples is provided with the product; this source includes comments that explain the message queuing techniques demonstrated in the programs.

There is one set of ILE sample programs:

### 1. Programs using prototyped calls to the MQI (static bound calls)

The source exists in QMQMSAMP/QRPGLESRC. The members are named AMQ3xxx4, where xxx indicates the sample function. Copy members exist in QMQM/QRPGLESRC. Each member name has a suffix of G or H.

Table 811 on page 1414 gives a complete list of the sample programs delivered with IBM MQ for IBM i, and shows the names of the programs in each of the supported programming languages. Notice that their names all start with the prefix AMQ, the fourth character in the name indicates the programming language.

<i>Table 811. Names of the sample programs</i>	
	<b>RPG (ILE)</b>
Put samples	AMQ3PUT4
Browse samples	AMQ3GBR4
Get samples	AMQ3GET4
Request samples	AMQ3REQ4
Echo samples	AMQ3ECH4
Inquire samples	AMQ3INQ4
Set samples	AMQ3SET4
Trigger Monitor sample	AMQ3TRG4
Trigger Server sample	AMQ3SRV4

In addition to these, the IBM MQ for IBM i sample option includes a sample data file, AMQSDATA, which can be used as input to certain sample programs and sample CL programs that demonstrate administration tasks. The CL samples are described in [Administering IBM i](#). You could use the sample CL program to create queues to use with the sample programs described in this topic.

For information about how to run the sample programs, see [“Preparing and running the sample programs on IBM i”](#) on page 1415.

### **Features demonstrated in the sample programs on IBM i**

A table that shows the techniques demonstrated by the IBM MQ for IBM i sample programs.

Some techniques occur in more than one sample program, but only one program is listed in the table. All the samples open and close queues using the MQOPEN and MQCLOSE calls, so these techniques are not listed separately in the table.

<i>Table 812. Sample programs demonstrating use of the MQI</i>	
<b>Technique</b>	<b>RPG (ILE)</b>
Using the MQCONN and MQDISC calls	AMQ3ECH4 or AMQ3INQ4
Implicitly connecting and disconnecting	AMQ3PUT4
Putting messages using the MQPUT call	AMQ3PUT4

Table 812. Sample programs demonstrating use of the MQI (continued)

Technique	RPG (ILE)
Putting a single message using the MQPUT1 call	AMQ3ECH4 or AMQ3INQ4
Replying to a request message	AMQ3INQ4
Getting messages (no wait)	AMQ3GBR4
Getting messages (wait with a time limit)	AMQ3GET4
Getting messages (with data conversion)	AMQ3ECH4
Browsing a queue	AMQ3GBR4
Using a shared input queue	AMQ3INQ4
Using an exclusive input queue	AMQ3REQ4
Using the MQINQ call	AMQ3INQ4
Using the MQSET call	AMQ3SET4
Using a reply-to queue	AMQ3REQ4
Requesting exception messages	AMQ3REQ4
Accepting a truncated message	AMQ3GBR4
Using a resolved queue name	AMQ3GBR4
Trigger processing	AMQ3SRV4 or AMQ3TRG4

**Note:** All the sample programs produce a spool file that contains the results of the processing.

### ***Preparing and running the sample programs on IBM i***

Before you can run the IBM MQ for IBM i sample programs, you must compile them as you would any other IBM MQ for IBM i applications. To do so, you can use the IBM i commands CRTRPGMOD and CRTPGM.

When you create the AMQ3xxx4 programs, you must specify BNDSRVPGM(QMQM/LIBMQM) in the CRTPGM command. Doing so includes the various IBM MQ procedures in your program.

The sample programs are provided in library QMQMSAMP as members of QRPGLSRC. They use the copy files provided in library QMQM, so make sure that this library is in the library list when you compile them. The RPG compiler gives information messages because the samples do not use many of the variables that are declared in the copy files.

### **Running the sample programs**

You can use your own queues when you run the samples, or you can compile and run AMQSAMP4 to create some sample queues. The source for this program is shipped in file QCLSRC in library QMQMSAMP. It can be compiled using the CRTCLPGM command.

To call one of the sample programs, use a command like:

```
CALL PGM(QMQMSAMP/AMQ3PUT4) PARM('Queue_Name','Queue_Manager_Name')
```

Where Queue\_Name and Queue\_Manager\_Name must be 48 characters in length, which you achieve by padding the Queue\_Name and Queue\_Manager\_Name with the required number of blanks.

For the Inquire and Set sample programs, the sample definitions created by AMQSAMP4 cause the C versions of these samples to be triggered. If you want to trigger the RPG versions, you must change the process definitions SYSTEM.SAMPLE.ECHOPROCESS and SYSTEM.SAMPLE.INQPROCESS and SYSTEM.SAMPLE.SETPROCESS. You can use the CHGMQMPCRC command (described in [Change MQ Process \(CHGMQMPCRC\)](#)) to do so, or edit and run AMQSAMP4 with the alternative definition.

### ***The Put sample program on IBM i***

The Put sample program, AMQ3PUT4, puts messages on a queue using the MQPUT call.

To start the program, call the program and give the name of your target queue as a program parameter. The program puts a set of fixed messages on the queue; these messages are taken from the data block at the end of the program source code. A sample put program is AMQ3PUT4 in library QMQMSAMP.

Using this example program, the command is:

```
CALL PGM(QMQMSAMP/AMQ3PUT4) PARM('Queue_Name','Queue_Manager_Name')
```

Where Queue\_Name and Queue\_Manager\_Name must be 48 characters in length, which you achieve by padding the Queue\_Name and Queue\_Manager\_Name with the required number of blanks.

### **Design of the Put sample program**

The program uses the MQOPEN call with the OOOUT option to open the target queue for putting messages. The results are output to a spool file. If it cannot open the queue, the program writes an error message containing the reason code returned by the MQOPEN call. To keep the program simple, on this and on subsequent MQI calls, the program uses default values for many of the options.

For each line of data contained in the source code, the program reads the text into a buffer and uses the MQPUT call to create a datagram message containing the text of that line. The program continues until either it reaches the end of the input or the MQPUT call fails. If the program reaches the end of the input, it closes the queue using the MQCLOSE call.

### ***The Browse sample program on IBM i***

The Browse sample program, AMQ3GBR4, browses messages on a queue using the MQGET call.

The program retrieves copies of all the messages on the queue you specify when you call the program; the messages remain on the queue. You could use the supplied queue SYSTEM.SAMPLE.LOCAL; run the Put sample program first to put some messages on the queue. You could use the queue SYSTEM.SAMPLE.ALIAS, which is an alias name for the same local queue. The program continues until it reaches the end of the queue or an MQI call fails.

An example of a command to call the RPG program is:

```
CALL PGM(QMQMSAMP/AMQ3GBR4) PARM('Queue_Name','Queue_Manager_Name')
```

Where Queue\_Name and Queue\_Manager\_Name must be 48 characters in length, which you achieve by padding the Queue\_Name and Queue\_Manager\_Name with the required number of blanks. Therefore, if you are using SYSTEM.SAMPLE.LOCAL as your target queue, you will need 29 blank characters.

### **Design of the Browse sample program**

The program opens the target queue using the MQOPEN call with the OOBROW option. If it cannot open the queue, the program writes an error message to its spool file, containing the reason code returned by the MQOPEN call.

For each message on the queue, the program uses the MQGET call to copy the message from the queue, then displays the data contained in the message. The MQGET call uses these options:

## GMBRWN

After the MQOPEN call, the browse cursor is positioned logically before the first message in the queue, so this option causes the *first* message to be returned when the call is first made.

## GMNWT

The program does not wait if there are no messages on the queue.

## GMATM

The MQGET call specifies a buffer of fixed size. If a message is longer than this buffer, the program displays the truncated message, together with a warning that the message has been truncated.

The program demonstrates how you must clear the *MDMID* and *MDCID* fields of the MQMD structure after each MQGET call because the call sets these fields to the values contained in the message it retrieves. Clearing these fields means that successive MQGET calls retrieve messages in the order in which the messages are held in the queue.

The program continues to the end of the queue; here, the MQGET call returns the RC2033 (no message available) reason code and the program displays a warning message. If the MQGET call fails, the program writes an error message that contains the reason code in its spool file.

The program then closes the queue using the MQCLOSE call.

## ***The Get sample program on IBM i***

The Get sample program, AMQ3GET4, gets messages from a queue using the MQGET call.

When the program is called, it removes messages from the specified queue. You could use the supplied queue SYSTEM.SAMPLE.LOCAL; run the Put sample program first to put some messages on the queue. You could use the SYSTEM.SAMPLE.ALIAS queue, which is an alias name for the same local queue. The program continues until the queue is empty or an MQI call fails.

An example of a command to call the RPG program is:

```
CALL PGM(QMQMSAMP/AMQ3GET4) PARM('Queue_Name', 'Queue_Manager_Name')
```

where *Queue\_Name* and *Queue\_Manager\_Name* must be 48 characters in length, which you achieve by padding the *Queue\_Name* and *Queue\_Manager\_Name* with the required number of blanks. Therefore, if you are using SYSTEM.SAMPLE.LOCAL as your target queue, you will need 29 blank characters.

## **Design of the Get sample program**

The program opens the target queue for getting messages; it uses the MQOPEN call with the OOINPQ option. If it cannot open the queue, the program writes an error message containing the reason code returned by the MQOPEN call in its spool file.

For each message on the queue, the program uses the MQGET call to remove the message from the queue; it then displays the data contained in the message. The MQGET call uses the GMWT option, specifying a wait interval (*GMWT*) of 15 seconds, so that the program waits for this period if there is no message on the queue. If no message arrives before this interval expires, the call fails and returns the RC2033 (no message available) reason code.

The program demonstrates how you must clear the *MDMID* and *MDCID* fields of the MQMD structure after each MQGET call because the call sets these fields to the values contained in the message it retrieves. Clearing these fields means that successive MQGET calls retrieve messages in the order in which the messages are held in the queue.

The MQGET call specifies a buffer of fixed size. If a message is longer than this buffer, the call fails and the program stops.

The program continues until either the MQGET call returns the RC2033 (no message available) reason code or the MQGET call fails. If the call fails, the program displays an error message that contains the reason code.

The program then closes the queue using the MQCLOSE call.

## The Request sample program on IBM i

The Request sample program, AMQ3REQ4, demonstrates client/server processing. The sample is the client that puts request messages on a queue that is processed by a server program. It waits for the server program to put a reply message on a reply-to queue.

The Request sample puts a series of request messages on a queue using the MQPUT call. These messages specify SYSTEM.SAMPLE.REPLY as the reply-to queue. The program waits for reply messages, then displays them. Replies are sent only if the target queue (which we will call the *server queue*) is being processed by a server application, or if an application is triggered for that purpose (the Inquire and Set sample programs are designed to be triggered). The sample waits 5 minutes for the first reply to arrive (to allow time for a server application to be triggered) and 15 seconds for subsequent replies, but it can end without getting any replies.

To start the program, call the program and give the name of your target queue as a program parameter. The program puts a set of fixed messages on the queue; these messages are taken from the data block at the end of the program source code.

## Design of the Request sample program

The program opens the server queue so that it can put messages. It uses the MQOPEN call with the OOOOUT option. If it cannot open the queue, the program displays an error message containing the reason code returned by the MQOPEN call.

The program then opens the reply-to queue called SYSTEM.SAMPLE.REPLY so that it can get reply messages. For this, the program uses the MQOPEN call with the OOINPX option. If it cannot open the queue, the program displays an error message containing the reason code returned by the MQOPEN call.

For each line of input, the program then reads the text into a buffer and uses the MQPUT call to create a request message containing the text of that line. On this call the program uses the ROEXCD report option to request that any report messages sent about the request message will include the first 100 bytes of the message data. The program continues until either it reaches the end of the input or the MQPUT call fails.

The program then uses the MQGET call to remove reply messages from the queue, and displays the data contained in the replies. The MQGET call uses the GMWT option, specifying a wait interval (*GMWT*) of 5 minutes for the first reply (to allow time for a server application to be triggered) and 15 seconds for subsequent replies. The program waits for these periods if there is no message on the queue. If no message arrives before this interval expires, the call fails and returns the RC2033 (no message available) reason code. The call also uses the GMATM option, so messages longer than the declared buffer size are truncated.

The program demonstrates how you must clear the *MDMID* and *MDCOD* fields of the MQMD structure after each MQGET call because the call sets these fields to the values contained in the message it retrieves. Clearing these fields means that successive MQGET calls retrieve messages in the order in which the messages are held in the queue.

The program continues until either the MQGET call returns the RC2033 (no message available) reason code or the MQGET call fails. If the call fails, the program displays an error message that contains the reason code.

The program then closes both the server queue and the reply-to queue using the MQCLOSE call. Table 813 on page 1418 shows the changes to the Echo sample program that are necessary to run the Inquire and Set sample programs.

**Note:** The details for the Echo sample program are included as a reference.

Program name	SYSTEM/SAMPLE queue	Program started
Echo	ECHO	AMQ3ECH4
Inquire	INQ	AMQ3INQ4

Table 813. Client/Server sample program details (continued)

Program name	SYSTEM/SAMPLE queue	Program started
Set	SET	AMQ3SET4

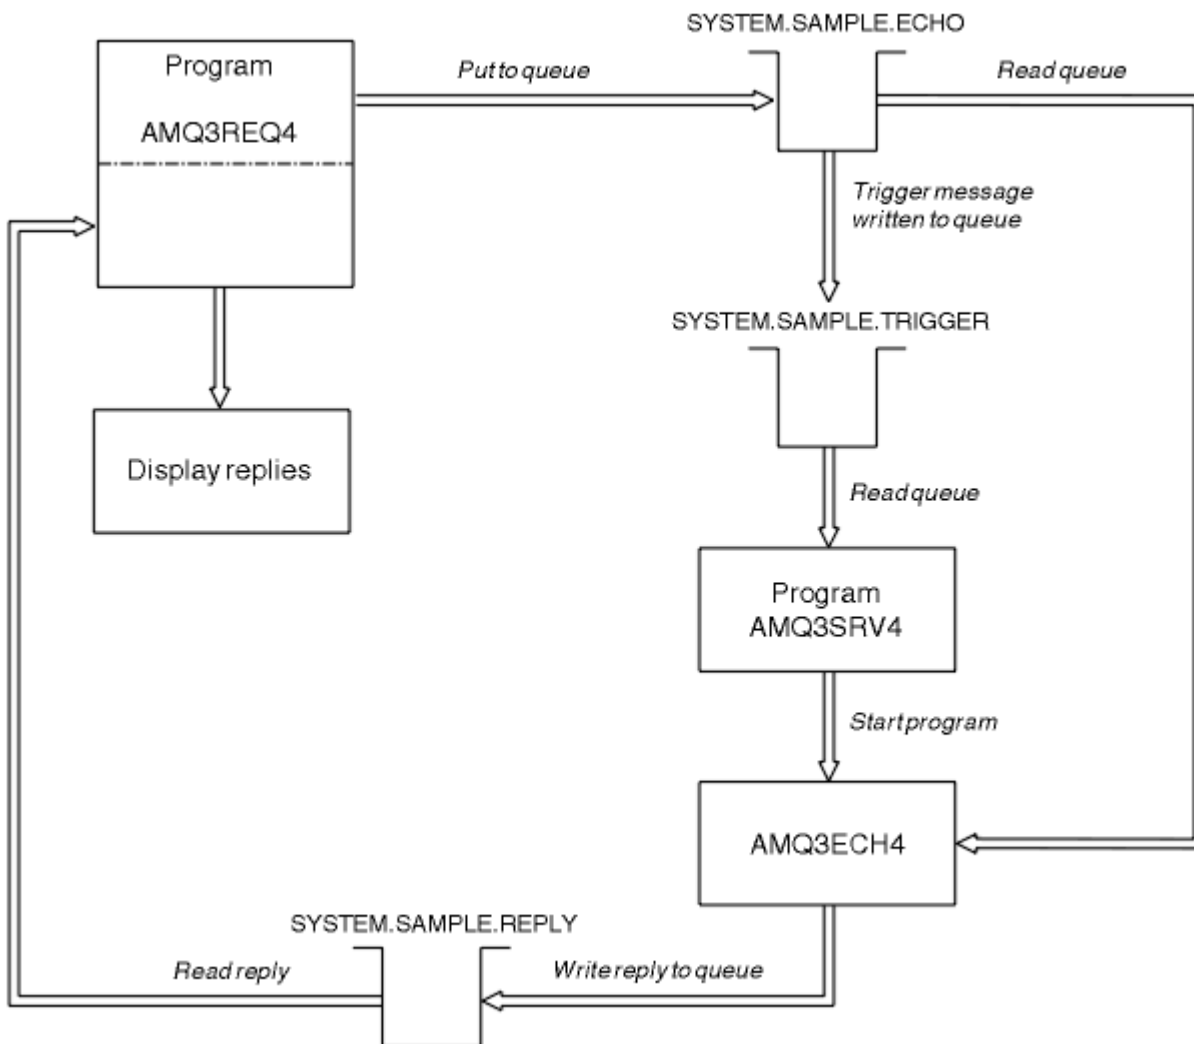

Figure 9. Sample Client/Server (Echo) program flowchart

**IBM i** Using triggering with the Request sample on IBM i

To run the sample using triggering, start the trigger server program, AMQ3SRV4, against the required initiation queue in one job, then start AMQ3REQ4 in another job.

This means that the trigger server is ready when the Request sample program sends a message.

**Note:**

1. The samples use the SYSTEM SAMPLE TRIGGER queue as the initiation queue for SYSTEM.SAMPLE.ECHO, SYSTEM.SAMPLE.INQ, or SYSTEM.SAMPLE.SET local queues. Alternatively, you can define your own initiation queue.
2. The sample definitions created by AMQSAMP4 cause the C version of the sample to be triggered. If you want to trigger the RPG version, you must change the process definitions SYSTEM.SAMPLE.ECHOPROCESS and SYSTEM.SAMPLE.INQPROCESS and SYSTEM.SAMPLE.SETPROCESS. You can use the CHGMQMPCRC command (see [Change MQ Process \(CHGMQMPCRC\)](#) for more details) to do this, or edit and run your own version of AMQSAMP4.
3. You must compile the trigger server program from the source provided in QMQMSAMP/QRPGLESRC.

Depending on the trigger process you want to run, AMQ3REQ4 should be called with the parameter specifying request messages to be placed on one of these sample server queues:

- SYSTEM.SAMPLE.ECHO (for the Echo sample programs)
- SYSTEM.SAMPLE.INQ (for the Inquire sample programs)
- SYSTEM.SAMPLE.SET (for the Set sample programs)

A flow chart for the SYSTEM.SAMPLE.ECHO program is shown in [Figure 9 on page 1419](#). Using the example the command to issue the RPG program request to this server is:

```
CALL PGM(QMQMSAMP/AMQ3REQ4) PARM('SYSTEM.SAMPLE.ECHO
+ 30 blank characters','Queue_Manager_Name')
```

because the queue name and queue manager name must be 48 characters in length.

**Note:** This sample queue has a trigger type of FIRST, so if there are already messages on the queue before you run the Request sample, server applications are not triggered by the messages you send.

If you want to attempt further examples, you can try the following variations:

- Use AMQ3TRG4 instead of AMQ3SRV4 to submit the job instead, but potential job submission delays could make it less easy to follow what is happening.
- Use the SYSTEM.SAMPLE.INQ and SYSTEM.SAMPLE.SET sample queues. Using the example data file, the commands to issue the RPG program requests to these servers are:

```
CALL PGM(QMQMSAMP/AMQ3INQ4) PARM('SYSTEM.SAMPLE.INQ
+ 31 blank characters')
CALL PGM(QMQMSAMP/AMQ3SET4) PARM('SYSTEM.SAMPLE.SET
+ 31 blank characters')
```

because the queue name must be 48 characters in length.

These sample queues also have a trigger type of FIRST.

### ***The Echo sample program on IBM i***

The Echo sample programs return the message send to a reply queue. The program is named AMQ3ECH4

For the triggering process to work, you must ensure that the Echo sample program you want to use is triggered by messages arriving on queue SYSTEM.SAMPLE.ECHO. To do this, specify the name of the Echo sample program you want to use in the *AppLId* field of the process definition SYSTEM.SAMPLE.ECHOPROCESS. (For this, you can use the CHGMQMPCRC command, described in [Administering IBM i](#).) The sample queue has a trigger type of FIRST, so if there are already messages on the queue before you run the Request sample, the Echo sample is not triggered by the messages you send.

When you have set the definition correctly, first start AMQ3SRV4 in one job, then start AMQ3REQ4 in another. You could use AMQ3TRG4 instead of AMQ3SRV4, but potential job submission delays could make it less easy to follow what is happening.

Use the Request sample programs to send messages to queue SYSTEM.SAMPLE.ECHO. The Echo sample programs send a reply message containing the data in the request message to the reply-to queue specified in the request message.

### **Design of the Echo sample program**

When the program is triggered, it explicitly connects to the default queue manager using the MQCONN call. Although this is not necessary on IBM i, this means you could use the same program on other platforms without changing the source code.

The program then opens the queue named in the trigger message structure it was passed when it started. (For clarity, we will call this the *request queue*.) The program uses the MQOPEN call to open this queue for shared input.

The program uses the MQGET call to remove messages from this queue. This call uses the GMATM and GMWT options, with a wait interval of 5 seconds. The program tests the descriptor of each message to see if it is a request message; if it is not, the program discards the message and displays a warning message.

For each request message removed from the request queue, the program uses the MQPUT call to put a reply message on the reply-to queue. This message contains the contents of the request message.

When there are no messages remaining on the request queue, the program closes that queue and disconnects from the queue manager.

This program can also respond to messages sent to the queue from platforms other than IBM i, although no sample is supplied for this situation. To make the ECHO program work, you:

- Write a program, correctly specifying the *Format*, *Encoding*, and *CCSID* fields, to send text request messages.

The ECHO program requests the queue manager to perform message data conversion, if this is needed.

- Specify CONVERT(\*YES) on the IBM MQ for IBM i sending channel, if the program you have written does not provide similar conversion for the reply.

### ***The Inquire sample program on IBM i***

The Inquire sample program, AMQ3INQ4, inquires about some of the attributes of a queue using the MQINQ call.

The program is intended to run as a triggered program, so its only input is an MQTMC (trigger message) structure. This structure contains the name of a target queue with attributes that are to be inquired upon.

For the triggering process to work, you must ensure that the Inquire sample program is triggered by messages arriving on queue SYSTEM.SAMPLE.INQ. To do so, specify the name of the Inquire sample program in the *AppLId* field of the SYSTEM.SAMPLE.INQPROCESS process definition. (For this, you can use the CHGMQMPCRC command, described in [Change MQ Process \(CHGMQMPCRC\)](#) ). The sample queue has a trigger type of FIRST, so if there are already messages on the queue before you run the Request sample, the Inquire sample is not triggered by the messages you send.

When you have set the definition correctly, first start AMQ3SRV4 in one job, then start AMQ3REQ4 in another. You could use AMQ3TRG4 instead of AMQ3SRV4, but potential job submission delays might make it less easy to follow what is happening.

Use the Request sample program to send request messages, each containing just a queue name, to queue SYSTEM.SAMPLE.INQ. For each request message, the Inquire sample program sends a reply message containing information about the queue specified in the request message. The replies are sent to the reply-to queue specified in the request message.

## **Design of the Inquire sample program**

When the program is triggered, it explicitly connects to the default queue manager using the MQCONN call. Although not necessary on IBM i, this design feature means you could use the same program on other platforms without changing the source code.

The program then opens the queue named in the trigger message structure it was passed when it started. (For clarity, we will call this the *request queue*.) The program uses the MQOPEN call to open this queue for shared input.

The program uses the MQGET call to remove messages from this queue. This call uses the GMATM and GMWT options, with a wait interval of 5 seconds. The program tests the descriptor of each message to see if it is a request message; if it is not, the program discards the message, and displays a warning message.

For each request message removed from the request queue, the program reads the name of the queue (which we will call the *target queue* ) contained in the data and opens that queue using the MQOPEN call with the OOINQ option. The program then uses the MQINQ call to inquire about the values of the **InhibitGet**, **CurrentQDepth**, and **OpenInputCount** attributes of the target queue.

If the MQINQ call is successful, the program uses the MQPUT call to put a reply message on the reply-to queue. This message contains the values of the three attributes.

If the MQOPEN or MQINQ call is unsuccessful, the program uses the MQPUT call to put a *report* message on the reply-to queue. In the *MDFB* field of the message descriptor of this report message is the reason code returned by either the MQOPEN or MQINQ call, depending on which one failed.

After the MQINQ call, the program closes the target queue using the MQCLOSE call.

When there are no messages remaining on the request queue, the program closes that queue and disconnects from the queue manager.

### **The Set sample program on IBM i**

The Set sample program, AMQ3SET4, inhibits put operations on a queue by using the MQSET call to change the queue's **InhibitPut** attribute.

The program is intended to run as a triggered program, so its only input is an MQTMC (trigger message) structure that contains the name of a target queue with attributes that are to be inquired upon.

For the triggering process to work, you must ensure that the Set sample program is triggered by messages arriving on queue SYSTEM.SAMPLE.SET. To do this, specify the name of the Set sample program in the *AppLId* field of the process definition SYSTEM.SAMPLE.SETPROCESS. (For this, you can use the CHGMQMPCRC command, described in the *Administering IBM i*.) The sample queue has a trigger type of FIRST, so if there are already messages on the queue before you run the Request sample, the Set sample is not triggered by the messages you send.

When you have set the definition correctly, first start AMQ3SRV4 in one job, then start AMQ3REQ4 in another. You could use AMQ3TRG4 instead of AMQ3SRV4, but potential job submission delays could make it less easy to follow what is happening.

Use the Request sample program to send request messages, each containing just a queue name, to queue SYSTEM.SAMPLE.SET. For each request message, the Set sample program sends a reply message containing a confirmation that put operations have been inhibited on the specified queue. The replies are sent to the reply-to queue specified in the request message.

### **Design of the Set sample program**

When the program is triggered, it explicitly connects to the default queue manager using the MQCONN call. Although not necessary on IBM i, this means you could use the same program on other platforms without changing the source code.

The program then opens the queue named in the trigger message structure it was passed when it started. (For clarity, we will call this the *request queue*.) The program uses the MQOPEN call to open this queue for shared input.

The program uses the MQGET call to remove messages from this queue. This call uses the GMATM and GMWT options, with a wait interval of 5 seconds. The program tests the descriptor of each message to see if it is a request message; if it is not, the program discards the message and displays a warning message.

For each request message removed from the request queue, the program reads the name of the queue (which we will call the *target queue*) contained in the data and opens that queue using the MQOPEN call with the OOSSET option. The program then uses the MQSET call to set the value of the **InhibitPut** attribute of the target queue to QAPUTI.

If the MQSET call is successful, the program uses the MQPUT call to put a reply message on the reply-to queue. This message contains the string PUT inhibited.

If the MQOPEN or MQSET call is unsuccessful, the program uses the MQPUT call to put a *report* message on the reply-to queue. In the *MDFB* field of the message descriptor of this report message is the reason code returned by either the MQOPEN or MQSET call, depending on which one failed.

After the MQSET call, the program closes the target queue using the MQCLOSE call.

When there are no messages remaining on the request queue, the program closes that queue and disconnects from the queue manager.

## ***The Triggering sample programs on IBM i***

IBM MQ for IBM i supplies two Triggering sample programs that are written in ILE/RPG.

The programs are:

### **AMQ3TRG4**

This is a trigger monitor for the IBM i environment. It submits an IBM i job for the application to be started, but this means that there is additional processing cost associated with each trigger message.

### **AMQ3SRV4**

This is a trigger server for the IBM i environment. For each trigger message, this server runs the start command in its own job to start the specified application. The trigger server can call CICS transactions.

C language versions of these samples are also available as executable programs in library QMQM, called AMQSTRG4 and AMQSERV4.

#### *The AMQ3TRG4 sample trigger monitor on IBM i*

AMQ3TRG4 is a trigger monitor. It takes one parameter: the name of the initiation queue it is to serve. AMQSAMP4 defines a sample initiation queue, SYSTEM.SAMPLE.TRIGGER, that you can use when you try the sample programs.

AMQ3TRG4 submits an IBM i job for each valid trigger message it gets from the initiation queue.

## **Design of the trigger monitor**

The trigger monitor opens the initiation queue and gets messages from the queue, specifying an unlimited wait interval.

The trigger monitor submits an IBM i job to start the application specified in the trigger message, and passes an MQTMC (a character version of the trigger message) structure. The environment data in the trigger message is used as job submission parameters.

Finally, the program closes the initiation queue.

#### *The AMQ3SRV4 sample trigger server*

AMQ3SRV4 is a trigger server. It takes one parameter: the name of the initiation queue it is to serve. AMQSAMP4 defines a sample initiation queue, SYSTEM.SAMPLE.TRIGGER, that you can use when you try the sample programs.

For each trigger message, AMQ3SRV4 runs a start command in its own job to start the specified application.

Using the example trigger queue the command to issue is:

```
CALL PGM(QMQM/AMQ3SRV4) PARM('Queue Name')
```

Where Queue Name must be 48 characters in length, which you achieve by padding the queue name with the required number of blanks. Therefore, if you are using SYSTEM.SAMPLE.TRIGGER as your target queue, you will need 28 blank characters.

## **Design of the trigger server**

The design of the trigger server is like that of the trigger monitor, except the trigger server:

- Allows CICS as well as IBM i applications
- Does not use the environment data from the trigger message
- Calls IBM i applications in its own job (or uses STRCICSUSR to start CICS applications) rather than submitting an IBM i job
- Opens the initiation queue for shared input, so many trigger servers can run at the same time

**Note:** Programs started by AMQ3SRV4 must not use the MQDISC call because this will stop the trigger server. If programs started by AMQ3SRV4 use the MQCONN call, they will get the RC2002 reason code.

#### *Ending the Triggering sample programs on IBM i*

A trigger monitor program can be ended by the sysrequest option 2 (ENDRQS) or by inhibiting gets from the trigger queue.

If the sample trigger queue is used the command is:

```
CHGMQM QNAME('SYSTEM.SAMPLE.TRIGGER') GETENBL(*NO)
```

**Note:** To start triggering again on this queue, you must enter the command:

```
CHGMQM QNAME('SYSTEM.SAMPLE.TRIGGER') GETENBL(*YES)
```

### ***Running the samples using remote queues on IBM i***

You can demonstrate remote queuing by running the samples on connected message queue managers.

Program AMQSAMP4 provides a local definition of a remote queue (SYSTEM.SAMPLE.REMOTE) that uses a remote queue manager named OTHER. To use this sample definition, change OTHER to the name of the second message queue manager you want to use. You must also set up a message channel between your two message queue managers; for information about how to do so, see [Channel-exit programs for messaging channels](#).

The Request sample program puts its own local queue manager name in the *MDRM* field of messages it sends. The Inquire and Set samples send reply messages to the queue and message queue manager named in the *MDRQ* and *MDRM* fields of the request messages they process.

## **Return codes for IBM i (ILE RPG)**

This information describes the return codes associated with the MQI and MQAI.

The return codes associated with:

- Programmable Command Format (PCF) commands are listed in [Programmable command formats reference](#).
- C++ calls are listed in [Using C++](#).

For each call, a completion code and a reason code are returned by the queue manager or by an exit routine, to indicate the success or failure of the call.

Applications must not depend upon errors being checked for in a specific order, except where specifically noted. If more than one completion code or reason code could arise from a call, the particular error reported depends on the implementation.

### **Completion codes for IBM i (ILE RPG)**

The completion code parameter (*CMPCOD*) allows the caller to see quickly whether the call completed successfully, completed partially, or failed.

#### **CCOK**

(MQCC\_OK on other platforms)

Successful completion.

The call completed fully; all output parameters have been set. The **REASON** parameter always has the value RCNONE in this case.

#### **CCWARN**

(MQCC\_WARN on other platforms)

Warning (partial completion).

The call completed partially. Some output parameters might have been set in addition to the *CMPCOD* and *REASON* output parameters. The **REASON** parameter gives additional information about the partial completion.

### **CCFAIL**

(MQCC\_FAIL on other platforms)

Call failed.

The processing of the call did not complete, and the state of the queue manager is normally unchanged; exceptions are specifically noted. The *CMPCOD* and *REASON* output parameters have been set; other parameters are unchanged, except where noted.

The reason might be a fault in the application program, or it might be a result of some situation external to the program, for example the user's authority might have been revoked. The **REASON** parameter gives additional information about the error.

## **Reason codes for IBM i (ILE RPG)**

The reason code parameter (*REASON*) is a qualification to the completion code parameter (*CMPCOD*).

If there is no special reason to report, RCNONE is returned. A successful call returns CCOK and RCNONE.

If the completion code is either CCWARN or CCFAIL, the queue manager always reports a qualifying reason; details are given under each call description.

Where user exit routines set completion codes and reasons, they should adhere to these rules. In addition, any special reason values defined by user exits should be less than zero, to ensure that they do not conflict with values defined by the queue manager. Exits can set reasons already defined by the queue manager, where these are appropriate.

Reason codes also occur in:

- The *DLREA* field of the MQDLH structure
- The *MDFB* field of the MQMD structure

For the full list of reason codes, see [API completion and reason codes](#).

To find your IBM i reason code in that list, remove the "RC" from the front, for example RC2002 becomes 2002. Also the completion codes there are shown as they are on other platforms:

<b>IBM i</b>	<b>Other platforms</b>
CCOK	MQCC_OK
CCWARN	MQCC_WARN
CCFAIL	MQCC_FAIL

## **Rules for validating MQI options for IBM i (ILE RPG)**

This topic gives information about the situations that produce an RC2046 reason code from an MQOPEN, MQPUT, MQPUT1, MQGET, or MQCLOSE call.

### **MQOPEN call on IBM i**

For the options of the MQOPEN call:

- *At least one* of the following must be specified:
  - OOBROW

- OOINPQ
- OOINPX
- OOINPS
- OOINQ
- OOOOUT
- OOSET
- Only *one* of the following is allowed:
  - OOINPQ
  - OOINPX
  - OOINPS
- Only *one* of the following is allowed:
  - OOBNDO
  - OOBNDN
  - OOBNDQ

**Note:** The options listed previously are mutually exclusive. However, because the value of OOBNDQ is zero, specifying it with either of the other two bind options does not result in reason code RC2046. OOBNDQ is provided to aid program documentation.

- If OOSAVA is specified, one of the OOINP\* options must also be specified.
- If one of the OOSET\* or OOPAS\* options is specified, OOOOUT must also be specified.

## **MQPUT call on IBM i**

For the put-message options:

- The combination of PMSYP and PMNSYP is not allowed.
- Only *one* of the following is allowed:
  - PMDEFC
  - PMNOC
  - PMPASA
  - PMPASI
  - PMSETA
  - PMSETI
- PMALTU is not allowed (it is valid only on the MQPUT1 call).

## **MQPUT1 call on IBM i**

For the put-message options, the rules are the same as for the MQPUT call, except for the following options:

- PMALTU is allowed.
- PMLOGO is not allowed.

## **MQGET call on IBM i**

For the get-message options:

- Only *one* of the following options is allowed:
  - GMNSYP
  - GMSYP

- GMPSYP
- Only *one* of the following options is allowed:
  - GMBRWF
  - GMBRWC
  - GMBRWN
  - GMMUC
- GMSYP is not allowed with any of the following options:
  - GMBRWF
  - GMBRWC
  - GMBRWN
  - GMLK
  - GMUNLK
- GMPSYP is not allowed with any of the following options:
  - GMBRWF
  - GMBRWC
  - GMBRWN
  - GMCMPM
  - GMUNLK
- If GMLK is specified, one of the following options must also be specified:
  - GMBRWF
  - GMBRWC
  - GMBRWN
- If GMUNLK is specified, only the following options are allowed:
  - GMNSYP
  - GMNWT

### **MQCLOSE call on IBM i**

- For the options of the MQCLOSE call. The combination of CODEL and COPURG is not allowed.
- Only one of the following is allowed:
  - COKPSB
  - CORMSB

### **MQSUB call on IBM i**

For the options of the MQSUB call:

- At least one of the following must be specified:
- At least one of the following must be specified:
  - SOALT
  - SORES
  - SOCRT
- Only one of the following is allowed:
  - SODUR
  - SONDUR

**Note:** The options listed previously are mutually exclusive. However, as the value of SONDUR is zero, specifying it with SODUR does not result in reason code RC2046. SONDUR is provided to aid program documentation.

- The combination of SOGRP and SOMAN is not allowed.
- SOGRP requires SOSCID to be specified.
- Only one of the following is allowed: SOAUID SOFUID
- The combination of SONEWP and SOPUBR is not allowed.
- SONEWP is only allowed in combination with SOCRT.
- Only one of the following is allowed:
  - SOWCHR
  - SOWTOP

## Machine encodings on IBM i

Use this information to learn about the structure of the *MDENC* field in the message descriptor.

For more information about the message descriptor, see [“MQMD \(Message descriptor\) on IBM i” on page 1110.](#)

The *MDENC* field is a 32-bit integer that is divided into four separate subfields; these subfields identify:

- The encoding used for binary integers
- The encoding used for packed-decimal integers
- The encoding used for floating-point numbers
- Reserved bits

Each subfield is identified by a bit mask which has 1-bits in the positions corresponding to the subfield, and 0-bits elsewhere. The bits are numbered such that bit 0 is the most significant bit, and bit 31 the least significant bit. The following masks are defined:

### **ENIMSK**

Mask for binary-integer encoding.

This subfield occupies bit positions 28 through 31 within the *MDENC* field.

### **ENDMSK**

Mask for packed-decimal-integer encoding.

This subfield occupies bit positions 24 through 27 within the *MDENC* field.

### **ENFMSK**

Mask for floating-point encoding.

This subfield occupies bit positions 20 through 23 within the *MDENC* field.

### **ENRMSK**

Mask for reserved bits.

This subfield occupies bit positions 0 through 19 within the *MDENC* field.

## Binary-integer encoding on IBM i

Valid values for binary-integer encoding.

The following values are valid for the binary-integer encoding:

### **ENIUND**

Undefined integer encoding.

Binary integers are represented using an encoding that is undefined.

**ENINOR**

Normal integer encoding.

Binary integers are represented in the conventional way:

- The least significant byte in the number has the highest address of any of the bytes in the number; the most significant byte has the lowest address.
- The least significant bit in each byte is next to the byte with the next higher address; the most significant bit in each byte is next to the byte with the next lower address.

**ENIREV**

Reversed integer encoding.

Binary integers are represented in the same way as ENINOR, but with the bytes arranged in reverse order. The bits within each byte are arranged in the same way as ENINOR.

**IBM i Packed-decimal-integer encoding on IBM i**

Valid values for packed-decimal-integer encoding

The following values are valid for the packed-decimal-integer encoding:

**ENDUND**

Undefined packed-decimal encoding.

Packed-decimal integers are represented using an encoding that is undefined.

**ENDNOR**

Normal packed-decimal encoding.

Packed-decimal integers are represented in the conventional way:

- Each decimal digit in the printable form of the number is represented in packed decimal by a single hexadecimal digit in the range X'0' through X'9'. Each hexadecimal digit occupies 4 bits, and so each byte in the packed decimal number represents two decimal digits in the printable form of the number.
- The least significant byte in the packed-decimal number is the byte which contains the least significant decimal digit. Within that byte, the most significant 4 bits contain the least significant decimal digit, and the least significant 4 bits contain the sign. The sign is either X'C' (positive), X'D' (negative), or X'F' (unsigned).
- The least significant byte in the number has the highest address of any of the bytes in the number; the most significant byte has the lowest address.
- The least significant bit in each byte is next to the byte with the next higher address; the most significant bit in each byte is next to the byte with the next lower address.

**ENDREV**

Reversed packed-decimal encoding.

Packed-decimal integers are represented in the same way as ENDNOR, but with the bytes arranged in reverse order. The bits within each byte are arranged in the same way as ENDNOR.

**IBM i Floating-point encoding on IBM i**

Valid values for floating-point encoding

The following values are valid for the floating-point encoding:

**ENFUND**

Undefined floating-point encoding.

Floating-point numbers are represented using an encoding that is undefined.

**ENFNOR**

Normal IEEE (The Institute of Electrical and Electronics Engineers) float encoding.

Floating-point numbers are represented using the standard IEEE floating-point format, with the bytes arranged as follows:

- The least significant byte in the mantissa has the highest address of any of the bytes in the number; the byte containing the exponent has the lowest address
- The least significant bit in each byte is next to the byte with the next higher address; the most significant bit in each byte is next to the byte with the next lower address

Details of the IEEE float encoding might be found in IEEE Standard 754.

### **ENFREV**

Reversed IEEE float encoding.

Floating-point numbers are represented in the same way as ENFNOR, but with the bytes arranged in reverse order. The bits within each byte are arranged in the same way as ENFNOR.

### **ENF390**

System/390 architecture float encoding.

Floating-point numbers are represented using the standard System/390 floating-point format; this is also used by System/370.

## **IBM i Constructing encodings on IBM i**

To construct a value for the *MDENC* field in MQMD, the relevant constants that describe the required encodings should be added.

Be sure to combine only one of the ENI\* encodings with one of the END\* encodings and one of the ENF\* encodings.

## **IBM i Analyzing encodings on IBM i**

The *MDENC* field contains subfields; because of this, applications that need to examine the integer, packed decimal, or float encoding should use the technique described in this topic.

### **Using arithmetic**

The following steps should be performed using integer arithmetic:

1. Select one of the following values, according to the type of encoding required:

- 1 for the binary integer encoding
- 16 for the packed decimal integer encoding
- 256 for the floating point encoding

Call the value A.

2. Divide the value of the *MDENC* field by A ; call the result B.
3. Divide B by 16; call the result C.
4. Multiply C by 16 and subtract from B ; call the result D.
5. Multiply D by A ; call the result E.
6. E is the encoding required, and can be tested for equality with each of the values that is valid for that type of encoding.

## **IBM i Summary of machine architecture encodings on IBM i**

A table summarizing encodings for machine architectures.

Encodings for machine architectures are shown in [Table 815 on page 1431](#).

Table 815. Summary of encodings for machine architectures

Machine architecture	Binary integer encoding	Packed-decimal integer encoding	Floating-point encoding
IBM i	normal	normal	IEEE normal
Intel x86	reversed	reversed	IEEE reversed
PowerPC	normal	normal	IEEE normal
System/390	normal	normal	System/390

## IBM i

### Report options and message flags on IBM i

This topic concerns the *MDREP* and *MDMFL* fields that are part of the message descriptor MQMD specified on the MQGET, MQPUT, and MQPUT1 calls.

For more information about the message descriptor, see [“MQMD \(Message descriptor\) on IBM i”](#) on page 1110. This information describes:

- The structure of the report field and how the queue manager processes it
- How an application should analyze the report field
- The structure of the message-flags field

#### Structure of the report field

The *MDREP* field is a 32-bit integer that is divided into three separate subfields.

These subfields identify:

- Report options that are rejected if the local queue manager does not recognize them
- Report options that are always accepted, even if the local queue manager does not recognize them
- Report options that are accepted only if certain other conditions are satisfied

Each subfield is identified by a bit mask which has 1-bits in the positions corresponding to the subfield, and 0-bits elsewhere. Note that the bits in a subfield are not necessarily adjacent. The bits are numbered such that bit 0 is the most significant bit, and bit 31 the least significant bit. The following masks are defined to identify the subfields:

#### RORUM

Mask for unsupported report options that are rejected.

This mask identifies the bit positions within the *MDREP* field where report options which are not supported by the local queue manager will cause the MQPUT or MQPUT1 call to fail with completion code CCFAIL and reason code RC2061.

This subfield occupies bit positions 3, and 11 through 13.

#### ROAUM

Mask for unsupported report options that are accepted.

This mask identifies the bit positions within the *MDREP* field where report options which are not supported by the local queue manager will nevertheless be accepted on the MQPUT or MQPUT1 calls. Completion code CCWARN with reason code RC2104 are returned in this case.

This subfield occupies bit positions 0 through 2, 4 through 10, and 24 through 31.

The following report options are included in this subfield:

- ROCMTC
- RODLQ
- RODISC
- ROEXC

- ROEXCD
- ROEXCF
- ROEXP
- ROEXPD
- ROEXPF
- RONAN
- RONMI
- RONONE
- ROPAN
- ROPCI
- ROPMI

### **ROAUXM**

Mask for unsupported report options that are accepted only in certain circumstances.

This mask identifies the bit positions within the *MDREP* field where report options which are not supported by the local queue manager will nevertheless be accepted on the MQPUT or MQPUT1 calls *provided* that both of the following conditions are satisfied:

- The message is destined for a remote queue manager.
- The application is not putting the message directly on a local transmission queue (that is, the queue identified by the *ODMN* and *ODON* fields in the object descriptor specified on the MQOPEN or MQPUT1 call is not a local transmission queue).

Completion code CCWARN with reason code RC2104 are returned if these conditions are satisfied, and CCFAIL with reason code RC2061 if not.

This subfield occupies bit positions 14 through 23.

The following report options are included in this subfield:

- ROCOA
- ROCOAD
- ROCOAF
- ROCOD
- ROCODD
- ROCODF

If there are any options specified in the *MDREP* field which the queue manager does not recognize, the queue manager checks each subfield in turn by using the bitwise AND operation to combine the *MDREP* field with the mask for that subfield. If the result of that operation is not zero, the completion code and reason codes described previously are returned.

If CCWARN is returned, it is not defined which reason code is returned if other warning conditions exist.

The ability to specify and have accepted report options which are not recognized by the local queue manager is useful when it is necessary to send a message with a report option which will be recognized and processed by a *remote* queue manager.

## Analyzing the report field on IBM i

The MDREP field contains subfields. Because of this, some applications need to check whether the sender of the message requested a particular report. Those applications should use the technique described in this topic.

### Using arithmetic

The following steps should be performed using integer arithmetic:

1. Select one of the following values, according to the type of report to be checked:

- ROCOA for COA report
- ROCOD for COD report
- ROEXC for exception report
- ROEXP for expiration report

Call the value A.

2. Divide the MDREP field by A ; call the result B.

3. Divide B by 8 ; call the result C.

4. Multiply C by 8 and subtract from B ; call the result D.

5. Multiply D by A ; call the result E.

6. Test E for equality with each of the values that is possible for that type of report.

For example, if A is ROEXC, test E for equality with each of the following to determine what was specified by the sender of the message:

- RONONE
- ROEXC
- ROEXCD
- ROEXCF

The tests can be performed in whatever order is most convenient for the application logic.

The following pseudocode illustrates this technique for exception report messages:

```
A = ROEXC
B = Report/A
C = B/8
D = B - C*8
E = D*A
```

A similar method can be used to test for the ROPMI or ROPCI options; select as the value A whichever of these two constants is appropriate, and then proceed as described previously, but replacing the value 8 in the previous steps by the value 2.

## Structure of the message-flags field on IBM i

The MDMFL field is a 32-bit integer that is divided into three separate subfields.

These subfields identify:

- Message flags that are rejected if the local queue manager does not recognize them
- Message flags that are always accepted, even if the local queue manager does not recognize them
- Message flags that are accepted only if certain other conditions are satisfied

**Note:** All subfields in MDMFL are reserved for use by the queue manager.

Each subfield is identified by a bit mask which has 1-bits in the positions corresponding to the subfield, and 0-bits elsewhere. The bits are numbered such that bit 0 is the most significant bit, and bit 31 the least significant bit. The following masks are defined to identify the subfields:

#### **MFRUM**

Mask for unsupported message flags that are rejected.

This mask identifies the bit positions within the *MDMFL* field where message flags which are not supported by the local queue manager will cause the MQPUT or MQPUT1 call to fail with completion code CCFAIL and reason code RC2249.

This subfield occupies bit positions 20 through 31.

The following message flags are included in this subfield:

- MFLMIG
- MFLSEG
- MFMIG
- MFSEG
- MFSEGA
- MFSEGI

#### **MFAUM**

Mask for unsupported message flags that are accepted.

This mask identifies the bit positions within the *MDMFL* field where message flags which are not supported by the local queue manager will nevertheless be accepted on the MQPUT or MQPUT1 calls. The completion code is CCOK.

This subfield occupies bit positions 0 through 11.

#### **MFAUXM**

Mask for unsupported message flags that are accepted only in certain circumstances.

This mask identifies the bit positions within the *MDMFL* field where message flags which are not supported by the local queue manager will nevertheless be accepted on the MQPUT or MQPUT1 calls *provided* that both of the following conditions are satisfied:

- The message is destined for a remote queue manager.
- The application is not putting the message directly on a local transmission queue (that is, the queue identified by the *ODMN* and *ODON* fields in the object descriptor specified on the MQOPEN or MQPUT1 call is not a local transmission queue).

Completion code CCOK is returned if these conditions are satisfied, and CCFAIL with reason code RC2249 if not.

This subfield occupies bit positions 12 through 19.

If there are flags specified in the *MDMFL* field that the queue manager does not recognize, the queue manager checks each subfield in turn by using the bitwise AND operation to combine the *MDMFL* field with the mask for that subfield. If the result of that operation is not zero, the completion code and reason codes described previously are returned.

This topic describes the interface to the data-conversion exit, and the processing performed by the queue manager when data conversion is required.

The data-conversion exit is invoked as part of the processing of the MQGET call. It is used to convert the application message data to the representation required by the receiving application. Conversion of the application message data is optional, and requires the GMCONV option to be specified on the MQGET call.

The following aspects of data conversion are described:

- The processing performed by the queue manager in response to the GMCONV option; see [“Conversion processing on IBM i” on page 1435](#).
- Processing conventions used by the queue manager when processing a built-in format; these conventions are recommended for user-written exits too. See [“Processing conventions on IBM i” on page 1436](#).
- Special considerations for the conversion of report messages; see [“Conversion of report messages on IBM i” on page 1440](#).
- The parameters passed to the data-conversion exit; see [“MQCONVX \(Data conversion exit\) on IBM i” on page 1450](#).
- A call that can be used from the exit in order to convert character data between different representations; see [“MQXCNVC \(Convert characters\) on IBM i” on page 1446](#).
- The data-structure parameter which is specific to the exit; see [“MQDXP \(Data-conversion exit parameter\) on IBM i” on page 1441](#).

## IBM i Conversion processing on IBM i

This information describes the processing performed by the queue manager in response to the GMCONV option.

The queue manager performs the following actions if the GMCONV option is specified on the MQGET call, and there is a message to be returned to the application:

1. If one or more of the following is true, no conversion is necessary:
  - The message data is already in the character set and encoding required by the application issuing the MQGET call. The application must set the *MDCSI* and *MDENC* fields in the **MSGDSC** parameter of the MQGET call to the values required, before issuing the call.
  - The length of the message data is zero.
  - The length of the **BUFFER** parameter of the MQGET call is zero.

In these cases the message is returned without conversion to the application issuing the MQGET call; the *MDCSI* and *MDENC* values in the **MSGDSC** parameter are set to the values in the control information in the message, and the call completes with one of the following combinations of completion code and reason code:

**Completion code**  
**Reason code**

**CCOK**  
RCNONE

**CCWARN**  
RC2079

**CCWARN**  
RC2080

The following steps are performed only if the character set or encoding of the message data differs from the corresponding value in the **MSGDSC** parameter, and there is data to be converted:

1. If the *MDFMT* field in the control information in the message has the value FMNONE, the message is returned unconverted, with completion code CCWARN and reason code RC2110.  
In all other cases conversion processing continues.
2. The message is removed from the queue and placed in a temporary buffer which is the same size as the **BUFFER** parameter. For browse operations, the message is copied into the temporary buffer, instead of being removed from the queue.
3. If the message has to be truncated to fit in the buffer, the following is done:
  - If the GMATM option was not specified, the message is returned unconverted, with completion code CCWARN and reason code RC2080.

- If the GMATM option *was* specified, the completion code is set to CCWARN, the reason code is set to RC2079, and conversion processing continues.
4. If the message can be accommodated in the buffer without truncation, or the GMATM option was specified, the following is done:
- If the format is a built-in format, the buffer is passed to the queue manager's data-conversion service.
  - If the format is not a built-in format, the buffer is passed to a user-written exit which has the same name as the format. If the exit cannot be found, the message is returned unconverted, with completion code CCWARN and reason code RC2110.

If no error occurs, the output from the data-conversion service or from the user-written exit is the converted message, plus the completion code and reason code to be returned to the application issuing the MQGET call.

5. If the conversion is successful, the queue manager returns the converted message to the application. In this case, the completion code and reason code returned by the MQGET call will typically be one of the following combinations:

**Completion code**  
**Reason code**

**CCOK**  
RCNONE

**CCWARN**  
RC2079

However, if the conversion is performed by a user-written exit, other reason codes can be returned, even when the conversion is successful.

If the conversion fails (for whatever reason), the queue manager returns the unconverted message to the application, with the *MDCSI* and *MDENC* fields in the **MSGDSC** parameter set to the values in the control information in the message, and with completion code CCWARN.

## IBM i Processing conventions on IBM i

When converting a built-in format, the queue manager follows the processing conventions described in this topic.

Consider applying these conventions to user-written exits, although this is not enforced by the queue manager. The built-in formats converted by the queue manager are as follows:

- FMADMN
- FMMDE
- FMCICS
- FMPCF
- FMCMD1
- FMRMH
- FMCMD2
- FMRFH
- FMDLH
- FMRFH2
- FMDH
- FMSTR
- FMEVNT
- FMTM
- FMIMS

- FMXQH
- FMIMVS

1. If the message expands during conversion, and exceeds the size of the **BUFFER** parameter, the following is done:

- If the GMATM option was not specified, the message is returned unconverted, with completion code CCWARN and reason code RC2120.
- If the GMATM option was specified, the message is truncated, the completion code is set to CCWARN, the reason code is set to RC2079, and conversion processing continues.

2. If truncation occurs (either before or during conversion), it is possible for the number of valid bytes returned in the **BUFFER** parameter to be *less than* the length of the buffer.

This can occur, for example, if a 4-byte integer or a DBCS character straddles the end of the buffer. The incomplete element of information is not converted, and so those bytes in the returned message do not contain valid information. This can also occur if a message that was truncated before conversion shrinks during conversion.

If the number of valid bytes returned is less than the length of the buffer, the unused bytes at the end of the buffer are set to nulls.

3. If an array or string straddles the end of the buffer, as much of the data as possible is converted; only the particular array element or DBCS character which is incomplete is not converted - preceding array elements or characters are converted.

4. If truncation occurs (either before or during conversion), the length returned for the **DATLEN** parameter is the length of the *unconverted* message before truncation.

5. When strings are converted between single-byte character sets (SBCS), double-byte character sets (DBCS), or multi-byte character sets (MBCS), the strings can expand or contract.

- In the PCF formats FMADMN, FMEVNT, and FMPCF, the strings in the MQCFST and MQCFSL structures expand or contract as necessary to accommodate the string after conversion.

For the string-list structure MQCFSL, the strings in the list might expand or contract by different amounts. If this happens, the queue manager pads the shorter strings with blanks to make them the same length as the longest string after conversion.

- In the format FMRMH, the strings addressed by the RMSEO, RMSNO, RMDEO, and RMDNO fields expand or contract as necessary to accommodate the strings after conversion.
- In the format FMRFH, the RFNVS field expands or contracts as necessary to accommodate the name-value pairs after conversion.
- In structures with fixed field sizes, the queue manager allows strings to expand or contract within their fixed fields, if no significant information is lost. In this regard, trailing blanks and characters following the first null character in the field are treated as insignificant.
  - If the string expands, but only insignificant characters need to be discarded to accommodate the converted string in the field, the conversion succeeds and the call completes with CCOK and reason code RCNONE (assuming no other errors).
  - If the string expands, but the converted string requires significant characters to be discarded in order to fit in the field, the message is returned unconverted and the call completes with CCWARN and reason code RC2190.

**Note:** Reason code RC2190 results in this case whether the GMATM option was specified.

  - If the string contracts, the queue manager pads the string with blanks to the length of the field.

6. For messages consisting of one or more IBM MQ header structures followed by user data, it is possible for one or more of the header structures to be converted, while the remainder of the message is not. However, with two exceptions, the MDCSI and MDENC fields in each header structure always correctly indicate the character set and encoding of the data that follows the header structure.

The two exceptions are the MQCIH and MQIIH structures, where the values in the MDCSI and MDENC fields in those structures are not significant. For those structures, the data following the structure is in the same character set and encoding as the MQCIH or MQIIH structure itself.

7. If the MDCSI or MDENC fields in the control information of the message being retrieved, or in the **MSGDSC** parameter, specify values which are undefined or not supported, the queue manager might ignore the error if the undefined or unsupported value does not need to be used in converting the message.

For example, if the MDENC field in the message specifies an unsupported float encoding, but the message contains only integer data, or contains floating-point data which does not require conversion (because the source and target float encodings are identical), the error might or might not be diagnosed.

If the error is diagnosed, the message is returned unconverted, with completion code CCWARN and one of the RC2111, RC2112, RC2113, RC2114 or RC2115, RC2116, RC2117, RC2118 reason codes (as appropriate); the MDCSI and MDENC fields in the **MSGDSC** parameter are set to the values in the control information in the message.

If the error is not diagnosed and the conversion completes successfully, the values returned in the MDCSI and MDENC fields in the **MSGDSC** parameter, are those specified by the application issuing the MQGET call.

8. In all cases, if the message is returned to the application unconverted the completion code is set to CCWARN, and the MDCSI and MDENC fields in the **MSGDSC** parameter are set to the values appropriate to the unconverted data. This is done for FMNONE also.

The **REASON** parameter is set to a code that indicates why the conversion could not be carried out, unless the message also had to be truncated; reason codes related to truncation take precedence over reason codes related to conversion. (To determine if a truncated message was converted, check the values returned in the MDCSI and MDENC fields in the **MSGDSC** parameter.)

When an error is diagnosed, either a specific reason code is returned, or the general reason code RC2119. The reason code returned depends on the diagnostic capabilities of the underlying data-conversion service.

9. If completion code CCWARN is returned, and more than one reason code is relevant, the order of precedence is as follows:

- a. The following reason takes precedence over all others:
  - RC2079
- b. Next in precedence is the following reason:
  - RC2110
- c. The order of precedence within the remaining reason codes is not defined.

10. On completion of the MQGET call:

- The following reason code indicates that the message was converted successfully:
  - RCNONE
- The following reason code indicates that the message *may* have been converted successfully (check the MDCSI and MDENC fields in the **MSGDSC** parameter to find out):
  - RC2079
- All other reason codes indicate that the message was not converted.

The following processing is specific to the built-in formats; it is not applicable to user-defined formats:

1. Except for the following formats:

- FMADMN
- FMEVNT
- FMIMVS

- FMPCF
- FMSTR

none of the built-in formats can be converted from or to character sets that do not have SBCS characters for the characters that are valid in queue names. If an attempt is made to perform such a conversion, the message is returned unconverted, with completion code CCWARN and reason code RC2111 or RC2115, as appropriate.

The Unicode character set UTF-16 is an example of a character set that does not have SBCS characters for the characters that are valid in queue names.

2. If the message data for a built-in format is truncated, fields within the message which contain lengths of strings, or counts of elements or structures, are not adjusted to reflect the length of the data returned to the application; the values returned for such fields within the message data are the values applicable to the message before truncation.

When processing messages such as a truncated FMADMN message, care must be taken to ensure that the application does not attempt to access data beyond the end of the data returned.

3. If the format name is FMDLH, the message data begins with an MQDLH structure, and this may be followed by zero or more bytes of application message data. The format, character set, and encoding of the application message data are defined by the DLFMT, DLCSE, and DLENC fields in the MQDLH structure at the start of the message. Since the MQDLH structure and application message data can have different character sets and encodings, it is possible for one, other, or both of the MQDLH structure and application message data to require conversion.

The queue manager converts the MQDLH structure first, as necessary. If conversion is successful, or the MQDLH structure does not require conversion, the queue manager checks the DLCSE and DLENC fields in the MQDLH structure to see if conversion of the application message data is required. If conversion is required, the queue manager invokes the user-written exit with the name given by the DLFMT field in the MQDLH structure, or performs the conversion itself (if DLFMT is the name of a built-in format).

If the MQGET call returns a completion code of CCWARN, and the reason code is one of those indicating that conversion was not successful, one of the following applies:

- The MQDLH structure could not be converted. In this case the application message data will not have been converted either.
- The MQDLH structure was converted, but the application message data was not.

The application can examine the values returned in the MDCSE and MDENC fields in the **MSGDSC** parameter, and those in the MQDLH structure, in order to determine which of the previous applies.

4. If the format name is FMXQH, the message data begins with an MQXQH structure, and this may be followed by zero or more bytes of additional data. This additional data is typically the application message data (which may be of zero length), but there can also be one or more further IBM MQ header structures present, at the start of the additional data.

The MQXQH structure must be in the character set and encoding of the queue manager. The format, character set, and encoding of the data following the MQXQH structure are given by the MDFMT, MDCSE, and MDENC fields in the MQMD structure contained within the MQXQH. For each subsequent IBM MQ header structure present, the MDFMT, MDCSE, and MDENC fields in the structure describe the data that follows that structure; that data is either another IBM MQ header structure, or the application message data.

If the GMCONV option is specified for an FMXQH message, the application message data and certain of the MQ header structures are converted, but the data in the MQXQH structure is not. On return from the MQGET call, therefore:

- The values of the MDFMT, MDCSE, and MDENC fields in the **MSGDSC** parameter, describe the data in the MQXQH structure, and not the application message data; the values will therefore not be the same as those specified by the application that issued the MQGET call.

The effect of this is that an application which repeatedly gets messages from a transmission queue with the GMCONV option specified must reset the MDCSI and MDENC fields in the **MSGDSC** parameter to the values necessary for the application message data, before each MQGET call.

- The values of the MDFMT, MDCSI, and MDENC fields in the last MQ header structure present describe the application message data. If there are no other IBM MQ header structures present, the application message data is described by these fields in the MQMD structure within the MQXQH structure. If conversion is successful, the values will be the same as those specified in the **MSGDSC** parameter by the application that issued the MQGET call.

If the message is a distribution-list message, the MQXQH structure is followed by an MQDH structure (plus its arrays of MQOR and MQPMR records), which in turn may be followed by zero or more further IBM MQ header structures and zero or more bytes of application message data. Like the MQXQH structure, the MQDH structure must be in the character set and encoding of the queue manager, and it is not converted on the MQGET call, even if the GMCONV option is specified.

The processing of the MQXQH and MQDH structures described previously are primarily intended for use by message channel agents when they get messages from transmission queues.

IBM i

## Conversion of report messages on IBM i

A report message can contain varying amounts of application message data, according to the report options specified by the sender of the original message.

In particular, a report message can contain either:

1. No application message data
2. Some of the application message data from the original message

This occurs when the sender of the original message specifies RO\*D and the message is longer than 100 bytes.

3. All of the application message data from the original message

This occurs when the sender of the original message specifies RO\*F, or specifies RO\*D and the message is 100 bytes or shorter.

When the queue manager or message channel agent generates a report message, it copies the format name from the original message into the *MDFMT* field in the control information in the report message. The format name in the report message might therefore imply a length of data which is different from the length present in the report message (cases 1 and 2 described previously).

If the GMCONV option is specified when the report message is retrieved:

- For case 1 described previously, the data-conversion exit will not be invoked (because the report message will have no data).
- For case 3 described previously, the format name correctly implies the length of the message data.
- But for case 2 described previously, the data-conversion exit will be invoked to convert a message which is *shorter* than the length implied by the format name.

In addition, the reason code passed to the exit will typically be RCNONE (that is, the reason code will not indicate that the message has been truncated). This happens because the message data was truncated by the *sender* of the report message, and not by the receiver's queue manager in response to the MQGET call.

Because of these possibilities, the data-conversion exit should not use the format name to deduce the length of data passed to it; instead the exit should check the length of data provided, and be prepared to convert less data than the length implied by the format name. If the data can be converted successfully, completion code CCOK and reason code RCNONE should be returned by the exit. The length of the message data to be converted is passed to the exit as the **INLEN** parameter.

## Product-sensitive programming interface

If a report message contains information about an activity that has taken place, it is known as an activity report. Examples of activities are:

- an MCA sending a message from a queue down a channel
- an MCA receiving a message from a channel and putting it onto a queue
- an MCA dead-letter queuing an undeliverable message
- an MCA getting a message off a queue and discarding it
- a dead-letter handler placing a message back on a queue
- the command server processing a PCF request - a broker processing a publish request
- a user application getting a message from a queue - a user application browsing a message on a queue

Any application, including the queue manager, can add some of the message data to the activity report following the report header. The amount of data that should be supplied if some is sent is not fixed, and is decided by the application. The information returned should be useful to the application processing the activity report. Queue manager activity reports will return with them any standard IBM MQ header structures (beginning 'MQH') contained in the original message. This includes, for example, any MQRFH2 headers that were included in the original message. Also the queue manager will return an MQCFH header found, but not the PCF parameters associated with it. This gives monitoring applications an idea of what the message was about.

## IBM i MQDXP (Data-conversion exit parameter) on IBM i

Data-conversion exit parameter block.

### Overview

**Purpose:** The MQDXP structure is a parameter that the queue manager passes to the data-conversion exit when the exit is invoked to convert the message data as part of the processing of the MQGET call. See the description of the MQCONVX call for details of the data conversion exit.

**Character set and encoding:** Character data in MQDXP is in the character set of the local queue manager; this is given by the **CodedCharSetId** queue manager attribute. Numeric data in MQDXP is in the native machine encoding; this is given by ENNAT.

**Usage:** Only the *DXLEN*, *DXCC*, *DXREA* and *DXRES* fields in MQDXP might be changed by the exit; changes to other fields are ignored. However, the *DXLEN* field cannot be changed if the message being converted is a segment that contains only part of a logical message.

When control returns to the queue manager from the exit, the queue manager checks the values returned in MQDXP. If the values returned are not valid, the queue manager continues processing as though the exit had returned XRFAIL in *DXRES* ; however, the queue manager ignores the values of the *DXCC* and *DXREA* fields returned by the exit in this case, and uses instead the values those fields had on *input* to the exit. The following values in MQDXP cause this processing to occur:

- *DXRES* field not XROK and not XRFAIL
- *DXCC* field not CCOK and not CCWARN
- *DXLEN* field less than zero, or *DXLEN* field changed when the message being converted is a segment that contains only part of a logical message.
- [“Fields” on page 1441](#)
- [“RPG declaration \(copy file CMQDXPH\)” on page 1445](#)

### Fields

The MQDXP structure contains the following fields; the fields are described in **alphabetical order**:

#### **DXAOP (10-digit signed integer)**

Application options.

This is a copy of the *GMOPT* field of the MQGMO structure specified by the application issuing the MQGET call. The exit may need to examine these to ascertain whether the GMATM option was specified.

This is an input field to the exit.

#### **DXCC (10-digit signed integer)**

Completion code.

When the exit is invoked, this contains the completion code that will be returned to the application that issued the MQGET call, if the exit chooses to do nothing. It is always CCWARN, because either the message was truncated, or the message requires conversion and this has not yet been done.

On output from the exit, this field contains the completion code to be returned to the application in the **CMPCOD** parameter of the MQGET call; only CCOK and CCWARN are valid. See the description of the *DXREA* field for suggestions on how the exit should set this field on output.

This is an input/output field to the exit.

#### **DXCSI (10-digit signed integer)**

Character set required by application.

This is the coded character-set identifier of the character set required by the application issuing the MQGET call; see the *MDCSI* field in the MQMD structure for more details. If the application specifies the special value CSQM on the MQGET call, the queue manager changes this to the actual character-set identifier of the character set used by the queue manager, before invoking the exit.

If the conversion is successful, the exit should copy this to the *MDCSI* field in the message descriptor.

This is an input field to the exit.

#### **DXENC (10-digit signed integer)**

Numeric encoding required by application.

This is the numeric encoding required by the application issuing the MQGET call; see the *MDENC* field in the MQMD structure for more details.

If the conversion is successful, the exit should copy this to the *MDENC* field in the message descriptor.

This is an input field to the exit.

#### **DXHCN (10-digit signed integer)**

Connection handle.

