IBM Spectrum Protect dokumentáció

Az IBM Spectrum Protect rendszer automatizált, központilag ütemezett, irányelvvezérelt biztonsági mentési, archiválási és tárhelykezelési képességeket biztosít a fájlkiszolgálók, munkaállomások, virtuális gépek és alkalmazások számára. Az IBM Spectrum Protect dokumentációja segítséget nyújt az adatvédelmi megoldások beállításához, konfigurálásához és kezeléséhez.

Kezdeti lépések

Kiszolgálók telepítése és frissítése
Az Operations Center telepítése és frissítése
Mentési-archiválási ügyfelek telepítése
Adatvédelmi megoldások kiválasztása és megvalósítása
A kiszolgáló újdonságai
Az ügyfelek újdonságai
Új videók
PDF fájlok

Általános feladatok

Napi megfigyelési feladatok
Ügyfél hozzáadása
Ügyféladatok replikálása egy másik kiszolgálóra
Kiszolgáló, ügyfelek és az Operations Center kezelése
Tároló konfigurálása
Mentési-archiválási ügyfelek beállítása
Adatok biztonsági mentése
Kiszolgáló parancsok, paraméterek és segédprogramok

Hibaelhárítás és terméktámogatás

Hibaelhárítás
Teljesítményoptimalizálás
A IBM Spectrum Protect ügyfelek és kiszolgálók legújabb javítócsomagjai
IBM szoftvertámogatás

Kisegítő lehetőségek
A termék jogi nyilatkozatai

A IBM Spectrum Protect termékcsalád kisegítő lehetőségei

A kisegítő lehetőségek a fogyatékkal élő felhasználóknak (mozgáskorlátozottaknak, látáskárosultaknak) hivatottak az információtechnológiai tartalom sikeres használatában segítséget nyújtani.

Áttekintés

Az IBM Spectrum Protect termékcsalád a következő főbb kisegítő lehetőségeket foglalja magában:

- Navigáció csak a billentyűzettel

- Képernyőolvasót használó műveletek

A IBM Spectrum Protect termékcsalád a legújabb W3C szabványt, a WAI-ARIA 1.0 használja, hogy megfeleljen a US Section 508 és Web Content Accessibility Guidelines (WCAG) 2.0 kompatibilitási követelményeknek. A kisegítő lehetőségek kihasználása érdekében használja a képernyőolvasó legújabb kiadását és a termék által támogatott legfrissebb böngészőt.

Az IBM Knowledge Centerben található termékdokumentációban használhatók a kisegítő lehetőségek. Az IBM Knowledge Center kisegítő lehetőségeinek leírását az IBM Knowledge Center súgó tartalmazza.

Navigáció a billentyűzettel

Ez a termék a szabványos navigációs billentyűket használja.

Felület információk

A felhasználói felületek nem tartalmaznak másodpercenként 2 - 55 alkalommal villogó tartalmat.

A webes felhasználói felület a Lépcsőzetes stíluslap-dokumentum (CSS) technológiára támaszkodik a tartalom megfelelő megjelenítéséhez és használható élményt biztosít. Az alkalmazás biztosít egy egyenértékű módot a gyengénlátó felhasználók számára a rendszermegjelenítési beállítások használatára, beleértve a magas kontrasztú módot. A betűméretet az eszköz vagy a webböngésző beállításainak használatával szabályozhatja.

A webes felhasználói felületek WAI-ARIA navigációs jelzéseket tartalmaznak, amelyekkel gyorsan a funkcionális területekhez navigálhat az alkalmazásban.

Szállítói szoftverek

A IBM Spectrum Protect termékcsalád bizonyos szállítói szoftvereket is tartalmaz, amelyekre nem terjed ki az IBM licencszerződésének hatálya. Az IBM nem garantálja ezen termékek kisegítő lehetőségeinek elérhetőségét. A termékek kisegítő lehetőségeire vonatkozó információkért lépjen kapcsolatba azok szállítóval.

Kapcsolódó információk a kisegítő lehetőségekről

A szabványos IBM Help Desk és támogatási webhelyek mellett az IBM biztosít egy TTY telefonos szolgáltatást a siket vagy gyengénhalló vásárlók számára az értékesítési és támogatási szolgáltatások eléréséhez:

TTY szolgáltatás
800-IBM-3383 (800-426-3383)
(Észak-Amerikán belül)

Az IBM kisegítő lehetőségekkel kapcsolatos elkötelezettségéről az IBM kisegítő lehetőségek oldalon tudhat meg további információkat.

Termékcsomagok és kapcsolódó termékek

Az IBM Spectrum Protect szoftvercsomagok és kapcsolódó tárolási termékek az alapvető IBM Spectrum Protect rendszer szolgáltatásait fejlesztik tovább, illetve bővítik ki.

Termékcsomagok és licenclehetőségek

A IBM Spectrum Protect, valamint a IBM Spectrum Protect Extended Edition termék a központosított biztonsági mentési és visszaállítási műveletek számára kínál alapvető összetevőket. A kiszolgáló, valamint a mentési-archiválási ügyfél összetevő a biztonsági mentési és visszaállítási műveletek alapfunkciói mellett a fájlok, könyvtárak és lemezképfájlok számára nyújt archiválási és lekérési műveleteket.

A termékdokumentáció a IBM Spectrum Protect és a IBM Spectrum Protect Extended Edition termékre vonatkozóan is tartalmaz információkat.

A IBM Spectrum Protect rendszert a kapcsolódó termékekkel egyesítő termékcsomagok egyszerűbb módot kínálhatnak a IBM Spectrum Protect szoftverek megvásárlására és kezelésére. A szoftvercsomagok olyan termékeket foglalnak magukban, amelyek egyszerűsített licenckezeléssel az adatvédelmi és -helyreállítási követelmények széles választékát teljesítik. További információk a IBM Spectrum Protect termékcsomagokról.

Kapcsolódó termékek

A kapcsolódó termékekben rendelkezésre álló funkciók és szolgáltatások segítségével kibővítheti a IBM Spectrum Protect rendszert.

Termék	Legfontosabb előnyök	Hivatkozások
IBM Spectrum Copy Data Management	Katalogizálja a NetApp és VMware pillanatképeket a biztonsági mentés adatok szerep alapú kezelésének és helyreállításának megkönnyítése érdekében.	• További információk és vásárlás • Termékdokumentáció
IBM Spectrum Protect High Speed Data Transfer	Ez a termék lehetővé teszi a Fast Adaptive Secure Protocol (FASP-gyorsalkalmazkodású biztonságos protokoll) technológia használatát az adatátvitel javítása érdekében nagy kiterjedésű hálózati (WAN) környezetben, ahol teljesítményproblémák merülnek fel.	• További információk és vásárlás • Szempontok annak meghatározására, hogy az Aspera FASP technológia optimalizálni tudja-e az adatátvitelt az Ön rendszerkörnyezetében.
IBM Spectrum Protect for Data Retention	Hosszú távú adatmegtartás-védelmet biztosít az üzleti feljegyzések, fájlok vagy adatok archiválásakor. Az adatok hatósági megfelelőségi követelmények szerinti archiválása az adatmegtartás-védelemnek nevezett kiegészítő biztonságot, illetve védelmi megoldásokat igényli. Ezek a védelmi megoldások segítenek gondoskodni arról, hogy ne kerüljön sor az adatok idő előtti - véletlen vagy gondatlan - törlésére. A megfelelőségi követelmények teljesítéséhez a IBM Spectrum Protect for Data Retention további védelmet nyújt a IBM Spectrum Protect rendszer által archivált adatok számára.	• További információk és vásárlás • Termékdokumentáció Tipp: A termék dokumentációja a IBM Spectrum Protect rendszer dokumentációjának részét képezi.
IBM Spectrum Protect Snapshot	Integrált, alkalmazástudatos pillanatkép-mentési és -visszaállítási képességekkel védi az adatokat. Az IBM® DB2, SAP, Oracle, Microsoft Exchange és Microsoft SQL Server alkalmazás által tárolt adatok védelméről lehet a IBM Spectrum Protect Snapshot szoftverrel gondoskodni. A szoftver segítségével fájlrendszerek és egyéni alkalmazások kötetszintű pillanatképeinek létrehozását, valamint kezelését hajthatja végre. Eldöntheti, hogy kívánja-e integrálni a IBM Spectrum Protect Snapshot terméket a IBM Spectrum Protect rendszerrel.	• További információk és vásárlás • Termékdokumentáció

Termék	Legfontosabb előnyök	Hivatkozások
IBM Spectrum Protect for Databases	Automatizált feladatok, segédprogramok és felületek révén gondoskodik az Oracle és Microsoft SQL adatok védelméről. Ez a szoftver online, következetes és központosított biztonsági mentéseket készít, hogy elősegítse az állásidő elkerülését, a létfontosságú vállalati adatok védelmét, valamint a működési költségek minimális szintre való csökkentését. Tipp: Az IBM DB2 és IBM Informix adatbázisok online biztonsági mentésének támogatása a IBM Spectrum Protect kiszolgálók része. Ezen adatbázisok biztonsági mentéséhez nem szükséges telepítenie a IBM Spectrum Protect for Databases terméket. További információkért tekintse meg a DB2 és az Informix termékekhez kapcsolódó dokumentációt.	• További információk és vásárlás • Termékdokumentáció
IBM Spectrum Protect for Enterprise Resource Planning	Védelmet biztosít kifejezetten SAP rendszeradatok számára.	• További információk és vásárlás • Termékdokumentáció
IBM Spectrum Protect for Mail	Automatizálja az adatok védelmét, így a biztonsági mentések a Microsoft Exchange vagy IBM Domino kiszolgálók leállítása nélkül hajthatók végre.	• További információk és vásárlás • Termékdokumentáció
IBM Spectrum Protect for Space Management	Egy hierarchikus tárolókezelési termék, amely anélkül csökkenti a ritkán használt információk tárolási költségeit, hogy megváltoztatná a felhasználók és alkalmazások adataikkal való együttműködésének módját. Ez a termék AIX és Linux operációs rendszereken használható.	• További információk és vásárlás • Termékdokumentáció
IBM Spectrum Protect HSM for Windows	Egy hierarchikus tárolókezelési termék, amely anélkül csökkenti a ritkán használt információk tárolási költségeit, hogy megváltoztatná a felhasználók és alkalmazások adataikkal való együttműködésének módját. Ez a termék Windows operációs rendszereken használható.	• További információk és vásárlás • Termékdokumentáció
IBM Spectrum Protect for SAN	Kiszolgáló- és ügyfélszámítógépekkel működik együtt az adatok helyi hálózat (LAN) helyett tárolóhálózaton (SAN) keresztüli átvitele érdekében. A termék olyan tárolóügynök, amely LAN nélküli biztonsági mentési és visszaállítási műveleteket tesz lehetővé.	• További információk és vásárlás • Termékdokumentáció Termékdokumentáció verzió: Az IBM Spectrum Protect for SAN V7.1 dokumentációja a IBM Spectrum Protect V8.1 termékcsaládhoz készült.
IBM Spectrum Protect for Virtual Environments	VMware és Hyper-V virtuális környezetekre szabott védelmet biztosít.	• További információk és vásárlás • Termékdokumentáció
IBM Tivoli Storage Manager for z/OS Media	AIX vagy Linux on System z rendszereken futó IBM Spectrum Protect kiszolgálók z/OS lemez- és szalagerőforrásait kezeli.	• Termékdokumentáció

PDF fájlok

Az előregyártott PDF fájlokat letöltheti az IBM® tudásközpontból vagy egy FTP letöltési helyről.

Előregyártott PDF fájlok

A jelen kiadáshoz rendelkezésre álló előregyártott PDF fájlokért tekintse meg az alábbi témaköröket:

- Adatvédelmi megoldások

IBM Spectrum Protect concepts

IBM Spectrum Protect™ provides a comprehensive data protection environment.

- IBM Spectrum Protect overview
  IBM Spectrum Protect provides centralized, automated data protection that helps to reduce data loss and manage compliance with data retention and availability requirements.
- Data storage concepts in IBM Spectrum Protect
  IBM Spectrum Protect provides functions to store data in a range of device and media storage.
- Data protection strategies with IBM Spectrum Protect
  IBM Spectrum Protect provides ways for you to implement various data protection strategies.

IBM Spectrum Protect overview

IBM Spectrum Protect™ provides centralized, automated data protection that helps to reduce data loss and manage compliance with data retention and availability requirements.

- Data protection components
  The data protection solutions that IBM Spectrum Protect provides consist of a server, client systems and applications, and storage media. IBM Spectrum Protect provides management interfaces for monitoring and reporting the data protection status.
- Data protection services
  IBM Spectrum Protect provides data protection services to store and recover data from various types of clients. The data protection services are implemented through policies that are defined on the server. You can use client scheduling to automate the data protection services.

- Processes for managing data protection with IBM Spectrum Protect
  The IBM Spectrum Protect server inventory has a key role in the processes for data protection. You define policies that the server uses to manage data storage.
- User interfaces for the IBM Spectrum Protect environment
  For monitoring and configuration tasks, IBM Spectrum Protect provides various interfaces, including the Operations Center, a command-line interface, and an SQL administrative interface.

Data protection components

The data protection solutions that IBM Spectrum Protect™ provides consist of a server, client systems and applications, and storage media. IBM Spectrum Protect provides management interfaces for monitoring and reporting the data protection status.

Server

Client systems send data to the server to be stored as backups or archived data. The server includes an *inventory*, which is a repository of information about client data.

The inventory includes the following components:

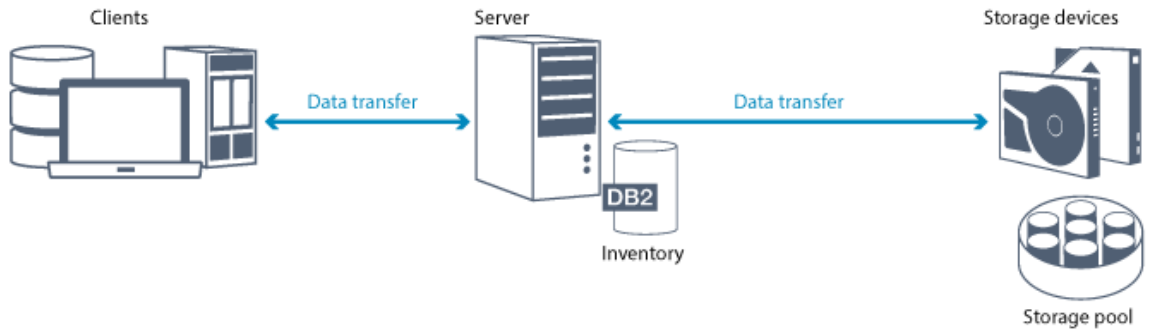
Database
: Information about each file, logical volume, or database that the server backs up, archives, or migrates is stored in the server database. The server database also contains information about the policy and schedules for data protection services.

Recovery log
: Records of database transactions are kept in this log. The database uses the recovery log to ensure data consistency in the database.

Client systems and applications

Clients are applications, virtual machines, and systems that must be protected. The clients send data to the server, as shown in Figure 1.

Figure 1. Components in the data protection solution



Client software
: For IBM Spectrum Protect to protect client data, the appropriate software must be installed on the client system and the client must be registered with the server.

Client nodes
: A *client node* is equivalent to a computer, virtual machine, or application, such as a backup-archive client that is installed on a workstation for file system backups. Each client node must be registered with the server. Multiple nodes can be registered on a single computer.

Storage media

The server stores client data to storage media. The following types of media are used:

Storage devices

: The server can write data to hard disk drives, disk arrays and subsystems, stand-alone tape drives, tape libraries, and other types of random-access and sequential-access storage. Storage devices can be connected directly to the server or

connected through a local area network (LAN) or a storage area network (SAN).

Storage pools

Storage devices that are connected to the server are grouped into *storage pools*. Each storage pool represents a set of storage devices of the same media type, such as disk or tape drives. IBM Spectrum Protect stores all of the client data in storage pools. You can organize storage pools into a *hierarchy*, so that data storage can transfer from disk storage to lower-cost storage such as tape devices.

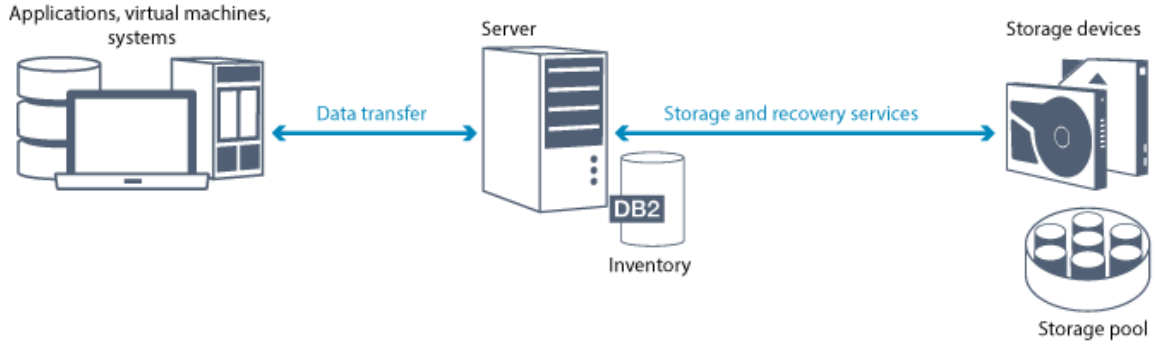
Data protection services

IBM Spectrum Protect™ provides data protection services to store and recover data from various types of clients. The data protection services are implemented through policies that are defined on the server. You can use client scheduling to automate the data protection services.

Types of data protection services

IBM Spectrum Protect provides services to store and recover client data as shown in Figure 1.

Figure 1. Data protection services



IBM Spectrum Protect provides the following types of data protection services:

Back up and restore services

You run a backup process to create a copy of a *data object* that can be used for recovery if the original data object is lost. A data object can be a file, a directory, or a user-defined data object, such as a database.

To minimize the use of system resources during the backup operation, IBM Spectrum Protect uses the *progressive incremental backup* method. For this backup method, a first full backup of all data objects is created and in subsequent backup operations only changed data is moved to storage. Compared to incremental and differential backup methods that require taking periodic full backups, the progressive incremental backup method provides the following benefits:

- Reduces data redundancy
- Uses less network bandwidth
- Requires less storage pool space

To further reduce storage capacity requirements and network bandwidth usage, IBM Spectrum Protect includes *data deduplication* for data backups. The data deduplication technique removes duplicate data extents from backups.

You run a restore process to copy an object from a storage pool to the client. You can restore a single file, all files in a directory, or all of the data on a computer.

Archive and retrieve services

You use the archive service to preserve data that must be stored for a long time, such as for regulatory compliance. The archive service provides the following features:

- When you archive data, you specify how long the data must be stored.
- You can request that files and directories are copied to long-term storage on media. For example, you might choose to store this data on a tape device, which can reduce the cost of storage.
- You can specify that the original files are erased from the client after the files are archived.

The retrieve service provides the following features:

- When you retrieve data, the data is copied from a storage pool to a client node.
- The retrieve operation does not affect the archive copy in the storage pool.

Migrate and recall services
: You use migrate and recall services to manage space on client systems. The goal of space management is to maximize available media capacity for new data and to minimize access time to data. You can migrate data to server storage to maintain sufficient free storage space on a local file system. You can store migrated data in the following ways:

  - On disk storage for long-term storage
  - In a *virtual tape library* (VTL) for fast recall of files

  You can recall files to the client node on demand, either automatically or selectively.

Types of client data that can be protected

You can protect data for the following types of clients with IBM Spectrum Protect:

Application clients
: IBM Spectrum Protect can protect data for specific products or applications. These clients are called *application clients*. To protect the *structured data* for these clients, in other words the data in database fields, you must back up components that are specific to the application. IBM Spectrum Protect can protect the following applications:

  - IBM Spectrum Protect for Enterprise Resource Planning clients:
    - Data Protection for SAP HANA
    - Data Protection for SAP for DB2®
    - Data Protection for SAP for Oracle
  - IBM Spectrum Protect for Databases clients:
    - Data Protection for Microsoft SQL server
    - Data Protection for Oracle
  - IBM Spectrum Protect for Mail clients:
    - Data Protection for IBM® Domino®
    - Data Protection for Microsoft Exchange Server

Virtual machines
: Virtual machines that are backed up by using application client software that is installed on the virtual machine. In the IBM Spectrum Protect environment, a virtual machine can be protected by the IBM Spectrum Protect for Virtual Environments.

System clients
: The following IBM Spectrum Protect clients are called *system clients*:

  - All clients that back up data in files and directories, in other words *unstructured data*, such as backup-archive clients and API clients that are installed on workstations.
  - A server that is included in a server-to-server virtual volume configuration.
  - A virtual machine that is backed up by using backup-archive client software that is installed on the virtual machine.

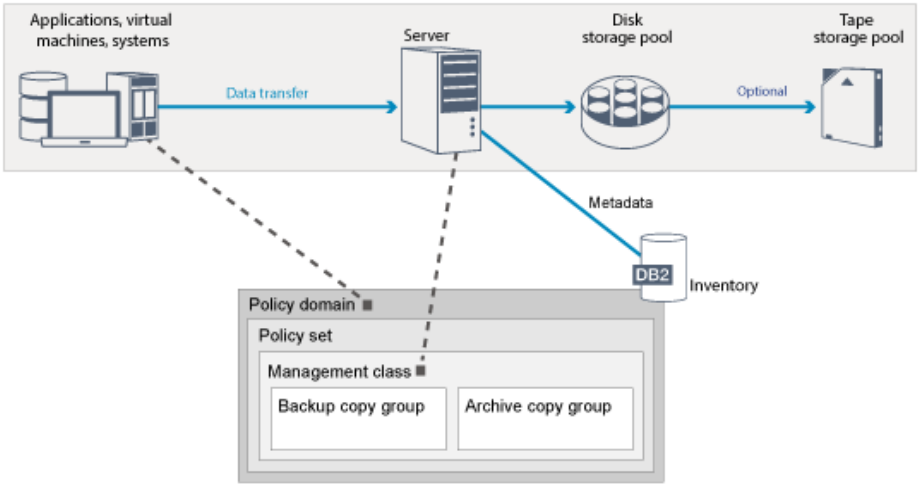
Processes for managing data protection with IBM Spectrum Protect

The IBM Spectrum Protect™ server inventory has a key role in the processes for data protection. You define policies that the server uses to manage data storage.

Data management process

Figure 1 shows the IBM Spectrum Protect data management process.

Figure 1. Data management process



IBM Spectrum Protect uses policies to control how the server stores and manages data objects on various types of storage devices and media. You associate a client with a policy domain that contains one active policy set. When a client backs up, archives, or migrates a file, the file is bound to a management class in the active policy set of the policy domain. The management class and the backup and archive copy groups specify where files are stored and how they are managed. If you set up server storage in a hierarchy, you can migrate files to different storage pools.

Inventory components

The following inventory components are key to the operation of the server:

Server database
: The server database contains information about client data and server operations. The database stores information about client data, called *metadata*. Information about client data includes the file name, file size, file owner, management class, copy group, and location of the file in server storage. The database includes the following information that is necessary for the operation of the server:

- Definitions of client nodes and administrators
- Policies and schedules
- Server settings
- Records of server operations, such as activity logs and event records
- Intermediate results for administrative queries

Recovery log
: The server records database transactions in the recovery log. The recovery log helps to ensure that a failure does not leave the database in an inconsistent state. The recovery log is also used to maintain consistency across server start operations. The recovery log consists of the following logs:

  Active log
  : This log records current transactions on the server. This information is required to start the server and database after a disaster.

  Log mirror (optional)
  : The active log mirror is a copy of the active log that can be used if the active log files cannot be read. All changes that are made to the active log are also written to a log mirror. You can set up one active log mirror.

  Archive log
  : The archive log contains copies of closed log files that were in the active log. The archive log is included in database backups and is used for recovery of the server database. Archive log files that are included in a database backup are automatically pruned after a full database backup cycle is complete. The archive log must have enough space to store the log files for database backups.

  Archive failover log (optional)
  : The archive failover log, also called a secondary archive log, is the directory that the server uses to store archive log files when the archive log directory is full.

Policy-based data management

In the IBM Spectrum Protect environment, a *policy* for data protection management contains rules that determine how client data is stored and managed. The primary purpose of a policy is to implement the following data management objectives:

- Control which storage pool client data is initially stored in
- Define retention criteria that controls how many copies of objects are stored
- Define how long copies of objects are retained

Policy-based data management helps you to focus on the business requirements for protecting data rather than on managing storage devices and media. Administrators define policies and assign client nodes to a *policy domain*.

Depending on your business needs, you can have one policy or many. In a business organization, for example, different departments with different types of data can have customized storage management plans. Policies can be updated, and the updates can be applied to data that is already managed.

When you install IBM Spectrum Protect, a default policy that is named STANDARD is already defined. The STANDARD policy provides basic backup protection for user workstations. To provide different levels of service for different clients, you can add to the default policy or create a new policy.

You create policies by defining the following policy components:

Policy domain
: The policy domain is the primary organizational method of grouping client nodes that share common rules for data management. Although a client node can be defined to more than one server, the client node can be defined to only one policy domain on each server.

Policy set
: A *policy set* is a number of policies that are grouped so that the policy for the client nodes in the domain can be activated or deactivated as required. An administrator uses a policy set to implement different management classes based on business and user needs. A policy domain can contain multiple policy sets, but only one policy set can be active in the domain. Each policy set contains a default management class and any number of extra management classes.

Management class
: A *management class* is a policy object that you can bind to each category of data to specify how the server manages the data. There can be one or more management classes. One management class is assigned to be the default management class that is used by clients unless they specifically override the default to use a specific management class.

  The management class can contain a backup copy group, an archive copy group, and space management attributes. A copy group determines how the server manages backup versions or archived copies of the file. The space management attributes determine whether the file is eligible for migration by the space manager client to server storage, and under what conditions the file is migrated.

Copy group
: A *copy group* is a set of attributes in a management class that controls the following factors:

  - Where the server stores versions of backed up files or archive copies
  - How long the server keeps versions of backed up files or archive copies
  - How many versions of backup copies are retained
  - What method to use to generate versions of backed up files or archive copies

Security management

IBM Spectrum Protect includes security features for registration of administrators and users. After administrators are registered, they must be granted authority by being assigned one or more administrative privilege classes. An administrator with system privilege can perform any server function. Administrators with policy, storage, operator, or node privileges can perform subsets of server functions. The server can be accessed by using the following methods, each controlled with a password:

- Administrator access to manage the server
- Client access to nodes to store and retrieve data

Also included are features that can help to ensure security when clients connect to the server. Depending on business requirements, as an administrator, you can choose one of the following client registration methods:

Open registration
: When the client first connects to the server, the user is requested for a node name, password, and contact information. Open registration provides the user with following default settings:

  - The client node is assigned to the STANDARD policy domain.
  - The user can define whether files are compressed to decrease the amount of data that is sent over networks and the space that is occupied by the data in storage.

- The user can delete archived copies of files from server storage, but not backup versions of files.

Closed registration
: Closed registration is the default method for client registration to the server. For this type of registration, an administrator registers all clients. The administrator can implement the following settings:

  - Assign the node to any policy domain
  - Determine whether the user can use compression or not, or if the user can choose
  - Control whether the user can delete backed up files or archived files

You can add more protection for your data and passwords by using Secure Sockets Layer (SSL). SSL is the standard technology that you use to create encrypted sessions for servers and clients, and provides a secure channel to communicate over open communication paths. With SSL, the identity of the server is verified by using digital certificates. If you authenticate with a Lightweight Directory Access Protocol (LDAP) server, passwords between the server and the LDAP server are protected by Transport Layer Security (TLS). The TLS protocol is the successor to the SSL protocol. When a server and client communicate, TLS ensures that third parties cannot intercept messages.

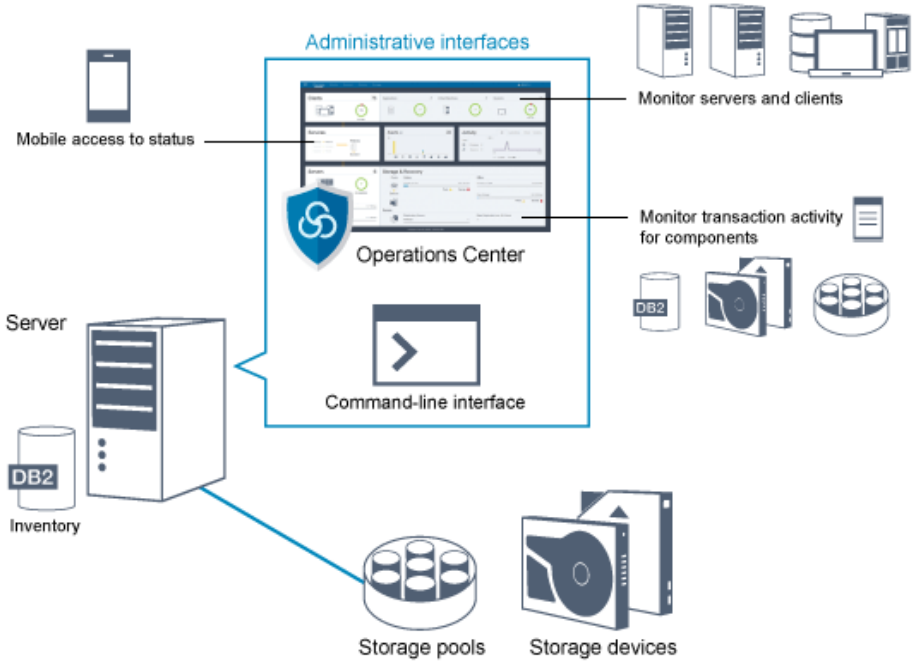
User interfaces for the IBM Spectrum Protect environment

For monitoring and configuration tasks, IBM Spectrum Protect™ provides various interfaces, including the Operations Center, a command-line interface, and an SQL administrative interface.

Interfaces for data storage management

The Operations Center is the primary interface for administrators to monitor and administer servers. A key benefit of the Operations Center is that you can monitor multiple servers, as shown in Figure 1. You can also monitor and administer IBM Spectrum Protect from a command-line administrative interface.

Figure 1. User interfaces for data storage management



You use the following interfaces to interact with IBM Spectrum Protect:

Operations Center
: The Operations Center provides web and mobile access to status information about the IBM Spectrum Protect environment. You can use the Operations Center to complete monitoring and certain administration tasks, for example:

  - You can monitor multiple servers and clients.
  - You can monitor the transaction activity for specific components in the data path, such as the server database, the recovery log, storage devices, and storage pools.