This is a connection handle which can be used on the MQXCNVC call. This handle is not necessarily the same as the handle specified by the application which issued the MQGET call.

#### **DXLEN (10-digit signed integer)**

Length in bytes of message data.

When the exit is invoked, this field contains the original length of the application message data. If the message was truncated in order to fit into the buffer provided by the application, the size of the message provided to the exit will be *smaller* than the value of *DXLEN*. The size of the message provided to the exit is always given by the **INLEN** parameter of the exit, irrespective of any truncation that may have occurred.

Truncation is indicated by the *DXREA* field having the value RC2079 on input to the exit.

Most conversions will not need to change this length, but an exit can do so if necessary; the value set by the exit is returned to the application in the **DATLEN** parameter of the MQGET call. However, this length cannot be changed if the message being converted is a segment that contains only part of a logical message. This is because changing the length would cause the offsets of later segments in the logical message to be incorrect.

Note that, if the exit wants to change the length of the data, be aware that the queue manager has already decided whether the message data will fit into the application's buffer, based on the length of the *unconverted* data. This decision determines whether the message is removed from the queue (or the browse cursor moved, for a browse request), and is not affected by any change to the data length caused by the conversion. For this reason it is recommended that conversion exits do not cause a change in the length of the application message data.

If character conversion does imply a change of length, a string can be converted into another string with the same length in bytes, truncating trailing blanks, or padding with blanks as necessary.

The exit is not invoked if the message contains no application message data; hence *DXLEN* is always greater than zero.

This is an input/output field to the exit.

### **DXREA (10-digit signed integer)**

Reason code qualifying *DXCC*.

When the exit is invoked, this contains the reason code that will be returned to the application that issued the MQGET call, if the exit chooses to do nothing. Among possible values are RC2079, indicating that the message was truncated in order fit into the buffer provided by the application, and RC2119, indicating that the message requires conversion but that this has not yet been done.

On output from the exit, this field contains the reason to be returned to the application in the **REASON** parameter of the MQGET call; the following is recommended:

- If *DXREA* had the value RC2079 on input to the exit, the *DXREA* and *DXCC* fields should not be altered, irrespective of whether the conversion succeeds or fails.

(If the *DXCC* field is not CCOK, the application which retrieves the message can identify a conversion failure by comparing the returned *MDENC* and *MDCSI* values in the message descriptor with the values requested; in contrast, the application cannot distinguish a truncated message from a message that just fitted the buffer. For this reason, RC2079 should be returned in preference to any of the reasons that indicate conversion failure.)

- If *DXREA* had any other value on input to the exit:
  - If the conversion succeeds, *DXCC* should be set to CCOK and *DXREA* set to RCNONE.
  - If the conversion fails, or the message expands and has to be truncated to fit in the buffer, *DXCC* should be set to CCWARN (or left unchanged), and *DXREA* set to one of the values in the following list, to indicate the nature of the failure.

Note that, if the message after conversion is too big for the buffer, it should be truncated only if the application that issued the MQGET call specified the GMATM option:

- If it did specify that option, reason RC2079 should be returned.
- If it did not specify that option, the message should be returned unconverted, with reason code RC2120.

The reason codes in the following list are recommended for use by the exit to indicate the reason that conversion failed, but the exit can return other values from the set of RC\* codes if deemed appropriate. In addition, the range of values RC0900 through RC0999 are allocated for use by the exit to indicate conditions that the exit wants to communicate to the application issuing the MQGET call.

**Note:** If the message cannot be converted successfully, the exit must return XRFAIL in the *DXRES* field, in order to cause the queue manager to return the unconverted message. This is true regardless of the reason code returned in the *DXREA* field.

#### **RC0900**

(900, X'384') Lowest value for application-defined reason code.

#### **RC0999**

(999, X'3E7') Highest value for application-defined reason code.

**RC2120**

(2120, X'848') Converted data too big for buffer.

**RC2119**

(2119, X'847') Message data not converted.

**RC2111**

(2111, X'83F') Source coded character set identifier not valid.

**RC2113**

(2113, X'841') Packed-decimal encoding in message not recognized.

**RC2114**

(2114, X'842') Floating-point encoding in message not recognized.

**RC2112**

(2112, X'840') Source integer encoding not recognized.

**RC2115**

(2115, X'843') Target coded character set identifier not valid.

**RC2117**

(2117, X'845') Packed-decimal encoding specified by receiver not recognized.

**RC2118**

(2118, X'846') Floating-point encoding specified by receiver not recognized.

**RC2116**

(2116, X'844') Target integer encoding not recognized.

**RC2079**

(2079, X'81F') Truncated message returned (processing completed).

This is an input/output field to the exit.

**DXRES (10-digit signed integer)**

Response from exit.

This is set by the exit to indicate the success or otherwise of the conversion. It must be one of the following:

**XR0K**

Conversion was successful.

If the exit specifies this value, the queue manager returns the following to the application that issued the MQGET call:

- The value of the *DXCC* field on output from the exit
- The value of the *DXREA* field on output from the exit
- The value of the *DXLEN* field on output from the exit
- The contents of the exit's output buffer *OUTBUF*. The number of bytes returned is the lesser of the exit's **OUTLEN** parameter, and the value of the *DXLEN* field on output from the exit

If the *MDENC* and *MDCSI* fields in the exit's message descriptor parameter are *both* unchanged, the queue manager returns:

- The value of the *MDENC* and *MDCSI* fields in the MQDXP structure on *input* to the exit

If one or both of the *MDENC* and *MDCSI* fields in the exit's message descriptor parameter has been changed, the queue manager returns:

- The value of the *MDENC* and *MDCSI* fields in the exit's message descriptor parameter on output from the exit
- 

**XRFAIL**

Conversion was unsuccessful.

If the exit specifies this value, the queue manager returns the following to the application that issued the MQGET call:

- The value of the *DXCC* field on output from the exit
- The value of the *DXREA* field on output from the exit
- The value of the *DXLEN* field on *input* to the exit
- The contents of the exit's input buffer *INBUF*. The number of bytes returned is given by the **INLEN** parameter

If the exit has altered *INBUF*, the results are undefined.

*DXRES* is an output field from the exit.

### **DXSID (4-byte character string)**

Structure identifier.

The value must be:

#### **DXSIDV**

Identifier for data conversion exit parameter structure.

This is an input field to the exit.

### **DXVER (10-digit signed integer)**

Structure version number.

The value must be:

#### **DXVER1**

Version number for data-conversion exit parameter structure.

The following constant specifies the version number of the current version:

#### **DXVERC**

Current version of data-conversion exit parameter structure.

**Note:** When a new version of this structure is introduced, the layout of the existing part is not changed. The exit should therefore check that the *DXVER* field is equal to or greater than the lowest version which contains the fields that the exit needs to use.

This is an input field to the exit.

### **DXXOP (10-digit signed integer)**

Reserved.

This is a reserved field; its value is 0.

## IBM i MQXCNV (Convert characters) on IBM i

The MQXCNV call converts characters from one character set to another.

This call is part of the IBM MQ Data Conversion Interface (DCI), which is one of the IBM MQ framework interfaces. Note: This call can be used only from a data-conversion exit.

- [“Syntax” on page 1446](#)
- [“Parameters” on page 1446](#)
- [“RPG invocation \(ILE\)” on page 1450](#)

### Syntax

**MQXCNV HCONN, OPTS, SRCCSI, SRCLEN, SRCBUF, TGTCSI, TGTLEN, TGTBUF, DATLEN, CMPCOD, REASON)**

### Parameters

The MQXCNV call has the following parameters:

#### HCONN (10-digit signed integer) - input

Connection handle.

This handle represents the connection to the queue manager. It should normally be the handle passed to the data-conversion exit in the DXHCN field of the MQDXP structure; this handle is not necessarily the same as the handle specified by the application which issued the MQGET call.

On IBM i, the following special value can be specified for HCONN:

#### HCDEFH

Default connection handle.

#### OPTS (10-digit signed integer) - input

Options that control the action of MQXCNV.

Zero or more of the options described later in this section can be specified. If more than one is required, the values can be added (do not add the same constant more than once).

**Default-conversion option:** The following option controls the use of default character conversion:

#### DCCDEF

Default conversion.

This option specifies that default character conversion can be used if one or both of the character sets specified on the call is not supported. This allows the queue manager to use an installation-specified default character set that approximates the specified character set, when converting the string.

**Note:** The result of using an approximate character set to convert the string is that some characters may be converted incorrectly. This can be avoided by using in the string only characters which are common to both the specified character set and the default character set.

The default character sets are defined by a configuration option when the queue manager is installed or restarted.

If DCCDEF is not specified, the queue manager uses only the specified character sets to convert the string, and the call fails if one or both of the character sets is not supported.

**Padding option:** The following option allows the queue manager to pad the converted string with blanks or discard insignificant trailing characters, in order to make the converted string fit the target buffer:

#### **DCCFIL**

Fill target buffer.

This option requests that conversion take place in such a way that the target buffer is filled completely:

- If the string contracts when it is converted, trailing blanks are added in order to fill the target buffer.
- If the string expands when it is converted, trailing characters that are not significant are discarded to make the converted string fit the target buffer. If this can be done successfully, the call completes with CCOK and reason code RCNONE.

If there are too few insignificant trailing characters, as much of the string as will fit is placed in the target buffer, and the call completes with CCWARN and reason code RC2120.

Insignificant characters are:

- Trailing blanks
- Characters following the first null character in the string (but excluding the first null character itself)
- If the string, TGTCSI , and TGTLEN are such that the target buffer cannot be set completely with valid characters, the call fails with CCFAIL and reason code RC2144. This can occur when TGTCSI is a pure DBCS character set (such as UTF-16), but TGTLEN specifies a length that is an odd number of bytes.
- TGTLEN can be less than or greater than SRCLEN. On return from MQXCNVC, DATLEN has the same value as TGTLEN.

If this option is not specified:

- The string is allowed to contract or expand within the target buffer as required. Insignificant trailing characters are not added or discarded.

If the converted string fits in the target buffer, the call completes with CCOK and reason code RCNONE.

If the converted string is too large for the target buffer, as much of the string as will fit is placed in the target buffer, and the call completes with CCWARN and reason code RC2120. Note that fewer than *TGTLEN* bytes can be returned in this case.

- TGTLEN can be less than or greater than SRCLEN. On return from MQXCNVC, DATLEN is less than or equal to TGTLEN.

**Encoding options:** The following options can be used to specify the integer encodings of the source and target strings. The relevant encoding is used only when the corresponding character set identifier indicates that the representation of the character set in main storage is dependent on the encoding used for binary integers. This affects only certain multibyte character sets (for example, UTF-16 character sets).

The encoding is ignored if the character set is a single-byte character set (SBCS), or a multibyte character set with representation in main storage that is not dependent on the integer encoding.

Only one of the DCCS\* values should be specified, combined with one of the DCCT\* values:

#### **DCCSNA**

Source encoding is the default for the environment and programming language.

#### **DCCSNO**

Source encoding is normal.

**DCCSRE**

Source encoding is reversed.

**DCCSUN**

Source encoding is undefined.

**DCCTNA**

Target encoding is the default for the environment and programming language.

**DCCTNO**

Target encoding is normal.

**DCCTRE**

Target encoding is reversed.

**DCCTUN**

Target encoding is undefined.

The encoding values defined previously can be added directly to the OPTS field. However, if the source or target encoding is obtained from the MDENC field in the MQMD or other structure, the following processing must be done:

1. The integer encoding must be extracted from the MDENC field by eliminating the float and packed-decimal encodings; see [“Analyzing encodings on IBM i” on page 1430](#) for details of how to do this.
2. The integer encoding resulting from step 1 must be multiplied by the appropriate factor before being added to the OPTS field. These factors are:

**DCCSFA**

Factor for source encoding

**DCCTFA**

Factor for target encoding

If not specified, the encoding options default to undefined (DCC\*UN). In most cases, this does not affect the successful completion of the MQXCNVC call. However, if the corresponding character set is a multibyte character set with representation that is dependent on the encoding (for example, a UTF-16 character set), the call fails with reason code RC2112 or RC2116 as appropriate.

**Default option:** If none of the options described previously is specified, the following option can be used:

**DCCNON**

No options specified.

DCCNON is defined to aid program documentation. It is not intended that this option be used with any other, but as its value is zero, such use cannot be detected.

**SRCCSI (10-digit signed integer) - input**

Coded character set identifier of string before conversion.

This is the coded character set identifier of the input string in SRCBUF.

**SRCLLEN (10-digit signed integer) - input**

Length of string before conversion.

This is the length in bytes of the input string in SRCBUF ; it must be zero or greater.

**SRCBUF (1-byte character string x SRCLLEN) - input**

String to be converted.

This is the buffer containing the string to be converted from one character set to another.

**TGTCSI (10-digit signed integer) - input**

Coded character set identifier of string after conversion.

This is the coded character set identifier of the character set to which SRCBUF is to be converted.

**TGTLEN (10-digit signed integer) - input**

Length of output buffer.

This is the length in bytes of the output buffer TGTBUF ; it must be zero or greater. It can be less than or greater than SRCLLEN.

**TGTBUF (1-byte character string x TGTLEN) - output**

String after conversion.

This is the string after it has been converted to the character set defined by TGTCSI. The converted string can be shorter or longer than the unconverted string. The **DATLEN** parameter indicates the number of valid bytes returned.

**DATLEN (10-digit signed integer) - output**

Length of output string.

This is the length of the string returned in the output buffer TGTBUF. The converted string can be shorter or longer than the unconverted string.

**CMPCOD (10-digit signed integer) - output**

Completion code.

It is one of the following:

**CCOK**

Successful completion.

**CCWARN**

Warning (partial completion).

**CCFAIL**

Call failed.

**REASON (10-digit signed integer) - output**

Reason code qualifying CMPCOD.

If CMPCOD is CCOK:

**RCNONE**

(0, X'000') No reason to report.

If CMPCOD is CCWARN:

**RC2120**

(2120, X'848') Converted data too large for buffer.

If CMPCOD is CCFAIL:

**RC2010**

(2010, X'7DA') Data length parameter not valid.

**RC2150**

(2150, X'866') DBCS string not valid.

**RC2018**

(2018, X'7E2') Connection handle not valid.

**RC2046**

(2046, X'7FE') Options not valid or not consistent.

**RC2102**

(2102, X'836') Insufficient system resources available.

**RC2145**

(2145, X'861') Source buffer parameter not valid.

**RC2111**

(2111, X'83F') Source coded character set identifier not valid.

**RC2112**

(2112, X'840') Source integer encoding not recognized.

**RC2143**

(2143, X'85F') Source length parameter not valid.

**RC2071**

(2071, X'817') Insufficient storage available.

**RC2146**

(2146, X'862') Target buffer parameter not valid.

**RC2115**

(2115, X'843') Target coded character set identifier not valid.

**RC2116**

(2116, X'844') Target integer encoding not recognized.

**RC2144**

(2144, X'860') Target length parameter not valid.

**RC2195**

(2195, X'893') Unexpected error occurred.

D* Reason code qualifying CMPCOD
D REASON            10I 0

```

**IBM i MQCONVX (Data conversion exit) on IBM i**

This call definition describes the parameters that are passed to the data-conversion exit.

No entry point called MQCONVX is provided by the queue manager (see usage note [“11” on page 1452](#)).

This definition is part of the IBM MQ Data Conversion Interface (DCI), which is one of the IBM MQ framework interfaces.

- [“Syntax” on page 1451](#)
- [“Usage notes” on page 1451](#)
- [“Parameters” on page 1452](#)
- [“RPG invocation \(ILE\)” on page 1454](#)

## Syntax

**MQCONVX (MQDXP, MQMD, INLEN, INBUF, OUTLEN, OUTBUF)**

## Usage notes

1. A data-conversion exit is a user-written exit which receives control during the processing of an MQGET call. The function performed by the data-conversion exit is defined by the provider of the exit; however, the exit must conform to the rules described here, and in the associated parameter structure MQDXP.

The programming languages that can be used for a data-conversion exit are determined by the environment.

2. The exit is invoked only if *all* of the following statements are true:
  - The GMCONV option is specified on the MQGET call
  - The *MDFMT* field in the message descriptor is not FMNONE
  - The message is not already in the required representation; that is, one or both of the message's *MDCSI* and *MDENC* is different from the value specified by the application in the message descriptor supplied on the MQGET call
  - The queue manager has not already done the conversion successfully
  - The length of the application's buffer is greater than zero
  - The length of the message data is greater than zero
  - The reason code so far during the MQGET operation is RCNONE or RC2079
3. When an exit is being written, consideration should be given to coding the exit in a way that will allow it to convert messages that have been truncated. Truncated messages can arise in the following ways:
  - The receiving application provides a buffer that is smaller than the message, but specifies the GMATM option on the MQGET call.  
 In this case, the *DXREA* field in the **MQDXP** parameter on input to the exit will have the value RC2079.
  - The sender of the message truncated it before sending it. This can happen with report messages, for example (see [“Conversion of report messages on IBM i” on page 1440](#) for more details).  
 In this case, the *DXREA* field in the **MQDXP** parameter on input to the exit will have the value RCNONE (if the receiving application provided a buffer that was large enough for the message).

Thus the value of the *DXREA* field on input to the exit cannot always be used to decide whether the message has been truncated.

The distinguishing characteristic of a truncated message is that the length provided to the exit in the **INLEN** parameter will be *less than* the length implied by the format name contained in the *MDFMT* field in the message descriptor. The exit should therefore check the value of *INLEN* before attempting to convert any of the data; the exit *should not* assume that the full amount of data implied by the format name has been provided.

If the exit has not been written to convert truncated messages, and **INLEN** is less than the value expected, the exit should return XRFAIL in the *DXRES* field of the **MQDXP** parameter, with the *DXCC* field set to CCWARN and the *DXREA* field set to RC2110.

If the exit *has* been written to convert truncated messages, the exit should convert as much of the data as possible (see next usage note), taking care not to attempt to examine or convert data beyond the end of *INBUF*. If the conversion completes successfully, the exit should leave the *DXREA* field in the **MQDXP** parameter unchanged. This returns RC2079 if the message was truncated by the receiver's queue manager, and RCNONE if the message was truncated by the sender of the message.

It is also possible for a message to expand *during* conversion, to the point where it is bigger than *OUTBUF*. In this case the exit must decide whether to truncate the message; the *DXAOP* field in the **MQDXP** parameter will indicate whether the receiving application specified the GMATM option.

4. Generally it is recommended that all of the data in the message provided to the exit in *INBUF* is converted, or that none of it is. An exception to this, however, occurs if the message is truncated, either before conversion or during conversion; in this case there may be an incomplete item at the end of the buffer (for example: one byte of a double-byte character, or 3 bytes of a 4-byte integer). In this situation it is recommended that the incomplete item should be omitted, and unused bytes in *OUTBUF* set to nulls. However, complete elements or characters within an array or string *should* be converted.
5. When an exit is needed for the first time, the queue manager attempts to load an object that has the same name as the format (apart from extensions). The object loaded must contain the exit that processes messages with that format name. It is recommended that the exit name, and the name of the object that contain the exit, should be identical, although not all environments require this.
6. A new copy of the exit is loaded when an application attempts to retrieve the first message that uses that *MDFMT* since the application connected to the queue manager. A new copy might also be loaded at other times, if the queue manager has discarded a previously loaded copy. For this reason, an exit should not attempt to use static storage to communicate information from one invocation of the exit to the next - the exit may be unloaded between the two invocations.
7. If there is a user-supplied exit with the same name as one of the built-in formats supported by the queue manager, the user-supplied exit does not replace the built-in conversion routine. The only circumstances in which such an exit is invoked are:
  - If the built-in conversion routine cannot handle conversions to or from either the *MDCSI* or *MDENC* involved, or
  - If the built-in conversion routine has failed to convert the data (for example, because there is a field or character which cannot be converted).
8. The scope of the exit is environment-dependent. *MDFMT* names should be chosen so as to minimize the risk of clashes with other formats. It is recommended that they start with characters that identify the application defining the format name.
9. The data-conversion exit runs in an environment like that of the program which issued the MQGET call; environment includes address space and user profile (where applicable). The program could be a message channel agent sending messages to a destination queue manager that does not support message conversion. The exit cannot compromise the queue manager's integrity, since it does not run in the queue manager's environment.
10. The only MQI call which can be used by the exit is MQXCNVC; attempting to use other MQI calls fails with reason code RC2219, or other unpredictable errors.
11. No entry point called MQCONVX is provided by the queue manager. The name of the exit should be the same as the format name (the name contained in the *MDFMT* field in MQMD), although this is not required in all environments.

## Parameters

The MQCONVX call has the following parameters:

### **MQDXP (MQDXP) - input/output**

Data-conversion exit parameter block.

This structure contains information relating to the invocation of the exit. The exit sets information in this structure to indicate the outcome of the conversion. See “MQDXP (Data-conversion exit parameter) on IBM i” on page 1441 for details of the fields in this structure.

### **MQMD (MQMD) - input/output**

Message descriptor.

On input to the exit, this is the message descriptor that would be returned to the application if no conversion were performed. It therefore contains the *MDFMT*, *MDENC*, and *MDCSI* of the unconverted message contained in *INBUF*.

**Note:** The **MQMD** parameter passed to the exit is always the most recent version of MQMD supported by the queue manager which invokes the exit. If the exit is intended to be portable between different environments, the exit should check the *MDVER* field in *MQMD* to verify that the fields that the exit needs to access are present in the structure.

On IBM i, the exit is passed a version-2 MQMD.

On output, the exit should change the *MDENC* and *MDCSI* fields to the values requested by the application, if conversion was successful; these changes will be reflected back to the application. Any other changes that the exit makes to the structure are ignored; they are not reflected back to the application.

If the exit returns XROK in the *DXRES* field of the MQDXP structure, but does not change the *MDENC* or *MDCSI* fields in the message descriptor, the queue manager returns for those fields the values that the corresponding fields in the MQDXP structure had on input to the exit.

### **INLEN (10-digit signed integer) - input**

Length in bytes of *INBUF*.

This is the length of the input buffer *INBUF*, and specifies the number of bytes to be processed by the exit. *INLEN* is the lesser of the length of the message data before conversion, and the length of the buffer provided by the application on the MQGET call.

The value is always greater than zero.

### **INBUF (1-byte bit string x INLEN) - input**

Buffer containing the unconverted message.

This contains the message data before conversion. If the exit is unable to convert the data, the queue manager returns the contents of this buffer to the application after the exit has completed.

**Note:** The exit should not alter *INBUF* ; if this parameter is altered, the results are undefined.

### **OUTLEN (10-digit signed integer) - input**

Length in bytes of *OUTBUF*.

This is the length of the output buffer *OUTBUF*, and is the same as the length of the buffer provided by the application on the MQGET call.

The value is always greater than zero.

### **OUTBUF (1-byte bit string x OUTLEN) - output**

Buffer containing the converted message.

On output from the exit, if the conversion was successful (as indicated by the value XROK in the *DXRES* field of the **MQDXP** parameter), **OUTBUF** contains the message data to be delivered to the application, in the requested representation. If the conversion was unsuccessful, any changes that the exit has made to this buffer are ignored.

## RPG invocation (ILE)

```
C*..1.....2.....3.....4.....5.....6.....7..  
C          CALLP      exitname(MQDXP : MQMD : INLEN :  
C                               INBUF : OUTLEN : OUTBUF)
```

The prototype definition for the call is:

```
D*..1.....2.....3.....4.....5.....6.....7..  
Dexitname      PR          EXTPROC('exitname')  
D* Data-conversion exit parameter block  
D MQDXP                44A  
D* Message descriptor  
D MQMD                  364A  
D* Length in bytes of INBUF  
D INLEN                10I 0 VALUE  
D* Buffer containing the unconverted message  
D INBUF                *   VALUE  
D* Length in bytes of OUTBUF  
D OUTLEN              10I 0 VALUE  
D* Buffer containing the converted message  
D OUTBUF              *   VALUE
```

## MQIEP structure

The MQIEP structure contains an entry point for each function call that exits are permitted to make.

### Fields

#### StrucId

Type: MQCHAR4 - input

Structure identifier. The value is as follows:

#### **MQIEP\_STRUC\_ID**

#### Version

Type: MQLONG - input

Structure version number. The value is as follows:

#### **MQIEP\_VERSION\_1**

Version 1 structure version number.

**MQIEP\_CURRENT\_VERSION**

Current version of the structure.

**StrucLength**

Type: MQLONG

Size of the MQIEP structure in bytes. The value is as follows:

**MQIEP\_LENGTH\_1****Flags**

Type: MQLONG

Provides information about the function addresses. A flag to indicate if the library is threaded can be used with a flag to indicate if the library is a client or server library.

The following value is used to specify no library information:

**MQIEPF\_NONE**

One of the following values is used to specify if the shared library is threaded or non-threaded:

**MQIEPF\_NON\_THREADED\_LIBRARY**

A non-threaded shared library

**MQIEPF\_THREADED\_LIBRARY**

A threaded shared library

One of the following values is used to specify if the shared library is a client or a server shared library:

**MQIEPF\_CLIENT\_LIBRARY**

A client shared library

**MQIEPF\_LOCAL\_LIBRARY**

A server shared library

**Reserved**

Type: MQPTR

**MQBACK\_Call**

Type: PMQ\_BACK\_CALL

Address of the MQBACK call.

**MQBEGIN\_Call**

Type: PMQ\_BEGIN\_CALL

Address of the MQBEGIN call.

**MQBUFMH\_Call**

Type: PMQ\_BUFMH\_CALL

Address of the MQBUFMH call.

**MQCB\_Call**

Type: PMQ\_CB\_CALL

Address of the MQCB call.

**MQCLOSE\_Call**

Type: PMQ\_CLOSE\_CALL

Address of the MQCLOSE call.

**MQCMIT\_Call**

Type: PMQ\_CMIT\_CALL

Address of the MQCMIT call.

**MQCONN\_Call**

Type: PMQ\_CONN\_CALL

Address of the MQCONN call.

**MQCONNX\_Call**

Type: PMQ\_CONNX\_CALL

Address of the MQCONNX call.

**MQCRTMH\_Call**

Type: PMQ\_CRTMH\_CALL

Address of the MQCRTMH call.

**MQCTL\_Call**

Type: PMQ\_CTL\_CALL

Address of the MQCTL call.

**MQDISC\_Call**

Type: PMQ\_DISC\_CALL

Address of the MQDISC call.

**MQDLTMH\_Call**

Type: PMQ\_DLTMH\_CALL

Address of the MQDLTMH call.

**MQDLTMP\_Call**

Type: PMQ\_DLTMP\_CALL

Address of the MQDLTMP call.

**MQGET\_Call**

Type: PMQ\_GET\_CALL

Address of the MQGET call.

**MQINQ\_Call**

Type: PMQ\_INQ\_CALL

Address of the MQINQ call.

**MQINQMP\_Call**

Type: PMQ\_INQMP\_CALL

Address of the MQINQMP call.

**MQMHBUF\_Call**

Type: PMQ\_MHBUF\_CALL

Address of the MQMHBUF call.

**MQOPEN\_Call**

Type: PMQ\_OPEN\_CALL

Address of the MQOPEN call.

**MQPUT\_Call**

Type: PMQ\_PUT\_CALL

Address of the MQPUT call.

**MQPUT1\_Call**

Type: PMQ\_PUT1\_CALL

Address of the MQPUT1 call.

**MQSET\_Call**

Type: PMQ\_SET\_CALL

Address of the MQSET call.

### **MQSETMP\_Call**

Type: PMQ\_SETMP\_CALL

Address of the MQSETMP call.

### **MQSTAT\_Call**

Type: PMQ\_STAT\_CALL

Address of the MQSTAT call.

### **MQSUB\_Call**

Type: PMQ\_SUB\_CALL

Address of the MQSUB call.

### **MQSUBRQ\_Call**

Type: PMQ\_SUBRQ\_CALL

Address of the MQSUBRQ call.

### **MQXCNVC\_Call**

Type: PMQ\_XCNVC\_CALL

Address of the MQXCNVC call.

### **MQXCLWLN\_Call**

Type: PMQ\_XCLWLN\_CALL

Address of the MQXCLWLN call.

### **MQXDX\_Call**

Type: PMQ\_XDX\_CALL

Address of the MQXDX call.

### **MQXEP\_Call**

Type: PMQ\_XEP\_CALL

Address of the MQXEP call.

### **MQZEP\_Call**

Type: PMQ\_ZEP\_CALL

Address of the MQZEP call.

## **C Declaration**

```

PMQ_XDX_CALL     MQXDX_Call;    /* Address of MQXDX */
PMQ_XEP_CALL     MQXEP_Call;    /* Address of MQXEP */
PMQ_ZEP_CALL     MQZEP_Call;    /* Address of MQZEP */
};

```

## Data-conversion exit reference

For z/OS, you must write data-conversion exits in assembler language. For other platforms, it is recommended that you use the C programming language.

To help you to create a data-conversion exit program, the following resources are supplied:

- A skeleton source file
- A convert characters call
- A utility that creates a fragment of code that performs data conversion on data type structures This utility takes C input only. On z/OS, it produces assembler code.

For the procedure for writing the programs see:

- [IBM i](#) Writing a data-conversion exit program for IBM MQ for IBM i
- [z/OS](#) Writing a data-conversion exit program for IBM MQ for z/OS
- [Writing a data-conversion exit for IBM MQ for AIX or Linux systems](#)
- [Writing a data-conversion exit for IBM MQ for Windows](#)

### Skeleton source file

These can be used as your starting point when writing a data-conversion exit program.

The files supplied are listed in [Table 816 on page 1458](#).

Table 816. Skeleton source files	
Platform	File
<a href="#">AIX</a> AIX	amqsvfc0.c
<a href="#">IBM i</a> IBM i	QMOMSAMP/QCSRC(AMQSVFC4)
<a href="#">Linux</a> Linux	amqsvfc0.c
<a href="#">Windows</a> Windows systems	amqsvfc0.c
<a href="#">z/OS</a> z/OS	CSQ4BAX8 ( <a href="#">“1” on page 1458</a> ) CSQ4BAX9 ( <a href="#">“2” on page 1458</a> ) CSQ4CAX9 ( <a href="#">“3” on page 1458</a> )
<b>Notes:</b> <ol style="list-style-type: none"> <li>1. Illustrates the MQXCVC call.</li> <li>2. A wrapper for the code fragments generated by the utility for use in all environments except CICS.</li> <li>3. A wrapper for the code fragments generated by the utility for use in the CICS environment.</li> </ol>	

## Convert characters call

Use the MQXCNVC (convert characters) call from within a data-conversion exit program to convert character message data from one character set to another. For certain multibyte character sets (for example, UTF-16 character sets), the appropriate options must be used.

No other MQI calls can be made from within the exit; an attempt to make such a call fails with reason code MQRC\_CALL\_IN\_PROGRESS.

See “MQXCNVC - Convert characters” on page 919 for further information on the MQXCNVC call and appropriate options.

## Utility for creating conversion-exit code

Use this information to learn more about creating conversion-exit code.

The commands for creating conversion-exit code are:

**IBM i**  
CVTMQMDTA (Convert IBM MQ Data Type)

**ALW**  
crtmqcvx (Create IBM MQ conversion-exit)

**z/OS**  
CSQUCVX

The command for your platform produces a fragment of code that performs data conversion on data type structures, for use in your data-conversion exit program. The command takes a file containing one or more C language structure definitions. **z/OS** On z/OS, it then generates a data set containing assembler code fragments and conversion functions. On other platforms, it generates a file with a C function to convert each structure definition. On z/OS, the utility requires access to the LE/370 runtime library SCEERUN.

## Invoking the CSQUCVX utility on z/OS

**z/OS**

Figure 10 on page 1459 shows an example of the JCL used to invoke the CSQUCVX utility.

```
//CVX      EXEC PGM=CSQUCVX
//STEPLIB DD DISP=SHR,DSN=thlqua1.SCSQANLE
//        DD DISP=SHR,DSN=thlqua1.SCSQLOAD
//        DD DISP=SHR,DSN=le370qua1.SCEERUN
//SYSPRINT DD SYSOUT=*
//CSQUINP DD DISP=SHR,DSN=MY.MQSERIES.FORMATS(MSG1)
//CSQUOUT DD DISP=OLD,DSN=MY.MQSERIES.EXIT(SMSG1)
```

Figure 10. Sample JCL used to invoke the CSQUCVX utility

## z/OS data definition statements

**z/OS**

The CSQUCVX utility requires DD statements with the following DD names shown in Table 817 on page 1459:

Table 817. Data definition statement names and descriptions	
DD statement	Description
SYSPRINT	Specifies a data set or print spool class for reports and error messages.

Table 817. Data definition statement names and descriptions (continued)

DD statement	Description
CSQUINP	Specifies the partitioned data set containing the definitions of the data structures to be converted.
CSQUOUT	Specifies the partitioned data set where the conversion code fragments are to be written. The logical record length (LRECL) must be 80 and the record format (RECFM) must be FB.

## Error messages in AIX, Linux, and Windows systems

The `crtmqcvx` command returns messages in the range AMQ7953 through AMQ7970.

These messages are listed in [Messages and reason codes IBM MQ Messages](#).

There are two main types of error:

- Major errors, such as syntax errors, when processing cannot continue.

A message is displayed on the screen giving the line number of the error in the input file. The output file might have been partially created.

- Other errors when a message is displayed stating that a problem has been found but that parsing of the structure can continue.

The output file has been created and contains error information about the problems that have occurred. This error information is prefixed by `#ERROR` so that the code produced is not accepted by any compiler without intervention to rectify the problems.

## Valid syntax

Your input file for the utility must conform to the C language syntax.

If you are unfamiliar with C, refer to the [C example](#) in this topic.

In addition, be aware of the following rules:

- `typedef` is recognized only before the `struct` keyword.
- A structure tag is required on your structure declarations.
- You can use empty square brackets `[ ]` to denote a variable length array or string at the end of a message.
- Multidimensional arrays and arrays of strings are not supported.
- The following additional data types are recognized:
  - `MQBOOL`
  - `MQBYTE`
  - `MQCHAR`
  - `MQFLOAT32`
  - `MQFLOAT64`
  - `MQSHORT`
  - `MQLONG`
  - `MQINT8`
  - `MQUINT8`
  - `MQINT16`
  - `MQUINT16`
  - `MQINT32`

- MQUINT32
- MQINT64
- MQUINT64

MQCHAR fields are code page converted, but MQBYTE, MQINT8 and MQUINT8 are left untouched. If the encoding is different, MQSHORT, MQLONG, MQINT16, MQUINT16, MQINT32, MQUINT32, MQINT64, MQUINT64, MQFLOAT32, MQFLOAT64 and MQBOOL are converted accordingly.

- Do not use the following types of data:

- double
- pointers
- bit-fields

This is because the utility for creating conversion-exit code does not provide the facility to convert these data types. To overcome this, you can write your own routines and call them from the exit.

Other points to note:

- Do not use sequence numbers in the input data set.
- If there are fields for which you want to provide your own conversion routines, declare them as MQBYTE, and then replace the generated CMQXCFBA macros with your own conversion code.

## C example

```
struct TEST { MQLONG    SERIAL_NUMBER;
              MQCHAR    ID[5];
              MQINT16   VERSION;
              MQBYTE    CODE[4];
              MQLONG    DIMENSIONS[3];
              MQCHAR    NAME[24];
            } ;
```

This corresponds to the following declarations in other programming languages:

## COBOL

```
10 TEST.
  15 SERIAL-NUMBER PIC S9(9) BINARY.
  15 ID            PIC X(5).
  15 VERSION      PIC S9(4) BINARY.
* CODE IS NOT TO BE CONVERTED
  15 CODE         PIC X(4).
  15 DIMENSIONS   PIC S9(9) BINARY OCCURS 3 TIMES.
  15 NAME         PIC X(24).
```

## System/390

```
TEST          EQU *
SERIAL_NUMBER DS F
ID            DS CL5
VERSION       DS H
CODE          DS XL4
DIMENSIONS    DS 3F
NAME          DS CL24
```

## PL/I

Supported on z/OS only

```
DCL 1 TEST,
```

```

2 SERIAL_NUMBER  FIXED BIN(31),
2 ID             CHAR(5),
2 VERSION       FIXED BIN(15),
2 CODE          CHAR(4),      /* not to be converted */
2 DIMENSIONS(3) FIXED BIN(31),
2 NAME          CHAR(24);

```

## MQ\_PUBLISH\_EXIT - Publish exit

The MQ\_PUBLISH\_EXIT call can inspect and alter messages delivered to subscribers.

### Purpose

Use the publish exit to inspect and alter messages delivered to subscribers:

- Examine the contents of a message published to each subscriber
- Modify the contents of a message published to each subscriber
- Alter the queue to which a message is put
- Stop the delivery of a message to a subscriber

This exit is not available on IBM MQ for z/OS.

### Syntax

**MQ\_PUBLISH\_EXIT** (*ExitParms*, *PubContext*, *SubContext*)

### Parameters

#### ***ExitParms*** (MQPSXP) - Input/Output

*ExitParms* contains information about the invocation of the exit.

#### ***PubContext*** (MQPBC) - Input

*PubContext* contains contextual information about the publisher of the publication.

#### ***SubContext*** (MQSBC) - Input/Output

*SubContext* contains contextual information about the subscriber receiving the publication.

## MQPSXP - Publish exit data structure

The MQPSXP structure describes the information that is passed to and returned from the publish exit.

Table 818 on page 1462 summarizes the fields in the structure:

Table 818. Fields in MQPSXP	
Field	Description
<i>StrucID</i>	Structure identifier
<i>Version</i>	Structure version number
<i>ExitId</i>	Type of exit that is being called
<i>ExitReason</i>	Reason for calling the exit
<i>ExitResponse</i>	Response from the exit
<i>ExitResponse2</i>	Secondary response from exit
<i>Feedback</i>	Feedback code
<i>ExitUserArea</i>	Exit user area
<i>ExitData</i>	Exit data
<i>QMgrName</i>	Name of local queue manager

Table 818. Fields in MQPSXP (continued)

Field	Description
<u>Hconn</u>	Connection handle
<u>MsgDescPtr</u>	Address of message descriptor (MQMD)
<u>MsgHandle</u>	Handle to message properties (MQHMSG)
<u>MsgInPtr</u>	Address of input message
<u>MsgInLength</u>	Length of input message
<u>MsgOutPtr</u>	Address of output message
<u>MsgOutLength</u>	Length of output message
<u>pEntryPoints</u>	Address of the MQIEP structure

## Fields

### **StrucID (MQCHAR4)**

*StrucID* is the structure identifier. The value is as follows:

#### **MQPSXP\_STRUCID**

MQPSXP\_STRUCID is the identifier for the publish exit parameter structure. For the C programming language, the constant MQPSXP\_STRUC\_ID\_ARRAY is also defined; it has the same value as MQPSXP\_STRUC\_ID, but is an array of characters instead of a string.

*StrucID* is an input field to the exit.

### **Version (MQLONG)**

*Version* is the structure version number. The value is as follows:

#### **MQPSXP\_VERSION\_1**

MQPSXP\_VERSION\_1 is the Version 1 publish exit parameter structure. The constant MQPSXP\_CURRENT\_VERSION is also defined with the same value.

*Version* is an input field to the exit.

### **ExitId (MQLONG)**

*ExitId* is the type of exit that is being called. The value is as follows:

#### **MQXT\_PUBLISH\_EXIT**

Publish exit.

*ExitId* is an input field to the exit.

### **ExitReason (MQLONG)**

*ExitReason* is the reason for calling the exit. The possible values are:

#### **MQXR\_INIT**

The exit for this connection is called for initialization. The exit might acquire and initialize the resources that it needs; for example, main storage.

#### **MQXR\_TERM**

The exit for this connection is called because the exit is about to be stopped. The exit must free any resources that it has acquired since it was initialized; for example, main storage.

#### **MQXR\_PUBLICATION**

The exit is called by the queue manager before it puts a publication onto a message queue of a subscriber. The exit can change the message, not put the message on the queue, or halt publication.

*ExitReason* is an input field to the exit.

### **ExitResponse (MQLONG)**

Set *ExitResponse* in the exit to specify how processing must continue. *ExitResponse* is one of the following values:

#### **MQXCC\_OK**

Set MQXCC\_OK to continue processing normally. Set MQXCC\_OK in response to any values of *ExitReason*.

If *ExitReason* has the value MQXR\_PUBLICATION, the *DestinationQName* and *DestinationQMGrName* fields of the MQSBC structure identify the destination to which the message is sent.

#### **MQXCC\_FAILED**

Set MQXCC\_FAILED to stop the publish operation. The completion code MQCC\_FAILED and reason code 2557 (09FD) (RC2557): MQRC\_PUBLISH\_EXIT\_ERROR is set on return from the exit.

#### **MQXCC\_SUPPRESS\_FUNCTION**

Set MQXCC\_SUPPRESS\_FUNCTION to stop normal processing of the message. Only set MQXCC\_SUPPRESS\_FUNCTION if *ExitReason* has the value MQXR\_PUBLICATION.

The message continues to be processed by the queue manager according to the MQRO\_DISCARD\_MSG option in the *Report* field in the message descriptor of the message.

- If the MQRO\_DISCARD\_MSG option is specified, the message is not delivered to the subscriber.
- If the MQRO\_DISCARD\_MSG option is not specified, the message is placed on the dead-letter queue. If there is no dead-letter queue, or the message cannot be placed successfully on the dead-letter queue, the publication is not delivered to the subscriber. The delivery of the publication to other subscribers depends on the values of the PMSGDLV and NPMSGDLV topic object attributes. For an explanation of these attributes, see the parameter descriptions for the [DEFINE TOPIC](#) command.

*ExitResponse* is an output field from the exit.

### **ExitResponse2 (MQLONG)**

*ExitResponse2* is reserved for future use.

### **Feedback (MQLONG)**

*Feedback* is the feedback code to be used if the exit returns MQXCC\_SUPPRESS\_FUNCTION in *ExitResponse*.

On input to the exit, *Feedback* always has the value MQFB\_NONE. If the exit returns MQXCC\_SUPPRESS\_FUNCTION, set *Feedback* to the value to be used for the message when the queue manager places it on the dead-letter queue. On return from the exit, if *Feedback* has the original value MQFB\_NONE, the queue manager sets *Feedback* to MQFB\_STOPPED\_BY\_PUBSUB\_EXIT.

*Feedback* is an input/output field to the exit.

### **ExitUserArea (MQBYTE16)**

*ExitUserArea* is a field that is available for the exit to use. Each connection has a separate *ExitUserArea*. The length of *ExitUserArea* is given by MQ\_EXIT\_USER\_AREA\_LENGTH.

The *ExitReason* field has the value MQXR\_INIT on the first invocation of the exit. *ExitUserArea* is initialized to MQXUA\_NONE on the first invocation of the exit for a connection. Subsequent changes to *ExitUserArea* are preserved across invocations of the exit.

*ExitUserArea* is an input/output field to the exit.

### **ExitData (MQCHAR32)**

*ExitData* is fixed exit data defined by the **PublishExitData** parameter of the stanza in the initialization file of the queue manager. The data is padded with blanks to the full length of the field. If there is no fixed exit data defined in the initialization file, *ExitData* is blank. The length of *ExitData* is given by MQ\_EXIT\_DATA\_LENGTH.

*ExitData* is an input field to the exit.

**QMgrName (MQCHAR48)**

*QMgrName* is the name of the local queue manager. The name is padded with blanks to the full length of the field. The length of this field is given by `MQ_Q_MGR_NAME_LENGTH`.

*QMgrName* is an input field to the exit.

**Hconn (MQHCONN)**

*Hconn* is the handle representing a connection to the queue manager. Only use *Hconn* as a parameter to the `MQSETMP`, `MQINQMMP`, or `MQDLTMP` message property function calls to work with message properties.

*Hconn* is an input field to the exit.

**MsgDescPtr (PMQMD)**

*MsgDescPtr* is the address of message descriptor (MQMD) of the message being processed, and is a copy of the MQMD returned from the `MQPUT` call. The exit can change the contents of the message descriptor. Any change to the contents of the message descriptor must be done with care. In particular, in the case where the *SubType* field of the MQSBC structure is of value `MQSUBTYPE_PROXY`, the *CorrelId* field in the message descriptor must not be changed.

No message descriptor is passed to the exit if *ExitReason* is `MQXR_INIT` or `MQXR_TERM`; in these cases, *MsgDescPtr* is the null pointer.

*MsgDescPtr* is an input field to the exit.

**MsgHandle (MQHMSG)**

*MsgHandle* is the handle to message properties. Only use *MsgHandle* with the `MQSETMP`, `MQINQMMP`, or `MQDLTMP` message property function calls to work with message properties.

*MsgHandle* is an input field to the exit.

**MsgInPtr (PMQVOID)**

*MsgInPtr* is the address of the input message data. The contents of the buffer addressed by *MsgInPtr* can be modified by the exit; see [MsgOutPtr](#).

*MsgInPtr* is an input field to the exit.

**MsgInLength (MQLONG)**

*MsgInLength* is the length in bytes of the message data passed to the exit. The address of the data is given by *MsgInPtr*.

*MsgInLength* is an input field to the exit.

**MsgOutPtr (PMQVOID)**

*MsgOutPtr* is the address of a buffer containing message data that is returned from the exit. On entry to the exit, *MsgOutPtr* is null. On return from the exit, if the value is still null, the queue manager sends the message specified by *MsgInPtr*, with the length given by *MsgInLength*.

If the exit modifies the message data, use one of the following procedures:

- If the length of the data does not change, the data can be modified in the buffer addressed by *MsgInPtr*. In this case, do not change *MsgOutPtr* and *MsgOutLength*.
- If the modified data is shorter than the original data, the data can be modified in the buffer addressed by *MsgInPtr*. In this case *MsgOutPtr* must be set to the address of the input message buffer, and *MsgOutLength* set to the new length of the message data.
- If the modified data is, or might be, longer than the original data, the exit must obtain a new message buffer. Copy the modified data into it. Set *MsgOutPtr* to the address of the new buffer, and set *MsgOutLength* to the length of the new message data. The exit is responsible for freeing the buffer addressed by *MsgOutPtr* when the exit is next called.

**Note:** *MsgOutPtr* is always the null pointer on input to the exit, and not the address of a previously obtained message buffer. To free the previously obtained buffer, the exit must save its address and length. Save the information either in *ExitUserArea*, or in a control block that has its address saved in *ExitUserArea*.

*MsgOutPtr* is an input/output field to the exit.

### **MsgOutLength (MQLONG)**

*MsgOutLength* is the length in bytes of the message data returned by the exit. On input to the exit, this field is always zero. On return from the exit, this field is ignored if *MsgOutPtr* is null. See [MsgOutPtr](#) for information about modifying the message data.

*MsgOutLength* is an input/output field to the exit.

### **pEntryPoints (PMQIEP)**

*pEntryPoints* is the address of an MQIEP structure through which MQI and DCI calls can be made.

## **C language declaration - MQPSXP**

```
typedef struct tagMQPSXP {
    MQCHAR4    StrucId;           /* Structure identifier */
    MQLONG     Version;          /* Structure version number */
    MQLONG     ExitId;           /* Type of exit */
    MQLONG     ExitReason;       /* Reason for invoking exit */
    MQLONG     ExitResponse;     /* Response from exit */
    MQLONG     ExitResponse2;   /* Reserved */
    MQLONG     Feedback;        /* Feedback code */
    MQBYTE16   ExitUserArea;    /* Exit user area */
    MQCHAR32   ExitData;        /* Exit data */
    MQCHAR48   QMgrName;        /* Name of local queue manager */
    MQHCONN    Hconn;           /* Connection handle */
    MQHMSG     MsgHandle;       /* Handle to message properties */
    PMQMD      MsgDescPtr;      /* Address of message descriptor */
    PMQVOID    MsgInPtr;        /* Address of input message data */
    MQLONG     MsgInLength;     /* Length of input message data */
    PMQVOID    MsgOutPtr;       /* Address of output message data */
    MQLONG     MsgOutLength;    /* Length of output message data */
    /* Ver:1 */
    PMQIEP     pEntryPoints;    /* Address of the MQIEP structure */
    /* Ver:2 */
} MQPSXP;
```

## **MQPBC - Publication context data structure**

The MQPBC structure contains the contextual information, relating to the publisher of the publication, that is passed to the publish exit.

Table 819 on page 1466 summarizes the fields in the structure:

Field	Description
<a href="#"><i>StrucID</i></a>	Structure identifier
<a href="#"><i>Version</i></a>	Structure version number
<a href="#"><i>PubTopicString</i></a>	Publish topic string
<a href="#"><i>MsgDescPtr</i></a>	Address of message descriptor (MQMD)

### **Fields**

#### **StrucID (MQCHAR4)**

*StrucID* is the structure identifier. The value is as follows:

#### **MQPBC\_STRUCID**

MQPBC\_STRUCID is the identifier for the publication context structure. For the C programming language, the constant MQPBC\_STRUC\_ID\_ARRAY is also defined; it has the same value as MQPBC\_STRUC\_ID, but is an array of characters instead of a string.

*StrucID* is an input field to the exit.

### Version (MQLONG)

*Version* is the structure version number. The value is as follows:

#### MQPBC\_VERSION\_1

MQPBC\_VERSION\_1 is the Version 1 publish exit parameter structure.

#### MQPBC\_VERSION\_2

MQPBC\_VERSION\_2 is the Version 2 publish exit parameter structure. The constant MQPBC\_CURRENT\_VERSION is also defined with the same value.

*Version* is an input field to the exit.

### PubTopicString (MQCHARV)

*PubTopicString* is the topic string being published to.

*PubTopicString* is an input field to the exit.

### MsgDescPtr (PMQMD)

*MsgDescPtr* is the address of a copy of the message descriptor (MQMD) for the message being processed.

*MsgDescPtr* is an input field to the exit.

## C language declaration - MQPBC

```
typedef struct tagMQPBC {
    MQCHAR4    StrucId;           /* Structure identifier */
    MQLONG     Version;          /* Structure version number */
    MQCHARV    PubTopicString;   /* Publish topic string */
    PMQMD      MsgDescPtr;       /* Address of message descriptor */
} MQPBC;
```

## MQSBC - Subscription context data structure

The MQSBC structure contains the contextual information, relating to the subscriber that is receiving the publication, that is passed to the publish exit.

Table 820 on page 1467 summarizes the fields in the structure:

Field	Description
<u>StrucID</u>	Structure identifier
<u>Version</u>	Structure version number
<u>DestinationQMGrName</u>	Name of destination queue manager
<u>DestinationQName</u>	Name of destination queue
<u>SubType</u>	Type of subscription
<u>SubOptions</u>	Subscription options
<u>ObjectName</u>	Object name
<u>ObjectString</u>	Object string
<u>SubTopicString</u>	Subscription topic string
<u>SubName</u>	Subscription name
<u>SubId</u>	Subscription identifier
<u>SelectionString</u>	Address of selection string
<u>SubLevel</u>	Subscription level

Table 820. Fields in MQSBC (continued)

Field	Description
<i>PSProperties</i>	Publish/subscribe properties

## Fields

### **StrucID (MQCHAR4)**

Structure identifier. The value is as follows:

#### **MQSBC\_STRUCID**

MQSBC\_STRUCID is the identifier for the publish exit parameter structure. For the C programming language, the constant MQSBC\_STRUC\_ID\_ARRAY is also defined; MQSBC\_STRUC\_ID\_ARRAY has the same value as MQSBC\_STRUC\_ID, but is an array of characters instead of a string.

*StrucID* is an input field to the exit.

### **Version (MQLONG)**

Structure version number. The value is as follows:

#### **MQSBC\_VERSION\_1**

Version 1 publish exit parameter structure. The constant MQSBC\_CURRENT\_VERSION is also defined with the same value.

*Version* is an input field to the exit.

### **DestinationQMgrName (MQCHAR48)**

*DestinationQMgrName* is the name of the queue manager to which the message is being sent. The name is padded with blanks to the full length of the field. The name can be altered by the exit. The length of this field is given by MQ\_Q\_MGR\_NAME\_LENGTH.

*DestinationQMgrName* is an input/output field to the exit; see [note](#).

### **DestinationQName (MQCHAR48)**

*DestinationQName* is the name of the queue to which the message is being sent. The name is padded with blanks to the full length of the field. The name can be altered by the exit. The length of this field is given by MQ\_Q\_NAME\_LENGTH.

*DestinationQName* is an input/output field to the exit; see [note](#).

### **SubType (MQLONG)**

*SubType* indicates how the subscription was created. Valid values are MQSUBTYPE\_API, MQSUBTYPE\_ADMIN and MQSUBTYPE\_PROXY ; see [Inquire Subscription Status \(Response\)](#).

*SubType* is an input field to the exit.

### **SubOptions (MQLONG)**

*SubOptions* are the subscription options; see [“Options \(MQLONG\) for MQSD” on page 573](#) for a description of values this field can take.

*SubOptions* is an input field to the exit.

### **ObjectName (MQCHAR48)**

*ObjectName* is the name of the topic object as defined on the local queue manager. The length of this field is given by MQ\_TOPIC\_NAME\_LENGTH. The object name is the name of the administrative topic object that the queue manager has associated with the topic string. Even if the subscriber provided a topic object as part of the subscription, the *ObjectName* might be a different topic object. The association of a topic object with a subscription depends upon the full resolution of *SubTopicString*.

*ObjectName* is an input field to the exit.

### **ObjectString (MQCHARV)**

*ObjectString* is the full topic string of the publication that was subscribed to. Any wildcards in the original subscription string are resolved. It is different to the MQSD subscription *ObjectString* field

described in [“ObjectString \(MQCHARV\) for MQSD”](#) on page 583, which might contain wildcards, and is exclusive of any object name provided by the subscriber.

*ObjectString* is an input field to the exit.

### **SubTopicString (MQCHARV)**

*SubTopicString* is the complete topic string as supplied by the subscriber. *SubTopicString* is the combination of the topic string defined in a topic object, and a topic string. A subscriber must provide either a topic object, a topic string, or both. If the subscriber provides a topic string, it might contain wildcards.

*SubTopicString* is an input field to the exit.

### **SubName (MQCHARV)**

*SubName* is the subscription name that is provided either by the subscriber, or is a generated name.

*SubName* is an input field to the exit.

### **SubId (MQBYTE 24)**

*SubId* is the unique internal subscription identifier.

*SubId* is an input field to the exit.

### **SelectionString (MQCHARV)**

*SelectionString* is the selection criteria used when subscribing for messages from a topic; see [Selectors](#).

*SelectionString* is an input field to the exit.

### **SubLevel (MQLONG)**

*SubLevel* is the interception level associated with the subscription; see [“SubLevel \(MQLONG\) for MQSD”](#) on page 586 for further details.

*SubLevel* is an input field to the exit.

### **PSPProperties (MQLONG)**

*PSPProperties* are the publish/subscribe properties. They specify how publish/subscribe related message properties are added to messages sent to this subscription. Possible values are MQPSPROP\_NONE, MQPSPROP\_COMPAT, MQPSPROP\_RFH2, MQPSPROP\_MSGPROP. See [Optional parameters \(Change, Copy, and Create Subscription\)](#) for a description of these values.

*PSPProperties* is an input field to the exit.

**Note:** Authorization checks are only performed on the original values of *DestinationQMgrName* and *DestinationQName* before they are passed to the publish exit. No new authorization checks are performed when the exit changes the destination queue, either by changing *DestinationQMgrName* or *DestinationQName*.

## **C language declaration - MQSBC**

```
typedef struct tagMQSBC {
    MQCHAR4    StrucId;           /* Structure identifier */
    MQLONG     Version;          /* Structure version number */
    MQCHAR48   DestinationQMgrName; /* Destination queue manager */
    MQCHAR48   DestinationQName;  /* Destination queue name */
    MQLONG     SubType;          /* Type of subscription */
    MQLONG     SubOptions;        /* Subscription options */
    MQCHAR48   ObjectName;        /* Object name */
    MQCHARV    ObjectString;      /* Object string */
    MQCHARV    SubTopicString;    /* Subscription topic string */
    MQCHARV    SubName;          /* Subscription name */
    MQBYTE24   SubId;            /* Subscription identifier */
    MQCHARV    SelectionString;   /* Subscription selection string */
    MQLONG     SubLevel;         /* Subscription level */
    MQLONG     PSPProperties;     /* Publish/subscribe properties */
} MQSBC;
```

## Channel-exit calls and data structures

This collection of topics provide reference information about the special IBM MQ calls and data structures that you can use when you write channel exit programs.

This information is product-sensitive programming interface information. You can write IBM MQ user exits in the following programming languages:

Platform	Programming languages
IBM MQ for z/OS	Assembler and C (which must conform to the C system programming environment for system exits, described in the <i>z/OS C/C++ Programming Guide</i> .)
IBM MQ for IBM i	ILE C, ILE COBOL, and ILE RPG
All other IBM MQ platforms	C

You can also write user exits in Java for use only with Java and JMS applications. For more information about creating and using channel exits with the IBM MQ classes for Java, see [Using channel exits in IBM MQ classes for Java](#) and for IBM MQ classes for JMS, see [Using channel exits with IBM MQ classes for JMS](#).

You cannot write IBM MQ user exits in TAL or Visual Basic. However, a declaration for the MQCD structure is provided in Visual Basic for use on the MQCONN call from an IBM MQ MQI client program.

In a number of cases in the descriptions that follow, parameters are arrays or character strings with a size that is not fixed. For these parameters, a lowercase "n" is used to represent a numeric constant. When the declaration for that parameter is coded, the "n" must be replaced by the numeric value required. For further information about the conventions used in these descriptions, see the ["Elementary data types"](#) on page 235.

### Data definition files

Data definition files are supplied with IBM MQ for each of the supported programming languages. For details of these files, see [Copy, header, include, and module files](#).

### MQ\_CHANNEL\_EXIT - Channel exit

The MQ\_CHANNEL\_EXIT call describes the parameters that are passed to each of the channel exits called by the Message Channel Agent.

No entry point called MQ\_CHANNEL\_EXIT is provided by the queue manager; the name MQ\_CHANNEL\_EXIT is of no special significance since the names of the channel exits are provided in the channel definition MQCD.

There are five types of channel exit:

- Channel security exit
- Channel message exit
- Channel send exit
- Channel receive exit
- Channel message-retry exit

The parameters are similar for each type of exit, and the description given here applies to all of them, except where specifically noted.

## Syntax

**MQ\_CHANNEL\_EXIT** (*ChannelExitParms*, *ChannelDefinition*, *DataLength*,  
*AgentBufferLength*, *AgentBuffer*, *ExitBufferLength*, *ExitBufferAddr*)

## Parameters

The MQ\_CHANNEL\_EXIT call has the following parameters.

### ChannelExitParms (MQCXP) - input/output

Channel exit parameter block.

This structure contains additional information relating to the invocation of the exit. The exit sets information in this structure to indicate how the MCA proceeds.

### ChannelDefinition (MQCD) - input/output

Channel definition.

This structure contains parameters set by the administrator to control the behavior of the channel.

### DataLength (MQLONG) - input/output

Length of data.

The data depends on the type of exit:

- For a channel security exit, when the exit is invoked this parameter contains the length of any security message in the *AgentBuffer* field, if *ExitReason* is MQXR\_SEC\_MSG. It is zero if there is no message. The exit must set this field to the length of any security message to be sent to its partner if it sets *ExitResponse* to MQXCC\_SEND\_SEC\_MSG or MQXCC\_SEND\_AND\_REQUEST\_SEC\_MSG. The message data is in either *AgentBuffer* or *ExitBufferAddr*.

The content of security messages is the sole responsibility of the security exits.

- For a channel message exit, when the exit is invoked this parameter contains the length of the message (including the transmission queue header). The exit must set this field to the length of the message in either *AgentBuffer* or *ExitBufferAddr* that is to proceed. This must be greater than or equal to the length of the transmission queue header (MQXQH).
- For a channel send or channel receive exit, when the exit is invoked this parameter contains the length of the transmission. The exit must set this field to the length of the transmission in either *AgentBuffer* or *ExitBufferAddr* that is to proceed.

If a security exit sends a message, and there is no security exit at the other end of the channel, or the other end sets an *ExitResponse* of MQXCC\_OK, the initiating exit is re-invoked with MQXR\_SEC\_MSG and a null response (*DataLength* =0).

### AgentBufferLength (MQLONG) - input

Length of agent buffer.

This parameter can be greater than *DataLength* on invocation.

For channel message, send, and receive exits, any unused space on invocation can be used by the exit to expand the data in place. If this is done, the **DataLength** parameter must be set appropriately by the exit.

In the C programming language, this parameter is passed by address.

### AgentBuffer (MQBYTE x AgentBufferLength) - input/output

Agent buffer.

The contents of this parameter depend upon the exit type:

- For a channel security exit, on invocation of the exit it contains a security message if *ExitReason* is MQXR\_SEC\_MSG. To send a security message back, the exit can either use this buffer or its own buffer (*ExitBufferAddr*).
- For a channel message exit, on invocation of the exit this parameter contains:
  - The transmission queue header (MQXQH), which includes the message descriptor (which itself contains the context information for the message), immediately followed by
  - The message data

If the message is to proceed, the exit can do one of the following:

- Leave the contents of the buffer untouched
- Modify the contents in place (returning the new length of the data in *DataLength* ; this must not be greater than *AgentBufferLength*)
- Copy the contents to the *ExitBufferAddr*, making any required changes

Any changes that the exit makes to the transmission queue header are not checked; however, erroneous modifications might mean that the message cannot be put at the destination.

- For a channel send or receive exit, on invocation of the exit this contains the transmission data. The exit can do one of the following:
  - Leave the contents of the buffer untouched
  - Modify the contents in place (returning the new length of the data in *DataLength* ; this must not be greater than *AgentBufferLength*)
  - Copy the contents to the *ExitBufferAddr*, making any required changes

The first 8 bytes of the data must not be changed by the exit.

#### **ExitBufferLength (MQLONG) - input/output**

Length of exit buffer.

On the first invocation of the exit, this parameter is set to zero. Thereafter whatever value is passed back by the exit, on each invocation, is presented to the exit next time it is invoked. The value is not used by the MCA.

**Note:** This parameter must not be used by exits written in programming languages which do not support the pointer data type.

#### **ExitBufferAddr (MQPTR) - input/output**

Address of exit buffer.

This parameter is a pointer to the address of a buffer of storage managed by the exit, where it can choose to return message or transmission data (depending upon the type of exit) to the agent if the buffer of the agent is or might not be large enough, or if it is more convenient for the exit to do so.

On the first invocation of the exit, the address passed to the exit is null. Thereafter whatever address is passed back by the exit, on each invocation, is presented to the exit the next time it is invoked.

If *ExitBufferAddr* is null the data used is taken from the *AgentBuffer* parameter.

If *ExitBufferAddr* is not null the data used is taken from the buffer pointed to by the *ExitBufferAddr* parameter.

**Note:** This parameter must not be used by exits written in programming languages that do not support the pointer data type.

## **C invocation**

```
exitname (&ChannelExitParms, &ChannelDefinition,
          &DataLength, &AgentBufferLength, AgentBuffer,
          &ExitBufferLength, &ExitBufferAddr);
```

The parameters passed to the exit are declared as follows:

```
MQCXP  ChannelExitParms; /* Channel exit parameter block */
MQCD   ChannelDefinition; /* Channel definition */
MQLONG DataLength; /* Length of data */
MQLONG AgentBufferLength; /* Length of agent buffer */
MQBYTE AgentBuffer[n]; /* Agent buffer */
MQLONG ExitBufferLength; /* Length of exit buffer */
MQPTR  ExitBufferAddr; /* Address of exit buffer */
```

## COBOL invocation

```
CALL 'exitname' USING CHANNELEXITPARMS, CHANNELDEFINITION,
                     DATALENGTH, AGENTBUFFERLENGTH, AGENTBUFFER,
                     EXITBUFFERLENGTH, EXITBUFFERADDR.
```

The parameters passed to the exit are declared as follows:

```
** Channel exit parameter block
01 CHANNELEXITPARMS.
   COPY CMQCXPV.
** Channel definition
01 CHANNELDEFINITION.
   COPY CMQCDV.
** Length of data
01 DATALENGTH      PIC S9(9) BINARY.
** Length of agent buffer
01 AGENTBUFFERLENGTH PIC S9(9) BINARY.
** Agent buffer
01 AGENTBUFFER       PIC X(n).
** Length of exit buffer
01 EXITBUFFERLENGTH PIC S9(9) BINARY.
** Address of exit buffer
01 EXITBUFFERADDR    POINTER.
```

## RPG invocation (ILE)

```
C*..1.....2.....3.....4.....5.....6.....7..
C          CALLP      exitname(MQCXP : MQCD : DATLEN :
C                               ABUFL : ABUF : EBUFL :
C                               EBUF)
```

The prototype definition for the call is:

```
D*..1.....2.....3.....4.....5.....6.....7..
Dexitname      PR          EXTPROC('exitname')
D* Channel exit parameter block
D MQCXP                160A
D* Channel definition
D MQCD                1328A
D* Length of data
D DATLEN              10I 0
D* Length of agent buffer
D ABUFL               10I 0
D* Agent buffer
D ABUF                *   VALUE
D* Length of exit buffer
D EBUFL              10I 0
D* Address of exit buffer
D EBUF                *
```

## System/390 assembler invocation

```
CALL EXITNAME, (CHANNELEXITPARMS, CHANNELDEFINITION, DATALENGTH, X
```

```
AGENTBUFFERLENGTH, AGENTBUFFER, EXITBUFFERLENGTH,
EXITBUFFERADDR) X
```

The parameters passed to the exit are declared as follows:

```
CHANNELEXITPARMS  CMQXPA  ,      Channel exit parameter block
CHANNELDEFINITION CMQCDA  ,      Channel definition
DATALENGTH        DS      F      Length of data
AGENTBUFFERLENGTH DS      F      Length of agent buffer
AGENTBUFFER       DS      CL(n)  Agent buffer
EXITBUFFERLENGTH  DS      F      Length of exit buffer
EXITBUFFERADDR    DS      F      Address of exit buffer
```

## Usage notes

1. The function performed by the channel exit is defined by the provider of the exit. The exit, however, must conform to the rules defined here and in the associated control block, the MQCXP.
2. The **ChannelDefinition** parameter passed to the channel exit might be one of several versions. See the *Version* field in the MQCD structure for more information.
3. If the channel exit receives an MQCD structure with the *Version* field set to a value greater than MQCD\_VERSION\_1, the exit must use the *ConnectionName* field in MQCD, in preference to the *ShortConnectionName* field.
4. In general, channel exits are allowed to change the length of message data. This can arise as a result of the exit adding data to the message, or removing data from the message, or compressing or encrypting the message. However, special restrictions apply if the message is a segment that contains only part of a logical message. In particular, there must be no net change in the length of the message as a result of the actions of complementary sending and receiving exits.

For example, it is permissible for a sending exit to shorten the message by compressing it, but the complementary receiving exit must restore the original length of the message by decompressing it, so that there is no net change in the length of the message.

This restriction arises because changing the length of a segment would cause the offsets of later segments in the message to be incorrect, and this would inhibit the ability of the queue manager to recognize that the segments formed a complete logical message.

## MQ\_CHANNEL\_AUTO\_DEF\_EXIT - Channel auto-definition exit

The MQ\_CHANNEL\_AUTO\_DEF\_EXIT call describes the parameters that are passed to the channel auto-definition exit called by the Message Channel Agent.

No entry point called MQ\_CHANNEL\_AUTO\_DEF\_EXIT is provided by the queue manager; the name MQ\_CHANNEL\_AUTO\_DEF\_EXIT is of no special significance because the names of the auto-definition exits are provided in the queue manager.

## Syntax

**MQ\_CHANNEL\_AUTO\_DEF\_EXIT** (*ChannelExitParms*, *ChannelDefinition*)

## Parameters

The MQ\_CHANNEL\_AUTO\_DEF\_EXIT call has the following parameters.

### ChannelExitParms (MQCXP) - input/output

Channel exit parameter block.

This structure contains additional information relating to the invocation of the exit. The exit sets information in this structure to indicate how the MCA proceeds.

### ChannelDefinition (MQCD) - input/output

Channel definition.

This structure contains parameters set by the administrator to control the behavior of channels which are created automatically. The exit sets information in this structure to modify the default behavior set by the administrator.

The MQCD fields listed must not be altered by the exit:

- *ChannelName*
- *ChannelType*
- *StrucLength*
- *Version*

If other fields are changed, the value set by the exit must be valid. If the value is not valid, an error message is written to the error log file or displayed on the console (as appropriate to the environment).

**Attention:** Auto-defined channels created by a channel automatic definition (CHAD) exit cannot set the certificate label, because the TLS handshake has occurred by the time the channel is created. Setting the certificate label in a CHAD exit for inbound channels has no effect.

## C invocation