Command-line interface

You can use a command-line interface to run administration tasks for servers. You can access the command-line interface through either the IBM Spectrum Protect administrative client or the Operations Center.

Access to information in the server database by using SQL statements

You can use SQL SELECT statements to query the server database and display the results. Third-party SQL tools are available to aid administrators in database management.

Interfaces for client activity management

IBM Spectrum Protect provides the following types of interfaces for managing client activity:

- An application programming interface (API)
- Graphical user interfaces for clients
- Browser interface for the backup-archive client
- Command-line interfaces for clients

Data storage concepts in IBM Spectrum Protect

IBM Spectrum Protect™ provides functions to store data in a range of device and media storage.

To make storage devices available to the server, you must attach the storage devices and map storage pools to device classes, libraries, and drives.

- Types of storage devices
  You can use various storage devices with IBM Spectrum Protect to meet specific data protection goals.
- Data storage in storage pools
  Logical storage pools are the principal components in the IBM Spectrum Protect model of data storage. You can optimize the usage of storage devices by manipulating the properties of storage pools and volumes.
- Data transport to storage across networks
  The IBM Spectrum Protect environment provides ways to securely move data to storage across various types of networks and configurations.

Types of storage devices

You can use various storage devices with IBM Spectrum Protect™ to meet specific data protection goals.

Storage devices and storage objects

The IBM Spectrum Protect server can connect to a combination of manual and automated storage devices. You can connect the following types of storage devices to IBM Spectrum Protect:

- Disk devices that are directly attached, SAN-attached, or network attached
- Physical tape devices that are either manually operated or automated
- Virtual tape devices
- Cloud object storage

IBM Spectrum Protect represents physical storage devices and media with storage objects that you define in the server database. Storage objects classify available storage resources and manage migration from one storage pool to another. Table 1 describes the storage objects in the server storage environment.

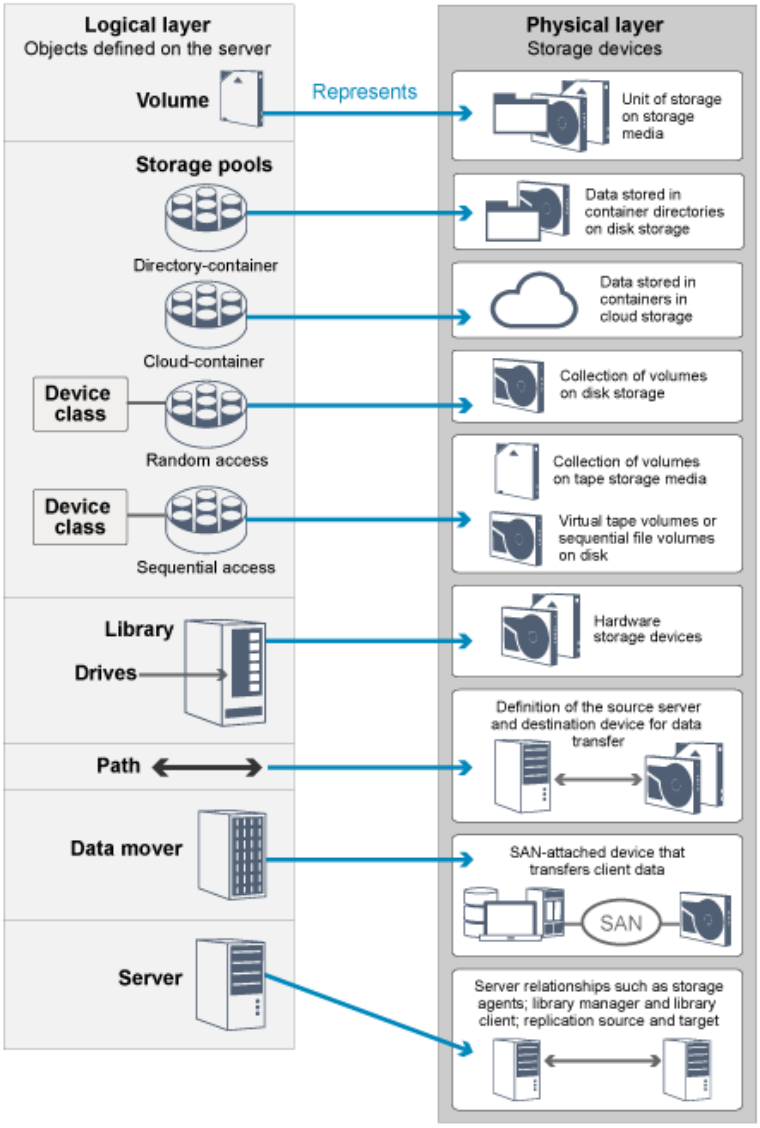
Table 1. Storage objects and representations

Storage object	What the object represents
Volume	A discrete unit of storage on disk, tape, or other storage media. Each volume is associated with a single storage pool.

Storage object	What the object represents
Storage pool	A set of storage volumes or containers that is the destination that is used to store client data. IBM Spectrum Protect uses the following types of storage pool: • Directory-container storage pools • Cloud-container storage pools • Sequential-access storage pools that are associated with a device class • Random-access storage pools that are associated with a device class
Container	A data storage location, for example, a file, directory, or device.
Container storage pool	A primary storage pool that a server uses to store data. Data is stored in containers in file system directories or in cloud storage. Data is deduplicated, if necessary, as the server writes data to the storage pool.
Device class	The type of storage device that can use the volumes that are defined in a sequential-access or random-access storage pool. Each device class of removable media type is associated with a single library.
Library	A storage device. For example, a library can represent a stand-alone drive, a set of stand-alone drives, a multiple-drive automated device, or a set of drives that is controlled by a media manager.
Drive	An object of a tape library device that provides the capability to read and write data to tape library media. Each drive is associated with a single library.
Path	The specification of the data source and the device destination. Before a storage device can be used, a path must be defined between the device and the source server that is moving data.
Data mover	A SAN-attached device that is used to transfer client data. A data mover is used only in a data transfer where the server is not present, such as in a Network Data Management Protocol (NDMP) environment. Data movers transfer data between storage devices without using significant server, client, or network resources.
Server	A server that is managed by another IBM Spectrum Protect server.

The administrator defines the storage objects in the logical layer of the server, as illustrated in Figure 1.

Figure 1. Storage objects



Disk devices

You can store client data on disk devices with the following types of volumes:

- Directories in directory-container storage pools
- Random-access volumes of device type DISK
- Sequential-access volumes of device type FILE

IBM Spectrum Protect offers the following features when you use directory-container storage pools for data storage:

- You can apply data deduplication and disk caching techniques to maximize data storage usage.
- You can retrieve data from disk much faster than you can retrieve data from tape storage.

Physical tape devices

In a physical tape library, the storage capacity is defined in terms of the total number of volumes in the library. Physical tape devices can be used for the following activities:

- Storing client data that is backed up, archived, or migrated from client nodes
- Storing database backups
- Exporting data to another server or offsite storage

Moving data to tape provides the following benefits:

- You can keep data for clients on a disk device at the same time that the data is moved to tape.
- You can improve tape drive performance by streaming the data migration from disk to tape.

- You can spread out the times when the drives are in use to improve the efficiency of the tape drives.
- You can move data on tape to off-site vaults.
- You can limit power consumption because tape devices do not consume power after data is written to tape.
- You can apply encryption that is provided by the tape drive hardware to protect the data on tape.

Compared to equivalent disk and virtual tape storage, the unit cost to store data tends to be much less for physical tape devices.

Virtual tape libraries

A virtual tape library (VTL) does not use physical tape media. When you use VTL storage, you emulate the access mechanisms of tape hardware. In a VTL, you can define volumes and drives to provide greater flexibility for the storage environment. The storage capacity of a VTL is defined in terms of total available disk space. You can increase or decrease the number and size of volumes on disk.

Defining a VTL to the IBM Spectrum Protect server can improve performance because the server handles mount point processing for VTLs differently than for real tape libraries. Although the logical limitations of tape devices are still present, the physical limitations for tape hardware are not applicable to a VTL thus affording better scalability. You can use the IBM Spectrum Protect VTL when the following conditions are met:

- Only one type and generation of drive and media is emulated in the VTL.
- Every server and storage agent with access to the VTL has paths that are defined for all drives in the library.

Data storage in storage pools

Logical storage pools are the principal components in the IBM Spectrum Protect™ model of data storage. You can optimize the usage of storage devices by manipulating the properties of storage pools and volumes.

Types of storage pools

The group of storage pools that you set up for the server is called *server storage*. You can define the following types of storage pools in server storage:

Primary storage pools
: A named set of volumes that the server uses to store backup versions of files, archive copies of files, and files that are migrated from client nodes.

Copy storage pools
: A named set of volumes that contain copies of files that reside in primary storage pools. Copy storage pools are used only to back up the data that is stored in primary storage pools. A copy storage pool cannot be a destination for a backup copy group, an archive copy group, or a management class for space-managed files.

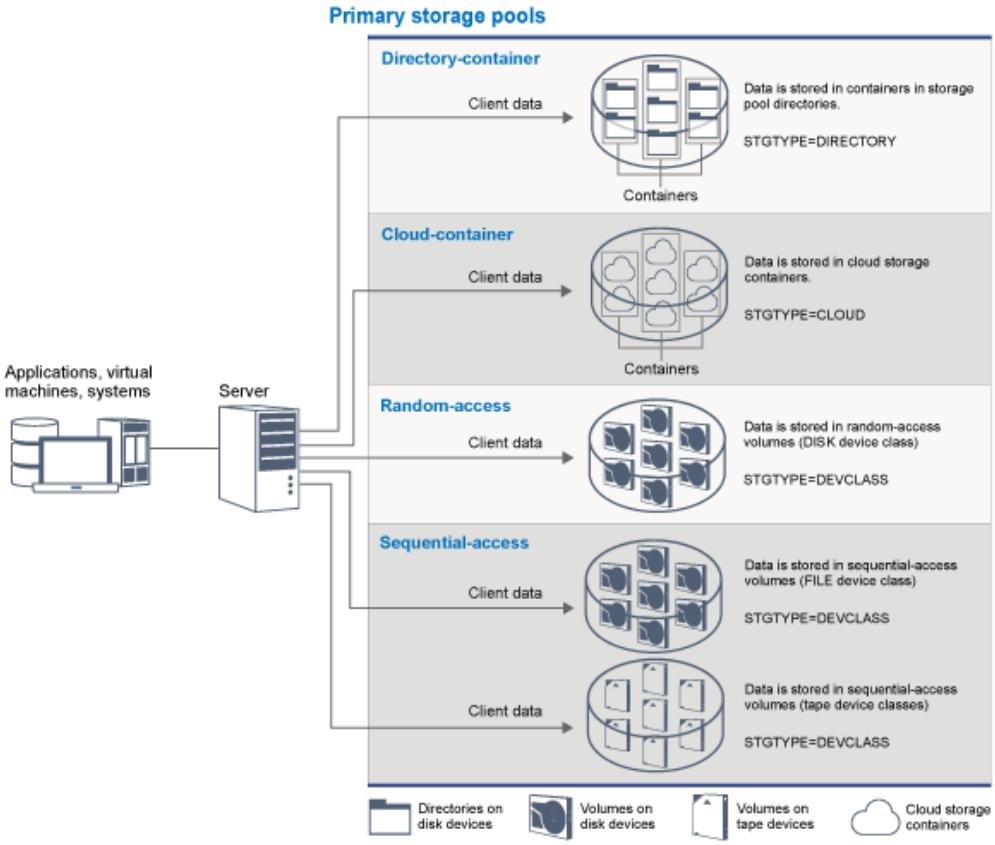
Container-copy storage pools
: A named set of volumes that contain a copy of data extents that reside in directory-container storage pools. Container-copy storage pools are used only to protect the data that is stored in directory-container storage pools.

Active-data storage pools
: A named set of storage pool volumes that contain only active versions of client backup data.

Primary storage pools

When you restore, retrieve, recall, or export file data, the requested file is obtained from a primary storage pool. Depending on the type of primary storage pool, the storage pools can be onsite or offsite. You can arrange primary storage pools in a storage hierarchy so that data can be transferred from disk storage to lower-cost storage such as tape devices. Figure 1 illustrates the concept of primary storage pools.

Figure 1. Primary storage pools



You can define the following types of primary storage pool:

Directory-container storage pools

A storage pool that the server uses to store data in containers in storage pool directories. Data that is stored in a directory-container storage pool can use either inline data deduplication, client-side data deduplication, inline compression, or client-side compression. Inline data deduplication or inline compression reduces data at the time it is stored. By using directory-container storage pools, you remove the need for volume reclamation, which improves server performance and reduces the cost of storage hardware. You can protect and repair data in directory-container storage pools at the level of the storage pool.

Restriction: You cannot use any of the following functions with directory-container storage pools:

- Migration
- Reclamation
- Aggregation
- Collocation
- Simultaneous-write
- Storage pool backup
- Virtual volumes

Cloud-container storage pools

A storage pool that a server uses to store data in cloud storage. The cloud storage can be on premises or off premises. The cloud-container storage pools that are provided by IBM Spectrum Protect can store data to cloud storage that is object-based. By storing data in cloud-container storage pools, you can exploit the cost per unit advantages that clouds offer along with the scaling capabilities that cloud storage provides. IBM Spectrum Protect manages the credentials, security, read and write I/Os, and the lifecycle for data that is stored to the cloud. When cloud-container storage pools are implemented on the server, you can write directly to the cloud by configuring a cloud-container storage pool with the cloud credentials. Data that is stored in a cloud-container storage pool can use both inline data deduplication and inline compression. The server writes deduplicated and encrypted data directly to the cloud. You can back up and restore data or archive and retrieve data directly from the cloud-container storage pool.

You can define the following types of cloud-container storage pools:

On premises

You can use the on premises type of cloud-container storage pool to store data in a private cloud, for more security and maximum control over your data. The disadvantages of a private cloud are higher costs due to hardware requirements and onsite maintenance.

Off premises

You can use the off premises type of cloud-container storage pool to store data in a public cloud. The advantage of using a public cloud is that you can achieve lower costs than for a private cloud, for example by eliminating maintenance. However, you must balance this benefit against possible performance issues due to connection speeds and reduced control over your data.

Storage pools that are associated with device classes

You can define a primary storage pool to use the following types of storage devices:

DISK device class

In a DISK device type of storage pool, data is stored in random access disk blocks. You can use caching in DISK storage pools to increase client restore performance with some limitations on server processing. Space allocation and tracking by blocks uses more database storage space and requires more processing power than allocation and tracking by volume.

FILE device class

In a FILE device type of storage pool, files are stored in sequential volumes for better sequential performance than for storage in disk blocks. To the server, these files have the characteristics of a tape volume so that this type of storage pool is better suited for migration to tape. FILE volumes are useful for *electronic vaulting*, where data is transferred electronically to a remote site rather than by physical shipment of tape. In general, this type of storage pool is preferred over DISK storage pools.

The server uses the following default random-access primary storage pools:

ARCHIVEPOOL

In the STANDARD policy, this storage pool is the destination for files that are archived from client nodes.

BACKUPPOOL

In the STANDARD policy, this storage pool is the destination for files that are backed up from client nodes.

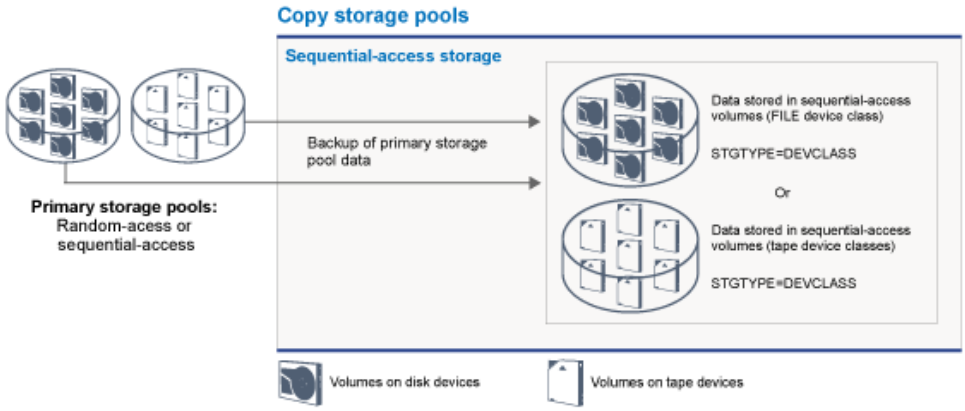
SPACEMGPOOL

This storage pool is for space-managed files that are migrated from IBM Spectrum Protect for Space Management client nodes.

Copy storage pools

Copy storage pools contain active and inactive versions of data that is backed up from primary storage pools. A directory-container storage pool cannot be used as a copy storage pool. In addition, data from a directory-container storage pool cannot be copied into a copy storage pool. To protect directory-container storage pools, copy the data to a container-copy storage pool. Figure 2 illustrates the concept of copy storage pools.

Figure 2. Copy storage pools



Copy storage pools provide a means of recovering from disasters or media failures. For example, when a client attempts to retrieve a damaged file from the primary storage pool, the client can restore the data from the copy storage pool.

You can move the volumes of copy storage pools offsite and still have the server track the volumes. Moving these volumes offsite provides a means of recovering from an onsite disaster. A copy storage pool can use sequential-access storage only, such as a tape device class or FILE device class.

Container-copy storage pools

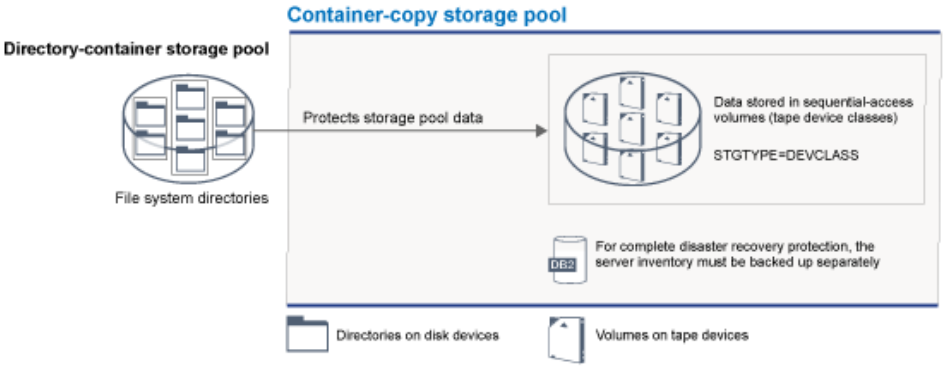
A server can protect a directory-container storage pool by storing copies of the data in a container-copy storage pool. Data in container-copy storage pools is stored on tape volumes, which can be stored onsite or offsite. Damaged data in directory-container storage pools can be repaired by using deduplicated extents in container-copy storage pools. Container-copy storage pools provide an alternative to using a replication server to protect data in a directory-container storage pool.

Restriction: If all server data is lost, container-copy storage pools alone do not provide the same level of protection as replication:

- With replication, you can directly restore client data from the target server if the source server is unavailable.
- With container-copy storage pools, you must first restore the server from a database backup and then repair directory-container storage pools from tape volumes.

Figure 3 illustrates the concept of container-copy storage pools.

Figure 3. Container-copy storage pools



Depending on your system configuration, you can create protection schedules to simultaneously copy the directory-container storage pool data to onsite or offsite container-copy storage pools to meet your requirements:

- If replication is enabled, you can create one offsite container-copy pool. The offsite copy can be used to provide extra protection in a replicated environment.
- If replication is not enabled, you can create one onsite and one offsite storage pool.

Depending on the resources and requirements of your site, the ability to copy directory-container storage pools to tape has the following benefits:

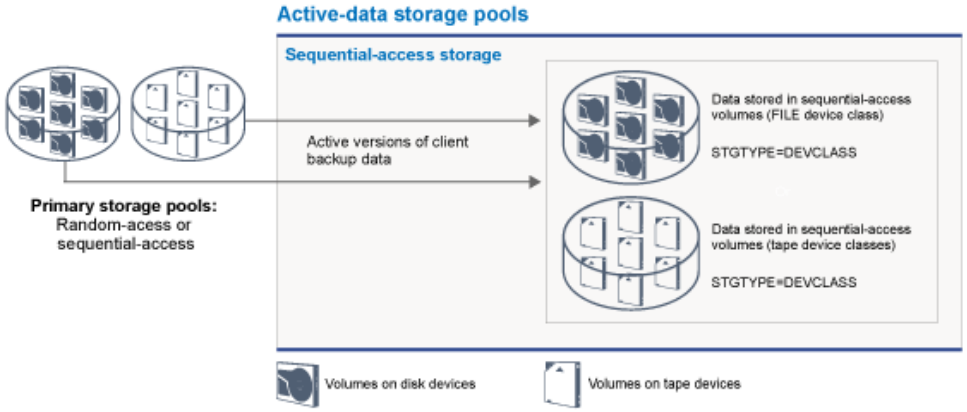
- You avoid maintaining another server and more disk storage space.
- Data is copied to storage pools that are defined on the server. Performance is not dependent on, or affected by, the network connection between servers.
- You can satisfy regulatory and business requirements for offsite tape copies.

Active-data storage pools

An active-data pool contains only active versions of client backup data. In this case, the server does not have to position past inactive files that do not have to be restored. A directory-container storage pool cannot be used as an active-data storage pool. You use active-data pools to improve the efficiency of data storage and restore operations, for example this type of storage pool can help you to achieve the following objectives:

- Increase the speed of client data restore operations
- Reduce the number of onsite or offsite storage volumes
- Reduce the amount of data that is transferred when you copy or restore files that are vaulted electronically in a remote location

Data that is migrated by hierarchical storage management (HSM) clients and archive data are not permitted in active-data pools. As updated versions of backup data are stored in active-data pools, older versions are removed as the remaining data is consolidated from many sequential-access volumes onto fewer, new sequential-access volumes. Figure 4 illustrates the concept of active-data storage pools.
Figure 4. Active-data storage pools



Active-data pools can use any type of sequential-access storage. However, the benefits of an active-data pool depend on the device type that is associated with the pool. For example, active-data pools that are associated with a FILE device class are ideal for fast client restore operations because of the following reasons:

- FILE volumes do not have to be physically mounted
- Client sessions that are restoring from FILE volumes in an active-data pool can access the volumes concurrently, which improves restore performance

Directory-container storage pools FAQs

Cloud-container storage pools FAQs

Data transport to storage across networks

The IBM Spectrum Protect™ environment provides ways to securely move data to storage across various types of networks and configurations.

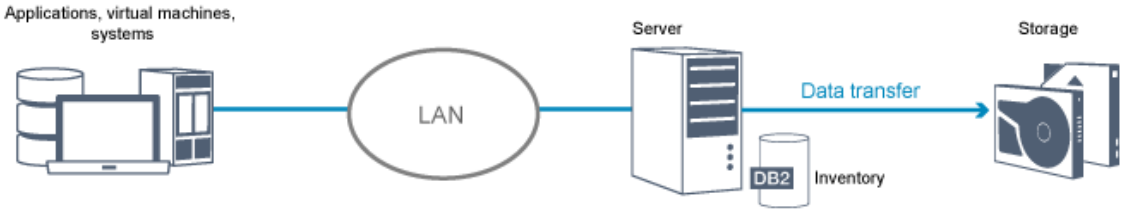
Network configurations for storage devices

IBM Spectrum Protect provides methods for configuring clients and servers on a local area network (LAN), on a storage area network (SAN), LAN-free data movement, and as network-attached storage.

Data backup operations over a LAN

Figure 1 shows the data path for IBM Spectrum Protect backup operations over a LAN.

Figure 1. IBM Spectrum Protect backup operations over a LAN

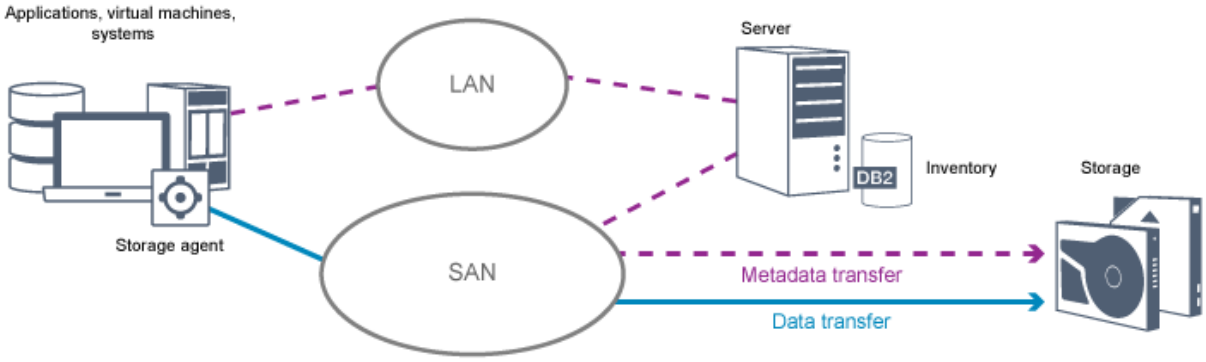


In a LAN configuration, one or more tape libraries are associated with a single IBM Spectrum Protect server. In this type of configuration, client data, electronic mail, terminal connection, application program, and device control information must all be handled by the same network. Device control information and client backup and restore data flow across the LAN.

Data backup operations over a SAN

Figure 2 shows the data path for IBM Spectrum Protect backup operations over a SAN.

Figure 2. IBM Spectrum Protect backup operations over a SAN



A SAN is a dedicated storage network that can improve system performance. On a SAN, you can consolidate storage and relieve the distance, scalability, and bandwidth limitations of LANs and wide area networks (WANs). By using IBM Spectrum Protect in a SAN, you can take advantage of the following functions:

- Share storage devices among multiple IBM Spectrum Protect servers. Devices that use the GENERICTAPE device type are not included.
- Move data from a client system directly to storage devices without using the LAN. LAN-free data movement requires the installation of a storage agent on the client system. The storage agent is available with the IBM Spectrum Protect for SAN product.

  Through the storage agent, the client can directly back up and restore data to a tape library or shared file system such as GPFS™. The IBM Spectrum Protect server maintains the server database and recovery log, and acts as the library manager to control device operations. The storage agent on the client handles the data transfer to the device on the SAN. This implementation frees bandwidth on the LAN that would otherwise be used for client data movement.

- Share tape drives and libraries that are supported by the IBM Spectrum Protect server.
- Consolidate multiple clients under a single client node name in a General Parallel File System (GPFS) cluster.

Network-attached storage

Network-attached storage (NAS) file servers are dedicated storage servers whose operating systems are optimized for file-serving functions. NAS file servers typically interact with IBM Spectrum Protect through industry-standard network protocols, such as network data management protocol (NDMP) or as primary storage for random-access or sequential access storage pools. IBM Spectrum Protect provides the following basic types of configurations that use NDMP for backing up and managing NAS file servers:

- IBM Spectrum Protect backs up a NAS file server to a library device that is directly attached to the NAS file server. The NAS file server, which can be remote from the IBM Spectrum Protect server, transfers backup data directly to a drive in a SCSI-attached tape library. Data is stored in NDMP-formatted storage pools, which can be backed up to storage media that can be moved offsite for protection in case of an onsite disaster.
- IBM Spectrum Protect backs up a NAS file server over the LAN to a storage-pool hierarchy. In this type of configuration, you can store NAS data directly to disk, either random access or sequential access, and then migrate the data to tape. You can also use this type of configuration for system replication. Data can also be backed up to storage media that can be moved offsite. The advantage of this type of configuration is that you have all of the data management features associated with a storage pool hierarchy.
- The IBM Spectrum Protect client reads the data from the NAS system by using NFS or CIFS protocols and sends the data to the server to be stored.

Storage management

You manage the devices and media that are used to store client data through the IBM Spectrum Protect server. The server integrates storage management with the policies that you define for managing client data in the following areas:

Types of devices for server storage

With IBM Spectrum Protect, you can use directly attached devices and network-attached devices for server storage. IBM Spectrum Protect represents physical storage devices and media with administrator-defined storage objects.

Data migration through the storage hierarchy

For primary storage pools other than directory-container storage pools, you can organize the storage pools into one or more hierarchical structures. This storage hierarchy provides flexibility in a number of ways. For example, you can set a policy to back up data to disks for faster backup operations. The IBM Spectrum Protect server can then automatically migrate data from disk to tape.

Removal of expired data

The policy that you define controls when client data automatically expires from the IBM Spectrum Protect server. To remove data that is eligible for expiration, a server expiration process marks data as expired and deletes metadata for the expired data from the database. The space that is occupied by the expired data is then available for new data. You can control the frequency of the expiration process by using a server option.

Media reuse by reclamation

As server policies automatically expire data, the media where the data is stored accumulates unused space. For storage media other than directory-container storage pools or random disk storage pools, the IBM Spectrum Protect server implements *reclamation*, a process that frees media for reuse without traditional tape rotation. Reclamation automatically defragments media by consolidating unexpired data onto other media when the free space on media reaches a defined level. The reclaimed media can then be used again by the server. Reclamation allows media to be automatically circulated through the storage management process and minimize the number of media that are required.

Consolidating backed up client data

By grouping the client data that is backed up, you can minimize the number of media mounts required for client recovery. The IBM Spectrum Protect server provides the following methods for grouping client files on storage media other than directory-container storage pools:

Collocating client data

The IBM Spectrum Protect server can *collocate* client data, in other words store client data on a few volumes instead of spreading the data across many volumes. Collocation by client minimizes the number of volumes that are required to back up and restore client data. Data collocation might increase the number of volume mounts because each client might have a dedicated volume instead of data storage from several clients in the same volume.

You can set the server to collocate client data when the data is initially placed in server storage. In a storage hierarchy, you can collocate the data when the server migrates the data from the initial storage pool to the next storage pool in the storage hierarchy. You can collocate by client, by file space per client, or by a group of clients. Your selection depends on the size of the file spaces that are stored and restore requirements.

Associating active-data pools with various devices

Active-data pools are useful for fast restoration of client data. Benefits include a reduction in the number of onsite or offsite storage volumes, or reducing bandwidth when you copy or restore files that are vaulted electronically in a remote location. Active-data pools that use removable media, such as tape, offer similar benefits. Although tape devices must be mounted, the server does not have to position past inactive files. However, the primary benefit of using removable media in active-data pools is that the number of volumes that are used for onsite and offsite storage is reduced. If you store data to a remote location, you can minimize the amount of data that must be transferred by copying and restoring only active data.

Creating a backup set

A backup set contains all of the active backed-up files that exist for that client in server storage. The backup set is portable and is retained for the time that you specify. A backup set is in addition to the backups that are already stored and requires extra media.

Moving data for a client node

You can consolidate data for a client node by moving the data within server storage. You can move a backup set to different media, where the backup set is retained until the time that you specify. Consolidating data can help to improve efficiency during client restore or retrieve operations.

Data protection strategies with IBM Spectrum Protect

IBM Spectrum Protect™ provides ways for you to implement various data protection strategies.

You can configure IBM Spectrum Protect to send data to storage devices that are on the local site or on a remote site. To maximize data protection, you can configure replication to a remote server.

- Strategies to minimize the use of storage space for backups
  To minimize the amount of storage space that is required, IBM Spectrum Protect backs up data by using the data deduplication and progressive incremental backup techniques.
- Strategies for disaster protection
  IBM Spectrum Protect provides strategies to protect data if a disaster occurs. These strategies include node replication to a

remote site, storage pool protection, database backups, moving backup tapes offsite, and device replication to a standby server.

- Strategies for disaster recovery with IBM Spectrum Protect
  IBM Spectrum Protect provides several ways to recover the server if the database or storage pools fail.

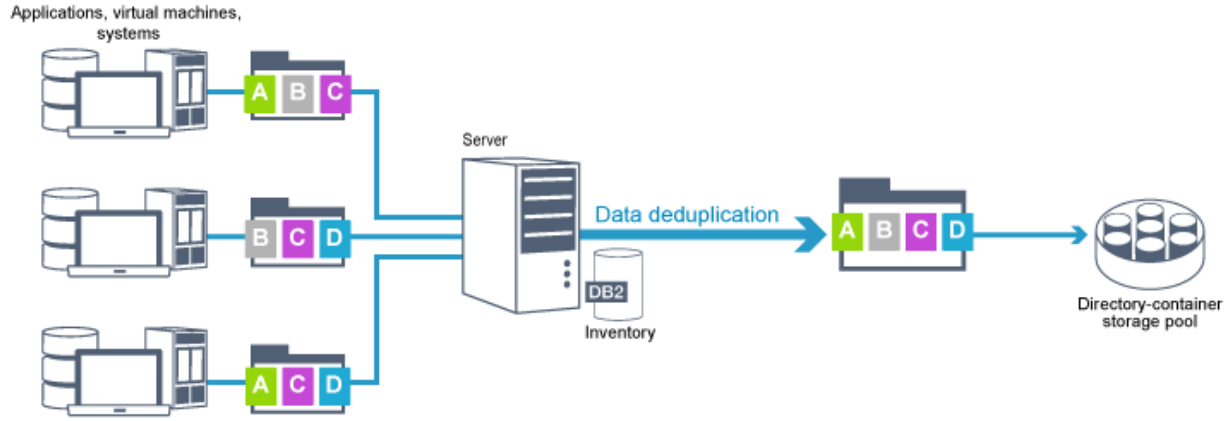
Strategies to minimize the use of storage space for backups

To minimize the amount of storage space that is required, IBM Spectrum Protect™ backs up data by using the data deduplication and progressive incremental backup techniques.

Data deduplication

When the IBM Spectrum Protect server receives data from a client, the server identifies duplicate data extents and stores unique instances of the data extents in a directory-container storage pool. The data deduplication technique improves storage utilization and eliminates the need for a dedicated data deduplication appliance.

Figure 1. Data deduplication process



If the same byte pattern occurs many times, data deduplication greatly reduces the amount of data that must be stored or transferred. In addition to whole files, IBM Spectrum Protect can also deduplicate parts of files that are common with parts of other files.

IBM Spectrum Protect provides the following types of data deduplication:

Server-side data deduplication
: The server identifies duplicate data extents and moves the data to a directory-container storage pool. The server-side process uses *inline data deduplication*, where data is deduplicated at the same time that the data is written to a directory-container storage pool. Deduplicated data can also be stored in other types of storage pools. Inline data deduplication on the server provides the following benefits:

  - Eliminates the need for reclamation
  - Reduces the space that is occupied by the stored data

Client-side data deduplication
: With this method, processing is distributed between the server and the client during a backup process. The client and the server identify and remove duplicate data to save storage space on the server. In client-side data deduplication, only compressed, deduplicated data is sent to the server. The server stores the data in the compressed format that is provided by the client. Client-side data deduplication provides the following benefits:

  - Reduces the amount of data that is sent over the local area network (LAN)
  - Eliminates extra processing power and time that is required to remove duplicate data on the server
  - Improves database performance because the client-side data deduplication is also inline

You can combine both client-side and server-side data deduplication in the same production environment. The ability to deduplicate data on either the client or the server provides flexibility in terms of resource utilization, policy management, and data protection.

Compression

Use inline compression to reduce the amount of space that is stored in container storage pools. Data is compressed as it is written to the container storage pool.
Restriction: The IBM Spectrum Protect server cannot compress encrypted data.

Progressive incremental backup

In a progressive incremental backup process, the server monitors client activity and backs up any files that change since the initial full backup. Entire files are backed up, so that the server does not need to reference base versions of the files. This backup technique eliminates the need for multiple full backups of client data thus saving network resources and storage space.

Strategies for disaster protection

IBM Spectrum Protect™ provides strategies to protect data if a disaster occurs. These strategies include node replication to a remote site, storage pool protection, database backups, moving backup tapes offsite, and device replication to a standby server.

Replication to a remote site

Node replication is the process of incrementally copying data from one server to another server. The server from which client data is replicated is called a *source replication server*. The server to which client data is replicated is called a *target replication server*. For the purposes of disaster protection, the target replication server is on a remote site. A replication server can function as a source server, a target server, or both. You use replication processing to maintain the same level of files on the source and the target servers.

Node replication provides for immediate availability of data through failover. Although node replication protects most of the metadata, this approach does not provide adequate protection for database damage. You can provide more comprehensive protection by using storage pools to store data backups.

Advantages

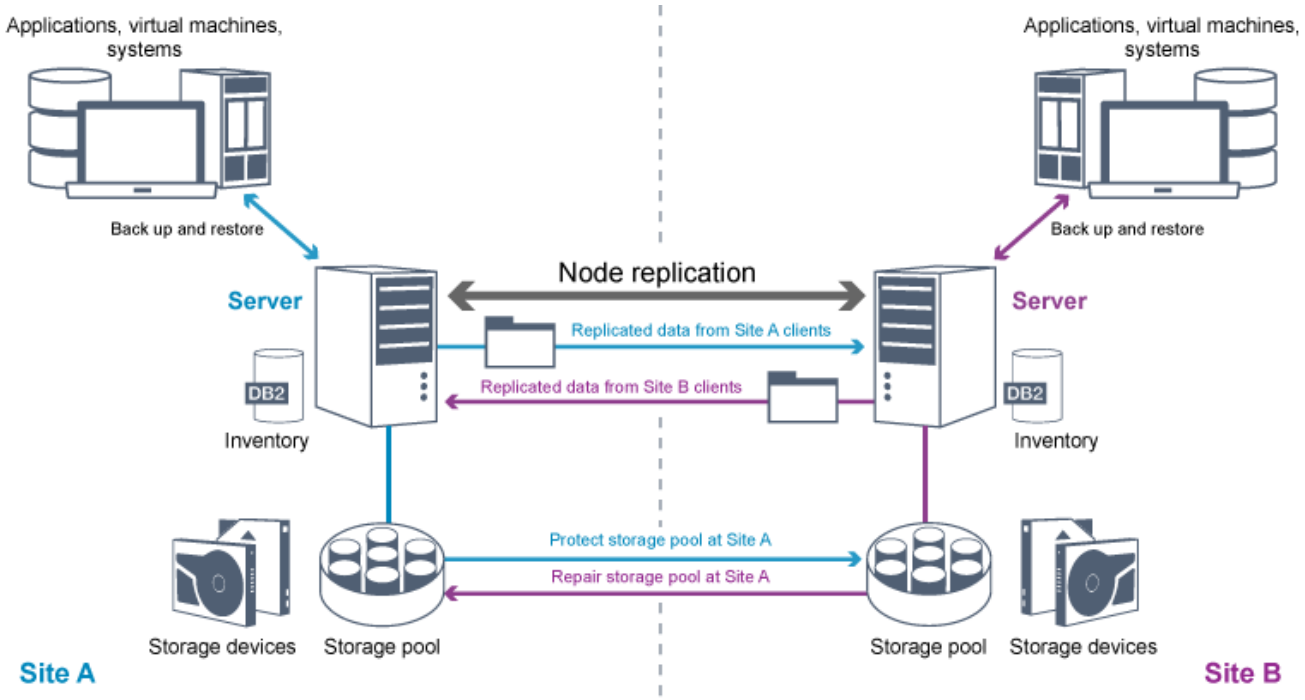
- Failover so that data is available immediately if a disaster occurs.
- Incremental replication, which results in fast transmission of data.
- Electronic transfer
- Protects both data and most metadata

Disadvantages

- Both data and metadata must be recovered.
- Data on the source server must be replicated again from the remote site.

Figure 1 shows the node replication process to a remote site.

Figure 1. Node replication process



When client data is replicated, data that is not on the target server is copied to the target server. When replicated data exceeds the retention limit, the target server automatically removes the data from the source server. To maximize data protection, you synchronize the local server and the remote server; for example, Site B replicates data from Site A and Site A replicates data from Site B. As part of replication processing, client data that was deleted from the source server is also deleted from the target server.

IBM Spectrum Protect provides the following replication functions:

- You can define policies for the target server in the following ways:
  - Identical policies on the source server and target server
  - Different policies on the source server and target server to meet different business requirements.

  If a disaster occurs and the source server is not available, clients can recover data from the target server. If the source server cannot be recovered, you can direct clients to store data on the target server. When an outage occurs, the clients that are backed up to the source server can automatically fail over to restore their data from the target server.
- You can use replication processing to recover damaged files from storage pools. You must replicate the client data to the target server before the file damage occurs. Subsequent replication processes detect damaged files on the source server and replace the files with undamaged files from the target server.

Role of replication in disaster protection

If a disaster occurs, you can recover replicated data from the remote site and maintain the same level of files on the source and target servers. You use replication to achieve the following objectives:

- Control network throughput by scheduling node replication at specific times
- Recover data after a site loss.
- Recover damaged files on the source server.

Storage pool protection

As part of a disaster recovery strategy, ensure that a backup copy of data in storage pools is available at a remote site.

Advantages

- Fast recovery and rebuild of the source system.

Disadvantages

- Only data is protected; metadata is not protected.
- For each storage pool, you must define the storage medium.

You use different techniques to protect against the permanent loss of data that is stored in container storage pools and in FILE and DISK storage pools.

Directory-container storage pools

If you do not need to replicate all the data that is contained in a client node, you use container-copy storage pools to protect some directory-container storage pools. By protecting a directory-container storage pool, you do not use resources that replicate existing data and metadata, which improves server performance.

The preferred method is to protect the directory-container storage pool before you replicate the client node. When node replication is started, the data extents that are already replicated through storage pool protection are skipped, which reduces the replication processing time. If the data in a directory-container storage pool becomes damaged, you can repair the data from a copy in a container-copy storage pool.

Container-copy storage pools

You protect directory-container storage pools by copying the data in the directory-container storage pool to container-copy storage pools. Use container-copy storage pools to create up to two tape copies of a directory-container storage pool. The tape copies can be stored onsite or offsite. Damaged data in directory-container storage pools can be repaired by using container-copy storage pools. Container-copy storage pools provide an alternative to using a replication server to protect data in a directory-container storage pool.

Storage pools that are associated with FILE and DISK device classes

For storage pools that are associated with FILE and DISK device classes, you use node replication to maintain a node-consistent copy of the data at the target server. The data copy can be directly restored from the target server to the storage pools.

Database backups

You use database backups to recover your system following database damage. Also, database backup operations must be used to prevent DB2 from running out of archive log space. Database backup operations are not part of node replication. A database backup can be full, incremental, or snapshot. To provide for disaster recovery, a copy of the database backups must be stored offsite. To restore the database, you must have the backup volumes for the database. You can restore the database from backup volumes by either a point-in-time restore or a most current restore operation.

Point-in-time restore

Use point-in-time restore operations for situations such as disaster recovery or to remove the effects of errors that can cause inconsistencies in the database. Restore operations for the database that use snapshot backups are a form of point-in-time restore operation. The point-in-time restore operation includes the following actions:

- Removes and re-creates the active log directory and archive log directory that are specified in the dsmserv.opt file.
- Restores the database image from backup volumes to the database directories that are recorded in a database backup or to new directories.
- Restores archive logs from backup volumes to the overflow directory.
- Uses log information from the overflow directory up to a specified point in time.

Most current restore

If you want to recover the database to the time when the database was lost, recover the database to the most current state. The most current restore operation includes the following actions:

- Restores a database image from the backup volumes to the database directories that are recorded in a database backup or to new directories.
- Restores archive logs from backup volumes to the overflow directory.
- Uses log information from the overflow directory and archive logs from archive log directory.

The most current restore does not remove and re-create the active log directory or archive log directory.

Alternative methods for disaster protection

In addition to replication, storage pool protection, and database backups, you can also use the following methods to protect data and implement disaster recovery with IBM Spectrum Protect:

Sending backup tapes to a remote site

Data is backed up to tape at scheduled times by the source server. The tapes are sent to a remote site. If a disaster occurs, the tapes are returned to the site of the source server and the data is restored on the source clients. Offsite copies of data on backup tape can also help you to recover from ransomware attacks.

Multisite appliance replication to a standby server

In the multisite appliance configuration, the source appliance is replicated to a remote server in a SAN architecture. In this configuration, if the client hardware at the original site is damaged, the source device can be replicated from the standby server at the remote site. This configuration provides disk-based backup and restore operations.

Comparison of protection configuration strategies

Consider the following potential data-loss scenarios:

- Database data is damaged: protect against loss of data in the database by using onsite database backup.
- Storage pool data is damaged: protect against loss of data in storage pools by using onsite copy storage pools or node replication.
- Disaster scenario where both the onsite database and storage pools are lost: protect against a full disaster by using node replication and both off-site database backup and storage pool backup copies.

The following possible configurations address the most common data protection scenarios:

Configurations for damage protection only

- Implement database backup operations onsite with an optional container-copy storage pool onsite to protect data in directory-container storage pools.
- Implement database backup operations onsite and node replication onsite.

Configurations for disaster recovery and damage protection

- Implement database backup operations offsite with container-copy storage pools offsite to protect data in directory-container storage pools.
- Implement database backup operations onsite and node replication offsite with an optional container-copy storage pool onsite for faster recovery of damaged data.

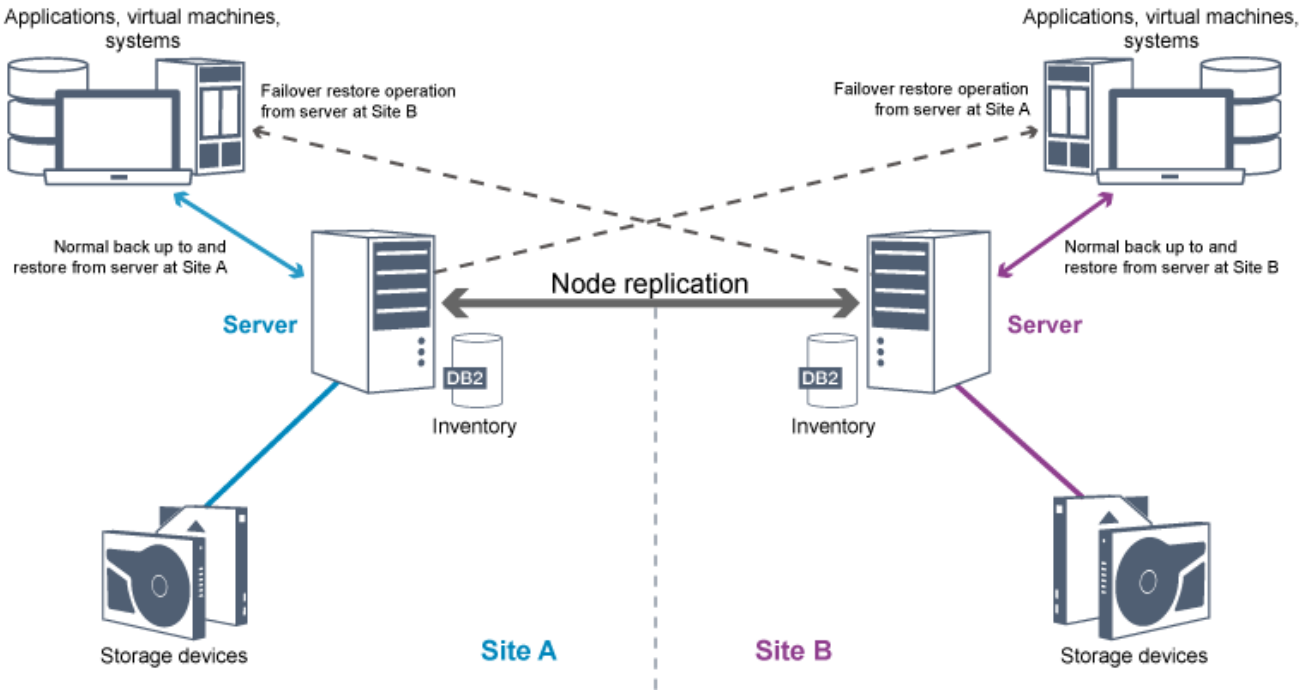
Strategies for disaster recovery with IBM Spectrum Protect

IBM Spectrum Protect™ provides several ways to recover the server if the database or storage pools fail.

Automatic failover for disaster recovery

Automatic failover is an operation that switches to a standby system if a software, hardware, or network interruption occurs. Automatic failover is used with node replication to recover data after a system failure. Figure 1 shows the IBM Spectrum Protect automatic failover process.

Figure 1. Automatic failover process



Automatic failover for data recovery occurs if the source replication server is unavailable because of a disaster or a system outage. During normal operations, when the client accesses a source replication server, the client receives connection information for the target replication server. The client node stores the failover connection information in the client options file.

During client restore operations, the server automatically changes clients from the source replication server to the target replication server and back again. Only one server per node can be used for failover protection at any time. When a new client operation is started, the client attempts to connect to the source replication server. The client resumes operations on the source server if the source replication server is available.

To use automatic failover for replicated client nodes, the source replication server, the target replication server, and the client must be at the V7.1 level or later. If any of the servers are at an earlier level, automatic failover is disabled and you must rely on a manual failover process.

Recovery of IBM Spectrum Protect components

The server database, recovery log, and storage pools are critical to the operation of IBM Spectrum Protect and must be protected. If the database is unusable, the entire server is unavailable and recovering data that is managed by the server might be difficult or impossible.

Even without the database, fragments of data or complete files might be read from storage pool volumes that are not encrypted and security can be compromised. Therefore, you must always back up the database. Also, always encrypt sensitive data by using the client or the storage device, unless the storage media is physically secured.

IBM Spectrum Protect provides several data protection methods, which include backing up storage pools and the database. For example, you can define schedules so that the following operations occur:

- After the initial full backup of your storage pools, incremental storage pool backups are run every night.
- Incremental database backups are run every night.
- Full database backups are run once a week.

For tape-based environments, you can use disaster recovery manager (DRM) to assist you in many of the tasks that are associated with protecting and recovering data. DRM is available with IBM Spectrum Protect Extended Edition.

Preventive actions for recovery

Recovery is based on the following preventive actions:

- Mirroring, by which the server maintains a copy of the active log
- Backing up the database
- Backing up the storage pools

- Auditing storage pools for damaged files and recovery of damaged files when necessary
- Backing up the device configuration and volume history files
- Validating the data in storage pools by using cyclic redundancy checking
- Storing the cert.kdb file in a safe place to ensure that the Secure Sockets Layer (SSL) is secure

If you are using tape for storage, you can also create a disaster recovery plan to guide you through the recovery process by using DRM. You can use the disaster recovery plan for audit purposes to certify the recoverability of the server. The disaster recovery methods of DRM are based on taking the following actions:

- Creating a disaster recovery plan file for the server
- Backing up server data to tape
- Sending the server backup data to a remote site or to another server
- Storing client system information
- Defining and tracking the storage media that is used for storing and recovering client data

IBM Spectrum Protect data protection solutions

IBM Spectrum Protect™ servers and clients provide data protection solutions for the most common business and compliance requirements.

- Selecting a data protection solution for your environment
  To help you to deploy a data protection environment, review information about best practice IBM Spectrum Protect configurations, and select the best solution for your business needs.
- Single-site disk solution
  This data protection solution provides cost-effective data storage at a single site with minimal hardware setup.
- Multisite disk solution
  This data protection solution provides replication at multiple sites so that each server protects data for the other site.
- Tape solution
  This data protection solution provides storage to tape media, a flexible and affordable option for long-term data retention.
- Server solution documentation in PDF files
  Prebuilt PDF files for IBM Spectrum Protect documentation are available for you to download.

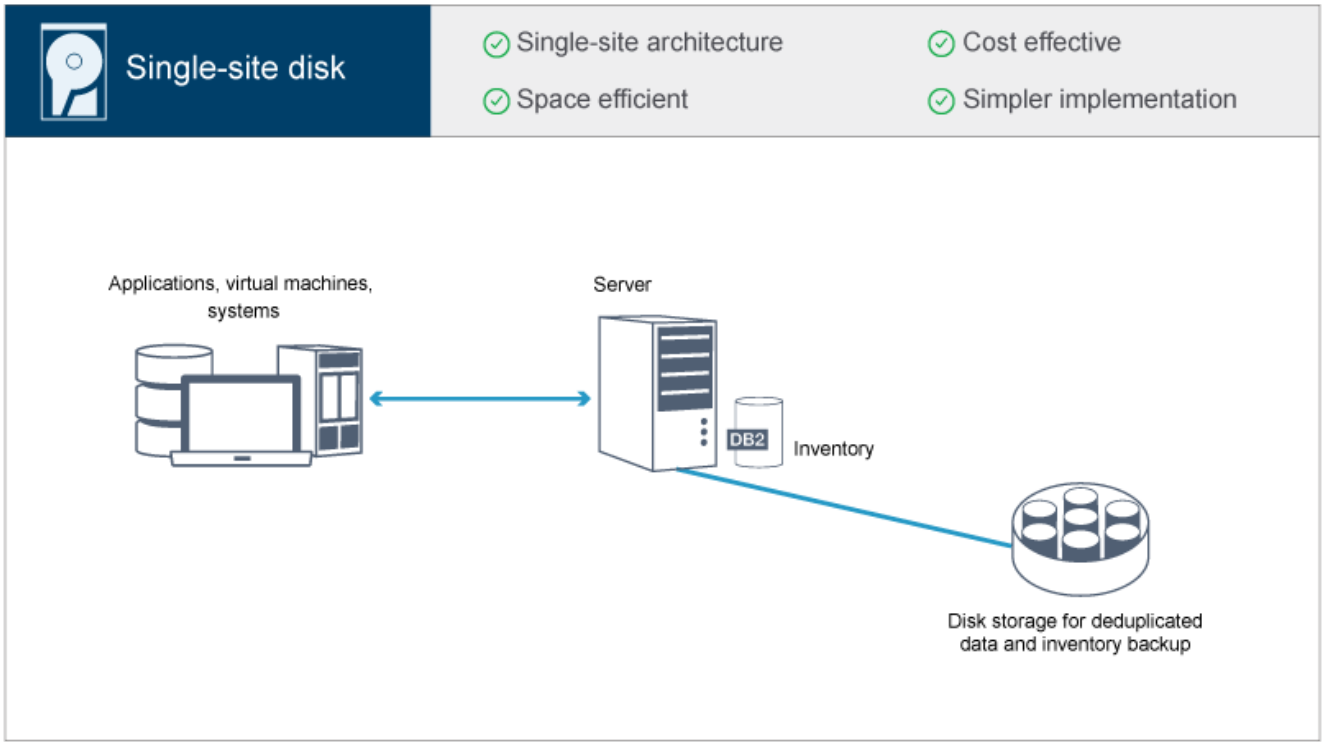
Selecting a data protection solution for your environment

To help you to deploy a data protection environment, review information about best practice IBM Spectrum Protect™ configurations, and select the best solution for your business needs.

- Disk-based implementation of a data protection solution for a single site
  This disk-based implementation of a data protection solution with IBM Spectrum Protect uses inline data deduplication and provides protection for data on a single site.
- Disk-based implementation of a data protection solution for multiple sites
  This disk-based implementation of a data protection solution with IBM Spectrum Protect uses inline data deduplication and replication at two sites.
- Appliance-based implementation of a data protection solution for multiple sites
  This implementation of a multi-site IBM Spectrum Protect data protection solution uses appliance-based data deduplication and replication. A standby server is configured at a second site to recover data if the primary server is unavailable.
- Tape-based implementation of a data protection solution
  This implementation of a data protection solution with IBM Spectrum Protect uses one or more tape storage devices to back up data. Tape backup provides low-cost scalability that is optimized for long-term retention.
- Comparison of data protection solutions
  Compare the key features for each IBM Spectrum Protect solution to determine which configuration best meets your data protection requirements. Then, review the available documentation to implement the solution.
- Roadmap for implementing a data protection solution
  Plan and implement the most suitable data protection solution for your business environment with IBM Spectrum Protect.

Disk-based implementation of a data protection solution for a single site

This disk-based implementation of a data protection solution with IBM Spectrum Protect™ uses inline data deduplication and provides protection for data on a single site.



This data protection solution provides the following benefits:

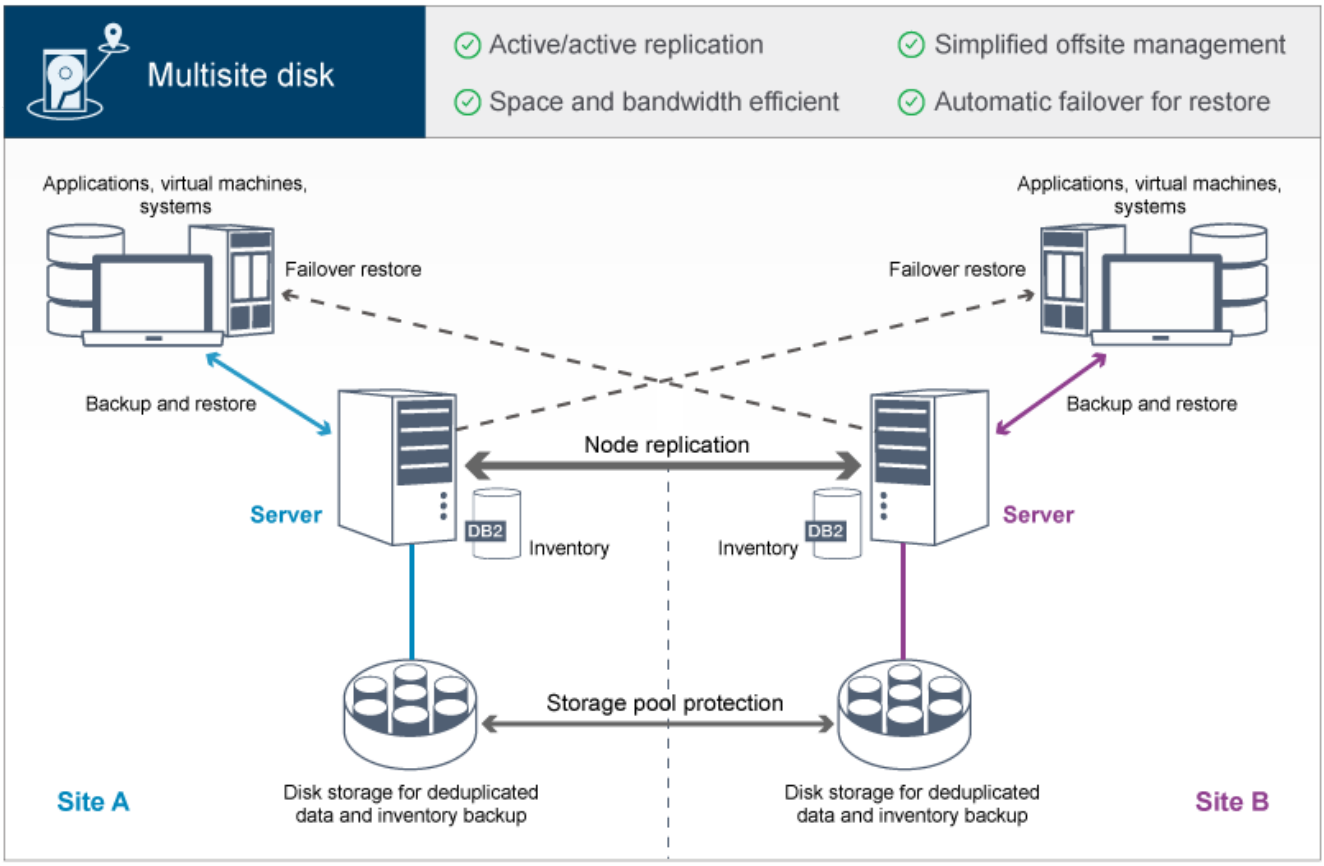
- Server system and storage hardware at a single site
- Cost-effective use of storage through the data deduplication feature
- Space-efficient solution with minimal hardware setup
- Minimal implementation that requires installation and configuration for only one server and supporting storage hardware

In this solution, the client sends data to the IBM Spectrum Protect server, where the data is deduplicated and stored in a directory-container storage pool that is implemented in disk storage. Data from the inventory is also backed up to disk storage. This solution is suitable for entry-level environments for which a second copy of data is not required.

Related reference:
Comparison of data protection solutions
Roadmap for implementing a data protection solution

Disk-based implementation of a data protection solution for multiple sites

This disk-based implementation of a data protection solution with IBM Spectrum Protect™ uses inline data deduplication and replication at two sites.



This data protection solution provides the following benefits:

- Replication can be configured at both sites so that each server protects data for the other site
- Offsite data storage for each location is simplified
- Bandwidth is used efficiently because only deduplicated data is replicated between the sites
- Clients can automatically fail over to a target replication server if the source replication server is unavailable

In this solution, clients send data to the source server, where the data is deduplicated and stored in a directory-container storage pool that is implemented in disk storage. The data is replicated to the storage pool on the target server for each site. This solution is suitable for environments that require disaster protection. If mutual replication is configured, clients at both sites can use failover recovery for continued backups and data recovery from the available server on the other site.