```
exitname (&ChannelExitParms, &ChannelDefinition);
```

The parameters passed to the exit are declared as follows:

```
MQCXP  ChannelExitParms;  /* Channel exit parameter block */
MQCD   ChannelDefinition; /* Channel definition */
```

## COBOL invocation

```
CALL 'exitname' USING CHANNELEXITPARMS, CHANNELDEFINITION.
```

The parameters passed to the exit are declared as follows:

```
** Channel exit parameter block
01 CHANNELEXITPARMS.
   COPY CMQCXPV.
** Channel definition
01 CHANNELDEFINITION.
   COPY CMQCDV.
```

## RPG invocation (ILE)

```
C*.1.....2.....3.....4.....5.....6.....7..
C          CALLP          exitname(MQCXP : MQCD)
```

The prototype definition for the call is:

```
D*.1.....2.....3.....4.....5.....6.....7..
Dexitname          PR          EXTPROC('exitname')
D* Channel exit parameter block
D MQCXP            160A
D* Channel definition
D MQCD            1328A
```

## System/390 assembler invocation

```
CALL EXITNAME, (CHANNELEXITPARMS, CHANNELDEFINITION)
```

The parameters passed to the exit are declared as follows:

```
CHANNELEXITPARMS  CMQXPA  , Channel exit parameter block  
CHANNELDEFINITION CMQCDA  , Channel definition
```

### Usage notes

1. The function performed by the channel exit is defined by the provider of the exit. The exit, however, must conform to the rules defined here and in the associated control block, the MQCXP.
2. The **ChannelExitParms** parameter passed to the channel auto-definition exit is an MQCXP structure. The version of MQCXP passed depends on the environment in which the exit is running; see the description of the *Version* field in [“MQCXP - Channel exit parameter”](#) on page 1517 for details.
3. The **ChannelDefinition** parameter passed to the channel auto-definition exit is an MQCD structure. The version of MQCD passed depends on the environment in which the exit is running; see the description of the *Version* field in [“MQCD - Channel definition”](#) on page 1477 for details.

### MQXWAIT - Wait in exit

The MQXWAIT call waits for an event to occur. It can be used only from a channel exit on z/OS.

The use of MQXWAIT helps to avoid performance problems that might otherwise occur if a channel exit does something that causes a wait. The event MQXWAIT is waiting on is signaled by an MVS ECB (event control block). The ECB is described in the MQXWD control block description.

 For more information about the use of MQXWAIT and writing channel-exit programs, see [Writing channel exit programs on z/OS](#)

### Syntax

**MQXWAIT** (*Hconn*, *WaitDesc*, *CompCode*, *Reason*)

### Parameters

The MQXWAIT call has the following parameters.

#### **Hconn** (MQHCONN) - input

Connection handle.

This handle represents the connection to the queue manager. The value of *Hconn* was returned by a previous MQCONN call issued in the same or earlier invocation of the exit.

#### **WaitDesc** (MQXWD) - input/output

Wait descriptor.

This parameter describes the event to wait for. See [“MQXWD - Exit wait descriptor”](#) on page 1531 for details of the fields in this structure.

#### **CompCode** (MQLONG) - output

Completion code.

It is one of the following codes:

##### **MQCC\_OK**

Successful completion.

## **MQCC\_FAILED**

Call failed.

### **Reason (MQLONG) - output**

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

#### **MQRC\_NONE**

(0, X'000') No reason to report.

#### **MQRC\_ADAPTER\_NOT\_AVAILABLE**

(2204, X'89C') Adapter not available.

#### **MQRC\_OPTIONS\_ERROR**

(2046, X'7FE') Options not valid or not consistent.

#### **MQRC\_XWAIT\_CANCELED**

(2107, X'83B') MQXWAIT call canceled.

#### **MQRC\_XWAIT\_ERROR**

(2108, X'83C') Invocation of MQXWAIT call not valid.

## **C invocation**

```
MQXWAIT (Hconn, &WaitDesc, &CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHCONN  Hconn;      /* Connection handle */
MQXWD    WaitDesc;  /* Wait descriptor */
MQLONG   CompCode;  /* Completion code */
MQLONG   Reason;    /* Reason code qualifying CompCode */
```

## **System/390 assembler invocation**

```
CALL MQXWAIT,(HCONN,WAITDESC,COMPCODE,REASON)
```

Declare the parameters as follows:

```
HCONN      DS      F  Connection handle
WAITDESC   CMQXWDA ,  Wait descriptor
COMPCODE   DS      F  Completion code
REASON     DS      F  Reason code qualifying COMPCODE
```

## **MQCD - Channel definition**

The MQCD structure contains the parameters which control execution of a channel. It is passed to each channel exit that is called from a Message Channel Agent (MCA).

For more information about channel exits, see [“MQ\\_CHANNEL\\_EXIT - Channel exit” on page 1470](#). The description in this topic relates both to message channels and to MQI channels.

### **Exit name fields**

When an exit is called, the relevant field from *SecurityExit*, *MsgExit*, *SendExit*, *ReceiveExit*, and *MsgRetryExit* contains the name of the exit currently being invoked. The meaning of the name in these fields depends on the environment in which the MCA is running. Except where noted, the name is left-aligned within the field, with no embedded blanks; the name is padded with blanks to the length of the field. In the descriptions that follow, square brackets ([ ]) denote optional information:

## AIX and Linux

The exit name is the name of a dynamically loadable module or library, suffixed with the name of a function residing in that library. The function name must be enclosed in parentheses. The library name can optionally be prefixed with a directory path:

```
[ path ] library ( function )
```

The name is limited to a maximum of 128 characters.

## z/OS

The exit name is the name of a load module that is valid for specification on the EP parameter of the LINK or LOAD macro. The name is limited to a maximum of eight characters.

## Windows

The exit name is the name of a dynamic-link library, suffixed with the name of a function residing in that library. The function name must be enclosed in parentheses. The library name can optionally be prefixed with a directory path and drive:

```
[d:][ path ] library ( function )
```

The name is limited to a maximum of 128 characters.

## IBM i

The exit name is a 10 byte program name followed by a 10 byte library name. If the names are less than 10 bytes long, each name is padded with blanks to make it 10 bytes. The library name can be \*LIBL except when calling a channel auto-definition exit, in which case a fully qualified name is required.

## Changing MQCD fields in a channel exit

A channel exit can change fields in the MQCD. The changed value remains in the MQCD and is passed to any remaining exits in an exit chain and to any conversation sharing the channel instance. The changed MQCD is also used by the MCA for its normal processing during the continuing lifetime of the channel.

The following MQCD fields must not be altered by the exit:

- ChannelName
- ChannelType
- StrucLength
- Version

A channel exit can change fields in the MQCD. However, these changes are not typically acted on, except in the circumstances listed.

## **Fields**

This topic lists all the fields in the MQCD structure and describes each field.

### *BatchDataLimit (MQLONG)*

This field specifies the the limit, in kilobytes, of the amount of data that can be sent through a channel before taking a sync point.

A sync point is taken after the message that caused the limit to be reached has flowed across the channel.

The batch is terminated when one of the following conditions is met:

- **BatchSize** messages have been sent.
- **BatchDataLimit** bytes have been sent.
- The transmission queue is empty and **BatchInterval** is exceeded.

The value must be in the range 0 - 999999. The default value is 5000.

A value of zero in this attribute means that no data limit is applied to batches over this channel.

This parameter only applies to channels with a *ChannelType* of MQCHT\_SENDER, MQCHT\_SERVER, MQCHT\_CLUSRCVR, or MQCHT\_CLUSSDR.

This is an input field to the exit. The field is not present if *Version* is less than MQCD\_VERSION\_11.

### *BatchHeartbeat (MQLONG)*

This field specifies the time interval that is used to trigger a batch heartbeat for the channel.

Batch heartbeating allows sender channels to determine whether the remote channel instance is still active before going indoubt. A batch heartbeat occurs if a sender channel has not communicated with the remote channel instance within the specified time interval.

The value is in the range 0 through 999 999; the units are milliseconds. A value of zero indicates that batch heartbeating is not enabled.

This field is relevant only for channels that have a *ChannelType* of MQCHT\_SENDER, MQCHT\_SERVER, MQCHT\_CLUSSDR, or MQCHT\_CLUSRCVR.

This is an input field to the exit. The field is not present if *Version* is less than MQCD\_VERSION\_7.

### *BatchInterval (MQLONG)*

This field specifies the approximate time in milliseconds that a channel keeps a batch open, if fewer than *BatchSize* messages have been transmitted in the current batch.

If *BatchInterval* is greater than zero, the batch is terminated by whichever of the following events occur first:

- *BatchSize* messages have been sent, or
- *BatchInterval* milliseconds have elapsed since the start of the batch.

If *BatchInterval* is zero, the batch is terminated by whichever of the following events occur first:

- *BatchSize* messages have been sent, or
- the transmission queue becomes empty.

*BatchInterval* must be in the range zero through 999 999 999.

This field is relevant only for channels with a *ChannelType* of MQCHT\_SENDER, MQCHT\_SERVER, MQCHT\_CLUSSDR, or MQCHT\_CLUSRCVR.

This is an input field to the exit. The field is not present when *Version* is less than MQCD\_VERSION\_4.

#### *BatchSize (MQLONG)*

This field specifies the maximum number of messages that can be sent through a channel before synchronizing the channel.

This field is not relevant for channels with a *ChannelType* of MQCHT\_SVRCONN or MQCHT\_CLNTCONN.

#### *CertificateLabel (MQCHAR64)*

This field gives details of the certificate label being used.

IBM MQ initializes the default value for the *CertificateLabel* field as blanks.

This is interpreted at runtime as the default value, and is backwards compatible.

For example, specifying a MQCD version less than 11, or using the default value of blanks for the *CertificateLabel* field, means that this field is ignored.

The length of this field is given by MQ\_CERT\_LABEL\_LENGTH.

#### *ChannelMonitoring (MQLONG)*

This field specifies the current level of monitoring data collection for the channel.

This field is not relevant for channels with a *ChannelType* of MQCHT\_CLNTCONN.

It is one of the following values:

- MQMON\_OFF
- MQMON\_LOW
- MQMON\_MEDIUM
- MQMON\_HIGH

This is an input field to the exit. It is not present if *Version* is less than MQCD\_VERSION\_8.

#### *ChannelName (MQCHAR20)*

This field specifies the channel definition name.

There must be a channel definition of the same name at the remote machine to be able to communicate.

The name must use only the characters:

- Uppercase A-Z
- Lowercase a-z
- Numerics 0-9
- Period (.)
- Forward slash (/)
- Underscore (\_)
- Percent sign (%)

and be padded to the right with blanks. Leading or embedded blanks are not allowed.

The length of this field is given by MQ\_CHANNEL\_NAME\_LENGTH.

#### *ChannelStatistics (MQLONG)*

This field specifies the current level of statistics data collection for the channel.

This field is not relevant for channels with a *ChannelType* of MQCHT\_CLNTCONN or MQCHT\_SVRCONN.

It is one of the following values:

- MQMON\_OFF
- MQMON\_LOW
- MQMON\_MEDIUM
- MQMON\_HIGH

This is an input field to the exit. It is not present if *Version* is less than MQCD\_VERSION\_8.

*ChannelType (MQLONG)*

This field specifies the type of channel.

It is one of the following values:

**MQCHT\_SENDER**

Sender.

**MQCHT\_SERVER**

Server.

**MQCHT\_RECEIVER**

Receiver.

**MQCHT\_REQUESTER**

Requester.

**MQCHT\_CLNTCONN**

Client connection.

**MQCHT\_SVRCONN**

Server-connection (for use by clients).

**MQCHT\_CLUSSDR**

Cluster sender.

**MQCHT\_CLUSRCVR**

Cluster receiver.

*ClientChannelWeight (MQLONG)*

This field specifies a weighting to influence which client-connection channel definition is used.

The ClientChannelWeight attribute is used so that client channel definitions can be selected at random based on their weighting when more than one suitable definition is available. When a client issues an MQCONN requesting connection to a queue manager group, by specifying a queue manager name starting with an asterisk, and more than one suitable channel definition is available in the client channel definition table (CCDT), the definition to use is randomly selected based on the weighting, with any applicable ClientChannelWeight(0) definitions selected first in alphabetical order.

Specify a value in the range 0 - 99. The default is 0.

A value of 0 indicates that no load balancing is performed and applicable definitions are selected in alphabetical order. To enable load balancing choose a value in the range 1 - 99 where 1 is the lowest weighting and 99 is the highest. The distribution of messages between two or more channels with non-zero weightings is proportional to the ratio of those weightings. For example, three channels with ClientChannelWeight values of 2, 4, and 14 are selected approximately 10%, 20%, and 70% of the time. This distribution is not guaranteed.

This attribute is valid for the client-connection channel type only.

This is an input field to the exit. The field is not present if *Version* is less than MQCD\_VERSION\_9.

*ClusterPtr (MQPTR)*

This field specifies the address a list of cluster names.

If *ClustersDefined* is greater than zero, this address is the address of a list of cluster names. The channel belongs to each cluster listed.

This field is relevant only for channels with a *ChannelType* of MQCHT\_CLUSSDR or MQCHT\_CLUSRCVR.

This is an input field to the exit. The field is not present if *Version* is less than MQCD\_VERSION\_5.

*ClustersDefined (MQLONG)*

This field specifies the number of clusters to which the channel belongs.

This field is the number of cluster names pointed to by *ClusterPtr*. It is zero or greater.

This field is relevant only for channels with a *ChannelType* of MQCMT\_CLUSSDR or MQCMT\_CLUSRCVR.

This is an input field to the exit. The field is not present if *Version* is less than MQCD\_VERSION\_5.

#### *CLWLChannelPriority (MQLONG)*

This field specifies the cluster workload channel priority.

The workload manager choose algorithm selects a destination with the highest priority from the set of destinations selected based on rank. If there are two possible destination queue managers, this attribute can be used to make one queue manager failover onto the other queue manager. All the messages go to the queue manager with the highest priority until that ends, then the messages go to the queue manager with the next highest priority.

The value is in the range 0 through 9. The default is 0.

This is an input field to the exit. The field is not present if *Version* is less than MQCD\_VERSION\_8.

For further information, see [Configuring a queue manager cluster](#).

#### *CLWLChannelRank (MQLONG)*

This field specifies the cluster workload channel rank.

The workload manager choose algorithm selects a destination with the highest rank. When the final destination is a queue manager on a different cluster, you can set the rank of intermediate gateway queue managers (at the intersection of neighboring clusters) so the choose algorithm correctly chooses a destination queue manager nearer the final destination.

The value is in the range 0 through 9. The default is 0.

This is an input field to the exit. The field is not present if *Version* is less than MQCD\_VERSION\_8.

For further information, see [Configuring a queue manager cluster](#).

#### *CLWLChannelWeight (MQLONG)*

This field specifies the cluster workload channel weight.

Cluster workload channel weight.

The workload manager choose algorithm uses the "weight" attribute of the channel to skew the destination choice so that more messages can be sent to a particular machine. For example, you can give a channel on a large UNIX server a larger "weight" than another channel on small desktop PC, and the choose algorithm chooses the UNIX server more frequently than the PC.

The value is in the range 1 through 99. The default is 50.

This is an input field to the exit. The field is not present if *Version* is less than MQCD\_VERSION\_8.

For further information, see [Configuring a queue manager cluster](#).

#### *ConnectionAffinity (MQLONG)*

This field specifies whether client applications that connect multiple times using the same queue manager name, use the same client channel.

Use this attribute when multiple applicable channel definitions are available.

The value is one of the following:

#### **MQCAFTY\_PREFERRED**

The first connection in a process reading a client channel definition table (CCDT) creates a list of applicable definitions based on the weighting with any applicable CLNTWGHT(0) definitions first and in alphabetical order. Each connection in the process attempts to connect using the first definition in the list. If a connection is unsuccessful the next definition is used. Unsuccessful definitions with CLNTWGHT values other than 0 are moved to the end of the list. CLNTWGHT(0) definitions remain at the start of the list and are selected first for each connection.

Each client process with the same host name always creates the same list.

For client applications written in C, C++, or the .NET programming framework (including fully managed .NET) the list is updated if the CCDT has been modified since the list was created.

This value is the default value.

### **MQCAFTY\_NONE**

The first connection in a process reading a CCDT creates a list of applicable definitions. All connections in a process select an applicable definition based on the weighting with any applicable CLNTWGHT(0) definitions selected first in alphabetical order.

For client applications written in C, C++, or the .NET programming framework (including fully managed .NET) the list is updated if the CCDT has been modified since the list was created.

This attribute is valid for the client-connection channel type only.

This is an input field to the exit. The field is not present if *Version* is less than MQCD\_VERSION\_9.

#### *ConnectionName (MQCHAR264)*

This field specifies the connection name for the channel.

For cluster-receiver channels (when specified) CONNAME relates to the local queue manager, and for other channels it relates to the target queue manager. The value you specify depends on the transmission protocol (*TransportType*) to be used:

- For MQXPT\_LU62, it is the fully-qualified name of the partner Logical Unit.
- For MQXPT\_NETBIOS, it is the NetBIOS name defined on the remote machine.
- For MQXPT\_TCP, it is either the host name, the network address of the remote machine specified in IPv4 dotted decimal or IPv6 hexadecimal format, or the local machine for cluster-receiver channels.
- For MQXPT\_SPX, it is an SPX-style address comprising a 4 byte network address, a 6 byte node address, and a 2 byte socket number.

When defining a channel, this field is not relevant for channels with a *ChannelType* of MQCHT\_SVRCONN or MQCHT\_RECEIVER. However, when the channel definition is passed to an exit, this field contains the address of the partner, whatever the channel type.

The length of this field is given by MQ\_CONN\_NAME\_LENGTH. This field is not present if *Version* is less than MQCD\_VERSION\_2.

#### *DataConversion (MQLONG)*

This field specifies whether the sending message channel agent attempts conversion of the application message data if the receiving message channel agent is unable to perform this conversion.

This field applies only to messages that are not segments of logical messages; the MCA never attempts to convert messages which are segments.

This field is relevant only for channels with a *ChannelType* of MQCHT\_SENDER, MQCHT\_SERVER, MQCHT\_CLUSSDR, or MQCHT\_CLUSRCVR. It is one of the following:

#### **MQCDC\_SENDER\_CONVERSION**

Conversion by sender.

#### **MQCDC\_NO\_SENDER\_CONVERSION**

No conversion by sender.

#### *DefReconnect (MQLONG)*

The DefReconnect channel attribute sets the default reconnection attribute value for a client connection channel.

The default automatic client reconnection option. You can configure an IBM MQ MQI client to automatically reconnect a client application. The IBM MQ MQI client tries to reconnect to a queue manager after a connection failure. It tries to reconnect without the application client issuing an MQCONN or MQCONNX MQI call.

Reconnection is an MQCONN option. By using the DefReconnect channel attribute you can add reconnection behavior to existing applications that use MQCONN. You can also change the reconnection behavior of applications that use MQCONN.

You can also set the DefRecon value from the mqclient.ini file to set or modify reconnection behavior. The DefRecon value from the mqclient.ini file takes precedence over the DefReconnect channel attribute.

## Syntax

**DefReconnect** (MQRCN\_NO (default) |MQRCN\_YES|MQRCN\_Q\_MGR|MQRCN\_DISABLED)

## Parameters

### MQRCN\_NO

MQRCN\_NO is the default value.

Unless overridden by **MQCONN**, the client is not reconnected automatically.

### MQRCN\_YES

Unless overridden by **MQCONN**, the client reconnects automatically.

### MQRCN\_Q\_MGR

Unless overridden by **MQCONN**, the client reconnects automatically, but only to the same queue manager. The QMGR option has the same effect as MQCNO\_RECONNECT\_Q\_MGR.

### MQRCN\_DISABLED

Reconnection is disabled, even if requested by the client program using the **MQCONN** MQI call.

Automatic client reconnection is not supported by IBM MQ classes for Java.

<i>Table 822. Automatic reconnection depends on the values set in the application and in the channel definition</i>				
<b>DefReconnect</b>	<b>Reconnection options set in the application</b>			
	MQCNO_RECONNE CT	MQCNO_RECONNE CT_Q_MGR	MQCNO_RECONNE CT_AS_DEF	MQCNO_RECONNE CT_DISABLED
MQRCN_NO	YES	QMGR	NO	NO
MQRCN_YES	YES	QMGR	YES	NO
MQRCN_Q_MGR	YES	QMGR	QMGR	NO
MQRCN_DISABLED	NO	NO	NO	NO

[“Options \(MQLONG\) for MQCNO” on page 322](#)

Options that control the action of MQCONN.

*Desc (MQCHAR64)*

This field can be used for descriptive commentary.

The content of the field is of no significance to Message Channel Agents. However, it must contain only characters that can be displayed. It cannot contain any null characters; if necessary, it is padded to the right with blanks. In a DBCS installation, the field can contain DBCS characters (subject to a maximum field length of 64 bytes).

**Note:** If this field contains characters that are not in the character set of the queue manager (as defined by the **CodedCharSetId** queue manager attribute), those characters might be translated incorrectly if this field is sent to another queue manager.

The length of this field is given by MQ\_CHANNEL\_DESC\_LENGTH.

#### *DiscInterval (MQLONG)*

This field specifies the maximum time in seconds for which the channel waits for a message to arrive on the transmission queue, before terminating the channel.

In other words, it specifies the disconnect interval.

The A value of zero causes the MCA to wait indefinitely.

For server-connection channels using the TCP protocol, the interval represents the client inactivity disconnect value, specified in seconds. If a server-connection has received no communication from its partner client for this duration, it terminates the connection. The server-connection inactivity interval only applies between IBM MQ API calls from a client, so no client is disconnected during a long-running MQGET with wait call.

This attribute is not applicable for server-connection channels using protocols other than TCP.

This field is relevant only for channels with a *ChannelType* of MQCHT\_SENDER, MQCHT\_SERVER, MQCHT\_CLUSSDR, MQCHT\_CLUSRCVR, or MQCHT\_SVRCONN.

#### *ExitDataLength (MQLONG)*

This field specifies length in bytes of each of the user data items in the lists of exit user data items addressed by the *MsgUserDataPtr*, *SendUserDataPtr*, and *ReceiveUserDataPtr* fields.

This length is not necessarily the same as MQ\_EXIT\_DATA\_LENGTH.

This is an input field to the exit. The field is not present if *Version* is less than MQCD\_VERSION\_4.

#### *ExitNameLength (MQLONG)*

This field specifies the length in bytes of each of the names in the lists of exit names addressed by the *MsgExitPtr*, *SendExitPtr*, and *ReceiveExitPtr* fields.

This length is not necessarily the same as MQ\_EXIT\_NAME\_LENGTH.

This is an input field to the exit. The field is not present if *Version* is less than MQCD\_VERSION\_4.

#### *HdrCompList [2] (MQLONG)*

This field specifies the list of header data compression techniques which are supported by the channel.

The list contains one or more of the following values:

#### **MQCOMPRESS\_NONE**

No header data compression is performed.

#### **MQCOMPRESS\_SYSTEM**

Header data compression is performed.

#### **MQCOMPRESS\_NOT\_AVAILABLE**

Unused values in the list are set to this value.

This is an input field to the exit. The field is not present if *Version* is less than MQCD\_VERSION\_8.

#### *HeartbeatInterval (MQLONG)*

This field specifies the time in seconds between heartbeat flows.

The interpretation of this field depends on the channel type, as follows:

- For a channel type of MQCHT\_SENDER, MQCHT\_SERVER, MQCHT\_RECEIVER, MQCHT\_REQUESTER, MQCHT\_CLUSSDR, or MQCHT\_CLUSRCVR, this field is the time in seconds between heartbeat flows passed from the sending MCA when there are no messages on the transmission queue. This gives the receiving MCA the opportunity to quiesce the channel. To be useful, *HeartbeatInterval* must be less than *DiscInterval*.

- For a channel type of MQCHT\_CLNTCONN or MQCHT\_SVRCONN with the MQCD Sharing Conversations field set to zero, this field is the time in seconds between heartbeat flows passed from the server MCA when that MCA has issued an MQGET call with the MQGMO\_WAIT option on behalf of a client application. This allows the server MCA to handle situations where the client connection fails during an MQGET with MQGMO\_WAIT.
- For a channel type of MQCHT\_CLNTCONN or MQCHT\_SVRCONN with the MQCD Sharing Conversations field set to a non-zero value, this field is the time in seconds between heartbeat flow when there are no data flows sent or received. This allows the channel to be quiesced efficiently.

The value is in the range 0 through 999 999. The value that is used is the larger of the values specified at the sending side and receiving side unless a value of 0 is specified at either side, in which case no heartbeat exchange occurs.

This is an input field to the exit. The field is not present if *Version* is less than MQCD\_VERSION\_4.

#### *KeepAliveInterval (MQLONG)*

This field specifies the value passed to the communications stack for keepalive timing for the channel.

The value is applicable for the TCP/IP and SPX communications protocols, though not all implementations support this parameter.

The value is in the range 0 through 99 999; the units are seconds. A value of zero indicates that channel keepalive is not enabled, although keepalive might still occur if TCP/IP keepalive (rather than channel keepalive) is enabled. The following special value is also valid:

#### **MQKAI\_AUTO**

Automatic.

This value indicates that the keepalive interval is calculated from the negotiated heartbeat interval, as follows:

- If the negotiated heartbeat interval is greater than zero, the keepalive interval that is used is the heartbeat interval plus 60 seconds.
- If the negotiated heartbeat interval is zero, the keepalive interval that is used is zero.
- On z/OS, TCP/IP keepalive occurs when TCPKEEP(YES) is specified on the queue manager object.
- In other environments, TCP/IP keepalive occurs when the **KEEPALIVE=YES** parameter is specified in the TCP stanza in the distributed queuing configuration file.

This field is relevant only for channels that have a *TransportType* of MQXPT\_TCP or MQXPT\_SPX.

This is an input field to the exit. The field is not present if *Version* is less than MQCD\_VERSION\_7.

#### *LocalAddress (MQCHAR48)*

This field specifies the local TCP/IP address defined for the channel for outbound communications.

This field is blank if no specific address is defined for outbound communications. The address can optionally include a port number or range of port numbers. The format of this address is:

```
[ip-addr][ (low-port[, high-port]) ]
```

where square brackets ([ ]) denote optional information, *ip-addr* is specified in IPv4 dotted decimal, IPv6 hexadecimal, or alphanumeric form, and *low-port* and *high-port* are port numbers enclosed in parentheses. All are optional.

A specific IP address, port, or port range for outbound communications is useful in recovery scenarios where a channel is restarted on a different TCP/IP stack.

*LocalAddress* is similar in form to *ConnectionName*, but must not be confused with it. *LocalAddress* specifies the characteristics of the local communications, whereas *ConnectionName* specifies how to reach a remote queue manager.

From IBM MQ 9.3.0, the Java Message Queuing Interface (JMQUI) has been updated to ensure that the local address field is set on an MQCD object after a channel instance has been created and is

connected to a queue manager. This means that when a channel exit written in Java calls the method `MQCD.getLocalAddress()`, the method returns the local address that the channel instance is using. Before IBM MQ 9.3.0, the channel security exit was unable to access the local address being used by the channel instance and the method `MQCD.getLocalAddress()` returned null.

This field is relevant only for channels with a *TransportType* of `MQXPT_TCP`, and a *ChannelType* of `MQCHT_SENDER`, `MQCHT_SERVER`, `MQCHT_REQUESTER`, `MQCHT_CLNTCONN`, `MQCHT_CLUSSDR`, or `MQCHT_CLUSRCVR`.

The length of this field is given by `MQ_LOCAL_ADDRESS_LENGTH`. This field is not present if *Version* is less than `MQCD_VERSION_7`.

#### *LongMCAUserIdLength (MQLONG)*

This field specifies the length in bytes of the full MCA user identifier pointed to by *LongMCAUserIdPtr*.

This field is not relevant for channels with a *ChannelType* of `MQCHT_CLNTCONN`.

This is an input/output field to the exit. The field is not present if *Version* is less than `MQCD_VERSION_6`.

#### *LongMCAUserIdPtr (MQPTR)*

This field specifies the address of the long MCA user identifier.

If *LongMCAUserIdLength* is greater than zero, this field is the address of the full MCA user identifier. The length of the full identifier is given by *LongMCAUserIdLength*. The first 12 bytes of the MCA user identifier are also contained in the field *MCAUserIdentifier*.

See the description of the *MCAUserIdentifier* field for details of the MCA user identifier.

This field is not relevant for channels with a *ChannelType* of `MQCHT_SDR`, `MQCHT_SVR`, `MQCHT_CLNTCONN`, or `MQCHT_CLUSSDR`.

This is an input/output field to the exit. The field is not present if *Version* is less than `MQCD_VERSION_6`.

#### *LongRemoteUserIdLength (MQLONG)*

This field specifies the length in bytes of the full remote user identifier pointed to by *LongRemoteUserIdPtr*.

This field is relevant only for channels with a *ChannelType* of `MQCHT_CLNTCONN` or `MQCHT_SVRCONN`.

This is an input field to the exit. The field is not present if *Version* is less than `MQCD_VERSION_6`.

#### *LongRemoteUserIdPtr (MQPTR)*

This field specifies the address of the long remote user identifier.

If *LongRemoteUserIdLength* is greater than zero, this flag is the address of the full remote user identifier. The length of the full identifier is given by *LongRemoteUserIdLength*. The first 12 bytes of the remote user identifier are also contained in the field *RemoteUserIdentifier*.

See the description of the *RemoteUserIdentifier* field for details of the remote user identifier.

This field is relevant only for channels with a *ChannelType* of `MQCHT_CLNTCONN` or `MQCHT_SVRCONN`.

This is an input field to the exit. The field is not present if *Version* is less than `MQCD_VERSION_6`.

#### *LongRetryCount (MQLONG)*

This field specifies the count used after the count specified by the *ShortRetryCount* has been exhausted.

It specifies the maximum number of further attempts that are made to connect to the remote machine, at intervals specified by *LongRetryInterval*, before logging an error to the operator.

This field is relevant only for channels with a *ChannelType* of `MQCHT_SENDER`, `MQCHT_SERVER`, `MQCHT_CLUSSDR`, or `MQCHT_CLUSRCVR`.

#### *LongRetryInterval (MQLONG)*

This field specifies the maximum number of seconds to wait before reattempting connection to the remote machine.

The interval between retries can be extended if the channel has to wait to become active.

This field is relevant only for channels with a *ChannelType* of MQCHT\_SENDER, MQCHT\_SERVER, MQCHT\_CLUSSDR, or MQCHT\_CLUSRCVR.

#### *MaxInstances (MQLONG)*

This field specifies the maximum number of simultaneous instances of an individual server-connection channel that can be started.

This field is used only on server-connection channels.

The field can have a value in the range 0 - 999 999 999. A value of zero prevents all client access.

The default value of this field is 999 999 999.

If the value of this field is reduced to a number that is less than the number of instances of the server-connection channel that are currently running, then those running instances are not affected. However, new instances cannot start until sufficient existing instances have ceased to run so that the number of currently running instances is less than the value of the field.

#### *MaxInstancesPerClient (MQLONG)*

This field specifies the maximum number of simultaneous instances of an individual server-connection channel that can be started from a single client.

In this context, connections that originate from the same remote network address are regarded as coming from the same client.

This field is used only on server-connection channels.

The field can have a value in the range 0 - 999 999 999. A value of zero prevents all client access.

The default value of this field is 999 999 999.

If the value of this field is reduced to a number that is less than the number of instances of the server-connection channel that are currently running from individual clients, then those running instances are not affected. However, new instances from any of those clients cannot start until sufficient existing instances have ceased to run such that the number of currently running instances, originating from the client attempting to start a new one, is less than the value of the field.

#### *MaxMsgLength (MQLONG)*

This field specifies the maximum message length that can be transmitted on the channel.

This is compared with the value for the remote channel and the actual maximum is the lower of the two values.

#### *MCAName (MQCHAR20)*

This field is a reserved field.

The value of this field is blank.

The length of this field is given by MQ\_MCA\_NAME\_LENGTH.

#### *MCASecurityId (MQBYTE40)*

This field specifies the security identifier for the MCA.

This field is not relevant for channels with a *ChannelType* of MQCHT\_CLNTCONN.

The following special value indicates that there is no security identifier:

## **MQSID\_NONE**

No security identifier specified.

The value is binary zero for the length of the field.

For the C programming language, the constant `MQSID_NONE_ARRAY` is also defined; this constant has the same value as `MQSID_NONE`, but is an array of characters instead of a string.

This is an input/output field to the exit. The length of this field is given by `MQ_SECURITY_ID_LENGTH`. This field is not present if *Version* is less than `MQCD_VERSION_6`.

## *MCAType (MQLONG)*

This field specifies the type of message channel agent program.

This field is relevant only for channels with a *ChannelType* of `MQCHT_SENDER`, `MQCHT_SERVER`, `MQCHT_REQUESTER`, `MQCHT_CLUSSDR`, or `MQCHT_CLUSRCVR`.

The value is one of the following:

## **MQMCAT\_PROCESS**

Process.

The message channel agent runs as a separate process.

## **MQMCAT\_THREAD**

Thread (Multiplatforms).

The message channel agent runs as a separate thread.

This field is not present when *Version* is less than `MQCD_VERSION_2`.

## *MCAUserIdentifier (MQCHAR12)*

This field specifies the user identifier for the message channel agent (MCA).

This field uses the first 12 bytes of the MCA user identifier, and can be set by a security agent.

There are two fields that contain the MCA user identifier:

- *MCAUserIdentifier* contains the first 12 bytes of the MCA user identifier, and is padded with blanks if the identifier is shorter than 12 bytes. *MCAUserIdentifier* can be blank.
- *LongMCAUserIdPtr* points to the full MCA user identifier, which can be longer than 12 bytes. Its length is given by *LongMCAUserIdLength*. The full identifier contains no trailing blanks, and is not null-terminated. If the identifier is blank, *LongMCAUserIdLength* is zero, and the value of *LongMCAUserIdPtr* is undefined.

**Note:** *LongMCAUserIdPtr* is not present if *Version* is less than `MQCD_VERSION_6`.

If the MCA user identifier is nonblank, it specifies the user identifier to be used by the message channel agent for authorization to access IBM MQ resources. For channel types `MQCHT_REQUESTER`, `MQCHT_RECEIVER`, and `MQCHT_CLUSRCVR`, if *PutAuthority* is `MQPA_DEFAULT` this is the user identifier used for authorization checks for the put operation to destination queues.

If the MCA user identifier is blank, the message channel agent uses its default user identifier.

The MCA user identifier can be set by a security exit to indicate the user identifier that the message channel agent must use. The exit can change either *MCAUserIdentifier*, or the string pointed at by *LongMCAUserIdPtr*. If both are changed but differ from each other, the MCA uses *LongMCAUserIdPtr* in preference to *MCAUserIdentifier*. If the exit changes the length of the string addressed by *LongMCAUserIdPtr*, *LongMCAUserIdLength* must be set correspondingly. If the exit increases the length of the identifier, the exit must allocate storage of the required length, set that storage to the required identifier, and place the address of that storage in *LongMCAUserIdPtr*. The exit is responsible for freeing that storage when the exit is later invoked with the `MQXR_TERM` reason.

For channels with a *ChannelType* of `MQCHT_SVRCONN`, if *MCAUserIdentifier* in the channel definition is blank, any user identifier transferred from the client is copied into it. This user identifier (after any modification by the security exit at the server) is the one which the client application is assumed to be running under.

The MCA user identifier is not relevant for channels with a *ChannelType* of MQCHT\_SDR, MQCHT\_SVR, MQCHT\_CLNTCONN, MQCHT\_CLUSSDR.

This is an input/output field to the exit. The length of this field is given by MQ\_USER\_ID\_LENGTH. This field is not present when *Version* is less than MQCD\_VERSION\_2.

#### *ModeName (MQCHAR8)*

This field specifies the LU 6.2 mode name.

This field is relevant only if the transmission protocol (*TransportType*) is MQXPT\_LU62, and the *ChannelType* is not MQCHT\_SVRCONN or MQCHT\_RECEIVER.

This field is always blank. The information is contained in the communications Side Object instead.

The length of this field is given by MQ\_MODE\_NAME\_LENGTH.

#### *MsgCompList [16] (MQLONG)*

This field specifies the list of message data compression techniques which are supported by the channel.

The list contains one or more of the following values:

#### **MQCOMPRESS\_NONE**

No message data compression is performed.

#### **MQCOMPRESS\_RLE**

Message data compression is performed using run-length encoding.

#### **MQCOMPRESS\_ZLIBFAST**

Message data compression is performed using the zlib compression technique. A fast compression time is preferred.

#### **MQCOMPRESS\_ZLIBHIGH**

Message data compression is performed using the zlib compression technique. A high level of compression is preferred.

#### **LZ4FAST**

Message data compression is performed using LZ4 encoding with speed prioritized.

#### **LZ4HIGH**

Message data compression is performed using LZ4 encoding with compression prioritized.

#### **MQCOMPRESS\_ANY**

Any compression technique supported by the queue manager can be used for message compression. MQCOMPRESS\_ANY is only valid for receiver, requester, and server-connection channels.

#### **MQCOMPRESS\_NOT\_AVAILABLE**

Unused values in the list are set to this value.

This is an input field to the exit. The field is not present if *Version* is less than MQCD\_VERSION\_8.

#### *MsgExit (MQCHARn)*

This field specifies the channel message exit name.

If this name is nonblank, the exit is called at the following times:

- Immediately after a message has been retrieved from the transmission queue (sender or server), or immediately before a message is put to a destination queue (receiver or requester).

The exit is given the entire application message and transmission queue header for modification.

- At initialization and termination of the channel.

This field is not relevant for channels with a *ChannelType* of MQCHT\_SVRCONN or MQCHT\_CLNTCONN; a message exit is never invoked for such channels.

See “MQCD - Channel definition” on page 1477 for a description of the content of this field in various environments.

The length of this field is given by MQ\_EXIT\_NAME\_LENGTH.

**Note:** The value of this constant is environment-specific.

*MsgExitPtr (MQPTR)*

This field specifies the address of the first *MsgExit* field.

If *MsgExitsDefined* is greater than zero, this address is the address of the list of names of each channel message exit in the chain.

Each name is in a field of length *ExitNameLength*, padded to the right with blanks. There are *MsgExitsDefined* fields adjoining one another - one for each exit.

Any changes made to these names by an exit are preserved, although the message channel exit takes no explicit action - it does not change which exits are invoked.

If *MsgExitsDefined* is zero, this field is the null pointer.

On platforms where the programming language does not support the pointer data type, this field is declared as a byte string of the appropriate length.

This is an input field to the exit. The field is not present if *Version* is less than MQCD\_VERSION\_4.

*MsgExitsDefined (MQLONG)*

This field specifies the number of channel message exits defined in the chain.

It is greater than or equal to zero.

This is an input field to the exit. The field is not present if *Version* is less than MQCD\_VERSION\_4.

*MsgRetryCount (MQLONG)*

This field specifies the number of times MCA tries to put the message, after the first attempt has failed.

This field indicates the number of times that the MCA tries the open or put operation, if the first MQOPEN or MQPUT fails with completion code MQCC\_FAILED. The effect of this attribute depends on whether *MsgRetryExit* is blank or nonblank:

- If *MsgRetryExit* is blank, the **MsgRetryCount** attribute controls whether the MCA attempts retries. If the attribute value is zero, no retries are attempted. If the attribute value is greater than zero, the retries are attempted at intervals given by the **MsgRetryInterval** attribute.

Retries are attempted only for the following reason codes:

- MQRC\_PAGESET\_FULL
- MQRC\_PUT\_INHIBITED
- MQRC\_Q\_FULL

For other reason codes, the MCA proceeds immediately to its normal failure processing, without retrying the failing message.

- If *MsgRetryExit* is nonblank, the **MsgRetryCount** attribute does not affect the MCA; instead it is the message retry exit that determines how many times the retry is attempted, and at what intervals; the exit is invoked even if the **MsgRetryCount** attribute is zero.

The **MsgRetryCount** attribute is made available to the exit in the MQCD structure, but the exit is not required to honor it - retries continue indefinitely until the exit returns MQXCC\_SUPPRESS\_FUNCTION in the *ExitResponse* field of MQCXP.

This field is relevant only for channels with a *ChannelType* of MQCHT\_REQUESTER, MQCHT\_RECEIVER, or MQCHT\_CLUSRCVR.

This field is not present when *Version* is less than MQCD\_VERSION\_3.

*MsgRetryExit (MQCHARn)*

This field specifies the channel message retry exit name.

The message retry exit is an exit that is invoked by the MCA when the MCA receives a completion code of MQCC\_FAILED from an MQOPEN or MQPUT call. The purpose of the exit is to specify a time interval for

which the MCA waits before trying the MQOPEN or MQPUT operation again. Alternatively, the exit can be set to not try the operation again.

The exit is invoked for all reason codes that have a completion code of MQCC\_FAILED - the settings of the exit determine which reason codes it wants the MCA to try again, for how many attempts, and at what time intervals.

When the operation is not to be attempted any more, the MCA performs its normal failure processing; this processing includes generating an exception report message (if specified by the sender), and either placing the original message on the dead-letter queue or discarding the message (according to whether the sender specified MQRO\_DEAD\_LETTER\_Q or MQRO\_DISCARD\_MSG). Failures involving the dead-letter queue (for example, dead-letter queue full) do not cause the message-retry exit to be invoked.

If the exit name is nonblank, the exit is called at the following times:

- Immediately before performing the wait before trying to deliver a message again
- At initialization and termination of the channel

See “MQCD - Channel definition” on page 1477 for a description of the content of this field in various environments.

This field is relevant only for channels with a *ChannelType* of MQCHT\_REQUESTER, MQCHT\_RECEIVER, or MQCHT\_CLUSRCVR.

The length of this field is given by MQ\_EXIT\_NAME\_LENGTH.

**Note:** The value of this constant is environment-specific.

This field is not present when *Version* is less than MQCD\_VERSION\_3.

#### *MsgRetryInterval (MQLONG)*

This field specifies the minimum interval in milliseconds after which the open or put operation is retried.

The effect of this attribute depends on whether *MsgRetryExit* is blank or nonblank:

- If *MsgRetryExit* is blank, the **MsgRetryInterval** attribute specifies the minimum period that the MCA waits before retrying a message, if the first MQOPEN or MQPUT fails with completion code MQCC\_FAILED. A value of zero means that the retry will be performed as soon as possible after the previous attempt. Retries are performed only if *MsgRetryCount* is greater than zero.

This attribute is also used as the wait time if the message-retry exit returns an invalid value in the *MsgRetryInterval* field in MQCXP.

- If *MsgRetryExit* is not blank, the **MsgRetryInterval** attribute does not affect the MCA; instead it is the message-retry exit which determines how long the MCA waits. The **MsgRetryInterval** attribute is made available to the exit in the MQCD structure, but the exit is not required to honor it.

The value is in the range 0 through 999 999 999.

This field is relevant only for channels with a *ChannelType* of MQCHT\_REQUESTER, MQCHT\_RECEIVER, or MQCHT\_CLUSRCVR.

This field is not present when *Version* is less than MQCD\_VERSION\_3.

The following fields in this structure are not present if *Version* is less than MQCD\_VERSION\_4.

#### *MsgRetryUserData (MQCHAR32)*

This field specifies the channel message retry exit user data.

This data is passed to the channel message-retry exit in the *ExitData* field of the **ChannelExitParms** parameter (see MQ\_CHANNEL\_EXIT).

This field initially contains the data that was set in the channel definition. However, during the lifetime of this MCA instance, any changes made to the contents of this field by an exit of any type are preserved by the MCA, and made visible to subsequent invocations of exits (regardless of type) for this MCA instance.

Such changes do not affect the channel definition used by other MCA instances. Any characters (including binary data) can be used.

This field is relevant only for channels with a *ChannelType* of MQCHT\_REQUESTER, MQCHT\_RECEIVER, or MQCHT\_CLUSRCVR.

The length of this field is given by MQ\_EXIT\_DATA\_LENGTH. This field is not present when *Version* is less than MQCD\_VERSION\_3.

This field is not relevant in IBM MQ for IBM i.

#### *MsgUserData (MQCHAR32)*

This field specifies channel message exit user data.

This data is passed to the channel message exit in the *ExitData* field of the **ChannelExitParms** parameter (see MQ\_CHANNEL\_EXIT).

This field initially contains the data that was set in the channel definition. However, during the lifetime of this MCA instance, any changes made to the contents of this field by an exit of any type are preserved by the MCA, and made visible to subsequent invocations of exits (regardless of type) for this MCA instance. Such changes do not affect the channel definition used by other MCA instances. Any characters (including binary data) can be used.

The length of this field is given by MQ\_EXIT\_DATA\_LENGTH.

This field is not relevant in IBM MQ for IBM i.

#### *MsgUserDataPtr (MQPTR)*

This field specifies the address of the first *MsgUserData* field.

If *MsgExitsDefined* is greater than zero, this address is the address of the list of user data items for each channel message exit in the chain.

Each user data item is in a field of length *ExitDataLength*, padded to the right with blanks. There are *MsgExitsDefined* fields adjoining one another - one for each exit. If the number of user data items defined is less than the number of exit names, undefined user data items are set to blanks. Conversely, if the number of user data items defined is greater than the number of exit names, the excess user data items are ignored and not presented to the exit.

Any changes made to these values by an exit are preserved. This allows one exit to pass information to another exit. No validation is carried out on any changes so, for example, binary data can be written to these fields if required.

If *MsgExitsDefined* is zero, this field is the null pointer.

On platforms where the programming language does not support the pointer data type, this field is declared as a byte string of the appropriate length.

This is an input field to the exit. The field is not present if *Version* is less than MQCD\_VERSION\_4.

#### *NetworkPriority (MQLONG)*

This field specifies the priority of the network connection for the channel.

When multiple paths to a particular destination are available, the path with the highest priority is chosen. The value is in the range 0 through 9; 0 is the lowest priority.

This field is relevant only for channels with a *ChannelType* of MQCHT\_CLUSSDR or MQCHT\_CLUSRCVR.

This is an input field to the exit. The field is not present if *Version* is less than MQCD\_VERSION\_5.

The following fields in this structure are not present if *Version* is less than MQCD\_VERSION\_6.

#### *NonPersistentMsgSpeed (MQLONG)*

This field specifies the speed at which nonpersistent messages travel through the channel.

This field is relevant only for channels with a *ChannelType* of MQCHT\_SENDER, MQCHT\_SERVER, MQCHT\_RECEIVER, MQCHT\_REQUESTER, MQCHT\_CLUSSDR, or MQCHT\_CLUSRCVR.

The value is one of the following:

### **MQNPMS\_NORMAL**

Normal speed.

If a channel is defined to be MQNPMS\_NORMAL, nonpersistent messages travel through the channel at normal speed. This has the advantage that these messages are not lost if there is a channel failure. Also, persistent and nonpersistent messages on the same transmission queue maintain their order relative to each other.

### **MQNPMS\_FAST**

Fast speed.

If a channel is defined to be MQNPMS\_FAST, nonpersistent messages travel through the channel at fast speed. This improves the throughput of the channel, but means that nonpersistent messages are lost if there is a channel failure. Also, it is possible for nonpersistent messages to jump ahead of persistent messages waiting on the same transmission queue, that is, the order of nonpersistent messages is not maintained relative to persistent messages. However the order of nonpersistent messages relative to each other is maintained. Similarly, the order of persistent messages relative to each other is maintained.

### *Password (MQCHAR12)*

This field specifies the password used by the message channel agent when attempting to initiate a secure SNA session with a remote message channel agent.

This field can be nonblank only on AIX, Linux, and Windows, and is relevant only for channels with a *ChannelType* of MQCHT\_SENDER, MQCHT\_SERVER, MQCHT\_REQUESTER, or MQCHT\_CLNTCONN. On z/OS, this field is not relevant.

The length of this field is given by MQ\_PASSWORD\_LENGTH. However, only the first 10 characters are used.

This field is not present if *Version* is less than MQCD\_VERSION\_2.

### *PropertyControl (MQLONG)*

This field specifies what happens to properties of messages when the message is about to be sent to a V6 or prior queue manager (a queue manager that does not understand the concept of a property descriptor).

The value can be any of the following values:

### **MQPROP\_COMPATIBILITY**

If the message contains a property with a prefix of **mcd.**, **jms.**, **usr.**, or **mqext.**, all message properties are delivered to the application in an MQRFH2 header. Otherwise all properties of the message, except those properties contained in the message descriptor (or extension), are discarded and are no longer accessible to the application.

This value is the default value; it allows applications, which expect JMS-related properties to be in an MQRFH2 header in the message data, to continue to work unmodified.

### **MQPROP\_NONE**

All properties of the message, except those properties in the message descriptor (or extension), are removed from the message before the message is sent to the remote queue manager.

### **MQPROP\_ALL**

All properties of the message are included with the message when it is sent to the remote queue manager. The properties, except those properties in the message descriptor (or extension), are placed in one or more MQRFH2 headers in the message data.

This attribute is applicable to Sender, Server, Cluster Sender, and Cluster Receiver channels.

[“MQIA\\_\\* \(Integer Attribute Selectors\)” on page 129](#)

[“MQPROP\\_\\* \(Queue and Channel Property Control Values and Maximum Properties Length\)” on page 169](#)

### *PutAuthority (MQLONG)*

This field specifies whether the user identifier in the context information associated with a message is used to establish authority to put the message to the destination queue.

This field is relevant only for channels with a *ChannelType* of MQCHT\_REQUESTER, MQCHT\_RECEIVER, or MQCHT\_CLUSRCVR. It is one of the following:

#### **MQPA\_DEFAULT**

Default user identifier is used.

#### **MQPA\_CONTEXT**

Context user identifier is used.

#### **z/OS MQPA\_ALTERNATE\_OR\_MCA**

The user ID from the *UserIdentifier* field of the message descriptor is used. Any user ID received from the network is not used. This value is supported only on z/OS.

#### **z/OS MQPA\_ONLY\_MCA**

The default user ID is used. Any user ID received from the network is not used. This value is supported only on z/OS.

### *QMgrName (MQCHAR48)*

This field specifies the name of the queue manager that an exit can connect to.

For channels with a *ChannelType* other than MQCHT\_CLNTCONN, this field is the name of the queue manager that an exit can connect to, which on AIX, Linux, and Windows, is always nonblank.

The length of this field is given by MQ\_Q\_MGR\_NAME\_LENGTH.

### *ReceiveExit (MQCHARn)*

This field specifies the channel receive exit name.

If this name is nonblank, the exit is called at the following times:

- Immediately before the received network data is processed.

The exit is given the complete transmission buffer as received. The contents of the buffer can be modified as required.

- At initialization and termination of the channel.

See “MQCD - Channel definition” on page 1477 for a description of the content of this field in various environments.

The length of this field is given by MQ\_EXIT\_NAME\_LENGTH.

**Note:** The value of this constant is environment-specific.

### *ReceiveExitPtr (MQPTR)*

This field specifies the address of the first *ReceiveExit* field.

If *ReceiveExitsDefined* is greater than zero, this address is the address of the list of names of each channel receive exit in the chain.

Each name is in a field of length *ExitNameLength*, padded to the right with blanks. There are *ReceiveExitsDefined* fields adjoining one another - one for each exit.

Any changes made to these names by an exit are preserved, although the message channel exit takes no explicit action - it does not change which exits are invoked.

If *ReceiveExitsDefined* is zero, this field is the null pointer.

On platforms where the programming language does not support the pointer data type, this field is declared as a byte string of the appropriate length.

This is an input field to the exit. The field is not present if *Version* is less than MQCD\_VERSION\_4.

#### *ReceiveExitsDefined (MQLONG)*

This field specifies the number of channel receive exits defined in the chain.

It is greater than or equal to zero.

This is an input field to the exit. The field is not present if *Version* is less than MQCD\_VERSION\_4.

#### *ReceiveUserData (MQCHAR32)*

This channel specifies channel receive exit user data.

This data is passed to the channel receive exit in the *ExitData* field of the **ChannelExitParms** parameter (see MQ\_CHANNEL\_EXIT).

This field initially contains the data that was set in the channel definition. However, during the lifetime of this MCA instance, any changes made to the contents of this field by an exit of any type are preserved by the MCA, and made visible to subsequent invocations of exits (regardless of type) for this MCA instance. This applies to exits on different conversations. Such changes do not affect the channel definition used by other MCA instances. Any characters (including binary data) can be used.

The length of this field is given by MQ\_EXIT\_DATA\_LENGTH.

This field is not relevant in IBM MQ for IBM i.

The following fields in this structure are not present if *Version* is less than MQCD\_VERSION\_2.

#### *ReceiveUserDataPtr (MQPTR)*

This field specifies the address of the first *ReceiveUserData* field.

If *ReceiveExitsDefined* is greater than zero, this address is the address of the list of user data item for each channel receive exit in the chain.

Each user data item is in a field of length *ExitDataLength*, padded to the right with blanks. There are *ReceiveExitsDefined* fields adjoining one another - one for each exit. If the number of user data items defined is less than the number of exit names, undefined user data items are set to blanks. Conversely, if the number of user data items defined is greater than the number of exit names, the excess user data items are ignored and not presented to the exit.

Any changes made to these values by an exit are preserved. This allows one exit to pass information to another exit. No validation is carried out on any changes so, for example, binary data can be written to these fields if required.

If *ReceiveExitsDefined* is zero, this field is the null pointer.

On platforms where the programming language does not support the pointer data type, this field is declared as a byte string of the appropriate length.

This is an input field to the exit. The field is not present if *Version* is less than MQCD\_VERSION\_4.

The following fields in this structure are not present if *Version* is less than MQCD\_VERSION\_5.

#### *RemotePassword (MQCHAR12)*

This field specifies the password from a partner.

This field contains valid information only if *ChannelType* is MQCHT\_CLNTCONN or MQCHT\_SVRCONN.

- For a security exit at an MQCHT\_CLNTCONN channel, this password is a password which has been obtained from the environment. The exit can choose to send it to the security exit at the server.
- For a security exit at an MQCHT\_SVRCONN channel, this field might contain a password which has been obtained from the environment at the client, if there is no client security exit. The exit can use this password to validate the user identifier in *RemoteUserIdentifier*.

If there is a security exit at the client, then this information can be obtained in a security flow from the client.

The length of this field is given by MQ\_PASSWORD\_LENGTH. This field is not present if *Version* is less than MQCD\_VERSION\_2.

#### *RemoteSecurityId (MQBYTE40)*

This field specifies the security identifier for the remote user.

This field is relevant only for channels with a *ChannelType* of MQCHT\_CLNTCONN or MQCHT\_SVRCONN.

The following special value indicates that there is no security identifier:

#### **MQSID\_NONE**

No security identifier specified.

The value is binary zero for the length of the field.

For the C programming language, the constant MQSID\_NONE\_ARRAY is also defined; this constant has the same value as MQSID\_NONE, but is an array of characters instead of a string.

This is an input field to the exit. The length of this field is given by MQ\_SECURITY\_ID\_LENGTH. This field is not present if *Version* is less than MQCD\_VERSION\_6.

The following fields in this structure are not present if *Version* is less than MQCD\_VERSION\_7.

#### *RemoteUserIdentifier (MQCHAR12)*

This field specifies the first 12 bytes of a user identifier from a partner.

There are two fields that contain the remote user identifier:

- *RemoteUserIdentifier* contains the first 12 bytes of the remote user identifier, and is padded with blanks if the identifier is shorter than 12 bytes. *RemoteUserIdentifier* can be blank.
- *LongRemoteUserIdPtr* points to the full remote user identifier, which can be longer than 12 bytes. Its length is given by *LongRemoteUserIdLength*. The full identifier contains no trailing blanks, and is not null-terminated. If the identifier is blank, *LongRemoteUserIdLength* is zero, and the value of *LongRemoteUserIdPtr* is undefined.

*LongRemoteUserIdPtr* is not present if *Version* is less than MQCD\_VERSION\_6.

The remote user identifier is relevant only for channels with a *ChannelType* of MQCHT\_CLNTCONN or MQCHT\_SVRCONN.

- For a security exit on an MQCHT\_CLNTCONN channel, this value is a user identifier that has been obtained from the environment. The exit can choose to send it to the security exit at the server.
- For a security exit on an MQCHT\_SVRCONN channel, this field might contain a user identifier which has been obtained from the environment at the client, if there is no client security exit. The exit might validate this user ID (possibly with the password in *RemotePassword*) and update the value in *MCAUserIdentifier*.

If there is a security exit at the client, then this information can be obtained in a security flow from the client.

The length of this field is given by MQ\_USER\_ID\_LENGTH. This field is not present if *Version* is less than MQCD\_VERSION\_2.

#### *SecurityExit (MQCHARn)*

This field specifies the channel security exit name.

If this name is nonblank, the exit is called at the following times:

- Immediately after establishing a channel.
  - Before any messages are transferred, the exit is given the opportunity to instigate security flows to validate connection authorization.
- Upon receipt of a response to a security message flow.
  - Any security message flows received from the remote processor on the remote machine are given to the exit.
- At initialization and termination of the channel.

See “MQCD - Channel definition” on page 1477 for a description of the content of this field in various environments.

The length of this field is given by MQ\_EXIT\_NAME\_LENGTH.

**Note:** The value of this constant is environment-specific.

#### *SecurityUserData (MQCHAR32)*

This channel specifies the channel security exit user data.

This data is passed to the channel security exit in the *ExitData* field of the **ChannelExitParms** parameter (see MQ\_CHANNEL\_EXIT).

This field initially contains the data that was set in the channel definition. However, during the lifetime of this MCA instance, any changes made to the contents of this field by an exit of any type are preserved by the MCA, and made visible to subsequent invocations of exits (regardless of type) for this MCA instance. This applies to exits on different conversations. Such changes do not effect on the channel definition used by other MCA instances. Any characters (including binary data) can be used.

The length of this field is given by MQ\_EXIT\_DATA\_LENGTH.

This field is not relevant in IBM MQ for IBM i.

#### *SendExit (MQCHARn)*

This field specifies the channel send exit name.

If this name is nonblank, the exit is called at the following times:

- Immediately before data is sent out on the network.

The exit is given the complete transmission buffer before it is transmitted. The contents of the buffer can be modified as required.

- At initialization and termination of the channel.

See “MQCD - Channel definition” on page 1477 for a description of the content of this field in various environments.

The length of this field is given by MQ\_EXIT\_NAME\_LENGTH.

**Note:** The value of this constant is environment-specific.

#### *SendExitPtr (MQPTR)*

This field specifies the address of the first *SendExit* field.

If *SendExitsDefined* is greater than zero, this address is the address of the list of names of each channel send exit in the chain.

Each name is in a field of length *ExitNameLength*, padded to the right with blanks. There are *SendExitsDefined* fields adjoining one another - one for each exit.

Any changes made to these names by an exit are preserved, although the message send exit takes no explicit action - it does not change which exits are invoked.

If *SendExitsDefined* is zero, this field is the null pointer.

On platforms where the programming language does not support the pointer data type, this field is declared as a byte string of the appropriate length.

This is an input field to the exit. The field is not present if *Version* is less than MQCD\_VERSION\_4.

#### *SendExitsDefined (MQLONG)*

This field specifies the number of channel send exits defined in the chain.

It is greater than or equal to zero.

This is an input field to the exit. The field is not present if *Version* is less than MQCD\_VERSION\_4.

#### *SendUserData (MQCHAR32)*

This field specifies the channel send exit user data.

This data is passed to the channel send exit in the *ExitData* field of the **ChannelExitParms** parameter (see MQ\_CHANNEL\_EXIT).

This field initially contains the data that was set in the channel definition. However, during the lifetime of this MCA instance, any changes made to the contents of this field by an exit of any type are preserved by the MCA, and made visible to subsequent invocations of exits (regardless of type) for this MCA instance. This applies to exits on different conversations. Such changes do not affect the channel definition used by other MCA instances. Any characters (including binary data) can be used.

The length of this field is given by MQ\_EXIT\_DATA\_LENGTH.

This field is not relevant in IBM MQ for IBM i.

#### *SendUserDataPtr (MQPTR)*

This field specifies the address of the *SendUserData* field.

If *SendExitsDefined* is greater than zero, this address is the address of the list of user data items for each channel message exit in the chain.

Each user data item is in a field of length *ExitDataLength*, padded to the right with blanks. There are *MsgExitsDefined* fields adjoining one another - one for each exit. If the number of user data items defined is less than the number of exit names, undefined user data items are set to blanks. Conversely, if the number of user data items defined is greater than the number of exit names, the excess user data items are ignored and not presented to the exit.

Any changes made to these values by an exit are preserved. This allows one exit to pass information to another exit. No validation is carried out on any changes so, for example, binary data can be written to these fields if required.

If *SendExitsDefined* is zero, this field is the null pointer.

On platforms where the programming language does not support the pointer data type, this field is declared as a byte string of the appropriate length.

This is an input field to the exit. The field is not present if *Version* is less than MQCD\_VERSION\_4.

#### *SeqNumberWrap (MQLONG)*

This field specifies the highest allowable message sequence number.

When this value is reached, sequence numbers wrap to start again at 1.

This value is non-negotiable and must match in both the local and remote channel definitions.

This field is not relevant for channels with a *ChannelType* of MQCHT\_SVRCONN or MQCHT\_CLNTCONN.

#### *SharingConversations (MQLONG)*

This field specifies the maximum number of conversations that can share a channel instance associated with this channel.

This field is used on client connection and server-connection channels.

A value of 0 means that the channel operates as it did in versions earlier than IBM WebSphere MQ 7.0 with respect to the following attributes:

- Conversation sharing
- Read ahead
- STOP CHANNEL(*channelname*) MODE(QUIESCE)
- Heartbeating
- Client asynchronous consumption

A value of 1 is the minimum value for IBM MQ behavior. Although only one conversation is allowed on the channel instance, read ahead, asynchronous consumption, and the behavior of CLNTCONN - SVRCONN heartbeating and quiescent channel stopping are available.

This is an input field to the exit. It is not present if *Version* is less than MQCD\_VERSION\_9.

The default value of this field is 10.

**Note:** *MaxInstances* and *MaxInstancesPerClient* limits applied to a channel restrict the number of channel instances, not the number of conversations that might be sharing those instances.

#### *ShortConnectionName (MQCHAR20)*

This field specifies the first 20 bytes of a connection name.

If the *Version* field is MQCD\_VERSION\_1, *ShortConnectionName* contains the full connection name.

If the *Version* field is MQCD\_VERSION\_2 or greater, *ShortConnectionName* contains the first 20 characters of the connection name. The full connection name is given by the *ConnectionName* field; *ShortConnectionName* and the first 20 characters of *ConnectionName* are identical.

See *ConnectionName* for details of the contents of this field.

**Note:** The name of this field was changed for MQCD\_VERSION\_2 and subsequent versions of MQCD; the field was previously called *ConnectionName*.

The length of this field is given by MQ\_SHORT\_CONN\_NAME\_LENGTH.

#### *ShortRetryCount (MQLONG)*

This field specifies the maximum number of attempts that are made to connect to a remote machine.

This field is the maximum number of attempts that are made to connect to the remote machine, at intervals specified by *ShortRetryInterval*, before the (normally longer) *LongRetryCount* and *LongRetryInterval* are used.

This field is relevant only for channels with a *ChannelType* of MQCHT\_SENDER, MQCHT\_SERVER, MQCHT\_CLUSSDR, or MQCHT\_CLUSRCVR.

#### *ShortRetryInterval (MQLONG)*

This field specifies the maximum number of seconds to wait before reattempting connection to the remote machine.

The interval between retries might be extended if the channel has to wait to become active.

This field is relevant only for channels with a *ChannelType* of MQCHT\_SENDER, MQCHT\_SERVER, MQCHT\_CLUSSDR, or MQCHT\_CLUSRCVR.

#### *SPLProtection (MQLONG)*

This field specifies the value of the AMS security policy protection.

The value is one of the following:

##### **MQSPL\_PASSTHRU**

Pass through, unchanged, any messages sent or received by the MCA for this channel.

This value is relevant only for channels with a *ChannelType* of MQCHT\_SENDER, MQCHT\_SERVER, MQCHT\_RECEIVER, or MQCHT\_REQUESTER, and is the default value.

##### **MQSPL\_REMOVE**

Remove any AMS protection from messages retrieved from the transmission queue by the MCA, and send the messages to the partner.

This value is relevant only for channels with a *ChannelType* of MQCHT\_SENDER or MQCHT\_SERVER.

##### **MQSPL\_ ASPOLICY**

Based on the policy defined for the target queue, apply AMS protection to inbound messages prior to putting them on to the target queue.

This value is relevant only for channels with a *ChannelType* of MQCHT\_RECEIVER or MQCHT\_REQUESTER.

This is an input field to the exit. This field is not present if *Version* is less than MQCD\_VERSION\_12.

#### *SSLCipherSpec (MQCHAR32)*

This field specifies the Cipher Spec that is in use when using TLS.

If SSLCipherSpec is blank, the channel is not using TLS. If it is not blank, this field contains a string specifying the CipherSpec in use.

This parameter is valid for all channel types. It is supported on the following platforms:

-  AIX
-  IBM i
-  Linux
-  Windows
-  z/OS

It is valid only for channel types of a transport type (TRPTYPE) of TCP.

This is an input field to the exit. The length of this field is given by MQ\_SSL\_CIPHER\_SPEC\_LENGTH. The field is not present if *Version* is less than MQCD\_VERSION\_7.

#### *SSLClientAuth (MQLONG)*

This field specifies whether TLS client authentication is required.

This field is relevant only to SVRCONN channel definitions.

It is one of the following values:

#### **MQSCA\_REQUIRED**

Client authentication required.

#### **MQSCA\_OPTIONAL**

Client authentication optional.

This is an input field to the exit. The field is not present if *Version* is less than MQCD\_VERSION\_7.

#### *SSLPeerNameLength (MQLONG)*

This field specifies the length in bytes of the TLS peer name pointed to by *SSLPeerNamePtr*.

This is an input field to the exit. The field is not present if *Version* is less than MQCD\_VERSION\_7.

#### *SSLPeerNamePtr (MQPTR)*

This field specifies the address of the TLS peer name.

When a certificate is received during a successful TLS handshake, the Distinguished Name of the subject of the certificate is copied into the MQCD field accessed by *SSLPeerNamePtr* at the end of the channel which receives the certificate. It overwrites the *SSLPeerName* value for the channel if this value is present in the channel definition of the local user. If a security exit is specified at this end of the channel it receives the Distinguished Name from the peer certificate in the MQCD.

This is an input field to the exit. The field is not present if *Version* is less than MQCD\_VERSION\_7.

**Note:** Security exit applications constructed prior to the release of IBM WebSphere MQ 7.1 may require updating. For more information see [Channel security exit programs](#).

#### *StrucLength (MQLONG)*

This field specifies the length in bytes of the MQCD structure.

The length does not include any of the strings addressed by pointer fields contained within the structure. The value is one of the following:

**MQCD\_LENGTH\_4**

Length of version-4 channel definition structure.

**MQCD\_LENGTH\_5**

Length of version-5 channel definition structure.

**MQCD\_LENGTH\_6**

Length of version-6 channel definition structure.

**MQCD\_LENGTH\_7**

Length of version-7 channel definition structure.

**MQCD\_LENGTH\_8**

Length of version-8 channel definition structure.

**MQCD\_LENGTH\_9**

Length of version-9 channel definition structure.

**MQCD\_LENGTH\_10**

Length of version-10 channel definition structure.

**MQCD\_LENGTH\_11**

Length of version-11 channel definition structure.

**z/OS MQCD\_LENGTH\_12**

Length of version-12 channel definition structure.

The following constant specifies the length of the current version:

**MQCD\_CURRENT\_LENGTH**

Length of current version of channel definition structure.

**Note:** These constants have values that are environment-specific.

The field is not present if *Version* is less than MQCD\_VERSION\_4.

*TpName (MQCHAR64)*

This field specifies the LU 6.2 transaction program name.

This field is relevant only if the transmission protocol (*TransportType*) is MQXPT\_LU62, and the *ChannelType* is not MQCHT\_SVRCONN or MQCHT\_RECEIVER.

This field is always blank on platforms on which the information is contained in the communications Side Object instead.

The length of this field is given by MQ\_TP\_NAME\_LENGTH.

*TransportType (MQLONG)*

This field specifies the transmission protocol to be used.

The value is not checked if the channel was initiated from the other end.

It is one of the following values:

**MQXPT\_LU62**

LU 6.2 transport protocol.

**MQXPT\_TCP**

TCP/IP transport protocol.

**MQXPT\_NETBIOS**

NetBIOS transport protocol.

This value is supported in the following environments: Windows.

**MQXPT\_SPX**

SPX transport protocol.

This value is supported in the following environments: Windows, plus IBM MQ clients connected to these systems.

#### *UseDLQ (MQLONG)*

This field specifies whether the dead-letter queue (or undelivered message queue) is used when messages cannot be delivered by channels.

It can contain one of the following values:

#### **MQUSEDLQ\_NO**

Messages that cannot be delivered by a channel are treated as a failure. The channel either discards the message, or the channel ends, in accordance with the NPMSPEED setting.

#### **MQUSEDLQ\_YES**

When the DEADQ queue manager attribute provides the name of a dead-letter queue, then it is used, else the behavior is as for NO. YES is the default value.

#### *UserIdentifier (MQCHAR12)*

This field specifies the user identifier used by the message channel agent when attempting to initiate a secure SNA session with a remote message channel agent.

This field can be nonblank only on AIX, Linux, and Windows, and is relevant only for channels with a *ChannelType* of MQCHT\_SENDER, MQCHT\_SERVER, MQCHT\_REQUESTER, or MQCHT\_CLNTCONN. On z/OS, this field is not relevant.

The length of this field is given by MQ\_USER\_ID\_LENGTH. However, only the first 10 characters are used.

This field is not present when *Version* is less than MQCD\_VERSION\_2.

#### *Version (MQLONG)*

The *Version* field specifies the highest version number that you can set for the structure.

The value depends on the environment:

#### **MQCD \_VERSION\_1**

Version 1 channel definition structure.

#### **MQCD \_VERSION\_2**

Version 2 channel definition structure.

#### **MQCD \_VERSION\_3**

Version 3 channel definition structure.

#### **MQCD \_VERSION\_4**

Version 4 channel definition structure.

#### **MQCD \_VERSION\_5**

Version 5 channel definition structure.

#### **MQCD \_VERSION\_6**

Version 6 channel definition structure.

#### **MQCD \_VERSION\_7**

Version 7 channel definition structure.

#### **MQCD \_VERSION\_8**

Version 8 channel definition structure.

#### **MQCD \_VERSION\_9**

Version 9 channel definition structure.

#### **MQCD \_VERSION\_10**

Version 10 channel definition structure.

#### **MQCD \_VERSION\_11**

Version 11 channel definition structure.

Version 11 is the highest that you can set the field to on IBM MQ 8.0 on all platforms.

Version 12 channel definition structure.

Version 12 is the highest that you can set the field to on IBM MQ 9.1.3.

Fields that exist only in the more recent versions of the structure are identified as such in the descriptions of the fields. The following constant specifies the version number of the current version:

### MQCD\_CURRENT\_VERSION

The value set in MQCD\_CURRENT\_VERSION is the current version of the channel definition structure being used.

The value of MQCD\_CURRENT\_VERSION depends on the environment. It contains the highest value supported by the platform.

MQCD\_CURRENT\_VERSION is not used to initialize the default structures provided in the header, copy, and include files provided for different programming languages. The default initialization of Version depends on the platform and release.

The MQCD declarations in the header, copy, and include files are initialized to MQCD\_VERSION\_6. To use additional MQCD fields, applications must set the version number to MQCD\_CURRENT\_VERSION. If you are writing an application that is portable between several environments, you must choose a version that is supported in all the environments.

**Tip:** When a new version of the MQCD structure is introduced, the layout of the existing part is not changed. The exit must check the version number. It must be equal to or greater than the lowest version that contains the fields that the exit needs to use.

### XmitQName (MQCHAR48)

This field specifies the name of the transmission queue from which messages are retrieved.

This field is relevant only for channels with a *ChannelType* of MQCHT\_SENDER or MQCHT\_SERVER.

The length of this field is given by MQ\_Q\_NAME\_LENGTH.

### C declaration

This declaration is the C declaration for the MQCD structure.