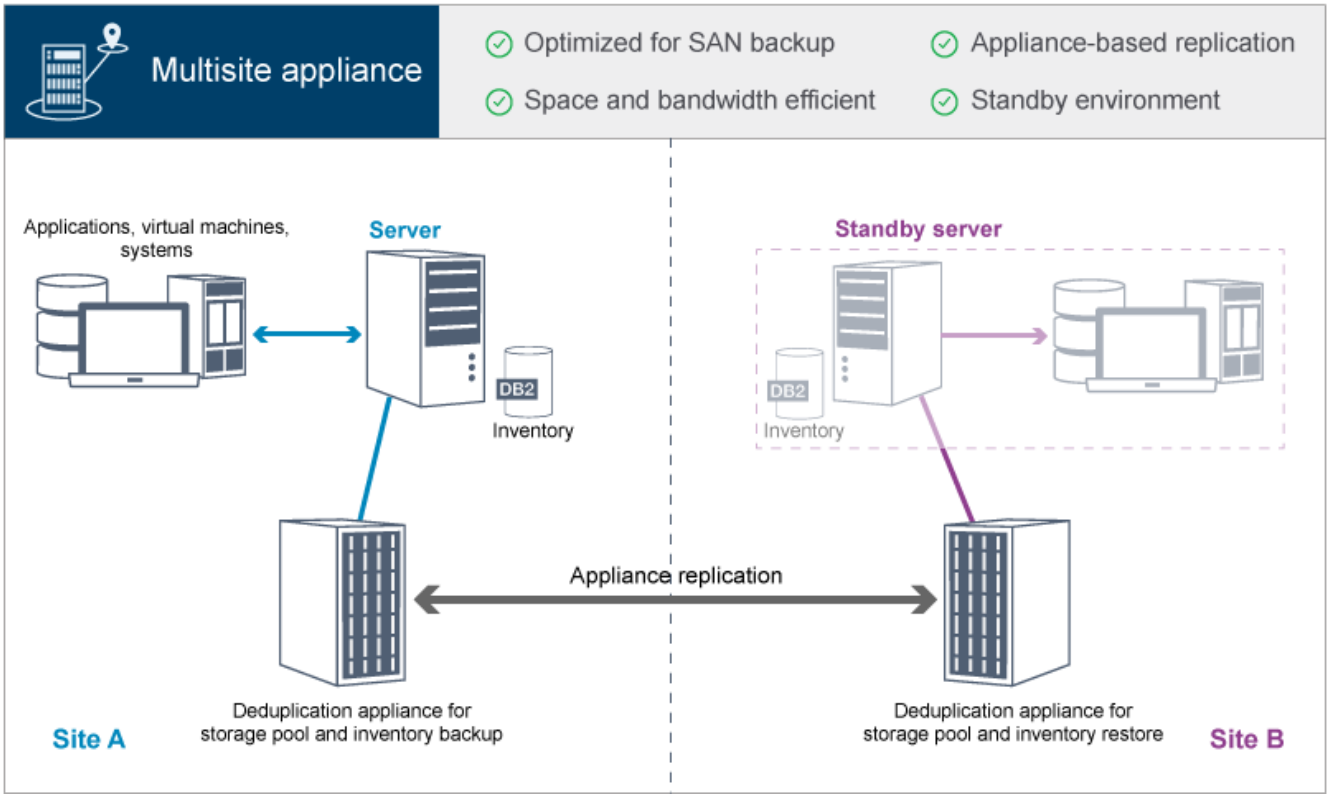
Comparison of data protection solutions
Roadmap for implementing a data protection solution

Appliance-based implementation of a data protection solution for multiple sites

This implementation of a multi-site IBM Spectrum Protect™ data protection solution uses appliance-based data deduplication and replication. A standby server is configured at a second site to recover data if the primary server is unavailable.



This data protection solution provides the following benefits:

- Performance is optimized for backups on high-speed storage area networks (SAN) and for use with IBM Spectrum Protect for SAN, when clients back up directly to SAN-attached virtual tape devices.
- Fast, appliance-based replication frees the server from having to track replication metadata in the server database.
- Bandwidth and storage space are used efficiently because only deduplicated data is replicated between the sites.
- A standby environment provides for disaster recovery, but does not require the amount of resources that are needed for a fully active site.

In this data protection configuration, the server uses hardware appliances to deduplicate and replicate data. The appliance at Site A deduplicates data and then replicates the data to the appliance at Site B for disaster protection. If a failure at Site A occurs, you make the standby server active by restoring the most recent database backup, and by activating the replicated copy of data.

For more information about configuring virtual tape libraries, see Configuring virtual tape libraries.

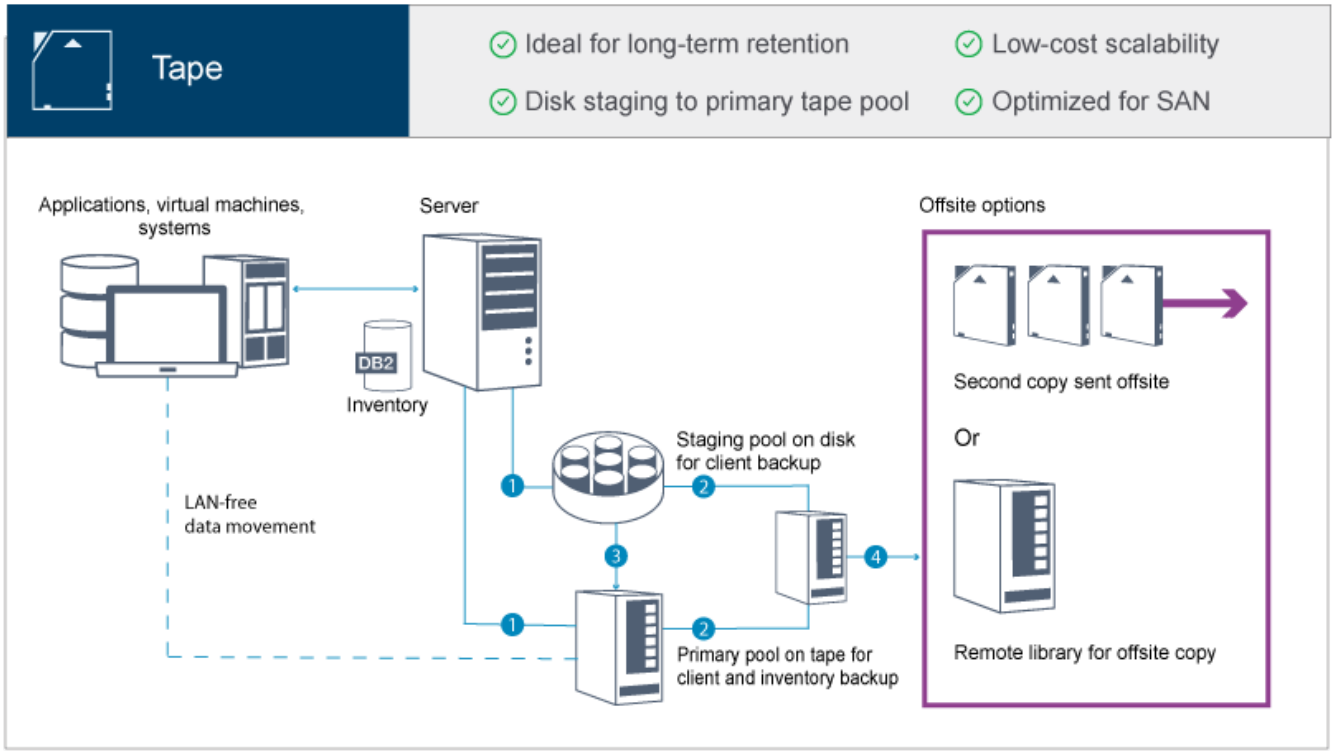
Roadmap for implementing a data protection solution

Tape-based implementation of a data protection solution

This implementation of a data protection solution with IBM Spectrum Protect™ uses one or more tape storage devices to back up data. Tape backup provides low-cost scalability that is optimized for long-term retention.



This data protection solution provides the following benefits:

- Performance is optimized for backup operations on high-speed storage area networks (SAN) directly to tape for large data types and for long-term retention of data.
- Data availability is optimized by storing copies of data at offsite locations for disaster recovery.
- Low-cost scalability is achieved by reducing the need for additional disk hardware and lowering energy costs.

Roadmap for implementing a data protection solution

Plan and implement the most suitable data protection solution for your business environment with IBM Spectrum Protect™.

Single-site disk solution

For steps that describe how to plan for, implement, monitor, and operate a single-site disk solution, see Single-site disk solution.

Multisite disk solution

For steps that describe how to plan for, implement, monitor, and operate a multisite disk solution, see Multisite disk solution.

Tape solution

For steps that describe how to plan for, implement, monitor, and operate a tape device solution, see Tape solution.

Multisite appliance solution

For an overview of the tasks that are required to implement a multisite appliance solution, review the following steps:

1. Begin planning for the solution by reviewing information at the following links:
    - AIX: Capacity planning
    - Linux: Capacity planning
    - Windows: Capacity planning
2. Install the server and optionally, the Operations Center. Review information at the following links:
    - Installing the server
    - Installing and upgrading the Operations Center
3. Configure the server for storage in a virtual tape library.
    - Managing virtual tape libraries
    - Attaching tape devices for the server

    For guidance about improving system performance, see Configuration best practices.

4. Configure policies to protect your data. Review the information in Customizing policies.
5. Set up client schedules. Review the information in Scheduling backup and archive operations.
6. Install and configure clients. To determine the type of client software that you need, review the information in Adding clients for details.
7. Configure monitoring for your system. Review the information in Monitoring storage solutions.

Appliance-based implementation of a data protection solution for multiple sites
Tape-based implementation of a data protection solution

Single-site disk solution

This data protection solution provides cost-effective data storage at a single site with minimal hardware setup.

- Planning for a single-site disk data protection solution
  Plan for a data protection implementation that includes a server at a single site that uses data deduplication.
- Single-site disk implementation of a data protection solution
  The single-site disk solution is configured at one site and uses data deduplication.
- Monitoring a single-site disk solution
  After you implement a single-site disk solution with IBM Spectrum Protect, monitor the solution for correct operation. By

monitoring the solution daily and periodically, you can identify existing and potential issues. The information that you gather can be used to troubleshoot problems and optimize system performance.

- Managing operations for a single-site disk solution
  Use this information to manage operations for a single-site disk solution with IBM Spectrum Protect that includes a server and uses data deduplication for a single location.

Planning for a single-site disk data protection solution

Plan for a data protection implementation that includes a server at a single site that uses data deduplication.

Implementation options

You can configure the server for a single-site disk solution in the following ways:

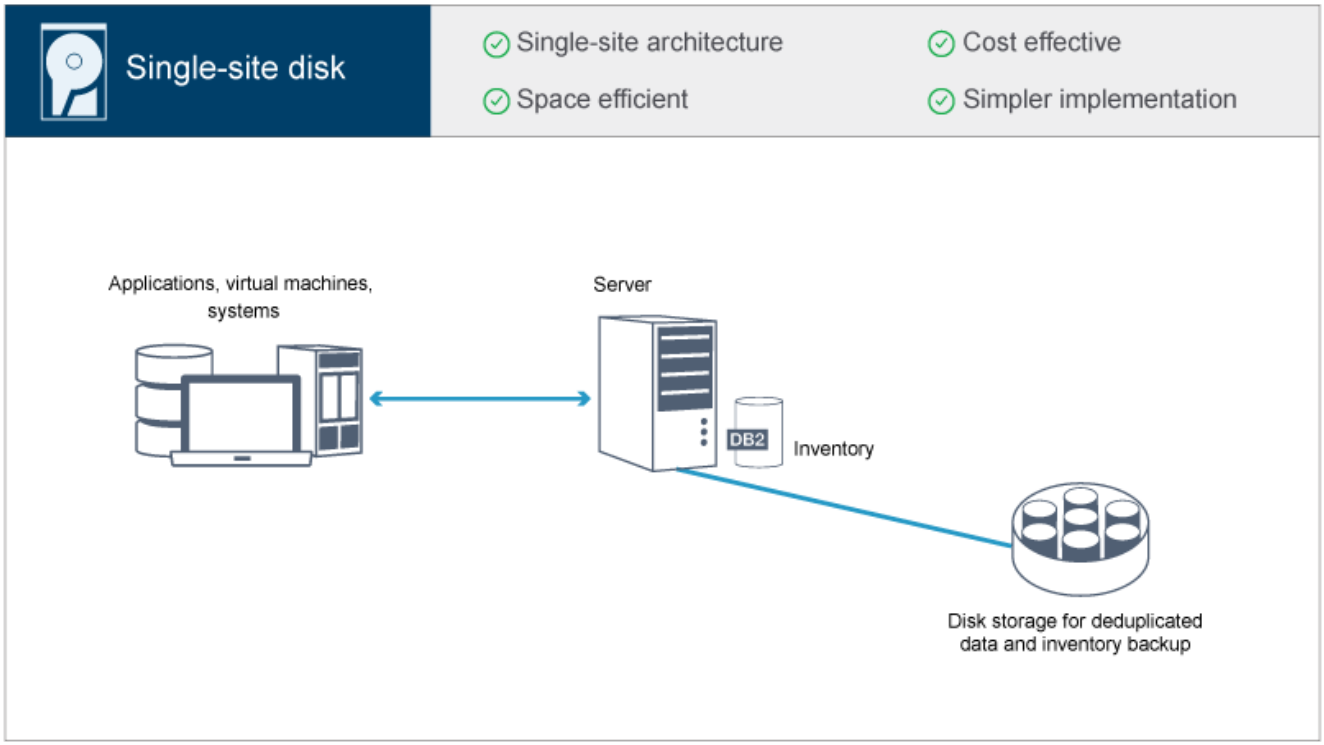
Configure the server by using the Operations Center and administrative commands
: This documentation provides steps to configure a range of storage systems and the server software for your solution. Configuration tasks are completed by using wizards and options in the Operations Center and IBM Spectrum Protect™ commands. For information about getting started, see the Planning roadmap.

Configure the server by using automated scripts
: For detailed guidance on implementing a single-site disk solution with specific IBM® Storwize® storage systems, and by using automated scripts to configure the server, see the IBM Spectrum Protect blueprints. The documentation and scripts are available on IBM developerWorks® at: IBM Spectrum Protect Blueprints.

  The blueprint documentation does not include steps for installing and configuring the Operations Center, or setting up secure communications by using Transport Security Layer (TLS). An option for using Elastic Storage Server, based on IBM Spectrum Scale™ technology, is included.

Planning roadmap

Plan for the single-site disk solution by reviewing the architecture layout in the following figure and then completing the roadmap tasks that follow the diagram.



The following steps are required to plan for a single-site disk environment.

1. Select your system size.
2. Meet system requirements for hardware and software.
3. Record values for your system configuration in the planning worksheets.

4. Plan for storage.
5. Plan for security.
    a. Plan for administrator roles.
    b. Plan for secure communications.
    c. Plan for storage of encrypted data.
    d. Plan for firewall access.

Selecting a system size

Select the size of the IBM Spectrum Protect™ server based on the amount of data that you manage and the systems to be protected.

About this task

You can use the information in the table to determine the size of the server that is required, based on the amount of data that you manage.

The following table describes the volume of data that a server manages. This amount includes all versions. The daily amount of data is how much new data you back up each day. Both the total managed data and daily amount of new data are measured as the size before any data reduction.

Table 1. Determining the size of the server

Total managed data	Daily amount of new data to back up	Required server size
48 TB - 192 TB	Up to 10 TB per day	Small
200 TB - 800 TB	10 - 20 TB per day	Medium
1000 TB - 4000 TB	20 - 100 TB per day	Large

The daily backup values in the table are based on test results with 128 MB sized objects, which are used by IBM Spectrum Protect for Virtual Environments. Workloads that consist of objects that are smaller than 128 KB might not be able to achieve these daily limits.

System requirements for a single-site disk solution

After you select the IBM Spectrum Protect™ solution that best fits your data protection requirements, review the system requirements to plan for implementation of the data protection solution.

Ensure that your system meets the hardware and software prerequisites for the size of server that you plan to use.

- Hardware requirements
  Hardware requirements for your IBM Spectrum Protect solution are based on system size. Choose equivalent or better components than those items that are listed to ensure optimum performance for your environment.
- Software requirements
  Documentation for the single-site disk IBM Spectrum Protect solution includes installation and configuration tasks for the following operating systems. You must meet the minimum software requirements that are listed.

Related information:
IBM Spectrum Protect Supported Operating Systems

Hardware requirements

Hardware requirements for your IBM Spectrum Protect™ solution are based on system size. Choose equivalent or better components than those items that are listed to ensure optimum performance for your environment.

For a definition of system sizes, see Selecting a system size.

The following table includes minimum hardware requirements for the server and storage, based on the size of the server that you plan to build. If you are using local partitions (LPARs) or work partitions (WPARs), adjust the network requirements to take account of the partition sizes.

Hardware component	Small system	Medium system	Large system

Hardware component	Small system	Medium system	Large system
Server processor	AIX 6 processor cores, 3.42 GHz or faster Linux Windows 12 processor cores, 1.9 GHz or faster	AIX 8 processor cores, 3.42 GHz or faster Linux Windows 16 processor cores, 2.0 GHz or faster	AIX 20 processor cores, 3.42 GHz Linux Windows 32 processor cores, 2.0 GHz or faster
Server memory	64 GB RAM	128 GB RAM	192 GB RAM
Network	• 10 GB Ethernet (1 port) • 8 GB Fibre Channel adapter (2 ports)	• 10 GB Ethernet (2 ports) • 8 GB Fibre Channel adapter (2 ports)	• 10 GB Ethernet (4 ports) • 8 GB Fibre Channel adapter (4 ports)
Storage	• 1.3 TB inventory, plus space for Operations Center records • 46 TB deduplicated directory-container storage pool	• 2 TB inventory, plus space for Operations Center records • 200 TB deduplicated directory-container storage pool	• 6 TB inventory, plus space for Operations Center records • 1000 TB deduplicated directory-container storage pool

Estimating database space requirements for the Operations Center

Hardware requirements for the Operations Center are included in the preceding table, except for the database and archive log space (inventory) that the Operations Center uses to hold records for managed clients.

If you do not plan to install the Operations Center on the same system as the server, you can estimate system requirements separately. To calculate system requirements for the Operations Center, see the system requirements calculator in technote 1641684.

Managing the Operations Center on the server is a workload that requires extra space for database operations. The amount of space depends on the number of clients that are monitored on a server. Review the following guidelines to estimate how much space your server requires.

Database space

The Operations Center uses approximately 1.2 GB of database space for every 1000 clients that are monitored on a server. For example, consider a hub server with 2000 clients that also manages three spoke servers, each with 1500 clients. This configuration has a total of 6500 clients across the four servers and requires approximately 8.4 GB of database space. This value is calculated by rounding the 6500 clients up to the next closest 1000, which is 7000:

```
7 x 1.2 GB=8.4 GB
```

Archive log space

The Operations Center uses approximately 8 GB of archive log space every 24 hours, for every 1000 clients. In the example of 6500 clients across the hub server and the spoke servers, 56 GB of archive log space is used over a 24-hour period for the hub server.

For each spoke server in the example, the archive log space that is used over 24 hours is approximately 16 GB. These estimates are based on the default status collection interval of 5 minutes. If you reduce the collection interval from once every 5 minutes to once every 3 minutes, the space requirements increase. The following examples show the approximate increase in the log space requirement with a collection interval of once every 3 minutes:

- Hub server: 56 GB to approximately 94 GB
- Each spoke server: 16 GB to approximately 28 GB

Increase the archive log space so that you have sufficient space available to support the Operations Center, without affecting the existing server operations.

Software requirements

Documentation for the single-site disk IBM Spectrum Protect™ solution includes installation and configuration tasks for the following operating systems. You must meet the minimum software requirements that are listed.

For information about software requirements for IBM® lin_tape device drivers, refer to the IBM Tape Device Drivers Installation and User's Guide.

AIX systems

Type of software	Minimum software requirements
Operating system	IBM AIX® 7.1 For more information about operating system requirements, see AIX: Minimum system requirements for AIX systems.
Gunzip utility	The gunzip utility must be available on your system before you install or upgrade the IBM Spectrum Protect server. Ensure that the gunzip utility is installed and the path to it is set in the PATH environment variable.
File system type	JFS2 file systems AIX systems can cache a large amount of file system data, which can reduce memory that is required for server and IBM DB2® processes. To avoid paging with the AIX server, use the rbrw mount option for the JFS2 file system. Less memory is used for the file system cache and more is available for IBM Spectrum Protect. Do not use the file system mount options, Concurrent I/O (CIO), and Direct I/O (DIO), for file systems that contain the IBM Spectrum Protect database, logs, or storage pool volumes. These options can cause performance degradation of many server operations. IBM Spectrum Protect and DB2 can still use DIO where it is beneficial to do so, but IBM Spectrum Protect does not require the mount options to selectively take advantage of these techniques.
Other software	Korn Shell (ksh)

Linux systems

Type of software	Minimum software requirements
Operating system	Red Hat Enterprise Linux 7 (x86_64)
Libraries	GNU C libraries, Version 2.3.3-98.38 or later that is installed on the IBM Spectrum Protect system. Red Hat Enterprise Linux Servers: • libaio • libstdc++.so.6 (32-bit and 64-bit packages are required) • numactl.x86_64
File system type	Format database-related file systems with ext3 or ext4. For storage pool-related file systems, use XFS.
Other software	Korn Shell (ksh)

Windows systems

Type of software	Minimum software requirements
Operating system	Microsoft Windows Server 2012 R2 (64-bit) or Windows Server 2016
File system type	NTFS
Other software	Windows 2012 R2 or Windows 2016 with .NET Framework 3.5 is installed and enabled. The following User Account Control policies must be disabled: • User Account Control: Admin Approval Mode for the Built-in Administrator account • User Account Control: Run all administrators in Admin Approval Mode

Related tasks:
Setting AIX network options

Planning worksheets

Use the planning worksheets to record values that you use to set up your system and configure the IBM Spectrum Protect™ server. Use the best practice default values that are listed in the worksheets.

Each worksheet helps you prepare for different parts of the system configuration by using best practice values:

Server system preconfiguration
: Use the preconfiguration worksheets to plan for the file systems and directories that you create when you configure file systems for IBM Spectrum Protect during system setup. All directories that you create for the server must be empty.

Server configuration
: Use the configuration worksheets when you configure the server. Default values are suggested for most items, except where noted.

AIX®

Table 1. Worksheet for preconfiguration of an AIX server system

Item	Default value	Your value	Minimum directory size	Notes
TCP/IP port address for communications with the server	1500		Not applicable	Ensure that this port is available when you install and configure the operating system The port number can be a number in the range 1024 - 32767.
Directory for the server instance	/home/tsminst1/tsminst1		50 GB	If you change the value for the server instance directory from the default, also modify the DB2® instance owner value in Table 2.
Directory for server installation	/		Available space that is required for the directory: 5 GB	
Directory for server installation	/usr		Available space that is required for the directory: 5 GB	
Directory for server installation	/var		Available space that is required for the directory: 5 GB	
Directory for server installation	/tmp		Available space that is required for the directory: 5 GB	
Directory for server installation	/opt		Available space that is required for the directory: 10 GB	
Directory for the active log	/tsminst1/TSMalog		• Small and medium: 140 GB • Large: 300 GB	When you create the active log during the initial configuration of the server, set the size to 128 GB.

Item	Default value	Your value	Minimum directory size	Notes
Directory for the archive log	/tsminst1/TSMarchlog		• Small: 1 TB • Medium: 3 TB • Large: 4 TB	
Directories for the database	/tsminst1/TSMdbspace00 /tsminst1/TSMdbspace01 /tsminst1/TSMdbspace02 /tsminst1/TSMdbspace03 ...		Minimum total space for all directories: • Small: At least 1 TB • Medium: At least 2 TB • Large: At least 4 TB	Create a minimum number of file systems for the database, depending on the size of your system: • Small: At least 4 file systems • Medium: At least 4 file systems • Large: At least 8 file systems
Directories for storage	/tsminst1/TSMfile00 /tsminst1/TSMfile01 /tsminst1/TSMfile02 /tsminst1/TSMfile03 ...		Minimum total space for all directories: • Small: At least 38 TB • Medium: At least 180 TB • Large: At least 500 TB	Create a minimum number of file systems for storage, depending on the size of your system: • Small: At least 10 file systems • Medium: At least 20 file systems • Large: At least 40 file systems
Directories for database backup	/tsminst1/TSMbkup00 /tsminst1/TSMbkup01 /tsminst1/TSMbkup02 /tsminst1/TSMbkup03		Minimum total space for all directories: • Small: At least 3 TB • Medium: At least 10 TB • Large: At least 16 TB	Create a minimum number of file systems for backing up the database, depending on the size of your system: • Small: At least 2 file systems • Medium: At least 4 file systems • Large: At least 4 file systems, but preferably 6 The first database backup directory is also used for the archive log failover directory and a second copy of the volume history and device configuration files.

Table 2. Worksheet for IBM Spectrum Protect configuration

Item	Default value	Your value	Notes
DB2 instance owner	tsminst1		If you changed the value for the server instance directory in Table 1 from the default, also modify the value for the DB2 instance owner.
DB2 instance owner password	passw0rd		Select a different value for the instance owner password than the default. Ensure that you record this value in a secure location.
Primary group for the DB2 instance owner	tsmsrvrs		
Server name	The default value for the server name is the system host name.		
Server password	passw0rd		Select a different value for the server password than the default. Ensure that you record this value in a secure location.
Administrator ID: user ID for the server instance	admin		
Administrator ID password	passw0rd		Select a different value for the administrator password than the default. Ensure that you record this value in a secure location.
Schedule start time	22:00		The default schedule start time begins the client workload phase, which is predominantly the client backup and archive activities. During the client workload phase, server resources support client operations. Normally, these operations are completed during the nightly schedule window. Schedules for server maintenance operations are defined to begin 10 hours after the start of the client backup window.

Linux

Table 3. Worksheet for preconfiguration of a Linux server system

Item	Default value	Your value	Minimum directory size	Notes

Item	Default value	Your value	Minimum directory size	Notes
TCP/IP port address for communications with the server	1500		Not applicable	Ensure that this port is available when you install and configure the operating system The port number can be a number in the range 1024 - 32767.
Directory for the server instance	/home/tsminst1/tsminst1		25 GB	If you change the value for the server instance directory from the default, also modify the DB2 instance owner value in Table 4.
Directory for the active log	/tsminst1/TSMalog		• Small and medium: 140 GB • Large: 300 GB	
Directory for the archive log	/tsminst1/TSMarchlog		• Small: 1 TB • Medium: 3 TB • Large: 4 TB	
Directories for the database	/tsminst1/TSMdbspace00 /tsminst1/TSMdbspace01 /tsminst1/TSMdbspace02 /tsminst1/TSMdbspace03 ...		Minimum total space for all directories: • Small: At least 1 TB • Medium: At least 2 TB • Large: At least 4 TB	Create a minimum number of file systems for the database, depending on the size of your system: • Small: At least 4 file systems • Medium: At least 4 file systems • Large: At least 8 file systems
Directories for storage	/tsminst1/TSMfile00 /tsminst1/TSMfile01 /tsminst1/TSMfile02 /tsminst1/TSMfile03 ...		Minimum total space for all directories: • Small: At least 38 TB • Medium: At least 180 TB • Large: At least 500 TB	Create a minimum number of file systems for storage, depending on the size of your system: • Small: At least 10 file systems • Medium: At least 20 file systems • Large: At least 40 file systems

Item	Default value	Your value	Minimum directory size	Notes
Directories for database backup	/tsminst1/TSMbkup00 /tsminst1/TSMbkup01 /tsminst1/TSMbkup02 /tsminst1/TSMbkup03		Minimum total space for all directories: • Small: At least 3 TB • Medium: At least 10 TB • Large: At least 16 TB	Create a minimum number of file systems for backing up the database, depending on the size of your system: • Small: At least 2 file systems • Medium: At least 4 file systems • Large: At least 4 file systems, but preferably 6 The first database backup directory is also used for the archive log failover directory and a second copy of the volume history and device configuration files.

Table 4. Worksheet for IBM Spectrum Protect configuration

Item	Default value	Your value	Notes
DB2 instance owner	tsminst1		If you changed the value for the server instance directory in Table 3 from the default, also modify the value for the DB2 instance owner.
DB2 instance owner password	passw0rd		Select a different value for the instance owner password than the default. Ensure that you record this value in a secure location.
Primary group for the DB2 instance owner	tsmsrvrs		
Server name	The default value for the server name is the system host name.		
Server password	passw0rd		Select a different value for the server password than the default. Ensure that you record this value in a secure location.
Administrator ID: user ID for the server instance	admin		
Administrator ID password	passw0rd		Select a different value for the administrator password than the default. Ensure that you record this value in a secure location.

Item	Default value	Your value	Notes
Schedule start time	22:00		The default schedule start time begins the client workload phase, which is predominantly the client backup and archive activities. During the client workload phase, server resources support client operations. Normally, these operations are completed during the nightly schedule window. Schedules for server maintenance operations are defined to begin 10 hours after the start of the client backup window.

Windows

Because many volumes are created for the server, configure the server by using the Windows feature of mapping disk volumes to directories rather than to drive letters.

For example, C:\tsminst1\TSMdbpsace00 is a mount point to a volume with its own space. The volume is mapped to a directory under the C: drive, but does not take up space from the C: drive. The exception is the server instance directory, C:\tsminst1, which can be a mount point or a regular directory.

Table 5. Worksheet for preconfiguration of a Windows server system

Item	Default value	Your value	Minimum directory size	Notes
TCP/IP port address for communications with the server	1500		Not applicable	Ensure that this port is available when you install and configure the operating system The port number can be a number in the range 1024 - 32767.
Directory for the server instance	C:\tsminst1		25 GB	If you change the value for the server instance directory from the default, also modify the DB2 instance owner value in Table 6.
Directory for the active log	C:\tsminst1\TSMalog		• Small and medium: 140 GB • Large: 300 GB	
Directory for the archive log	C:\tsminst1\TSMarchlog		• Small: 1 TB • Medium: 3 TB • Large: 4 TB	

Item	Default value	Your value	Minimum directory size	Notes
Directories for the database	C:\tsminst1\TSMdbspace00 C:\tsminst1\TSMdbspace01 C:\tsminst1\TSMdbspace02 C:\tsminst1\TSMdbspace03 ...		Minimum total space for all directories: • Small: At least 1 TB • Medium: At least 2 TB • Large: At least 4 TB	Create a minimum number of file systems for the database, depending on the size of your system: • Small: At least 4 file systems • Medium: At least 4 file systems • Large: At least 8 file systems
Directories for storage	C:\tsminst1\TSMfile00 C:\tsminst1\TSMfile01 C:\tsminst1\TSMfile02 C:\tsminst1\TSMfile03 ...		Minimum total space for all directories: • Small: At least 38 TB • Medium: At least 180 TB • Large: At least 500 TB	Create a minimum number of file systems for storage, depending on the size of your system: • Small: At least 10 file systems • Medium: At least 20 file systems • Large: At least 40 file systems
Directories for database backup	C:\tsminst1\TSMbkup00 C:\tsminst1\TSMbkup01 C:\tsminst1\TSMbkup02 C:\tsminst1\TSMbkup03		Minimum total space for all directories: • Small: At least 3 TB • Medium: At least 10 TB • Large: At least 16 TB	Create a minimum number of file systems for backing up the database, depending on the size of your system: • Small: At least 2 file systems • Medium: At least 4 file systems • Large: At least 4 file systems, but preferably 6 The first database backup directory is also used for the archive log failover directory and a second copy of the volume history and device configuration files.

Table 6. Worksheet for IBM Spectrum Protect configuration

Item	Default value	Your value	Notes

Item	Default value	Your value	Notes
DB2 instance owner	tsminst1		If you changed the value for the server instance directory in Table 5 from the default, also modify the value for the DB2 instance owner.
DB2 instance owner password	pAssW0rd		Select a different value for the instance owner password than the default. Ensure that you record this value in a secure location.
Server name	The default value for the server name is the system host name.		
Server password	passw0rd		Select a different value for the server password than the default. Ensure that you record this value in a secure location.
Administrator ID: user ID for the server instance	admin		
Administrator ID password	passw0rd		Select a different value for the administrator password than the default. Ensure that you record this value in a secure location.
Schedule start time	22:00		The default schedule start time begins the client workload phase, which is predominantly the client backup and archive activities. During the client workload phase, server resources support client operations. Normally, these operations are completed during the nightly schedule window. Schedules for server maintenance operations are defined to begin 10 hours after the start of the client backup window.

Planning for storage

Choose the most effective storage technology for IBM Spectrum Protect™ components to ensure efficient server performance and operations.

Storage hardware devices have different capacity and performance characteristics, which determine how they can be used effectively with IBM Spectrum Protect. For general guidance on selecting the appropriate storage hardware and set up for your solution, review the following guidelines.

Database and active log

- Use a fast disk for the IBM Spectrum Protect database and active log, for example with the following characteristics:
  - High performance, 15k rpm disk with Fibre Channel or serial-attached SCSI (SAS) interface
  - Solid-state disk (SSD)
- Isolate the active log from the database unless you use SSD or flash hardware

- When you create arrays for the database, use RAID level 5

Storage pool

- You can use less expensive and slower disks for the storage pool
- The storage pool can share disks for the archive log and database backup storage
- Use RAID level 6 for storage pool arrays to add protection against double drive failures when you use large disk types

- Planning the storage arrays
  Prepare for disk storage configuration by planning for RAID arrays and volumes, according to the size of your IBM Spectrum Protect system.

Related reference:
Storage system requirements and reducing the risk of data corruption

Planning for security

Plan to protect the security of systems in the IBM Spectrum Protect™ solution with access and authentication controls, and consider encrypting data and password transmission.

- Planning for administrator roles
  Define the authority levels that you want to assign to administrators who have access to the IBM Spectrum Protect solution.
- Planning for secure communications
  Plan for protecting communications among the IBM Spectrum Protect solution components.
- Planning for storage of encrypted data
  Determine whether your company requires stored data to be encrypted, and choose the option that best suits your needs.
- Planning firewall access
  Determine the firewalls that are set and the ports that must be open for the IBM Spectrum Protect solution to work.

Planning for administrator roles

Define the authority levels that you want to assign to administrators who have access to the IBM Spectrum Protect™ solution.

You can assign one of the following levels of authority to administrators:

System
: Administrators with system authority have the highest level of authority. Administrators with this level of authority can complete any task. They can manage all policy domains and storage pools, and grant authority to other administrators.

Policy
: Administrators who have policy authority can manage all of the tasks that are related to policy management. This privilege can be unrestricted, or can be restricted to specific policy domains.

Storage
: Administrators who have storage authority can allocate and control storage resources for the server.

Operator
: Administrators who have operator authority can control the immediate operation of the server and the availability of storage media such as tape libraries and drives.

The scenarios in Table 1 provide examples about why you might want to assign varying levels of authority so that administrators can perform tasks:

Table 1. Scenarios for administrator roles

Scenario	Type of administrator ID to set up
An administrator at a small company manages the server and is responsible for all server activities.	• System authority: 1 administrator ID
An administrator for multiple servers also manages the overall system. Several other administrators manage their own storage pools.	• System authority on all servers: 1 administrator ID for the overall system administrator • Storage authority for designated storage pools: 1 administrator ID for each of the other administrators

Scenario	Type of administrator ID to set up
An administrator manages 2 servers. Another person helps with the administration tasks. Two assistants are responsible for helping to ensure that important systems are backed up. Each assistant is responsible for monitoring the scheduled backups on one of the IBM Spectrum Protect servers.	• System authority on both servers: 2 administrator IDs • Operator authority: 2 administrator IDs for the assistants with access to the server that each person is responsible for

Planning for secure communications

Plan for protecting communications among the IBM Spectrum Protect™ solution components.

Determine the level of protection that is required for your data, based on regulations and business requirements under which your company operates.

If your business requires a high level of security for passwords and data transmission, plan on implementing secure communication with Transport Layer Security (TLS) or Secure Sockets Layer (SSL) protocols.

TLS and SSL provide secure communications between the server and client, but can affect system performance. To improve system performance, use TLS for authentication without encrypting object data. To specify whether the server uses TLS 1.2 for the entire session or only for authentication, see the SSL client option for client-to-server communication, and the UPDATE SERVER=SSL parameter for server-to-server communication. Beginning in V8.1.2, TLS is used for authentication by default. If you decide to use TLS to encrypt entire sessions, use the protocol only for sessions where it is necessary and add processor resources on the server to manage the increase in network traffic. You can also try other options. For example, some networking devices such as routers and switches provide the TLS or SSL function.

You can use TLS and SSL to protect some or all of the different possible communication paths, for example:

- Operations Center: browser to hub; hub to spoke
- Client to server
- Server to server: node replication

Related tasks:
Securing communications

Planning for storage of encrypted data

Determine whether your company requires stored data to be encrypted, and choose the option that best suits your needs.

If your company requires the data in storage pools to be encrypted, then you have the option of using IBM Spectrum Protect™ encryption, or an external device such as tape for encryption.

If you choose IBM Spectrum Protect to encrypt the data, extra computing resources are required at the client that might affect the performance of backup and restore processes.

Related information:
technote 1963635

Planning firewall access

Determine the firewalls that are set and the ports that must be open for the IBM Spectrum Protect™ solution to work.

Table 1 describes the ports that are used by the server, client, and Operations Center.

Table 1. Ports that are used by the server, client, and Operations Center

Item	Default	Direction	Description

Item	Default	Direction	Description
Base port (TCPPORT)	1500	Outbound/inbound	Each server instance requires a unique port. You can specify an alternative port number instead of using the default. The TCPPORT option listens for both TCP/IP and SSL-enabled sessions from the client. For administrative client traffic, you can use the TCPADMINPORT and ADMINONCLIENTPORT options to set port values.
SSL-only port (SSLTCPPORT)	No default	Outbound/inbound	This port is used if you want to restrict communication on the port to SSL-enabled sessions only. To support both SSL and non-SSL communications, use the TCPPORT or TCPADMINPORT options.
SMB	45	Inbound/outbound	This port is used by configuration wizards that communicate by using native protocols with multiple hosts.
SSH	22	Inbound/outbound	This port is used by configuration wizards that communicate by using native protocols with multiple hosts.
SMTP	25	Outbound	This port is used to send email alerts from the server.
NDMP	No default	Inbound/outbound	The server must be able to open an outbound NDMP control port connection to the NAS device. The outbound control port is the Low-Level Address in the data mover definition for the NAS device. During an NDMP filer-to-server restore, the server must be able to open an outbound NDMP data connection to the NAS device. The data connection port that is used during a restore can be configured on the NAS device. During NDMP filer-to-server backups, the NAS device must be able to open outbound data connections to the server and the server must be able to accept inbound NDMP data connections. You can use the server option NDMPPORTRANGE to restrict the set of ports available for use as NDMP data connections. You can configure a firewall for connections to these ports.
Replication	No default	Outbound/inbound	The port and protocol for the outbound port for replication are set by the DEFINE SERVER command that is used to set up replication. The inbound ports for replication are the TCP ports and SSL ports that the source server names in the DEFINE SERVER command.
Client schedule port	Client port: 1501	Outbound	The client listens on the port that is named and communicates the port number to the server. The server contacts the client if server prompted scheduling is used. You can specify an alternative port number in the client options file.
Long running sessions	KEEPALIVE setting: YES	Outbound	When the KEEPALIVE option is enabled, keepalive packets are sent during client-server sessions to prevent the firewall software from closing long-running, inactive connections.
Operations Center	HTTPS: 11090	Inbound	These ports are used for the Operations Center web browser. You can specify an alternative port number.
Client management service port	Client port: 9028	Inbound	The client management service port must be accessible from the Operations Center. Ensure that firewalls cannot prevent connections. The client management service uses the TCP port of the server for the client node for authentication by using an administrative session.

Single-site disk implementation of a data protection solution

The single-site disk solution is configured at one site and uses data deduplication.

Implementation roadmap

The following steps are required to set up the IBM Spectrum Protect™ single-site disk environment.

1. Set up the system.
    a. Configure the storage hardware and set up storage arrays for your environment size.
    b. Install the server operating system.
    c. Configure multipath I/O.
    d. Create the user ID for the server instance.
    e. Prepare file systems for IBM Spectrum Protect.
2. Install the server and Operations Center.
3. Configure the server and Operations Center.
    a. Complete the initial configuration of the server.
    b. Set server options.
    c. Configure Secure Sockets Layer for the server and client.
    d. Configure the Operations Center.
    e. Register your IBM Spectrum Protect license.
    f. Configure data deduplication.
    g. Define data retention rules for your business.
    h. Define server maintenance schedules.
    i. Define client schedules.
4. Install and configure clients.
    a. Register and assign clients to schedules.
    b. Install and verify the client management service.
    c. Configure the Operations Center to use the client management service.
5. Complete the implementation.

Setting up the system

To set up the system, you must first configure your disk storage hardware and the server system for IBM Spectrum Protect™.

- Configuring the storage hardware
  To configure your storage hardware, review general guidance for disk systems and IBM Spectrum Protect.
- Installing the server operating system
  Install the operating system on the server system and ensure that IBM Spectrum Protect server requirements are met. Adjust operating system settings as directed.
- Configuring multipath I/O
  You can enable and configure multipathing for disk storage. Use the documentation that is provided with your hardware for detailed instructions.
- Creating the user ID for the server
  Create the user ID that owns the IBM Spectrum Protect server instance. You specify this user ID when you create the server instance during initial configuration of the server.
- Preparing file systems for the server
  You must complete file system configuration for the disk storage to be used by the server.

Configuring the storage hardware

To configure your storage hardware, review general guidance for disk systems and IBM Spectrum Protect™.

Procedure

1. Provide a connection between the server and the storage devices by following these guidelines:
    - Use a switch or direct connection for Fibre Channel connections.
    - Consider the number of ports that are connected and account for the amount of bandwidth that is needed.
    - Consider the number of ports on the server and the number of host ports on the disk system that are connected.
2. Verify that device drivers and firmware for the server system, adapters, and operating system are current and at the recommended levels.
3. Configure storage arrays. Make sure that you planned properly to ensure optimal performance. See Planning for storage for more information.
4. Ensure that the server system has access to disk volumes that are created. Complete the following steps:

a. If the system is connected to a Fibre Channel switch, zone the server to see the disks.
b. Map all of the volumes to tell the disk system that this specific server is allowed to see each disk.

Installing the server operating system

Install the operating system on the server system and ensure that IBM Spectrum Protect™ server requirements are met. Adjust operating system settings as directed.

- Installing on AIX systems
  Complete the following steps to install AIX® on the server system.
- Installing on Linux systems
  Complete the following steps to install Linux x86_64 on the server system.
- Installing on Windows systems
  Install Microsoft Windows Server 2012 Standard Edition on the server system and prepare the system for installation and configuration of the IBM Spectrum Protect server.

Installing on AIX systems

Complete the following steps to install AIX® on the server system.

Procedure

1. Install AIX Version 7.1, TL4, SP2, or later according to the manufacturer instructions.
2. Configure your TCP/IP settings according to the operating system installation instructions.
3. Open the /etc/hosts file and complete the following actions:
   - Update the file to include the IP address and host name for the server. For example:

     ```
     192.0.2.7  server.yourdomain.com  server
     ```

   - Verify that the file contains an entry for localhost with an address of 127.0.0.1. For example:

     ```
     127.0.0.1  localhost
     ```

4. Enable AIX I/O completion ports by issuing the following command:

   ```
   chdev -l iocp0 -P
   ```

   Server performance can be affected by the Olson time zone definition.
5. To optimize performance, change your system time zone format from Olson to POSIX. Use the following command format to update the time zone setting:

   ```
   chtz=local_timezone,date/time,date/time
   ```

   For example, if you lived in Tucson, Arizona, where Mountain Standard Time is used, you would issue the following command to change to the POSIX format:

   ```
   chtz MST7MDT,M3.2.0/2:00:00,M11.1.0/2:00:00
   ```

6. Add an entry in the .profile of the instance user so that the following environment is set:

   ```
   export MALLOCOPTIONS=multiheap:16
   ```

7. Set the system to create full application core files. Issue the following command:

   ```
   chdev -l sys0 -a fullcore=true -P
   ```

8. For communications with the server and Operations Center, make sure that the following ports are open on any firewalls that might exist:
   - For communications with the server, open port 1500.
   - For secure communications with the Operations Center, open port 11090 on the hub server.

   If you are not using the default port values, make sure that the ports that you are using are open.

9. Enable TCP high-performance enhancements. Issue the following command:

   ```
   no -p -o rfc1323=1
   ```

10. For optimal throughput and reliability, bond four 10 Gb Ethernet ports together. Use the System Management Interface Tool (SMIT) to bond the ports together by using Etherchannel. The following settings were used during testing:

```
mode            8023ad
auto_recovery   yes             Enable automatic recovery after failover
backup_adapter  NONE            Adapter used when whole channel fails
hash_mode       src_dst_port    Determines how outgoing adapter is chosen
interval        long            Determines interval value for IEEE
                                802.3ad mode
mode            8023ad          EtherChannel mode of operation
netaddr         0               Address to ping
noloss_failover yes             Enable lossless failover after ping
                                failure
num_retries     3               Times to retry ping before failing
retry_time      1               Wait time (in seconds) between pings
use_alt_addr    no              Enable Alternate EtherChannel Address
use_jumbo_frame no              Enable Gigabit Ethernet Jumbo Frames
```

11. Verify that user process resource limits, also known as *ulimits*, are set according to guidelines in Table 1. If ulimit values are not set correctly, you might experience server instability or a failure of the server to respond.

Table 1. User limits (ulimit) values

User limit type	Setting	Value	Command to query value
Maximum size of core files created	core	Unlimited	`ulimit -Hc`
Maximum size of a data segment for a process	data	Unlimited	`ulimit -Hd`
Maximum file size	fsize	Unlimited	`ulimit -Hf`
Maximum number of open files	nofile	65536	`ulimit -Hn`
Maximum amount of processor time in seconds	cpu	Unlimited	`ulimit -Ht`
Maximum number of user processes	nproc	16384	`ulimit -Hu`

If you need to modify any user limit values, follow the instructions in the documentation for your operating system.

Installing on Linux systems

Complete the following steps to install Linux x86_64 on the server system.

Before you begin

The operating system will be installed on the internal hard disks. Configure the internal hard disks by using a hardware RAID 1 array. For example, if you are configuring a small system, the two 300 GB internal disks are mirrored in RAID 1 so that a single 300 GB disk appears available to the operating system installer.

Procedure

1. Install Red Hat Enterprise Linux Version 7.1 or later, according to the manufacturer instructions. Obtain a bootable DVD that contains Red Hat Enterprise Linux Version 7.1 and start your system from this DVD. See the following guidance for installation options. If an item is not mentioned in the following list, leave the default selection.
    a. After you start the DVD, choose Install or upgrade an existing system from the menu.
    b. On the Welcome screen, select Test this media & install Red Hat Enterprise Linux 7.1.
    c. Select your language and keyboard preferences.
    d. Select your location to set the correct time zone.
    e. Select Software Selection and then on the next screen, select Server with GUI.
    f. From the installation summary page, click Installation Destination and verify the following items:
        - The local 300 GB disk is selected as the installation target.
        - Under Other Storage Options, Automatically configure partitioning is selected.

       Click Done.
    g. Click Begin Installation. After the installation starts, set the root password for your root user account.

After the installation is completed, restart the system and log in as the root user. Issue the df command to verify your basic partitioning. For example, on a test system, the initial partitioning produced the following result:

```
[root@tvapp02]# df -h
Filesystem             Size  Used Avail Use% Mounted on
/dev/mapper/rhel-root   50G  3.0G   48G   6% /
devtmpfs                32G     0   32G   0% /dev
tmpfs                   32G   92K   32G   1% /dev/shm
tmpfs                   32G  8.8M   32G   1% /run
tmpfs                   32G     0   32G   0% /sys/fs/cgroup
/dev/mapper/rhel-home  220G   37M  220G   1% /home
/dev/sda1              497M  124M  373M  25% /boot
```

2. Configure your TCP/IP settings according to the operating system installation instructions.
   For optimal throughput and reliability, consider bonding multiple network ports together. This can be accomplished by creating a Link Aggregation Control Protocol (LACP) network connection, which aggregates several subordinate ports into a single logical connection. The preferred method is to use a bond mode of 802.3ad, miimon setting of 100, and a xmit_hash_policy setting of layer3+4.
   Restriction: To use an LACP network connection, you must have a network switch that supports LACP.

   For additional instructions about configuring bonded network connections with Red Hat Enterprise Linux Version 7, see Create a Channel Bonding Interface.

3. Open the /etc/hosts file and complete the following actions:
   - Update the file to include the IP address and host name for the server. For example:

     ```
     192.0.2.7  server.yourdomain.com  server
     ```

   - Verify that the file contains an entry for localhost with an address of 127.0.0.1. For example:

     ```
     127.0.0.1  localhost
     ```

4. Install components that are required for the server installation. Complete the following steps to create a Yellowdog Updater Modified (YUM) repository and install the prerequisite packages.
   a. Mount your Red Hat Enterprise Linux installation DVD to a system directory. For example, to mount it to the /mnt directory, issue the following command:

      ```
      mount -t iso9660 -o ro /dev/cdrom /mnt
      ```

   b. Verify that the DVD mounted by issuing the mount command. You should see output similar to the following example:

      ```
      /dev/sr0 on /mnt type iso9660
      ```

   c. Change to the YUM repository directory by issuing the following command:

      ```
      cd /etc/yum/repos.d
      ```

      If the repos.d directory does not exist, create it.
   d. List directory contents:

      ```
      ls rhel-source.repo
      ```

   e. Rename the original repo file by issuing the mv command. For example:

      ```
      mv rhel-source.repo rhel-source.repo.orig
      ```

   f. Create a new repo file by using a text editor. For example, to use the vi editor, issue the following command:

      ```
      vi rhel71_dvd.repo
      ```

   g. Add the following lines to the new repo file. The baseurl parameter specifies your directory mount point:

      ```
      [rhel71_dvd]
      name=DVD Redhat Enterprise Linux 7.1
      baseurl=file:///mnt
      enabled=1
      gpgcheck=0
      ```

   h. Install the prerequisite package ksh.x86_64, by issuing the yum command. For example:

      ```
      yum install ksh.x86_64
      ```

Exception: You do not need to install the compat-libstdc++-33-3.2.3-69.el6.i686 and libstdc++.i686 libraries for Red Hat Enterprise Linux Version 7.1.

5. When the software installation is complete, you can restore the original YUM repository values by completing the following steps:
   a. Unmount the Red Hat Enterprise Linux installation DVD by issuing the following command:

      ```
      unmount /mnt
      ```

   b. Change to the YUM repository directory by issuing the following command:

      ```
      cd /etc/yum/repos.d
      ```

   c. Rename the repo file that you created:

      ```
      mv rhel71_dvd.repo rhel71_dvd.repo.orig
      ```

   d. Rename the original file to the original name:

      ```
      mv rhel-source.repo.orig rhel-source.repo
      ```

6. Determine whether kernel parameter changes are required. Complete the following steps:
   a. Use the sysctl -a command to list the parameter values.
   b. Analyze the results by using the guidelines in Table 1 to determine whether any changes are required.
   c. If changes are required, set the parameters in the /etc/sysctl.conf file. The file changes are applied when the system is started.

   Tip: Automatically adjust kernel parameter settings and eliminate the need for manual updates to these settings. On Linux, the DB2® database software automatically adjusts interprocess communication (IPC) kernel parameter values to the preferred settings. For more information about kernel parameter settings, search for Linux kernel parameters in the IBM DB2 Version 11.1 Knowledge Center.

Table 1. Linux kernel parameter optimum settings

Parameter	**Description**
kernel.shmmni	The maximum number of segments.
kernel.shmmax	The maximum size of a shared memory segment (bytes). This parameter must be set before automatically starting the IBM Spectrum Protect™ server on system startup.
kernel.shmall	The maximum allocation of shared memory pages (pages).
kernel.sem There are four values for the kernel.sem parameter.	(SEMMSL) The maximum semaphores per array.
	(SEMMNS) The maximum semaphores per system.
	(SEMOPM) The maximum operations per semaphore call.
	(SEMMNI) The maximum number of arrays.
kernel.msgmni	The maximum number of system-wide message queues.
kernel.msgmax	The maximum size of messages (bytes).
kernel.msgmnb	The default maximum size of queue (bytes).
kernel.randomize_va_space	The kernel.randomize_va_space parameter configures the use of memory ASLR for the kernel. Disable ASLR because it can cause errors for the DB2 software. To learn more details about the Linux ASLR and DB2, see technote 1365583.

Parameter	Description
vm.swappiness	The vm.swappiness parameter defines whether the kernel can swap application memory out of physical random access memory (RAM). For more information about kernel parameters, see the DB2 product information.
vm.overcommit_memory	The vm.overcommit_memory parameter influences how much virtual memory the kernel permits allocating. For more information about kernel parameters, see the DB2 product information.

7. Open firewall ports to communicate with the server. Complete the following steps:
   a. Determine the zone that is used by the network interface. The zone is public, by default.
      Issue the following command:

      ```
      #  firewall-cmd --get-active-zones
      public
        interfaces: ens4f0
      ```

   b. To use the default port address for communications with the server, open TCP/IP port 1500 in the Linux firewall.
      Issue the following command:

      ```
      firewall-cmd --zone=public --add-port=1500/tcp --permanent
      ```

      If you want to use a value other than the default, you can specify a number in the range 1024 - 32767. If you open a port other than the default, you will need to specify that port when you run the configuration script.

   c. If you plan to use this system as a hub, open port 11090, which is the default port for secure (https) communications.
      Issue the following command:

      ```
      firewall-cmd --zone=public --add-port=11090/tcp --permanent
      ```

   d. Reload the firewall definitions for the changes to take effect.
      Issue the following command:

      ```
      firewall-cmd --reload
      ```

8. Verify that user process resource limits, also known as *ulimits*, are set according to guidelines in Table 2. If ulimit values are not set correctly, you might experience server instability or a failure of the server to respond.

Table 2. User limits (ulimit) values

User limit type	Setting	Value	Command to query value
Maximum size of core files created	core	Unlimited	`ulimit -Hc`
Maximum size of a data segment for a process	data	Unlimited	`ulimit -Hd`
Maximum file size	fsize	Unlimited	`ulimit -Hf`
Maximum number of open files	nofile	65536	`ulimit -Hn`
Maximum amount of processor time in seconds	cpu	Unlimited	`ulimit -Ht`
Maximum number of user processes	nproc	16384	`ulimit -Hu`

If you need to modify any user limit values, follow the instructions in the documentation for your operating system.

Installing on Windows systems

Install Microsoft Windows Server 2012 Standard Edition on the server system and prepare the system for installation and configuration of the IBM Spectrum Protect™ server.

Procedure

1. Install Microsoft Windows Server 2012 R2 Standard Edition, according to the manufacturer instructions.
2. Change the Windows account control policies by completing the following steps.
    a. Open the Local Security Policy editor by running secpol.msc.
    b. Click Local Policies > Security Options and ensure that the following User Account Control policies are disabled:
        - Admin Approval Mode for the Built-in Administrator account
        - Run all administrators in Admin Approval Mode
3. Configure your TCP/IP settings according to installation instructions for the operating system.
4. Apply Windows updates and enable optional features by completing the following steps:
    a. Apply the latest Windows 2012 R2 updates.
    b. Install and enable the Windows 2012 R2 feature Microsoft .NET Framework 3.5 from the Windows Server Manager.
    c. If required, update the FC and Ethernet HBA device drivers to newer levels.
    d. Install the multipath I/O driver that is appropriate for the disk system that you are using.
5. Open the default TCP/IP port, 1500, for communications with the IBM Spectrum Protect server. For example, issue the following command:

```
netsh advfirewall firewall add rule name="Backup server port 1500"
dir=in action=allow protocol=TCP localport=1500
```

6. On the Operations Center hub server, open the default port for secure (https) communications with the Operations Center. The port number is 11090. For example, issue the following command:

```
netsh advfirewall firewall add rule name="Operations Center port 11090"
dir=in action=allow protocol=TCP localport=11090
```

Configuring multipath I/O

You can enable and configure multipathing for disk storage. Use the documentation that is provided with your hardware for detailed instructions.

- AIX systems
- Linux systems
- Windows systems

AIX systems

Procedure

1. Determine the Fibre Channel port address that you must use for the host definition on the disk subsystem. Issue the lscfg command for every port.
    - On small and medium systems, issue the following commands:

```
lscfg -vps -l fcs0 | grep "Network Address"
lscfg -vps -l fcs1 | grep "Network Address"
```

    - On large systems, issue the following commands:

```
lscfg -vps -l fcs0 | grep "Network Address"
lscfg -vps -l fcs1 | grep "Network Address"
lscfg -vps -l fcs2 | grep "Network Address"
lscfg -vps -l fcs3 | grep "Network Address"
```

2. Ensure that the following AIX® file sets are installed:
    - devices.common.IBM.mpio.rte
    - devices.fcp.disk.array.rte
    - devices.fcp.disk.rte
3. Issue the cfgmgr command to have AIX rescan the hardware and discover available disks. For example:

```
cfgmgr
```

4. To list the available disks, issue the following command:

```
lsdev -Ccdisk
```

    You should see output similar to the following:

```
hdisk0  Available 00-00-00 SAS Disk Drive
hdisk1  Available 00-00-00 SAS Disk Drive
hdisk2  Available 01-00-00 SAS Disk Drive
hdisk3  Available 01-00-00 SAS Disk Drive
hdisk4  Available 06-01-02 MPIO IBM 2076 FC Disk
hdisk5  Available 07-01-02 MPIO IBM 2076 FC Disk
...
```

5. Use the output from the lsdev command to identify and list device IDs for each disk device.

   For example, a device ID could be `hdisk4`. Save the list of device IDs to use when you create file systems for the IBM Spectrum Protect™ server.

6. Correlate the SCSI device IDs to specific disk LUNs from the disk system by listing detailed information about all physical volumes in the system. Issue the following command:

   ```
   lspv -u
   ```

   On an IBM® Storwize® system, the following information is an example of what is shown for each device:

   ```
   hdisk4  00f8cf083fd97327  None  active
    3321360050763008101057800000000000030042145 03IBMfcp
   ```

   In the example, *600507630081010578000000000000030* is the UID for the volume, as reported by the Storwize management interface.
   To verify disk size in megabytes and compare the value with what is listed for the system, issue the following command:

   ```
   bootinfo -s hdisk4
   ```

Linux systems

Procedure

1. Edit the /etc/multipath.conf file to enable multipathing for Linux hosts. If the multipath.conf file does not exist, you can create it by issuing the following command:

   ```
   mpathconf --enable
   ```

   The following parameters were set in multipath.conf for testing on an IBM Storwize® system:

   ```
   defaults {
                user_friendly_names no
   }

   devices {
                device {
                            vendor "IBM "
                            product "2145"
                            path_grouping_policy group_by_prio
                            user_friendly_names no
                            path_selector "round-robin 0"
                            prio "alua"
                            path_checker "tur"
                            failback "immediate"
                            no_path_retry 5
                            rr_weight uniform
                            rr_min_io_rq "1"
                            dev_loss_tmo 120
               }
   }
   ```

2. Set the multipath option to start when the system is started. Issue the following commands:

   ```
   systemctl enable multipathd.service
   systemctl start multipathd.service
   ```

3. To verify that disks are visible to the operating system and are managed by multipath, issue the following command:

   ```
   multipath -l
   ```

4. Ensure that each device is listed and that it has as many paths as you expect. You can use size and device ID information to identify which disks are listed.
   For example, the following output shows that a 2 TB disk has two path groups and four active paths. The 2 TB size confirms that the disk corresponds to a pool file system. Use part of the long device ID number (12, in this example) to search for the volume on the disk-system management interface.

```
[root@tapsrv01 code]# multipath -l
36005076802810c509800000000000012 dm-43 IBM,2145
 size=2.0T features='1 queue_if_no_path' hwhandler='0' wp=rw
|-+- policy='round-robin 0' prio=0 status=active
| |- 2:0:1:18 sdcw 70:64   active undef running
| `- 4:0:0:18 sdgb 131:112 active undef running
`-+- policy='round-robin 0' prio=0 status=enabled
  |- 1:0:1:18 sdat 66:208  active undef running
  `- 3:0:0:18 sddy 128:0   active undef running
```

   a. If needed, correct disk LUN host assignments and force a bus rescan. For example:

```
echo "- - -" > /sys/class/scsi_host/host0/scan
echo "- - -" > /sys/class/scsi_host/host1/scan
echo "- - -" > /sys/class/scsi_host/host2/scan
```

      You can also restart the system to rescan disk LUN host assignments.
   b. Confirm that disks are now available for multipath I/O by reissuing the multipath -l command.
5. Use the multipath output to identify and list device IDs for each disk device.