```
typedef struct tagMQCD MQCD;
typedef MQCD MQPOINTER PMQCD;
typedef PMQCD MQPOINTER PPMQCD;

struct tagMQCD {
    MQCHAR    ChannelName[20];           /* Channel definition name */
    MQLONG    Version;                  /* Structure version number */
    MQLONG    ChannelType;              /* Channel type */
    MQLONG    TransportType;           /* Transport type */
    MQCHAR    Desc[64];                 /* Channel description */
    MQCHAR    QMgrName[48];            /* Queue manager name */
    MQCHAR    XmitQName[48];           /* Transmission queue name */
    MQCHAR    ShortConnectionName[20]; /* First 20 bytes of */
                                           /* connection name */
    MQCHAR    MCAName[20];             /* Reserved */
    MQCHAR    ModeName[8];             /* LU 6.2 Mode name */
    MQCHAR    TpName[64];              /* LU 6.2 transaction program */
                                           /* name */
    MQLONG    BatchSize;               /* Batch size */

## COBOL declaration

This declaration is the COBOL declaration for the MQCD structure.

```

** MQCD structure
  10 MQCD.
    ** Channel definition name
    15 MQCD-CHANNELNAME PIC X(20).
    ** Structure version number
    15 MQCD-VERSION PIC S9(9) BINARY.
    ** Channel type
    15 MQCD-CHANNELTYPE PIC S9(9) BINARY.
    ** Transport type
    15 MQCD-TRANSPORTTYPE PIC S9(9) BINARY.
    ** Channel description
    15 MQCD-DESC PIC X(64).
    ** Queue manager name
    15 MQCD-QMGRNAME PIC X(48).
    ** Transmission queue name
    15 MQCD-XMITQNAME PIC X(48).
    ** First 20 bytes of connection name
    15 MQCD-SHORTCONNECTIONNAME PIC X(20).
    ** Reserved
    15 MQCD-MCANAME PIC X(20).
    ** LU 6.2 Mode name
    15 MQCD-MODENAME PIC X(8).
    ** LU 6.2 transaction program name
    15 MQCD-TPNAME PIC X(64).
    ** Batch size
    15 MQCD-BATCHSIZE PIC S9(9) BINARY.
    ** Disconnect interval
    15 MQCD-DISCINTERVAL PIC S9(9) BINARY.
    ** Short retry count
    15 MQCD-SHORTRETRYCOUNT PIC S9(9) BINARY.
    ** Short retry wait interval
    15 MQCD-SHORTRETRYINTERVAL PIC S9(9) BINARY.
    ** Long retry count
    15 MQCD-LONGRETRYCOUNT PIC S9(9) BINARY.
    ** Long retry wait interval
    15 MQCD-LONGRETRYINTERVAL PIC S9(9) BINARY.
    ** Channel security exit name
    15 MQCD-SECURITYEXIT PIC X(20).
    ** Channel message exit name

```

```

15 MQCD-MSGEXIT PIC X(20).
** Channel send exit name
15 MQCD-SENDEXIT PIC X(20).
** Channel receive exit name
15 MQCD-RECEIVEEXIT PIC X(20).
** Highest allowable message sequence number
15 MQCD-SEQNUMBERWRAP PIC S9(9) BINARY.
** Maximum message length
15 MQCD-MAXMSGLENGTH PIC S9(9) BINARY.
** Put authority
15 MQCD-PUTAUTHORITY PIC S9(9) BINARY.
** Data conversion
15 MQCD-DATACONVERSION PIC S9(9) BINARY.
** Channel security exit user data
15 MQCD-SECURITYUSERDATA PIC X(32).
** Channel message exit user data
15 MQCD-MSGUSERDATA PIC X(32).
** Channel send exit user data
15 MQCD-SENDUSERDATA PIC X(32).
** Channel receive exit user data
15 MQCD-RECEIVEUSERDATA PIC X(32).
** Ver:1 **
** User identifier
15 MQCD-USERIDENTIFIER PIC X(12).
** Password
15 MQCD-PASSWORD PIC X(12).
** First 12 bytes of MCA user identifier
15 MQCD-MCAUSERIDENTIFIER PIC X(12).
** Message channel agent type
15 MQCD-MCATYPE PIC S9(9) BINARY.
** Connection name
15 MQCD-CONNECTIONNAME PIC X(264).
** First 12 bytes of user identifier from partner
15 MQCD-REMOTEUSERIDENTIFIER PIC X(12).
** Password from partner
15 MQCD-REMOTEPASSWORD PIC X(12).
** Ver:2 **
** Channel message retry exit name
15 MQCD-MSGRETRYEXIT PIC X(20).
** Channel message retry exit user data
15 MQCD-MSGRETRYUSERDATA PIC X(32).
** Number of times MCA will try to put the message, after first
** attempt has failed
15 MQCD-MSGRETRYCOUNT PIC S9(9) BINARY.
** Minimum interval in milliseconds after which the open or put
** operation will be retried
15 MQCD-MSGRETRYINTERVAL PIC S9(9) BINARY.
** Ver:3 **
** Time in seconds between heartbeat flows
15 MQCD-HEARTBEATINTERVAL PIC S9(9) BINARY.
** Batch duration
15 MQCD-BATCHINTERVAL PIC S9(9) BINARY.
** Speed at which nonpersistent messages are sent
15 MQCD-NONPERSISTENTMSGSPPEED PIC S9(9) BINARY.
** Length of MQCD structure
15 MQCD-STRUCLength PIC S9(9) BINARY.
** Length of exit name
15 MQCD-EXITNAMELENGTH PIC S9(9) BINARY.
** Length of exit user data
15 MQCD-EXITDATALENGTH PIC S9(9) BINARY.
** Number of message exits defined
15 MQCD-MSGEXITSDEFINED PIC S9(9) BINARY.
** Number of send exits defined
15 MQCD-SENDEXITSDEFINED PIC S9(9) BINARY.
** Number of receive exits defined
15 MQCD-RECEIVEEXITSDEFINED PIC S9(9) BINARY.
** Address of first MsgExit field
15 MQCD-MSGEXITPTR POINTER.
** Address of first MsgUserData field
15 MQCD-MSGUSERDATAPTR POINTER.
** Address of first SendExit field
15 MQCD-SENDEXITPTR POINTER.
** Address of first SendUserData field
15 MQCD-SENDUSERDATAPTR POINTER.
** Address of first ReceiveExit field
15 MQCD-RECEIVEEXITPTR POINTER.
** Address of first ReceiveUserData field
15 MQCD-RECEIVEUSERDATAPTR POINTER.
** Ver:4 **
** Address of a list of cluster names
15 MQCD-CLUSTERPTR POINTER.
** Number of clusters to which the channel belongs

```

```

15 MQCD-CLUSTERSDEFINED PIC S9(9) BINARY.
** Network priority
15 MQCD-NETWORKPRIORITY PIC S9(9) BINARY.
** Ver:5 **
** Length of long MCA user identifier
15 MQCD-LONGMCAUSERIDLENGTH PIC S9(9) BINARY.
** Length of long remote user identifier
15 MQCD-LONGREMOTEUSERIDLENGTH PIC S9(9) BINARY.
** Address of long MCA user identifier
15 MQCD-LONGMCAUSERIDPTR POINTER.
** Address of long remote user identifier
15 MQCD-LONGREMOTEUSERIDPTR POINTER.
** MCA security identifier
15 MQCD-MCASESECURITYID PIC X(40).
** Remote security identifier
15 MQCD-REMOTESESECURITYID PIC X(40).
** Ver:6 **
** TLS CipherSpec
15 MQCD-SSLCIPHERSPEC PIC X(32).
** Address of TLS peer name
15 MQCD-SSLPEERNAMEPTR POINTER.
** Length of TLS peer name
15 MQCD-SSLPEERNAMELENGTH PIC S9(9) BINARY.
** Whether TLS client authentication is required
15 MQCD-SSLCLIENTAUTH PIC S9(9) BINARY.
** Keepalive interval
15 MQCD-KEEPALIVEINTERVAL PIC S9(9) BINARY.
** Local communications address
15 MQCD-LOCALADDRESS PIC X(48).
** Batch heartbeat interval
15 MQCD-BATCHHEARTBEAT PIC S9(9) BINARY.
** Ver:7 **
** Header data compression list
15 MQCD-HDRCOMPLIST PIC S9(9) BINARY.
** Message data compression list
15 MQCD-MSGCOMPLIST PIC S9(9) BINARY.
** Channel rank
15 MQCD-CLWLCHANNELRANK PIC S9(9) BINARY.
** Channel priority
15 MQCD-CLWLCHANNELPRIORITY PIC S9(9) BINARY.
** Channel weight
15 MQCD-CLWLCHANNELWEIGHT PIC S9(9) BINARY.
** Channel monitoring
15 MQCD-CHANNELMONITORING PIC S9(9) BINARY.
** Channel statistics
15 MQCD-CHANNELSTATISTICS PIC S9(9) BINARY.
** Ver:8 **
** Limit on sharing conversations
15 MQCD-SHARINGCONVERSATIONS PIC S9(9) BINARY.
** Message property control
15 MQCD-PROPERTYCONTROL PIC S9(9) BINARY.
** Limit on SVRCONN channel instances
15 MQCD-MAXINSTANCES PIC S9(9) BINARY.
** Limit on SVRCONN channel instances per client
15 MQCD-MAXINSTANCESPERCLIENT PIC S9(9) BINARY.
** Client channel weight
15 MQCD-CLIENTCHANNELWEIGHT PIC S9(9) BINARY.
** Connection affinity
15 MQCD-CONNECTIONAFFINITY PIC S9(9) BINARY.
** Ver:9 **
** Batch data limit
15 MQCD-BATCHDATALIMIT PIC S9(9) BINARY.
** Use Dead Letter Queue
15 MQCD-USEDLQ PIC S9(9) BINARY.
** Default client reconnect option
15 MQCD-DEFRECONNECT PIC S9(9) BINARY.

CLWLChannelWeight	As Long	'Channel Weight'
ChannelMonitoring	As Long	'Channel Monitoring control'
ChannelStatistics	As Long	'Channel Statistics'
End Type		

### Changing MQCD fields in a channel exit

A channel exit can change fields in the MQCD. However, these changes are not typically acted on, except in the circumstances listed.

If a channel exit program changes a field in the MQCD data structure, the new value is typically ignored by the IBM MQ channel process. However, the new value remains in the MQCD and is passed to any remaining exits in an exit chain and to any conversation sharing the channel instance.

If SharingConversations is set to FALSE in the MQCXP structure, changes to certain fields can be acted on, depending on the type of exit program, the type of channel, and the exit reason code. The following table shows the fields that can be changed and affect the behavior of the channel, and in what circumstances. If an exit program changes one of these fields in any other circumstances, or any field not listed, the new value is ignored by the channel process. The new value remains in the MQCD and is passed to any remaining exits in an exit chain and to any conversation sharing the channel instance.

Any type of exit program when called for initialization (MQXR\_INIT) can change the ChannelName field of any type of channel, as long as MQCXP SharingConversations is set to FALSE. Only a security exit can change the MCAUserIdentifier field, regardless of the value of MQCXP SharingConversations.

Field	Exit reason code	Exit type	Channel type
ChannelName	MQXR_INIT	All	All
TransportType	MQXR_INIT	All	All
XmitQName	MQXR_INIT	All	SDR, RCVR
ModeName	MQXR_INIT	All	All

Table 823. Fields that can be changed and affect the behavior of the channel (continued)

Field	Exit reason code	Exit type	Channel type
TpName	MQXR_INIT	All	All
BatchSize	MQXR_INIT	All	SDR, SVR, RCVR, RQSTR, CLUSSDR, CLUSRCVR
DiscInterval	MQXR_INIT	All	SDR, SVR, RCVR, RQSTR, CLUSSDR, CLUSRCVR

## MQCXP - Channel exit parameter

The MQCXP structure is passed to each type of exit called by a Message Channel Agent (MCA), client-connection channel, or server-connection channel.

See MQ\_CHANNEL\_EXIT.

The fields described as "input to the exit" in the descriptions that follow are ignored by the channel when the exit returns control to the channel. Any input fields that the exit changes in the channel exit parameter block will not be preserved for its next invocation. Changes made to input/output fields (for example, the *ExitUserArea* field), are preserved for invocations of that instance of the exit only. Such changes cannot be used to pass data between different exits defined on the same channel, or between the same exit defined on different channels.

## Fields

This topic lists all the fields in the MQCXP structure and describes each field.

*StrucId (MQCHAR4)*

This field specifies the structure identifier.

The value must be:

### **MQCXP\_STRUC\_ID**

Identifier for channel exit parameter structure.

For the C programming language, the constant MQCXP\_STRUC\_ID\_ARRAY is also defined; this constant has the same value as MQCXP\_STRUC\_ID, but is an array of characters instead of a string.

This is an input field to the exit.

*Version (MQLONG)*

This field specifies the structure version number.

The value depends on the environment:

### **MQCXP\_VERSION\_1**

Version-1 channel exit parameter structure.

### **MQCXP\_VERSION\_2**

Version-2 channel exit parameter structure.

### **MQCXP\_VERSION\_3**

Version-3 channel exit parameter structure.

 The field has this value in AIX and Linux systems not listed elsewhere.

### **MQCXP\_VERSION\_4**

Version-4 channel exit parameter structure.

### **MQCXP\_VERSION\_5**

Version-5 channel exit parameter structure.

### **MQCXP\_VERSION\_6**

Version-6 channel exit parameter structure.

### **MQCXP\_VERSION\_8**

Version-8 channel exit parameter structure.

 The field has this value in z/OS.

### **MQCXP\_VERSION\_9**

Version-9 channel exit parameter structure.

The field has this value in the following environments:

-  AIX
-  IBM i
-  Linux
-  Windows
-  z/OS

Fields that exist only in the more-recent versions of the structure are identified as such in the descriptions of the fields. The following constant specifies the version number of the current version:

## **MQCXP\_CURRENT\_VERSION**

Current version of channel exit parameter structure.

The value depends on the environment.

**Note:** When a new version of the MQCXP structure is introduced, the layout of the existing part is not changed. The exit must therefore check that the version number is equal to or greater than the lowest version which contains the fields that the exit needs to use.

This is an input field to the exit.

### *ExitId (MQLONG)*

This field specifies the type of exit being called and is set on entry to the exit routine.

The following values are possible:

#### **MQXT\_CHANNEL\_SEC\_EXIT**

Channel security exit.

#### **MQXT\_CHANNEL\_MSG\_EXIT**

Channel message exit.

#### **MQXT\_CHANNEL\_SEND\_EXIT**

Channel send exit.

#### **MQXT\_CHANNEL\_RCV\_EXIT**

Channel receive exit.

#### **MQXT\_CHANNEL\_MSG\_RETRY\_EXIT**

Channel message-retry exit.

#### **MQXT\_CHANNEL\_AUTO\_DEF\_EXIT**

Channel auto-definition exit.

On z/OS, this type of exit is supported only for channels of type MQCHT\_CLUSSDR and MQCHT\_CLUSRCVR.

This is an input field to the exit.

### *ExitReason (MQLONG)*

This field specifies the reason why the exit is being called and is set on entry to the exit routine.

It is not used by the auto-definition exit. The following values are possible:

#### **MQXR\_INIT**

Exit initialization.

This value indicates that the exit is being invoked for the first time. It allows the exit to acquire and initialize any resources that it needs (for example: memory).

#### **MQXR\_TERM**

Exit termination.

This value indicates that the exit is about to be terminated. The exit should free any resources that it has acquired since it was initialized (for example: memory).

#### **MQXR\_MSG**

Process a message.

This value indicates that the exit is being invoked to process a message. This value occurs for channel message exits only.

#### **MQXR\_XMIT**

Process a transmission.

This value occurs for channel send and receive exits only.

#### **MQXR\_SEC\_MSG**

Security message received.

This value occurs for channel security exits only.

### **MQXR\_INIT\_SEC**

Initiate security exchange.

This value occurs for channel security exits only.

The security exit of the receiver is always invoked with this reason immediately after being invoked with MQXR\_INIT, to give it the opportunity to initiate a security exchange. If it declines the opportunity (by returning MQXCC\_OK instead of MQXCC\_SEND\_SEC\_MSG or MQXCC\_SEND\_AND\_REQUEST\_SEC\_MSG), the security exit of the sender is invoked with MQXR\_INIT\_SEC.

If the security exit of the receiver does initiate a security exchange (by returning MQXCC\_SEND\_SEC\_MSG or MQXCC\_SEND\_AND\_REQUEST\_SEC\_MSG), the security exit of the sender is never invoked with MQXR\_INIT\_SEC; instead it is invoked with MQXR\_SEC\_MSG to process the message of the receiver. (In either case it is first invoked with MQXR\_INIT.)

Unless one of the security exits requests termination of the channel (by setting *ExitResponse* to MQXCC\_SUPPRESS\_FUNCTION or MQXCC\_CLOSE\_CHANNEL), the security exchange must complete at the side that initiated the exchange. Therefore, if a security exit is invoked with MQXR\_INIT\_SEC and it does initiate an exchange, the next time the exit is invoked it will be with MQXR\_SEC\_MSG. This happens whether there is a security message for the exit to process or not. There is a security message if the partner returns MQXCC\_SEND\_SEC\_MSG or MQXCC\_SEND\_AND\_REQUEST\_SEC\_MSG, but not if the partner returns MQXCC\_OK or there is no security exit at the partner. If there is no security message to process, the security exit at the initiating end is re-invoked with a *DataLength* of zero.

### **MQXR\_RETRY**

Retry a message.

This value occurs for message-retry exits only.

### **MQXR\_AUTO\_CLUSSDR**

Automatic definition of a cluster-sender channel.

This value occurs for channel auto-definition exits only.

### **MQXR\_AUTO\_RECEIVER**

Automatic definition of a receiver channel.

This value occurs for channel auto-definition exits only.

### **MQXR\_AUTO\_SVRCONN**

Automatic definition of a server-connection channel.

This value occurs for channel auto-definition exits only.

### **MQXR\_AUTO\_CLUSRCVR**

Automatic definition of a cluster-receiver channel.

This value occurs for channel auto-definition exits only.

### **MQXR\_SEC\_PARMS**

Security parameters

This value applies to security exits only and indicates that an MQCSP structure is being passed to the exit. For more information, see [“MQCSP - Security parameters” on page 335](#)

#### **Note:**

1. If you have more than one exit defined for a channel, they are each invoked with MQXR\_INIT when the MCA is initialized. Also, they are each invoked with MQXR\_TERM when the MCA is terminated.
2. For the channel auto-definition exit, *ExitReason* is not set if *Version* is less than MQCXP\_VERSION\_4. The value MQXR\_AUTO\_SVRCONN is implied in this case.

This is an input field to the exit.

### *ExitResponse (MQLONG)*

This field specifies the response from the exit.

This field is set by the exit to communicate with the MCA. It must be one of the following values:

#### **MQXCC\_OK**

Exit completed successfully.

- For the channel security exit, this value indicates that message transfer can now proceed normally.
- For the channel message retry exit, this value indicates that the MCA must wait for the time interval returned by the exit in the *MsgRetryInterval* field in MQCXP, and then try the message again.

The *ExitResponse2* field might contain additional information.

#### **MQXCC\_SUPPRESS\_FUNCTION**

Suppress function.

- For the channel security exit, this value indicates that the channel must be terminated.
- For the channel message exit, this value indicates that the message is not to proceed any further towards its destination. Instead the MCA generates an exception report message (if one was requested by the sender of the original message), and places the message contained in the original buffer on the dead-letter queue (if the sender specified MQRO\_DEAD\_LETTER\_Q), or discards it (if the sender specified MQRO\_DISCARD\_MSG).

For persistent messages, if the sender specified MQRO\_DEAD\_LETTER\_Q, but the put to the dead-letter queue fails, or there is no dead-letter queue, the original message is left on the transmission queue and the report message is not generated. The original message is also left on the transmission queue if the report message cannot be generated successfully.

The *Feedback* field in the MQDLH structure at the start of the message on the dead-letter queue indicates why the message was put on the dead-letter queue; this feedback code is also used in the message descriptor of the exception report message (if one was requested by the sender).

- For the channel message retry exit, this value indicates that the MCA does not wait and try the message again; instead, the MCA continues immediately with its normal failure processing (the message is placed on the dead-letter queue or discarded, as specified by the sender of the message).
- For the channel auto-definition exit, either MQXCC\_OK or MQXCC\_SUPPRESS\_FUNCTION must be specified. If neither of these values is specified, MQXCC\_SUPPRESS\_FUNCTION is assumed by default and the auto-definition is abandoned.

This response is not supported for the channel send and receive exits.

#### **MQXCC\_SEND\_SEC\_MSG**

Send security message.

This value can be set only by a channel security exit. It indicates that the exit has provided a security message which must be transmitted to the partner.

#### **MQXCC\_SEND\_AND\_REQUEST\_SEC\_MSG**

Send security message that requires a reply.

This value can be set only by a channel security exit. It indicates

- that the exit has provided a security message which can be transmitted to the partner, and
- that the exit requires a response from the partner. If no response is received, the channel must be terminated, because the exit has not yet decided whether communications can proceed.

#### **MQXCC\_SUPPRESS\_EXIT**

Suppress exit.

- This value can be set by all types of channel exit other than a security exit or an auto-definition exit. It suppresses any further invocation of that exit (as if its name had been blank in the channel definition), until termination of the channel, when the exit is again invoked with an *ExitReason* of MQXR\_TERM.

- If a message retry exit returns this value, message retries for subsequent messages are controlled by the *MsgRetryCount* and *MsgRetryInterval* channel attributes as normal. For the current message, the MCA performs the number of outstanding retries, at intervals given by the *MsgRetryInterval* channel attribute, but only if the reason code is one that the MCA would normally retry (see the *MsgRetryCount* field described in “MQCD - Channel definition” on page 1477). The number of outstanding retries is the value of the **MsgRetryCount** attribute, less the number of times the exit returned MQXCC\_OK for the current message; if this number is negative, no further retries are performed by the MCA for the current message.

### **MQXCC\_CLOSE\_CHANNEL**

Close channel.

This value can be set by any type of channel exit except an auto-definition exit.

If sharing conversations is not enabled, this value closes the channel.

If sharing conversations is enabled, this value ends the conversation. If this conversation is the only conversation on the channel, the channel also closes.

This field is an input/output field from the exit.

*ExitResponse2 (MQLONG)*

This field specifies the secondary response from the exit.

This field is set to zero on entry to the exit routine. It can be set by the exit to provide further information to the IBM MQ channel functions. It is not used by the auto-definition exit.

The exit can set one or more of the following values. If more than one is required, the values are added. Combinations that are not valid are noted; other combinations are allowed.

### **MQXR2\_PUT\_WITH\_DEF\_ACTION**

Put with default action.

This value is set by the channel message exit of the receiver. It indicates that the message is to be put with the default action of the MCA, that is either the default user ID of the MCA, or the context *UserIdentifier* in the MQMD (message descriptor) of the message.

The value is zero, which corresponds to the initial value set when the exit is invoked. The constant is provided for documentation purposes.

### **MQXR2\_PUT\_WITH\_DEF\_USERID**

Put with default user identifier.

This value can only be set by the channel message exit of the receiver. It indicates that the message is to be put with the default user identifier of the MCA.

### **MQXR2\_PUT\_WITH\_MSG\_USERID**

Put with user identifier of the message.

This value can only be set by the channel message exit of the receiver. It indicates that the message is to be put with the context *UserIdentifier* in the MQMD (message descriptor) of the message (this might have been modified by the exit).

Only one of MQXR2\_PUT\_WITH\_DEF\_ACTION, MQXR2\_PUT\_WITH\_DEF\_USERID, and MQXR2\_PUT\_WITH\_MSG\_USERID should be set.

### **MQXR2\_USE\_AGENT\_BUFFER**

Use agent buffer.

This value indicates that any data to be passed on is in *AgentBuffer*, not *ExitBufferAddr*.

The value is zero, which corresponds to the initial value set when the exit is invoked. The constant is provided for documentation purposes.

### **MQXR2\_USE\_EXIT\_BUFFER**

Use exit buffer.

This value indicates that any data to be passed on is in *ExitBufferAddr*, not *AgentBuffer*.

Only one of MQXR2\_USE\_AGENT\_BUFFER and MQXR2\_USE\_EXIT\_BUFFER should be set.

### **MQXR2\_DEFAULT\_CONTINUATION**

Default continuation.

Continuation with the next exit in the chain depends on the response from the last exit invoked:

- If MQXCC\_SUPPRESS\_FUNCTION or MQXCC\_CLOSE\_CHANNEL are returned, no further exits in the chain are called.
- Otherwise, the next exit in the chain is invoked.

### **MQXR2\_CONTINUE\_CHAIN**

Continue with the next exit.

### **MQXR2\_SUPPRESS\_CHAIN**

Skip remaining exits in chain.

This is an input/output field to the exit.

#### *Feedback (MQLONG)*

This field specifies the feedback code.

This field is set to MQFB\_NONE on entry to the exit routine.

If a channel message exit sets the *ExitResponse* field to MQXCC\_SUPPRESS\_FUNCTION, the *Feedback* field specifies the feedback code that identifies why the message was put on the dead-letter (undelivered-message) queue, and is also used to send an exception report if one has been requested. In this case, if the *Feedback* field is MQFB\_NONE, the following feedback code is used:

### **MQFB\_STOPPED\_BY\_MSG\_EXIT**

Message stopped by channel message exit.

The value returned in this field by channel security, send, receive, and message-retry exits is not used by the MCA.

The value returned in this field by auto-definition exits is not used if *ExitResponse* is MQXCC\_OK, but otherwise is used for the *AuxErrorDataInt1* parameter in the event message.

This is an input/output field from the exit.

#### *MaxSegmentLength (MQLONG)*

This field specifies the maximum length in bytes that can be sent in a single transmission.

It is not used by the auto-definition exit. It is of interest to a channel send exit, because this exit must ensure that it does not increase the size of a transmission segment to a value greater than *MaxSegmentLength*. The length includes the initial 8 bytes that the exit must not change. The value is negotiated between the IBM MQ channel functions when the channel is initiated. See [Writing channel-exit programs](#) for more information about segment lengths.

The value in this field is not meaningful if *ExitReason* is MQXR\_INIT.

This is an input field to the exit.

#### *ExitUserArea (MQBYTE16)*

This field specifies the exit user area - a field available for the exit to use.

It is initialized to binary zero before the first invocation of the exit (which has an *ExitReason* set to MQXR\_INIT), and thereafter any changes made to this field by the exit are preserved across invocations of the exit.

The following value is defined:

### **MQXUA\_NONE**

No user information.

The value is binary zero for the length of the field.

For the C programming language, the constant MQXUA\_NONE\_ARRAY is also defined; this constant has the same value as MQXUA\_NONE, but is an array of characters instead of a string.

The length of this field is given by MQ\_EXIT\_USER\_AREA\_LENGTH. This is an input/output field to the exit.

#### *ExitData (MQCHAR32)*

This field specifies the exit data.

This field is set on entry to the exit routine to information that IBM MQ channel functions took from the channel definition. If no such information is available, this field is all blanks.

The length of this field is given by MQ\_EXIT\_DATA\_LENGTH.

This is an input field to the exit.

The following fields in this structure are not present if *Version* is less than MQCXP\_VERSION\_2.

#### *MsgRetryCount (MQLONG)*

This field specifies the number of times the message has been retried.

The first time the exit is invoked for a particular message, this field has the value zero (no retries yet attempted). On each subsequent invocation of the exit for that message, the value is incremented by one by the MCA.

This is an input field to the exit. The value in this field is not meaningful if *ExitReason* is MQXR\_INIT. The field is not present if *Version* is less than MQCXP\_VERSION\_2.

#### *MsgRetryInterval (MQLONG)*

This field specifies the minimum interval in milliseconds after which the put operation is retried.

The first time the exit is invoked for a particular message, this field contains the value of the *MsgRetryInterval* channel attribute. The exit can leave the value unchanged, or modify it to specify a different time interval in milliseconds. If the exit returns MQXCC\_OK in *ExitResponse*, the MCA waits for at least this time interval before retrying the MQOPEN or MQPUT operation. The time interval specified must be zero or greater.

The second and subsequent times the exit is invoked for that message, this field contains the value returned by the previous invocation of the exit.

If the value returned in the *MsgRetryInterval* field is less than zero or greater than 999 999 999, and *ExitResponse* is MQXCC\_OK, the MCA ignores the *MsgRetryInterval* field in MQCXP and waits instead for the interval specified by the *MsgRetryInterval* channel attribute.

This is an input/output field to the exit. The value in this field is not meaningful if *ExitReason* is MQXR\_INIT. The field is not present if *Version* is less than MQCXP\_VERSION\_2.

#### *MsgRetryReason (MQLONG)*

This field specifies the reason code from the previous attempt to put the message.

This field is the reason code from the previous attempt to put the message; it is one of the MQRC\_\* values.

This is an input field to the exit. The value in this field is not meaningful if *ExitReason* is MQXR\_INIT. The field is not present if *Version* is less than MQCXP\_VERSION\_2.

The following fields in this structure are not present if *Version* is less than MQCXP\_VERSION\_3.

#### *HeaderLength (MQLONG)*

This field specifies the length of header information.

This field is relevant only for a message exit and a message-retry exit. The value is the length of the routing header structures at the start of the message data; these are the MQXQH structure, the MQMDE (message description extension header), and (for a distribution-list message) the MQDH structure and arrays of MQOR and MQPMR records that follow the MQXQH structure.

The message exit can examine this header information, and modify it if necessary, but the data that the exit returns must still be in the correct format. The exit must not, for example, encrypt or compress the header data at the sending end, even if the message exit at the receiving end makes compensating changes.

If the message exit modifies the header information in such a way as to change its length (for example, by adding another destination to a distribution-list message), it must change the value of *HeaderLength* correspondingly before returning.

This is an input/output field to the exit. The value in this field is not meaningful if *ExitReason* is MQXR\_INIT. The field is not present if *Version* is less than MQCXP\_VERSION\_3.

#### *PartnerName (MQCHAR48)*

This field specifies the name of the partner.

The name of the partner, as follows:

- For SVRCONN channels, it is the logged-on user ID at the client.
- For all other types of channel, it is the queue manager name of the partner.

When the exit is initialized this field is blank because the queue manager does not know the name of the partner until after initial negotiation has taken place.

This is an input field to the exit. The field is not present if *Version* is less than MQCXP\_VERSION\_3.

#### *FAPLevel (MQLONG)*

Negotiated Formats and Protocols level.

This is an input field to the exit. Changes to this field should only be made under the direction of IBM service. The field is not present if *Version* is less than MQCXP\_VERSION\_3.

#### *CapabilityFlags (MQLONG)*

You can set the capability flag to either MQCF\_NONE or MQCF\_DIST\_LISTS.

You can set either of the following capability flags:

##### **MQCF\_NONE**

No flags.

##### **MQCF\_DIST\_LISTS**

Distribution lists supported.

This is an input field to the exit. The field is not present if *Version* is less than MQCXP\_VERSION\_3.

#### *ExitNumber (MQLONG)*

This field specifies the ordinal number of the exit.

The ordinal number of the exit, within the type defined in *ExitId*. For example, if the exit being invoked is the third message exit defined, this field contains the value 3. If the exit type is one for which a list of exits cannot be defined (for example, a security exit), this field has the value 1.

This is an input field to the exit. The field is not present if *Version* is less than MQCXP\_VERSION\_3.

The following fields in this structure are not present if *Version* is less than MQCXP\_VERSION\_5.

#### *ExitSpace (MQLONG)*

This field specifies the number of bytes in the transmission buffer reserved for the exit to use.

This field is relevant only for a send exit. It specifies the amount of space in bytes that the IBM MQ channel functions reserve in the transmission buffer for the exit to use. This field allows the exit to add to the transmission buffer a small amount of data (typically not exceeding a few hundred bytes) for use by a complementary receive exit at the other end. The data added by the send exit must be removed by the receive exit.

The value is always zero on z/OS.

**Note:** This facility must not be used to send large amounts of data, as it might degrade performance, or even inhibit operation of the channel.

By setting *ExitSpace* the exit is guaranteed that there is always at least that number of bytes available in the transmission buffer for the exit to use. However, the exit can use less than the amount reserved, or more than the amount reserved if there is space available in the transmission buffer. The exit space in the buffer is provided following the existing data.

*ExitSpace* can be set by the exit only when *ExitReason* has the value MQXR\_INIT; in all other cases the value returned by the exit is ignored. On input to the exit, *ExitSpace* is zero for the MQXR\_INIT call, and is the value returned by the MQXR\_INIT call in other cases.

If the value returned by the MQXR\_INIT call is negative, or there are fewer than 1024 bytes available in the transmission buffer for message data after reserving the requested exit space for all the send exits in the chain, the MCA outputs an error message and closes the channel. Similarly, if during data transfer the exits in the send exit chain allocate more user space than they reserved such that fewer than 1024 bytes remain in the transmission buffer for message data, the MCA outputs an error message and closes the channel. The limit of 1024 allows the control and administrative flows of the channel to be processed by the chain of send exits, without the need for the flows to be segmented.

This is an input/output field to the exit if *ExitReason* is MQXR\_INIT, and an input field in all other cases. The field is not present if *Version* is less than MQCXP\_VERSION\_5.

#### *SSLCertUserId (MQCHAR12)*

This field specifies the UserId associated with the remote certificate.

It is blank on all platforms except z/OS

This is an input field to the exit. The field is not present if *Version* is less than MQCXP\_VERSION\_6.

#### *SSLRemCertIssNameLength (MQLONG)*

This field specifies the length in bytes of the full Distinguished Name of the issuer of the remote certificate pointed to by SSLCertRemoteIssuerNamePtr.

This is an input field to the exit. The field is not present if *Version* is less than MQCXP\_VERSION\_6. The value is zero if it is not a TLS channel.

#### *SSLRemCertIssNamePtr (PMQVOID)*

This field specifies the address of the full Distinguished Name of the issuer of the remote certificate.

Its value is the null pointer if it is not a TLS channel.

This is an input field to the exit. The field is not present if *Version* is less than MQCXP\_VERSION\_6.

**Note:** The behavior of channel security exits in determining the Subject Distinguished Name and the Issuer Distinguished Name is changed from IBM WebSphere MQ 7.1. For more information see [Channel security exit programs](#).

#### *SecurityParms (PMQCSP)*

This field specifies the address of the MQCSP structure that is used to specify authentication credentials.

The initial value of this field is the null pointer.

This is an input/output field to the exit. The field is not present if *Version* is less than MQCXP\_VERSION\_6.

The value that the exit returns in this field must be usable by IBM MQ until MQXR\_TERM.

#### *CurHdrCompression (MQLONG)*

This field specifies which technique is currently being used to compress the header data.

It is set to one of the following:

#### **MQCOMPRESS\_NONE**

No header data compression is performed.

## **MQCOMPRESS\_SYSTEM**

Header data compression is performed.

The value can be altered by a sending channel's message exit to one of the negotiated supported values accessed from the `HdrCompList` field of the MQCD. This enables the technique used to compress the header data to be chosen for each message based on the content of the message. The altered value is used for the current message only. The channel ends if the attribute is altered to an unsupported value. The value is ignored if altered outside a sending channel's message exit.

This is an input/output field to the exit. The field is not present if *Version* is less than `MQCXP_VERSION_6`.

*CurMsgCompression (MQLONG)*

This field specifies which technique is currently being used to compress the message data.

It is set to one of the following:

### **MQCOMPRESS\_NONE**

No header data compression is performed.

### **MQCOMPRESS\_RLE**

Message data compression is performed using run-length encoding.

### **MQCOMPRESS\_ZLIBFAST**

Message data compression is performed using the zlib compression technique. A fast compression time is preferred.

### **MQCOMPRESS\_ZLIBHIGH**

Message data compression is performed using the zlib compression technique. A high level of compression is preferred.

The value can be altered by a sending channel's message exit to one of the negotiated supported values accessed from the `MsgCompList` field of the MQCD. This enables the technique used to compress the message data to be decided for each message based on the content of the message. The altered value is used for the current message only. The channel ends if the attribute is altered to an unsupported value. The value is ignored if altered outside a sending channel's message exit.

This is an input/output field to the exit. The field is not present if *Version* is less than `MQCXP_VERSION_6`.

*Hconn (MQHCONN)*

This field specifies the connection handle that the exit uses if it needs to make any MQI calls within the exit.

This field is not relevant to exits running on client-connection channels, where it contains the value `MQHC_UNUSABLE_HCONN` (-1).

This is an input field to the exit. The field is not present if *Version* is less than `MQCXP_VERSION_7`.

*SharingConversations (MQBOOL)*

This field specifies whether the conversation is the only one that can currently be running on this channel instance, or whether more than one conversation can currently be running on this channel instance.

It also indicates whether the exit program is subject to the risk of the MQCD being altered by another exit program running at the same time.

This field is only relevant for exit programs running on client-connection or server-connection channels.

It is set to one of the following:

### **FALSE**

The exit instance is the only exit instance that can currently be running on this channel instance. This allows the exit to safely update the MQCD fields without contention from other exits running on other channel instances. Whether changes to the MQCD fields are acted upon by the channel is defined by the table of MQCD fields in [“Changing MQCD fields in a channel exit” on page 1514](#).

## TRUE

The exit instance is not the only exit instance that can currently be running on this channel instance. Any changes made to the MQCD are not acted upon by the channel, except for changes listed in the table of MQCD fields in [“Changing MQCD fields in a channel exit”](#) on page 1514 for Exit Reasons other than MQXR\_INIT. If this exit updates the MQCD fields, ensure there is no contention from other exits running on other conversations at the same time by providing serialization among the exits that run on this channel instance.

This is an input field to the exit. The field is not present if *Version* is less than MQCXP\_VERSION\_7.

### *MCAUserSource (MQLONG)*

This field specifies the source of the provided MCA user ID.

It can contain one of the following values:

### **MQUSRC\_MAP**

The user ID is specified in the MCAUSER attribute.

### **MQUSRC\_CHANNEL**

The user ID is flowed from the inbound partner or specified in the MCAUSER field defined in the channel object.

This is an input field to the exit. The field is not present if *Version* is less than MQCXP\_VERSION\_8.

### *pEntryPoints (PMQIEP)*

This field specifies the address of the interface entry point for the MQI or DCI call.

The field is not present if *Version* is less than MQCXP\_VERSION\_8.

### *RemoteProduct (MQCHAR4)*

This field specifies the remote product name.

This field identifies the remote product of the client, for example, C or Java, as displayed in the **RPRODUCT** field of [DISPLAY CHSATUS](#).

The field is not present if *Version* is less than MQCXP\_VERSION\_9.

### *RemoteVersion (MQCHAR8)*

This field specifies the name of the remote version.

This field identifies the version of the client libraries, as displayed in the **RVERSION** field of [DISPLAY CHSTATUS](#).

The field is not present if *Version* is less than MQCXP\_VERSION\_9.

## **C declaration**

This declaration is the C declaration for the MQCXP structure.

```
typedef struct tagMQCXP MQCXP;
struct tagMQCXP {
    MQCHAR4    StrucId;           /* Structure identifier */
    MQLONG     Version;          /* Structure version number */
    MQLONG     ExitId;           /* Type of exit */
    MQLONG     ExitReason;       /* Reason for invoking exit */
    MQLONG     ExitResponse;     /* Response from exit */
    MQLONG     ExitResponse2;    /* Secondary response from exit */
    MQLONG     Feedback;         /* Feedback code */

## MQXWD - Exit wait descriptor

The MQXWD structure is an input/output parameter on the MQXWAIT call.

This structure is supported only on z/OS.

### Related reference

[“Fields” on page 1532](#)

This topic lists all the fields in the MQXWD structure and describes each field.

[“C declaration” on page 1532](#)

This declaration is the C declaration for the MQXWD structure.

[“System/390 assembler declaration” on page 1533](#)

This declaration is the System/390 assembler declaration for the MQXWD structure.

## **Fields**

This topic lists all the fields in the MQXWD structure and describes each field.

*StrucId (MQCHAR4)*

This field specifies the structure identifier.

The value must be:

### **MQXWD\_STRUC\_ID**

Identifier for exit wait descriptor structure.

For the C programming language, the constant MQXWD\_STRUC\_ID\_ARRAY is also defined; this constant has the same value as MQXWD\_STRUC\_ID, but is an array of characters instead of a string.

The initial value of this field is MQXWD\_STRUC\_ID.

*Version (MQLONG)*

This field specifies the structure version number.

The value must be:

### **MQXWD\_VERSION\_1**

Version number for exit wait descriptor structure.

The initial value of this field is MQXWD\_VERSION\_1.

*Reserved1 (MQLONG)*

This field is reserved. Its value must be zero.

This is an input field.

*Reserved2 (MQLONG)*

This field is reserved. Its value must be zero.

This is an input field.

*Reserved3 (MQLONG)*

This field is reserved. Its value must be zero.

This is an input field.

*ECB (MQLONG)*

This field specifies the event control block to wait on.

This field is the event control block (ECB) to wait on. It must be set to zero before the MQXWAIT call is issued; on successful completion it contains the post code.

This field is an input/output field.

## **C declaration**

This declaration is the C declaration for the MQXWD structure.

```
typedef struct tagMQXWD MQXWD;
struct tagMQXWD {
    MQCHAR4  StrucId;      /* Structure identifier */
    MQLONG   Version;     /* Structure version number */
    MQLONG   Reserved1;   /* Reserved */
    MQLONG   Reserved2;   /* Reserved */
    MQLONG   Reserved3;   /* Reserved */
}
```

```

MQLONG ECB; /* Event control block to wait on */
};

```

### System/390 assembler declaration

This declaration is the System/390 assembler declaration for the MQXWD structure.

```

MQXWD          DSECT

MQXWD_ECB      DS F    Event control block to wait on
*
MQXWD_LENGTH  EQU *-MQXWD
               ORG MQXWD
MQXWD_AREA    DS CL(MQXWD_LENGTH)

```

## Cluster workload exit call and data structures

This section provides reference information for the cluster workload exit and the data structures. This is general-use programming interface information.

You can write cluster workload exits in the following programming languages:

- C
- System/390 assembler ( IBM MQ for z/OS )

The call is described in:

- [“MQ\\_CLUSTER\\_WORKLOAD\\_EXIT - Call description” on page 1534](#)

The structure data types used by the exit are described in:

- [“MQXCLWLN - Navigate Cluster workload records” on page 1535](#)
- [“MQWXP - Cluster workload exit parameter structure” on page 1539](#)
- [“MQWDR - Cluster workload destination record structure” on page 1547](#)
- [“MQWQR - Cluster workload queue record structure” on page 1551](#)
- [“MQWCR - Cluster workload cluster record structure” on page 1556](#)
-  [Asynchronous behavior of CLUSTER commands on z/OS](#)

Throughout this section, queue manager attributes and queue attributes are shown in full. The equivalent names that are used in the MQSC commands are shown below. For details of MQSC commands, see [MQSC commands](#).

Full name	Name used in MQSC
<i>ClusterWorkloadData</i>	CLWLDATA
<i>ClusterWorkloadExit</i>	CLWLEXIT
<i>ClusterWorkloadLength</i>	CLWLLEN

Full name	Name used in MQSC
<i>DefBind</i>	DEFBIND
<i>DefPersistence</i>	DEFPSIST
<i>DefPriority</i>	DEFPRTY

<i>Table 825. Queue attributes (continued)</i>	
<b>Full name</b>	<b>Name used in MQSC</b>
<i>InhibitPut</i>	PUT
<i>QDesc</i>	DESCR

### **Related tasks**

[Writing and compiling cluster workload exits](#)

## **MQ\_CLUSTER\_WORKLOAD\_EXIT - Call description**

The cluster workload exit is called by the queue manager to route a message to an available queue manager.

**Note:** No entry point called MQ\_CLUSTER\_WORKLOAD\_EXIT is provided by the queue manager. Instead, the name of the cluster workload exit is defined by the ClusterWorkloadExit queue manager attribute.

The MQ\_CLUSTER\_WORKLOAD\_EXIT exit is supported on all platforms.

## **Syntax**

```
MQ_CLUSTER_WORKLOAD_EXIT (ExitParms)
```

### **Related reference**

[MQXCLWLN - Navigate Cluster workload records](#)

The MQXCLWLN call is used to navigate through the chains of MQWDR, MQWQR, and MQWCR records stored in the cluster cache.

### **Parameters for MQ\_CLUSTER\_WORKLOAD\_EXIT**

Description of the parameters in the MQ\_CLUSTER\_WORKLOAD\_EXIT call.

#### **ExitParms (MQWXP) - input/output**

Exit parameter block.

- The exit sets information in MQWXP to indicate how to manage the workload.

### **Related reference**

[Usage notes](#)

The function performed by the cluster workload exit is defined by the provider of the exit. The exit, however, must conform to the rules defined in the associated control block MQWXP.

[Language invocations for MQ\\_CLUSTER\\_WORKLOAD\\_EXIT](#)

The MQ\_CLUSTER\_WORKLOAD\_EXIT supports two languages, C and High Level Assembler.

### **Usage notes**

The function performed by the cluster workload exit is defined by the provider of the exit. The exit, however, must conform to the rules defined in the associated control block MQWXP.

No entry point called MQ\_CLUSTER\_WORKLOAD\_EXIT is provided by the queue manager. However, a typedef is provided for the name MQ\_CLUSTER\_WORKLOAD\_EXIT in the C programming language. Use the typedef to declare the user-written exit, to ensure that the parameters are correct.

### **Related reference**

[Description of the parameters in the MQ\\_CLUSTER\\_WORKLOAD\\_EXIT call.](#)

[Language invocations for MQ\\_CLUSTER\\_WORKLOAD\\_EXIT](#)

The MQ\_CLUSTER\_WORKLOAD\_EXIT supports two languages, C and High Level Assembler.

### **Language invocations for MQ\_CLUSTER\_WORKLOAD\_EXIT**

The MQ\_CLUSTER\_WORKLOAD\_EXIT supports two languages, C and High Level Assembler.

### **C invocation**

```
MQ_CLUSTER_WORKLOAD_EXIT (&ExitParms);
```

Replace *MQ\_CLUSTER\_WORKLOAD\_EXIT* with the name of your cluster workload exit function.

Declare the **MQ\_CLUSTER\_WORKLOAD\_EXIT** parameters as follows:

```
MQWXP ExitParms; /* Exit parameter block */
```

### **High Level Assembler invocation**

```
CALL EXITNAME,(EXITPARMS)
```

Declare the parameters as follows:

```
EXITPARMS      CMQWXP      Exit parameter block
```

### **Related reference**

[Parameters for MQ\\_CLUSTER\\_WORKLOAD\\_EXIT](#)

[Description of the parameters in the MQ\\_CLUSTER\\_WORKLOAD\\_EXIT call.](#)

### **Usage notes**

The function performed by the cluster workload exit is defined by the provider of the exit. The exit, however, must conform to the rules defined in the associated control block MQWXP.

## **MQXCLWLN - Navigate Cluster workload records**

The MQXCLWLN call is used to navigate through the chains of MQWDR, MQWQR, and MQWCR records stored in the cluster cache.

The cluster cache is an area of main storage used to store information relating to the cluster.

If the cluster cache is static, it has a fixed size. If you set it to dynamic, the cluster cache can expand as required.

Set the type of cluster cache to STATIC or DYNAMIC using either a system parameter or macro.

-  Use the system parameter ClusterCacheType on [Multiplatforms](#).

-  Use the CLCACHE parameter in the CSQ6SYSP macro on z/OS.

## Syntax

MQXCLWLN (*ExitParms, CurrentRecord, NextOffset, NextRecord, Compcode, Reason*)

### Related reference

[MQ\\_CLUSTER\\_WORKLOAD\\_EXIT - Call description](#)

The cluster workload exit is called by the queue manager to route a message to an available queue manager.

The following table summarizes the fields in the MQWQR - Cluster workload queue record structure.

[MQWCR - Cluster workload cluster record structure](#)

The following table summarizes the fields in the MQWCR cluster workload record structure.

### **Parameters for MQXCLWLN - Navigate Cluster workload records**

Description of the parameters in the MQXCLWLN call.

#### **ExitParms ( MQWXP ) - input/output**

Exit parameter block.

This structure contains information relating to the invocation of the exit. The exit sets information in this structure to indicate how to manage the workload.

#### **CurrentRecord ( MQPTR ) - input**

Address of current record.

This structure contains information relating to the address of the record currently being examined by the exit. The record must be one of the following types:

- Cluster workload destination record ( MQWDR )
- Cluster workload queue record ( MQWQR )
- Cluster workload cluster record ( MQWCR )

#### **NextOffset ( MQLONG ) - input**

Offset of next record.

This structure contains information relating to the offset of the next record or structure. *NextOffset* is the value of the appropriate offset field in the current record, and must be one of the following fields:

- ChannelDefOffset field in MQWDR
- ClusterRecOffset field in MQWDR
- ClusterRecOffset field in MQWQR
- ClusterRecOffset field in MQWCR

#### **NextRecord ( MQPTR ) - output**

Address of next record or structure.

This structure contains information relating to the address of the next record or structure.

If *CurrentRecord* is the address of an MQWDR, and *NextOffset* is the value of the ChannelDefOffset field, *NextRecord* is the address of the channel definition structure ( MQCD ).

If there is no next record or structure, the queue manager sets *NextRecord* to the null pointer, and the call returns completion code MQCC\_WARNING and reason code MQRC\_NO\_RECORD\_AVAILABLE.

### CompCode ( MQLONG ) - output

Completion code.

The completion code has one of the following values:

#### MQCC\_OK

Successful completion.

#### MQCC\_WARNING

Warning (partial completion).

#### MQCC\_FAILED

Call failed.

### Reason ( MQLONG ) - output

Reason code qualifying CompCode

If CompCode is MQCC\_OK:

#### MQRC\_NONE

( 0, X'0000' )

No reason to report.

If CompCode is MQCC\_WARNING:

#### MQRC\_NO\_RECORD\_AVAILABLE

( 2359, X'0937' )

No record available. An MQXCLWLN call was issued from a cluster workload exit to obtain the address of the next record in the chain. The current record is the last record in the chain.  
Corrective action: None.

If CompCode is MQCC\_FAILED:

#### MQRC\_CURRENT\_RECORD\_ERROR

( 2357, X'0935' )

**CurrentRecord** parameter not valid. An MQXCLWLN call was issued from a cluster workload exit to obtain the address of the next record in the chain. The address specified by the **CurrentRecord** parameter is not the address of a valid record.

**CurrentRecord** must be the address of a destination record, MQWDR, queue record ( MQWQR ), or cluster record ( MQWCR ) residing within the cluster cache. Corrective action: Ensure that the cluster workload exit passes the address of a valid record residing in the cluster cache.

#### MQRC\_ENVIRONMENT\_ERROR

( 2012, X'07DC' )

Call not valid in environment. An MQXCLWLN call was issued, but not from a cluster workload exit.

#### MQRC\_NEXT\_OFFSET\_ERROR

( 2358, X'0936' )

**NextOffset** parameter not valid. An MQXCLWLN call was issued from a cluster workload exit to obtain the address of the next record in the chain. The offset specified by the **NextOffset** parameter is not valid. **NextOffset** must be the value of one of the following fields:

- ChannelDefOffset field in MQWDR
- ClusterRecOffset field in MQWDR
- ClusterRecOffset field in MQWQR
- ClusterRecOffset field in MQWCR

Corrective action: Ensure that the value specified for the **NextOffset** parameter is the value of one of the fields listed previously.

#### MQRC\_NEXT\_RECORD\_ERROR

( 2361, X'0939' )

**NextRecord** parameter not valid.

## **MQRC\_WXP\_ERROR (2356, X'0934')**

Workload exit parameter structure not valid. An MQXCLWLN call was issued from a cluster workload exit to obtain the address of the next record in the chain. The workload exit parameter structure **ExitParms** is not valid, for one of the following reasons:

- The parameter pointer is not valid. It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.
- The `StrucId` field is not `MQWXP_STRUC_ID`.
- The `Version` field is not `MQWXP_VERSION_2`.
- The `Context` field does not contain the value passed to the exit by the queue manager.

Corrective action: Ensure that the parameter specified for **ExitParms** is the `MQWXP` structure that was passed to the exit when the exit was invoked.

### **Related reference**

[Usage notes for MQXCLWLN - Navigate Cluster workload records](#)

Use `MQXCLWLN` to navigate through cluster records, even if the cache is static.

[Language invocations of MQXCLWLN](#)

`MQXCLWLN` supports two languages, C and High Level Assembler.

### **Usage notes for MQXCLWLN - Navigate Cluster workload records**

Use `MQXCLWLN` to navigate through cluster records, even if the cache is static.

If the cluster cache is dynamic, the `MQXCLWLN` call must be used to navigate through the records. The exit ends abnormally if simple pointer-and-offset arithmetic is used to navigate through the records.

If the cluster cache is static, `MQXCLWLN` need not be used to navigate through the records. Typically use `MQXCLWLN` even when the cache is static. You can then change the cluster cache to being dynamic without needing to change the workload exit.

### **Related reference**

[Parameters for MQXCLWLN - Navigate Cluster workload records](#)

Description of the parameters in the `MQXCLWLN` call.

[Language invocations of MQXCLWLN](#)

`MQXCLWLN` supports two languages, C and High Level Assembler.

### **Language invocations of MQXCLWLN**

`MQXCLWLN` supports two languages, C and High Level Assembler.

## **C invocation**

```
MQXCLWLN (&ExitParms, CurrentRecord, NextOffset, &NextRecord, &CompCode, &Reason) ;
```

Declare the parameters as follows:

```
typedef struct tagMQXCLWLN {  
MQWXP   ExitParms;      /* Exit parameter block */  
MQPTR   CurrentRecord; /* Address of current record*/  
MQLONG  NextOffset;    /* Offset of next record */  
MQPTR   NextRecord;    /* Address of next record or structure */  
MQLONG  CompCode;      /* Completion code */  
MQLONG  Reason;        /* Reason code qualifying CompCode */  
};
```

## **High Level Assembler invocation**

```
CALL MQXCLWLN, (CLWLEXITPARMS, CURRENTRECORD, NEXTOFFSET, NEXTRECORD, COMPCODE, REASON)
```

Declare the parameters as follows:

```
CLWLEXITPARMS CMQWXP, Cluster workload exit parameter block
CURRENTRECORD CMQWDRA, Current record
NEXTOFFSET DS F Next offset
NEXTRECORD DS F Next record
COMPCODE DS F Completion code
REASON DS F Reason code qualifying COMPCODE
```

## MQWXP - Cluster workload exit parameter structure

The following table summarizes the fields in the MQWXP - Cluster workload exit parameter structure.

<i>Table 826. Fields in MQWXP</i>		
<b>Field</b>	<b>Description</b>	<b>Page</b>
<i>StrucId</i>	Structure identifier	<a href="#">StrucId</a>
<i>Version</i>	Structure version number	<a href="#">Version</a>
<i>ExitId</i>	Type of exit	<a href="#">ExitId</a>
<i>ExitReason</i>	Reason for invoking exit	<a href="#">ExitReason</a>
<i>ExitResponse</i>	Response from exit	<a href="#">ExitResponse</a>
<i>ExitResponse2</i>	Secondary response from exit	<a href="#">ExitResponse2</a>
<i>Feedback</i>	Feedback code	<a href="#">Feedback</a>
<i>Flags</i>	Flags values. These bit flags are used to indicate information about the message being put	<a href="#">Flags</a>
<i>ExitUserArea</i>	Exit user area	<a href="#">ExitUserArea</a>
<i>ExitData</i>	Exit data	<a href="#">ExitData</a>
<i>MsgDescPtr</i>	Address of message descriptor ( MQMD )	<a href="#">MsgDescPtr</a>
<i>MsgBufferPtr</i>	Address of buffer containing some or all the message data	<a href="#">MsgBufferPtr</a>
<i>MsgBufferLength</i>	Length of buffer containing message data	<a href="#">MsgBufferLength</a>
<i>MsgLength</i>	Length of complete message	<a href="#">MsgLength</a>
<i>QName</i>	Name of queue	<a href="#">QName</a>
<i>QMgrName</i>	Name of local queue manager	<a href="#">QMgrName</a>
<i>DestinationCount</i>	Number of possible destinations	<a href="#">DestinationCount</a>
<i>DestinationChosen</i>	Destination chosen	<a href="#">DestinationChosen</a>
<i>DestinationArrayPtr</i>	Address of an array of pointers to destination records ( MQWDR )	<a href="#">DestinationArrayPtr</a>
<i>QArrayPtr</i>	Address of an array of pointers to queue records ( MQWQR )	<a href="#">QArrayPtr</a>

Table 826. Fields in MQWXP (continued)		
Field	Description	Page
<b>Note:</b> The remaining fields are ignored if Version is less than MQWXP_VERSION_2.		
<i>CacheContext</i>	Context information	<a href="#">CacheContext</a>
<i>CacheType</i>	Type of cluster cache	<a href="#">CacheType</a>
<b>Note:</b> The remaining fields are ignored if Version is less than MQWXP_VERSION_3.		
<i>CLWLMRUChannels</i>	Maximum number of allowed active outbound cluster channels	<a href="#">CLWLMRUChannels</a>
<b>Note:</b> The remaining fields are ignored if Version is less than MQWXP_VERSION_4.		
<i>pEntryPoints</i>	Address of the MQIEP structure to allow MQI and DCI calls to be made	<a href="#">pEntryPoints</a>

The cluster workload exit parameter structure describes the information that is passed to the cluster workload exit.

The cluster workload exit parameter structure is supported on all platforms

Additionally, the MQWXP1, MQWXP2 and MQWXP3 structures are available for backwards compatibility.

[MQWCR - Cluster workload cluster record structure](#)

The following table summarizes the fields in the MQWCR cluster workload record structure.

#### ***Fields in MQWXP - Cluster workload exit parameter structure***

Description of the fields in the MQWXP - Cluster workload exit parameter structure

##### **StrucId (MQCHAR4) - input**

The structure identifier for the cluster workload exit parameter structure.

- The StrucId value is MQWXP\_STRUC\_ID.
- For the C programming language, the constant MQWXP\_STRUC\_ID\_ARRAY is also defined. It has the same value as MQWXP\_STRUC\_ID. It is an array of characters instead of a string.

##### **Version (MQLONG) - input**

Indicates the structure version number. Version takes one of the following values:

###### **MQWXP\_VERSION\_1**

Version-1 cluster workload exit parameter structure.

MQWXP\_VERSION\_1 is supported in all environments.

###### **MQWXP\_VERSION\_2**

Version-2 cluster workload exit parameter structure.

MQWXP\_VERSION\_2 is supported in the following environments:

-  AIX
-  IBM i
-  Linux
-  Windows

### **MQWXP\_VERSION\_3**

Version-3 cluster workload exit parameter structure.

MQWXP\_VERSION\_3 is supported in the following environments:

-  AIX
-  IBM i
-  Linux
-  Windows

### **MQWXP\_VERSION\_4**

Version-4 cluster workload exit parameter structure.

MQWXP\_VERSION\_4 is supported in the following environments:

-  AIX
-  IBM i
-  Linux
-  Windows

### **MQWXP\_CURRENT\_VERSION**

Current version of cluster workload exit parameter structure.

#### **ExitId (MQLONG) - input**

Indicates the type of exit being called. The cluster workload exit is the only supported exit.

- The `ExitId` value must be `MQXT_CLUSTER_WORKLOAD_EXIT`

#### **ExitReason (MQLONG) - input**

Indicates the reason for invoking the cluster workload exit. `ExitReason` takes one of the following values:

##### **MQXR\_INIT**

Indicates that the exit is being invoked for the first time.

Acquire and initialize any resources that the exit might need, such as main storage.

##### **MQXR\_TERM**

Indicates that the exit is about to be terminated.

Free any resources that the exit might have acquired since it was initialized, such as main storage.

##### **MQXR\_CLWL\_OPEN**

Called by `MQOPEN`.

##### **MQXR\_CLWL\_PUT**

Called by `MQPUT` or `MQPUT1`.

##### **MQXR\_CLWL\_MOVE**

Called by MCA when the channel state has changed.

##### **MQXR\_CLWL\_REPOS**

Called by `MQPUT` or `MQPUT1` for a repository-manager PCF message.

### **MQXR\_CLWL\_REPOS\_MOVE**

Called by MCA for a repository-manager PCF message if the channel state has changed.

### **ExitResponse (MQLONG) - output**

Set ExitResponse to indicate whether processing of the message continues. It must be one of the following values:

#### **MQXCC\_OK**

Continue processing the message normally.

- DestinationChosen identifies the destination to which the message is to be sent.

#### **MQXCC\_SUPPRESS\_FUNCTION**

Discontinue processing the message.

- The actions taken by the queue manager depend on the reason the exit was invoked:

ExitReason	Action taken
– MQXR_CLWL_OPEN – MQXR_CLWL_REPOS – MQXR_CLWL_PUT	MQOPEN, MQPUT, or MQPUT1 call fail with completion code MQCC_FAILED and reason code MQRC_STOPPED_BY_CLUSTER_EXIT.
– MQXR_CLWL_MOVE – MQXR_CLWL_REPOS_MOVE	The message is placed on the dead-letter queue.

#### **MQXCC\_SUPPRESS\_EXIT**

Continue processing the current message normally. Do not invoke the exit again until the queue manager shuts down.

The queue manager processes subsequent messages as if the ClusterWorkloadExit queue manager attribute is blank. DestinationChosen identifies the destination to which the current message is sent.

#### **Any other value**

Process the message as if MQXCC\_SUPPRESS\_FUNCTION is specified.

### **ExitResponse2 (MQLONG) - input/output**

Set ExitResponse2 to provide the queue manager with more information.

- MQXR2\_STATIC\_CACHE is the default value, and is set on entry to the exit.
- When ExitReason has the value MQXR\_INIT, the exit can set one of the following values in ExitResponse2:

#### **MQXR2\_STATIC\_CACHE**

The exit requires a static cluster cache.

- If the cluster cache is static, the exit need not use the MQXCLWLN call to navigate the chains of records in the cluster cache.
- If the cluster cache is dynamic, the exit cannot navigate correctly through the records in the cache.

**Note:** The queue manager processes the return from the MQXR\_INIT call as though the exit had returned MQXCC\_SUPPRESS\_EXIT in the ExitResponse field.

#### **MQXR2\_DYNAMIC\_CACHE**

The exit can operate with either a static or dynamic cache.

- If the exit returns this value, the exit must use the MQXCLWLN call to navigate the chains of records in the cluster cache.

### **Feedback (MQLONG) - input**

A reserved field. The value is zero.

**Flags (MQLONG) - input**

Indicates information about the message being put.

- The value of `Flags` is `MQWXP_PUT_BY_CLUSTER_CHL`. The message originates from a cluster channel, rather than locally or from a non-cluster channel. In other words, the message has come from another cluster queue manager.

**Reserved (MQLONG) - input**

A reserved field. The value is zero.

**ExitUserArea (MQBYTE16) - input/output**

Set `ExitUserArea` to communicate between calls to the exit.

- `ExitUserArea` is initialized to binary zero before the first invocation of the exit. Any changes made to this field by the exit are preserved across the invocations of the exit that occur between the `MQCONN` call and the matching `MQDISC` call. The field is reset to binary zero when the `MQDISC` call occurs.
- The first invocation of the exit is indicated by the `ExitReason` field having the value `MQXR_INIT`.
- The following constants are defined:

**MQXUA\_NONE** - string

**MQXUA\_NONE\_ARRAY** - character array

No user information. Both constants are binary zero for the length of the field.