   For example, the device ID for your 2 TB disk is `36005076802810c509800000000000012`.

   Save the list of device IDs to use in the next step.

Windows systems

Procedure

1. Ensure that the Multipath I/O feature is installed. If needed, install additional vendor-specific multipath drivers.
2. To verify that disks are visible to the operating system and are managed by multipath I/O, issue the following command:

```
c:\program files\IBM\SDDDSM\datapath.exe query device
```

3. Review the multipath output and ensure that each device is listed and that it has as many paths as you expect. You can use size and device serial information to identify which disks are listed.
   For example, by using part of the long device serial number (34, in this example) you can search for the volume on the disk-system management interface. The 2 TB size confirms that the disk corresponds to a storage pool file system.

```
DEV#:   4  DEVICE NAME: Disk5 Part0   TYPE: 2145    POLICY: OPTIMIZED
SERIAL: 60050763008101057800000000000034          LUN SIZE: 2.0TB
============================================================================
Path#          Adapter/Hard Disk       State   Mode    Select  Errors
    0   Scsi Port2 Bus0/Disk5 Part0    OPEN    NORMAL       0       0
    1   Scsi Port2 Bus0/Disk5 Part0    OPEN    NORMAL   27176       0
    2   Scsi Port3 Bus0/Disk5 Part0    OPEN    NORMAL   28494       0
    3   Scsi Port3 Bus0/Disk5 Part0    OPEN    NORMAL       0       0
```

4. Create a list of disk device IDs by using the serial numbers that are returned from the multipath output in the previous step.

   For example, the device ID for your 2 TB disk is `60050763008101057800000000000034`

   Save the list of device IDs to use in the next step.

5. To bring new disks online and clear the read-only attribute, run diskpart.exe with the following commands. Repeat for each of the disks:

```
diskpart
   select Disk 1
   online disk
   attribute disk clear readonly
   select Disk 2
   online disk
   attribute disk clear readonly
```

```
< ... >
select Disk 49
online disk
attribute disk clear readonly
exit
```

Creating the user ID for the server

Create the user ID that owns the IBM Spectrum Protect™ server instance. You specify this user ID when you create the server instance during initial configuration of the server.

About this task

You can specify only lowercase letters (a-z), numerals (0-9), and the underscore character (_) for the user ID. The user ID and group name must comply with the following rules:

- The length must be 8 characters or fewer.
- The user ID and group name cannot start with *ibm*, *sql*, *sys*, or a numeral.
- The user ID and group name cannot be *user*, *admin*, *guest*, *public*, *local*, or any SQL reserved word.

Procedure

1. Use operating system commands to create a user ID.
   - AIX Linux Create a group and user ID in the home directory of the user that owns the server instance.

     For example, to create the user ID tsminst1 in group tsmsrvrs with a password of tsminst1, issue the following commands from an administrative user ID:

     AIX

     ```
     mkgroup id=1001 tsmsrvrs
     mkuser id=1002 pgrp=tsmsrvrs home=/home/tsminst1 tsminst1
     passwd tsminst1
     ```

     Linux

     ```
     groupadd tsmsrvrs
     useradd -d /home/tsminst1 -m -g tsmsrvrs -s /bin/bash tsminst1
     passwd tsminst1
     ```

     Log off, and then log in to your system. Change to the user account that you created. Use an interactive login program, such as telnet, so that you are prompted for the password and can change it if necessary.
   - Windows Create a user ID and then add the new ID to the Administrators group. For example, to create the user ID tsminst1, issue the following command:

     ```
     net user tsminst1 * /add
     ```

     After you create and verify a password for the new user, add the user ID to the Administrators group by issuing the following commands:

     ```
     net localgroup Administrators tsminst1 /add
     net localgroup DB2ADMNS tsminst1 /add
     ```

2. Log off the new user ID.

Preparing file systems for the server

You must complete file system configuration for the disk storage to be used by the server.

- Preparing file systems on AIX systems
  You must create volume groups, logical volumes, and file systems for the server by using the AIX® Logical Volume Manager.
- Preparing file systems on Linux systems
  You must format ext4 or xfs file systems on each of the disk LUNs to be used by the IBM Spectrum Protect server.
- Preparing file systems on Windows systems
  You must format New Technology File System (NTFS) file systems on each of the disk LUNs to be used by the IBM

Spectrum Protect server.

Preparing file systems on AIX systems

You must create volume groups, logical volumes, and file systems for the server by using the AIX® Logical Volume Manager.

Procedure

1. Increase the queue depth and maximum transfer size for all of the available *hdiskX* disks. Issue the following commands for each disk:

   ```
   chdev -l hdisk4 -a max_transfer=0x100000
   chdev -l hdisk4 -a queue_depth=32
   chdev -l hdisk4 -a reserve_policy=no_reserve
   chdev -l hdisk4 -a algorithm=round_robin
   ```

   Do not run these commands for operating system internal disks, for example, *hdisk0*.
2. Create volume groups for the IBM Spectrum Protect™ database, active log, archive log, database backup, and storage pool. Issue the mkvg command, specifying the device IDs for corresponding disks that you previously identified.
   For example, if the device names *hdisk4, hdisk5*, and *hdisk6* correspond to database disks, include them in the database volume group and so on.
   System size: The following commands are based on the medium system configuration. For small and large systems, you must adjust the syntax as required.

   ```
   mkvg -S -y tsmdb hdisk2 hdisk3 hdisk4
   mkvg -S -y tsmactlog hdisk5
   mkvg -S -y tsmarchlog hdisk6
   mkvg -S -y tsmdbback hdisk7 hdisk8 hdisk9 hdisk10
   mkvg -S -y tsmstgpool hdisk11 hdisk12 hdisk13 hdisk14 ... hdisk49
   ```

3. Determine the physical volume names and the number of free physical partitions to use when you create logical volumes. Issue the lsvg for each volume group that you created in the previous step.
   For example:

   ```
   lsvg -p tsmdb
   ```

   The output is similar to the following. The *FREE PPs* column represents the free physical partitions:

   ```
   tsmdb:
   PV_NAME  PV STATE   TOTAL PPs  FREE PPs  FREE DISTRIBUTION
   hdisk4   active     1631       1631      327..326..326..326..326
   hdisk5   active     1631       1631      327..326..326..326..326
   hdisk6   active     1631       1631      327..326..326..326..326
   ```

4. Create logical volumes in each volume group by using the mklv command. The volume size, volume group, and device names vary, depending on the size of your system and variations in your disk configuration.
   For example, to create the volumes for the IBM Spectrum Protect database on a medium system, issue the following commands:

   ```
   mklv -y tsmdb00 -t jfs2 -u 1 -x 1631 tsmdb 1631 hdisk2
   mklv -y tsmdb01 -t jfs2 -u 1 -x 1631 tsmdb 1631 hdisk3
   mklv -y tsmdb02 -t jfs2 -u 1 -x 1631 tsmdb 1631 hdisk4
   ```

5. Format file systems in each logical volume by using the crfs command.
   For example, to format file systems for the database on a medium system, issue the following commands:

   ```
   crfs -v jfs2 -d tsmdb00 -p rw -a logname=INLINE -a options=rbrw
    -a agblksize=4096 -m /tsminst1/TSMdbspace00 -A yes
   crfs -v jfs2 -d tsmdb01 -p rw -a logname=INLINE -a options=rbrw
    -a agblksize=4096 -m /tsminst1/TSMdbspace01 -A yes
   crfs -v jfs2 -d tsmdb02 -p rw -a logname=INLINE -a options=rbrw
    -a agblksize=4096 -m /tsminst1/TSMdbspace02 -A yes
   ```

6. Mount all of the newly created file systems by issuing the following command:

   ```
   mount -a
   ```

7. List all file systems by issuing the df command. Verify that file systems are mounted at the correct LUN and correct mount point. Also, verify the available space.

The following example of command output shows that the amount of used space is typically 1%:

```
tapsrv07> df -g /tsminst1/*
Filesystem      GB blocks  Free     %Used   Iused   %Iused   Mounted on
/dev/tsmact00   195.12     194.59   1%      4       1%       /tsminst1/TSMalog
```

8. Verify that the user ID you created in Creating the user ID for the server has read and write access to the directories for the server.

Preparing file systems on Linux systems

You must format ext4 or xfs file systems on each of the disk LUNs to be used by the IBM Spectrum Protect™ server.

Procedure

1. Using the list of device IDs that you generated previously, issue the mkfs command to create and format a file system for each storage LUN device. Specify the device ID in the command. See the following examples. For the database, format ext4 file systems:

   ```
   mkfs -t ext4 -T largefile -m 2 /dev/mapper/36005076802810c509800000000000012
   ```

   For storage pool LUNs, format xfs file systems:

   ```
   mkfs -t xfs /dev/mapper/360050763008101057800000000002c3
   ```

   You might issue the mkfs command as many as 50 times, depending on how many different devices you have.

2. Create mount point directories for file systems.

   Issue the mkdir command for each directory that you must create. Use the directory values that you recorded in the planning worksheets.

   For example, to create the server instance directory by using the default value, issue the following command:

   ```
   mkdir /tsminst1
   ```

   Repeat the mkdir command for each file system.
3. Add an entry in the /etc/fstab file for each file system so that file systems are mounted automatically when the server is started.
   For example:

   ```
   /dev/mapper/36005076802810c509800000000000012 /tsminst1/TSMdbspace00 ext4 defaults 0 0
   ```

4. Mount the file systems that you added to the /etc/fstab file by issuing the mount -a command.
5. List all file systems by issuing the df command. Verify that file systems are mounted at the correct LUN and correct mount point. Also, verify the available space.
   The following example on an IBM® Storwize® system shows that the amount of used space is typically 1%:

   ```
   [root@tapsrv04 ~]# df -h /tsminst1/*
   Filesystem                                      Size  Used Avail Use% Mounted on
   /dev/mapper/360050763008101057800000000000003 134G  188M 132G  1%   /tsminst1/TSMalog
   ```

6. Verify that the user ID you created in Creating the user ID for the server has read and write access to the directories for the IBM Spectrum Protect server.

Preparing file systems on Windows systems

You must format New Technology File System (NTFS) file systems on each of the disk LUNs to be used by the IBM Spectrum Protect™ server.

Procedure

1. Create mount point directories for file systems.
   Issue the md command for each directory that you must create. Use the directory values that you recorded in the planning worksheets. For example, to create the server instance directory by using the default value, issue the following command:

```
md c:\tsminst1
```

Repeat the md command for each file system.

2. Create a volume for every disk LUN that is mapped to a directory under the server instance directory by using the Windows volume manager.

   Go to Server Manager > File and Storage Services and complete the following steps for each disk that corresponds to the LUN mapping that was created in the previous step:

   a. Bring the disk online.
   b. Initialize the disk to the GPT basic type, which is the default.
   c. Create a simple volume that occupies all of the space on the disk. Format the file system by using NTFS, and assign a label that matches the purpose of the volume, such as TSMfile00. Do not assign the new volume to a drive letter. Instead, map the volume to a directory under the instance directory, such as C:\tsminst1\TSMfile00.
      Tip: Determine the volume label and directory mapping labels based on the size of the disk that is reported.
3. Verify that file systems are mounted at the correct LUN and correct mount point. List all file systems by issuing the mountvol command and then review the output. For example:

```
\\?\Volume{8ffb9678-3216-474c-a021-20e420816a92}\
  C:\tsminst1\TSMdbspace00\
```

4. After the disk configuration is complete, restart the system.

What to do next

You can confirm the amount of free space for each volume by using Windows Explorer.

Installing the server and Operations Center

Use the IBM® Installation Manager graphical wizard to install the components.

- Installing on AIX and Linux systems
  Install the IBM Spectrum Protect™ server and the Operations Center on the same system.
- Installing on Windows systems
  Install the IBM Spectrum Protect server and the Operations Center on the same system.

Installing on AIX® and Linux systems

Install the IBM Spectrum Protect™ server and the Operations Center on the same system.

Before you begin

Verify that the operating system is set to the language that you require. By default, the language of the operating system is the language of the installation wizard.

Procedure

1. AIX Verify that the required RPM files are installed on your system.

   See Installing prerequisite RPM files for the graphical wizard for details.

2. Before you download the installation package, verify that you have enough space to store the installation files when they are extracted from the product package. For space requirements, see the download document at technote 4042992.
3. Go to Passport Advantage® and download the package file to an empty directory of your choice.
4. Ensure that executable permission is set for the package. If necessary, change the file permissions by issuing the following command:

```
chmod a+x package_name.bin
```

5. Extract the package by issuing the following command:

```
./package_name.bin
```

   where *package_name* is the name of the downloaded file.

6. AIX Ensure that the following command is enabled so that the wizards work properly:

   ```
   lsuser
   ```

   By default, the command is enabled.
7. Change to the directory where you placed the executable file.
8. Start the installation wizard by issuing the following command:

   ```
   ./install.sh
   ```

   When you select the packages to install, choose both the server and Operations Center.

What to do next

- If errors occur during the installation process, the errors are recorded in log files that are stored in the IBM Installation Manager logs directory.

  To view installation log files from the Installation Manager tool, click File > View Log. To collect these log files from the Installation Manager tool, click Help > Export Data for Problem Analysis.

- After you install the server and before you customize it for your use, go to the IBM Spectrum Protect support site. Click Support and downloads and apply any applicable fixes.

- Installing prerequisite RPM files for the graphical wizard
  RPM files are required for the IBM Installation Manager graphical wizard.

Related tasks:
Other methods for installing IBM Spectrum Protect components (AIX)
Other methods for installing IBM Spectrum Protect components (Linux)

Installing on Windows systems

Install the IBM Spectrum Protect™ server and the Operations Center on the same system.

Before you begin

Make sure that the following prerequisites are met:

- Verify that the operating system is set to the language that you require. By default, the language of the operating system is the language of the installation wizard.
- Ensure that the user ID that you plan to use during the installation is a user with local Administrator authority.

Procedure

1. Before you download the installation package, verify that you have enough space to store the installation files when they are extracted from the product package. For space requirements, see the download document at technote 4042993.
2. Go to Passport Advantage® and download the package file to an empty directory of your choice.
3. Change to the directory where you placed the executable file.
4. Double-click the executable file to extract to the current directory.
5. In the directory where the installation files were extracted, start the installation wizard by double-clicking the install.bat file. When you select the packages to install, choose both the server and Operations Center.

What to do next

- If errors occur during the installation process, the errors are recorded in log files that are stored in the IBM® Installation Manager logs directory.

  To view installation log files from the Installation Manager tool, click File > View Log. To collect these log files from the Installation Manager tool, click Help > Export Data for Problem Analysis.

- After you install the server and before you customize it for your use, go to the IBM Spectrum Protect support site. Click Support and downloads and apply any applicable fixes.

Related tasks:

Configuring the server and the Operations Center

After you install the components, complete the configuration for the IBM Spectrum Protect™ server and the Operations Center.

- Configuring the server instance
  Use the IBM Spectrum Protect server instance configuration wizard to complete the initial configuration of the server.
- Installing the backup-archive client
  As a best practice, install the IBM Spectrum Protect backup-archive client on the server system so that the administrative command-line client and scheduler are available.
- Setting options for the server
  Review the server options file that is installed with the IBM Spectrum Protect server to verify that the correct values are set for your system.
- Configuring secure communications with Transport Layer Security
  To encrypt data and secure communications in your environment, Secure Sockets Layer (SSL) or Transport Layer Security (TLS) is enabled on the IBM Spectrum Protect server and backup-archive client. An SSL certificate is used to verify communication requests between the server and client.
- Configuring the Operations Center
  After you install the Operations Center, complete the following configuration steps to start managing your storage environment.
- Registering the product license
  To register your license for the IBM Spectrum Protect product, use the REGISTER LICENSE command.
- Configuring data deduplication
  Create a directory-container storage pool and at least one directory to use inline data deduplication.
- Defining data retention rules for your business
  After you create a directory-container storage pool for data deduplication, update the default server policy to use the new storage pool. The Add Storage Pool wizard opens the Services page in the Operations Center to complete this task.
- Defining schedules for server maintenance activities
  Create schedules for each server maintenance operation by using the DEFINE SCHEDULE command in the Operations Center command builder.
- Defining client schedules
  Use the Operations Center to create schedules for client operations.

Configuring the server instance

Use the IBM Spectrum Protect™ server instance configuration wizard to complete the initial configuration of the server.

Before you begin

Ensure that the following requirements are met:
AIX Linux

- The system where you installed IBM Spectrum Protect must have the X Window System client. You must also be running an X Window System server on your desktop.
- The system must have the Secure Shell (SSH) protocol enabled. Ensure that the port is set to the default value, 22, and that the port is not blocked by a firewall. You must enable password authentication in the sshd_config file in the /etc/ssh/directory. Also, ensure that the SSH daemon service has access rights to connect to the system by using the *localhost* value.
- You must be able to log in to IBM Spectrum Protect with the user ID that you created for the server instance, by using the SSH protocol. When you use the wizard, you must provide this user ID and password to access that system.
- If you changed any settings in the preceding steps, restart the server before you proceed with the configuration wizard.

Windows Verify that the remote registry service is started by completing the following steps:

1. Click Start > Administrative Tools > Services. In the Services window, select Remote Registry. If it is not started, click Start.
2. Ensure that port 137, 139, and 445 are not blocked by a firewall:
   a. Click Start > Control Panel > Windows Firewall.
   b. Select Advanced Settings.
   c. Select Inbound Rules.
   d. Select New Rule.

e. Create a port rule for TCP ports 137, 139, and 445 to allow connections for domain and private networks.

3. Configure the user account control by accessing the local security policy options and completing the following steps.
   a. Click Start > Administrative Tools > Local Security Policy. Expand Local Policies > Security Options.
   b. If not already enabled, enable the built-in administrator account by selecting Accounts: Administrator account status > Enable > OK.
   c. If not already disabled, disable user account control for all Windows administrators by selecting User Account Control: Run all administrators in Admin Approval Mode > Disable > OK.
   d. If not already disabled, disable the User Account Control for the built-in Administrator account by selecting User Account Control: Admin Approval Mode for the Built-in Administrator Account > Disable > OK.
4. If you changed any settings in the preceding steps, restart the server before you proceed with the configuration wizard.

About this task

The wizard can be stopped and restarted, but the server is not operational until the entire configuration process is complete.

Procedure

1. Start the local version of the wizard.
   - AIX Linux Open the dsmicfgx program in the /opt/tivoli/tsm/server/bin directory. This wizard can be only run as a root user.
   - Windows Click Start > All Programs > IBM Spectrum Protect > Configuration Wizard.
2. Follow the instructions to complete the configuration. Use the information that you recorded in Planning worksheets during IBM Spectrum Protect system set up to specify directories and options in the wizard.

   AIX Linux On the Server Information window, set the server to start automatically by using the instance user ID when the system boots.

   Windows By using the configuration wizard, the server is set to start automatically when rebooted.

Installing the backup-archive client

As a best practice, install the IBM Spectrum Protect™ backup-archive client on the server system so that the administrative command-line client and scheduler are available.

Procedure

To install the backup-archive client, follow the installation instructions for your operating system.

- Installing the UNIX and Linux backup-archive clients
- Installing the Windows backup-archive client

Setting options for the server

Review the server options file that is installed with the IBM Spectrum Protect™ server to verify that the correct values are set for your system.

Procedure

1. Go to the server instance directory and open the dsmserv.opt file.
2. Review the values in the following table and verify your server option settings, based on system size.

Server option	Small system value	Medium system value	Large system value
ACTIVELOGDIRECTORY	Directory path that was specified during configuration	Directory path that was specified during configuration	Directory path that was specified during configuration
ACTIVELOGSIZE	131072	131072	262144
ARCHLOGCOMPRESS	Yes	No	No

Server option	Small system value	Medium system value	Large system value
ARCHLOGDIRECTORY	Directory path that was specified during configuration	Directory path that was specified during configuration	Directory path that was specified during configuration
COMMMETHOD	TCPIP	TCPIP	TCPIP
COMMTIMEOUT	3600	3600	3600
DEDUPREQUIRESBACKUP	No	No	No
DEVCONFIG	devconf.dat	devconf.dat	devconf.dat
EXPINTERVAL	0	0	0
IDLETIMEOUT	60	60	60
MAXSESSIONS	250	500	1000
NUMOPENVOLSALLOWED	20	20	20
TCPADMINPORT	1500	1500	1500
TCPPORT	1500	1500	1500
VOLUMEHISTORY	volhist.dat	volhist.dat	volhist.dat

Update server option settings if necessary, to match the values in the table. To make updates, close the dsmserv.opt file and use the SETOPT command from the administrative command-line interface to set the options.
For example, to update the IDLETIMEOUT option to 60, issue the following command:

```
setopt idletimeout 60
```

3. To configure secure communications for the server, clients, and the Operations Center, verify the options in the following table.

Server option	All system sizes
SSLFIPSMODE	NO
TCPPORT	Specify the port number on which the server waits for requests for TCP/IP and SSL-enabled sessions from the client.
TCPADMINPORT	Specify the port address on which the server waits for requests for TCP/IP and SSL-enabled sessions from the command-line administrative client.

If any of the option values must be updated, edit the dsmserv.opt file by using the following guidelines:
   - Remove the asterisk at the beginning of a line to enable an option.
   - On each line, enter only one option and the specified value for the option.
   - If an option occurs in multiple entries in the file, the server uses the last entry.

Save your changes and close the file. If you edit the dsmserv.opt file directly, you must restart the server for the changes to take effect.

SETOPT (Set a server option for dynamic update)

Configuring secure communications with Transport Layer Security

To encrypt data and secure communications in your environment, Secure Sockets Layer (SSL) or Transport Layer Security (TLS) is enabled on the IBM Spectrum Protect™ server and backup-archive client. An SSL certificate is used to verify communication requests between the server and client.

About this task

As shown in the following figure, you can manually configure secure communications between the server and backup-archive client by setting options in the server and client options files, and then transferring the self-signed certificate that is generated on the server to the client. Alternatively, you can obtain and transfer a unique certificate that is signed by a certificate authority (CA).

For more information about configuring the server and clients for SSL or TLS communications, see Configuring storage agents, servers, clients, and the Operations Center to connect to the server by using SSL.

Configuring the Operations Center

After you install the Operations Center, complete the following configuration steps to start managing your storage environment.

Before you begin

When you connect to the Operations Center for the first time, you must provide the following information:

- Connection information for the server that you want to designate as a hub server
- Login credentials for an administrator ID that is defined for that server

Procedure

1. Designate the hub server. In a web browser, enter the following address:

   `https://hostname:secure_port/oc`

   where:
   - *hostname* represents the name of the computer where the Operations Center is installed
   - *secure_port* represents the port number that the Operations Center uses for HTTPS communication on that computer

   For example, if your host name is tsm.storage.mylocation.com and you are using the default secure port for the Operations Center, which is 11090, the address is:

   `https://tsm.storage.mylocation.com:11090/oc`

   When you log in to the Operations Center for the first time, a wizard guides you through an initial configuration to set up a new administrator with system authority on the server.

2. Set up secure communications between the Operations Center and the hub server by configuring the Secure Sockets Layer (SSL) protocol.

   Follow the instructions in Securing communications between the Operations Center and the hub server.

3. Optional: To receive a daily email report that summarizes system status, configure your email settings in the Operations Center.

   Follow the instructions in Tracking system status by using email reports.

- Securing communications between the Operations Center and the hub server
  To secure communications between the Operations Center and the hub server, add the Transport Layer Security (TLS) certificate of the hub server to the truststore file of the Operations Center.

Registering the product license

To register your license for the IBM Spectrum Protect™ product, use the REGISTER LICENSE command.

About this task

Licenses are stored in enrollment certificate files, which contain licensing information for the product. The enrollment certificate files are on the installation media, and are placed on the server during installation. When you register the product, the licenses are stored in a NODELOCK file within the current directory.

Procedure

Register a license by specifying the name of the enrollment certificate file that contains the license. To use the Operations Center command builder for this task, complete the following steps.

1. Open the Operations Center.
2. Open the Operations Center command builder by hovering over the settings icon  and clicking Command Builder.
3. Issue the REGISTER LICENSE command. For example, to register a base IBM Spectrum Protect license, issue the following command:

```
register license file=tsmbasic.lic
```

What to do next

Save the installation media that contains your enrollment certificate files. You might need to register your license again if, for example, one of the following conditions occur:

- The server is moved to a different computer.
- The NODELOCK file is corrupted. The server stores license information in the NODELOCK file, which is in the directory from which the server is started.
- Linux If you change the processor chip that is associated with the server on which the server is installed.

Related reference:
REGISTER LICENSE (Register a new license)

Configuring data deduplication

Create a directory-container storage pool and at least one directory to use inline data deduplication.

Before you begin

Use the storage pool directory information that you recorded in Planning worksheets for this task.

Procedure

1. Open the Operations Center.
2. On the Operations Center menu bar, hover over Storage.
3. From the list that is displayed, click Storage Pools.
4. Click the +Storage Pool button.
5. Complete the steps in the Add Storage Pool wizard:
    - To use inline data deduplication, select a Directory storage pool under Container-based storage.
    - When you configure directories for the directory-container storage pool, specify the directory paths that you created for storage during system setup.
6. After you configure the new directory-container storage pool, click Close & View Policies to update a management class and start using the storage pool.

Defining data retention rules for your business

After you create a directory-container storage pool for data deduplication, update the default server policy to use the new storage pool. The Add Storage Pool wizard opens the Services page in the Operations Center to complete this task.

Procedure

1. On the Services page of the Operations Center, select the STANDARD domain and click Details.
2. On the Summary page for the policy domain, click the Policy Sets tab. The Policy Sets page indicates the name of the active policy set and lists all of the management classes for that policy set.
3. Click the Configure toggle, and make the following changes:

- Change the backup destination for the STANDARD management class to the directory-container storage pool.
- Change the value for the Backups column to No limit.
- Change the retention period. Set the Keep Extra Backups column to 30 days or more, depending on your business requirements.

4. Save your changes and click the Configure toggle again so that the policy set is no longer editable.
5. Activate the policy set by clicking Activate.

Specifying rules for backing up and archiving client data

Defining schedules for server maintenance activities

Create schedules for each server maintenance operation by using the DEFINE SCHEDULE command in the Operations Center command builder.

About this task

Schedule server maintenance operations to run after client backup operations. You can control the timing of schedules by setting the start time in combination with the duration time for each operation.

The following example shows how you can schedule server maintenance operations in combination with the client backup schedule for a single-site disk solution.

Operation	Schedule
Client backup	Starts at 22:00.
Processing for database and disaster recovery files	• The database backup operation starts at 11:00, or 13 hours after the beginning of the client backup operation. This process runs until completion. • Device configuration information and volume history backup operations start at 17:00, or 6 hours after the start of the database backup operation. • Volume history deletion starts at 20:00, or 9 hours after the start of the database backup operation.
Inventory expiration	Starts at 12:00, or 14 hours after the beginning of the client backup operation. This process runs until completion.

Procedure

After you configure the device class for the database backup operations, create schedules for database backup and other required maintenance operations by using the DEFINE SCHEDULE command. Depending on the size of your environment, you might need to adjust the start times for each schedule in the example.

1. Define a device class for the backup operations. For example, use the DEFINE DEVCLASS command to create a device class that is named DBBACK_FILEDEV:

   ```
   define devclass dbback_filedev devtype=file
     directory=db_backup_directories
   ```

   where *db_backup_directories* is a list of the directories that you created for the database backup.
   AIX Linux For example, if you have four directories for database backups, starting with /tsminst1/TSMbkup00, issue the following command:

   ```
   define devclass dbback_filedev devtype=file
     directory=/tsminst1/TSMbkup00,
     /tsminst1/TSMbkup01,/tsminst1/TSMbkup02,
     /tsminst1/TSMbkup03"
   ```

   Windows For example, if you have four directories for database backups, starting with C:\tsminst1\TSMbkup00, issue the following command:

   ```
   define devclass dbback_filedev devtype=file
     directory="c:\tsminst1\TSMbkup00,
     c:\tsminst1\TSMbkup01,c:\tsminst1\TSMbkup02,
     c:\tsminst1\TSMbkup03"
   ```

2. Set the device class for automatic database backup operations. Use the SET DBRECOVERY command to specify the device class that you created in the preceding step. For example, if the device class is dbback_filedev, issue the following command:

```
set dbrecovery dbback_filedev
```

3. Create schedules for the maintenance operations by using the DEFINE SCHEDULE command. See the following table for the required operations with examples of the commands.

Operation	Example command
Back up the database.	Create a schedule to run the BACKUP DB command. If you are configuring a small system, set the COMPRESS parameter to YES. For example, on a small system, issue the following command to create a backup schedule that uses the new device class: `define schedule DBBACKUP type=admin cmd="backup db devclass=dbback_filedev type=full numstreams=3 wait=yes compress=yes" active=yes desc="Back up the database." startdate=today starttime=11:00:00 duration=45 durunits=minutes`
Back up the device configuration information.	Create a schedule to run the BACKUP DEVCONFIG command: `define schedule DEVCONFIGBKUP type=admin cmd="backup devconfig filenames=devconfig.dat" active=yes desc="Backup the device configuration file." startdate=today starttime=17:00:00 duration=45 durunits=minutes`
Back up the volume history.	Create a schedule to run the BACKUP VOLHISTORY command: `define schedule VOLHISTBKUP type=admin cmd="backup volhistory filenames=volhist.dat" active=yes desc="Back up the volume history." startdate=today starttime=17:00:00 duration=45 durunits=minutes`
Remove older versions of database backups that are no longer required.	Create a schedule to run the DELETE VOLHISTORY command: `define schedule DELVOLHIST type=admin cmd="delete volhistory type=dbb todate=today-6 totime=now" active=yes desc="Remove old database backups." startdate=today starttime=20:00:00 duration=45 durunits=minutes`
Remove objects that exceed their allowed retention.	Create a schedule to run the EXPIRE INVENTORY command. Set the RESOURCE parameter based on the system size that you are configuring: ○ Small systems: 10 ○ Medium systems: 30 ○ Large systems: 40 For example, on a medium-sized system, issue the following command to create a schedule that is named EXPINVENTORY: `define schedule EXPINVENTORY type=admin cmd="expire inventory wait=yes resource=30 duration=120" active=yes desc="Remove expired objects." startdate=today starttime=12:00:00 duration=45 durunits=minutes`

What to do next

After you create schedules for the server maintenance tasks, you can view them in the Operations Center by completing the following steps:

1. On the Operations Center menu bar, hover over Servers.
2. Click Maintenance.

Related reference:
DEFINE SCHEDULE (Define a schedule for an administrative command)

Defining client schedules

Use the Operations Center to create schedules for client operations.

Procedure

1. On the Operations Center menu bar, hover over Clients.
2. Click Schedules.
3. Click +Schedule.
4. Complete the steps in the Create Schedule wizard. Set client backup schedules to start at 22:00, based on the server maintenance activities that you scheduled in Defining schedules for server maintenance activities.

Installing and configuring backup-archive clients

Following the successful setup of your IBM Spectrum Protect™ server system, install and configure client software to begin backing up data.

Procedure

To install the backup-archive client, follow the installation instructions for your operating system.

- Installing the UNIX and Linux backup-archive clients
- Installing the Windows backup-archive client

What to do next

Register and assign your clients to schedules.

- Registering and assigning clients to schedules
  Add and register your clients through the Operations Center by using the Add Client wizard.
- Installing the client management service
  Install the client management service for backup-archive clients that run on Linux and Windows operating systems. The client management service collects diagnostic information about backup-archive clients and makes the information available to the Operations Center for basic monitoring capability.

Registering and assigning clients to schedules

Add and register your clients through the Operations Center by using the Add Client wizard.

Before you begin

Determine whether the client requires an administrative user ID with client owner authority over the client node. To determine which clients require an administrative user ID, see technote 7048963.
Restriction: For some types of clients, the client node name and the administrative user ID must match. You cannot authenticate those clients by using the Lightweight Directory Access Protocol authentication method that was introduced in V7.1.7. For details about this authentication method, sometimes referred to as integrated mode, see Authenticating users by using an Active Directory database.

Procedure

To register a client, complete one of the following actions.

- If the client requires an administrative user ID, register the client by using the REGISTER NODE command and specify the USERID parameter:

  ```
  register node node_name password userid=node_name
  ```

  where *node_name* specifies the node name and *password* specifies the node password. For details, see Register a node.
- If the client does not require an administrative user ID, register the client by using the Operations Center Add Client wizard. Complete the following steps:
  a. On the Operations Center menu bar, click Clients.
  b. In the Clients table, click +Client.
  c. Complete the steps in the Add Client wizard:
     i. Specify that redundant data can be eliminated on both the client and server. In the Client-side data deduplication area, select the Enable check box.
     ii. In the Configuration window, copy the TCPSERVERADDRESS, TCPPORT, NODENAME, and DEDUPLICATION option values.
     Tip: Record the option values and keep them in a safe place. After you complete the client registration and install the software on the client node, use the values to configure the client.
     iii. Follow the instructions in the wizard to specify the policy domain, schedule, and option set.
     iv. Set how risks are displayed for the client by specifying the at-risk setting.
     v. Click Add Client.

Installing the client management service

Install the client management service for backup-archive clients that run on Linux and Windows operating systems. The client management service collects diagnostic information about backup-archive clients and makes the information available to the Operations Center for basic monitoring capability.

Procedure

Install the client management service on the same computer as the backup-archive client by completing the following steps:

1. Download the installation package for the client management service from an IBM® download site such as IBM Passport Advantage® or IBM Fix Central. Look for a file name that is similar to `<version>-IBM_Spectrum_Protect-CMS-operating_system.bin`.
2. Create a directory on the client system that you want to manage, and copy the installation package there.
3. Extract the contents of the installation package file.
4. Run the installation batch file from the directory where you extracted the installation and associated files. This is the directory that you created in step 2.
5. To install the client management service, follow the instructions in the IBM Installation Manager wizard. If IBM Installation Manager is not already installed on the client system, you must select both IBM Installation Manager and IBM Spectrum Protect™ Client Management Services.

- Verifying that the client management service is installed correctly
  Before you use the client management service to collect diagnostic information about a backup-archive client, you can verify that the client management service is correctly installed and configured.
- Configuring the Operations Center to use the client management service
  If you did not use the default configuration for the client management service, you must configure the Operations Center to access the client management service.

Related tasks:
Configuring the client management service for custom client installations

Verifying that the client management service is installed correctly

Before you use the client management service to collect diagnostic information about a backup-archive client, you can verify that the client management service is correctly installed and configured.

Procedure

On the client system, at the command line, run the following commands to view the configuration of the client management service:

- On Linux client systems, issue the following command:

  ```
  client_install_dir/cms/bin/CmsConfig.sh list
  ```

  where *client_install_dir* is the directory where the backup-archive client is installed. For example, with the default client installation, issue the following command:

  ```
  /opt/tivoli/tsm/cms/bin/CmsConfig.sh list
  ```

  The output is similar to the following text:

  ```
  Listing CMS configuration

  server1.example.com:1500 NO_SSL HOSTNAME
  Capabilities: [LOG_QUERY]
      Opt Path: /opt/tivoli/tsm/client/ba/bin/dsm.sys

      Log File: /opt/tivoli/tsm/client/ba/bin/dsmerror.log
          en_US MM/dd/yyyy HH:mm:ss Windows-1252

      Log File: /opt/tivoli/tsm/client/ba/bin/dsmsched.log
          en_US MM/dd/yyyy HH:mm:ss Windows-1252
  ```

- On Windows client systems, issue the following command:

  ```
  client_install_dir\cms\bin\CmsConfig.bat list
  ```

  where *client_install_dir* is the directory where the backup-archive client is installed. For example, with the default client installation, issue the following command:

  ```
  C:\"Program Files"\Tivoli\TSM\cms\bin\CmsConfig.bat list
  ```

  The output is similar to the following text:

  ```
  Listing CMS configuration

  server1.example.com:1500 NO_SSL HOSTNAME
  Capabilities: [LOG_QUERY]
      Opt Path: C:\Program Files\Tivoli\TSM\baclient\dsm.opt

      Log File: C:\Program Files\Tivoli\TSM\baclient\dsmerror.log
          en_US MM/dd/yyyy HH:mm:ss Windows-1252

      Log File: C:\Program Files\Tivoli\TSM\baclient\dsmsched.log
          en_US MM/dd/yyyy HH:mm:ss Windows-1252
  ```

If the client management service is correctly installed and configured, the output displays the location of the error log file. The output text is extracted from the following configuration file:

- On Linux client systems:

  ```
  client_install_dir/cms/Liberty/usr/servers/cmsServer/client-configuration.xml
  ```

- On Windows client systems:

  ```
  client_install_dir\cms\Liberty\usr\servers\cmsServer\client-configuration.xml
  ```

If the output does not contain any entries, you must configure the client-configuration.xml file. For instructions to configure this file, see Configuring the client management service for custom client installations. You can use the CmsConfig verify command to verify that a node definition is correctly created in the client-configuration.xml file.

Configuring the Operations Center to use the client management service

If you did not use the default configuration for the client management service, you must configure the Operations Center to access the client management service.

Before you begin

Ensure that the client management service is installed and started on the client system. Verify whether the default configuration is used. The default configuration is not used if either of the following conditions is met:

- The client management service does not use the default port number, 9028.
- The backup-archive client is not accessed by the same IP address as the client system where the backup-archive client is installed. For example, a different IP address might be used in the following situations:
  - The computer system has two network cards. The backup-archive client is configured to communicate on one network, while the client management service communicates on the other network.
  - The client system is configured with the Dynamic Host Configuration Protocol (DHCP). As a result, the client system is dynamically assigned an IP address, which is saved on the server during the previous backup-archive client operation. When the client system is restarted, the client system might be assigned a different IP address. To ensure that the Operations Center can always find the client system, you specify a fully qualified domain name.

Procedure

To configure the Operations Center to use the client management service, complete the following steps:

1. On the Clients page of the Operations Center, select the client.
2. Click Details > Properties.
3. In the Remote diagnostics URL field in the General section, specify the URL for the client management service on the client system. The address must start with `https`. The following table shows examples of the remote diagnostics URL.

Type of URL	Example
With DNS host name and default port, 9028	https://server.example.com
With DNS host name and non-default port	https://server.example.com:1599
With IP address and non-default port	https://192.0.2.0:1599

4. Click Save.

What to do next

You can access client diagnostic information such as client log files from the Diagnosis tab in the Operations Center.

Completing the implementation

After the IBM Spectrum Protect™ solution is configured and running, test backup operations and set up monitoring to ensure that everything runs smoothly.

Procedure

1. Test backup operations to verify that your data is protected in the way that you expect.
   a. On the Clients page of the Operations Center, select the clients that you want to back up, and click Back Up.
   b. On the Servers page of the Operations Center, select the server for which you want to back up the database. Click Back Up, and follow the instructions in the Back Up Database window.
   c. Verify that the backup operations completed successfully with no warning or error messages.
   Tip: Alternatively, you can use the backup-archive client GUI to back up client data and you can backup the server database by issuing BACKUP DB command from an administrative command-line.
2. Set up monitoring for your solution by following the instructions in Monitoring a single-site disk solution.

Monitoring a single-site disk solution

After you implement a single-site disk solution with IBM Spectrum Protect™, monitor the solution for correct operation. By monitoring the solution daily and periodically, you can identify existing and potential issues. The information that you gather can be used to troubleshoot problems and optimize system performance.

About this task

The preferred way to monitor a solution is by using the Operations Center, which provides overall and detailed system status in a graphical user interface. In addition, you can configure the Operations Center to generate a daily email report that summarizes system status.

In some cases, you might want to use advanced monitoring tools to complete specific monitoring or troubleshooting tasks.

Tip: If you plan to diagnose issues with backup-archive clients on Linux or Windows operating systems, install IBM Spectrum Protect client management services on each computer where a backup-archive client is installed. In this way, you can ensure that the Diagnose button is available in the Operations Center for diagnosing issues with backup-archive clients. To install the client management service, follow the instructions in Installing the client management service.

Procedure

1. Complete daily monitoring tasks. For instructions, see Daily checklist.
2. Complete periodic monitoring tasks. For instructions, see Periodic checklist.
3. To verify that your IBM Spectrum Protect solution complies with licensing requirements, follow the instructions in Verifying license compliance.
4. To set up Operations Center to generate email status reports, see Tracking system status by using email reports

What to do next

Resolve any issues that you detect. To resolve an issue by changing the configuration of your solution, follow the instructions in Managing operations for a single-site disk solution. The following resources are also available:

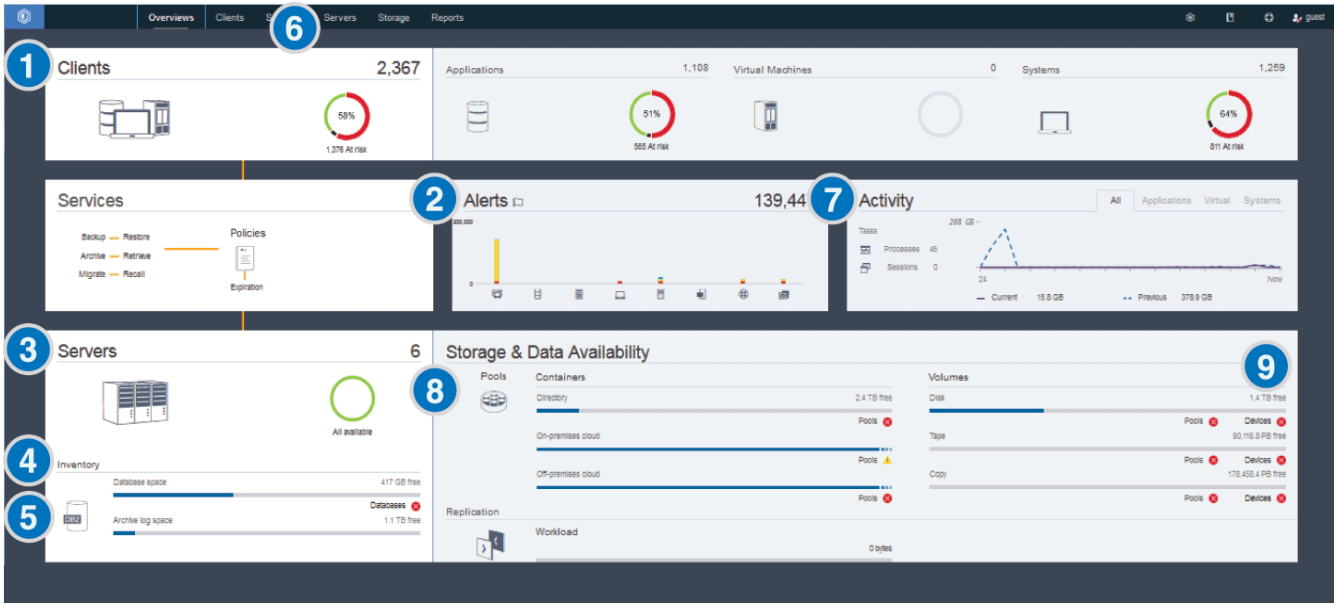
- To resolve performance issues, see Performance.
- To resolve other types of issues, see Troubleshooting.

Daily monitoring checklist

To ensure that you are completing the daily monitoring tasks for your IBM Spectrum Protect™ solution, review the daily monitoring checklist.

Complete the daily monitoring tasks from the Operations Center Overview page. You can access the Overview page by opening the Operations Center and clicking Overviews.

The following figure shows the location for completing each task.



Tip: To run administrative commands for advanced monitoring tasks, use the Operations Center command builder. The command builder provides a type-ahead function to guide you as you enter commands. To open the command builder, go to the Operations Center Overview page. On the menu bar, hover over the settings icon and click Command Builder.

The following table lists the daily monitoring tasks and provides instructions for completing each task.

Table 1. Daily monitoring tasks

Task	Basic procedures	Advanced procedures and troubleshooting information

Task	Basic procedures	Advanced procedures and troubleshooting information
1 Determine whether clients are at risk of being unprotected due to failed or missed backup operations.	To verify whether clients are at risk, in the Clients area, look for an At risk notification. To view details, click the Clients area. If you installed the client management service on a backup-archive client, you can view and analyze the client error and schedule logs by completing the following steps: 1. In the Clients table, select the client and click Details. 2. To diagnose an issue, click Diagnosis.	For clients that do not have the client management service installed, access the client system to review the client error logs.
2 Determine whether client-related or server-related errors require attention.	To determine the severity of any reported alerts, in the Alerts area, hover over the columns.	To view additional information about alerts, complete the following steps: 1. Click the Alerts area. 2. In the Alerts table, select an alert. 3. In the Activity Log pane, review the messages. The pane displays related messages that were issued before and after the selected alert occurred.
3 Determine whether servers that are managed by the Operations Center are available to provide data protection services to clients.	1. To verify whether servers are at risk, in the Servers area, look for an Unavailable notification. 2. To view additional information, click the Servers area. 3. Select a server in the Servers table and click Details.	Tip: If you detect an issue that is related to server properties, update the server properties: 1. In the Servers table, select a server and click Details. 2. To update server properties, click Properties.

Task	Basic procedures	Advanced procedures and troubleshooting information
4 Determine whether sufficient space is available for the server inventory, which consists of the server database, active log, and archive log.	1. Click the Servers area. 2. In the Status column of the table, view the status of the server and resolve any issues: ○ Normal Sufficient space is available for the server database, active log, and archive log. ○ Critical Insufficient space is available for the server database, active log, or archive log. You must add space immediately, or the data protection services that are provided by the server will be interrupted. ○ Warning The server database, active log, or archive log is running out of space. If this condition persists, you must add space. ○ Unavailable Status cannot be obtained. Ensure that the server is running, and that there are no network issues. This status is also shown if the monitoring administrator ID is locked or otherwise unavailable on the server. This ID is named IBM-OC-hub_server_name. ○ Unmonitored Unmonitored servers are defined to the hub server, but are not configured for management by the Operations Center. To configure an unmonitored server, select the server, and click Monitor Spoke.	You can also look for related alerts on the Alerts page. For additional instructions about troubleshooting, see Resolving server problems.

Task	Basic procedures	Advanced procedures and troubleshooting information
5 Verify server database backup operations.	To determine when a server was most recently backed up, complete the following steps: 1. Click the Servers area. 2. In the Servers table, review the Last Database Backup column.	To obtain more detailed information about backup operations, complete the following steps: 1. In the Servers table, select a row and click Details. 2. In the DB Backup area, hover over the check marks to review information about backup operations. If a database was not backed up recently (for example, in the last 24 hours), you can start a backup operation: 1. On the Operations Center Overview page, click the Servers area. 2. In the table, select a server and click Back Up. To determine whether the server database is configured for automatic backup operations, complete the following steps: 1. On the menu bar, hover over the settings icon  and click Command Builder. 2. Issue the QUERY DB command: `query db f=d` 3. In the output, review the `Full Device Class Name` field. If a device class is specified, the server is configured for automatic database backups.
6 Monitor other server maintenance tasks. Server maintenance tasks can include running administrative command schedules, maintenance scripts, and related commands.	To search for information about processes that failed because of server issues, complete the following steps: 1. Click Servers > Maintenance. 2. To obtain the two-week history of a process, view the History column. 3. To obtain more information about a scheduled process, hover over the check box that is associated with the process.	For more information about monitoring processes and resolving issues, see the Operations Center online help.
7 Verify that the amount of data that was recently sent to and from servers is within the expected range.	• To obtain an overview of activity in the last 24 hours, view the Activity area. • To compare activity in the last 24 hours with activity in the previous 24 hours, review the figures in the Current and Previous areas.	• If more data was sent to the server than you expected, determine which clients are backing up more data and investigate the cause. It is possible that client-side data deduplication is not working correctly. • If less data was sent to the server than you expected, investigate whether client backup operations are proceeding on schedule.

Task	Basic procedures	Advanced procedures and troubleshooting information
8 Verify that storage pools are available to back up client data.	1. If problems are indicated in the Storage & Data Availability area, click Pools to view the details: ○ If the Critical status is displayed, insufficient space is available in the storage pool, or its access status is unavailable. ○ If the Warning status is displayed, the storage pool is running out of space, or its access status is read-only. 2. To view the used, free, and total space for your selected storage pool, hover over the entries in the Capacity Used column.	To view the storage-pool capacity that was used over the past two weeks, select a row in the Storage Pools table and click Details.
9 Verify that storage devices are available for backup operations.	In the Storage & Data Availability area, in the Volumes section, under the capacity bars, review the status that is reported next to Devices. If a Critical or Warning status is displayed for any device, investigate the issue. To view details, click Devices.	Disk devices might have a critical or warning status for the following reasons: • For DISK device classes, volumes might be offline or have a read-only access status. The Disk Storage column of the Disk Devices table shows the state of volumes. • For FILE device classes that are not shared, directories might be offline. Also, insufficient free space might be available for allocating scratch volumes. The Disk Storage column of the Disk Devices table shows the state of directories. • For FILE device classes that are shared, drives might be unavailable. A drive is unavailable if it is offline, if it stopped responding to the server, or if its path is offline. Other columns of the Disk Devices table show the state of the drives and paths.

Periodic monitoring checklist

To help ensure that your IBM Spectrum Protect™ solution operates correctly, complete the tasks in the periodic monitoring checklist. Schedule periodic tasks frequently enough so that you can detect potential issues before they become problematic.

Tip: To run administrative commands for advanced monitoring tasks, use the Operations Center command builder. The command builder provides a type-ahead function to guide you as you enter commands. To open the command builder, go to the Operations Center Overview page. On the menu bar, hover over the settings icon and click Command Builder.

Table 1. Periodic monitoring tasks

Task	Basic procedures	Advanced procedures and troubleshooting

Task	Basic procedures	Advanced procedures and troubleshooting
Monitor system performance.	Determine the length of time that is required for client backup operations: 1. On the Operations Center Overview page, click Clients. Find the server that is associated with the client. 2. Click Servers. Select the server and click Details. 3. To view the duration of completed tasks in the last 24 hours, click Completed Tasks. 4. To view the duration of tasks that were completed more than 24 hours ago, use the QUERY ACTLOG command. Follow the instructions in QUERY ACTLOG (Query the activity log). 5. If the duration of client backup operations is increasing and the reasons are not clear, investigate the cause. If you installed the client management service on a backup-archive client, you can diagnose performance issues for the backup-archive client by completing the following steps: 1. On the Operations Center Overview page, click Clients. 2. Select a backup-archive client and click Details. 3. To retrieve client logs, click Diagnosis.	For instructions about reducing the time that it takes for the client to back up data to the server, see Resolving common client performance problems. Look for performance bottlenecks. For instructions, see Identifying performance bottlenecks. For information about identifying and resolving other performance issues, see Performance.
Determine the disk savings that are provided by data deduplication.	1. On the Operations Center Overview page, click Pools. 2. Select a pool and click Quick Look. 3. In the Data Deduplication area, view the Space saved row.	For advanced monitoring, to obtain detailed statistics about the data-deduplication process for a specific directory-container storage pool or cloud-container storage pool, complete the following steps: 1. On the Operations Center Overview page, hover over the settings icon  and click Command Builder. 2. Obtain a statistical report by issuing the GENERATE DEDUPSTATS command. Follow the instructions in GENERATE DEDUPSTATS (Generate data deduplication statistics for a directory-container storage pool). 3. View the statistical report by issuing the QUERY DEDUPSTATS command. Follow the instructions in QUERY DEDUPSTATS (Query data deduplication statistics).

Task	Basic procedures	Advanced procedures and troubleshooting
Verify that current backup files for device configuration and volume history information are saved.	Access your storage locations to ensure that the files are available. The preferred method is to save the backup files to two locations. To locate the volume history and device configuration files, complete the following steps: 1. On the Operations Center Overview page, hover over the settings icon  and click Command Builder. 2. To locate the volume history and device configuration files, issue the following commands: `query option volhistory` `query option devconfig` 3. In the output, review the Option Setting column to find the file locations. If a disaster occurs, both the volume history file and the device configuration file are required to restore the server database.	

Task	Basic procedures	Advanced procedures and troubleshooting
Determine whether sufficient space is available for the instance directory file system.	Verify that at least 20% of free space is available in the instance directory file system. Take the action that is appropriate for your operating system: • AIX To view available space in the file system, on the operating system command line, issue the following command: `df -g instance_directory` where *instance_directory* specifies the instance directory. • Linux To view available space in the file system, on the operating system command line, issue the following command: `df -h instance_directory` where *instance_directory* specifies the instance directory. • Windows In the Windows Explorer program, right-click the file system and click Properties. View the capacity information. The preferred location of the instance directory depends on the operating system where the server is installed: • AIX Linux /home/tsminst1/tsminst1 • Windows C:\tsminst1 Tip: If you completed a planning worksheet, the location of the instance directory is recorded in the worksheet.	
Identify unexpected client activity.	To monitor client activity to determine whether data volumes exceed expected amounts, complete the following steps: 1. On the Operations Center Overview page, click the Clients area. 2. To view activity over the past two weeks, double-click any client. 3. To view the number of bytes sent to the client, click the Properties tab. 4. In the Last Session area, view the Sent to client row.	When you double-click a client in the Clients table, the Activity over 2 Weeks area displays the amount of data that the client sent to the server each day.

Task	Basic procedures	Advanced procedures and troubleshooting
Monitor storage pool growth over time.	1. On the Operations Center Overview page, click the Pools area. 2. To view the capacity that was used over the last two weeks, select a pool and click Details.	Tips: • To specify the time period that must elapse before all deduplicated extents are removed from a directory-container storage pool or cloud-container storage pool after they are no longer referenced by the inventory, complete the following steps: 1. On the Storage Pools page of the Operations Center, select the storage pool. 2. Click Details > Properties. 3. Specify the duration in the `Delay period for container reuse` field. • To determine data deduplication performance for directory-container and cloud-container storage pools, use the GENERATE DEDUPSTATS command. • To view data deduplication statistics for a storage pool, complete the following steps: 1. On the Storage Pools page of the Operations Center, select the storage pool. 2. Click Details > Properties. Alternatively, use the QUERY EXTENTUPDATES command to display information about updates to data extents in directory-container or cloud-container storage pools. The command output can help you determine which data extents are no longer referenced and which ones are eligible to be deleted from the system. In the output, monitor the number of data extents that are eligible to be deleted from the system. This metric has a direct correlation to the amount of free space that will be available within the container storage pool. • To display the amount of physical space that is occupied by a file space after the removal of the data deduplication savings, use the select * from occupancy command. The command output includes the LOGICAL_MB value. LOGICAL_MB is the amount of space that is used by the file space.
Evaluate the timing of client schedules. Ensure that the start and end times of client schedules meet your business needs.	On the Operations Center Overview page, click Clients > Schedules. In the Schedules table, the Start column displays the configured start time for the scheduled operation. To see when the most recent operation was started, hover over the clock icon.	Tip: You can receive a warning message if a client operation runs longer than expected. Complete the following steps: 1. On the Operations Center Overview page, hover over Clients and click Schedules. 2. Select a schedule and click Details. 3. View the details of a schedule by clicking the blue arrow next to the row. 4. In the Run time alert field, specify the time when a warning message will be issued if the scheduled operation is not completed. 5. Click Save.

Task	Basic procedures	Advanced procedures and troubleshooting
Evaluate the timing of maintenance tasks. Ensure that the start and end times of maintenance tasks meet your business needs.	On the Operations Center Overview page, click Servers > Maintenance. In the Maintenance table, review the information in the Last Run Time column. To see when the last maintenance task was started, hover over the clock icon.	Tip: If a maintenance task is running too long, change the start time or the maximum run time. Complete the following steps: 1. On the Operations Center Overview page, hover over the settings icon and click Command Builder. 2. To change the start time or maximum run time for a task, issue the UPDATE SCHEDULE command. For instructions, see UPDATE SCHEDULE (Update a client schedule).

Verifying license compliance

Verify that your IBM Spectrum Protect™ solution complies with the provisions of your licensing agreement. By verifying compliance regularly, you can track trends in data growth or processor value unit (PVU) usage. Use this information to plan for future license purchasing.

About this task

The method that you use to verify that your solution complies with license terms varies depending on the provisions of your IBM Spectrum Protect licensing agreement.

Front-end capacity licensing
: The front-end model determines license requirements based on the amount of primary data that is reported as being backed up by clients. Clients include applications, virtual machines, and systems.

Back-end capacity licensing
: The back-end model determines license requirements based on the terabytes of data that are stored in primary storage pools and repositories.
Tips:

- To ensure the accuracy of front-end and back-end capacity estimates, install the most recent version of the client software on each client node.
- The front-end and back-end capacity information in the Operations Center is for planning and estimation purposes.

PVU licensing
: The PVU model is based on the use of PVUs by server devices.
Important: The PVU calculations that are provided by IBM Spectrum Protect are considered estimates and are not legally binding. The PVU licensing information that is reported by IBM Spectrum Protect is not considered an acceptable substitute for the IBM® License Metric Tool.

For the most recent information about licensing models, see the information about product details and licenses at the IBM Spectrum Protect product family website. If you have questions or concerns about licensing requirements, contact your IBM Spectrum Protect software provider.

Procedure

To monitor license compliance, complete the steps that correspond to the provisions of your licensing agreement.
Tip: The Operations Center provides an email report that summarizes front-end and back-end capacity usage. Reports can be sent automatically to one or more recipients regularly. To configure and manage email reports, click Reports on the Operations Center menu bar.

Option	Description

Option	Description
Front-end model	a. On the Operations Center menu bar, hover over the settings icon and click Licensing. The front-end capacity estimate is displayed on the Front-end Usage page. b. If a value is displayed in the Not Reporting column, click the number to identify clients that did not report capacity usage. c. To estimate capacity for clients that did not report capacity usage, go to the following FTP site, which provides measuring tools and instructions: ftp://public.dhe.ibm.com/storage/tivoli-storage-management/front_end_capacity_measurement_tools To measure front-end capacity by script, complete the instructions in the most recently available licensing guide. d. Add the Operations Center estimate and any estimates that you obtained by using a script. e. Verify that the estimated capacity complies with your licensing agreement.
Back-end model	Restriction: If the source and target replication servers do not use the same policy settings, you cannot use the Operations Center to monitor back-end capacity usage for replicated clients. For information about how to estimate capacity usage for these clients, see technote 1656476. a. On the Operations Center menu bar, hover over the settings icon and click Licensing. b. Click the Back-end tab. c. Verify that the estimated amount of data complies with your licensing agreement.
PVU model	For information about how to assess compliance with PVU licensing terms, see Assessing compliance with the PVU licensing model.

Tracking system status by using email reports

Set up the Operations Center to generate email reports that summarize system status. You can configure a mail server connection, change report settings, and optionally create custom SQL reports.

Before you begin

Before you set up email reports, ensure that the following requirements are met:

- A Simple Mail Transfer Protocol (SMTP) host server is available to send and receive reports by email. The SMTP server must be configured as an open mail relay. You must also ensure that the IBM Spectrum Protect™ server that sends email messages has access to the SMTP server. If the Operations Center is installed on a separate computer, that computer does not require access to the SMTP server.
- To set up email reports, you must have system privilege for the server.
- To specify the recipients, you can enter one or more email addresses or administrator IDs. If you plan to enter an administrator ID, the ID must be registered on the hub server and must have an email address associated with it. To specify an email address for an administrator, use the EMAILADDRESS parameter of the UPDATE ADMIN command.

About this task

You can configure the Operations Center to send a general operations report, a license compliance report, and one or more custom reports, which use SQL SELECT statements to query managed servers.

Procedure

To set up and manage email reports, complete the following steps:

1. On the Operations Center menu bar, click Reports.
2. If an email server connection is not yet configured, click Configure Mail Server and complete the fields. After you configure the mail server, the general operations report and license compliance report are enabled.
3. To change report settings, select a report, click Details, and update the form.

4. Optional: To add a custom SQL report, click + Report, and complete the fields.
   Tip: To immediately run and send a report, select the report and click Send.

Results

Enabled reports are sent according to the specified settings.

UPDATE ADMIN (Update an administrator)

Managing operations for a single-site disk solution

Use this information to manage operations for a single-site disk solution with IBM Spectrum Protect™ that includes a server and uses data deduplication for a single location.