**MQ\_EXIT\_USER\_AREA\_LENGTH**

The length of `ExitUserArea`.

**ExitData (MQCHAR32) - input**

The value of the `ClusterWorkloadData` queue manager attribute. If no value has been defined for that attribute, this field is all blanks.

- The length of `ExitData` is given by `MQ_EXIT_DATA_LENGTH`.

**MsgDescPtr (PMQMD) - input**

The address of a copy of the message descriptor (MQMD) for the message being processed.

- Any changes made to the message descriptor by the exit are ignored by the queue manager.
- If `ExitReason` has one of the following values `MsgDescPtr` is set to the null pointer, and no message descriptor is passed to the exit:

– `MQXR_INIT`

– `MQXR_TERM`

– `MQXR_CLWL_OPEN`

**MsgBufferPtr (PMQVOID) - input**

The address of a buffer containing a copy of the first `MsgBufferLength` bytes of the message data.

- Any changes made to the message data by the exit are ignored by the queue manager.
- No message data is passed to the exit when:
  - `MsgDescPtr` is the null pointer.
  - The message has no data.
  - The `ClusterWorkloadLength` queue manager attribute is zero.

In these cases, `MsgBufferPtr` is the null pointer.

**MsgBufferLength (MQLONG) - input**

The length of the buffer containing the message data passed to the exit.

- The length is controlled by the `ClusterWorkloadLength` queue manager attribute.
- The length might be less than the length of the complete message, see `MsgLength`.

**MsgLength (MQLONG) - input**

The length of the complete message passed to the exit.

- `MsgBufferLength` might be less than the length of the complete message.
- `MsgLength` is zero if `ExitReason` is `MQXR_INIT`, `MQXR_TERM`, or `MQXR_CLWL_OPEN`.

**QName (MQCHAR48) - input**

The name of the destination queue. The queue is a cluster queue.

- The length of `QName` is `MQ_Q_NAME_LENGTH`.

**QMgrName (MQCHAR48) - input**

The name of the local queue manager that has invoked the cluster workload exit.

- The length of `QMgrName` is `MQ_Q_MGR_NAME_LENGTH`.

**DestinationCount (MQLONG) - input**

The number of possible destinations. Destinations are instances of the destination queue and are described by destination records.

- A destination record is a `MQWDR` structure. There is one structure for each possible route to each instance of the queue.
- `MQWDR` structures are addressed by an array of pointers, see `DestinationArrayPtr`.

**DestinationChosen (MQLONG) - input/output**

The chosen destination.

- The number of the `MQWDR` structure that identifies the route and queue instance where the message is to be sent.
- The value is in the range 1 - `DestinationCount`.
- On input to the exit, `DestinationChosen` indicates the route and queue instance that the queue manager has selected. The exit can accept this choice, or choose a different route and queue instance.
- The value set by the exit must be in the range 1 - `DestinationCount`. If any other value is returned, the queue manager uses the value of `DestinationChosen` on input to the exit.

**DestinationArrayPtr (PPMQWDR) - input**

The address of an array of pointers to destination records (`MQWDR`).

- There are `DestinationCount` destination records.

**QArrayPtr (PPMQQR) - input**

The address of an array of pointers to queue records (`MQWQR`).

- If queue records are available, there are `DestinationCount` of them.
- If no queue records are available, `QArrayPtr` is the null pointer.

**Note:** `QArrayPtr` can be the null pointer even when `DestinationCount` is greater than zero.

**CacheContext (MQPTR) : Version 2 - input**

The `CacheContext` field is reserved for use by the queue manager. The exit must not alter the value of this field.

**CacheType (MQLONG) : Version 2 - input**

The cluster cache has one of the following types:

**MQCLCT\_STATIC**

The cache is static.

- The size of the cache is fixed, and cannot grow as the queue manager operates.
- You do not need to use the `MQXCLWLN` call to navigate the records in this type of cache.

**MQCLCT\_DYNAMIC**

The cache is dynamic.

- The size of the cache can increase in order to accommodate the varying cluster information.
- You must use the `MQXCLWLN` call to navigate the records in this type of cache.

**CLWLMRUChannels (MQLONG) : Version 3 - input**

Indicates the maximum number of active outbound cluster channels, to be considered for use by the cluster workload choice algorithm.

- CLWLMRUChannels is a value 1 - 999 999 999.

**pEntryPoints (PMQIEP) : Version 4**

The address of an MQIEP structure through which MQI and DCI calls can be made.

## MQWDR - Cluster workload destination record structure

The following table summarizes the fields in the MQWDR - Cluster workload destination record structure.

<i>Table 829. Fields in MQWDR</i>		
Field	Description	Page
<i>StrucId</i>	Structure identifier	<a href="#">StrucId</a>
<i>Version</i>	Structure version number	<a href="#">Version</a>
<i>StrucLength</i>	Length of MQWDR structure	<a href="#">StrucLength</a>
<i>QMgrFlags</i>	Queue manager flags	<a href="#">QMgrFlags</a>
<i>QMgrIdentifier</i>	Queue manager identifier	<a href="#">QMgrIdentifier</a>
<i>QMgrName</i>	Queue manager name	<a href="#">QMgrName</a>
<i>ClusterRecOffset</i>	Logical offset of first cluster record ( MQWCR )	<a href="#">ClusterRecOffset</a>
<i>ChannelState</i>	Channel state	<a href="#">ChannelState</a>
<i>ChannelDefOffset</i>	Logical offset of channel-definition structure ( MQCD )	<a href="#">ChannelDefOffset</a>
<b>Note:</b> The remaining fields are ignored if Version is less than MQWDR_VERSION_2.		
<i>DestSeqNumber</i>	Channel destination sequence number	<a href="#">DestSeqNumber</a>
<i>DestSeqFactor</i>	Channel destination sequence factor for weighting	<a href="#">DestSeqFactor</a>

The cluster workload destination record structure contains information relating to one of the possible destinations for the message. There is one cluster workload destination record structure for each instance of the destination queue.

The cluster workload destination record structure is supported in all environments.

Additionally, the MQWDR1 and MQWDR2 structures are available for backwards compatibility.

MQWQR - Cluster workload queue record structure

The following table summarizes the fields in the MQWQR - Cluster workload queue record structure.

MQWCR - Cluster workload cluster record structure

The following table summarizes the fields in the MQWCR cluster workload record structure.

### ***Fields in MQWDR - Cluster workload destination record structure***

Description of the parameters in the MQWDR - Cluster workload destination record structure.

#### **StrucId ( MQCHAR4 ) - input**

The structure identifier for the cluster workload destination record structure.

- The StrucId value is MQWDR\_STRUC\_ID.
- For the C programming language, the constant MQWDR\_STRUC\_ID\_ARRAY is also defined. It has the same value as MQWDR\_STRUC\_ID. It is an array of characters instead of a string.

#### **Version ( MQLONG ) - input**

The structure version number. Version takes one of the following values:

##### **MQWDR\_VERSION\_1**

Version-1 cluster workload destination record.

##### **MQWDR\_VERSION\_2**

Version-2 cluster workload destination record.

##### **MQWDR\_CURRENT\_VERSION**

Current version of cluster workload destination record.

#### **StrucLength ( MQLONG ) - input**

The length of MQWDR structure. StrucLength takes one of the following values:

##### **MQWDR\_LENGTH\_1**

Length of version-1 cluster workload destination record.

##### **MQWDR\_LENGTH\_2**

Length of version-2 cluster workload destination record.

##### **MQWDR\_CURRENT\_LENGTH**

Length of current version of cluster workload destination record.

#### **QMgrFlags ( MQLONG ) - input**

Queue manager flags indicating properties of the queue manager that hosts the instance of the destination queue described by the MQWDR structure. The following flags are defined:

##### **MQQMF\_REPOSITORY\_Q\_MGR**

Destination is a full repository queue manager.

##### **MQQMF\_CLUSSDR\_USER\_DEFINED**

Cluster-sender channel was defined manually.

##### **MQQMF\_CLUSSDR\_AUTO\_DEFINED**

Cluster-sender channel was defined automatically.

##### **MQQMF\_AVAILABLE**

Destination queue manager is available to receive messages.

#### ***Other values***

Other flags in the field might be set by the queue manager for internal purposes.

#### **QMgrIdentifier ( MQCHAR48 ) - input**

The queue manager identifier is a unique identifier for the queue manager that hosts the instance of the destination queue described by the MQWDR structure.

- The identifier is generated by the queue manager.

- The length of `QMgrIdentifier` is `MQ_Q_MGR_IDENTIFIER_LENGTH`.

#### **QMgrName ( MQCHAR48 ) - input**

The name of the queue manager that hosts the instance of the destination queue described by the `MQWDR` structure.

- `QMgrName` can be the name of the local queue manager, as well another queue manager in the cluster.
- The length of `QMgrName` is `MQ_Q_MGR_NAME_LENGTH`.

#### **ClusterRecOffset ( MQLONG ) - input**

The logical offset of the first `MQWCR` structure that belongs to the `MQWDR` structure.

- For static caches, `ClusterRecOffset` is the offset of the first `MQWCR` structure that belongs to the `MQWDR` structure.
- The offset is measured in bytes from the start of the `MQWDR` structure.
- Do not use the logical offset for pointer arithmetic with dynamic caches. To obtain the address of the next record, the `MQXCLWLN` call must be used.

#### **ChannelState ( MQLONG ) - input**

The state of the channel that links the local queue manager to the queue manager identified by the `MQWDR` structure. The following values are possible:

##### **MQCHS\_BINDING**

Channel is negotiating with the partner.

##### **MQCHS\_INACTIVE**

Channel is not active.

##### **MQCHS\_INITIALIZING**

Channel is initializing.

##### **MQCHS\_PAUSED**

Channel has paused.

##### **MQCHS\_REQUESTING**

Requester channel is requesting connection.

##### **MQCHS\_RETRYING**

Channel is reattempting to establish connection.

##### **MQCHS\_RUNNING**

Channel is transferring or waiting for messages.

##### **MQCHS\_STARTING**

Channel is waiting to become active.

##### **MQCHS\_STOPPING**

Channel is stopping.

##### **MQCHS\_STOPPED**

Channel has stopped.

#### **ChannelDefOffset ( MQLONG ) - input**

The logical offset of the channel definition (`MQCD`) for the channel that links the local queue manager to the queue manager identified by the `MQWDR` structure.

- `ChannelDefOffset` is like `ClusterRecOffset`
- The logical offset cannot be used in pointer arithmetic. To obtain the address of the next record, the `MQXCLWLN` call must be used.

#### **DestSeqFactor ( MQLONG ) - input**

The destination sequence factor that allows a choice of the channel based on weight.

- `DestSeqFactor` is used before the queue manager changes it.
- The workload manager increases `DestSeqFactor` in a way that ensures messages are distributed down channels according to their weight.

## DestSeqNumber ( MQLONG ) - input

The cluster channel destination value before the queue manager changes it.

- The workload manager increases DestSeqNumber every time a message is put down that channel.
- Workload exits can use DestSeqNumber to decide which channel to put a message down.

The following table summarizes the fields in the MQWCR cluster workload record structure.

### **Fields in MQWQR - Cluster workload queue record structure**

Description of the fields in the MQWQR - Cluster workload queue record structure.

#### **StrucId ( MQCHAR4 ) - input**

The structure identifier for the cluster workload queue record structure.

- The StrucId value is MQWQR\_STRUC\_ID.
- For the C programming language, the constant MQWQR\_STRUC\_ID\_ARRAY is also defined. It has the same value as MQWQR\_STRUC\_ID. It is an array of characters instead of a string.

#### **Version ( MQLONG ) - input**

The structure version number. Version takes one of the following values:

##### **MQWQR\_VERSION\_1**

Version-1 cluster workload queue record.

##### **MQWQR\_VERSION\_2**

Version-2 cluster workload queue record.

##### **MQWQR\_VERSION\_3**

Version-3 cluster workload queue record.

##### **MQWQR\_CURRENT\_VERSION**

Current version of cluster workload queue record.

#### **StrucLength ( MQLONG ) - input**

The length of MQWQR structure. StrucLength takes one of the following values:

##### **MQWQR\_LENGTH\_1**

Length of version-1 cluster workload queue record.

##### **MQWQR\_LENGTH\_2**

Length of version-2 cluster workload queue record.

##### **MQWQR\_LENGTH\_3**

Length of version-3 cluster workload queue record.

**MQWQR\_CURRENT\_LENGTH**

Length of current version of cluster workload queue record.

**QFlags ( MQLONG ) - input**

The queue flags indicate properties of the queue. The following flags are defined:

**MQQF\_LOCAL\_Q**

Destination is a local queue.

**MQQF\_CLWL\_USEQ\_ANY**

Allow use of local and remote queues in puts.

**MQQF\_CLWL\_USEQ\_LOCAL**

Allow only local queue puts.

**Other values**

Other flags in the field might be set by the queue manager for internal purposes.

**QName ( MQCHAR48 ) - input**

The name of the queue that is one of the possible destinations of the message.

- The length of QName is MQ\_Q\_NAME\_LENGTH.

**QMgrIdentifier ( MQCHAR48 ) - input**

The queue manager identifier is a unique identifier for the queue manager that hosts the instance of the queue described by the MQWQR structure.

- The identifier is generated by the queue manager.
- The length of QMgrIdentifier is MQ\_Q\_MGR\_IDENTIFIER\_LENGTH.

**ClusterRecOffset ( MQLONG ) - input**

The logical offset of the first MQWCR structure that belongs to the MQWQR structure.

- For static caches, ClusterRecOffset is the offset of the first MQWCR structure that belongs to the MQWQR structure.
- The offset is measured in bytes from the start of the MQWQR structure.
- Do not use the logical offset for pointer arithmetic with dynamic caches. To obtain the address of the next record, the MQXCLWLN call must be used.

**QType ( MQLONG ) - input**

The queue type of the destination queue. The following values are possible:

**MQCQT\_LOCAL\_Q**

Local queue.

**MQCQT\_ALIAS\_Q**

Alias queue.

**MQCQT\_REMOTE\_Q**

Remote queue.

**MQCQT\_Q\_MGR\_ALIAS**

Queue manager alias.

**QDesc ( MQCHAR64 ) - input**

The queue description queue attribute defined on the queue manager that hosts the instance of the destination queue described by the MQWQR structure.

- The length of QDesc is MQ\_Q\_DESC\_LENGTH.

**DefBind ( MQLONG ) - input**

The default binding queue attribute defined on the queue manager that hosts the instance of the destination queue described by the MQWQR structure. Either MQBND\_BIND\_ON\_OPEN or MQBND\_BIND\_ON\_GROUP must be specified when using groups with clusters. The following values are possible:

**MQBND\_BIND\_ON\_OPEN**

Binding fixed by MQOPEN call.

**MQBND\_BIND\_NOT\_FIXED**

Binding not fixed.

**MQBND\_BIND\_ON\_GROUP**

Allows an application to request that a group of messages are all allocated to the same destination instance.

**DefPersistence ( MQLONG ) - input**

The default message persistence queue attribute defined on the queue manager that hosts the instance of the destination queue described by the MQWQR structure. The following values are possible:

**MQPER\_PERSISTENT**

Message is persistent.

**MQPER\_NOT\_PERSISTENT**

Message is not persistent.

**DefPriority ( MQLONG ) - input**

The default message priority queue attribute defined on the queue manager that hosts the instance of the destination queue described by the MQWQR structure. The priority range is 0 - MaxPriority.

- 0 is the lowest priority.
- MaxPriority is the queue manager attribute of the queue manager that hosts this instance of the destination queue.

**InhibitPut ( MQLONG ) - input**

The put inhibited queue attribute defined on the queue manager that hosts the instance of the destination queue described by the MQWQR structure. The following values are possible:

**MQQA\_PUT\_INHIBITED**

Put operations are inhibited.

**MQQA\_PUT\_ALLOWED**

Put operations are allowed.

**CLWLQueuePriority ( MQLONG ) - input**

The cluster workload queue priority attribute defined on the queue manager that hosts the instance of the destination queue described by the MQWQR structure.

**CLWLQueueRank ( MQLONG ) - input**

The cluster workload queue rank defined on the queue manager that hosts the instance of the destination queue described by the MQWQR structure.

**DefPutResponse ( MQLONG ) - input**

The default put response queue attribute defined on the queue manager that hosts the instance of the destination queue described by the MQWQR structure. The following values are possible:

**MQPRT\_SYNC\_RESPONSE**

Synchronous response to MQPUT or MQPUT1 calls.

**MQPRT\_ASYNC\_RESPONSE**

Asynchronous response to MQPUT or MQPUT1 calls.

**Notes:**

1. The symbol ↵ represents a single blank character.
2. In the C programming language, the macro variable MQWQR\_DEFAULT contains the default values. Use it in the following way to provide initial values for the fields in the structure:

```
MQWQR MyWQR = {MQWQR_DEFAULT};
```
3. The initial values intentionally set the length of the structure to the length of the current version, and not version 1 of the structure.

### **C declaration**

```
typedef struct tagMQWQR {
    MQCHAR4   StrucId;           /* Structure identifier */
    MQLONG    Version;          /* Structure version number */

## MQWCR - Cluster workload cluster record structure

The following table summarizes the fields in the MQWCR cluster workload record structure.

<i>Table 833. Fields in MQWCR</i>		
Field	Description	Page
<i>ClusterName</i>	Name of cluster	<a href="#">ClusterName</a>
<i>ClusterRecOffset</i>	Offset of next cluster record ( MQWCR )	<a href="#">ClusterRecOffset</a>
<i>ClusterFlags</i>	Cluster flags	<a href="#">ClusterFlags</a>

The cluster workload cluster record structure contains information about a cluster. For each cluster the destination queue belongs to, there is one cluster workload cluster record structure.

The cluster workload cluster record structure is supported in all environments.

### ***Fields in the MQWCR - Cluster workload cluster record structure.***

Description of the fields in the MQWCR - Cluster workload cluster record structure.

#### **ClusterName ( MQCHAR48 ) - input**

The name of a cluster to which the instance of the destination queue that owns the MQWCR structure belongs. The destination queue instance is described by an MQWDR structure.

- The length of ClusterName is MQ\_CLUSTER\_NAME\_LENGTH.

#### **ClusterRecOffset ( MQLONG ) - input**

The logical offset of the next MQWCR structure.

- If there are no more MQWCR structures, ClusterRecOffset is zero.
- The offset is measured in bytes from the start of the MQWCR structure.

#### **ClusterFlags ( MQLONG ) - input**

The cluster flags indicate properties of the queue manager identified by the MQWCR structure. The following flags are defined:

##### **MQQMF\_REPOSITORY\_Q\_MGR**

Destination is a full repository queue manager.

##### **MQQMF\_CLUSSDR\_USER\_DEFINED**

Cluster-sender channel was defined manually.

##### **MQQMF\_CLUSSDR\_AUTO\_DEFINED**

Cluster-sender channel was defined automatically.

##### **MQQMF\_AVAILABLE**

Destination queue manager is available to receive messages.

##### **Other values**

Other flags in the field might be set by the queue manager for internal purposes.

## API exit reference

This section provides reference information mainly of interest to a programmer writing API exits.

### General usage notes

#### notes:

1. All exit functions can issue the MQXEP call; this call is designed specifically for use from API exit functions.
2. The MQ\_INIT\_EXIT function cannot issue any MQ calls other than MQXEP.
3. You cannot issue the MQDISC call for the current connection.
4. If an exit function issues the MQCONN call, or the MQCONNX call with the MQCNO\_HANDLE\_SHARE\_NONE option, the call completes with reason code MQRC\_ALREADY\_CONNECTED, and the handle returned is the same as the one passed to the exit as a parameter.
5. In general when an API exit function issues an MQI call, API exits are not be called recursively. However, if an exit function issues the MQCONNX call with the MQCNO\_HANDLE\_SHARE\_BLOCK or MQCNO\_HANDLE\_SHARE\_NO\_BLOCK options, the call returns a new shared handle. This provides the exit suite with a connection handle of its own, and hence a unit of work that is independent of the application's unit of work. The exit suite can use this handle to put and get messages within its own unit of work, and commit or back out that unit of work; all of this can be done without affecting the application's unit of work in any way.

Because the exit function is using a connection handle that is different from the handle being used by the application, MQ calls issued by the exit function result in the relevant API exit functions being invoked. Exit functions can therefore be invoked recursively. Note that both the *ExitUserArea* field in MQAXP and the exit chain area have connection-handle scope. Consequently, an exit function cannot use those areas to signal to another instance of itself invoked recursively that it is already active.

6. Exit functions can also put and get messages within the application's unit of work. When the application commits or backs out the unit of work, all messages within the unit of work are committed or backed out together, regardless of who placed them in the unit of work (application or exit function). However, the exit can cause the application to exceed system limits sooner than would otherwise be the case (for example, by exceeding the maximum number of uncommitted messages in a unit of work).

When an exit function uses the application's unit of work in this way, the exit function should usually avoid issuing the MQCMIT call, as this commits the application's unit of work and might impair the correct functioning of the application. However, the exit function might sometimes need to issue the MQBACK call, if the exit function encounters a serious error that prevents the unit of work being

committed (for example, an error putting a message as part of the application's unit of work). When MQBACK is called, take care to ensure that the application unit of work boundaries are not changed. In this situation the exit function must set the appropriate values to ensure that completion code MQCC\_WARNING and reason code MQRC\_BACKED\_OUT are returned to the application, so that the application can detect the fact that the unit of work has been backed out.

If an exit function uses the application's connection handle to issue MQ calls, those calls do not themselves result in further invocations of API exit functions.

7. If an MQXR\_BEFORE exit function terminates abnormally, the queue manager might be able to recover from the failure. If it can, the queue manager continues processing as though the exit function had returned MQXCC\_FAILED. If the queue manager cannot recover, the application is terminated.
8. If an MQXR\_AFTER exit function terminates abnormally, the queue manager might be able to recover from the failure. If it can, the queue manager continues processing as though the exit function had returned MQXCC\_FAILED. If the queue manager cannot recover, the application is terminated. Be aware that in the latter case, messages retrieved outside a unit of work are lost (this is the same situation as the application failing immediately after removing a message from the queue).
9. The MCA process performs a two phase commit.

If an API exit intercepts an MQCMIT from a prepared MCA process and attempts to perform an action within the unit of work, then the action will fail with reason code MQRC\_UOW\_NOT\_AVAILABLE.

10. Where multiple installations of IBM MQ are available, use the exits written for an earlier version of IBM MQ, as new functionality added in the later version might not work with earlier versions. For more information about changes between releases, see [What's changed in IBM MQ 8.0](#).

## IBM MQ API exit parameter structure (MQAXP)

The MQAXP structure, an external control block, is used as an input or output parameter to the API exit. This topic also gives information about how queue managers process exit functions.

MQAXP has the following C declaration:

```
typedef struct tagMQAXP {
    MQCHAR4   StrucId;           /* Structure identifier */
    MQLONG    Version;          /* Structure version number */
    MQLONG    ExitId;           /* Exit Identifier */
    MQLONG    ExitReason;       /* Exit invocation reason */
    MQLONG    ExitResponse;     /* Response code from exit */
    MQLONG    ExitResponse2;    /* Secondary response code from exit */
    MQLONG    Feedback;        /* Feedback code from exit */
    MQLONG    APICallerType;    /* MQSeries API caller type */
    MQBYTE16  ExitUserArea;    /* User area for use by exit */
    MQCHAR32  ExitData;        /* Exit data area */
    MQCHAR48  ExitInfoName;    /* Exit information name */
    MQBYTE48  ExitPDArea;      /* Problem determination area */
    MQCHAR48  QMgrName;        /* Name of local queue manager */
    PMQACH    ExitChainAreaPtr; /* Inter exit communication area */
    MQHCONFIG Hconfig;        /* Configuration handle */
    MQLONG    Function;        /* Function Identifier */
    /* Ver:1 */
    MQHMSG    ExitMsgHandle    /* Exit message handle */
    /* Ver:2 */
};
```

The following parameter list is passed when functions in an API exit are invoked:

### StrucId (MQCHAR4) - input

The exit parameter structure identifier, with a value of:

```
MQAXP_STRUC_ID.
```

The exit handler sets this field on entry to each exit function.

### Version (MQLONG) - input

The structure version number, with a value of:

**MQAXP\_VERSION\_1**

Version 1 API exit parameter structure.

**MQAXP\_VERSION\_2**

Version 2 API exit parameter structure.

**MQAXP\_CURRENT\_VERSION**

Current version number for the API exit parameter structure.

The exit handler sets this field on entry to each exit function.

**ExitId (MQLONG) - input**

The exit identifier, set on entry to the exit routine, indicating the type of exit:

**MQXT\_API\_EXIT**

API exit.

**ExitReason (MQLONG) - input**

The reason for invoking the exit, set on entry to each exit function:

**MQXR\_CONNECTION**

The exit is being invoked to initialize itself before an MQCONN or MQCONNX call, or to end itself after an MQDISC call.

**MQXR\_BEFORE**

The exit is being invoked before executing an API call, or before converting data on an MQGET.

**MQXR\_AFTER**

The exit is being invoked after executing an API call.

**ExitResponse (MQLONG) - output**

The response from the exit, initialized on entry to each exit function to:

**MQXCC\_OK**

Continue normally.

This field must be set by the exit function, to communicate to the queue manager the result of executing the exit function. The value must be one of the following:

**MQXCC\_OK**

The exit function completed successfully. Continue normally.

This value can be set by all MQXR\_\* exit functions. ExitResponse2 is used to decide whether to invoke exit functions later in the chain.

**MQXCC\_FAILED**

The exit function failed because of an error.

This value can be set by all MQXR\_\* exit functions. The queue manager sets CompCode to MQCC\_FAILED, and Reason to:

- MQRC\_API\_EXIT\_INIT\_ERROR if the function is MQ\_INIT\_EXIT
- MQRC\_API\_EXIT\_TERM\_ERROR if the function is MQ\_TERM\_EXIT
- MQRC\_API\_EXIT\_ERROR for all other exit functions

The values set can be altered by an exit function later in the chain.

ExitResponse2 is ignored; the queue manager continues processing as though MQXR2\_SUPPRESS\_CHAIN had been returned.

**MQXCC\_SUPPRESS\_FUNCTION**

Suppress IBM MQ API function.

This value can be set only by an MQXR\_BEFORE exit function. It bypasses the API call. If it is returned by the MQ\_DATA\_CONV\_ON\_GET\_EXIT, data conversion is bypassed. The queue manager sets CompCode to MQCC\_FAILED, and Reason to MQRC\_SUPPRESSED\_BY\_EXIT, but the values set can be altered by an exit function later in the chain. Other parameters for the call remain as the exit left them. ExitResponse2 is used to decide whether to invoke exit functions later in the chain.

If this value is set by an MQXR\_AFTER or MQXR\_CONNECTION exit function, the queue manager continues processing as though MQXCC\_FAILED had been returned.

### **MQXCC\_SKIP\_FUNCTION**

Skip IBM MQ API function.

This value can be set only by an MQXR\_BEFORE exit function. It bypasses the API call. If it is returned by the MQ\_DATA\_CONV\_ON\_GET\_EXIT, data conversion is bypassed. The exit function must set CompCode and Reason to the values to be returned to the application, but the values set can be altered by an exit function later in the chain. Other parameters for the call remain as the exit left them. ExitResponse2 is used to decide whether to invoke exit functions later in the chain.

If this value is set by an MQXR\_AFTER or MQXR\_CONNECTION exit function, the queue manager continues processing as though MQXCC\_FAILED had been returned.

### **MQXCC\_SUPPRESS\_EXIT**

Suppress all exit functions belonging to the set of exits.

This value can be set only by the MQXR\_BEFORE and MQXR\_AFTER exit functions. It bypasses *all* subsequent invocations of exit functions belonging to this set of exits for this logical connection. This bypassing continues until the logical disconnect request occurs, when MQ\_TERM\_EXIT function is invoked with an ExitReason of MQXR\_CONNECTION.

The exit function must set CompCode and Reason to the values to be returned to the application, but the values set can be altered by an exit function later in the chain. Other parameters for the call remain as the exit left them. ExitResponse2 is ignored.

If this value is set by an MQXR\_CONNECTION exit function, the queue manager continues processing as though MQXCC\_FAILED had been returned.

For information about the interaction between ExitResponse and ExitResponse2, and its effect on exit processing, see [“How queue managers process exit functions” on page 1563](#).

### **ExitResponse2 (MQLONG) - output**

This is a secondary exit response code that qualifies the primary exit response code for MQXR\_BEFORE exit functions. It is initialized to:

```
MQXR2_DEFAULT_CONTINUATION
```

on entry to an IBM MQ API call exit function. It can then be set to one of the values:

#### **MQXR2\_DEFAULT\_CONTINUATION**

Whether to continue with the next exit in the chain, depending on the value of ExitResponse.

If ExitResponse is MQXCC\_SUPPRESS\_FUNCTION or MQXCC\_SKIP\_FUNCTION, bypass exit functions later in the MQXR\_BEFORE chain and the matching exit functions in the MQXR\_AFTER chain. Invoke exit functions in the MQXR\_AFTER chain that match exit functions earlier in the MQXR\_BEFORE chain.

Otherwise, invoke the next exit in the chain.

#### **MQXR2\_SUPPRESS\_CHAIN**

Suppress the chain.

Bypass exit functions later in the MQXR\_BEFORE chain and the matching exit functions in the MQXR\_AFTER chain for this API call invocation. Invoke exit functions in the MQXR\_AFTER chain that match exit functions earlier in the MQXR\_BEFORE chain.

#### **MQXR2\_CONTINUE\_CHAIN**

Continue with the next exit in the chain.

For information about the interaction between ExitResponse and ExitResponse2, and its effect on exit processing, see [“How queue managers process exit functions” on page 1563](#).

### **Feedback (MQLONG) - input/output**

Communicate feedback codes between exit function invocations. This is initialized to:

MQFB\_NONE (0)

before invoking the first function of the first exit in a chain.

Exits can set this field to any value, including any valid MQFB\_\* or MQRC\_\* value. Exits can also set this field to a user-defined feedback value in the range MQFB\_APPL\_FIRST to MQFB\_APPL\_LAST.

#### **APICallerType (MQLONG) - input**

The API caller type, indicating whether the IBM MQ API caller is external or internal to the queue manager: MQXACT\_EXTERNAL or MQXACT\_INTERNAL.

#### **ExitUserArea (MQBYTE16) - input/output**

A user area, available to all the exits associated with a particular ExitInfoObject. It is initialized to MQXUA\_NONE (binary zeros for the length of the ExitUserArea) before invoking the first exit function (MQ\_INIT\_EXIT) for the hconn. From then on, any changes made to this field by an exit function are preserved across invocations of functions of the same exit.

This field is aligned to a multiple of 4 MQLONGs.

Exits can also anchor any storage that they allocate from this area.

For each hconn, each exit in a chain of exits has a different ExitUserArea. The ExitUserArea cannot be shared by exits in a chain, and the contents of the ExitUserArea for one exit are not available to another exit in a chain.

For C programs, the constant MQXUA\_NONE\_ARRAY is also defined with the same value as MQXUA\_NONE, but as an array of characters instead of a string.

The length of this field is given by MQ\_EXIT\_USER\_AREA\_LENGTH.

#### **ExitData (MQCHAR32) - input**

Exit data, set on input to each exit function to the 32 characters of exit-specific data that is provided in the exit. If you define no value in the exit this field is all blanks.

The length of this field is given by MQ\_EXIT\_DATA\_LENGTH.

#### **ExitInfoName (MQCHAR48) - input**

The exit information name, set on input to each exit function to the ApiExit\_name specified in the exit definitions in the stanzas.

#### **ExitPDArea (MQBYTE48) - input/output**

A problem determination area, initialized to MQXPDA\_NONE (binary zeros for the length of the field) for each invocation of an exit function.

For C programs, the constant MQXPDA\_NONE\_ARRAY is also defined with the same value as MQXPDA\_NONE, but as an array of characters instead of a string.

The exit handler always writes this area to the IBM MQ trace at the end of an exit, even when the function is successful.

The length of this field is given by MQ\_EXIT\_PD\_AREA\_LENGTH.

#### **QMgrName (MQCHAR48) - input**

The name of the queue manager the application is connected to, that has invoked an exit as a result of processing an IBM MQ API call.

If the name of a queue manager supplied on an MQCONN or MQCONNX calls is blank, this field is still set to the name of the queue manager to which the application is connected, whether the application is server or client.

The exit handler sets this field on entry to each EXIT function.

The length of this field is given by MQ\_Q\_MGR\_NAME\_LENGTH.

#### **ExitChainAreaPtr (PMQACH) - input/output**

This is used to communicate data across invocations of different exits in a chain. It is set to a NULL pointer before invoking the first function (MQ\_INIT\_EXIT with ExitReason MQXR\_CONNECTION) of the

first exit in a chain of exits. The value returned by the exit on one invocation is passed on to the next invocation.

Refer to [“The exit chain area and exit chain area header \(MQACH\)”](#) on page 1567 for more details about how to use the exit chain area.

### **Hconfig (MQHCONFIG) - input**

The configuration handle, representing the set of functions being initialized. This value is generated by the queue manager on the MQ\_INIT\_EXIT function, and is later passed to the API exit function. It is set on entry to each exit function.

You can use Hconfig as a pointer to the MQIEP structure to make MQI and DCI calls. You must check that the first 4 bytes of HConfig match the StrucId of the MQIEP structure before using the HConfig parameter as a pointer to the MQIEP structure.

### **Function (MQLONG) - input**

The function identifier, valid values for which are the MQXF\_\* constants described in [“External constants”](#) on page 1568.

The exit handler sets this field to the correct value, on entry to each exit function, depending on the IBM MQ API call that resulted in the exit being invoked.

### **ExitMsgHandle (MQHMSG) - input/output**

When Function is MQXF\_GET and ExitReason is MQXR\_AFTER, a valid message handle is returned in this field allowing the API exit access to the message descriptor fields and any other properties matching the ExitProperties string specified in the MQXEPO structure when registering the API exit.

Any non-message descriptor properties that are returned in the ExitMsgHandle will not be available from the MsgHandle in the MQGMO structure if one was specified, or in the message data.

When Function is MQXF\_GET and ExitReason is MQXR\_BEFORE, if the exit program sets this field to MQHM\_NONE then it will suppress the populating of the ExitMsgHandle properties.

This field is not set if Version is less than MQAXP\_VERSION\_2.

## **How queue managers process exit functions**

The processing performed by the queue manager on return from an exit function depends on both ExitResponse and ExitResponse2.

[Table 835 on page 1564](#) summarizes the possible combinations and their effects for an MQXR\_BEFORE exit function, showing:

- Who sets the CompCode and Reason parameters of the API call
- Whether the remaining exit functions in the MQXR\_BEFORE chain and the matching exit functions in the MQXR\_AFTER chain are invoked
- Whether the API call is invoked

For an MQXR\_AFTER exit function:

- CompCode and Reason are set in the same way as MQXR\_BEFORE
- ExitResponse2 is ignored (the remaining exit functions in the MQXR\_AFTER chain are always invoked)
- MQXCC\_SUPPRESS\_FUNCTION and MQXCC\_SKIP\_FUNCTION are not valid

For an MQXR\_CONNECTION exit function:

- CompCode and Reason are set in the same way as MQXR\_BEFORE
- ExitResponse2 is ignored
- MQXCC\_SUPPRESS\_FUNCTION, MQXCC\_SKIP\_FUNCTION, MQXCC\_SUPPRESS\_EXIT are not valid

In all cases, where an exit or the queue manager sets CompCode and Reason, the values set can be changed by an exit invoked later, or by the API call (if the API call is invoked later).

Table 835. MQXR\_BEFORE exit processing

Value of ExitResponse	CompCode and Reason set by	Value of ExitResponse2 (default continuation) Chain	Value of ExitResponse2 (default continuation) API
MQXCC_OK	exit	Y	Y
MQXCC_SUPPRESS_EXIT	exit	Y	Y
MQXCC_SUPPRESS_FUNCTION	queue manager	N	N
MQXCC_SKIP_FUNCTION	exit	N	N
MQXCC_FAILED	queue manager	N	N

## How clients process exit functions

In general, clients process exit functions in the same way that server applications do, and the *QMGrName* attribute in this structure applies whether the function is on a server or a client.

However, the client has no concept of the *mqs.ini* file, so the *ApiExitCommon* and *APIExitTemplate* stanzas do not apply. Only the *ApiExitLocal* stanza applies, and this stanza is configured in the *mqclient.ini* file.

## IBM MQ API exit context structure (MQAXC)

The MQAXC structure, an external control block, is used as an input parameter to an API exit.

MQAXC has the following C declaration:

```
typedef struct tagMQAXC {
    MQCHAR4   StrucId;           /* Structure identifier */
    MQLONG    Version;          /* Structure version number */
    MQLONG    Environment;      /* Environment */
    MQCHAR12  UserId;           /* UserId associated with appl */
    MQBYTE40  SecurityId;       /* Extension to UserId running appl */
    MQCHAR264 ConnectionName;   /* Connection name */
    MQLONG    LongMCAUserIdLength; /* long MCA user identifier length */
    MQLONG    LongRemoteUserIdLength; /* long remote user identifier length */
    MQPTR     LongMCAUserIdPtr;  /* long MCA user identifier address */
    MQPTR     LongRemoteUserIdPtr; /* long remote user identifier address */
    MQCHAR28  ApplName;         /* Application name */
    MQLONG    ApplType;         /* Application type */
    MQPID     ProcessId;        /* Process identifier */
    MQTID     ThreadId;         /* Thread identifier */

    /* Ver:1 */
    MQCHAR    ChannelName[20]   /* Channel Name */
    MQBYTE4   Reserved1;        /* Reserved */
    PMQCD     pChannelDefinition; /* Channel Definition pointer */
};
```

The parameters to MQAXC are:

### StrucId (MQCHAR4) - input

The exit context structure identifier, with a value of MQAXC\_STRUC\_ID. For C programs, the constant MQAXC\_STRUC\_ID\_ARRAY is also defined, with the same value as MQAXC\_STRUC\_ID, but as an array of characters instead of a string.

The exit handler sets this field on entry to each exit function.

### Version (MQLONG) - input

The structure version number, with a value of:

#### MQAXC\_VERSION\_2

Version number for the exit context structure.

**MQAXC\_CURRENT\_VERSION**

Current version number for the exit context structure.

The exit handler sets this field on entry to each exit function.

**Environment (MQLONG) - input**

The environment from which an IBM MQ API call was issued that resulted in an exit function being driven. Valid values for this field are:

**MQXE\_OTHER**

This value is consistent with invocations an API exit sees if the exit is called from a server application. This means that an API exit runs unchanged on a client and does not see anything different.

If the exit really needs to determine whether it is running on the client, the exit can do so by looking at the *ChannelName* and *ChannelDefinition* fields.

**MQXE\_MCA**

Message channel agent

**MQXE\_MCA\_SVRCONN**

A message channel agent acting on behalf of a client

**MQXE\_COMMAND\_SERVER**

The command server

**MQXE\_MQSC**

The runmqsc command interpreter

The exit handler sets this field on entry to each exit function.

**UserId (MQCHAR12) - input**

The user ID associated with the application. In particular, in the case of client connections, this field contains the user ID of the adopted user as opposed to the user ID under which the channel code is running. If a blank user ID flows from the client, then no change is made to the user ID already being used. That is, no new user ID is adopted.

The exit handler sets this field on entry to each exit function. The length of this field is given by MQ\_USER\_ID\_LENGTH.

In the case of a client, this is the user ID sent from the client to the server. Note, that this might not be the effective user ID the client is running against in the queue manager, as there could be an MCAUser or CHLAUTH configuration which changes the user ID.

**SecurityId (MQBYTE40) - input**

An extension to the user ID running the application. Its length is given by MQ\_SECURITY\_ID\_LENGTH.

In the case of a client, this is the user ID sent from the client to the server. Note, that this might not be the effective user ID the client is running against in the queue manager, as there could be an MCAUser or CHLAUTH configuration which changes the user ID.

**ConnectionName (MQCHAR264) - input**

The connection name field, set to the address of the client. For example, for TCP/IP, it would be the client IP address.

The length of this field is given by MQ\_CONN\_NAME\_LENGTH.

In the case of a client, this is the partner address of the queue manager.

**LongMCAUserIdLength (MQLONG) - input**

The length of the long MCA user identifier.

When MCA connects to the queue manager this field is set to the length of the long MCA user identifier (or zero if there is no such identifier).

In the case of a client, this is the client long user identifier.

**LongRemoteUserIdLength (MQLONG) - input**

The length of the long remote user identifier.

When MCA connects to the queue manager this field is set to the length of the long remote user identifier. Otherwise this field will be set to zero

In the case of a client, set this field to zero.

**LongMCAUserIntPtr (MQPTR) - input**

Address of long MCA user identifier.

When MCA connects to the queue manager this field is set to the address of the long MCA user identifier (or to a null pointer if there is no such identifier).

In the case of a client, this is the client long user identifier.

**LongRemoteUserIntPtr (MQPTR) - input**

The address of the long remote user identifier.

When MCA connects to the queue manager this field is set to the address of the long remote user identifier (or to a null pointer if there is no such identifier).

In the case of a client, set this field to zero.

**ApplName (MQCHAR28) - input**

The name of the application or component that issued the IBM MQ API call.

The rules for generating the ApplName are the same as for generating the default name for an MQPUT.

The value of this field is found by querying the operating system for the program name. Its length is given by MQ\_APPL\_NAME\_LENGTH.

**ApplType (MQLONG) - input**

The type of application or component that issued the IBM MQ API call.

The value is MQAT\_DEFAULT for the platform on which the application is compiled, or it equates to one of the defined MQAT\_\* values.

The exit handler sets this field on entry to each exit function.

**ProcessId (MQPID) - input**

The operating system process identifier.

Where applicable, the exit handler sets this field on entry to each exit function.

**ThreadId (MQTID) - input**

The MQ thread identifier. This is the same identifier used in MQ trace and FFST dumps, but might be different from the operating system thread identifier.

Where applicable, the exit handler sets this field on entry to each exit function.

**ChannelName (MQCHAR) - input**

The name of the channel, padded with blanks, if applicable and known.

If not applicable, this field is set to NULL characters.

**Reserved1 (MQBYTE4) - input**

This field is reserved.

**ChannelDefinition (PMQCD) - input**

A pointer to the channel definition being used, if applicable and known.

If not applicable, this field is set to NULL characters.

Note that the pointer is only completed if the connection is processing on behalf of an IBM MQ channel and that channel definition has been read.

In particular, the channel definition is not given on the server when the first MQCONN call is made for the channel. Furthermore, if the pointer is filled, the structure (and any sub structures) pointed to by the pointer must be treated as read only; any updating of the structure would lead to unpredictable results and is not supported.

In the case of a client, fields other than those with a value specified for a client, contain values that are appropriate for a client application.

## The exit chain area and exit chain area header (MQACH)

If required, an exit function can acquire storage for an exit chain area and set the `ExitChainAreaPtr` in `MQAXP` to point to this storage.

Exits (either the same or different exit functions) can acquire multiple exit chain areas and link them together. Exit chain areas must only be added or removed from this list while called from the exit handler. This ensures that there are no serialization issues caused by different threads adding or removing areas from the list at the same time.

An exit chain area must start with an `MQACH` header structure, the C declaration for which is:

```
typedef struct tagMQACH {
    MQCHAR4   StrucId;           /* Structure identifier */
    MQLONG    Version;          /* Structure version number */
    MQLONG    StrucLength;      /* Length of the MQACH structure */
    MQLONG    ChainAreaLength; /* Exit chain area length */
    MQCHAR48  ExitInfoName     /* Exit information name */
    PMQACH    NextChainAreaPtr; /* Pointer to next exit chain area */
};
```

The fields in the exit chain area header are:

### StrucId (MQCHAR4) - input

The exit chain area structure identifier, with an initial value, defined by `MQACH_DEFAULT`, of `MQACH_STRUC_ID`.

For C programs, the constant `MQACH_STRUC_ID_ARRAY` is also defined; this has the same value as `MQACH_STRUC_ID`, but as an array of characters instead of a string.

### Version (MQLONG) - input

The structure version number, as follows:

#### MQACH\_VERSION\_1

The version number for the exit parameter structure.

#### MQACH\_CURRENT\_VERSION

The current version number for the exit context structure.

The initial value of this field, defined by `MQACH_DEFAULT`, is `MQACH_CURRENT_VERSION`.

**Note:** If you introduce a new version of this structure, the layout of the existing part does not change. Exit functions must check that the version number is equal to or greater than the lowest version containing the fields that the exit function needs to use.

### StrucLength (MQLONG) - input

The length of the `MQACH` structure. Exits can use this field to determine the start of the exit data, setting it to the length of the structure created by the exit.

The initial value of this field, defined by `MQACH_DEFAULT`, is `MQACH_CURRENT_LENGTH`.

### ChainAreaLength (MQLONG) - input

The exit chain area length, set to the overall length of the current exit chain area, including the `MQACH` header.

The initial value of this field, defined by `MQACH_DEFAULT`, is zero.

### ExitInfoName (MQCHAR48) - input

The exit information name.

When an exit creates an `MQACH` structure, it must initialize this field with its own `ExitInfoName`, so that later this `MQACH` structure can be found by either another instance of this exit, or by a cooperating exit.

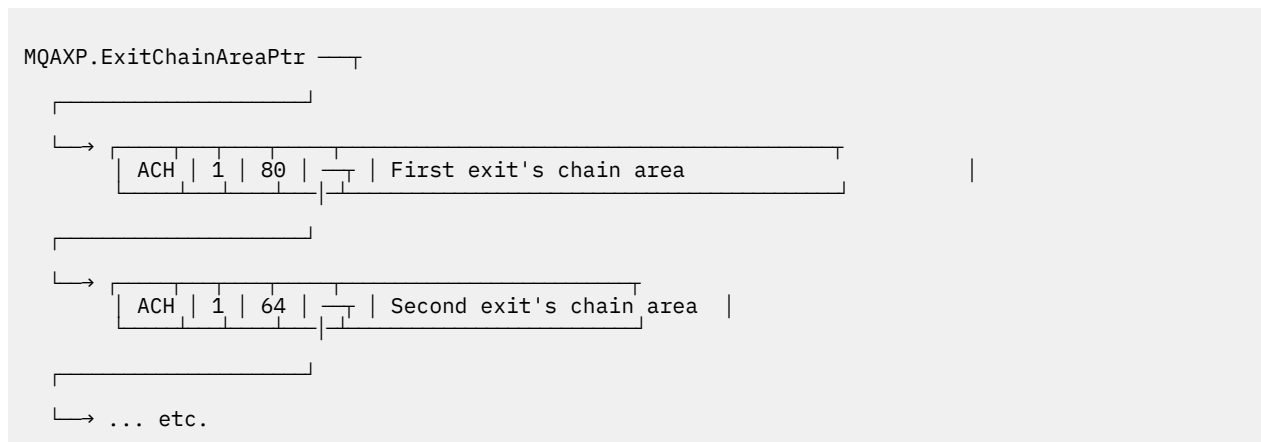

The initial value of this field, defined by `MQACH_DEFAULT`, is a zero length string (`{""}`).

### NextChainAreaPtr (PMQACH) - input

A pointer to the next exit chain area with an initial value, defined by MQACH\_DEFAULT, of null pointer (NULL).

Exit functions must release the storage for any exit chain areas that they acquire, and manipulate the chain pointers to remove their exit chain areas from the list.

An exit chain area can be constructed as follows:

### External constants

Use this topic as reference information for external constants available for API exits.

The following external constants are available for API exits:

#### MQXF\_\* (exit function identifiers)

MQXF_INIT	1	X'00000001'
MQXF_TERM	2	X'00000002'
MQXF_CONN	3	X'00000003'
MQXF_CONNX	4	X'00000004'
MQXF_DISC	5	X'00000005'
MQXF_OPEN	6	X'00000006'
MQXF_CLOSE	7	X'00000007'
MQXF_PUT1	8	X'00000008'
MQXF_PUT	9	X'00000009'
MQXF_GET	10	X'0000000A'
MQXF_DATA_CONV_ON_GET	11	X'0000000B'
MQXF_INQ	12	X'0000000C'
MQXF_SET	13	X'0000000D'
MQXF_BEGIN	14	X'0000000E'
MQXF_CMIT	15	X'0000000F'
MQXF_BACK	16	X'00000010'
MQXF_STAT	18	X'00000012'
MQXF_CB	19	X'00000013'
MQXF_CTL	20	X'00000014'
MQXF_CALLBACK	21	X'00000015'
MQXF_SUB	22	X'00000016'
MQXF_SUBRQ	23	X'00000017'
MQXF_XACLOSE	24	X'00000018'
MQXF_XACOMMIT	25	X'00000019'
MQXF_XACOMplete	26	X'0000001A'
MQXF_XAEND	27	X'0000001B'
MQXF_XAFORGET	28	X'0000001C'
MQXF_XAOPEN	29	X'0000001D'
MQXF_XAPREPARE	30	X'0000001E'
MQXF_XARECOVER	31	X'0000001F'
MQXF_XAROLLBACK	32	X'00000020'
MQXF_XASTART	33	X'00000021'
MQXF_AXREG	34	X'00000022'
MQXF_AXUNREG	35	X'00000023'

#### MQXR\_\* (exit reasons)

MQXR_BEFORE	1	X'00000001'
-------------	---	-------------

MQXR_AFTER	2	X'00000002'
MQXR_CONNECTION	3	X'00000003'

### MQXE\_\* (environments)

MQXE_OTHER	0	X'00000000'
MQXE_MCA	1	X'00000001'
MQXE_MCA_SVRCONN	2	X'00000002'
MQXE_COMMAND_SERVER	3	X'00000003'
MQXE_MQSC	4	X'00000004'

### MQ\*\_\* (additional constants)

MQAXP_VERSION_1	1	
MQAXP_VERSION_2	2	
MQAXC_VERSION_1	1	
MQACH_VERSION_1	1	
MQAXP_CURRENT_VERSION	1	
MQAXC_CURRENT_VERSION	1	
MQACH_CURRENT_VERSION	1	
MQXACT_EXTERNAL	1	
MQXACT_INTERNAL	2	
MQXT_API_EXIT	2	
MQACH_LENGTH_1	68 (32-bit platforms)	
	72 (64-bit platforms)	
	80 (128-bit platforms)	
MQACH_CURRENT_LENGTH	68 (32-bit platforms)	
	72 (64-bit platforms)	
	80 (128-bit platforms)	

### MQ\*\_\* (null constants)

MQXPDA_NONE	X'00...00' (48 nulls)
MQXPDA_NONE_ARRAY	'\0','\0',...,'\0','\0'

### MQXCC\_\* (completion codes)

MQXCC_FAILED	-8
--------------	----

### MQRC\_\* (reason codes)

#### MQRC\_API\_EXIT\_ERROR 2374 X'00000946'

An exit function invocation has returned an invalid response code, or has failed in some way, and the queue manager cannot determine the next action to take.

Examine both the ExitResponse and ExitResponse2 fields of the MQAXP to determine the bad response code, and change the exit to return a valid response code.

#### MQRC\_API\_EXIT\_INIT\_ERROR 2375 X'00000947'

The queue manager encountered an error while initializing the execution environment for an API exit function.

#### MQRC\_API\_EXIT\_TERM\_ERROR 2376 X'00000948'

The queue manager encountered an error while closing the execution environment for an API exit function.

#### MQRC\_EXIT\_REASON\_ERROR 2377 X'00000949'

The value of the ExitReason field supplied on an exit entry point registration call (MQXEP) call is in error.

Examine the value of the ExitReason field to determine and correct the bad exit reason value.

#### MQRC\_RESERVED\_VALUE\_ERROR 2378 X'0000094A'

The value of the Reserved field is in error.

Examine the value of the Reserved field to determine and correct the Reserved value.

## C language typedefs

This topic provides information about typedefs associated with API exits available in C language.

Here are the C language typedefs associated with the API exits:

```
typedef PMLONG MQPOINTER PPMQLONG;
typedef PMQBYTE MQPOINTER PPMQBYTE;
typedef PMQHOBJS MQPOINTER PPMQHOBJS;
typedef PMQOD MQPOINTER PPMQOD;
typedef PMQMD MQPOINTER PPMQMD;
typedef PMQPMO MQPOINTER PPMQPMO;
typedef PMQGMO MQPOINTER PPMQGMO;
typedef PMQCNO MQPOINTER PPMQCNO;
typedef PMQBO MQPOINTER PPMQBO;

typedef MQAXP MQPOINTER PMQAXP;
typedef MQACH MQPOINTER PMQACH;
typedef MQAXC MQPOINTER PMQAXC;

typedef MQCHAR MQCHAR16[16];
typedef MQCHAR16 MQPOINTER PMQCHAR16;

typedef MQLONG MQPID;
typedef MQLONG MQTID;
```

## The exit entry point registration call (MQXEP)

Use this information to learn about MQXEP, MQXEP C language invocation, and MQXEP C function prototype.

Use the MQXEP call to:

1. Register the before and after IBM MQ API exit invocation points at which to invoke exit functions
2. Specify the exit function entry points
3. Deregister the exit function entry points

You would typically code the MQXEP calls in the MQ\_INIT\_EXIT exit function, but you can specify them in any subsequent exit function.

If you use an MQXEP call to register an already registered exit function, the second MQXEP call completes successfully, replacing the registered exit function.

If you use an MQXEP call to register a NULL exit function, the MQXEP call completes successfully and the exit function is deregistered.

If MQXEP calls are used to register, deregister, and reregister a particular exit function during the life of a connection request, the previously registered exit function is reactivated. Any storage still allocated and associated with this exit function instance is available for use by the exit's functions. (This storage is typically released during the invocation of the termination exit function.)

The interface to MQXEP is:

```
MQXEP (Hconfig, ExitReason, Function, EntryPoint, &ExitOpts, &CompCode, &Reason)
```

where:

### Hconfig (MQHCONFIG) - input

The configuration handle, representing the API exit that includes the set of functions being initialized. This value is generated by the queue manager immediately before invoking the MQ\_INIT\_EXIT function, and is passed in the MQAXP to each API exit function.

### ExitReason (MQLONG) - input

The reason for which the entry point is being registered, from the following reasons:

- Connection level initialization or termination (MQXR\_CONNECTION)
- Before an IBM MQ API call (MQXR\_BEFORE)
- After an IBM MQ API call (MQXR\_AFTER)

**Function (MQLONG) - input**

The function identifier, valid values for which are the MQXF\_\* constants (see [“External constants” on page 1568](#)).

**EntryPoint (PMQFUNC) - input**

The address of the entry point for the exit function to be registered. The value NULL indicates either that the exit function has not been provided, or that a previous registration of the exit function is being deregistered.

**ExitOpts(MQXEPO)**

API exits can specify options that control how API exits are registered. If a null pointer is specified for this field, the default values of the MQXEPO structure are assumed.

**CompCode (MQLONG) - output**

The completion code, valid values for which are:

**MQCC\_OK**

Successful completion.

**MQCC\_FAILED**

Call failed.

**Reason (MQLONG) - output**

The reason code that qualifies the completion code.

If the completion code is MQCC\_OK:

**MQRC\_NONE**

(0, X'000') No reason to report.

If the completion code is MQCC\_FAILED:

**MQRC\_HCONFIG\_ERROR**

(2280, X'8E8') The supplied configuration handle is not valid. Use the configuration handle from the MQAXP.

**MQRC\_EXIT\_REASON\_ERROR**

(2377, X'949') The supplied exit function invocation reason is either not valid or is not valid for the supplied exit function identifier.

Either use one of the valid exit function invocation reasons (MQXR\_\* value), or use a valid function identifier and exit reason combination. (See [Table 836 on page 1571](#).)

**MQRC\_FUNCTION\_ERROR**

(2281, X'8E9') The supplied function identifier is not valid for API exit reason. The following table shows valid combinations of function identifiers and ExitReasons.

<i>Table 836. Valid combinations of function identifiers and ExitReasons</i>	
<b>Function</b>	<b>ExitReason</b>
MQXF_INIT MQXF_TERM	MQXR_CONNECTION

Table 836. Valid combinations of function identifiers and ExitReasons (continued)

Function	ExitReason
MQXF_CONN MQXF_CONNX MQXF_DISC MQXF_OPEN MQXF_CLOSE MQXF_PUT1 MQXF_PUT MQXF_GET MQXF_INQ MQXF_SET MQXF_BEGIN MQXF_CMIT MQXF_BACK MQXF_STAT MQXF_CB MQXF_CTL MQXF_CALLBACK MQXF_SUB MQXF_SUBRQ	MQXR_BEFORE MQXR_AFTER
MQXF_DATA_CONV_ON_GET	MQXR_BEFORE

#### **MQRC\_RESOURCE\_PROBLEM**

(2102, X'836') An attempt to register or deregister an exit function has failed because of a resource problem.

#### **MQRC\_UNEXPECTED\_ERROR**

(2195, X'893') An attempt to register or deregister an exit function has failed unexpectedly.

#### **MQRC\_PROPERTY\_NAME\_ERROR**

(2442, X'098A') Invalid ExitProperties name.

#### **MQRC\_XEPO\_ERROR**

(2507, X'09CB') Exit options structure not valid.

### **MQXEP C language invocation**

```
MQXEP (Hconfig, ExitReason, Function, EntryPoint, &ExitOpts, &CompCode, &Reason);
```

Declaration for parameter list:

```
MQHCONFIG    Hconfig;        /* Configuration handle */
MQLONG       ExitReason;     /* Exit reason */
MQLONG       Function;       /* Function identifier */
PMQFUNC      EntryPoint;     /* Function entry point */
MQXEPO       ExitOpts;       /* Options that control the action of MQXEP */
MQLONG       CompCode;       /* Completion code */
MQLONG       Reason;         /* Reason code qualifying completion
                             code */
```

### **MQXEP C function prototype**

```
void MQXEP (
MQLONG       Hconfig,        /* Configuration handle */
MQLONG       ExitReason,     /* Exit reason */
MQLONG       Function,       /* Function identifier */
```

```

PMQFUNC      EntryPoint,      /* Function entry point */
PMQXEPO      pExitOpts;      /* Options that control the action of MQXEP */
PMQLONG      pCompCode,      /* Address of completion code */
PMQLONG      pReason);      /* Address of reason code qualifying completion
                             code */

```

## Exit functions

This section provides some general information to help you when using the function calls and describes how to invoke the individual exit functions.

Use this information to understand the general rules for API exit routines, and setting up and cleaning up the exit execution environment.

### General rules for API exit routines

The following general rules apply when invoking API exit routines:

- In all cases, API exit functions are driven before validating API call parameters, and before any security checks (in the case of MQCONN, MQCONNX, or MQOPEN).
- The values of fields entered into and output from an exit routine are:
  - On input to a *before* IBM MQ API exit function, the value of a field can be set by the application program, or by a previous exit function invocation.
  - On output from a *before* IBM MQ API exit function, the value of a field can be left unchanged, or set to some other value by the exit function.
  - On input to an *after* IBM MQ API exit function, the value of a field can be the value set by the queue manager after processing the IBM MQ API call, or can be set to a value by a previous exit function invocation in the chain of exit functions.
  - On output from an *after* IBM MQ API call exit function, the value of a field can be left unchanged, or set to some other value by the exit function.
- Exit functions must communicate with the queue manager by using the ExitResponse and ExitResponse2 fields.
- The CompCode and Reason code fields communicate back to the application. The queue manager and exit functions can set the CompCode and Reason code fields.
- The MQXEP call returns new reason codes to the exit functions that call MQXEP. However, exit functions can translate these new reason codes to any existing reasons codes that existing and new applications can understand.
- Each exit function prototype has similar parameters to the API function with an extra level of indirection except for the CompCode and Reason.
- API exits can issue MQI calls (except MQDISC), but these MQI calls do not themselves invoke API exits.

Note, that whether the application is on a server or a client, you cannot predict the sequencing of the API exit calls. An API exit BEFORE call might not be followed immediately by an AFTER call.

The BEFORE call can be followed by another BEFORE call. For example:

```

BEFORE MQCTL
BEFORE Callback
BEFORE MQPUT
AFTER MQPUT
AFTER Callback
AFTER MQCTL

```

or

```

BEFORE XAOPEN
BEFORE MQCONNX
AFTER MQCONNX

```

## AFTER XAOPEN

On the client, there is an exit that can modify the behavior of the MQCONN or MQCONNX call, called the `PreConnect` exit. The `PreConnect` exit can modify any of the parameters on the MQCONN or MQCONNX call including the queue manager name. The client calls this exit first and then invokes the MQCONN or MQCONNX call. Note that only the initial MQCONN or MQCONNX call invokes the API exit; any subsequent reconnect calls have no effect.

### The execution environment

In general, all errors from exit functions are communicated back to the exit handler using the `ExitResponse` and `ExitResponse2` fields in MQAXP.

These errors in turn are converted into MQCC\_\* and MQRC\_\* values and communicated back to the application in the `CompCode` and `Reason` fields. However, any errors encountered in the exit handler logic are communicated back to the application as MQCC\_\* and MQRC\_\* values in the `CompCode` and `Reason` fields.

If an MQ\_TERM\_EXIT function returns an error:

- The MQDISC call has already taken place
- There is no other opportunity to drive the *after* MQ\_TERM\_EXIT exit function (and thus perform exit execution environment cleanup)
- Exit execution environment cleanup is not performed

The exit cannot be unloaded as it might still be in use. Also, other registered exits further down in the exit chain for which the *before* exit was successful, will be driven in the reverse order.

### Setting up the exit execution environment

While processing an explicit MQCONN or MQCONNX call, exit handling logic sets up the exit execution environment before invoking the exit initialization function (MQ\_INIT\_EXIT). Exit execution environment setup involves loading the exit, acquiring storage for, and initializing exit parameter structures. The exit configuration handle is also allocated.

If errors occur during this phase, the MQCONN or MQCONNX call fails with `CompCode` MQCC\_FAILED and one of the following reason codes:

#### **MQRC\_API\_EXIT\_LOAD\_ERROR**

An attempt to load an API exit module has failed.

#### **MQRC\_API\_EXIT\_NOT\_FOUND**

An API exit function could not be found in the API exit module.

#### **MQRC\_STORAGE\_NOT\_AVAILABLE**

An attempt to initialize the execution environment for an API exit function failed because insufficient storage was available.

#### **MQRC\_API\_EXIT\_INIT\_ERROR**

An error was encountered while initializing the execution environment for an API exit function.

### Cleaning up the exit execution environment

While processing an explicit MQDISC call, or an implicit disconnect request as a result of an application ending, exit handling logic might need to clean up the exit execution environment after invoking the exit termination function (MQ\_TERM\_EXIT), if registered.

Cleaning up the exit execution environment involves releasing storage for exit parameter structures, possibly deleting any modules previously loaded into memory.

If errors occur during this phase, an explicit MQDISC call fails with `CompCode` MQCC\_FAILED and the following reason code (errors are not highlighted on implicit disconnect requests):

## **MQRC\_API\_EXIT\_TERM\_ERROR**

An error was encountered while closing the execution environment for an API exit function. The exit should not return any failure from the MQDISC before or after the MQ\_TERM\* API exit function calls.

## **API exits on clients**

A client uses the PreConnect exit to modify the behavior of the MQCONN and MQCONNX calls and does not support API exit properties.

## **PreConnect exit**

On a client, the PreConnect exit can be used to look up the channel definition from a central repository, such as an LDAP server.

The PreConnect exit can also modify any parameter, or all the parameters, on an MQCONN or MQCONNX call itself, for example, the queue manager name.

In the case of client applications, the PreConnect exit must be called before the API exit because the MQCONN or MQCONNX API exit is called only once the name of the queue manager is known and this name can be changed by the PreConnect exit.

Note that only the initial MQCONN or MQCONNX call invokes the exit.

## **API exit properties**

On a server, API exits can register an MQXEPO structure at initialization time. The MQXEPO structure contains the ExitProperties field which details the group of properties the exit is interested in. This has the effect of generating a separate message property handle which the exit can manipulate separately from any application message property handle.

On a client, API exit properties are not supported. If an attempt is made to register a property group name on a client, the function fails with a reason code of MQRC\_EXIT\_PROPS\_NOT\_SUPPORTED.

## **Backout - MQ\_BACK\_EXIT**

MQ\_BACK\_EXIT provides a backout exit function to perform *before* and *after* backout processing. Use function identifier MQXF\_BACK with exit reasons MQXR\_BEFORE and MQXR\_AFTER to register *before* and *after* backout call exit functions.

The interface to this function is:

```
MQ_BACK_EXIT (&ExitParms, &ExitContext, &Hconn, &CompCode, &Reason)
```

where the parameters are:

### **ExitParms (MQAXP) - input/output**

Exit parameter structure.

### **ExitContext (MQAXC) - input/output**

Exit context structure.

### **Hconn (MQHCONN) - input**

Connection handle.

### **CompCode (MQLONG) - input/output**

Completion code, valid values for which are:

#### **MQCC\_OK**

Successful completion.

#### **MQCC\_WARNING**

Partial completion.

#### **MQCC\_FAILED**

Call failed

## Reason (MQLONG) - input/output

Reason code qualifying the completion code.

If the completion code is MQCC\_OK, the only valid value is:

### MQRC\_NONE

(0, x'000') No reason to report.

If the completion code is MQCC\_FAILED or MQCC\_WARNING, the exit function can set the reason code field to any valid MQRC\_\* value.

## C language invocation

The queue manager logically defines the following variables:

```
MQAXP    ExitParms;      /* Exit parameter structure */
MQAXC    ExitContext;    /* Exit context structure */
MQHCONN  Hconn;         /* Connection handle */
MQLONG   CompCode;      /* Completion code */
MQLONG   Reason;        /* Reason code qualifying completion code */
```

The queue manager then logically calls the exit as follows:

```
MQ_BACK_EXIT (&ExitParms, &ExitContext, &Hconn, &CompCode, &Reason);
```

Your exit must match the following C function prototype:

```
void MQENTRY MQ_BACK_EXIT (
PMQAXP   pExitParms,      /* Address of exit parameter structure */
PMQAXC   pExitContext,    /* Address of exit context structure */
PMQHCONN pHconn,         /* Address of connection handle */
PMQLONG  pCompCode,       /* Address of completion code */
PMQLONG  pReason);        /* Address of reason code qualifying completion
                           code */
```

## Begin - MQ\_BEGIN\_EXIT

MQ\_BEGIN\_EXIT provides a begin exit function to perform *before* and *after* MQBEGIN call processing. Use function identifier MQXF\_BEGIN with exit reasons MQXR\_BEFORE and MQXR\_AFTER to register *before* and *after* MQBEGIN call exit functions.

The interface to this function is:

```
MQ_BEGIN_EXIT (&ExitParms, &ExitContext, &Hconn, &pBeginOptions, &CompCode,
               &Reason)
```

where the parameters are:

### ExitParms (MQAXP) - input/output

Exit parameter structure.

### ExitContext (MQAXC) - input/output

Exit context structure.

### Hconn (MQHCONN) - input

Connection handle.

### pBeginOptions (PMQBO)- input/output

Pointer to begin options.

### CompCode (MQLONG) - input/output

Completion code, valid values for which are:

#### MQCC\_OK

Successful completion.

## **MQCC\_WARNING**

Partial completion.

## **MQCC\_FAILED**

Call failed

### **Reason (MQLONG) - input/output**

Reason code qualifying the completion code.

If the completion code is MQCC\_OK, the only valid value is:

## **MQRC\_NONE**

(0, x'000') No reason to report.

If the completion code is MQCC\_FAILED or MQCC\_WARNING, the exit function can set the reason code field to any valid MQRC\_\* value.

## **C language invocation**

The queue manager logically defines the following variables:

```
MQAXP    ExitParms;        /* Exit parameter structure */
MQAXC    ExitContext;     /* Exit context structure */
MQHCONN  Hconn;          /* Connection handle */
PMQBO    pBeginOptions;   /* Ptr to begin options */
MQLONG   CompCode;       /* Completion code */
MQLONG   Reason;         /* Reason code qualifying completion code */
```

The queue manager then logically calls the exit as follows:

```
MQ_BEGIN_EXIT (&ExitParms, &ExitContext, &Hconn, &pBeginOptions, &CompCode,
               &Reason);
```

Your exit must match the following C function prototype:

```
void MQENTRY MQ_BEGIN_EXIT (
PMQAXP    pExitParms,      /* Address of exit parameter structure */
PMQAXC    pExitContext,   /* Address of exit context structure */
PMQHCONN  pHconn,        /* Address of connection handle */
PPMQBO    ppBeginOptions, /* Address of ptr to begin options */
PMQLONG   pCompCode,     /* Address of completion code */
PMQLONG   pReason);      /* Address of reason code qualifying completion
                           code */
```

### **Callback - MQ\_CALLBACK\_EXIT**

MQ\_CALLBACK\_EXIT provides an exit function to perform *before* and *after* callback processing. Use function identifier MQXF\_CALLBACK with exit reasons MQXR\_BEFORE and MQXR\_AFTER to register *before* and *after* callback call exit functions.

The interface to this function is:

```
MQ_CALLBACK_EXIT (&ExitParms, &ExitContext, &Hconn, &pMsgDesc, &pGetMsgOpts,
                  &pBuffer, &pmqCBCContext)
```

where the parameters are:

#### **ExitParms (MQAXP) - input/output**

Exit parameter structure

#### **ExitContext (MQAXC) - input/output**

Exit context structure

#### **Hconn (MQHCONN) - input/output**

Connection handle

**pMsgDesc**

Message descriptor

**pGetMsgOpts**

Options that control the action of MQGET

**pBuffer**

Area to contain the message data

**pMQCBContext**

Context data for the callback

**C language invocation**

The queue manager logically defines the following variables:

```
MQAXP    ExitParms;      /* Exit parameter structure */
MQAXC    ExitContext;   /* Exit context structure */
MQHCONN  Hconn;        /* Connection handle */
PMQMD    pMsgDesc;     /* Message descriptor */
PMQGM0   pGetMsgOpts;  /* Options that define the operation of the consumer */
PMQVOID  pBuffer;     /* Area to contain the message data */
PMQCBC   pContext;    /* Context data for the callback */
```

The queue manager then logically calls the exit as follows:

```
MQ_SUBRQ_EXIT (&ExitParms, &ExitContext, &Hconn, &pMsgDesc, &pGetMsgOpts, &pBuffer,
               &pContext);
```

Your exit must match the following C function prototype:

```
void MQENTRY MQ_CALLBACK_EXIT (
PMQAXP    pExitParms;   /* Exit parameter structure */
PMQAXC    pExitContext; /* Exit context structure */
PMQHCONN  pHconn;     /* Connection handle */
PPMQMD    ppMsgDesc;   /* Message descriptor */
PPMQGM0   ppGetMsgOpts; /* Options that define the operation of the consumer */
PPMQVOID  ppBuffer;    /* Area to contain the message data */
PPMQCBC   ppContext;   /* Context data for the callback */
```

**Usage notes**

1. The Callback exit is invoked before the consumer is invoked and after the consumer's consumer function has completed. Although the MQMD and MQGMO structures are alterable, changing the values in the before exit does not redrive the retrieval of a message from the queue as the message has already been removed from the queue to be delivered to the consumer function

**Manage callback functions - MQ\_CB\_EXIT**

MQ\_CB\_EXIT provides an exit function to perform *before* and *after* the MQCB call. Use function identifier MQXF\_CB with exit reasons MQXR\_BEFORE and MQXR\_AFTER to register *before* and *after* MQCB call exit functions.

The interface to this function is:

```
MQ_CB_EXIT (&ExitParms, &ExitContext, &Hconn, &Operation, &pCallbackDesc,
            &Hobj, &pMsgDesc, &pGetMsgOpts, &CompCode, &Reason)
```

where the parameters are:

**ExitParms (MQAXP) - input/output**

Exit parameter structure

**ExitContext (MQAXC) - input/output**

Exit context structure

**Hconn (MQHCONN) - input/output**

Connection handle

**Operation (MQLONG) - input/output**

Operation value

**pCallbackDesc (PMQCBD) - input/output**

Callback descriptor

**Hobj (MQHOBJ) - input/output**

Object handle

**pMsgDesc (PMQMD) - input/output**

Message descriptor

**pGetMsgOpts (PMQGMO) - input/output**

Options that control the action of MQCB

**CompCode (MQLONG) - input/output**

Completion code

**Reason (MQLONG) - input/output**

Reason code qualifying CompCode

**C language invocation**

The queue manager logically defines the following variables:

```

MQAXP      ExitParms;      /* Exit parameter structure */
MQAXC      ExitContext;    /* Exit context structure */
MQHCONN    Hconn;         /* Connection handle */
MQLONG     Operation;     /* Operation value. */
MQCBD      pMsgDesc;      /* Callback descriptor. */
MQHOBJ     Hobj;          /* Object handle. */
PMQMD      pMsgDesc;      /* Message descriptor */
PMQGMO     pGetMsgOpts;   /* Options that define the operation of the consumer */
PMQLONG    CompCode;      /* Completion code. */
PMQLONG    Reason;        /* Reason code qualifying CompCode. */

```

The queue manager then logically calls the exit as follows:

```

MQ_CB_EXIT (&ExitParms, &ExitContext, &Hconn, &Operation, &Hobj, &pMsgDesc,
            &pGetMsgOpts, &CompCode, &Reason);

```

Your exit must match the following C function prototype:

```

void MQENTRY MQ_CB_EXIT (
PMQAXP      pExitParms;    /* Exit parameter structure */
PMQAXC      pExitContext;  /* Exit context structure */
PMQHCONN    pHconn;       /* Connection handle */
PMQLONG     pOperation;    /* Callback operation */
PMQHOBJ     pHobj;        /* Object handle */
PPMQMD      ppMsgDesc;    /* Message descriptor */
PPMQGMO     ppGetMsgOpts; /* Options that control the action of MQCB */
PMQLONG     pCompCode;    /* Completion code */
PMQLONG     pReason;      /* Reason code qualifying CompCode */

```

**Close - MQ\_CLOSE\_EXIT**

MQ\_CLOSE\_EXIT provides a close exit function to perform *before* and *after* MQCLOSE call processing. Use function identifier MQXF\_CLOSE with exit reasons MQXR\_BEFORE and MQXR\_AFTER to register *before* and *after* MQCLOSE call exit functions.

The interface to this function is:

```

MQ_CLOSE_EXIT (&ExitParms, &ExitContext, &Hconn, &pHobj,
               &Options, &CompCode, &Reason)

```

where the parameters are:

**ExitParms (MQAXP) - input/output**

Exit parameter structure.

**ExitContext (MQAXC) - input/output**

Exit context structure.

**Hconn (MQHCONN) - input**

Connection handle.

**pHobj (PMQHOBj) - input**

Pointer to object handle.

**Options (MQLONG)- input/output**

Close options.

**CompCode (MQLONG) - input/output**

Completion code, valid values for which are:

**MQCC\_OK**

Successful completion.

**MQCC\_FAILED**

Call failed

**Reason (MQLONG) - input/output**

Reason code qualifying the completion code.

If the completion code is MQCC\_OK, the only valid value is:

**MQRC\_NONE**

(0, x'000') No reason to report.

If the completion code is MQCC\_FAILED, the exit function can set the reason code field to any valid MQRC\_\* value.

## C language invocation

The queue manager logically defines the following variables:

```
MQAXP      ExitParms;      /* Exit parameter structure */
MQAXC      ExitContext;    /* Exit context structure */
MQHCONN    Hconn;         /* Connection handle */
PMQHOBj    pHobj;         /* Ptr to object handle */
MQLONG     Options;       /* Close options */
MQLONG     CompCode;      /* Completion code */
MQLONG     Reason;       /* Reason code */
```

The queue manager then logically calls the exit as follows:

```
MQ_CLOSE_EXIT (&ExitParms, &ExitContext,&Hconn, &pHobj, &Options,
               &CompCode, &Reason);
```

Your exit must match the following C function prototype:

```
void MQENTRY MQ_CLOSE_EXIT (
PMQAXP      pExitParms,    /* Address of exit parameter structure */
PMQAXC      pExitContext,  /* Address of exit context structure */
PMQHCONN    pHconn,       /* Address of connection handle */
PPMHOBj    ppHobj,        /* Address of ptr to object handle */
PMQLONG     pOptions,      /* Address of close options */
PMQLONG     pCompCode,     /* Address of completion code */
PMQLONG     pReason);     /* Address of reason code qualifying
                           completion code */
```

## **Commit - MQ\_CMIT\_EXIT**

MQ\_CMIT\_EXIT provides a commit exit function to perform *before* and *after* commit processing. Use function identifier MQXF\_CMIT with exit reasons MQXR\_BEFORE and MQXR\_AFTER to register *before* and *after* commit call exit functions.

If a commit operation fails, and the transaction is backed out, the MQCMIT call fails with MQCC\_WARNING and MQRC\_BACKED\_OUT. These return and reason codes are passed into any *after* MQCMIT exit functions to give the exit functions an indication that the unit of work has been backed out.

The interface to this function is:

```
MQ_CMIT_EXIT (&ExitParms, &ExitContext, &Hconn, &CompCode, &Reason)
```

where the parameters are:

### **ExitParms (MQAXP) - input/output**

Exit parameter structure.

### **ExitContext (MQAXC) - input/output**

Exit context structure.

### **Hconn (MQHCONN) - input**

Connection handle.

### **CompCode (MQLONG) - input/output**

Completion code, valid values for which are:

#### **MQCC\_OK**

Successful completion.

#### **MQCC\_WARNING**

Partial completion.

#### **MQCC\_FAILED**

Call failed

### **Reason (MQLONG) - input/output**

Reason code qualifying the completion code.

If the completion code is MQCC\_OK, the only valid value is:

#### **MQRC\_NONE**

(0, x'000') No reason to report.

If the completion code is MQCC\_FAILED or MQCC\_WARNING, the exit function can set the reason code field to any valid MQRC\_\* value.

## **C language invocation**

The queue manager logically defines the following variables:

```
MQAXP    ExitParms;        /* Exit parameter structure */
MQAXC    ExitContext;     /* Exit context structure */
MQHCONN  Hconn;          /* Connection handle */
MQLONG   CompCode;       /* Completion code */
MQLONG   Reason;         /* Reason code qualifying completion code */
```

The queue manager then logically calls the exit as follows:

```
MQ_CMIT_EXIT (&ExitParms, &ExitContext, &Hconn, &CompCode, &Reason);
```

Your exit must match the following C function prototype:

```
void MQENTRY MQ_CMIT_EXIT (
    PMQAXP    pExitParms,    /* Address of exit parameter structure */
```

```

PMQAXC    pExitContext,    /* Address of exit context structure */
PMQHCONN  pHconn,         /* Address of connection handle */
PMQLONG   pCompCode,      /* Address of completion code */
PMQLONG   pReason);       /* Address of reason code qualifying completion
                           code */

```

## Usage notes

1. The MQ\_GET\_EXIT function interface described here is used for both the MQXF\_GET exit function and the [“MQXF\\_DATA\\_CONV\\_ON\\_GET”](#) on page 1588 exit function.

Separate entry points are defined for these two exit functions, so to intercept *both* the MQXEP call must be used twice; for this call use function identifier MQXF\_GET.

Because the MQ\_GET\_EXIT interface is the same for MQXF\_GET and MQXF\_DATA\_CONV\_ON\_GET, a single exit function can be used for both; the *Function* field in the MQAXP structure indicates which exit function has been invoked. Alternatively, the MQXEP call can be used to register different exit functions for the two cases.

### **Connect and connect extension - MQ\_CONNX\_EXIT**

MQ\_CONNX\_EXIT provides connection exit function to perform *before* and *after* MQCONN processing, and connection extension exit function to perform *before* and *after* MQCONNX processing.

The same interface, as described here, is invoked for both MQCONN and MQCONNX call exit functions.

When the message channel agent (MCA) responds to an inbound client connection, the MCA can connect and make a number of IBM MQ API calls before the client state is fully known. These API calls call the API exit functions with the MQAXC based on the MCA program itself (for example in the UserId and ConnectionName fields of the MQAXC).

When the MCA responds to subsequent inbound client API calls, the MQAXC structure is based on the inbound client, setting the UserId and ConnectionName fields appropriately.

The queue manager name set by the application on an MQCONN or MQCONNX call is passed to the underlying connect call. Any attempt by a *before* MQ\_CONNX\_EXIT to change the name of the queue manager has no effect.

Use function identifiers MQXF\_CONN and MQXF\_CONNX with exit reasons MQXR\_BEFORE and MQXR\_AFTER to register *before* and *after* MQCONN and MQCONNX call exit functions.

An MQ\_CONNX\_EXIT exit called for reason MQXR\_BEFORE *must not* issue any IBM MQ API calls, as the correct environment has not been set up at this time.

An MQ\_CONNX\_EXIT cannot call MQDISC from an API exit call for the connection for which it is being called. This restriction is applicable to both client and server API exits.

The interface to MQCONN and MQCONNX is identical:

```

MQ_CONNX_EXIT (&ExitParms, &ExitContext, &pQMgrName, &pConnectOpts,
               &pHconn, &CompCode, &Reason);

```

where the parameters are:

#### **ExitParms (MQAXP) - input/output**

Exit parameter structure.

#### **ExitContext (MQAXC) - input/output**

Exit context structure.

#### **pQMgrName (PMQCHAR) - input**

Pointer to the queue manager name supplied on the MQCONNX call. The exit must not change this name on the MQCONN or MQCONNX call.

#### **pConnectOpts (PMQCNO) - input/output**

Pointer to the options that control the action of the MQCONNX call.

See [“MQCNO - Connect options”](#) on page 317 for details.

For exit function MQXF\_CONN, pConnectOpts points to the default connect options structure (MQCNO\_DEFAULT).

### **pHconn (PMQHCONN) - input**

Pointer to the connection handle.

### **CompCode (MQLONG) - input/output**

Completion code, valid values for which are:

#### **MQCC\_OK**

Successful completion.

#### **MQCC\_WARNING**

Warning (partial completion)

#### **MQCC\_FAILED**

Call failed

### **Reason (MQLONG) - input/output**

Reason code qualifying the completion code.

If the completion code is MQCC\_OK, the only valid value is:

#### **MQRC\_NONE**

(0, x'000') No reason to report.

If the completion code is MQCC\_FAILED or MQCC\_WARNING, the exit function can set the reason code field to any valid MQRC\_\* value.

## **C language invocation**

The queue manager logically defines the following variables:

```
MQAXP      ExitParms;      /* Exit parameter structure */
MQAXC      ExitContext;    /* Exit context structure */
PMQCHAR    pQMgrName;     /* Ptr to Queue manager name */
PMQCNO     pConnectOpts;  /* Ptr to Connection options */
PMQHCONN   pHconn;       /* Ptr to Connection handle */
MQLONG     CompCode;      /* Completion code */
MQLONG     Reason;       /* Reason code */
```

The queue manager then logically calls the exit as follows:

```
MQ_CONNX_EXIT (&ExitParms, &ExitContext, &pQMgrName, &pConnectOpts,
               &pHconn, &CompCode, &Reason);
```

Your exit must match the following C function prototype:

```
void MQENTRY MQ_CONNX_EXIT (
PMQAXP      pExitParms,    /* Address of exit parameter structure */
PMQAXC      pExitContext,  /* Address of exit context structure */
PPMQCHAR    ppQMgrName,   /* Address of ptr to queue manager name */
PPMQCNO     ppConnectOpts, /* Address of ptr to connection options */
PPMQHCONN   ppHconn,      /* Address of ptr to connection handle */
PMQLONG     pCompCode,    /* Address of completion code */
PMQLONG     pReason);     /* Address of reason code qualifying
                           completion code */
```

## **Usage notes**

1. The MQ\_CONNX\_EXIT function interface described here is used for both the MQCONN call and the MQCONNX call. However, separate entry points are defined for these two calls. To intercept *both* calls, the MQXEP call must be used at least twice - once with function identifier MQXF\_CONN, and again with MQXF\_CONNX.

Because the MQ\_CONNX\_EXIT interface is the same for MQCONN and MQCONNX, a single exit function can be used for both calls; the *Function* field in the MQAXP structure indicates which call

is in progress. Alternatively, the MQXEP call can be used to register different exit functions for the two calls.

2. When a message channel agent (MCA) responds to an inbound client connection, the MCA can issue a number of MQ calls before the client state is fully known. These MQ calls result in the API exit functions being invoked with the MQAXC structure containing data relating to the MCA, and not to the client (for example, user identifier and connection name). However, once the client state is fully known, subsequent MQ calls result in the API exit functions being invoked with the appropriate client data in the MQAXC structure.
3. All MQXR\_BEFORE exit functions are invoked before any parameter validation is performed by the queue manager. The parameters might therefore be invalid (including invalid pointers for the addresses of parameters).

The MQ\_CONN\_X\_EXIT function is invoked before any authorization checks are performed by the queue manager.

4. The exit function must not change the name of the queue manager specified on the MQCONN or MQCONN\_X call. If the name is changed by the exit function, the results are undefined.
5. An MQXR\_BEFORE exit function for the MQ\_CONN\_X\_EXIT cannot issue MQ calls other than MQXEP.

### **Control callback - MQ\_CTL\_EXIT**

MQ\_CTL\_EXIT provides a subscription request exit function to perform *before* and *after* control callback processing. Use function identifier MQXF\_CTL with exit reasons MQXR\_BEFORE and MQXR\_AFTER to register *before* and *after* control callback call exit functions.

The interface to this function is:

```
MQ_CTL_EXIT (&Hconn, &Operation, &ControlOpts, &CompCode, &Reason)
```

where the parameters are:

#### **Hconn (MQHCONN) - input/output**

Connection handle.

#### **Operation (MQLONG) input/output**

The operation being processed on the callback defined for the specified object handle

#### **ControlOpts (MQCTLO) input/output**

Options that control the action of MQCTL

#### **CompCode (MQLONG) - input/output**

Completion code, valid values for which are:

##### **MQCC\_OK**

Successful completion.

##### **MQCC\_WARNING**

Partial completion.

##### **MQCC\_FAILED**

Call failed

#### **Reason (MQLONG) - input/output**

Reason code qualifying the completion code.

If the completion code is MQCC\_OK, the only valid value is:

##### **MQRC\_NONE**

(0, x'000') No reason to report.

If the completion code is MQCC\_FAILED or MQCC\_WARNING, the exit function can set the reason code field to any valid MQRC\_\* value.

## **C language invocation**

The queue manager logically defines the following variables:

```

MQHCONN  Hconn;          /* Connection handle */
MQLONG   Operation;     /* Operation being processed */
MQCTLO   ControlOpts;  /* Options that control the action of MQCTL */
MQLONG   CompCode;     /* Completion code */
MQLONG   Reason;       /* Reason code qualifying completion code */

```

The queue manager then logically calls the exit as follows:

```
MQ_CTL_EXIT (&Hconn, &Operation, &ControlOpts, &CompCode, &Reason);
```

Your exit must match the following C function prototype:

```

void MQENTRY MQ_CTL_EXIT (
PMQHCONN pHconn;      /* Address of connection handle */
PMQLONG  pOperation;  /* Address of operation being processed */
PMQCTLO  pControlOpts; /* Address of options that control the action of MQCTL */
PMQLONG  pCompCode;   /* Address of completion code */
PMQLONG  pReason;     /* Address of reason code qualifying completion code */
)

```

### ***Disconnect - MQ\_DISC\_EXIT***

MQ\_DISC\_EXIT provides a disconnect exit function to perform *before* and *after* MQDISC exit processing. Use function identifier MQXF\_DISC with exit reasons MQXR\_BEFORE and MQXR\_AFTER to register *before* and *after* MQDISC call exit functions.

The interface to this function is

```
MQ_DISC_EXIT (&ExitParms, &ExitContext, &pHconn,
&CompCode, &Reason);
```

where the parameters are:

#### **ExitParms (MQAXP) - input/output**

Exit parameter structure.

#### **ExitContext (MQAXC) - input/output**

Exit context structure.

#### **pHconn (PMQHCONN) - input**

Pointer to the connection handle.

*For the before MQDISC call*, the value of this field is one of:

- The connection handle returned on the MQCONN or MQCONNX call
- Zero, for environments where an environment-specific adapter has connected to the queue manager
- A value set by a previous exit function invocation

*For the after MQDISC call*, the value of this field is zero or a value set by a previous exit function invocation.

#### **CompCode (MQLONG) - input/output**

Completion code, valid values for which are:

##### **MQCC\_OK**

Successful completion.

##### **MQCC\_WARNING**

Partial completion

##### **MQCC\_FAILED**

Call failed

#### **Reason (MQLONG) - input/output**

Reason code qualifying the completion code.

If the completion code is MQCC\_OK, the only valid value is:

### **MQRC\_NONE**

(0, x'000') No reason to report.

If the completion code is MQCC\_FAILED or MQCC\_WARNING, the exit function can set the reason code field to any valid MQRC\_\* value.

## **C language invocation**

The queue manager logically defines the following variables:

```
MQAXP      ExitParms;      /* Exit parameter structure */
MQAXC      ExitContext;    /* Exit context structure */
PMQHCONN   pHconn;        /* Ptr to Connection handle */
MQLONG     CompCode;      /* Completion code */
MQLONG     Reason;        /* Reason code */
```

The queue manager then logically calls the exit as follows:

```
MQ_DISC_EXIT (&ExitParms, &ExitContext, &pHconn,
              &CompCode, &Reason);
```

Your exit must match the following C function prototype:

```
void MQENTRY MQ_DISC_EXIT (
PMQAXP      pExitParms,    /* Address of exit parameter structure */
PMQAXC      pExitContext,  /* Address of exit context structure */
PPMHCONN    ppHconn,      /* Address of ptr to connection handle */
PMQLONG     pCompCode,    /* Address of completion code */
PMQLONG     pReason);     /* Address of reason code qualifying
                             completion code */
```

### **Get - MQ\_GET\_EXIT**

MQ\_GET\_EXIT provides a get exit function to perform *before* and *after* MQGET call processing.

There are two function identifiers:

1. Use MQXF\_GET with exit reasons MQXR\_BEFORE and MQXR\_AFTER to register *before* and *after* MQGET call exit functions.
2. See “MQXF\_DATA\_CONV\_ON\_GET” on page 1588 for information on using the MQXF\_DATA\_CONV\_ON\_GET function identifier.

The interface to this function is:

```
MQ_GET_EXIT (&ExitParms, &ExitContext, &Hconn, &Hobj, &pMsgDesc,
             &pGetMsgOpts, &BufferLength, &pBuffer, &pDataLength,
             &CompCode, &Reason)
```

where the parameters are:

#### **ExitParms (MQAXP) - input/output**

Exit parameter structure.

#### **ExitContext (MQAXC) - input/output**

Exit context structure.

#### **Hconn (MQHCONN) - input**

Connection handle.

#### **Hobj (MQHOBJ) - input/output**

Object handle.

#### **pMsgDesc (PMQMD) - input/output**

Pointer to message descriptor.

**pGetMsgOpts (PMQGMO) - input/output**

Pointer to get message options.

**BufferLength (MQLONG) - input/output**

Message buffer length.

**pBuffer (PMQBYTE) - input/output**

Pointer to message buffer.

**pDataLength (PMQLONG) - input/output**

Pointer to data length field.

**CompCode (MQLONG) - input/output**

Completion code, valid values for which are:

**MQCC\_OK**

Successful completion.

**MQCC\_WARNING**

Partial completion.

**MQCC\_FAILED**

Call failed

**Reason (MQLONG) - input/output**

Reason code qualifying the completion code.

If the completion code is MQCC\_OK, the only valid value is:

**MQRC\_NONE**

(0, x'000') No reason to report.

If the completion code is MQCC\_FAILED or MQCC\_WARNING, the exit function can set the reason code field to any valid MQRC\_\* value.

**C language invocation**

The queue manager logically defines the following variables:

```

MQAXP      ExitParms;      /* Exit parameter structure */
MQAXC      ExitContext;    /* Exit context structure */
MQHCONN    Hconn;         /* Connection handle */
MQHOBJ     Hobj;          /* Object handle */
PMQMD      pMsgDesc;      /* Ptr to message descriptor */
PMQPMO     pGetMsgOpts;   /* Ptr to get message options */
MQLONG     BufferLength;   /* Message buffer length */
PMQBYTE    pBuffer;      /* Ptr to message buffer */
PMQLONG    pDataLength;   /* Ptr to data length field */
MQLONG     CompCode;     /* Completion code */
MQLONG     Reason;       /* Reason code */

```

The queue manager then logically calls the exit as follows:

```

MQ_GET_EXIT (&ExitParms, &ExitContext, &Hconn, &Hobj, &pMsgDesc,
             &pGetMsgOpts, &BufferLength, &pBuffer, &pDataLength,
             &CompCode, &Reason)

```

Your exit must match the following C function prototype:

```

void MQENTRY MQ_GET_EXIT (
PMQAXP      pExitParms,    /* Address of exit parameter structure */
PMQAXC      pExitContext,  /* Address of exit context structure */
PMQHCONN    pHconn,       /* Address of connection handle */
PMQHOBJ     pHobj,        /* Address of object handle */
PPMQMD      ppMsgDesc,    /* Address of ptr to message descriptor */
PPMQGMO     ppGetMsgOpts, /* Address of ptr to get message options */
PMQLONG     pBufferLength, /* Address of message buffer length */
PPMQBYTE    ppBuffer,     /* Address of ptr to message buffer */
PPMQLONG    ppDataLength, /* Address of ptr to data length field */
PMQLONG     pCompCode,    /* Address of completion code */

```

```
PMQLONG          pReason);          /* Address of reason code qualifying
                                completion code */
```

## Usage notes

1. The MQ\_GET\_EXIT function interface described here is used for both the MQXF\_GET exit function and the “MQXF\_DATA\_CONV\_ON\_GET” on page 1588 exit function.

Separate entry points are defined for these two exit functions, so to intercept *both* the MQXEP call must be used twice; for this call use function identifier MQXF\_GET.

Because the MQ\_GET\_EXIT interface is the same for MQXF\_GET and MQXF\_DATA\_CONV\_ON\_GET, a single exit function can be used for both; the *Function* field in the MQAXP structure indicates which exit function has been invoked. Alternatively, the MQXEP call can be used to register different exit functions for the two cases.

### **MQXF\_DATA\_CONV\_ON\_GET**

The MQXF\_DATA\_CONV\_ON\_GET function identifier is used with MQ\_GET\_EXIT.

See [MQ\\_GET\\_EXIT](#) for information about the interface to this call, and a sample C language declaration.

## Usage notes

If registered, this entry point is called when messages arrive at the application but before any data conversion has occurred. This can be useful if the API exit needs to perform processing, such as decryption or decompression, before the message is passed to data conversion. The exit can, if necessary, cause data conversion to be bypassed by returning MQXCC\_SUPPRESS\_FUNCTION; for more information, see [MQAXP](#) structure.

Registering for this entry point on a client has the effect of causing the data conversion to be performed locally on the client machine. For correct operation it might, therefore, be necessary to install the application conversion exits on the client. Note that MQXF\_DATA\_CONV\_ON\_GET is also used for asynchronous consume.

When using the [MQ\\_GET\\_EXIT](#) call, use MQXF\_DATA\_CONV\_ON\_GET, with exit reason MQXR\_BEFORE, to register a *before* MQGET data conversion exit function.

There is no MQXR\_AFTER exit function for MQXF\_DATA\_CONV\_ON\_GET; the MQXR\_AFTER exit function for MQXF\_GET provides the required capability for exit processing after data conversion.

Separate entry points are defined for the [MQ\\_GET\\_EXIT](#) call, so to intercept *both* exit functions, the MQXEP call must be used twice; for this call use function identifier MQXF\_DATA\_CONV\_ON\_GET.

Because the MQ\_GET\_EXIT interface is the same for MQXF\_GET and MQXF\_DATA\_CONV\_ON\_GET, a single exit function can be used for both; the *Function* field in the MQAXP structure indicates which exit function has been invoked. Alternatively, the MQXEP call can be used to register different exit functions for the two cases.

### **Initialization - MQ\_INIT\_EXIT**

MQ\_INIT\_EXIT provides connection level initialization, indicated by setting ExitReason in MQAXP to MQXR\_CONNECTION.

During the initialization, note the following:

- The MQ\_INIT\_EXIT function calls MQXEP to register the IBM MQ API verbs and the ENTRY and EXIT points in which it is interested.
- Exits do not need to intercept all the IBM MQ API verbs. Exit functions are invoked only if an interest has been registered.
- Storage that is to be used by the exit can be acquired while initializing it.
- If a call to this function fails, the MQCONN or MQCONNX call that invoked it also fails with a CompCode and Reason that depend on the value of the ExitResponse field in MQAXP.

- An MQ\_INIT\_EXIT exit must not issue IBM MQ API calls, because the correct environment has not been set up at this time.
- If an MQ\_INIT\_EXIT fails with MQXCC\_FAILED, the queue manager returns from the MQCONN or MQCONNX call that called it with MQCC\_FAILED and MQRC\_API\_EXIT\_ERROR.
- If the queue manager encounters an error while initializing the API exit function execution environment before invoking the first MQ\_INIT\_EXIT, the queue manager returns from the MQCONN or MQCONNX call that invoked MQ\_INIT\_EXIT with MQCC\_FAILED and MQRC\_API\_EXIT\_INIT\_ERROR.

The interface to MQ\_INIT\_EXIT is:

```
MQ_INIT_EXIT (&ExitParms, &ExitContext, &CompCode, &Reason)
```

where the parameters are:

**ExitParms (MQAXP) - input/output**

Exit parameter structure.

**ExitContext (MQAXC) - input/output**

Exit context structure.

**CompCode (MQLONG) - input/output**

Pointer to completion code, valid values for which are:

**MQCC\_OK**

Successful completion.

**MQCC\_WARNING**

Partial completion.

**MQCC\_FAILED**

Call failed

**Reason (MQLONG) - input/output**

Pointer to reason code qualifying the completion code.

If the completion code is MQCC\_OK, the only valid value is:

**MQRC\_NONE**

(0, x'000') No reason to report.

If the completion code is MQCC\_FAILED or MQCC\_WARNING, the exit function can set the reason code field to any valid MQRC\_\* value.

The CompCode and Reason returned to the application depend on the value of the ExitResponse field in MQAXP.

## C language invocation

The queue manager logically defines the following variables:

```
MQAXP      ExitParms;      /* Exit parameter structure */
MQAXC      ExitContext;    /* Exit context structure */
MQLONG     CompCode;      /* Completion code */
MQLONG     Reason;        /* Reason code */
```

The queue manager then logically calls the exit as follows:

```
MQ_INIT_EXIT (&ExitParms, &ExitContext, &CompCode, &Reason)
```

Your exit must match the following C function prototype:

```
void MQENTRY MQ_INIT_EXIT (
PMQAXP      pExitParms,    /* Address of exit parameter structure */
PMQAXC      pExitContext,  /* Address of exit context structure */
PMQLONG     pCompCode,     /* Address of completion code */
```

```
PMQLONG      pReason);      /* Address of reason code qualifying
                             completion code */
```

## Usage notes

1. The MQ\_INIT\_EXIT function can issue the MQXEP call to register the addresses of the exit functions for the particular MQ calls to be intercepted. It is not necessary to intercept all MQ calls, or to intercept both MQXR\_BEFORE and MQXR\_AFTER calls. For example, an exit suite could choose to intercept only the MQXR\_BEFORE call of MQPUT.
2. Storage that is to be used by exit functions in the exit suite can be acquired by the MQ\_INIT\_EXIT function. Alternatively, exit functions can acquire storage when they are invoked, as and when needed. However, all storage should be freed before the exit suite is terminated; the MQ\_TERM\_EXIT function can free the storage, or an exit function invoked earlier.
3. If MQ\_INIT\_EXIT returns MQXCC\_FAILED in the ExitResponse field of MQAXP, or fails in some other way, the MQCONN or MQCONNX call that caused MQ\_INIT\_EXIT to be invoked also fails, with the **CompCode** and **Reason** parameters set to appropriate values.
4. An MQ\_INIT\_EXIT function cannot issue MQ calls other than MQXEP.

## Inquire - MQ\_INQ\_EXIT

MQ\_INQ\_EXIT provides an inquire exit function to perform *before* and *after* MQINQ call processing. Use function identifier MQXF\_INQ with exit reasons MQXR\_BEFORE and MQXR\_AFTER to register *before* and *after* MQINQ call exit functions.

The interface to this function is:

```
MQ_INQ_EXIT (&ExitParms, &ExitContext, &Hconn, &Hobj, &SelectorCount,
             &pSelectors, &IntAttrCount, &pIntAttrs, &CharAttrLength,
             &pCharAttrs, &CompCode, &Reason)
```

where the parameters are:

### ExitParms (MQAXP) - input/output

Exit parameter structure.

### ExitContext (MQAXC) - input/output

Exit context structure.

### Hconn (MQHCONN) - input

Connection handle.

### Hobj (MQHOBJ) - input

Object handle.

### SelectorCount (MQLONG) - input

Count of selectors

### pSelectors (PMQLONG) - input/output

Pointer to array of selector values.

### IntAttrCount (MQLONG) - input

Count of integer attributes.

### pIntAttrs (PMQLONG) - input/output

Pointer to array of integer attribute values.

### CharAttrLength (MQLONG) - input/output

Character attributes array length.

### pCharAttrs (PMQCHAR) - input/output

Pointer to character attributes array.

### CompCode (MQLONG) - input/output

Completion code, valid values for which are:

**MQCC\_OK**

Successful completion.

**MQCC\_WARNING**

Partial completion.

**MQCC\_FAILED**

Call failed

**Reason (MQLONG) - input/output**

Reason code qualifying the completion code.

If the completion code is MQCC\_OK, the only valid value is:

**MQRC\_NONE**

(0, x'000') No reason to report.

If the completion code is MQCC\_FAILED or MQCC\_WARNING, the exit function can set the reason code field to any valid MQRC\_\* value.

**C language invocation**

The queue manager logically defines the following variables:

```

MQAXP   ExitParms;      /* Exit parameter structure */
MQAXC   ExitContext;   /* Exit context structure */
MQHCONN Hconn;         /* Connection handle */
MQHOBJ  Hobj;          /* Object handle */
MQLONG  SelectorCount; /* Count of selectors */
PMQLONG pSelectors;    /* Ptr to array of attribute selectors */
MQLONG  IntAttrCount;  /* Count of integer attributes */
PMQLONG pIntAttr;     /* Ptr to array of integer attributes */
MQLONG  CharAttrLength; /* Length of char attributes array */
PMQCHAR pCharAttr;    /* Ptr to character attributes */
MQLONG  CompCode;     /* Completion code */
MQLONG  Reason;       /* Reason code qualifying completion code */

```

The queue manager then logically calls the exit as follows:

```

MQ_INQ_EXIT (&ExitParms, &ExitContext, &Hconn, &Hobj, &SelectorCount,
             &pSelectors, &IntAttrCount, &pIntAttr, &CharAttrLength,
             &pCharAttr, &CompCode, &Reason)

```

Your exit must match the following C function prototype:

```

void MQENTRY MQ_INQ_EXIT (
PMQAXP   pExitParms,      /* Address of exit parameter structure */
PMQAXC   pExitContext,   /* Address of exit context structure */
PMQHCONN pHconn,         /* Address of connection handle */
PMQHOBJ  pHobj,          /* Address of object handle */
PMQLONG  pSelectorCount, /* Address of selector count */
PPMQLONG ppSelectors,    /* Address of ptr to array of selectors */
PMQLONG  pIntAttrCount;  /* Address of count of integer attributes */
PPMQLONG ppIntAttr,     /* Address of ptr to array of integer attributes */
PMQLONG  pCharAttrLength, /* Address of character attribute length */
PPMQCHAR ppCharAttr,    /* Address of ptr to character attributes array */
PMQLONG  pCompCode,     /* Address of completion code */
PMQLONG  pReason);     /* Address of reason code qualifying completion
                        code */

```

**Open - MQ\_OPEN\_EXIT**

MQ\_OPEN\_EXIT provides an open exit function to perform *before* and *after* MQOPEN call processing. Use function identifier MQXF\_OPEN with exit reasons MQXR\_BEFORE and MQXR\_AFTER to register *before* and *after* MQOPEN call exit functions.

The interface to this function is

```
MQ_OPEN_EXIT (&ExitParms, &ExitContext, &Hconn, &pObjDesc, &Options,  
&pHobj, &CompCode, &Reason)
```

where the parameters are:

**ExitParms (MQAXP) - input/output**

Exit parameter structure.

**ExitContext (MQAXC) - input/output**

Exit context structure.

**Hconn (MQHCONN) - input**

Connection handle.

**pObjDesc (PMQOD) - input/output**

Pointer to object descriptor.

**Options (MQLONG) - input/output**

Open options.

**pHobj (PMQHOBj) - input**

Pointer to object handle.

**CompCode (MQLONG) - input/output**

Completion code, valid values for which are:

**MQCC\_OK**

Successful completion.

**MQCC\_WARNING**

Partial completion

**MQCC\_FAILED**

Call failed

**Reason (MQLONG) - input/output**

Reason code qualifying the completion code.

If the completion code is MQCC\_OK, the only valid value is:

**MQRC\_NONE**

(0, x'000') No reason to report.

If the completion code is MQCC\_FAILED or MQCC\_WARNING, the exit function can set the reason code field to any valid MQRC\_\* value.

## C language invocation

The queue manager logically defines the following variables:

```
MQAXP      ExitParms;      /* Exit parameter structure */  
MQAXC      ExitContext;    /* Exit context structure */  
MQHCONN    Hconn;         /* Connection handle */  
PMQOD      pObjDesc;      /* Ptr to object descriptor */  
MQLONG     Options;       /* Open options */  
PMQHOBj    pHobj;        /* Ptr to object handle */  
MQLONG     CompCode;      /* Completion code */  
MQLONG     Reason;        /* Reason code */
```

The queue manager then logically calls the exit as follows:

```
MQ_OPEN_EXIT (&ExitParms, &ExitContext, &Hconn, &pObjDesc, &Options,  
&pHobj, &CompCode, &Reason);
```

Your exit must match the following C function prototype:

```
void MQENTRY MQ_OPEN_EXIT (  
PMQAXP      pExitParms,    /* Address of exit parameter structure */
```

```

PMQAXC      pExitContext, /* Address of exit context structure */
PMQHCONN    pHconn,      /* Address of connection handle */
PMQOD       ppObjDesc,   /* Address of ptr to object descriptor */
PMQLONG     pOptions,    /* Address of open options */
PMQHOBJS    ppHobj,      /* Address of ptr to object handle */
PMQLONG     pCompCode,   /* Address of completion code */
PMQLONG     pReason);    /* Address of reason code qualifying
                           completion code */

```

### **Put - MQ\_PUT\_EXIT**

MQ\_PUT\_EXIT provides a put exit function to perform *before* and *after* MQPUT call processing. Use function identifier MQXF\_PUT with exit reasons MQXR\_BEFORE and MQXR\_AFTER to register *before* and *after* MQPUT call exit functions.

The interface to this function is:

```

MQ_PUT_EXIT (&ExitParms, &ExitContext, &Hconn, &Hobj, &pMsgDesc,
             &pPutMsgOpts, &BufferLength, &pBuffer, &CompCode, &Reason)

```

where the parameters are:

#### **ExitParms (MQAXP) - input/output**

Exit parameter structure.

#### **ExitContext (MQAXC) - input/output**

Exit context structure.

#### **Hconn (MQHCONN) - input**

Connection handle.

#### **Hobj (MQHOBJS) - input/output**

Object handle.

#### **pMsgDesc (PMQMD) - input/output**

Pointer to message descriptor.

#### **pPutMsgOpts (PMQPMO) - input/output**

Pointer to put message options.

#### **BufferLength (MQLONG) - input/output**

Message buffer length.

#### **pBuffer (PMQBYTE) - input/output**

Pointer to message buffer.

#### **CompCode (MQLONG) - input/output**

Completion code, valid values for which are:

##### **MQCC\_OK**

Successful completion.

##### **MQCC\_WARNING**

Partial completion.

##### **MQCC\_FAILED**

Call failed

#### **Reason (MQLONG) - input/output**

Reason code qualifying the completion code.

If the completion code is MQCC\_OK, the only valid value is:

##### **MQRC\_NONE**

(0, x'000') No reason to report.

If the completion code is MQCC\_FAILED or MQCC\_WARNING, the exit function can set the reason code field to any valid MQRC\_\* value.

## C language invocation

The queue manager logically defines the following variables:

```
MQAXP      ExitParms;      /* Exit parameter structure */
MQAXC      ExitContext;    /* Exit context structure */
MQHCONN    Hconn;         /* Connection handle */
MQHOBJ     Hobj;          /* Object handle */
PMQMD      pMsgDesc;      /* Ptr to message descriptor */
PMQPMO     pPutMsgOpts;   /* Ptr to put message options */
MQLONG     BufferLength;   /* Message buffer length */
PMQBYTE    pBuffer;      /* Ptr to message data */
MQLONG     CompCode;      /* Completion code */
MQLONG     Reason;       /* Reason code */
```

The queue manager then logically calls the exit as follows:

```
MQ_PUT_EXIT (&ExitParms, &ExitContext, &Hconn, &Hobj, &pMsgDesc,
             &pPutMsgOpts, &BufferLength, &pBuffer, &CompCode, &Reason)
```

Your exit must match the following C function prototype:

```
void MQENTRY MQ_PUT_EXIT (
PMQAXP      pExitParms,    /* Address of exit parameter structure */
PMQAXC      pExitContext, /* Address of exit context structure */
PMQHCONN    pHconn,       /* Address of connection handle */
PMQHOBJ     pHobj,        /* Address of object handle */
PPMMD       ppMsgDesc,    /* Address of ptr to message descriptor */
PPMOPMO     ppPutMsgOpts, /* Address of ptr to put message options */
MQLONG      pBufferLength, /* Address of message buffer length */
PMQBYTE     ppBuffer,     /* Address of ptr to message buffer */
PMQLONG     pCompCode,    /* Address of completion code */
PMQLONG     pReason);    /* Address of reason code qualifying
                           completion code */
```

## Usage notes

- Report messages generated by the queue manager skip the normal call processing. As a result, such messages cannot be intercepted by the MQ\_PUT\_EXIT function or the MQPUT1 function. However, report messages generated by the message channel agent are processed normally, and hence can be intercepted by the MQ\_PUT\_EXIT function or the MQ\_PUT1\_EXIT function. To be sure to intercepting all of the report messages generated by the MCA, both MQ\_PUT\_EXIT and MQ\_PUT1\_EXIT should be used.

### Put1 - MQ\_PUT1\_EXIT

MQ\_PUT1\_EXIT provides a *put one message only* exit function to perform *before* and *after* MQPUT1 call processing. Use function identifier MQXF\_PUT1 with exit reasons MQXR\_BEFORE and MQXR\_AFTER to register *before* and *after* MQPUT1 call exit functions.

The interface to this function is:

```
MQ_PUT1_EXIT (&ExitParms, &ExitContext, &Hconn, &pObjDesc, &pMsgDesc,
             &pPutMsgOpts, &BufferLength, &pBuffer, &CompCode, &Reason)
```

where the parameters are:

#### ExitParms (MQAXP) - input/output

Exit parameter structure.

#### ExitContext (MQAXC) - input/output

Exit context structure.

#### Hconn (MQHCONN) - input

Connection handle.

**pObjDesc (PMQOD) - input/output**

Pointer to object descriptor.

**pMsgDesc (PMQMD) - input/output**

Pointer to message descriptor.

**pPutMsgOpts (PMQPMO) - input/output**

Pointer to put message options.

**BufferLength (MQLONG) - input/output**

Message buffer length.

**pBuffer (PMQBYTE) - input/output**

Pointer to message buffer.

**CompCode (MQLONG) - input/output**

Completion code, valid values for which are:

**MQCC\_OK**

Successful completion.

**MQCC\_WARNING**

Partial completion.

**MQCC\_FAILED**

Call failed

**Reason (MQLONG) - input/output**

Reason code qualifying the completion code.

If the completion code is MQCC\_OK, the only valid value is:

**MQRC\_NONE**

(0, x'000') No reason to report.

If the completion code is MQCC\_FAILED or MQCC\_WARNING, the exit function can set the reason code field to any valid MQRC\_\* value.

## C language invocation

The queue manager logically defines the following variables:

```

MQAXP      ExitParms;      /* Exit parameter structure */
MQAXC      ExitContext;    /* Exit context structure */
MQHCONN    Hconn;          /* Connection handle */
PMQOD      pObjDesc;       /* Ptr to object descriptor */
PMQMD      pMsgDesc;       /* Ptr to message descriptor */
PMQPMO     pPutMsgOpts;    /* Ptr to put message options */
MQLONG     BufferLength;    /* Message buffer length */
PMQBYTE    pBuffer;        /* Ptr to message data */
MQLONG     CompCode;       /* Completion code */
MQLONG     Reason;         /* Reason code */

```

The queue manager then logically calls the exit as follows:

```

MQ_PUT1_EXIT (&ExitParms, &ExitContext, &Hconn, &pObjDesc, &pMsgDesc,
              &pPutMsgOpts, &BufferLength, &pBuffer, &CompCode, &Reason)

```

Your exit must match the following C function prototype:

```

void MQENTRY MQ_PUT1_EXIT (
PMQAXP      pExitParms,     /* Address of exit parameter structure */
PMQAXC      pExitContext,   /* Address of exit context structure */
MQHCONN     pHconn,         /* Address of connection handle */
PPMQOD      ppObjDesc,      /* Address of ptr to object descriptor */
PPMQMD      ppMsgDesc,      /* Address of ptr to message descriptor */
PPMQPMO     ppPutMsgOpts,   /* Address of ptr to put message options */
PMQLONG     pBufferLength,  /* Address of message buffer length */
PPMQBYTE    ppBuffer,       /* Address of ptr to message buffer */
PMQLONG     pCompCode,      /* Address of completion code */

```

```
PMQLONG      pReason);      /* Address of reason code qualifying
                             completion code */
```

### **Set - MQ\_SET\_EXIT**

MQ\_SET\_EXIT provides a set exit function to perform *before* and *after* MQSET call processing. Use function identifier MQXF\_SET with exit reasons MQXR\_BEFORE and MQXR\_AFTER to register *before* and *after* MQSET call exit functions.

The interface to this function is:

```
MQ_SET_EXIT (&ExitParms, &ExitContext, &Hconn, &Hobj, &SelectorCount,
             &pSelectors, &IntAttrCount, &pIntAttrs, &CharAttrLength,
             &pCharAttr, &CompCode, &Reason)
```

where the parameters are:

**ExitParms (MQAXP) - input/output**

Exit parameter structure.

**ExitContext (MQAXC) - input/output**

Exit context structure.

**Hconn (MQHCONN) - input**

Connection handle.

**Hobj (MQHOBJ) - input**

Object handle.

**SelectorCount (MQLONG) - input**

Count of selectors

**pSelectors (PMQLONG) - input/output**

Pointer to array of selector values.

**IntAttrCount (MQLONG) - input**

Count of integer attributes.

**pIntAttrs (PMQLONG) - input/output**

Pointer to array of integer attribute values.

**CharAttrLength (MQLONG) - input/output**

Character attributes array length.

**pCharAttrs (PMQCHAR) - input/output**

Pointer to character attribute values.

**CompCode (MQLONG) - input/output**

Completion code, valid values for which are:

**MQCC\_OK**

Successful completion.

**MQCC\_WARNING**

Partial completion.

**MQCC\_FAILED**

Call failed

**Reason (MQLONG) - input/output**

Reason code qualifying the completion code.

If the completion code is MQCC\_OK, the only valid value is:

**MQRC\_NONE**

(0, x'000') No reason to report.

If the completion code is MQCC\_FAILED or MQCC\_WARNING, the exit function can set the reason code field to any valid MQRC\_\* value.

## C language invocation

The queue manager logically defines the following variables:

```
MQAXP    ExitParms;        /* Exit parameter structure */
MQAXC    ExitContext;     /* Exit context structure */
MQHCONN  Hconn;          /* Connection handle */
MQHOBJ   Hobj;           /* Object handle */
MQLONG   SelectorCount;  /* Count of selectors */
PMQLONG  pSelectors;     /* Ptr to array of attribute selectors */
MQLONG   IntAttrCount;   /* Count of integer attributes */
PMQLONG  pIntAttr;       /* Ptr to array of integer attributes */
MQLONG   CharAttrLength; /* Length of char attributes array */
PMQCHAR  pCharAttr;      /* Ptr to character attributes */
MQLONG   CompCode;       /* Completion code */
MQLONG   Reason;         /* Reason code qualifying completion code */
```

The queue manager then logically calls the exit as follows:

```
MQ_SET_EXIT (&ExitParms, &ExitContext, &Hconn, &Hobj, &SelectorCount,
             &pSelectors, &IntAttrCount, &pIntAttr, &CharAttrLength,
             &pCharAttr, &CompCode, &Reason)
```

Your exit must match the following C function prototype:

```
void MQENTRY MQ_SET_EXIT (
PMQAXP    pExitParms,      /* Address of exit parameter structure */
PMQAXC    pExitContext,    /* Address of exit context structure */
PMQHCONN  pHconn,         /* Address of connection handle */
PMQHOBJ   pHobj,          /* Address of object handle */
PMQLONG   pSelectorCount, /* Address of selector count */
PPMQLONG  ppSelectors,    /* Address of ptr to array of selectors */
PMQLONG   pIntAttrCount;  /* Address of count of integer attributes */
PPMQLONG  ppIntAttr,      /* Address of ptr to array of integer attributes */
PMQLONG   pCharAttrLength, /* Address of character attribute length */
PPMQCHAR  ppCharAttr,     /* Address of ptr to character attributes array */
PMQLONG   pCompCode,      /* Address of completion code */
PMQLONG   pReason);       /* Address of reason code qualifying completion
                             code */
```

### Status - MQ\_STAT\_EXIT

MQ\_STAT\_EXIT provides a status exit function to perform *before* and *after* MQSTAT call processing. Use function identifier MQXF\_STAT with exit reasons MQXR\_BEFORE and MQXR\_AFTER to register *before* and *after* MQSTAT call exit functions.

The interface to this function is:

```
MQ_STAT_EXIT (&ExitParms, &ExitContext, &Hconn, &Type, &pStatus
              &CompCode, &Reason)
```

where the parameters are:

#### ExitParms (MQAXP) - input/output

Exit parameter structure.

#### ExitContext (MQAXC) - input/output

Exit context structure.

#### Hconn (MQHCONN) - input

Connection handle.

#### Type (MQLONG) - input

Type of status information to retrieve.

#### pStatus (PMQSTS) - output

Pointer to status buffer.

#### CompCode (MQLONG) - input/output

Completion code, valid values for which are:

**MQCC\_OK**

Successful completion.

**MQCC\_WARNING**

Partial completion.

**MQCC\_FAILED**

Call failed

**Reason (MQLONG) - input/output**

Reason code qualifying the completion code.

If the completion code is MQCC\_OK, the only valid value is:

**MQRC\_NONE**

(0, x'000') No reason to report.

If the completion code is MQCC\_FAILED or MQCC\_WARNING, the exit function can set the reason code field to any valid MQRC\_\* value.

**C language invocation**

Your exit must match the following C function prototype:

```
void MQENTRY MQ_STAT_EXIT (
PMQAXP    pExitParms,      /* Address of exit parameter structure */
PMQAXC    pExitContext,    /* Address of exit context structure */
PMQHCONN  pHconn,         /* Address of connection handle */
PMQLONG   pType,           /* Address of status type */
PPMQSTS   ppStatus,       /* Address of status buffer */
PMQLONG   pCompCode,      /* Address of completion code */
PMQLONG   pReason);       /* Address of reason code qualifying completion
                           code */
```

**Termination - MQ\_TERM\_EXIT**

MQ\_TERM\_EXIT provides connection level termination, registered with a function identifier of MQXF\_TERM and ExitReason MQXR\_CONNECTION. If registered, MQ\_TERM\_EXIT is called once for every disconnect request.

As part of the termination, storage no longer required by the exit can be released, and any clean up required can be performed.

If an MQ\_TERM\_EXIT fails with MQXCC\_FAILED, the queue manager returns from the MQDISC that called it with MQCC\_FAILED and MQRC\_API\_EXIT\_ERROR.

If the queue manager encounters an error while terminating the API exit function execution environment after invoking the last MQ\_TERM\_EXIT, the queue manager returns from the MQDISC call that invoked MQ\_TERM\_EXIT with MQCC\_FAILED and MQRC\_API\_EXIT\_TERM\_ERROR

The interface to this function is:

```
MQ_TERM_EXIT (&ExitParms, &ExitContext, &CompCode, &Reason)
```

where the parameters are:

**ExitParms (MQAXP) - input/output**

Exit parameter structure.

**ExitContext (MQAXC) - input/output**

Exit context structure.

**CompCode (MQLONG) - input/output**

Completion code, valid values for which are:

**MQCC\_OK**

Successful completion.

## MQCC\_FAILED

Call failed

### Reason (MQLONG) - input/output

Reason code qualifying the completion code.

If the completion code is MQCC\_OK, the only valid value is:

### MQRC\_NONE

(0, x'000') No reason to report.

If the completion code is MQCC\_FAILED, the exit function can set the reason code field to any valid MQRC\_\* value.

The CompCode and Reason returned to the application depend on the value of the ExitResponse field in MQAXP.

## C language invocation

The queue manager logically defines the following variables:

```
MQAXP      ExitParms;      /* Exit parameter structure */
MQAXC      ExitContext;    /* Exit context structure */
MQLONG     CompCode;      /* Completion code */
MQLONG     Reason;        /* Reason code */
```

The queue manager then logically calls the exit as follows:

```
MQ_TERM_EXIT (&ExitParms, &ExitContext, &CompCode, &Reason)
```

Your exit must match the following C function prototype:

```
void MQENTRY MQ_TERM_EXIT (
PMQAXP      pExitParms,    /* Address of exit parameter structure */
PMQAXC      pExitContext,  /* Address of exit context structure */
PMQLONG     pCompCode,     /* Address of completion code */
PMQLONG     pReason);      /* Address of reason code qualifying
                             completion code */
```

## Usage notes

1. The MQ\_TERM\_EXIT function is optional. It is not necessary for an exit suite to register a termination exit if there is no termination processing to be done.

If functions belonging to the exit suite acquire resources during the connection, an MQ\_TERM\_EXIT function is a convenient point at which to free those resources, for example, freeing storage obtained dynamically.

2. If an MQ\_TERM\_EXIT function is registered when the MQDISC call is issued, the exit function is invoked after all of the MQDISC exit functions have been invoked.
3. If MQ\_TERM\_EXIT returns MQXCC\_FAILED in the ExitResponse field of MQAXP, or fails in some other way, the MQDISC call that caused MQ\_TERM\_EXIT to be invoked also fails, with the **CompCode** and **Reason** parameters set to appropriate values.

### Register subscription - MQ\_SUB\_EXIT

MQ\_SUB\_EXIT provides an exit function to perform *before* and *after* subscription reregistration processing. Use function identifier MQXF\_SUB with exit reasons MQXR\_BEFORE and MQXR\_AFTER to register *before* and *after* subscription registration call exit functions.

The interface to this function is:

```
MQ_SUB_EXIT (&ExitParms, &ExitContext, &Hconn, &pSubDesc, &pHobj, &pHsub, &CompCode, &Reason)
```

where the parameters are:

**ExitParms (MQAXP) - input/output**

Exit parameter structure.

**ExitContext (MQAXC) - input/output**

Exit context structure.

**Hconn (MQHCONN) - input/output**

Connection handle.

**pSubDesc - input/output**

Array of attribute selectors.

**pHobj - input/output**

Object handle

**pHsub (MQHOBJ) input/output**

Subscription handle

**CompCode (MQLONG) - input/output**

Completion code, valid values for which are:

**MQCC\_OK**

Successful completion.

**MQCC\_WARNING**

Partial completion.

**MQCC\_FAILED**

Call failed

**Reason (MQLONG) - input/output**

Reason code qualifying the completion code.

If the completion code is MQCC\_OK, the only valid value is:

**MQRC\_NONE**

(0, x'000') No reason to report.

If the completion code is MQCC\_FAILED or MQCC\_WARNING, the exit function can set the reason code field to any valid MQRC\_\* value.

## C language invocation

The queue manager logically defines the following variables:

```
MQAXP      ExitParms;      /* Exit parameter structure */
MQAXC      ExitContext;    /* Exit context structure */
MQHCONN    Hconn;         /* Connection handle */
PMQSD      pSubDesc;      /* Subscription descriptor */
PMQHOBJS   pHobj;        /* Object Handle */
PMQHOBJS   pHsub;        /* Subscription handle */
MQLONG     CompCode;      /* Completion code */
MQLONG     Reason;        /* Reason code qualifying completion code */
```

The queue manager then logically calls the exit as follows:

```
MQ_SUB_EXIT (&ExitParms, &ExitContext, &Hconn, &pSubDesc, &pHobj, &pHsub,
             &CompCode, &Reason);
```

Your exit must match the following C function prototype:

```
PMQAXP     pExitParms;     /* Exit parameter structure */
PMQAXC     pExitContext;   /* Exit context structure */
PMQHCONN   pHconn;        /* Connection handle */
PPMQSD     ppSubDesc;     /* Subscription descriptor */
PPMQHOBJS  ppHobj;        /* Object Handle */
PPMQHOBJS  ppHsub;        /* Subscription handle */
```

```

PMQLONG  pCompCode;    /* Completion code */
PMQLONG  pReason;     /* Reason code qualifying completion code */

```

### **Subscription request - MQ\_SUBRQ\_EXIT**

MQ\_SUBRQ\_EXIT provides a subscription request exit function to perform *before* and *after* subscription request processing. Use function identifier MQXF\_SUBRQ with exit reasons MQXR\_BEFORE and MQXR\_AFTER to register *before* and *after* subscription request call exit functions.

The interface to this function is:

```

MQ_SUBRQ_EXIT (&ExitParms, &ExitContext, &Hconn, &pHsub, &Action, &pSubRqOpts,
              &CompCode, &Reason)

```

where the parameters are:

#### **ExitParms (MQAXP) - input/output**

Exit parameter structure.

#### **ExitContext (MQAXC) - input/output**

Exit context structure.

#### **Hconn (MQHCONN) - input/output**

Connection handle.

#### **pHsub (MQHOBJ) input/output**

Subscription handle

#### **Action (MQLONG) input/output**

Action

#### **pSubRqOpts (MQSRO) input/output**

#### **CompCode (MQLONG) - input/output**

Completion code, valid values for which are:

##### **MQCC\_OK**

Successful completion.

##### **MQCC\_WARNING**

Partial completion.

##### **MQCC\_FAILED**

Call failed

#### **Reason (MQLONG) - input/output**

Reason code qualifying the completion code.

If the completion code is MQCC\_OK, the only valid value is:

##### **MQRC\_NONE**

(0, x'000') No reason to report.

If the completion code is MQCC\_FAILED or MQCC\_WARNING, the exit function can set the reason code field to any valid MQRC\_\* value.

## **C language invocation**

The queue manager logically defines the following variables:

```

MQAXP    ExitParms;    /* Exit parameter structure */
MQAXC    ExitContext;  /* Exit context structure */
MQHCONN  Hconn;       /* Connection handle */
PMQLONG  pHsub;       /* Subscription handle */
MQLONG   Action;      /* Action */
MQSRO    pSubRqOpts;  /* Subscription Request Options */
MQLONG   CompCode;    /* Completion code */
MQLONG   Reason;      /* Reason code qualifying completion code */

```

The queue manager then logically calls the exit as follows:

```
MQ_SUBRQ_EXIT (&ExitParms, &ExitContext, &Hconn, &pHsub, &Action, &pSubRqOpts,
               &CompCode, &Reason);
```

Your exit must match the following C function prototype:

```
void MQENTRY MQ_SUBRQ_EXIT (
PMQAXP    pExitParms,      /* Address of exit parameter structure */
PMQAXC    pExitContext,    /* Address of exit context structure */
PMQHCONN  pHconn,         /* Address of connection handle */
PPMQHOBJS ppHsub;         /* Address of Subscription handle */
MQLONG    pAction;        /* Address of Action */
PPMQSRO   ppSubRqOpts;    /* Address of Subscription Request Options */
MQLONG    pCompCode,      /* Address of completion code */
MQLONG    pReason;        /* Address of reason code qualifying completion
                           code */
```

### ***xa\_close - XA\_CLOSE\_EXIT***

XA\_CLOSE\_EXIT provides an `xa_close` exit function to perform before and after `xa_close` processing. Use function identifier `MQXF_XACLOSE` with exit reasons `MQXR_BEFORE` and `MQXR_AFTER` to register the before and after `xa_close` call exit functions.

The interface to this function is:

```
XA_CLOSE_EXIT (&ExitParms, &ExitContext, &Hconn, &pXa_info, &Rmid, &Flags, &XARetCode)
```

where the parameters are:

#### **ExitParms (MQAXP) - input/output**

Exit parameter structure.

#### **ExitContext (MQAXC) - input/output**

Exit context structure.

#### **Hconn (MQHCONN) - input**

Connection handle.

#### **pXa\_info (PMQCHAR) - input/output**

Instance-specific resource manager information.

#### **Rmid (MQLONG) - input/output**

Resource manager identifier.

#### **Flags (MQLONG) - input/output**

Resource manager options.

#### **XARetCode (MQLONG) - input/output**

Response from XA call.

### **C language invocation**

The queue manager logically defines the following variables:

```
MQAXP    ExitParms;      /* Exit parameter structure */
MQAXC    ExitContext;    /* Exit context structure */
MQHCONN  Hconn;         /* Connection handle */
PMQCHAR  pXa_info;      /* Instance-specific RM info */
MQLONG    Rmid;         /* Resource manager identifier */
MQLONG    Flags;        /* Resource manager options*/
MQLONG    XARetCode;    /* Response from XA call */
```

The queue manager then logically calls the exit as follows:

```
XA_CLOSE_EXIT (&ExitParms, &ExitContext, &Hconn, &pXa_info, &Rmid, &Flags, &XARetCode);
```

Your exit must match the following C function prototype:

```

typedef void MQENTRY XA_CLOSE_EXIT (
    PMQAXP    pExitParms,    /* Address of exit parameter structure */
    PMQAXC    pExitContext, /* Address of exit context structure */
    PMQHCONN  pHconn,       /* Address of connection handle */
    PPMQCHAR  ppXa_info,    /* Address of instance-specific RM info */
    PMQLONG   pRmid,        /* Address of resource manager identifier */
    PMQLONG   pFlags,       /* Address of resource manager options*/
    PMQLONG   pXARetCode); /* Address of response from XA call */

```

### ***xa\_commit - XA\_COMMIT\_EXIT***

XA\_COMMIT\_EXIT provides an xa\_commit exit function to perform before and after xa\_commit processing. Use function identifier MQXF\_XACOMMIT with exit reasons MQXR\_BEFORE and MQXR\_AFTER to register the before and after xa\_commit call exit functions.

The interface to this function is:

```
XA_COMMIT_EXIT (&ExitParms, &ExitContext, &Hconn, &pXID, &Rmid, &Flags, &XARetCode)
```

where the parameters are:

#### **ExitParms (MQAXP) - input/output**

Exit parameter structure.

#### **ExitContext (MQAXC) - input/output**

Exit context structure.

#### **Hconn (MQHCONN) - input**

Connection handle.

#### **pXID (MQPTR) - input/output**

Transaction branch ID.

#### **Rmid (MQLONG) - input/output**

Resource manager identifier.

#### **Flags (MQLONG) - input/output**

Resource manager options.

#### **XARetCode (MQLONG) - input/output**

Response from XA call.

### **C language invocation**

The queue manager logically defines the following variables:

```

MQAXP    ExitParms;    /* Exit parameter structure */
MQAXC    ExitContext; /* Exit context structure */
MQHCONN  Hconn;       /* Connection handle */
MQPTR    pXID;        /* Transaction branch ID */
MQLONG   Rmid;        /* Resource manager identifier */
MQLONG   Flags;       /* Resource manager options*/
MQLONG   XARetCode;  /* Response from XA call */

```

The queue manager then logically calls the exit as follows:

```
XA_COMMIT_EXIT (&ExitParms, &ExitContext, &Hconn, &pXID, &Rmid, &Flags, &XARetCode);
```

Your exit must match the following C function prototype:

```

typedef void MQENTRY XA_COMMIT_EXIT (
    PMQAXP    pExitParms,    /* Address of exit parameter structure */
    PMQAXC    pExitContext, /* Address of exit context structure */
    PMQHCONN  pHconn,       /* Address of connection handle */
    PMQPTR    ppXID,        /* Address of transaction branch ID */
    PMQLONG   pRmid,        /* Address of resource manager identifier */

```

```

PMQLONG  pFlags,      /* Address of resource manager options*/
PMQLONG  pXARetCode); /* Address of response from XA call */

```

### ***xa\_complete* - XA\_COMPLETE\_EXIT**

XA\_COMPLETE\_EXIT provides an *xa\_complete* exit function to perform before and after *xa\_complete* processing. Use function identifier MQXF\_XACOMPLETE with exit reasons MQXR\_BEFORE and MQXR\_AFTER to register the before and after *xa\_complete* call exit functions.

The interface to this function is:

```

XA_COMPLETE_EXIT (&ExitParms, &ExitContext, &Hconn, &pHandle, &pRetVal, &Rmid, &Flags,
&XARetCode)

```

where the parameters are:

#### **ExitParms (MQAXP) - input/output**

Exit parameter structure.

#### **ExitContext (MQAXC) - input/output**

Exit context structure.

#### **Hconn (MQHCONN) - input**

Connection handle.

#### **pHandle (PMQLONG) - input/output**

Pointer to asynchronous operation.

#### **pRetVal (PMQLONG) - input/output**

Return value of asynchronous operation.

#### **Rmid (MQLONG) - input/output**

Resource manager identifier.

#### **Flags (MQLONG) - input/output**

Resource manager options.

#### **XARetCode (MQLONG) - input/output**

Response from XA call.

### **C language invocation**

The queue manager logically defines the following variables:

```

MQAXP  ExitParms;  /* Exit parameter structure */
MQAXC  ExitContext; /* Exit context structure */
MQHCONN Hconn;    /* Connection handle */
PMQLONG pHandle;  /* Ptr to asynchronous op */
PMQLONG pRetVal;  /* Return value of async op */
MQLONG  Rmid;     /* Resource manager identifier */
MQLONG  Flags;    /* Resource manager options */
MQLONG  XARetCode; /* Response from XA call */

```

The queue manager then logically calls the exit as follows:

```

XA_COMPLETE_EXIT (&ExitParms, &ExitContext, &Hconn, &pHandle, &pRetVal, &Rmid, &Flags,
&XARetCode);

```

Your exit must match the following C function prototype:

```

typedef void MQENTRY XA_COMPLETE_EXIT (
    PMQAXP  pExitParms, /* Address of exit parameter structure */
    PMQAXC  pExitContext, /* Address of exit context structure */
    PMQHCONN pHconn, /* Address of connection handle */
    PPMQLONG ppHandle, /* Address of ptr to asynchronous op */
    PPMQLONG ppRetVal, /* Address of return value of async op */
    PMQLONG pRmid, /* Address of resource manager identifier */

```

```

PMQLONG pFlags, /* Address of resource manager options*/
PMQLONG pXARetCode); /* Address of response from XA call */

```

### ***xa\_end - XA\_END\_EXIT***

XA\_END\_EXIT provides an xa\_end exit function to perform before and after xa\_end processing. Use function identifier MQXF\_XAEND with exit reasons MQXR\_BEFORE and MQXR\_AFTER to register the before and after xa\_end call exit functions.

The interface to this function is:

```

XA_END_EXIT (&ExitParms, &ExitContext, &Hconn, &pXID, &Rmid, &Flags, &XARetCode)

```

where the parameters are:

#### **ExitParms (MQAXP) - input/output**

Exit parameter structure.

#### **ExitContext (MQAXC) - input/output**

Exit context structure.

#### **Hconn (MQHCONN) - input**

Connection handle.

#### **pXID (MQPTR) - input/output**

Transaction branch ID.

#### **Rmid (MQLONG) - input/output**

Resource manager identifier.

#### **Flags (MQLONG) - input/output**

Resource manager options.

#### **XARetCode (MQLONG) - input/output**

Response from XA call.

### **C language invocation**

The queue manager logically defines the following variables:

```

MQAXP ExitParms; /* Exit parameter structure */
MQAXC ExitContext; /* Exit context structure */
MQHCONN Hconn; /* Connection handle */
MQPTR pXID; /* Transaction branch ID */
MQLONG Rmid; /* Resource manager identifier */
MQLONG Flags; /* Resource manager options*/
MQLONG XARetCode; /* Response from XA call */

```

The queue manager then logically calls the exit as follows:

```

XA_END_EXIT (&ExitParms, &ExitContext, &Hconn, &pXID, &Rmid, &Flags, &XARetCode);

```

Your exit must match the following C function prototype:

```

typedef void MQENTRY XA_END_EXIT (
    PMQAXP pExitParms, /* Address of exit parameter structure */
    PMQAXC pExitContext, /* Address of exit context structure */
    PMQHCONN pHconn, /* Address of connection handle */
    PMQPTR ppXID, /* Address of transaction branch ID */
    PMQLONG pRmid, /* Address of resource manager identifier */
    PMQLONG pFlags, /* Address of resource manager options*/
    PMQLONG pXARetCode); /* Address of response from XA call */

```

## ***xa\_forget - XA\_FORGET\_EXIT***

XA\_FORGET\_EXIT provides an `xa_forget` exit function to perform before and after `xa_forget` processing. Use function identifier MQXF\_XAFORGET with exit reasons MQXR\_BEFORE and MQXR\_AFTER to register the before and after `xa_forget` call exit functions.

The interface to this function is:

```
XA_FORGET_EXIT (&ExitParms, &ExitContext, &Hconn, &pXID, &Rmid, &Flags, &XARetCode)
```

where the parameters are:

### **ExitParms (MQAXP) - input/output**

Exit parameter structure.

### **ExitContext (MQAXC) - input/output**

Exit context structure.

### **Hconn (MQHCONN) - input**

Connection handle.

### **pXID (MQPTR) - input/output**

Transaction branch ID.

### **Rmid (MQLONG) - input/output**

Resource manager identifier.

### **Flags (MQLONG) - input/output**

Resource manager options.

### **XARetCode (MQLONG) - input/output**

Response from XA call.

## **C language invocation**

The queue manager logically defines the following variables:

```
MQAXP  ExitParms; /* Exit parameter structure */
MQAXC  ExitContext; /* Exit context structure */
MQHCONN Hconn; /* Connection handle */
MQPTR  pXID; /* Transaction branch ID */
MQLONG Rmid; /* Resource manager identifier */
MQLONG Flags; /* Resource manager options*/
MQLONG XARetCode; /* Response from XA call */
```

The queue manager then logically calls the exit as follows:

```
XA_FORGET_EXIT (&ExitParms, &ExitContext, &Hconn, &pXID, &Rmid, &Flags, &XARetCode);
```

Your exit must match the following C function prototype:

```
typedef void MQENTRY XA_FORGET_EXIT (
    PMQAXP  pExitParms, /* Address of exit parameter structure */
    PMQAXC  pExitContext, /* Address of exit context structure */
    PMQHCONN pHconn, /* Address of connection handle */
    PMQPTR  ppXID, /* Address of transaction branch ID */
    PMQLONG pRmid, /* Address of resource manager identifier */
    PMQLONG pFlags, /* Address of resource manager options*/
    PMQLONG pXARetCode); /* Address of response from XA call */
```

## ***xa\_open - XA\_OPEN\_EXIT***

XA\_OPEN\_EXIT provides an `xa_open` exit function to perform before and after `xa_open` processing. Use function identifier MQXF\_XAOPEN with exit reasons MQXR\_BEFORE and MQXR\_AFTER to register the before and after `xa_open` call exit functions.

The interface to this function is:

```
XA_OPEN_EXIT (&ExitParms, &ExitContext, &Hconn, &pXa_info, &Rmid, &Flags, &XARetCode)
```

where the parameters are:

**ExitParms (MQAXP) - input/output**

Exit parameter structure.

**ExitContext (MQAXC) - input/output**

Exit context structure.

**Hconn (MQHCONN) - input**

Connection handle.

**pXa\_info (PMQCHAR) - input/output**

Instance-specific resource manager information.

**Rmid (MQLONG) - input/output**

Resource manager identifier.

**Flags (MQLONG) - input/output**

Resource manager options.

**XARetCode (MQLONG) - input/output**

Response from XA call.

## C language invocation

The queue manager logically defines the following variables:

```
MQAXP  ExitParms; /* Exit parameter structure */
MQAXC  ExitContext; /* Exit context structure */
MQHCONN Hconn; /* Connection handle */
PMQCHAR pXa_info; /* Instance-specific RM info */
MQLONG  Rmid; /* Resource manager identifier */
MQLONG  Flags; /* Resource manager options*/
MQLONG  XARetCode; /* Response from XA call */
```

The queue manager then logically calls the exit as follows:

```
XA_OPEN_EXIT (&ExitParms, &ExitContext, &Hconn, &pXa_info, &Rmid, &Flags, &XARetCode);
```

Your exit must match the following C function prototype:

```
typedef void MQENTRY XA_OPEN_EXIT (
    PMQAXP  pExitParms, /* Address of exit parameter structure */
    PMQAXC  pExitContext, /* Address of exit context structure */
    PMQHCONN pHconn, /* Address of connection handle */
    PPMQCHAR ppXa_info, /* Address of instance-specific RM info */
    PMQLONG pRmid, /* Address of resource manager identifier */
    PMQLONG pFlags, /* Address of resource manager options*/
    PMQLONG pXARetCode); /* Address of response from XA call */
```

### ***xa\_prepare - XA\_PREPARE\_EXIT***

XA\_PREPARE\_EXIT provides an *xa\_prepare* exit function to perform before and after *xa\_prepare* processing. Use function identifier MQXF\_XAPREPARE with exit reasons MQXR\_BEFORE and MQXR\_AFTER to register the before and after *xa\_prepare* call exit functions.

The interface to this function is:

```
XA_PREPARE_EXIT (&ExitParms, &ExitContext, &Hconn, &pXID, &Rmid, &Flags, &XARetCode)
```

where the parameters are:

**ExitParms (MQAXP) - input/output**

Exit parameter structure.

**ExitContext (MQAXC) - input/output**

Exit context structure.

**Hconn (MQHCONN) - input**

Connection handle.

**pXID (MQPTR) - input/output**

Transaction branch ID.

**Rmid (MQLONG) - input/output**

Resource manager identifier.

**Flags (MQLONG) - input/output**

Resource manager options.

**XARetCode (MQLONG) - input/output**

Response from XA call.

**C language invocation**

The queue manager logically defines the following variables:

```
MQAXP  ExitParms; /* Exit parameter structure */
MQAXC  ExitContext; /* Exit context structure */
MQHCONN Hconn; /* Connection handle */
MQPTR  pXID; /* Transaction branch ID */
MQLONG Rmid; /* Resource manager identifier */
MQLONG Flags; /* Resource manager options*/
MQLONG XARetCode; /* Response from XA call */
```

The queue manager then logically calls the exit as follows:

```
XA_PREPARE_EXIT (&ExitParms, &ExitContext, &Hconn, &pXID, &Rmid, &Flags, &XARetCode);
```

Your exit must match the following C function prototype:

```
typedef void MQENTRY XA_PREPARE_EXIT (
    PMQAXP  pExitParms, /* Address of exit parameter structure */
    PMQAXC  pExitContext, /* Address of exit context structure */
    PMQHCONN pHconn, /* Address of connection handle */
    PMQPTR  ppXID, /* Address of transaction branch ID */
    PMQLONG pRmid, /* Address of resource manager identifier */
    PMQLONG pFlags, /* Address of resource manager options*/
    PMQLONG pXARetCode); /* Address of response from XA call */
```

***xa\_recover - XA\_RECOVER\_EXIT***

XA\_RECOVER\_EXIT provides an `xa_recover` exit function to perform before and after `xa_recover` processing. Use function identifier `MQXF_XARECOVER` with exit reasons `MQXR_BEFORE` and `MQXR_AFTER` to register the before and after `xa_recover` call exit functions.

The interface to this function is:

```
XA_RECOVER_EXIT (&ExitParms, &ExitContext, &Hconn, &pXID, &Count, &Rmid, &Flags, &XARetCode)
```

where the parameters are:

**ExitParms (MQAXP) - input/output**

Exit parameter structure.

**ExitContext (MQAXC) - input/output**

Exit context structure.

**Hconn (MQHCONN) - input**

Connection handle.

**pXID (MQPTR) - input/output**

Transaction branch ID.

**Count (MQLONG) - input/output**

Maximum XIDs in XID array

**Rmid (MQLONG) - input/output**

Resource manager identifier.

**Flags (MQLONG) - input/output**

Resource manager options.

**XARetCode (MQLONG) - input/output**

Response from XA call.

**C language invocation**

The queue manager logically defines the following variables:

```

MQAXP  ExitParms;    /* Exit parameter structure */
MQAXC  ExitContext; /* Exit context structure */
MQHCONN Hconn;      /* Connection handle */
MQPTR  pXID;        /* Transaction branch ID */
MQLONG Count;       /* Max XIDs in XID array */
MQLONG Rmid;        /* Resource manager identifier */
MQLONG Flags;       /* Resource manager options */
MQLONG XARetCode;   /* Response from XA call */

```

The queue manager then logically calls the exit as follows:

```
XA_RECOVER_EXIT (&ExitParms, &ExitContext, &Hconn, &pXID, &Count, &Rmid, &Flags, &XARetCode);
```

Your exit must match the following C function prototype:

```

typedef void MQENTRY XA_RECOVER_EXIT (
    PMQAXP  pExitParms, /* Address of exit parameter structure */
    PMQAXC  pExitContext, /* Address of exit context structure */
    PMQHCONN pHconn, /* Address of connection handle */
    PMQPTR  ppXID, /* Address of transaction branch ID */
    PMQLONG pCount, /* Address of max XIDs in XID array */
    PMQLONG pRmid, /* Address of resource manager identifier */
    PMQLONG pFlags, /* Address of resource manager options */
    PMQLONG pXARetCode); /* Address of response from XA call */

```

***xa\_rollback - XA\_ROLLBACK\_EXIT***

XA\_ROLLBACK\_EXIT provides an *xa\_rollback* exit function to perform before and after *xa\_rollback* processing. Use function identifier MQXF\_XAROLLBACK with exit reasons MQXR\_BEFORE and MQXR\_AFTER to register the before and after *xa\_rollback* call exit functions.

The interface to this function is:

```
XA_ROLLBACK_EXIT (&ExitParms, &ExitContext, &Hconn, &pXID, &Rmid, &Flags, &XARetCode)
```

where the parameters are:

**ExitParms (MQAXP) - input/output**

Exit parameter structure.

**ExitContext (MQAXC) - input/output**

Exit context structure.

**Hconn (MQHCONN) - input**

Connection handle.

**pXID (MQPTR) - input/output**

Transaction branch ID.

**Rmid (MQLONG) - input/output**

Resource manager identifier.

**Flags (MQLONG) - input/output**

Resource manager options.

**XARetCode (MQLONG) - input/output**

Response from XA call.

**C language invocation**

The queue manager logically defines the following variables:

```

MQAXP  ExitParms;    /* Exit parameter structure */
MQAXC  ExitContext; /* Exit context structure */
MQHCONN Hconn;      /* Connection handle */
MQPTR  pXID;        /* Transaction branch ID */
MQLONG Rmid;        /* Resource manager identifier */
MQLONG Flags;       /* Resource manager options */
MQLONG XARetCode;   /* Response from XA call */

```

The queue manager then logically calls the exit as follows:

```
XA_ROLLBACK_EXIT (&ExitParms, &ExitContext, &Hconn, &pXID, &Rmid, &Flags, &XARetCode);
```

Your exit must match the following C function prototype:

```

typedef void MQENTRY XA_ROLLBACK_EXIT (
    PMQAXP  pExitParms, /* Address of exit parameter structure */
    PMQAXC  pExitContext, /* Address of exit context structure */
    PMQHCONN pHconn, /* Address of connection handle */
    PMQPTR  ppXID, /* Address of transaction branch ID */
    PMQLONG pRmid, /* Address of resource manager identifier */
    PMQLONG pFlags, /* Address of resource manager options */
    PMQLONG pXARetCode); /* Address of response from XA call */

```

***xa\_start - XA\_START\_EXIT***

XA\_START\_EXIT provides an `xa_start` exit function to perform before and after `xa_start` processing. Use function identifier `MQXF_XASTART` with exit reasons `MQXR_BEFORE` and `MQXR_AFTER` to register the before and after `xa_start` call exit functions.

The interface to this function is:

```
XA_START_EXIT (&ExitParms, &ExitContext, &Hconn, &pXID, &Rmid, &Flags, &XARetCode)
```

where the parameters are:

**ExitParms (MQAXP) - input/output**

Exit parameter structure.

**ExitContext (MQAXC) - input/output**

Exit context structure.

**Hconn (MQHCONN) - input**

Connection handle.

**pXID (MQPTR) - input/output**

Transaction branch ID.

**Rmid (MQLONG) - input/output**

Resource manager identifier.

**Flags (MQLONG) - input/output**

Resource manager options.

## **XARetCode (MQLONG) - input/output**

Response from XA call.

## **C language invocation**

The queue manager logically defines the following variables:

```
MQAXP  ExitParms;    /* Exit parameter structure */
MQAXC  ExitContext; /* Exit context structure */
MQHCONN Hconn;      /* Connection handle */
MQPTR  pXID;        /* Transaction branch ID */
MQLONG Rmid;        /* Resource manager identifier */
MQLONG Flags;       /* Resource manager options*/
MQLONG XARetCode;   /* Response from XA call */
```

The queue manager then logically calls the exit as follows:

```
XA_START_EXIT (&ExitParms, &ExitContext, &Hconn, &pXID, &Rmid, &Flags, &XARetCode);
```

Your exit must match the following C function prototype:

```
typedef void MQENTRY XA_START_EXIT (
    PMQAXP  pExitParms, /* Address of exit parameter structure */
    PMQAXC  pExitContext, /* Address of exit context structure */
    PMQHCONN pHconn, /* Address of connection handle */
    PMQPTR  ppXID, /* Address of transaction branch ID */
    PMQLONG pRmid, /* Address of resource manager identifier */
    PMQLONG pFlags, /* Address of resource manager options*/
    PMQLONG pXARetCode); /* Address of response from XA call */
```

## **ax\_reg - AX\_REG\_EXIT**

AX\_REG\_EXIT provides an ax\_reg exit function to perform before and after ax\_reg processing. Use function identifier MQXF\_AXREG with exit reasons MQXR\_BEFORE and MQXR\_AFTER to register the before and after ax\_reg call exit functions.

The interface to this function is:

```
AX_REG_EXIT (&ExitParms, &ExitContext, &pXID, &Rmid, &Flags, &XARetCode)
```

where the parameters are:

### **ExitParms (MQAXP) - input/output**

Exit parameter structure.

### **ExitContext (MQAXC) - input/output**

Exit context structure.

### **Hconn (MQHCONN) - input**

Connection handle.

### **pXID (MQPTR) - input/output**

Transaction branch ID.

### **Rmid (MQLONG) - input/output**

Resource manager identifier.

### **Flags (MQLONG) - input/output**

Resource manager options.

### **XARetCode (MQLONG) - input/output**

Response from XA call.

## **C language invocation**

The queue manager logically defines the following variables:

```

MQAXP  ExitParms;    /* Exit parameter structure */
MQAXC  ExitContext; /* Exit context structure */
MQPTR  pXID;        /* Transaction branch ID */
MQLONG Rmid;        /* Resource manager identifier */
MQLONG Flags;       /* Resource manager options*/
MQLONG XARetCode;   /* Response from XA call */

```

The queue manager then logically calls the exit as follows:

```
AX_REG_EXIT (&ExitParms, &ExitContext, &pXID, &Rmid, &Flags, &XARetCode);
```

Your exit must match the following C function prototype:

```

typedef void MQENTRY AX_REG_EXIT (
    PMQAXP pExitParms, /* Address of exit parameter structure */
    PMQAXC pExitContext, /* Address of exit context structure */
    PMQPTR ppXID, /* Address of transaction branch ID */
    PMQLONG pRmid, /* Address of resource manager identifier */
    PMQLONG pFlags, /* Address of resource manager options*/
    PMQLONG pXARetCode); /* Address of response from XA call */

```

### ***ax\_unreg - AX\_UNREG\_EXIT***

AX\_UNREG\_EXIT provides an ax\_unreg exit function to perform before and after ax\_unreg processing. Use function identifier MQXF\_AXUNREG with exit reasons MQXR\_BEFORE and MQXR\_AFTER to register the before and after ax\_unreg call exit functions.

The interface to this function is:

```
AX_UNREG_EXIT (&ExitParms, &ExitContext, &Rmid, &Flags, &XARetCode);
```

where the parameters are:

#### **ExitParms (MQAXP) - input/output**

Exit parameter structure.

#### **ExitContext (MQAXC) - input/output**

Exit context structure.

#### **Rmid (MQLONG) - input/output**

Resource manager identifier.

#### **Flags (MQLONG) - input/output**

Resource manager options.

#### **XARetCode (MQLONG) - input/output**

Response from XA call.

### **C language invocation**

The queue manager logically defines the following variables:

```

MQAXP  ExitParms;    /* Exit parameter structure */
MQAXC  ExitContext; /* Exit context structure */
MQLONG Rmid;        /* Resource manager identifier */
MQLONG Flags;       /* Resource manager options*/
MQLONG XARetCode;   /* Response from XA call */

```

The queue manager then logically calls the exit as follows:

```
AX_UNREG_EXIT (&ExitParms, &ExitContext, &Rmid, &Flags, &XARetCode);
```

Your exit must match the following C function prototype:

```

typedef void MQENTRY AX_UNREG_EXIT (
    PMQAXP pExitParms, /* Address of exit parameter structure */
    PMQAXC pExitContext, /* Address of exit context structure */
    PMQLONG pRmid, /* Address of resource manager identifier */
    PMQLONG pFlags, /* Address of resource manager options */
    PMQLONG pXARetCode); /* Address of response from XA call */

```

## General information on invoking exit functions

This topic provides some general guidance to help you to plan your exits, particularly related to handling errors and unexpected events.

### Exit failure

If an exit function abnormally terminates after a destructive, out of syncpoint, MQGET call but before the message has been passed to the application, the exit handler can recover from the failure, and pass control to the application.

In this case, the message might be lost. This is like what happens when an application fails immediately after receiving a message from a queue.

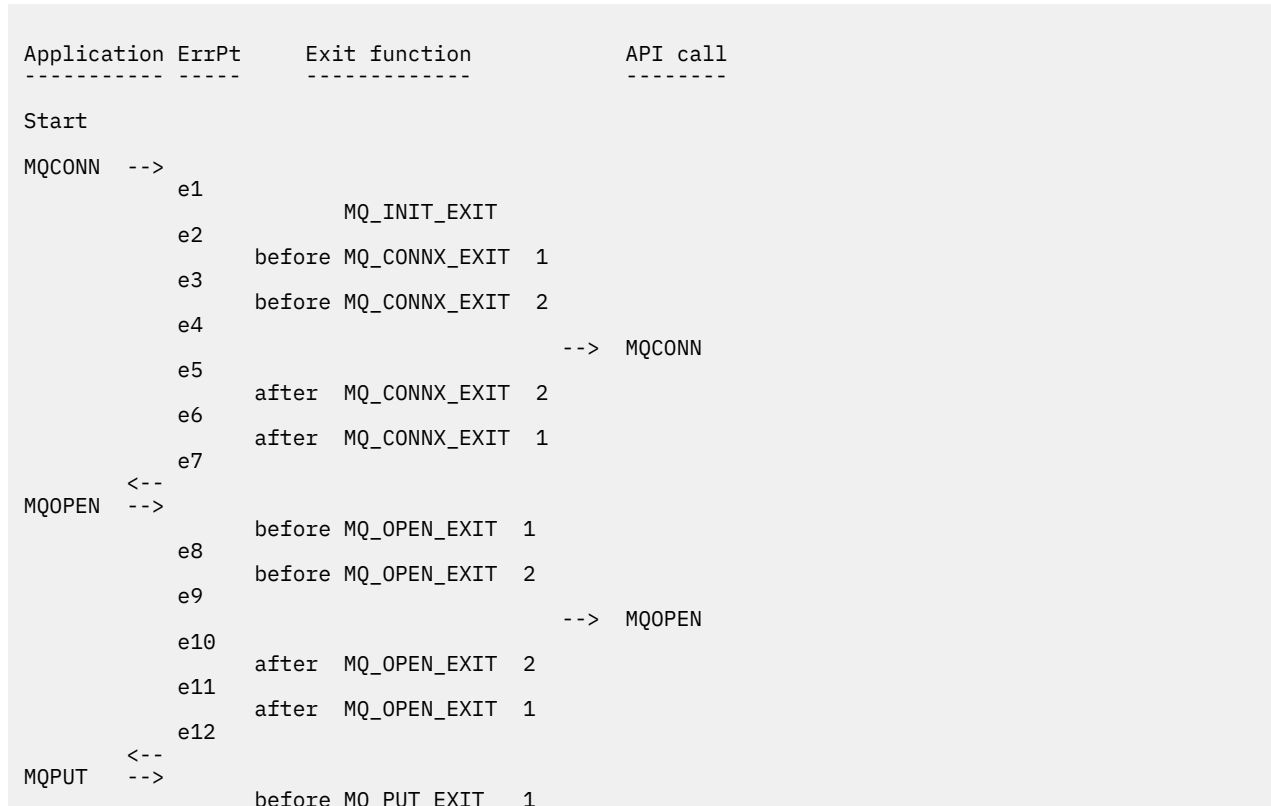

The MQGET call might complete with MQCC\_FAILED and MQRC\_API\_EXIT\_ERROR.

If a *before* API call exit function terminates abnormally, the exit handler can recover from the failure and pass control to the application without processing the API call. In this event, the exit function must recover any resources that it owns.

If chained exits are in use, the *after* API call exits for any *before* API call exits that had successfully been driven can themselves be driven. The API call might fail with MQCC\_FAILED and MQRC\_API\_EXIT\_ERROR.

### Example error handling for exit functions

The following diagram shows the points (e N) at which errors can occur. It is only an example to show how exits behave and should be read together with the following table. In this example, two exit functions are invoked both before and after each API call to show the behavior with chained exits.

```

e13    before MQ_PUT_EXIT  2
e14                                         --> MQPUT
e15    after  MQ_PUT_EXIT  2
e16    after  MQ_PUT_EXIT  1
e17
MQCLOSE <--
      -->
e18    before MQ_CLOSE_EXIT 1
e19    before MQ_CLOSE_EXIT 2
e20                                         --> MQCLOSE
e21    after  MQ_CLOSE_EXIT 2
e22    after  MQ_CLOSE_EXIT 1
e22
MQDISC <--
      -->
e23    before MQ_DISC_EXIT 1
e24    before MQ_DISC_EXIT 2
e25                                         --> MQDISC
e26    after  MQ_DISC_EXIT 2
e27    after  MQ_DISC_EXIT 1
e27
      <--
end

```

The following table lists the actions to be taken at each error point. Only a subset of the error points have been covered, as the rules shown here can apply to all others. It is the actions that specify the intended behavior in each case.

<i>Table 837. API exit errors and appropriate actions to take</i>		
<b>Err Pt</b>	<b>Description</b>	<b>Actions</b>
e1	Error while setting up environment setup.	<ol style="list-style-type: none"> <li>1. Undo environment setup as required</li> <li>2. Drive no exit functions</li> <li>3. Fail MQCONN with MQCC_FAILED, MQRC_API_EXIT_LOAD_ERROR</li> </ol>
e2	MQ_INIT_EXIT function completes with: <ul style="list-style-type: none"> <li>• MQXCC_FAILED</li> <li>• MQXCC_*</li> </ul>	<ul style="list-style-type: none"> <li>• For MQXCC_FAILED:               <ol style="list-style-type: none"> <li>1. Clean up environment</li> <li>2. Fail MQCONN with MQCC_FAILED, MQRC_API_EXIT_INIT_ERROR</li> </ol> </li> <li>• For MQXCC_*               <ol style="list-style-type: none"> <li>1. Act as for the values of MQXCC_* and MQXR2_*<sup>1</sup></li> <li>2. Clean up environment</li> </ol> </li> </ul>

Table 837. API exit errors and appropriate actions to take (continued)

Err Pt	Description	Actions
e3	<p>Before MQ_CONNX_EXIT 1 function completes with:</p> <ul style="list-style-type: none"> <li>• MQXCC_FAILED</li> <li>• MQXCC_*</li> </ul>	<ul style="list-style-type: none"> <li>• For MQXCC_FAILED:               <ol style="list-style-type: none"> <li>1. Drive <i>after</i> MQ_DISC_EXIT 1 function</li> <li>2. Drive MQ_TERM_EXIT function</li> <li>3. Clean up exit execution environment</li> <li>4. Complete MQDISC call with MQCC_FAILED, MQRC_API_EXIT_ERROR</li> </ol> </li> <li>• For MQXCC_*               <ol style="list-style-type: none"> <li>1. Act as for the values of MQXCC_* and MQXR2_*<sup>1</sup></li> <li>2. Drive MQ_TERM_EXIT function</li> <li>3. Clean up exit execution environment</li> </ol> </li> </ul>

**Note:**

1. The values of MQXCC\_\* and MQXR2\_\* and their corresponding actions are defined in How queue managers process exit functions.

## ***ExitResponse fields set incorrectly***

This topic gives information about what would happen when the ExitResponse field is set to anything but the supported values.

If the ExitResponse field is set to a value other than one of the supported values, the following actions apply:

- For a *before* MQCONN or MQDISC API exit function:
  - The ExitResponse2 value is ignored.
  - No further *before* exit functions in the exit chain (if any) are invoked; the API call itself is not issued.
  - For any *before* exits that were successfully called, the *after* exits are called in reverse order.
  - If registered, the termination exit functions for those *before* MQCONN or MQDISC exit functions in the chain that were successfully invoked are driven to clean up after these exit functions.
  - The MQCONN or MQDISC call fails with MQRC\_API\_EXIT\_ERROR.
- For a *before* IBM MQ API exit function other than MQCONN or MQDISC:
  - The ExitResponse2 value is ignored.
  - No further *before* or *after* data conversion functions in the exit chain (if any) are invoked.
  - For any *before* exits that were successfully called, the *after* exits are called in reverse order.
  - The IBM MQ API call itself is not issued.
  - The IBM MQ API call fails with MQRC\_API\_EXIT\_ERROR.
- For an *after* MQCONN or MQDISC API exit function:
  - The ExitResponse2 value is ignored.
  - The remaining exit functions that were successfully called before the API call are called in reverse order.
  - If registered, the termination exit functions for those *before* or *after* MQCONN or MQDISC exit functions in the chain that were successfully invoked are driven to clean up after the exit.
  - A CompCode of the more severe of MQCC\_WARNING and the CompCode returned by the exit is returned to the application.
  - A Reason of MQRC\_API\_EXIT\_ERROR is returned to the application.
  - The IBM MQ API call is successfully issued.
- For an *after* IBM MQ API call exit function other than MQCONN or MQDISC:
  - The ExitResponse2 value is ignored.
  - The remaining exit functions that were successfully called before the API call are called in reverse order.
  - A CompCode of the more severe of MQCC\_WARNING and the CompCode returned by the exit is returned to the application.
  - A Reason of MQRC\_API\_EXIT\_ERROR is returned to the application.
  - The IBM MQ API call is successfully issued.
- For the *before* data conversion on get exit function:
  - The ExitResponse2 value is ignored.
  - The remaining exit functions that were successfully called before the API call are called in reverse order.
  - The message is not converted, and the unconverted message is returned to the application.
  - A CompCode of the more severe of MQCC\_WARNING and the CompCode returned by the exit is returned to the application.
  - A Reason of MQRC\_API\_EXIT\_ERROR is returned to the application.
  - The IBM MQ API call is successfully issued.

**Note:** As the error is with the exit, it is better to return MQRC\_API\_EXIT\_ERROR than to return MQRC\_NOT\_CONVERTED.

If an exit function sets the ExitResponse2 field to a value other than one of the supported values, a value of MQXR2\_DEFAULT\_CONTINUATION is assumed instead.

## Installable services interface reference information

This collection of topics provides reference information for the installable services.

The functions and data types are listed in alphabetical order within the group for each service type.

## How the functions are shown

How the installable services functions are documented.

For each function there is a description, including the function identifier (for MQZEP).

The *parameters* are shown listed in the order they must occur. They must all be present.

Each parameter name is followed by its data type. These are the elementary data types described in the “Elementary data types” on page 235.

The C language invocation is also given, after the description of the parameters.

## MQZ\_AUTHENTICATE\_USER - Authenticate user

This function is provided by an MQZAS\_VERSION\_5 authorization service component, and is invoked by the queue manager to authenticate a user, or to set identity context fields. It is invoked when the IBM MQ user application context is established.

The application context is established during connect calls at the point where the application's user context is initialized, and at each point where the application's user context is changed. Each time a connect call is made, the application's user context information is reacquired in the *IdentityContext* field.

The function identifier for this function (for MQZEP) is MQZID\_AUTHENTICATE\_USER.

### Syntax

MQZ\_AUTHENTICATE\_USER ( *QMgrName* , *SecurityParms* , *ApplicationContext* , *IdentityContext* , *CorrelationPtr* , *ComponentData* , *Continuation* , *CompCode* , *Reason* )

### Parameters

#### QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

## SecurityParms

Type: MQCSP - input

Security parameters. Data relating to the user ID, password, and authentication type. If the AuthenticationType attribute of the MQCSP structure is specified as MQCSP\_AUTH\_USER\_ID\_AND\_PWD, both the user ID and password are compared against the equivalent fields in the IdentityContext (MQZIC) parameter to determine whether they match. For more information, see [“MQCSP - Security parameters” on page 335](#).

During an MQCONN MQI call this parameter contains null, or default values.

## ApplicationContext

Type: MQZAC - input

Application context. Data relating to the calling application. See [MQZAC - Application context](#) for details.

During every MQCONN or MQCONNX MQI call, the user context information in the MQZAC structure is reacquired.

## IdentityContext

Type: MQZIC - input/output

Identity context. On input to the authenticate user function, this identifies the current identity context. The authenticate user function can change this, at which point the queue manager adopts the new identity context. See [MQZIC - Identity context](#) for more details on the MQZIC structure.

## CorrelationPtr

Type: MQPTR - output

Correlation pointer. Specifies the address of any correlation data. This pointer is subsequently passed on to other OAM calls.

## ComponentData

Type: MQBYTE x ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of this component's functions is called.

The length of this data area is passed by the queue manager in the ComponentDataLength parameter of the MQZ\_INIT\_AUTHORITY call.

## Continuation

Type: MQLONG - output

Continuation flag. You can specify the following values:

### MQZCI\_DEFAULT

Continuation dependent on other components.

### MQZCI\_STOP

Do not continue with next component.

## CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

### MQCC\_OK

Successful completion.

### MQCC\_FAILED

Call failed.

## Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

**MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

**MQRC\_SERVICE\_ERROR**

(2289, X'8F1') Unexpected error occurred accessing service.

For more information about these reason codes, see [Messages and reason codes](#).

## C invocation

```
MQZ_AUTHENTICATE_USER (QMgrName, SecurityParms, ApplicationContext,  
                      IdentityContext, &CorrelationPtr, ComponentData,  
                      &Continuation, &CompCode, &Reason);
```

Declare the parameters passed to the service as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */  
MQCSP     SecurityParms;      /* Security parameters */  
MQZAC     ApplicationContext; /* Application context */  
MQZIC     IdentityContext;    /* Identity context */  
MQPTR     CorrelationPtr;     /* Correlation pointer */  
MQBYTE    ComponentData[n];  /* Component data */  
MQLONG    Continuation;      /* Continuation indicator set by  
                             component */  
MQLONG    CompCode;          /* Completion code */  
MQLONG    Reason;           /* Reason code qualifying CompCode */
```

## MQZ\_CHECK\_AUTHORITY - Check authority

This function is provided by a MQZAS\_VERSION\_1 authorization service component, and is started by the queue manager to check whether an entity has authority to perform a particular action, or actions, on a specified object.

The function identifier for this function (for MQZEP) is MQZID\_CHECK\_AUTHORITY.

### Syntax

```
MQZ_CHECK_AUTHORITY( QMgrName , EntityName , EntityType , ObjectName ,  
ObjectType , Authority , ComponentData , Continuation , CompCode , Reason )
```

### Parameters

#### QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

#### EntityName

Type: MQCHAR12 - input

Entity name. The name of the entity whose authorization to the object is to be checked. The maximum length of the string is 12 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

It is not essential for this entity to be known to the underlying security service. If it is not known, the authorizations of the special **nobody** group (to which all entities are assumed to belong) are used for the check. An all-blank name is valid and can be used in this way.

**EntityType**

Type: MQLONG - input

Entity type. The type of entity specified by *EntityName*. It must be one of the following values:

**MQZAET\_PRINCIPAL**

Principal.

**MQZAET\_GROUP**

Group.

**ObjectName**

Type: MQCHAR48 - input

Object name. The name of the object to which access is required. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

If *ObjectType* is MQOT\_Q\_MGR, this name is the same as *QMgrName*.

**ObjectType**

Type: MQLONG - input

Object type. The type of entity specified by *ObjectName*. It must be one of the following values:

**MQOT\_AUTH\_INFO**

Authentication information.

**MQOT\_CHANNEL**

Channel.

**MQOT\_CLNTCONN\_CHANNEL**

Client connection channel.

**MQOT\_LISTENER**

Listener.

**MQOT\_NAMELIST**

Namelist.

**MQOT\_PROCESS**

Process definition.

**MQOT\_Q**

Queue.

**MQOT\_Q\_MGR**

Queue manager.

**MQOT\_SERVICE**

Service.

**Authority**

Type: MQLONG - input

Authority to be checked. If one authorization is being checked, this field is equal to the appropriate authorization operation (MQZAO\_\* constant). If more than one authorization is being checked, it is the bitwise OR of the corresponding MQZAO\_\* constants.

The following authorizations apply to use of the MQI calls:

**MQZAO\_CONNECT**

Ability to use the MQCONN call.

**MQZAO\_BROWSE**

Ability to use the MQGET call with a browse option.

This allows the MQGMO\_BROWSE\_FIRST, MQGMO\_BROWSE\_MSG\_UNDER\_CURSOR, or MQGMO\_BROWSE\_NEXT option to be specified on the MQGET call.

**MQZAO\_INPUT**

Principal. Ability to use the MQGET call with an input option.

This allows the MQOO\_INPUT\_SHARED, MQOO\_INPUT\_EXCLUSIVE, or MQOO\_INPUT\_AS\_Q\_DEF option to be specified on the MQOPEN call.

**MQZAO\_OUTPUT**

Ability to use the MQPUT call.

This allows the MQOO\_OUTPUT option to be specified on the MQOPEN call.

**MQZAO\_INQUIRE**

Ability to use the MQINQ call.

This allows the MQOO\_INQUIRE option to be specified on the MQOPEN call.

**MQZAO\_SET**

Ability to use the MQSET call.

This allows the MQOO\_SET option to be specified on the MQOPEN call.

**MQZAO\_PASS\_IDENTITY\_CONTEXT**

Ability to pass identity context.

This allows the MQOO\_PASS\_IDENTITY\_CONTEXT option to be specified on the MQOPEN call, and the MQPMO\_PASS\_IDENTITY\_CONTEXT option to be specified on the MQPUT and MQPUT1 calls.

**MQZAO\_PASS\_ALL\_CONTEXT**

Ability to pass all context.

This allows the MQOO\_PASS\_ALL\_CONTEXT option to be specified on the MQOPEN call, and the MQPMO\_PASS\_ALL\_CONTEXT option to be specified on the MQPUT and MQPUT1 calls.

**MQZAO\_SET\_IDENTITY\_CONTEXT**

Ability to set identity context.

This allows the MQOO\_SET\_IDENTITY\_CONTEXT option to be specified on the MQOPEN call, and the MQPMO\_SET\_IDENTITY\_CONTEXT option to be specified on the MQPUT and MQPUT1 calls.

**MQZAO\_SET\_ALL\_CONTEXT**

Ability to set all context.

This allows the MQOO\_SET\_ALL\_CONTEXT option to be specified on the MQOPEN call, and the MQPMO\_SET\_ALL\_CONTEXT option to be specified on the MQPUT and MQPUT1 calls.

**MQZAO\_ALTERNATE\_USER\_AUTHORITY**

Ability to use alternate user authority.

This allows the MQOO\_ALTERNATE\_USER\_AUTHORITY option to be specified on the MQOPEN call, and the MQPMO\_ALTERNATE\_USER\_AUTHORITY option to be specified on the MQPUT1 call.

**MQZAO\_ALL\_MQI**

All of the MQI authorizations.

This enables all of the authorizations.

The following authorizations apply to administration of a queue manager:

**MQZAO\_CREATE**

Ability to create objects of a specified type.

**MQZAO\_DELETE**

Ability to delete a specified object.

**MQZAO\_DISPLAY**

Ability to display the attributes of a specified object.

**MQZAO\_CHANGE**

Ability to change the attributes of a specified object.

**MQZAO\_CLEAR**

Ability to delete all messages from a specified queue.

**MQZAO\_AUTHORIZE**

Ability to authorize other users for a specified object.

**MQZAO\_CONTROL**

Ability to start or stop a listener, service, or non-client channel object, and the ability to ping a non-client channel object.

**MQZAO\_CONTROL\_EXTENDED**

Ability to reset a sequence number, or resolve an indoubt message on a non-client channel object.

**MQZAO\_ALL\_ADMIN**

Ability to set identity context.

All of the administration authorizations, other than MQZAO\_CREATE.

The following authorizations apply to both use of the MQI and to administration of a queue manager:

**MQZAO\_ALL**

All authorizations, other than MQZAO\_CREATE.

**MQZAO\_NONE**

No authorizations.

**ComponentData**

Type: MQBYTE x ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the **ComponentDataLength** parameter of the MQZ\_INIT\_AUTHORITY call.

**Continuation**

Type: MQLONG - output

Continuation indicator set by component. The following values can be specified:

**MQZCI\_DEFAULT**

Continuation dependent on queue manager.

For MQZ\_CHECK\_AUTHORITY, this has the same effect as MQZCI\_STOP.

**MQZCI\_CONTINUE**

Continue with next component.

**MQZCI\_STOP**

Do not continue with next component.

If the call to a component fails (that is, *CompCode* returns MQCC\_FAILED), and the *Continuation* parameter is MQZCI\_DEFAULT or MQZCI\_CONTINUE, the queue manager continues to call other components if there are any.

If the call succeeds (that is, *CompCode* returns MQCC\_OK) no other components are called no matter what the setting of *Continuation* is.

If the call fails and the *Continuation* parameter is MQZCI\_STOP then no other components are called and the error is returned to the queue manager. Components have no knowledge of previous calls, so the *Continuation* parameter is always set to MQZCI\_DEFAULT before the call.

**CompCode**

Type: MQLONG - output

Completion code. It must be one of the following values:

**MQCC\_OK**

Successful completion.

## **MQCC\_FAILED**

Call failed.

### **Reason**

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

### **MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

### **MQRC\_NOT\_AUTHORIZED**

(2035, X'7F3') Not authorized for access.

### **MQRC\_SERVICE\_ERROR**

(2289, X'8F1') Unexpected error occurred accessing service.

### **MQRC\_SERVICE\_NOT\_AVAILABLE**

(2285, X'8ED') Underlying service not available.

For more information about these reason codes, see [API completion and reason codes](#).

## **C invocation**

```
MQZ_CHECK_AUTHORITY (QMgrName, EntityName, EntityType, ObjectName,  
                    ObjectType, Authority, ComponentData,  
                    &Continuation, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */  
MQCHAR12  EntityName;        /* Entity name */  
MQLONG    EntityType;        /* Entity type */  
MQCHAR48  ObjectName;        /* Object name */  
MQLONG    ObjectType;        /* Object type */  
MQLONG    Authority;         /* Authority to be checked */  
MQBYTE    ComponentData[n]; /* Component data */  
MQLONG    Continuation;      /* Continuation indicator set by  
                             component */  
MQLONG    CompCode;          /* Completion code */  
MQLONG    Reason;           /* Reason code qualifying CompCode */
```

## **MQZ\_CHECK\_AUTHORITY\_2 - Check authority (extended)**

This function is provided by a MQZAS\_VERSION\_2 authorization service component, and is started by the queue manager to check whether an entity has authority to perform a particular action, or actions, on a specified object.

The function identifier for this function (for MQZEP) is MQZID\_CHECK\_AUTHORITY.

MQZ\_CHECK\_AUTHORITY\_2 is like MQZ\_CHECK\_AUTHORITY, but with the **EntityName** parameter replaced by the **EntityData** parameter.

### **Syntax**

```
MQZ_CHECK_AUTHORITY_2( QMgrName , EntityData , EntityType , ObjectName ,  
ObjectType , Authority , ComponentData , Continuation , CompCode , Reason )
```

### **Parameters**

#### **QMgrName**

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

### **EntityData**

Type: MQZED - input

Entity data. Data relating to the entity with authorization to the object that is to be checked. See [“MQZED - Entity descriptor” on page 1675](#) for details.

It is not essential for this entity to be known to the underlying security service. If it is not known, the authorizations of the special **nobody** group (to which all entities are assumed to belong) are used for the check. An all-blank name is valid and can be used in this way.

### **EntityType**

Type: MQLONG - input

Entity type. The type of entity specified by *EntityData*. It must be one of the following values:

#### **MQZAET\_PRINCIPAL**

Principal.

#### **MQZAET\_GROUP**

Group.

### **ObjectName**

Type: MQCHAR48 - input

Object name. The name of the object to which access is required. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

If *ObjectType* is MQOT\_Q\_MGR, this name is the same as *QMgrName*.

### **ObjectType**

Type: MQLONG - input

Object type. The type of entity specified by *ObjectName*. It must be one of the following values:

#### **MQOT\_AUTH\_INFO**

Authentication information.

#### **MQOT\_CHANNEL**

Channel.

#### **MQOT\_CLNTCONN\_CHANNEL**

Client connection channel.

#### **MQOT\_LISTENER**

Listener.

#### **MQOT\_NAMELIST**

Namelist.

#### **MQOT\_PROCESS**

Process definition.

#### **MQOT\_Q**

Queue.

#### **MQOT\_Q\_MGR**

Queue manager.

#### **MQOT\_SERVICE**

Service.

#### **MQOT\_TOPIC**

Topic.

## Authority

Type: MQLONG - input

Authority to be checked. If one authorization is being checked, this field is equal to the appropriate authorization operation (MQZAO\_\* constant). If more than one authorization is being checked, it is the bitwise OR of the corresponding MQZAO\_\* constants.

The following authorizations apply to use of the MQI calls:

### **MQZAO\_CONNECT**

Ability to use the MQCONN call.

### **MQZAO\_BROWSE**

Ability to use the MQGET call with a browse option.

This allows the MQGMO\_BROWSE\_FIRST, MQGMO\_BROWSE\_MSG\_UNDER\_CURSOR, or MQGMO\_BROWSE\_NEXT option to be specified on the MQGET call.

### **MQZAO\_INPUT**

Principal. Ability to use the MQGET call with an input option.

This allows the MQOO\_INPUT\_SHARED, MQOO\_INPUT\_EXCLUSIVE, or MQOO\_INPUT\_AS\_Q\_DEF option to be specified on the MQOPEN call.

### **MQZAO\_OUTPUT**

Ability to use the MQPUT call.

This allows the MQOO\_OUTPUT option to be specified on the MQOPEN call.

### **MQZAO\_INQUIRE**

Ability to use the MQINQ call.

This allows the MQOO\_INQUIRE option to be specified on the MQOPEN call.

### **MQZAO\_SET**

Ability to use the MQSET call.

This allows the MQOO\_SET option to be specified on the MQOPEN call.

### **MQZAO\_PASS\_IDENTITY\_CONTEXT**

Ability to pass identity context.

This allows the MQOO\_PASS\_IDENTITY\_CONTEXT option to be specified on the MQOPEN call, and the MQPMO\_PASS\_IDENTITY\_CONTEXT option to be specified on the MQPUT and MQPUT1 calls.

### **MQZAO\_PASS\_ALL\_CONTEXT**

Ability to pass all context.

This allows the MQOO\_PASS\_ALL\_CONTEXT option to be specified on the MQOPEN call, and the MQPMO\_PASS\_ALL\_CONTEXT option to be specified on the MQPUT and MQPUT1 calls.

### **MQZAO\_SET\_IDENTITY\_CONTEXT**

Ability to set identity context.

This allows the MQOO\_SET\_IDENTITY\_CONTEXT option to be specified on the MQOPEN call, and the MQPMO\_SET\_IDENTITY\_CONTEXT option to be specified on the MQPUT and MQPUT1 calls.

### **MQZAO\_SET\_ALL\_CONTEXT**

Ability to set all context.

This allows the MQOO\_SET\_ALL\_CONTEXT option to be specified on the MQOPEN call, and the MQPMO\_SET\_ALL\_CONTEXT option to be specified on the MQPUT and MQPUT1 calls.

### **MQZAO\_ALTERNATE\_USER\_AUTHORITY**

Ability to use alternate user authority.

This allows the MQOO\_ALTERNATE\_USER\_AUTHORITY option to be specified on the MQOPEN call, and the MQPMO\_ALTERNATE\_USER\_AUTHORITY option to be specified on the MQPUT1 call.

**MQZAO\_ALL\_MQI**

All of the MQI authorizations.

This enables all of the authorizations.

The following authorizations apply to administration of a queue manager:

**MQZAO\_CREATE**

Ability to create objects of a specified type.

**MQZAO\_DELETE**

Ability to delete a specified object.

**MQZAO\_DISPLAY**

Ability to display the attributes of a specified object.

**MQZAO\_CHANGE**

Ability to change the attributes of a specified object.

**MQZAO\_CLEAR**

Ability to delete all messages from a specified queue.

**MQZAO\_AUTHORIZE**

Ability to authorize other users for a specified object.

**MQZAO\_CONTROL**

Ability to start or stop a listener, service, or non-client channel object, and the ability to ping a non-client channel object.

**MQZAO\_CONTROL\_EXTENDED**

Ability to reset a sequence number, or resolve an indoubt message on a non-client channel object.

**MQZAO\_ALL\_ADMIN**

Ability to set identity context.

All of the administration authorizations, other than MQZAO\_CREATE.

The following authorizations apply to both use of the MQI and to administration of a queue manager:

**MQZAO\_ALL**

All authorizations, other than MQZAO\_CREATE.

**MQZAO\_NONE**

No authorizations.

**ComponentData**

Type: MQBYTE x ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the **ComponentDataLength** parameter of the MQZ\_INIT\_AUTHORITY call.

**Continuation**

Type: MQLONG - output

Continuation indicator set by component. The following values can be specified:

**MQZCI\_DEFAULT**

Continuation dependent on queue manager.

For MQZ\_CHECK\_AUTHORITY, this has the same effect as MQZCI\_STOP.

**MQZCI\_CONTINUE**

Continue with next component.

**MQZCI\_STOP**

Do not continue with next component.

## CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

### MQCC\_OK

Successful completion.

### MQCC\_FAILED

Call failed.

## Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

### MQRC\_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

### MQRC\_NOT\_AUTHORIZED

(2035, X'7F3') Not authorized for access.

### MQRC\_SERVICE\_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

### MQRC\_SERVICE\_NOT\_AVAILABLE

(2285, X'8ED') Underlying service not available.

For more information about these reason codes, see [API completion and reason codes](#).

## C invocation

```
MQZ_CHECK_AUTHORITY_2 (QMgrName, &EntityData, EntityType,  
                        ObjectName, ObjectType, Authority, ComponentData,  
                        &Continuation, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */  
MQZED     EntityData;        /* Entity data */  
MQLONG    EntityType;        /* Entity type */  
MQCHAR48  ObjectName;        /* Object name */  
MQLONG    ObjectType;        /* Object type */  
MQLONG    Authority;         /* Authority to be checked */  
MQBYTE    ComponentData[n]; /* Component data */  
MQLONG    Continuation;      /* Continuation indicator set by  
                             component */  
MQLONG    CompCode;          /* Completion code */  
MQLONG    Reason;           /* Reason code qualifying CompCode */
```

## MQZ\_CHECK\_PRIVILEGED - Check if user is privileged

This function is provided by an MQZAS\_VERSION\_6 authorization service component, and is invoked by the queue manager to determine whether a specified user is a privileged user.

The function identifier for this function (for MQZEP) is MQZID\_CHECK\_PRIVILEGED.

## Syntax

```
MQZ_CHECK_PRIVILEGED( QMgrName , EntityData , EntityType , ComponentData ,  
Continuation , CompCode , Reason )
```

## Parameters

### QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

### EntityData

Type: MQZED - input

Entity data. Data relating to the entity that is to be checked. For more information, see [“MQZED - Entity descriptor” on page 1675](#).

### EntityType

Type: MQLONG - input

Entity type. The type of entity specified by EntityData. It must be one of the following values:

#### **MQZAET\_PRINCIPAL**

Principal.

#### **MQZAET\_GROUP**

Group.

### ComponentData

Type: MQBYTEExComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the **ComponentDataLength** parameter of the MQZ\_INIT\_AUTHORITY call.

### Continuation

Type: MQLONG - output

Continuation indicator set by component. The following values can be specified:

#### **MQZCI\_DEFAULT**

Continuation dependent on queue manager.

For MQZ\_CHECK\_AUTHORITY, this has the same effect as MQZCI\_STOP.

#### **MQZCI\_CONTINUE**

Continue with next component.

#### **MQZCI\_STOP**

Do not continue with next component.

If the call to a component fails (that is, *CompCode* returns MQCC\_FAILED), and the *Continuation* parameter is MQZCI\_DEFAULT or MQZCI\_CONTINUE, the queue manager continues to call other components if there are any.

If the call succeeds (that is, *CompCode* returns MQCC\_OK) no other components are called no matter what the setting of *Continuation* is.

If the call fails and the *Continuation* parameter is MQZCI\_STOP then no other components are called and the error is returned to the queue manager. Components have no knowledge of previous calls, so the *Continuation* parameter is always set to MQZCI\_DEFAULT before the call.

### CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

**MQCC\_OK**

Successful completion.

**MQCC\_FAILED**

Call failed.

**Reason**

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

**MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

**MQRC\_NOT\_PRIVILEGED**

(2584, X'A18') This user is not a privileged user ID.

**MQRC\_UNKNOWN\_ENTITY**

(2292, X'8F4') Entity unknown to service.

**MQRC\_SERVICE\_ERROR**

(2289, X'8F1') Unexpected error occurred accessing service.

**MQRC\_SERVICE\_NOT\_AVAILABLE**

(2285, X'8ED') Underlying service not available.

For more information about these reason codes, see [API completion and reason codes](#).

**C invocation**

```
MQZ_CHECK_PRIVILEGED (QMgrName, &EntityData, EntityType,
                    ComponentData, &Continuation,
                    &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */
MQZED     EntityData;        /* Entity name */
MQLONG    EntityType;        /* Entity type */
MQBYTE    ComponentData[n]; /* Component data */
MQLONG    Continuation;      /* Continuation indicator set by
                             component */
MQLONG    CompCode;          /* Completion code */
MQLONG    Reason;            /* Reason code qualifying CompCode */
```

**MQZ\_COPY\_ALL\_AUTHORITY - Copy all authority**

This function is provided by an authorization service component. It is started by the queue manager to copy all of the authorizations that are currently in force for a reference object to another object.

The function identifier for this function (for MQZEP) is MQZID\_COPY\_ALL\_AUTHORITY.

**Syntax**

```
MQZ_COPY_ALL_AUTHORITY( QMgrName , RefObjectName , ObjectName , ObjectType ,
                        ComponentData , Continuation , CompCode , Reason )
```

**Parameters****QMgrName**

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

### **RefObjectName**

Type: MQCHAR48 - input

Reference object name. The name of the reference object, the authorizations for which are to be copied. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

### **ObjectName**

Type: MQCHAR48 - input

Object name. The name of the object for which accesses are to be set. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

### **ObjectType**

Type: MQLONG - input

Object type. The type of entity specified by *RefObjectName* and *ObjectName*. It must be one of the following values:

#### **MQOT\_AUTH\_INFO**

Authentication information.

#### **MQOT\_CHANNEL**

Channel.

#### **MQOT\_CLNTCONN\_CHANNEL**

Client connection channel.

#### **MQOT\_LISTENER**

Listener.

#### **MQOT\_NAMELIST**

Namelist.

#### **MQOT\_PROCESS**

Process definition.

#### **MQOT\_Q**

Queue.

#### **MQOT\_Q\_MGR**

Queue manager.

#### **MQOT\_SERVICE**

Service.

#### **MQOT\_TOPIC**

Topic.

### **ComponentData**

Type: MQBYTEExComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the ComponentDataLength parameter of the MQZ\_INIT\_AUTHORITY call.

### **Continuation**

Type: MQLONG - output

Continuation indicator set by component. The following values can be specified:

**MQZCI\_DEFAULT**

Continuation dependent on queue manager.

For MQZ\_CHECK\_AUTHORITY, this has the same effect as MQZCI\_STOP.

**MQZCI\_CONTINUE**

Continue with next component.

**MQZCI\_STOP**

Do not continue with next component.

**CompCode**

Type: MQLONG - output

Completion code. It must be one of the following values:

**MQCC\_OK**

Successful completion.

**MQCC\_FAILED**

Call failed.

**Reason**

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

**MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

**MQRC\_SERVICE\_ERROR**

(2289, X'8F1') Unexpected error occurred accessing service.

**MQRC\_SERVICE\_NOT\_AVAILABLE**

(2285, X'8ED') Underlying service not available.

**MQRC\_UNKNOWN\_REF\_OBJECT**

(2294, X'8F6') Reference object unknown.

For more information about these reason codes, see [API completion and reason codes](#).

**C invocation**

```
MQZ_COPY_ALL_AUTHORITY (QMgrName, RefObjectName, ObjectName, ObjectType,
                        ComponentData, &Continuation, &CompCode,
                        &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48 QMgrName;           /* Queue manager name */
MQCHAR48 RefObjectName;      /* Reference object name */
MQCHAR48 ObjectName;        /* Object name */
MQLONG   ObjectType;        /* Object type */
MQBYTE   ComponentData[n]; /* Component data */
MQLONG   Continuation;      /* Continuation indicator set by
                             component */
MQLONG   CompCode;         /* Completion code */
MQLONG   Reason;          /* Reason code qualifying CompCode */
```

**MQZ\_DELETE\_AUTHORITY - Delete authority**

This function is provided by an authorization service component, and is started by the queue manager to delete all of the authorizations associated with the specified object.

The function identifier for this function (for MQZEP) is MQZID\_DELETE\_AUTHORITY.

## Syntax

`MQZ_DELETE_AUTHORITY( QMgrName , ObjectName , ObjectType , ComponentData , Continuation , CompCode , Reason )`

## Parameters

### QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

### ObjectName

Type: MQCHAR48 - input

Object name. The name of the object for which accesses are to be deleted. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

If *ObjectType* is MQOT\_Q\_MGR, this name is the same as *QMgrName*.

### ObjectType

Type: MQLONG - input

Object type. The type of entity specified by *ObjectName*. It must be one of the following values:

#### **MQOT\_AUTH\_INFO**

Authentication information.

#### **MQOT\_CHANNEL**

Channel.

#### **MQOT\_CLNTCONN\_CHANNEL**

Client connection channel.

#### **MQOT\_LISTENER**

Listener.

#### **MQOT\_NAMELIST**

Namelist.

#### **MQOT\_PROCESS**

Process definition.

#### **MQOT\_Q**

Queue.

#### **MQOT\_Q\_MGR**

Queue manager.

#### **MQOT\_SERVICE**

Service.

#### **MQOT\_TOPIC**

Topic.

### ComponentData

Type: MQBYTE x ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the ComponentDataLength parameter of the MQZ\_INIT\_AUTHORITY call.

## Continuation

Type: MQLONG - output

Continuation indicator set by component. The following values can be specified:

### **MQZCI\_DEFAULT**

Continuation dependent on queue manager.

For MQZ\_CHECK\_AUTHORITY, this has the same effect as MQZCI\_STOP.

### **MQZCI\_CONTINUE**

Continue with next component.

### **MQZCI\_STOP**

Do not continue with next component.

## CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

### **MQCC\_OK**

Successful completion.

### **MQCC\_FAILED**

Call failed.

## Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

### **MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

### **MQRC\_SERVICE\_ERROR**

(2289, X'8F1') Unexpected error occurred accessing service.

### **MQRC\_SERVICE\_NOT\_AVAILABLE**

(2285, X'8ED') Underlying service not available.

For more information about these reason codes, see [API completion and reason codes](#).

## C invocation

```
MQZ_DELETE_AUTHORITY (QMgrName, ObjectName, ObjectType, ComponentData,  
&Continuation, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48 QMgrName;          /* Queue manager name */  
MQCHAR48 ObjectName;       /* Object name */  
MQLONG   ObjectType;       /* Object type */  
MQBYTE   ComponentData[n]; /* Component data */  
MQLONG   Continuation;     /* Continuation indicator set by  
                           component */  
MQLONG   CompCode;         /* Completion code */  
MQLONG   Reason;          /* Reason code qualifying CompCode */
```

## MQZ\_ENUMERATE\_AUTHORITY\_DATA - Enumerate authority data

This function is provided by an MQZAS\_VERSION\_4 authorization service component, and is started repeatedly by the queue manager to retrieve all of the authority data that matches the selection criteria specified on the first invocation.

The function identifier for this function (for MQZEP) is MQZID\_ENUMERATE\_AUTHORITY\_DATA.

### Syntax

```
MQZ_ENUMERATE_AUTHORITY_DATA( QMgrName , StartEnumeration , Filter ,  
AuthorityBufferLength , AuthorityBuffer , AuthorityDataLength , ComponentData ,  
Continuation , CompCode , Reason )
```

### Parameters

#### QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

#### StartEnumeration

Type: MQLONG - input

Flag indicating whether call can start enumeration. This indicates whether the call can start the enumeration of authority data, or continue the enumeration of authority data started by a previous call to MQZ\_ENUMERATE\_AUTHORITY\_DATA. The value is one of the following values:

##### MQZSE\_START

Start enumeration. The call is started with this value to start the enumeration of authority data. The **Filter** parameter specifies the selection criteria to be used to select the authority data returned by this and successive calls.

##### MQZSE\_CONTINUE

Continue enumeration. The call is started with this value to continue the enumeration of authority data. The **Filter** parameter is ignored in this case, and can be specified as the null pointer (the selection criteria are determined by the **Filter** parameter specified by the call that had *StartEnumeration* set to MQZSE\_START).

#### Filter

Type: MQZAD - input

Filter. If *StartEnumeration* is MQZSE\_START, *Filter* specifies the selection criteria to be used to select the authority data to return. If *Filter* is the null pointer, no selection criteria are used, that is, all authority data is returned. See [“MQZAD - Authority data” on page 1672](#) for details of the selection criteria that can be used.

If *StartEnumeration* is MQZSE\_CONTINUE, *Filter* is ignored, and can be specified as the null pointer.

#### AuthorityBufferLength

Type: MQLONG - input

Length of *AuthorityBuffer*. This is the length in bytes of the **AuthorityBuffer** parameter. The authority buffer must be large enough to accommodate the data to be returned.

#### AuthorityBuffer

Type: MQZAD - output

Authority data. This is the buffer in which the authority data is returned. The buffer must be large enough to accommodate an MQZAD structure, an MQZED structure, plus the longest entity name and longest domain name defined.

**Note:** Note: This parameter is defined as an MQZAD, as the MQZAD always occurs at the start of the buffer. However, if the buffer is declared as an MQZAD, the buffer will be too small - it must be bigger than an MQZAD so that it can accommodate the MQZAD, MQZED, plus entity and domain names.

### **AuthorityDataLength**

Type: MQLONG - output

Length of data returned in *AuthorityBuffer*. If the authority buffer is too small, *AuthorityDataLength* is set to the length of the buffer required, and the call returns completion code MQCC\_FAILED and reason code MQRC\_BUFFER\_LENGTH\_ERROR.

### **ComponentData**

Type: MQBYTE x ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the ComponentDataLength parameter of the MQZ\_INIT\_AUTHORITY call.

### **Continuation**

Type: MQLONG - output

Continuation indicator set by component. The following values can be specified:

#### **MQZCI\_DEFAULT**

Continuation dependent on queue manager.

For MQZ\_ENUMERATE\_AUTHORITY\_DATA, this has the same effect as MQZCI\_CONTINUE.

#### **MQZCI\_CONTINUE**

Continue with next component.

#### **MQZCI\_STOP**

Do not continue with next component.

### **CompCode**

Type: MQLONG - output

Completion code. It must be one of the following values:

#### **MQCC\_OK**

Successful completion.

#### **MQCC\_FAILED**

Call failed.

### **Reason**

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

#### **MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

#### **MQRC\_BUFFER\_LENGTH\_ERROR**

(2005, X'7D5') Buffer length parameter not valid.

#### **MQRC\_NO\_DATA\_AVAILABLE**

(2379, X'94B') No data available.

#### **MQRC\_SERVICE\_ERROR**

(2289, X'8F1') Unexpected error occurred accessing service.

For more information about these reason codes, see [API completion and reason codes](#).

## C invocation

```
MQZ_ENUMERATE_AUTHORITY_DATA (QMgrName, StartEnumeration, &Filter,  
                               AuthorityBufferLength,  
                               &AuthorityBuffer,  
                               &AuthorityDataLength, ComponentData,  
                               &Continuation, &CompCode,  
                               &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */  
MQLONG    StartEnumeration;  /* Flag indicating whether call should  
                               start enumeration */  
MQZAD     Filter;           /* Filter */  
MQLONG    AuthorityBufferLength; /* Length of AuthorityBuffer */  
MQZAD     AuthorityBuffer;   /* Authority data */  
MQLONG    AuthorityDataLength; /* Length of data returned in  
                               AuthorityBuffer */  
MQBYTE    ComponentData[n];  /* Component data */  
MQLONG    Continuation;      /* Continuation indicator set by  
                               component */  
MQLONG    CompCode;         /* Completion code */  
MQLONG    Reason;          /* Reason code qualifying CompCode */
```

## MQZ\_FREE\_USER - Free user

This function is provided by a MQZAS\_VERSION\_5 authorization service component, and is started by the queue manager to free associated allocated resource.

It is started when an application has finished running under all user contexts, for example during an MQDISC MQI call.

The function identifier for this function (for MQZEP) is MQZID\_FREE\_USER.

### Syntax

```
MQZ_FREE_USER( QMgrName , FreeParms , ComponentData , Continuation , CompCode ,  
Reason )
```

### Parameters

#### QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

#### FreeParms

Type: MQZFP - input

Free parameters. A structure containing data relating to the resource to be freed. See [“MQZFP - Free parameters”](#) on page 1678 for details.

#### ComponentData

Type: MQBYTE x ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the ComponentDataLength parameter of the MQZ\_INIT\_AUTHORITY call.

## Continuation

Type: MQLONG - output

Continuation flag. The following values can be specified:

### **MQZCI\_DEFAULT**

Continuation dependent on other components.

### **MQZCI\_STOP**

Do not continue with next component.

## CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

### **MQCC\_OK**

Successful completion.

### **MQCC\_FAILED**

Call failed.

## Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

### **MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

### **MQRC\_SERVICE\_ERROR**

(2289, X'8F1') Unexpected error occurred accessing service.

For more information about these reason codes, see [API completion and reason codes](#).

## C invocation

```
MQZ_AUTHENTICATE_USER (QMgrName, SecurityParms, ApplicationContext,  
IdentityContext, CorrelationPtr, ComponentData,  
&Continuation, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */  
MQZFP     FreeParms;         /* Resource to be freed */  
MQBYTE    ComponentData[n]; /* Component data */  
MQLONG    Continuation;     /* Continuation indicator set by  
                           component */  
MQLONG    CompCode;         /* Completion code */  
MQLONG    Reason;          /* Reason code qualifying CompCode */
```

## MQZ\_GET\_AUTHORITY - Get authority

This function is provided by a MQZAS\_VERSION\_1 authorization service component, and is started by the queue manager to retrieve the authority that an entity has to access the specified object, including (if the entity is a principal) authorities possessed by the groups in which the principal is a member. Authorities from generic profiles are included in the returned authority set.

The function identifier for this function (for MQZEP) is MQZID\_GET\_AUTHORITY.

## Syntax

`MQZ_GET_AUTHORITY( QMgrName , EntityName , EntityType , ObjectName , ObjectType , Authority , ComponentData , Continuation , CompCode , Reason )`

## Parameters

### QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

### EntityName

Type: MQCHAR12 - input

Entity name. The name of the entity whose access to the object is to be retrieved. The maximum length of the string is 12 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

### EntityType

Type: MQLONG - input

Entity type. The type of entity specified by *EntityName*. It must be one of the following values:

#### **MQZAET\_PRINCIPAL**

Principal.

#### **MQZAET\_GROUP**

Group.

### ObjectName

Type: MQCHAR48 - input

Object name. The name of the object to which access is to be retrieved. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

If *ObjectType* is MQOT\_Q\_MGR, this name is the same as *QMgrName*.

### ObjectType

Type: MQLONG - input

Object type. The type of entity specified by *ObjectName*. It must be one of the following values:

#### **MQOT\_AUTH\_INFO**

Authentication information.

#### **MQOT\_CHANNEL**

Channel.

#### **MQOT\_CLNTCONN\_CHANNEL**

Client connection channel.

#### **MQOT\_LISTENER**

Listener.

#### **MQOT\_NAMELIST**

Namelist.

#### **MQOT\_PROCESS**

Process definition.

#### **MQOT\_Q**

Queue.

**MQOT\_Q\_MGR**

Queue manager.

**MQOT\_SERVICE**

Service.

**MQOT\_TOPIC**

Topic.

**Authority**

Type: MQLONG - input

Authority of entity. If the entity has one authority, this field is equal to the appropriate authorization operation (MQZAO\_\* constant). If it has more than one authority, this field is the bitwise OR of the corresponding MQZAO\_\* constants.

**ComponentData**

Type: MQBYTE×ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the **ComponentDataLength** parameter of the MQZ\_INIT\_AUTHORITY call.

**Continuation**

Type: MQLONG - output

Continuation indicator set by component. The following values can be specified:

**MQZCI\_DEFAULT**

Continuation dependent on queue manager.

For MQZ\_GET\_AUTHORITY, this has the same effect as MQZCI\_CONTINUE.

**MQZCI\_CONTINUE**

Continue with next component.

**MQZCI\_STOP**

Do not continue with next component.

**CompCode**

Type: MQLONG - output

Completion code. It must be one of the following values:

**MQCC\_OK**

Successful completion.

**MQCC\_FAILED**

Call failed.

**Reason**

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

**MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

**MQRC\_NOT\_AUTHORIZED**

(2035, X'7F3') Not authorized for access.

**MQRC\_SERVICE\_ERROR**

(2289, X'8F1') Unexpected error occurred accessing service.

## **MQRC\_SERVICE\_NOT\_AVAILABLE**

(2285, X'8ED') Underlying service not available.

## **MQRC\_UNKNOWN\_ENTITY**

(2292, X'8F4') Entity unknown to service.

For more information about these reason codes, see [API completion and reason codes](#).

## **C invocation**

```
MQZ_GET_AUTHORITY (QMgrName, EntityName, EntityType, ObjectName,  
                  ObjectType, &Authority, ComponentData,  
                  &Continuation, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */  
MQCHAR12  EntityName;        /* Entity name */  
MQLONG    EntityType;        /* Entity type */  
MQCHAR48  ObjectName;        /* Object name */  
MQLONG    ObjectType;        /* Object type */  
MQLONG    Authority;         /* Authority of entity */  
MQBYTE    ComponentData[n]; /* Component data */  
MQLONG    Continuation;      /* Continuation indicator set by  
                             component */  
MQLONG    CompCode;          /* Completion code */  
MQLONG    Reason;           /* Reason code qualifying CompCode */
```

## **MQZ\_GET\_AUTHORITY\_2 - Get authority (extended)**

This function is provided by a MQZAS\_VERSION\_2 authorization service component, and is started by the queue manager to retrieve the authority that an entity has to access the specified object.

The function identifier for this function (for MQZEP) is MQZID\_GET\_AUTHORITY.

MQZ\_GET\_AUTHORITY\_2 is like MQZ\_GET\_AUTHORITY, but with the **EntityName** parameter replaced by the **EntityData** parameter.

### **Syntax**

```
MQZ_GET_AUTHORITY_2( QMgrName , EntityData , EntityType , ObjectName ,  
ObjectType , Authority , ComponentData , Continuation , CompCode , Reason )
```

### **Parameters**

#### **QMgrName**

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

#### **EntityData**

Type: MQZED - input

Entity data. Data relating to the entity for which authorization to the object is to be retrieved. See [“MQZED - Entity descriptor” on page 1675](#) for details.

#### **EntityType**

Type: MQLONG - input

Entity type. The type of entity specified by *EntityData*. It must be one of the following values:

**MQZAET\_PRINCIPAL**

Principal.

**MQZAET\_GROUP**

Group.

**ObjectName**

Type: MQCHAR48 - input

Object name. The name of the object for which the entity authority is to be retrieved. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

If *ObjectType* is MQOT\_Q\_MGR, this name is the same as *QMgrName*.

**ObjectType**

Type: MQLONG - input

Object type. The type of entity specified by *ObjectName*. It must be one of the following values:

**MQOT\_AUTH\_INFO**

Authentication information.

**MQOT\_CHANNEL**

Channel.

**MQOT\_CLNTCONN\_CHANNEL**

Client connection channel.

**MQOT\_LISTENER**

Listener.

**MQOT\_NAMELIST**

Namelist.

**MQOT\_PROCESS**

Process definition.

**MQOT\_Q**

Queue.

**MQOT\_Q\_MGR**

Queue manager.

**MQOT\_SERVICE**

Service.

**MQOT\_TOPIC**

Topic.

**Authority**

Type: MQLONG - input

Authority of entity. If the entity has one authority, this field is equal to the appropriate authorization operation (MQZAO\_\* constant). If it has more than one authority, this field is the bitwise OR of the corresponding MQZAO\_\* constants.

**ComponentData**

Type: MQBYTE×ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the **ComponentDataLength** parameter of the MQZ\_INIT\_AUTHORITY call.

**Continuation**

Type: MQLONG - output

Continuation indicator set by component. The following values can be specified:

**MQZCI\_DEFAULT**

Continuation dependent on queue manager.

For MQZ\_CHECK\_AUTHORITY, this has the same effect as MQZCI\_STOP.

**MQZCI\_CONTINUE**

Continue with next component.

**MQZCI\_STOP**

Do not continue with next component.

**CompCode**

Type: MQLONG - output

Completion code. It must be one of the following values:

**MQCC\_OK**

Successful completion.

**MQCC\_FAILED**

Call failed.

**Reason**

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

**MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

**MQRC\_NOT\_AUTHORIZED**

(2035, X'7F3') Not authorized for access.

**MQRC\_SERVICE\_ERROR**

(2289, X'8F1') Unexpected error occurred accessing service.

**MQRC\_SERVICE\_NOT\_AVAILABLE**

(2285, X'8ED') Underlying service not available.

**MQRC\_UNKNOWN\_ENTITY**

(2292, X'8F4') Entity unknown to service.

For more information about these reason codes, see [API completion and reason codes](#).

**C invocation**

```
MQZ_GET_AUTHORITY_2 (QMgrName, &EntityData, EntityType, ObjectName,
                    ObjectType, &Authority, ComponentData,
                    &Continuation, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */
MQZED     EntityData;        /* Entity data */
MQLONG    EntityType;        /* Entity type */
MQCHAR48  ObjectName;        /* Object name */
MQLONG    ObjectType;        /* Object type */
MQLONG    Authority;         /* Authority of entity */
MQBYTE    ComponentData[n]; /* Component data */
MQLONG    Continuation;      /* Continuation indicator set by
                             component */
MQLONG    CompCode;          /* Completion code */
MQLONG    Reason;           /* Reason code qualifying CompCode */
```

## MQZ\_GET\_EXPLICIT\_AUTHORITY - Get explicit authority

This function is provided by a MQZAS\_VERSION\_1 authorization service component, and is started by the queue manager to retrieve the authority that an entity has to access the specified object, including (if the entity is a principal) authorities possessed by the groups in which the principal is a member. Authorities from generic profiles are included in the returned authority set.

On AIX and Linux, for the built-in IBM MQ object authority manager (OAM), the returned authority is that possessed only by the principal's primary group.

The function identifier for this function (for MQZEP) is MQZID\_GET\_EXPLICIT\_AUTHORITY.

### Syntax

MQZ\_GET\_EXPLICIT\_AUTHORITY( *QMgrName* , *EntityName* , *EntityType* , *ObjectName* , *ObjectType* , *Authority* , *ComponentData* , *Continuation* , *CompCode* , *Reason* )

### Parameters

#### QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

#### EntityName

Type: MQCHAR12 - input

Entity name. The name of the entity for which access to the object is to be retrieved. The maximum length of the string is 12 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

#### EntityType

Type: MQLONG - input

Entity type. The type of entity specified by *EntityName*. It must be one of the following values:

##### **MQZAET\_PRINCIPAL**

Principal.

##### **MQZAET\_GROUP**

Group.

#### ObjectName

Type: MQCHAR48 - input

Object name. The name of the object for which the entity authority is to be retrieved. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

If *ObjectType* is MQOT\_Q\_MGR, this name is the same as *QMgrName*.

#### ObjectType

Type: MQLONG - input

Object type. The type of entity specified by *ObjectName*. It must be one of the following values:

##### **MQOT\_AUTH\_INFO**

Authentication information.

##### **MQOT\_CHANNEL**

Channel.

##### **MQOT\_CLNTCONN\_CHANNEL**

Client connection channel.

**MQOT\_LISTENER**

Listener.

**MQOT\_NAMELIST**

Namelist.

**MQOT\_PROCESS**

Process definition.

**MQOT\_Q**

Queue.

**MQOT\_Q\_MGR**

Queue manager.

**MQOT\_SERVICE**

Service.

**MQOT\_TOPIC**

Topic.

**Authority**

Type: MQLONG - input

Authority of entity. If the entity has one authority, this field is equal to the appropriate authorization operation (MQZAO\_\* constant). If it has more than one authority, this field is the bitwise OR of the corresponding MQZAO\_\* constants.

**ComponentData**

Type: MQBYTE x ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the **ComponentDataLength** parameter of the MQZ\_INIT\_AUTHORITY call.

**Continuation**

Type: MQLONG - output

Continuation indicator set by component. The following values can be specified:

**MQZCI\_DEFAULT**

Continuation dependent on queue manager.

For MQZ\_GET\_AUTHORITY, this has the same effect as MQZCI\_CONTINUE.

**MQZCI\_CONTINUE**

Continue with next component.

**MQZCI\_STOP**

Do not continue with next component.

**CompCode**

Type: MQLONG - output

Completion code. It must be one of the following values:

**MQCC\_OK**

Successful completion.

**MQCC\_FAILED**

Call failed.

**Reason**

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

**MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

**MQRC\_NOT\_AUTHORIZED**

(2035, X'7F3') Not authorized for access.

**MQRC\_SERVICE\_ERROR**

(2289, X'8F1') Unexpected error occurred accessing service.

**MQRC\_SERVICE\_NOT\_AVAILABLE**

(2285, X'8ED') Underlying service not available.

**MQRC\_UNKNOWN\_ENTITY**

(2292, X'8F4') Entity unknown to service.

For more information about these reason codes, see [API completion and reason codes](#).

**C invocation**

```
MQZ_GET_EXPLICIT_AUTHORITY (QMgrName, EntityName, EntityType,
                             ObjectName, ObjectType, &Authority,
                             ComponentData, &Continuation,
                             &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48 QMgrName;           /* Queue manager name */
MQCHAR12 EntityName;        /* Entity name */
MQLONG   EntityType;        /* Entity type */
MQCHAR48 ObjectName;        /* Object name */
MQLONG   ObjectType;        /* Object type */
MQLONG   Authority;         /* Authority of entity */
MQBYTE   ComponentData[n]; /* Component data */
MQLONG   Continuation;      /* Continuation indicator set by
                             component */
MQLONG   CompCode;          /* Completion code */
MQLONG   Reason;           /* Reason code qualifying CompCode */
```

**MQZ\_GET\_EXPLICIT\_AUTHORITY\_2 - Get explicit authority (extended)**

This function is provided by a MQZAS\_VERSION\_2 authorization service component, and is started by the queue manager to retrieve the authority that a named group has to access a specified object (but without the additional authority of the **nobody** group), or the authority that the primary group of the named principal has to access a specified object.

The function identifier for this function (for MQZEP) is MQZID\_GET\_EXPLICIT\_AUTHORITY.

MQZ\_GET\_EXPLICIT\_AUTHORITY\_2 is like MQZ\_GET\_EXPLICIT\_AUTHORITY, but with the **EntityName** parameter replaced by the **EntityData** parameter.

**Syntax**

MQZ\_GET\_EXPLICIT\_AUTHORITY\_2( QMgrName , EntityData , EntityType , ObjectName , ObjectType , Authority , ComponentData , Continuation , CompCode , Reason )

**Parameters****QMgrName**

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

### **EntityData**

Type: MQZED - input

Entity data. Data relating to the entity whose authorization to the object is to be retrieved. See [“MQZED - Entity descriptor” on page 1675](#) for details.

### **EntityType**

Type: MQLONG - input

Entity type. The type of entity specified by *EntityData*. It must be one of the following values:

#### **MQZAET\_PRINCIPAL**

Principal.

#### **MQZAET\_GROUP**

Group.

### **ObjectName**

Type: MQCHAR48 - input

Object name. The name of the object for which the entity authority is to be retrieved. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

If *ObjectType* is MQOT\_Q\_MGR, this name is the same as *QMgrName*.

### **ObjectType**

Type: MQLONG - input

Object type. The type of entity specified by *ObjectName*. It must be one of the following values:

#### **MQOT\_AUTH\_INFO**

Authentication information.

#### **MQOT\_CHANNEL**

Channel.

#### **MQOT\_CLNTCONN\_CHANNEL**

Client connection channel.

#### **MQOT\_LISTENER**

Listener.

#### **MQOT\_NAMELIST**

Namelist.

#### **MQOT\_PROCESS**

Process definition.

#### **MQOT\_Q**

Queue.

#### **MQOT\_Q\_MGR**

Queue manager.

#### **MQOT\_SERVICE**

Service.

#### **MQOT\_TOPIC**

Topic.

### **Authority**

Type: MQLONG - input

Authority of entity. If the entity has one authority, this field is equal to the appropriate authorization operation (MQZAO\_\* constant). If it has more than one authority, this field is the bitwise OR of the corresponding MQZAO\_\* constants.

## ComponentData

Type: MQBYTE×ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the **ComponentDataLength** parameter of the MQZ\_INIT\_AUTHORITY call.

## Continuation

Type: MQLONG - output

Continuation indicator set by component. The following values can be specified:

### MQZCI\_DEFAULT

Continuation dependent on queue manager.

For MQZ\_CHECK\_AUTHORITY, this has the same effect as MQZCI\_STOP.

### MQZCI\_CONTINUE

Continue with next component.

### MQZCI\_STOP

Do not continue with next component.

## CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

### MQCC\_OK

Successful completion.

### MQCC\_FAILED

Call failed.

## Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

### MQRC\_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

### MQRC\_NOT\_AUTHORIZED

(2035, X'7F3') Not authorized for access.

### MQRC\_SERVICE\_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

### MQRC\_SERVICE\_NOT\_AVAILABLE

(2285, X'8ED') Underlying service not available.

### MQRC\_UNKNOWN\_ENTITY

(2292, X'8F4') Entity unknown to service.

For more information about these reason codes, see [API completion and reason codes](#).

## C invocation

```
MQZ_GET_EXPLICIT_AUTHORITY_2 (QMgrName, &EntityData, EntityType,  
                               ObjectName, ObjectType, &Authority,  
                               ComponentData, &Continuation,  
                               &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;          /* Queue manager name */
MQZED     EntityData;     /* Entity data */
MQLONG    EntityType;     /* Entity type */
MQCHAR48  ObjectName;     /* Object name */
MQLONG    ObjectType;     /* Object type */
MQLONG    Authority;      /* Authority of entity */
MQBYTE    ComponentData[n]; /* Component data */
MQLONG    Continuation;   /* Continuation indicator set by
                           component */
MQLONG    CompCode;       /* Completion code */
MQLONG    Reason;        /* Reason code qualifying CompCode */
```

## MQZ\_INIT\_AUTHORITY - Initialize authorization service

This function is provided by an authorization service component, and is started by the queue manager during configuration of the component. It is expected to call MQZEP in order to provide information to the queue manager.

The function identifier for this function (for MQZEP) is MQZID\_INIT\_AUTHORITY.

### Syntax

```
MQZ_INIT_AUTHORITY( Hconfig , Options , QMgrName , ComponentDataLength ,
                   ComponentData , Version , CompCode , Reason )
```

### Parameters

#### Hconfig

Type: MQHCONFIG - input

Configuration handle. This handle represents the particular component being initialized. It is to be used by the component when calling the queue manager with the MQZEP function.

#### Options

Type: MQLONG - input

Initialization options. It must be one of the following values:

#### MQZIO\_PRIMARY

Primary initialization.

#### MQZIO\_SECONDARY

Secondary initialization.

#### QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

#### ComponentDataLength

Type: MQLONG - input

Length of component data. Length in bytes of the *ComponentData* area. This length is defined in the component configuration data.

#### ComponentData

Type: MQBYTE x ComponentDataLength - input/output

Component data. This is initialized to all zeros before calling the component primary initialization function. This data is kept by the queue manager on behalf of this particular component; any changes

made to it by any of the functions (including the initialization function) provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the **ComponentDataLength** parameter of the MQZ\_INIT\_AUTHORITY call.

### Version

Type: MQLONG - input/output

Version number. On input to the initialization function, this identifies the highest version number that the queue manager supports. The initialization function must change this, if necessary, to the version of the interface which it supports. If on return the queue manager does not support the version returned by the component, it calls the component MQZ\_TERM\_AUTHORITY function and makes no further use of this component.

The following values are supported:

#### **MQZAS\_VERSION\_1**

Version 1.

#### **MQZAS\_VERSION\_2**

Version 2.

#### **MQZAS\_VERSION\_3**

Version 3.

#### **MQZAS\_VERSION\_4**

Version 4.

#### **MQZAS\_VERSION\_5**

Version 5.

#### **MQZAS\_VERSION\_6**

IBM WebSphere MQ 6.

### CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

#### **MQCC\_OK**

Successful completion.

#### **MQCC\_FAILED**

Call failed.

### Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

#### **MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

#### **MQRC\_INITIALIZATION\_FAILED**

(2286, X'8EE') Initialization failed for an undefined reason.

#### **MQRC\_SERVICE\_NOT\_AVAILABLE**

(2285, X'8ED') Underlying service not available.

For more information about these reason codes, see [API completion and reason codes](#).

## C invocation

```
MQZ_INIT_AUTHORITY (Hconfig, Options, QMgrName, ComponentDataLength,
```

```
ComponentData, &Version, &CompCode,  
&Reason);
```

The parameters passed to the service are declared as follows:

```
MQHCONFIG  Hconfig;           /* Configuration handle */  
MQLONG     Options;          /* Initialization options */  
MQCHAR48   QMgrName;        /* Queue manager name */  
MQLONG     ComponentDataLength; /* Length of component data */  
MQBYTE     ComponentData[n]; /* Component data */  
MQLONG     Version;         /* Version number */  
MQLONG     CompCode;        /* Completion code */  
MQLONG     Reason;         /* Reason code qualifying CompCode */
```

## MQZ\_INQUIRE - Inquire authorization service

This function is provided by a MQZAS\_VERSION\_5 authorization service component, and is started by the queue manager to query the supported functionality.

Where multiple service components are used, service components are called in reverse order to the order they were installed in.

The function identifier for this function (for MQZEP) is MQZID\_INQUIRE.

### Syntax

```
MQZ_INQUIRE( QMgrName , SelectorCount , Selectors , IntAttrCount , IntAttrs ,  
CharAttrLength , CharAttrs , SelectorReturned , ComponentData , Continuation ,  
CompCode , Reason )
```

### Parameters

#### QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

#### SelectorCount

Type: MQLONG - input

Number of selectors. The number of selectors supplied in the **Selectors** parameter.

The value must be in the range 0 through 256.

#### Selectors

Type: MQLONGxSelectorCount - input

Array of selectors. Each selector identifies a required attribute and must be one of the following:

- MQIACF\_INTERFACE\_VERSION (integer)
- MQIACF\_USER\_ID\_SUPPORT (integer)
- MQCACF\_SERVICE\_COMPONENT (character)

Selectors can be specified in any order. The number of selectors in the array is indicated by the **SelectorCount** parameter.

Integer attributes identified by selectors are returned in the **IntAttrs** parameter in the same order as they appear in *Selectors*.

Character attributes identified by selectors are returned in the **CharAttrs** parameter in the same order as they appear *Selectors*.

**IntAttrCount**

Type: MQLONG - input

Number of integer attributes supplied in the *IntAttrs* parameter.

The value must be in the range 0 through 256.

**IntAttrs**

Type: MQLONG x IntAttrCount - output

Integer attributes. Array of integer attributes. The integer attributes are returned in the same order as the corresponding integer selectors in the *Selectors* array.

**CharAttrCount**

Type: MQLONG - input

Length of the character attributes buffer. The length in bytes of the **CharAttrs** parameter.

The value must be at least the sum of the lengths of the requested character attributes. If no character attributes are requested, zero is a valid value.

**CharAttrs**

Type: MQLONG x CharAttrCount - output

Character attributes buffer. Buffer containing character attributes, concatenated together. The character attributes are returned in the same order as the corresponding character selectors in the *Selectors* array.

The length of the buffer is given by the *CharAttrCount* parameter.

**SelectorReturned**

Type: MQLONG x SelectorCount - input

Selector returned. Array of values identifying which attributes have been returned from the set requested for by the selectors in the *Selectors* parameter. The number of values in this array is indicated by the **SelectorCount** parameter. Each value in the array relates to the selector from the corresponding position in the *Selectors* array. Each value is one of the following:

**MQZSL\_RETURNED**

The attribute requested by the corresponding selector in the **Selectors** parameter has been returned.

**MQZSL\_NOT\_RETURNED**

The attribute requested by the corresponding selector in the **Selectors** parameter has not been returned.

The array is initialized with all values as *MQZSL\_NOT\_RETURNED*. When an authorization service component returns an attribute, it sets the appropriate value in the array to *MQZSL\_NOT\_RETURNED*. This allows any other authorization service components, to which the inquire call is made, to identify which attributes have already been returned.

**ComponentData**

Type: MQBYTE x ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the **ComponentDataLength** parameter of the *MQZ\_INIT\_AUTHORITY* call.

**Continuation**

Type: MQLONG - output

Continuation indicator set by component. The following values can be specified:

**MQZCI\_DEFAULT**

Continuation dependent on queue manager.

For MQZ\_CHECK\_AUTHORITY, this has the same effect as MQZCI\_STOP.

### **MQZCI\_STOP**

Do not continue with next component.

### **CompCode**

Type: MQLONG - output

Completion code. It must be one of the following values:

#### **MQCC\_OK**

Successful completion.

#### **MQCC\_WARNING**

Partial completion.

#### **MQCC\_FAILED**

Call failed.

### **Reason**

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

#### **MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_WARNING:

#### **MQRC\_CHAR\_ATTRS\_TOO\_SHORT**

Not enough space for character attributes.

#### **MQRC\_INT\_COUNT\_TOO\_SMALL**

Not enough space for integer attributes.

If *CompCode* is MQCC\_FAILED:

#### **MQRC\_SELECTOR\_COUNT\_ERROR**

Number of selectors is not valid.

#### **MQRC\_SELECTOR\_ERROR**

Attribute selector not valid.

#### **MQRC\_SELECTOR\_LIMIT\_EXCEEDED**

Too many selectors specified.

#### **MQRC\_INT\_ATTR\_COUNT\_ERROR**

Number of integer attributes is not valid.

#### **MQRC\_INT\_ATTRS\_ARRAY\_ERROR**

Integer attributes array not valid.

#### **MQRC\_CHAR\_ATTR\_LENGTH\_ERROR**

Number of character attributes is not valid.

#### **MQRC\_CHAR\_ATTRS\_ERROR**

Character attributes string is not valid.

#### **MQRC\_SERVICE\_ERROR**

(2289, X'8F1') Unexpected error occurred accessing service.

For more information about these reason codes, see [API completion and reason codes](#).

## **C invocation**

```
MQZ_INQUIRE (QMgrName, SelectorCount, Selectors, IntAttrCount,  
             &IntAttrs, CharAttrLength, &CharAttrs,  
             SelectorReturned, ComponentData, &Continuation,  
             &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */
MQLONG    SelectorCount;    /* Selector count */
MQLONG    Selectors[n];     /* Selectors */
MQLONG    IntAttrCount;     /* IntAttrs count */
MQLONG    IntAttrs[n];      /* Integer attributes */
MQLONG    CharAttrCount;    /* CharAttrs count */
MQLONG    CharAttrs[n];     /* Character attributes */
MQLONG    SelectorReturned[n]; /* Selector returned */
MQBYTE    ComponentData[n]; /* Component data */
MQLONG    Continuation;     /* Continuation indicator set by
                             component */
MQLONG    CompCode;         /* Completion code */
MQLONG    Reason;          /* Reason code qualifying CompCode */
```

## MQZ\_REFRESH\_CACHE - Refresh all authorizations

This function is provided by an MQZAS\_VERSION\_3 authorization service component, and is invoked by the queue manager to refresh the list of authorizations held internally by the component.

The function identifier for this function (for MQZEP) is MQZID\_REFRESH\_CACHE (8L).

### Syntax

```
MQZ_REFRESH_CACHE( QMgrName , ComponentData , Continuation , CompCode ,
Reason )
```

### Parameters

#### QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to make use of it in any defined manner.

#### ComponentData

Type: MQBYTE×ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of this component's functions is called.

The length of this data area is passed by the queue manager in the **ComponentDataLength** parameter of the MQZ\_INIT\_AUTHORITY call.

#### Continuation

Type: MQLONG - output

Continuation indicator set by component. The following values can be specified:

##### MQZCI\_DEFAULT

Continuation dependent on queue manager.

For MQZ\_CHECK\_AUTHORITY this has the same effect as MQZCI\_STOP.

##### MQZCI\_CONTINUE

Continue with next component.

##### MQZCI\_STOP

Do not continue with next component.

#### CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

**MQCC\_OK**

Successful completion.

**MQCC\_FAILED**

Call failed.

**Reason**

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

**MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_WARNING:

**MQRC\_SERVICE\_ERROR**

(2289, X'8F1') Unexpected error occurred accessing service.

## C invocation

```
MQZ_REFRESH_CACHE (QMgrName, ComponentData,  
                  &Continuation, &CompCode, &Reason);
```

Declare the parameters as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */  
MQBYTE    ComponentData[n]; /* Component data */  
MQLONG    Continuation;      /* Continuation indicator set by  
                             component */  
MQLONG    CompCode;         /* Completion code */  
MQLONG    Reason;          /* Reason code qualifying CompCode */
```

## MQZ\_SET\_AUTHORITY - Set authority

This function is provided by a MQZAS\_VERSION\_1 authorization service component, and is started by the queue manager to set the authority that an entity has to access the specified object.

The function identifier for this function (for MQZEP) is MQZID\_SET\_AUTHORITY.

**Note:** This function overrides any existing authorities. To preserve any existing authorities you must set them again with this function.

### Syntax

```
MQZ_SET_AUTHORITY( QMgrName , EntityName , EntityType , ObjectName ,  
ObjectType , Authority , ComponentData , Continuation , CompCode , Reason )
```

### Parameters

**QMgrName**

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

**EntityName**

Type: MQCHAR12 - input

Entity name. The name of the entity for which access to the object is to be retrieved. The maximum length of the string is 12 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

#### **EntityType**

Type: MQLONG - input

Entity type. The type of entity specified by *EntityName*. It must be one of the following values:

#### **MQZAET\_PRINCIPAL**

Principal.

#### **MQZAET\_GROUP**

Group.

#### **ObjectName**

Type: MQCHAR48 - input

Object name. The name of the object to which access is required. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

If *ObjectType* is MQOT\_Q\_MGR, this name is the same as *QMgrName*.

#### **ObjectType**

Type: MQLONG - input

Object type. The type of entity specified by *ObjectName*. It must be one of the following values:

#### **MQOT\_AUTH\_INFO**

Authentication information.

#### **MQOT\_CHANNEL**

Channel.

#### **MQOT\_CLNTCONN\_CHANNEL**

Client connection channel.

#### **MQOT\_LISTENER**

Listener.

#### **MQOT\_NAMELIST**

Namelist.

#### **MQOT\_PROCESS**

Process definition.

#### **MQOT\_Q**

Queue.

#### **MQOT\_Q\_MGR**

Queue manager.

#### **MQOT\_SERVICE**

Service.

#### **MQOT\_TOPIC**

Topic.

#### **Authority**

Type: MQLONG - input

Authority of entity. If one authority is being set, this field is equal to the appropriate authorization operation (MQZAO\_\* constant). If more than one authority is being set, this field is the bitwise OR of the corresponding MQZAO\_\* constants.

#### **ComponentDataname>**

Type: MQBYTEExComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the **ComponentDataLength** parameter of the MQZ\_INIT\_AUTHORITY call.

### Continuation

Type: MQLONG - output

Continuation indicator set by component. The following values can be specified:

#### **MQZCI\_DEFAULT**

Continuation dependent on queue manager.

For MQZ\_GET\_AUTHORITY, this has the same effect as MQZCI\_CONTINUE.

#### **MQZCI\_CONTINUE**

Continue with next component.

#### **MQZCI\_STOP**

Do not continue with next component.

### CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

#### **MQCC\_OK**

Successful completion.

#### **MQCC\_FAILED**

Call failed.

### Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

#### **MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

#### **MQRC\_NOT\_AUTHORIZED**

(2035, X'7F3') Not authorized for access.

#### **MQRC\_SERVICE\_ERROR**

(2289, X'8F1') Unexpected error occurred accessing service.

#### **MQRC\_SERVICE\_NOT\_AVAILABLE**

(2285, X'8ED') Underlying service not available.

#### **MQRC\_UNKNOWN\_ENTITY**

(2292, X'8F4') Entity unknown to service.

For more information about these reason codes, see [API completion and reason codes](#).

## C invocation

```
MQZ_SET_AUTHORITY (QMgriName, EntityName, EntityType, ObjectName,  
                  ObjectType, Authority, ComponentData,  
                  &Continuation, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48 QMgriName;          /* Queue manager name */
```

```

MQCHAR12  EntityName;      /* Entity name */
MQLONG    EntityType;    /* Entity type */
MQCHAR48  ObjectName;    /* Object name */
MQLONG    ObjectType;    /* Object type */
MQLONG    Authority;     /* Authority to be checked */
MQBYTE    ComponentData[n]; /* Component data */
MQLONG    Continuation;  /* Continuation indicator set by
                           component */
MQLONG    CompCode;      /* Completion code */
MQLONG    Reason;        /* Reason code qualifying CompCode */

```

## MQZ\_SET\_AUTHORITY\_2 - Set authority (extended)

This function is provided by a MQZAS\_VERSION\_2 authorization service component, and is started by the queue manager to set the authority that an entity has to access the specified object.

The function identifier for this function (for MQZEP) is MQZID\_SET\_AUTHORITY.

**Note:** This function overrides any existing authorities. To preserve any existing authorities you must set them again with this function.

MQZ\_SET\_AUTHORITY\_2 is like MQZ\_SET\_AUTHORITY, but with the **EntityName** parameter replaced by the **EntityData** parameter.

### Syntax

```

MQZ_SET_AUTHORITY_2( QMgrName , EntityData , EntityType , ObjectName ,
ObjectType , Authority , ComponentData , Continuation , CompCode , Reason )

```

### Parameters

#### QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

#### EntityData

Type: MQZED - input

Entity data. Data relating to the entity whose authorization to the object is to be set. See [“MQZED - Entity descriptor”](#) on page 1675 for details.

#### EntityType

Type: MQLONG - input

Entity type. The type of entity specified by *EntityData*. It must be one of the following values:

#### **MQZAET\_PRINCIPAL**

Principal.

#### **MQZAET\_GROUP**

Group.

#### ObjectName

Type: MQCHAR48 - input

Object name. The name of the object to which the entity authority is to be set. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

If *ObjectType* is MQOT\_Q\_MGR, this name is the same as *QMgrName*.

#### ObjectType

Type: MQLONG - input

Object type. The type of entity specified by *ObjectName*. It must be one of the following values:

**MQOT\_AUTH\_INFO**

Authentication information.

**MQOT\_CHANNEL**

Channel.

**MQOT\_CLNTCONN\_CHANNEL**

Client connection channel.

**MQOT\_LISTENER**

Listener.

**MQOT\_NAMELIST**

Namelist.

**MQOT\_PROCESS**

Process definition.

**MQOT\_Q**

Queue.

**MQOT\_Q\_MGR**

Queue manager.

**MQOT\_SERVICE**

Service.

**MQOT\_TOPIC**

Topic.

**Authority**

Type: MQLONG - input

Authority of entity. If one authority is being set, this field is equal to the appropriate authorization operation (MQZAO\_\* constant). If more than one authority is being set, this field is the bitwise OR of the corresponding MQZAO\_\* constants.

**ComponentData**

Type: MQBYTE×ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the **ComponentDataLength** parameter of the MQZ\_INIT\_AUTHORITY call.

**Continuation**

Type: MQLONG - output

Continuation indicator set by component. The following values can be specified:

**MQZCI\_DEFAULT**

Continuation dependent on queue manager.

For MQZ\_CHECK\_AUTHORITY, this has the same effect as MQZCI\_STOP.

**MQZCI\_CONTINUE**

Continue with next component.

**MQZCI\_STOP**

Do not continue with next component.

**CompCode**

Type: MQLONG - output

Completion code. It must be one of the following values:

**MQCC\_OK**

Successful completion.

**MQCC\_FAILED**

Call failed.

**Reason**

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

**MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

**MQRC\_NOT\_AUTHORIZED**

(2035, X'7F3') Not authorized for access.

**MQRC\_SERVICE\_ERROR**

(2289, X'8F1') Unexpected error occurred accessing service.

**MQRC\_SERVICE\_NOT\_AVAILABLE**

(2285, X'8ED') Underlying service not available.

**MQRC\_UNKNOWN\_ENTITY**

(2292, X'8F4') Entity unknown to service.

For more information about these reason codes, see [API completion and reason codes](#).

**C invocation**

```
MQZ_SET_AUTHORITY_2 (QMgrName, &EntityData, EntityType, ObjectName,
                    ObjectType, Authority, ComponentData,
                    &Continuation, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */
MQZED     EntityData;        /* Entity data */
MQLONG    EntityType;        /* Entity type */
MQCHAR48  ObjectName;        /* Object name */
MQLONG    ObjectType;        /* Object type */
MQLONG    Authority;         /* Authority to be checked */
MQBYTE    ComponentData[n]; /* Component data */
MQLONG    Continuation;      /* Continuation indicator set by
                             component */
MQLONG    CompCode;          /* Completion code */
MQLONG    Reason;           /* Reason code qualifying CompCode */
```

**MQZ\_TERM\_AUTHORITY - Terminate authorization service**

This function is provided by an authorization service component, and is started by the queue manager when it no longer requires the services of this component. The function must perform any cleanup required by the component.

The function identifier for this function (for MQZEP) is MQZID\_TERM\_AUTHORITY.

**Syntax**

```
MQZ_TERM_AUTHORITY( Hconfig , Options , QMgrName , ComponentData , CompCode ,
                    Reason )
```

## Parameters

### Hconfig

Type: MQHCONFIG - input

Configuration handle. This handle represents the particular component being terminated. It is to be used by the component when calling the queue manager with the MQZEP function.

### Options

Type: MQLONG - input

Termination options. It must be one of the following values:

#### **MQZTO\_PRIMARY**

Primary termination.

#### **MQZTO\_SECONDARY**

Secondary termination.

### QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

### ComponentData

Type: MQBYTE x ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the ComponentDataLength parameter on the MQZ\_INIT\_AUTHORITY call.

When the MQZ\_TERM\_AUTHORITY call has completed, the queue manager discards this data.

### CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

#### **MQCC\_OK**

Successful completion.

#### **MQCC\_FAILED**

Call failed.

### Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

#### **MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

#### **MQRC\_SERVICE\_NOT\_AVAILABLE**

(2285, X'8ED') Underlying service not available.

#### **MQRC\_TERMINATION\_FAILED**

(2287, X'8FF') Termination failed for an undefined reason.

For more information about these reason codes, see [API completion and reason codes](#).

## C invocation

```
MQZ_TERM_AUTHORITY (Hconfig, Options, QMgrName, ComponentData,  
                    &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQHCONFIG  Hconfig;           /* Configuration handle */  
MQLONG     Options;          /* Termination options */  
MQCHAR48   QMgrName;        /* Queue manager name */  
MQBYTE     ComponentData[n]; /* Component data */  
MQLONG     CompCode;        /* Completion code */  
MQLONG     Reason;         /* Reason code qualifying CompCode */
```

## MQZ\_DELETE\_NAME - Delete name

This function is provided by a name service component, and is started by the queue manager to delete an entry for the specified queue.

The function identifier for this function (for MQZEP) is MQZID\_DELETE\_NAME.

### Syntax

```
MQZ_DELETE_NAME( QMgrName , QName , ComponentData , Continuation , CompCode ,  
Reason )
```

### Parameters

#### QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

#### QName

Type: MQCHAR48 - input

Queue name. The name of the queue for which an entry is to be deleted. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

#### ComponentData

Type: MQBYTE x ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the ComponentDataLength parameter on the MQZ\_INIT\_NAME call.

#### Continuation

Type: MQLONG - output

Continuation indicator set by component. It must be one of the following values:

##### MQZCI\_DEFAULT

Continuation dependent on queue manager.

##### MQZCI\_STOP

Do not continue with next component.

For the **MQZ\_DELETE\_NAME** command, the queue manager does not attempt to start another component, no matter what is returned in the **Continuation** parameter.

## CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

### MQCC\_OK

Successful completion.

### MQCC\_WARNING

Warning (partial completion).

### MQCC\_FAILED

Call failed.

## Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

### MQRC\_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC\_WARNING:

### MQRC\_UNKNOWN\_NAME

(2288, X'8F0') Queue name not found.

**Note:** It might not be possible to return this code if the underlying service responds with success for this case.

If *CompCode* is MQCC\_FAILED:

### MQRC\_SERVICE\_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

### MQRC\_SERVICE\_NOT\_AVAILABLE

(2285, X'8ED') Underlying service not available.

For more information about these reason codes, see [API completion and reason codes](#).

## C invocation

```
MQZ_DELETE_NAME (QMgrName, QName, ComponentData, &Continuation,  
&CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */  
MQCHAR48  QName;             /* Queue name */  
MQBYTE    ComponentData[n]; /* Component data */  
MQLONG    Continuation;      /* Continuation indicator set by  
                             component */  
MQLONG    CompCode;          /* Completion code */  
MQLONG    Reason;           /* Reason code qualifying CompCode */
```

## MQZ\_INIT\_NAME - Initialize name service

This function is provided by a name service component, and is started by the queue manager during configuration of the component. It is expected to call MQZEP in order to provide information to the queue manager.

The function identifier for this function (for MQZEP) is MQZID\_INIT\_NAME.

## Syntax

MQZ\_INIT\_NAME( *Hconfig* , *Options* , *QMgrName* , *ComponentDataLength* , *ComponentData* , *Version* , *CompCode* , *Reason* )

## Parameters

### Hconfig

Type: MQHCONFIG - input

Configuration handle. This handle represents the particular component being initialized. It is to be used by the component when calling the queue manager with the MQZEP function.

### Options

Type: MQLONG - input

Initialization options. It must be one of the following values:

#### **MQZIO\_PRIMARY**

Primary initialization.

#### **MQZIO\_SECONDARY**

Secondary initialization.

### QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

### ComponentDataLength

Type: MQLONG - input

Length of component data. Length in bytes of the *ComponentData* area. This length is defined in the component configuration data.

### ComponentData

Type: MQBYTE x ComponentDataLength - input/output

Component data. This is initialized to all zeros before calling the component primary initialization function. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions (including the initialization function) provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the **ComponentDataLength** parameter of the MQZ\_INIT\_AUTHORITY call.

### Version

Type: MQLONG - input/output

Version number. On input to the initialization function, this identifies the highest version number that the queue manager supports. The initialization function must change this, if necessary, to the version of the interface which it supports. If on return the queue manager does not support the version returned by the component, it calls the component MQZ\_TERM\_NAME function and makes no further use of this component.

The following values are supported:

#### **MQZAS\_VERSION\_1**

Version 1.

### CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

**MQCC\_OK**

Successful completion.

**MQCC\_FAILED**

Call failed.

**Reason**

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

**MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

**MQRC\_INITIALIZATION\_FAILED**

(2286, X'8EE') Initialization failed for an undefined reason.

**MQRC\_SERVICE\_NOT\_AVAILABLE**

(2285, X'8ED') Underlying service not available.

For more information about these reason codes, see [API completion and reason codes](#).

**C invocation**

```
MQZ_INIT_NAME (Hconfig, Options, QMgrName, ComponentDataLength,
               ComponentData, &Version, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQHCONFIG  Hconfig;           /* Configuration handle */
MQLONG     Options;          /* Initialization options */
MQCHAR48   QMgrName;        /* Queue manager name */
MQLONG     ComponentDataLength; /* Length of component data */
MQBYTE     ComponentData[n]; /* Component data */
MQLONG     Version;         /* Version number */
MQLONG     CompCode;        /* Completion code */
MQLONG     Reason;         /* Reason code qualifying CompCode */
```

**MQZ\_INSERT\_NAME - Insert name**

This function is provided by a name service component, and is started by the queue manager to insert an entry for the specified queue, containing the name of the queue manager that owns the queue. If the queue is already defined in the service, the call fails.

The function identifier for this function (for MQZEP) is MQZID\_INSERT\_NAME.

**Syntax**

```
MQZ_INSERT_NAME( QMgrName , QName , ResolvedQMgrName , ComponentData ,
                 Continuation , CompCode , Reason )
```

**Parameters****QMgrName**

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

**QName**

Type: MQCHAR48 - input

Queue name. The name of the queue for which an entry is to be inserted. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

**ResolvedQMgrName**

Type: MQCHAR48 - input

Resolved queue manager name. The name of the queue manager to which the queue resolves. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

**ComponentData**

Type: MQBYTE×ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions (including the initialization function) provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the **ComponentDataLength** parameter of the MQZ\_INIT\_NAME call.

**Continuation**

Type: MQLONG - input/output

Continuation indicator set by component. For MQZ\_INSERT\_NAME, the queue manager does not attempt to start another component, whatever is returned in the **Continuation** parameter.

The following values are supported:

**MQZCI\_DEFAULT**

Continuation dependent on queue manager.

**MQZCI\_STOP**

Do not continue with next component.

**CompCode**

Type: MQLONG - output

Completion code. It must be one of the following values:

**MQCC\_OK**

Successful completion.

**MQCC\_FAILED**

Call failed.

**Reason**

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

**MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

**MQRC\_Q\_ALREADY\_EXISTS**

(2290, X'8F2') Queue object already exists.

**MQRC\_SERVICE\_ERROR**

(2289, X'8F1') Unexpected error occurred accessing service.

**MQRC\_SERVICE\_NOT\_AVAILABLE**

(2285, X'8ED') Underlying service not available.

For more information about these reason codes, see [API completion and reason codes](#).

## C invocation

```
MQZ_INSERT_NAME (QMgrName, QName, ResolvedQMgrName, ComponentData,  
&Continuation, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;          /* Queue manager name */  
MQCHAR48  QName;           /* Queue name */  
MQCHAR48  ResolvedQMgrName; /* Resolved queue manager name */  
MQBYTE    ComponentData[n]; /* Component data */  
MQLONG    Continuation;    /* Continuation indicator set by  
                           component */  
MQLONG    CompCode;        /* Completion code */  
MQLONG    Reason;         /* Reason code qualifying CompCode */
```

## MQZ\_LOOKUP\_NAME - Lookup name

This function is provided by a name service component, and is started by the queue manager to retrieve the name of the owning queue manager, for a specified queue.

The function identifier for this function (for MQZEP) is MQZID\_LOOKUP\_NAME.

### Syntax

```
MQZ_LOOKUP_NAME( QMgrName , QName , ResolvedQMgrName , ComponentData ,  
Continuation , CompCode , Reason )
```

### Parameters

#### QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

#### QName

Type: MQCHAR48 - input

Queue name. The name of the queue for which an entry is to be resolved. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

#### ResolvedQMgrName

Type: MQCHAR48 - output

Resolved queue manager name. If the function completes successfully, this is the name of the queue manager that owns the queue.

The name returned by the service component must be padded on the right with blanks to the full length of the parameter; the name must not be terminated by a null character, or contain leading or embedded blanks.

#### ComponentData

Type: MQBYTEExComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions (including the initialization function) provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the **ComponentDataLength** parameter of the MQZ\_INIT\_NAME call.

## Continuation

Type: MQLONG - output

Continuation indicator set by component. For MQZ\_LOOKUP\_NAME, the queue manager specifies whether to start another name service component, as follows:

- If *CompCode* is MQCC\_OK, no further components are started, whatever value is returned in *Continuation*.
- If *CompCode* is not MQCC\_OK, a further component is started, unless *Continuation* is MQZCI\_STOP.

The following values are supported:

### MQZCI\_DEFAULT

Continuation dependent on queue manager.

### MQZCI\_CONTINUE

Continue with next component.

### MQZCI\_STOP

Do not continue with next component.

## CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

### MQCC\_OK

Successful completion.

### MQCC\_FAILED

Call failed.

## Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

### MQRC\_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

### MQRC\_SERVICE\_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

### MQRC\_SERVICE\_NOT\_AVAILABLE

(2285, X'8ED') Underlying service not available.

### MQRC\_UNKNOWN\_Q\_NAME

(2288, X'8F0') Queue name not found.

For more information about these reason codes, see [API completion and reason codes](#).

## C invocation

```
MQZ_LOOKUP_NAME (QMgrName, QName, ResolvedQMgrName, ComponentData,  
&Continuation, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48 QMgrName;          /* Queue manager name */  
MQCHAR48 QName;             /* Queue name */  
MQCHAR48 ResolvedQMgrName;  /* Resolved queue manager name */  
MQBYTE ComponentData[n];   /* Component data */  
MQLONG Continuation;       /* Continuation indicator set by  
                             component */
```

```
MQLONG   CompCode;          /* Completion code */
MQLONG   Reason;           /* Reason code qualifying CompCode */
```

## MQZ\_TERM\_NAME - Terminate name service

This function is provided by a name service component, and is started by the queue manager when it no longer requires the services of this component. The function must perform any cleanup required by the component.

The function identifier for this function (for MQZEP) is MQZID\_TERM\_NAME.

### Syntax

```
MQZ_TERM_NAME( Hconfig , Options , QMgrName , ComponentData , CompCode ,  
Reason )
```

### Parameters

#### Hconfig

Type: MQHCONFIG - input

Configuration handle. This handle represents the particular component being terminated. It is used by the component when calling the queue manager with the MQZEP function.

#### Options

Type: MQLONG - input

Termination options. It must be one of the following values:

##### **MQZTO\_PRIMARY**

Primary termination.

##### **MQZTO\_SECONDARY**

Secondary termination.

#### QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

#### ComponentData

Type: MQBYTE x ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions (including the initialization function) provided by this component are preserved, and presented the next time one of these component functions is called.

Component data is in shared memory accessible to all processes.

The length of this data area is passed by the queue manager in the **ComponentDataLength** parameter of the MQZ\_INIT\_NAME call.

When the MQZ\_TERM\_NAME call has completed, the queue manager discards this data.

#### CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

##### **MQCC\_OK**

Successful completion.

##### **MQCC\_FAILED**

Call failed.

## Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

### **MQRC\_NONE**

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

### **MQRC\_TERMINATION\_FAILED**

(2287, X'8FF') Termination failed for an undefined reason.

### **MQRC\_SERVICE\_NOT\_AVAILABLE**

(2285, X'8ED') Underlying service not available.

For more information about these reason codes, see [API completion and reason codes](#).

## C invocation

```
MQZ_TERM_NAME (Hconfig, Options, QMgrName, ComponentData, &CompCode,  
&Reason);
```

The parameters passed to the service are declared as follows:

```
MQHCONFIG  Hconfig;           /* Configuration handle */  
MQLONG     Options;          /* Termination options */  
MQCHAR48   QMgrName;        /* Queue manager name */  
MQBYTE     ComponentData[n]; /* Component data */  
MQLONG     CompCode;        /* Completion code */  
MQLONG     Reason;          /* Reason code qualifying CompCode */
```

## MQZAC - Application context

The MQZAC structure is used on the MQZ\_AUTHENTICATE\_USER call for the *ApplicationContext* parameter. This parameter specifies data related to the calling application.

*Table 1* summarizes the fields in the structure.

Field	Description
<u>StrucId</u>	Structure identifier
<u>Version</u>	Structure version number
<u>ProcessId</u>	Process identifier
<u>ThreadId</u>	Thread identifier
<u>ApplName</u>	Application name
<u>UserID</u>	User identifier
<u>EffectiveUserID</u>	Effective user identifier
<u>Environment</u>	Environment
<u>CallerType</u>	Caller type
<u>AuthenticationType</u>	Authentication type
<u>BindType</u>	Bind type

## Fields

### StrucId

Type: MQCHAR4 - input

Structure identifier. The value is as follows:

#### **MQZAC\_STRUC\_ID**

Identifier for application context structure.

For the C programming language, the constant MQZAC\_STRUC\_ID\_ARRAY is also defined; this has the same value as MQZAC\_STRUC\_ID, but is an array of characters instead of a string.

### Version

Type: MQLONG - input

Structure version number. The value is as follows:

#### **MQZAC\_VERSION\_1**

Version-1 application context structure. The constant MQZAC\_CURRENT\_VERSION specifies the version number of the current version.

### ProcessId

Type: MQPID - input

Process identifier of the application.

### ThreadId

Type: MQTID - input

Thread identifier of the application.

### ApplName

Type: MQCHAR28 - input

Application name.

### UserID

Type: MQCHAR12 - input

User identifier. On AIX and Linux this field specifies the application's real user ID. On Windows this field specifies the application's user ID.

### EffectiveUserID

Type: MQCHAR12 - input

Effective user identifier. On AIX and Linux this field specifies the application's effective user ID. On Windows this field is blank.

### Environment

Type: MQLONG - input

Environment. This field specifies the environment from which the call was made. The field is one of the following values:

#### **MQXE\_COMMAND\_SERVER**

Command server

#### **MQXE\_MQSC**

runmqsc command interpreter

#### **MQXE\_MCA**

Message channel agent MQXE\_OTHER

#### **MQXE\_OTHER**

Undefined environment

### CallerType

Type: MQLONG - input

Caller Type. This field specifies the type of program that made the call. The field is one of the following values:

#### **MQXACT\_EXTERNAL**

The call is external to the queue manager.

#### **MQXACT\_INTERNAL**

The call is internal to the queue manager.

### **AuthenticationType**

Type: MQLONG - input

Authentication Type. This field specifies the type of authentication being performed. The field is one of the following values:

#### **MQZAT\_INITIAL\_CONTEXT**

The authentication call is due to user context being initialized. This value is used during an MQCONN or MQCONNX call.

#### **MQZAT\_CHANGE\_CONTEXT**

The authentication call is due to the user context being changed. This value is used when the MCA changes the user context. Parent topic: MQZAC -

### **BindType**

Type: MQLONG - input

Bind Type. This field specifies the type of binding in use. The field is one of the following values:

#### **MQCNO\_FASTPATH\_BINDING**

Fastpath binding.

#### **MQCNO\_SHARED\_BINDING**

Shared binding.

#### **MQCNO\_ISOLATED\_BINDING**

Isolated binding.

## **C declaration**

Declare the fields of the structure as follows:

```
typedef struct tagMQZAC MQZAC;
struct tagMQZAC {
    MQCHAR4   StrucID;           /* Structure identifier */
    MQLONG    Version;          /* Structure version number */
    MQPID     ProcessID;        /* Process identifier */
    MQTID     ThreadID;         /* Thread identifier */
    MQCHAR28  ApplName;         /* Application name */
    MQCHAR12  UserID;           /* User identifier */
    MQCHAR12  EffectiveUserID;  /* Effective user identifier */
    MQLONG    Environment;      /* Environment */
    MQLONG    CallerType;       /* Caller type */
    MQLONG    AuthenticationType; /* Authentication type */
    MQLONG    BindType;         /* Bind type */
};
```

## **MQZAD - Authority data**

The MQZAD structure is used on the MQZ\_ENUMERATE\_AUTHORITY\_DATA call for two parameters, one input and one output.

See “MQZ\_ENUMERATE\_AUTHORITY\_DATA - Enumerate authority data” on page 1635 for further information on the **Filter** and **AuthorityBuffer** parameters:

- MQZAD is used for the **Filter** parameter which is input to the call. This parameter specifies the selection criteria that are to be used to select the authority data returned by the call.
- MQZAD is also used for the **AuthorityBuffer** parameter which is output from the call. This parameter specifies the authorizations for one combination of profile name, object type, and entity.

Table 1. summarizes the fields in the structure.

Table 839. Fields in MQZAD	
Field	Description
<u>StrucId</u>	Structure identifier
<u>Version</u>	Structure version number
<u>ProfileName</u>	Profile name
<u>ObjectType</u>	Object type
<u>Authority</u>	Authority
<u>EntityDataPtr</u>	Pointer to entity data
<u>EntityType</u>	Entity type
<u>Options</u>	Options

## Fields

### StrucId

Type: MQCHAR4 - input

Structure identifier. The value is as follows:

#### **MQZAD\_STRUC\_ID**

Identifier for authority data structure.

For the C programming language, the constant MQZAD\_STRUC\_ID\_ARRAY is also defined; this has the same value as MQZAD\_STRUC\_ID, but is an array of characters instead of a string.

### Version

Type: MQLONG - input

Structure version number. The value is as follows:

#### **MQZAD\_VERSION\_1**

Version-1 application context structure. The constant MQZAD\_CURRENT\_VERSION specifies the version number of the current version.

The following constant specifies the version number of the current version:

#### **MQZAD\_CURRENT\_VERSION**

Current version of authority data structure.

### ProfileName

Type: MQCHAR48 - input

Profile name.

For the **Filter** parameter, this field is the profile name for which authority data is required. If the name is entirely blank up to the end of the field or the first null character, authority data for all profile names is returned.

For the **AuthorityBuffer** parameter, this field is the name of a profile that matches the specified selection criteria.

### ObjectType

Type: MQLONG - input

Object type.

For the **Filter** parameter, this field is the object type for which authority data is required. If the value is MQOT\_ALL, authority data for all object types is returned.

For the **AuthorityBuffer** parameter, this field is the object type to which the profile identified by the **ProfileName** parameter applies.

The value is one of the following; for the **Filter** parameter, the value MQOT\_ALL is also valid:

**MQOT\_AUTH\_INFO**

Authentication information

**MQOT\_CHANNEL**

Channel

**MQOT\_CLNTCONN\_CHANNEL**

Client connection channel

**MQOT\_LISTENER**

Listener

**MQOT\_NAMELIST**

Namelist

**MQOT\_PROCESS**

Process definition

**MQOT\_Q**

Queue

**MQOT\_Q\_MGR**

Queue manager

**MQOT\_SERVICE**

Service

**Authority**

Type: MQLONG - input

Authority.

For the **Filter** parameter, this field is ignored.

For the **AuthorityBuffer** parameter, this field represents the authorizations that the entity has to the objects identified by **ProfileName** and **ObjectType**. If the entity has only one authority, the field is equal to the appropriate authorization value (MQZAO\_\* constant). If the entity has more than one authority, the field is the bitwise OR of the corresponding MQZAO\_\* constants.

**EntityDataPtr**

Type: PMQZED - input

Address of MQZED structure identifying an entity.

For the **Filter** parameter, this field points to an MQZED structure that identifies the entity for which authority data is required. If **EntityDataPtr** is the null pointer, authority data for all entities is returned.

For the **AuthorityBuffer** parameter, this field points to an MQZED structure that identifies the entity for which authority data has been returned.

**EntityType**

Type: MQLONG - input

Entity type.

For the **Filter** parameter, this field specifies the entity type for which authority data is required. If the value is MQZAET\_NONE, authority data for all entity types is returned.

For the **AuthorityBuffer** parameter, this field specifies the type of the entity identified by the MQZED structure pointed to by the **EntityDataPtr** parameter.

The value is one of the following; for the **Filter** parameter, the value MQZAET\_NONE is also valid:

**MQZAET\_PRINCIPAL**

Principal

## MQZAET\_GROUP

Group

### Options

Type: MQAUTHOPT - input

Options. This field specifies options that give control over the profiles that are displayed. One of the following values must be specified:

#### MQAUTHOPT\_NAME\_ALL\_MATCHING

Displays all profiles

#### MQAUTHOPT\_NAME\_EXPLICIT

Displays profiles that have exactly the same name as specified in the **ProfileName** field.

In addition, one of the following must also be specified:

#### MQAUTHOPT\_ENTITY\_SET

Display all profiles that are used to calculate the cumulative authority that the entity has to the object specified by the **ProfileName** parameter. The **ProfileName** parameter must not contain any wildcard characters.

- If the specified entity is a principal, for each member of the set {entity, groups} the most applicable profile that applies to the object is displayed.
- If the specified entity is a group, the most applicable profile from the group that applies to the object is displayed.
- If this value is specified, then the values of **ProfileName**, **ObjectType**, **EntityType**, and the entity name specified in the **EntityDataPtr** MQZED structure, must all be non-blank.

If you have specified MQAUTHOPT\_NAME\_ALL\_MATCHING, you can also specify the following value:

#### MQAUTHOPT\_ENTITY\_EXPLICIT

Displays profiles that have exactly the same entity name as the entity name specified in the **EntityDataPtr** MQZED structure.

## C declaration

```
typedef struct tagMQZAD MQZAD;
struct tagMQZAD {
    MQCHAR4   StrucId;           /* Structure identifier */
    MQLONG    Version;          /* Structure version number */
    MQCHAR48  ProfileName;     /* Profile name */
    MQLONG    ObjectType;       /* Object type */
    MQLONG    Authority;        /* Authority */
    PMQZED    EntityDataPtr;    /* Address of MQZED structure identifying an
    entity */
    MQLONG    EntityType;       /* Entity type */
    MQAUTHOPT Options;         /* Options */
};
```

## MQZED - Entity descriptor

The MQZED structure is used in a number of authorization service calls to specify the entity for which authorization is to be checked.

*Table 1.* summarizes the fields in the structure.

Field	Description
<u>StrucId</u>	Structure identifier
<u>Version</u>	Version
<u>EntityName Ptr</u>	Entity name

Table 840. Fields in MQZED (continued)

Field	Description
<a href="#">EntityDomainPtr</a>	Entity domain pointer
<a href="#">SecurityId</a>	Security identifier
<a href="#">CorrelationPtr</a>	Correlation pointer

## Fields

### StrucId

Type: MQCHAR4 - input

Structure identifier. The value is as follows:

#### **MQZED\_STRUC\_ID**

Identifier for entity descriptor structure.

For the C programming language, the constant MQZED\_STRUC\_ID\_ARRAY is also defined; this has the same value as MQZED\_STRUC\_ID, but is an array of characters instead of a string.

### Version

Type: MQLONG - input

Structure version number. The value is as follows:

#### **MQZED\_VERSION\_1**

Version-1 entity descriptor structure.

The following constant specifies the version number of the current version:

#### **MQZED\_CURRENT\_VERSION**

Current version of entity descriptor structure.

### EntityNamePtr

Type: PMQCHAR - input

Profile name.

Address of entity name. This is a pointer to the name of the entity whose authorization is to be checked.

### EntityDomainPtr

Type: PMQCHAR - input

Address of entity domain name. This is a pointer to the name of the domain containing the definition of the entity whose authorization is to be checked.

### SecurityId

Type: MQBYTE40 - input

Authority.

Security identifier. This is the security identifier whose authorization is to be checked.

### CorrelationPtr

Type: MQPTR - input

Correlation pointer. This facilitates the passing of correlational data between the authenticate user function and other appropriate OAM functions.

## C declaration

```
typedef struct tagMQZED MQZED;
struct tagMQZED {
    MQCHAR4    StrucId;           /* Structure identifier */
```

```

MQLONG    Version;          /* Structure version number */
PMQCHAR   EntityNamePtr;   /* Address of entity name */
PMQCHAR   EntityDomainPtr; /* Address of entity domain name */
MQBYTE40  SecurityId;      /* Security identifier */
MQPTR     CorrelationPtr;  /* Address of correlation data */

```

## MQZEP - Add component entry point

A service component starts this function, during initialization, to add an entry point to the entry point vector for that service component.

### Syntax

MQZEP ( *Hconfig* , *Function* , *EntryPoint* , *CompCode* , *Reason* )

### Parameters

#### Hconfig

Type: MQHCONFIG - input

Configuration handle. This handle represents the component that is being configured for this particular installable service. It must be the same as the component passed to the component configuration function by the queue manager on the component initialization call.

#### Function

Type: MQLONG - input

Function identifier. Valid values for this are defined for each installable service.

If MQZEP is called more than once for the same function, the last call made provides the entry point that is used.

#### EntryPoint

Type: PMQFUNC - input

Function entry point. This is the address of the entry point provided by the component to perform the function.

The value NULL is valid, and indicates that the function is not provided by this component. NULL is assumed for entry points that are not defined using MQZEP.

#### CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

##### MQCC\_OK

Successful completion.

##### MQCC\_FAILED

Call failed.

#### Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

##### MQRC\_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

##### MQRC\_FUNCTION\_ERROR

(2281, X'8E9') Function identifier not valid.

##### MQRC\_HCONFIG\_ERROR

(2280, X'8E8') Configuration handle not valid.

For more information about these reason codes, see [API completion and reason codes](#).

## C invocation

```
MQZEP (Hconfig, Function, EntryPoint, &CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHCONFIG  Hconfig;      /* Configuration handle */
MQLONG     Function;    /* Function identifier */
PMQFUNC    EntryPoint;  /* Function entry point */
MQLONG     CompCode;    /* Completion code */
MQLONG     Reason;      /* Reason code qualifying CompCode */
```

## MQZFP - Free parameters

The MQZFP structure is used on the MQZ\_FREE\_USER call for the *FreeParms* parameter. This parameter specifies data related to resource to be freed.

[Table 1.](#) summarizes the fields in the structure.

Field	Description
<a href="#">StrucId</a>	Structure identifier
<a href="#">Version</a>	Version
<a href="#">Reserved</a>	Reserved field
<a href="#">CorrelationPtr</a>	Correlation pointer

## Fields

### StrucId

Type: MQCHAR4 - input

Structure identifier. The value is as follows:

#### MQZIC\_STRUC\_ID

Identifier for identity context structure. For the C programming language, the constant MQZIC\_STRUC\_ID\_ARRAY is also defined; this has the same value as MQZIC\_STRUC\_ID, but is an array of characters instead of a string.

### Version

Type: MQLONG - input

Structure version number. The value is as follows:

#### MQZFP\_VERSION\_1

Version-1 free parameters structure.

The following constant specifies the version number of the current version:

#### MQZFP\_CURRENT\_VERSION

Current version of free parameters structure.

### Reserved

Type: MQBYTE8 - input

Reserved field. The initial value is null.

### CorrelationPtr

Type: MQPTR - input

Correlation pointer. Address of correlation data relating to the resource to be freed.

## C declaration

```
typedef struct tagMQZFP MQZFP;  
struct tagMQZFP {  
    MQCHAR4    StrucId;           /* Structure identifier */  
    MQLONG     Version;          /* Structure version number */  
    MQBYTE8    Reserved;        /* Reserved field */  
    MQPTR      CorrelationPtr;   /* Address of correlation data */  
};
```

## MQZIC - Identity context

The MQZIC structure is used on the MQZ\_AUTHENTICATE\_USER call for the *IdentityContext* parameter.

The MQZIC structure contains identity context information, which identifies the user of the application that first put the message on a queue:

- The queue manager fills the *UserIdentifier* field with a name that identifies the user, the way that the queue manager can do this depends on the environment in which the application is running.
- The queue manager fills the *AccountingToken* field with a token or number that it determined from the application that put the message.
- Applications can use the *AppIdentityData* field for any extra information that they want to include about the user (for example, an encrypted password).

Suitably authorized applications can set the identity context using the MQZ\_AUTHENTICATE\_USER function.

A Windows systems security identifier (SID) is stored in the *AccountingToken* field when a message is created under IBM MQ for Windows. The SID can be used to supplement the *UserIdentifier* field and to establish the credentials of a user.

*Table 1.* summarizes the fields in the structure.

Field	Description
<a href="#">StrucId</a>	Structure identifier
<a href="#">Version</a>	Version
<a href="#">UserIdentifier</a>	User identifier
<a href="#">AccountingToken</a>	Accounting token
<a href="#">AppIdentityData</a>	Application identity data

## Fields

### StrucId

Type: MQCHAR4 - input

Structure identifier. The value is as follows:

#### MQZIC\_STRUC\_ID

Identifier for identity context structure. For the C programming language, the constant MQZIC\_STRUC\_ID\_ARRAY is also defined; this has the same value as MQZIC\_STRUC\_ID, but is an array of characters instead of a string.

### Version

Type: MQLONG - input

Structure version number. The value is as follows:

## **MQZIC\_VERSION\_1**

Version-1 identity context structure.

The following constant specifies the version number of the current version:

## **MQZIC\_CURRENT\_VERSION**

Current version of identity context structure.

### **UserIdentifier**

Type: MQCHAR12 - input

User identifier. This is part of the identity context of the message. *UserIdentifier* specifies the user identifier of the application that originated the message. The queue manager treats this information as character data, but does not define the format of it. For more information on the *UserIdentifier* field, see [“UserIdentifier \(MQCHAR12\) for MQMD” on page 459](#).

### **AccountingToken**

Type: MQBYTE32 - input

Accounting token. This is part of the identity context of the message. *AccountingToken* allows an application to cause work done as a result of the message to be appropriately charged. The queue manager treats this information as a string of bits and does not check its content. For more information on the *AccountingToken* field, see [“AccountingToken \(MQBYTE32\) for MQMD” on page 460](#).

### **ApplIdentityData**

Type: MQCHAR32 - input

Application data relating to identity. This is part of the identity context of the message. *ApplIdentityData* is information that is defined by the application suite that can be used to provide additional information about the origin of the message. For example, it could be set by applications running with suitable user authority to indicate whether the identity data is trusted. For more information on the *ApplIdentityData* field, see [“ApplIdentityData \(MQCHAR32\) for MQMD” on page 462](#).

## **C declaration**

```
typedef struct tagMQZED MQZED;
struct tagMQZED {
    MQCHAR4    StrucId;           /* Structure identifier */
    MQLONG    Version;          /* Structure version number */
    MQCHAR12  UserIdentifier;    /* User identifier */
    MQBYTE32  AccountingToken;  /* Accounting token */
    MQCHAR32  ApplIdentityData; /* Application data relating to identity */
};
```

## **IBM i Installable services interface reference information on IBM i**

Use this information to understand the reference information for the installable services for IBM i.

For each function there is a description, including the function identifier (for MQZEP).

The *parameters* are shown listed in the order they must occur. They must all be present.

Each parameter name is followed by its data type in parentheses. These are the elementary data types described in [“Elementary data types” on page 998](#).

The C language invocation is also given, after the description of the parameters.

### **Related concepts**

**IBM i** [Installable services and components for IBM i](#)

**ALW** [Installable services and components for UNIX, Linux and Windows](#)

## Related reference

“Installable services interface reference information” on page 1618

This collection of topics provides reference information for the installable services.

## MQZEP (Add component entry point) on IBM i

This function is invoked by a service component, during initialization, to add an entry point to the entry point vector for that service component.

## Syntax

```
MQZEP (Hconfig, Function, EntryPoint, CompCode, Reason)
```

## Parameters

The MQZEP call has the following parameters.

### Hconfig (MQHCONFIG) - input

Configuration handle.

This handle represents the component which is being configured for this particular installable service. It must be the same as the one passed to the component configuration function by the queue manager on the component initialization call.

### Function (MQLONG) - input

Function identifier.

Valid values for this are defined for each installable service. If MQZEP is called more than once for the same function, the last call made provides the entry point which is used.

### EntryPoint (PMQFUNC) - input

Function entry point.

This is the address of the entry point provided by the component to perform the function. The value NULL is valid, and indicates that the function is not provided by this component. NULL is assumed for entry points which are not defined using MQZEP.

### CompCode (MQLONG) - output

Completion code.

It is one of the following:

#### MQCC\_OK

Successful completion.

#### MQCC\_FAILED

Call failed.

### Reason (MQLONG) - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC\_OK:

#### MQRC\_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC\_FAILED:

#### MQRC\_FUNCTION\_ERROR

(2281, X'8E9') Function identifier not valid.

#### MQRC\_HCONFIG\_ERROR

(2280, X'8E8') Configuration handle not valid.

For more information about these reason codes, see [Messages and reason codes](#).

## C invocation

```
MQZEP (Hconfig, Function, EntryPoint, &CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHCONFIG  Hconfig;    /* Configuration handle */
MQLONG     Function;   /* Function identifier */
PMQFUNC    EntryPoint; /* Function entry point */
MQLONG     CompCode;   /* Completion code */
MQLONG     Reason;     /* Reason code qualifying CompCode */
```

### IBM i MQHCONFIG (Configuration handle) on IBM i

The MQHCONFIG data type represents a configuration handle, that is, the component that is being configured for a particular installable service. A configuration handle must be aligned on its natural boundary.

Applications must test variables of this type for equality only.

## C declaration

```
typedef void MQPOINTER MQHCONFIG;
```

### IBM i PMQFUNC (Pointer to function) on IBM i

Pointer to a function.

## C declaration

```
typedef void MQPOINTER PMQFUNC;
```

### IBM i MQZ\_AUTHENTICATE\_USER (Authenticate user) on IBM i

This function is provided by a MQZAS\_VERSION\_5 authorization service component. It is invoked by the queue manager to authenticate a user, or to set identity context fields.

It is invoked when an IBM MQ user application context is established. This happens during connect calls at the point where the application's user context is initialized, and at each point where the application's user context is changed. Each time a connect call is made, the application's user context information is reacquired in the *IdentityContext* field.

The function identifier for this function (for MQZEP) is MQZID\_AUTHENTICATE\_USER.

## Syntax

```
MQZ_AUTHENTICATE_USER (QMgrName, SecurityParms, ApplicationContext,  
IdentityContext, CorrelationPtr, ComponentData, Continuation, CompCode,  
Reason)
```

## Parameters

The MQZ\_AUTHENTICATE\_USER call has the following parameters.

### QMgrName (MQCHAR48) - input

Queue manager name.

The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character. The queue manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

**SecurityParms (MQCSP) - input**

Security parameters.

Data relating to the user ID, password, and authentication type.

During an MQCONN MQI call this parameter contains null, or default values.

**ApplicationContext (MQZAC) - input**

Application context.

Data relating to the calling application. See [“MQZAC \(Application context\) on IBM i” on page 1712](#) for details. During every MQCONN or MQCONNX MQI call, the user context information in the MQZAC structure is reacquired.

**IdentityContext (MQZIC) - input/output**

Identity context.