- Managing the Operations Center
  The Operations Center provides web and mobile access to status information about the IBM Spectrum Protect environment. You can use the Operations Center to monitor multiple servers and to complete some administrative tasks. The Operations Center also provides web access to the IBM Spectrum Protect command line.
- Protecting applications, virtual machines, and systems
  The server protects data for clients, which can include applications, virtual machines, and systems. To start protecting client data, register the client node with the server and select a backup schedule to protect the client data.
- Managing data storage
  Manage your data for efficiency and add supported devices and media to the server to store client data.
- Securing the IBM Spectrum Protect server
  Secure the IBM Spectrum Protect server and data by controlling access to servers and client nodes, encrypting data, and maintaining secure access levels and passwords.
- Stopping and starting the server
  Before you complete maintenance or reconfiguration tasks, stop the server. Then, start the server in maintenance mode. When you are finished with the maintenance or reconfiguration tasks, restart the server in production mode.
- Planning to upgrade the server
  When a fix pack or interim fix becomes available, you can upgrade the IBM Spectrum Protect server to take advantage of product improvements. Servers and clients can be upgraded at different times. Ensure that you complete the planning steps before you upgrade the server.
- Preparing for an outage or system update
  Prepare IBM Spectrum Protect to maintain your system in a consistent state during a planned power outage or system update.
- Implementing a disaster recovery plan
  Implement a disaster recovery strategy to recover your applications if a disaster occurs and to ensure high server availability.
- Recovering from system outages
  For IBM Spectrum Protect single-site disk solutions, you can recover the inventory locally only and restore the database to protect your data.

Managing the Operations Center

The Operations Center provides web and mobile access to status information about the IBM Spectrum Protect™ environment. You can use the Operations Center to monitor multiple servers and to complete some administrative tasks. The Operations Center also provides web access to the IBM Spectrum Protect command line.

- Adding and removing spoke servers
  In a multiple-server environment, you can connect the other servers, called *spoke servers*, to the hub server.
- Starting and stopping the web server
  The web server of the Operations Center runs as a service and starts automatically. You might have to stop and start the web server, for example, to make configuration changes.
- Restarting the initial configuration wizard
  You might need to restart the initial configuration wizard of the Operations Center, for example, to make configuration changes.
- Changing the hub server
  You can use the Operations Center to remove the hub server of IBM Spectrum Protect, and configure another hub server.
- Restoring the configuration to the preconfiguration state
  If certain problems occur, you might want to restore the Operations Center configuration to the preconfigured state where

the IBM Spectrum Protect servers are not defined as hub or spoke servers.

Adding and removing spoke servers

In a multiple-server environment, you can connect the other servers, called *spoke servers*, to the hub server.

About this task

The spoke servers send alerts and status information to the hub server. The Operations Center shows you a consolidated view of alerts and status information for the hub server and any spoke servers.

- Adding a spoke server
  After you configure the hub server for the Operations Center, you can add one or more spoke servers to the hub server.
- Removing a spoke server
  You can remove a spoke server from the Operations Center.

Adding a spoke server

After you configure the hub server for the Operations Center, you can add one or more spoke servers to the hub server.

Before you begin

Communication between the spoke server and the hub server must be secured by using the Transport Layer Security (TLS) protocol. To secure communication, add the certificate of the spoke server to the truststore file of the hub server.

Procedure

1. In the Operations Center menu bar, click Servers. The Servers page opens.

   In the table on the Servers page, a server might have a status of "Unmonitored." This status means that although an administrator defined this server to the hub server by using the DEFINE SERVER command, the server is not yet configured as a spoke server.

2. Complete one of the following steps:
   - Click the server to highlight it, and in the table menu bar, click Monitor Spoke.
   - If the server that you want to add is not shown in the table, and secure SSL/TLS communication is not required, click + Spoke in the table menu bar.
3. Provide the necessary information, and complete the steps in the spoke configuration wizard.
   Tip: If the event-record retention period of the server is less than 14 days, the period is automatically reset to 14 days if you configure the server as a spoke server.

Removing a spoke server

You can remove a spoke server from the Operations Center.

About this task

You might need to remove a spoke server in the following situations, for example:

- You want to move the spoke server from one hub server to another hub server.
- You want to decommission the spoke server.

Procedure

To remove the spoke server from the group of servers that are managed by the hub server, complete the following steps:

1. From the IBM Spectrum Protect™ command line, issue the following command on the hub server:

   ```
   QUERY MONITORSETTINGS
   ```

2. From the output of the command, copy the name that is in the Monitored Group field.

3. Issue the following command on the hub server, where *group_name* represents the name of the monitored group, and *member_name* represents the name of the spoke server:

   ```
   DELETE GRPMEMBER group_name member_name
   ```

4. Optional: If you want to move the spoke server from one hub server to another hub server, do **not** complete this step. Otherwise, you can disable alerting and monitoring on the spoke server by issuing the following commands on the spoke server:

   ```
   SET STATUSMONITOR OFF
   SET ALERTMONITOR OFF
   ```

5. Optional: If the spoke server definition is used for other purposes, such as enterprise configuration, command routing, storing virtual volumes, or library management, do **not** complete this step. Otherwise, you can delete the spoke server definition on the hub server by issuing the following command on the hub server:

   ```
   DELETE SERVER spoke_server_name
   ```

Starting and stopping the web server

The web server of the Operations Center runs as a service and starts automatically. You might have to stop and start the web server, for example, to make configuration changes.

Procedure

1. Stop the web server.
   - AIX From the */installation_dir*/ui/utils directory, where *installation_dir* represents the directory where the Operations Center is installed, issue the following command:

     ```
     ./stopserver.sh
     ```

   - Linux Issue the following command:

     ```
     service opscenter.rc stop
     ```

   - Windows From the Services window, stop the IBM Spectrum Protect™ Operations Center service.
2. Start the web server.
   - AIX From the */installation_dir*/ui/utils directory, where *installation_dir* represents the directory where the Operations Center is installed, issue the following command:

     ```
     ./startserver.sh
     ```

   - Linux Issue the following commands:

     Start the server:

     ```
     service opscenter.rc start
     ```

     Restart the server:

     ```
     service opscenter.rc restart
     ```

     Determine whether the server is running:

     ```
     service opscenter.rc status
     ```

   - Windows From the Services window, start the IBM Spectrum Protect Operations Center service.

Restarting the initial configuration wizard

You might need to restart the initial configuration wizard of the Operations Center, for example, to make configuration changes.

Before you begin

To change the following settings, use the Settings page in the Operations Center rather than restarting the initial configuration wizard:

- The frequency at which status data is refreshed
- The duration that alerts remain active, inactive, or closed
- The conditions that indicate that clients are at risk

The Operations Center help includes more information about how to change these settings.

About this task

To restart the initial configuration wizard, you must delete a properties file that includes information about the hub server connection. However, any alerting, monitoring, at-risk, or multiserver settings that were configured for the hub server are not deleted. These settings are used as the default settings in the configuration wizard when the wizard restarts.

Procedure

1. Stop the Operations Center web server.
2. On the computer where the Operations Center is installed, go to the following directory, where *installation_dir* represents the directory in which the Operations Center is installed:
   - AIX Linux *installation_dir*/ui/Liberty/usr/servers/guiServer
   - Windows *installation_dir*\ui\Liberty\usr\servers\guiServer

   For example:
   - AIX Linux /opt/tivoli/tsm/ui/Liberty/usr/servers/guiServer
   - Windows c:\Program Files\Tivoli\TSM\ui\Liberty\usr\servers\guiServer
3. In the guiServer directory, delete the serverConnection.properties file.
4. Start the Operations Center web server.
5. Open the Operations Center.
6. Use the configuration wizard to reconfigure the Operations Center. Specify a new password for the monitoring administrator ID.
7. On any spoke servers that were previously connected to the hub server, update the password for the monitoring administrator ID by issuing the following command from the IBM Spectrum Protect™ command-line interface:

   ```
   UPDATE ADMIN IBM-OC-hub_server_name new_password
   ```

   Restriction: Do not change any other settings for this administrator ID. After you specify the initial password, this password is managed automatically by the Operations Center.

Changing the hub server

You can use the Operations Center to remove the hub server of IBM Spectrum Protect™, and configure another hub server.

Procedure

1. Restart the initial configuration wizard of the Operations Center. As part of this procedure, you delete the existing hub server connection.
2. Use the wizard to configure the Operations Center to connect to the new hub server.

Related tasks:
Restarting the initial configuration wizard

Restoring the configuration to the preconfiguration state

If certain problems occur, you might want to restore the Operations Center configuration to the preconfigured state where the IBM Spectrum Protect™ servers are not defined as hub or spoke servers.

Procedure

To restore the configuration, complete the following steps:

1. Stop the Operations Center web server.
2. Unconfigure the hub server by completing the following steps:
   a. On the hub server, issue the following commands:

```
SET MONITORINGADMIN ""
SET MONITOREDSERVERGROUP ""
SET STATUSMONITOR OFF
SET ALERTMONITOR OFF
REMOVE ADMIN IBM-OC-hub_server_name
```

Tip: `IBM-OC-hub_server_name` represents the monitoring administrator ID that was automatically created when you initially configured the hub server.

b. Reset the password for the hub server by issuing the following command on the hub server:

```
SET SERVERPASSWORD ""
```

Attention: Do not complete this step if the hub server is configured with other servers for other purposes, such as library sharing, exporting and importing of data, or node replication.

3. Unconfigure any spoke servers by completing the following steps:
   a. On the hub server, to determine whether any spoke servers remain as members of the server group, issue the following command:

```
QUERY SERVERGROUP IBM-OC-hub_server_name
```

Tip: `IBM-OC-hub_server_name` represents the name of the monitored server group that was automatically created when you configured the first spoke server. This server group name is also the same as the monitoring administrator ID that was automatically created when you initially configured the hub server.

   b. On the hub server, to delete spoke servers from the server group, issue the following command for each spoke server:

```
DELETE GRPMEMBER IBM-OC-hub_server_name spoke_server_name
```

   c. After all spoke servers are deleted from the server group, issue the following commands on the hub server:

```
DELETE SERVERGROUP IBM-OC-hub_server_name
SET MONITOREDSERVERGROUP ""
```

   d. On each spoke server, issue the following commands:

```
REMOVE ADMIN IBM-OC-hub_server_name
SETOPT PUSHSTATUS NO
SET ALERTMONITOR OFF
SET STATUSMONITOR OFF
```

   e. On each spoke server, delete the definition of the hub server by issuing the following command:

```
DELETE SERVER hub_server_name
```

Attention: Do not complete this step if the definition is used for other purposes, such as library sharing, exporting and importing of data, or node replication.

   f. On the hub server, delete the definition of each spoke server by issuing the following command:

```
DELETE SERVER spoke_server_name
```

Attention: Do not complete this step if the server definition is used for other purposes, such as library sharing, exporting and importing of data, or node replication.

4. Restore the default settings on each server by issuing the following commands:

```
SET STATUSREFRESHINTERVAL 5
SET ALERTUPDATEINTERVAL 10
SET ALERTACTIVEDURATION 480
SET ALERTINACTIVEDURATION 480
SET ALERTCLOSEDDURATION 60
SET STATUSATRISKINTERVAL TYPE=AP INTERVAL=24
SET STATUSATRISKINTERVAL TYPE=VM INTERVAL=24
SET STATUSATRISKINTERVAL TYPE=SY INTERVAL=24
SET STATUSSKIPASFAILURE YES TYPE=ALL
```

5. Restart the initial configuration wizard of the Operations Center.

Related tasks:
Restarting the initial configuration wizard
Starting and stopping the web server

Protecting applications, virtual machines, and systems

The server protects data for clients, which can include applications, virtual machines, and systems. To start protecting client data, register the client node with the server and select a backup schedule to protect the client data.

- Adding clients
  After you implement a data protection solution with IBM Spectrum Protect, you can expand the solution by adding clients.
- Managing client operations
  You can evaluate and resolve errors that are related to a backup-archive client by using the Operations Center, which provides suggestions for resolving errors. For errors on other types of clients, you must examine the error logs on the client and review the product documentation.
- Managing client upgrades
  When a fix pack or interim fix becomes available for a client, you can upgrade the client to take advantage of product improvements. Servers and clients can be upgraded at different times and can be at different levels with some restrictions.
- Decommissioning a client node
  If a client node is no longer required, you can start a process to remove it from the production environment. For example, if a workstation was backing up data to the IBM Spectrum Protect server, but the workstation is no longer used, you can decommission the workstation.
- Deactivating data to free storage space
  In some cases, you can deactivate data that is stored on the IBM Spectrum Protect server. When you run the deactivation process, any backup data that was stored before the specified date and time is deactivated and will be deleted as it expires. In this way, you can free space on the server.

Adding clients

After you implement a data protection solution with IBM Spectrum Protect™, you can expand the solution by adding clients.

About this task

The procedure describes basic steps for adding a client. For more specific instructions about configuring clients, see the documentation for the product that you install on the client node. You can have the following types of client nodes:

Application client nodes
: Application client nodes include email servers, databases, and other applications. For example, any of the following applications can be an application client node:

  - IBM Spectrum Protect Snapshot
  - IBM Spectrum Protect for Databases
  - IBM Spectrum Protect for Enterprise Resource Planning
  - IBM Spectrum Protect for Mail
  - IBM Spectrum Protect for Virtual Environments

System client nodes
: System client nodes include workstations, network-attached storage (NAS) file servers, and API clients.

Virtual machine client nodes
: Virtual machine client nodes consist of an individual guest host within a hypervisor. Each virtual machine is represented as a file space.

Procedure

To add a client, complete the following steps:

1. Select the software to install on the client node and plan the installation. Follow the instructions in Selecting the client software and planning the installation.
2. Specify how to back up and archive client data. Follow the instructions in Specifying rules for backing up and archiving client data.
3. Specify when to back up and archive client data. Follow the instructions in Scheduling backup and archive operations.
4. To allow the client to connect to the server, register the client. Follow the instructions in Registering clients.
5. To start protecting a client node, install and configure the selected software on the client node. Follow the instructions in Installing and configuring clients.

Selecting the client software and planning the installation

Different types of data require different types of protection. Identify the type of data that you must protect and select the appropriate software.

About this task

The preferred practice is to install the backup-archive client on all client nodes so that you can configure and start the client acceptor on the client node. The client acceptor is designed to efficiently run scheduled operations.

The client acceptor runs schedules for the following products: the backup-archive client, IBM Spectrum Protect™ for Databases, IBM Spectrum Protect for Enterprise Resource Planning, IBM Spectrum Protect for Mail, and IBM Spectrum Protect for Virtual Environments. If you install a product for which the client acceptor does not run schedules, you must follow the configuration instructions in the product documentation to ensure that scheduled operations can occur.

Procedure

Based on your goal, select the products to install and review the installation instructions.
Tip: If you install the client software now, you must also complete the client configuration tasks that are described in Installing and configuring clients before you can use the client.

Goal	Product and description	Installation instructions
Protect a file server or workstation	The backup-archive client backs up and archives files and directories from file servers and workstations to storage. You can also restore and retrieve backup versions and archived copies of files.	• Backup-archive client requirements • Installing the UNIX and Linux backup-archive clients • Installing the Windows backup-archive client
Protect applications with snapshot backup and restore capabilities	IBM Spectrum Protect Snapshot protects data with integrated, application-aware snapshot backup and restore capabilities. You can protect data that is stored by IBM DB2® database software and SAP, Oracle, Microsoft Exchange, and Microsoft SQL Server applications.	• Installing and upgrading IBM Spectrum Protect Snapshot for UNIX and Linux • Installing and upgrading IBM Spectrum Protect Snapshot for VMware • Installing and upgrading IBM Spectrum Protect Snapshot for Windows
Protect an email application on an IBM Domino® server	IBM Spectrum Protect for Mail: Data Protection for IBM® Domino automates data protection so that backups are completed without shutting down IBM Domino servers.	• Installation of Data Protection for IBM Domino on a UNIX, AIX, or Linux system (V7.1.0) • Installation of Data Protection for IBM Domino on a Windows system (V7.1.0)
Protect an email application on a Microsoft Exchange server	IBM Spectrum Protect for Mail: Data Protection for Microsoft Exchange Server automates data protection so that backups are completed without shutting down Microsoft Exchange servers.	Installing, upgrading, and migrating IBM Spectrum Protect for Mail: Data Protection for Microsoft Exchange Server
Protect an IBM DB2 database	The application programming interface (API) of the backup-archive client can be used to back up DB2 data to the IBM Spectrum Protect server.	Installing the IBM Spectrum Protect backup-archive clients (UNIX, Linux, and Windows)
Protect an IBM Informix® database	The API of the backup-archive client can be used to back up Informix data to the IBM Spectrum Protect server.	Installing the IBM Spectrum Protect backup-archive clients (UNIX, Linux, and Windows)
Protect a Microsoft SQL database	IBM Spectrum Protect for Databases: Data Protection for Microsoft SQL Server protects Microsoft SQL data.	Installing Data Protection for SQL Server on Windows Server Core
Protect an Oracle database	IBM Spectrum Protect for Databases: Data Protection for Oracle protects Oracle data.	Data Protection for Oracle installation

Goal	Product and description	Installation instructions
Protect an SAP environment	IBM Spectrum Protect for Enterprise Resource Planning: Data Protection for SAP provides protection that is customized for SAP environments. The product is designed to improve the availability of SAP database servers and reduce administration workload.	• Installing IBM Spectrum Protect for Enterprise Resource Planning: Data Protection for SAP for DB2 • Installing IBM Spectrum Protect for Enterprise Resource Planning: Data Protection for SAP for Oracle
Protect a virtual machine	IBM Spectrum Protect for Virtual Environments provides protection that is tailored for Microsoft Hyper-V and VMware virtual environments. You can use IBM Spectrum Protect for Virtual Environments to create incremental forever backups that are stored on a centralized server, create backup policies, and restore virtual machines or individual files. Alternatively, use the backup-archive client to back up and restore a full VMware or Microsoft Hyper-V virtual machine. You can also back up and restore files or directories from a VMware virtual machine.	• Installing Data Protection for Microsoft Hyper-V • Installing and upgrading Data Protection for VMware • Installing the IBM Spectrum Protect backup-archive clients (UNIX, Linux, and Windows)

Tip: To use the client for space management, you can install IBM Spectrum Protect for Space Management or IBM Spectrum Protect HSM for Windows.

Specifying rules for backing up and archiving client data

Before you add a client, ensure that appropriate rules are specified for backing up and archiving the client data. During the client registration process, you assign the client node to a policy domain, which has the rules that control how and when client data is stored.

Before you begin

Determine how to proceed:

- If you are familiar with the policies that are configured for your solution and you know that they do not require changes, continue with Scheduling backup and archive operations.
- If you are not familiar with the policies, follow the steps in this procedure.

About this task

Policies affect how much data is stored over time, and how long data is retained and available for clients to restore. To meet objectives for data protection, you can update the default policy and create your own policies. A policy includes the following rules:

- How and when files are backed up and archived to server storage
- The number of copies of a file and the length of time copies are kept in server storage

During the client registration process, you assign a client to a *policy domain*. The policy for a specific client is determined by the rules in the policy domain to which the client is assigned. In the policy domain, the rules that are in effect are in the active *policy set*.

When a client backs up or archives a file, the file is bound to a management class in the active policy set of the policy domain. A *management class* is the key set of rules for managing client data. The backup and archive operations on the client use the settings in the default management class of the policy domain unless you further customize policy. A policy can be customized by defining more management classes and assigning their use through client options.

Client options can be specified in a local, editable file on the client system and in a client option set on the server. The options in the client option set on the server can override or add to the options in the local client option file.

Procedure

1. Review the policies that are configured for your solution by following the instructions in Viewing policies.
2. If you need to make minor changes to meet data retention requirements, follow the instructions in Editing policies.
3. Optional: If you need to create policy domains or make extensive changes to policies to meet data retention requirements, see Customizing policies.

Viewing policies

View policies to determine whether they must be edited to meet your requirements.

Procedure

1. To view the active policy set for a policy domain, complete the following steps:
   a. On the Services page of the Operations Center, select a policy domain and click Details.
   b. On the Summary page for the policy domain, click the Policy Sets tab.
2. To view inactive policy sets for a policy domain, complete the following steps:
   a. On the Policy Sets page, click the Configure toggle. You can now view and edit the policy sets that are inactive.
   b. Scroll through the inactive policy sets by using the forward and back arrows. When you view an inactive policy set, the settings that differentiate the inactive policy set from the active policy set are highlighted.
   c. Click the Configure toggle. The policy sets are no longer editable.

Editing policies

To change the rules that apply to a policy domain, edit the active policy set for the policy domain. You can also activate a different policy set for a domain.

Before you begin

Changes to policy can affect data retention. Ensure that you continue to back up data that is essential to your organization so that you can restore that data if a disaster occurs. Also, ensure that your system has sufficient storage space for planned backup operations.

About this task

You edit a policy set by changing one or more management classes within the policy set. If you edit the active policy set, the changes are not available to clients unless you reactivate the policy set. To make the edited policy set available to clients, activate the policy set.

Although you can define multiple policy sets for a policy domain, only one policy set can be active. When you activate a different policy set, it replaces the currently active policy set.

To learn about preferred practices for defining policies, see Customizing policies.

Procedure

1. On the Services page of the Operations Center, select a policy domain and click Details.
2. On the Summary page for the policy domain, click the Policy Sets tab.

   The Policy Sets page indicates the name of the active policy set and lists all of the management classes for that policy set.

3. Click the Configure toggle. The policy set is editable.
4. Optional: To edit a policy set that is not active, click the forward and back arrows to locate the policy set.
5. Edit the policy set by completing any of the following actions:

Option	Description

Option	Description
Add a management class	a. In the Policy Sets table, click +Management Class. b. To specify the rules for backing up and archiving data, complete the fields in the Add Management Class window. c. To make the management class the default management class, select the Make default check box. d. Click Add.
Delete a management class	In the Management Class column, click -. Tip: To delete the default management class, you must first assign a different management class as the default.
Make a management class the default management class	In the Default column for the management class, click the radio button. Tip: The default management class manages client files when another management class is not assigned to, or appropriate for managing, a file. To ensure that clients can always back up and archive files, choose a default management class that contains rules for both backing up and archiving files.
Modify a management class	To change the properties of a management class, update the fields in the table.

6. Click Save.
   Attention: When you activate a new policy set, data might be lost. Data that is protected under one policy set might not be protected under another policy set. Therefore, before you activate a policy set, ensure that the differences between the previous policy set and the new policy set do not cause data to be lost.
7. Click Activate. A summary of the differences between the active policy set and the new policy set is displayed. Ensure that the changes in the new policy set are consistent with your data retention requirements by completing the following steps:
   a. Review the differences between corresponding management classes in the two policy sets, and consider the consequences for client files. Client files that are bound to management classes in the active policy set will be bound to the management classes with the same names in the new policy set.
   b. Identify management classes in the active policy set that do not have counterparts in the new policy set, and consider the consequences for client files. Client files that are bound to these management classes will be managed by the default management class in the new policy set.
   c. If the changes to be implemented by the policy set are acceptable, select the I understand that these updates can cause data loss check box and click Activate.

Scheduling backup and archive operations

Before you register a new client with the server, ensure that a schedule is available to specify when backup and archive operations take place. During the registration process, you assign a schedule to the client.

Before you begin

Determine how to proceed:

- If you are familiar with the schedules that are configured for the solution and you know that they do not require modification, continue with Registering clients.
- If you are not familiar with the schedules or the schedules require modification, follow the steps in this procedure.

About this task

Typically, backup operations for all clients must be completed daily. Carefully schedule client and server workloads to achieve the best performance for your storage environment. To avoid the overlap of client and server operations, consider scheduling client backup and archive operations so that they run at night. If client and server operations overlap or are not given enough time and resources to be processed, you might experience decreased system performance, failed operations, and other issues.

Procedure

1. Review available schedules by hovering over Clients on the Operations Center menu bar. Click Schedules.
2. Optional: Modify or create a schedule by completing the following steps:

Option	Description

Option	Description
Modify a schedule	a. In the Schedules view, select the schedule and click Details. b. On the Schedule Details page, view details by clicking the blue arrows at the beginning of the rows. c. Modify the settings in the schedule, and click Save.
Create a schedule	In the Schedules view, click +Schedule and complete the steps to create a schedule.

3. Optional: To configure schedule settings that are not visible in the Operations Center, use a server command. For example, you might want to schedule a client operation that backs up a specific directory and assigns it to a management class other than the default.
    a. On the Overview page of the Operations Center, hover over the settings icon and click Command Builder.
    b. Issue the DEFINE SCHEDULE command to create a schedule or the UPDATE SCHEDULE command to modify a schedule. For details about the commands, see DEFINE SCHEDULE (Define a schedule for an administrative command) or UPDATE SCHEDULE (Update a client schedule).

Related tasks:
Tuning the schedule for daily operations

Registering clients

Register a client to ensure that the client can connect to the server, and the server can protect client data.

Before you begin

Determine whether the client requires an administrative user ID with client owner authority over the client node. To determine which clients require an administrative user ID, see technote 7048963.
Restriction: For some types of clients, the client node name and the administrative user ID must match. You cannot authenticate those clients by using the Lightweight Directory Access Protocol authentication method that was introduced in V7.1.7. For details about this authentication method, sometimes referred to as integrated mode, see Authenticating users by using an Active Directory database.

Procedure

To register a client, complete one of the following actions.

- If the client requires an administrative user ID, register the client by using the REGISTER NODE command and specify the USERID parameter:

  ```
  register node node_name password userid=node_name
  ```

  where *node_name* specifies the node name and *password* specifies the node password. For details, see Register a node.
- If the client does not require an administrative user ID, register the client by using the Operations Center Add Client wizard. Complete the following steps:
    a. On the Operations Center menu bar, click Clients.
    b. In the Clients table, click +Client.
    c. Complete the steps in the Add Client wizard:
        i. Specify that redundant data can be eliminated on both the client and server. In the Client-side data deduplication area, select the Enable check box.
        ii. In the Configuration window, copy the TCPSERVERADDRESS, TCPPORT, NODENAME, and DEDUPLICATION option values.
        Tip: Record the option values and keep them in a safe place. After you complete the client registration and install the software on the client node, use the values to configure the client.
        iii. Follow the instructions in the wizard to specify the policy domain, schedule, and option set.
        iv. Set how risks are displayed for the client by specifying the at-risk setting.
        v. Click Add Client.

Installing and configuring clients

To start protecting a client node, you must install and configure the selected software.

Procedure

If you already installed the software, start at step 2.

1. Take one of the following actions:
   - To install software on an application or client node, follow the instructions.

Software	Link to instructions
IBM Spectrum Protect™ backup-archive client	▪ Installing the UNIX and Linux backup-archive clients ▪ Installing the Windows backup-archive client For information about manual deployment of client updates from the server, see the following documents: ▪ For IBM Spectrum Protect 8.1.2 or later servers, see technote 2004596. ▪ For IBM® Tivoli® Storage Manager V7.1 servers and IBM Spectrum Protect V8.1.0 and V8.1.1 servers, see technote 1673299.
IBM Spectrum Protect for Databases	▪ Data Protection for Oracle installation ▪ Installing Data Protection for SQL Server on Windows Server Core
IBM Spectrum Protect for Mail	▪ Installation of Data Protection for IBM Domino on a UNIX, AIX, or Linux system (V7.1.0) ▪ Installation of Data Protection for IBM Domino on a Windows system (V7.1.0) ▪ Installing, upgrading, and migrating IBM Spectrum Protect for Mail: Data Protection for Microsoft Exchange Server
IBM Spectrum Protect Snapshot	▪ Installing and upgrading IBM Spectrum Protect Snapshot for UNIX and Linux ▪ Installing and upgrading IBM Spectrum Protect Snapshot for VMware ▪ Installing and upgrading IBM Spectrum Protect Snapshot for Windows
IBM Spectrum Protect for Enterprise Resource Planning	▪ Installing IBM Spectrum Protect for Enterprise Resource Planning: Data Protection for SAP for DB2® ▪ Installing IBM Spectrum Protect for Enterprise Resource Planning: Data Protection for SAP for Oracle

   - To install software on a virtual machine client node, follow the instructions for the selected backup type.

Backup type	Link to instructions
If you plan to create full VMware backups of virtual machines, install and configure the IBM Spectrum Protect backup-archive client.	▪ Installing the UNIX and Linux backup-archive clients ▪ Installing the Windows backup-archive client
If you plan to create incremental forever full backups of virtual machines, install and configure IBM Spectrum Protect for Virtual Environments and the backup-archive client on the same client node or on different client nodes.	▪ IBM Spectrum Protect for Virtual Environments online product documentation Tip: You can obtain the software for IBM Spectrum Protect for Virtual Environments and the backup-archive client in the IBM Spectrum Protect for Virtual Environments installation package.

2. To allow the client to connect to the server, add or update the values for the TCPSERVERADDRESS, TCPPORT, and NODENAME options in the client options file. Use the values that you recorded when you registered the client (Registering clients).
   - For clients that are installed on an AIX®, Linux, or Mac OS X operating system, add the values to the client system-options file, dsm.sys.
   - For clients that are installed on a Windows operating system, add the values to the dsm.opt file.

By default, the options files are in the installation directory.

3. If you installed a backup-archive client on a Linux or Windows operating system, install the client management service on the client. Follow the instructions in Installing the client management service.
4. Configure the client to run scheduled operations. Follow the instructions in Configuring the client to run scheduled operations.
5. Optional: Configure communications through a firewall. Follow the instructions in Configuring client/server communications through a firewall.
6. Run a test backup to verify that data is protected as you planned. For example, for a backup-archive client, complete the following steps:
    a. On the Clients page of the Operations Center, select the client that you want to back up, and click Back Up.
    b. Verify that the backup completes successfully and that there are no warning or error messages.
7. Monitor the results of the scheduled operations for the client in the Operations Center.

What to do next

If you need to change what is getting backed up from the client, follow the instructions in Modifying the scope of a client backup.

Configuring the client to run scheduled operations

You must configure and start a client scheduler on the client node. The client scheduler enables communication between the client and server so that scheduled operations can occur. For example, scheduled operations typically include backing up files from a client.

About this task

The preferred method is to install the backup-archive client on all client nodes so that you can configure and start the client acceptor on the client node. The client acceptor is designed to efficiently run scheduled operations. The client acceptor manages the client scheduler so that the scheduler runs only when required:

- When it is time to query the server about the next scheduled operation
- When it is time to start the next scheduled operation

By using the client acceptor, you can reduce the number of background processes on the client and help to avoid memory retention problems.

The client acceptor runs schedules for the following products: the backup-archive client, IBM Spectrum Protect™ for Databases, IBM Spectrum Protect for Enterprise Resource Planning, IBM Spectrum Protect for Mail, and IBM Spectrum Protect for Virtual Environments. If you installed a product for which the client acceptor does not run schedules, follow the configuration instructions in the product documentation to ensure that scheduled operations can occur.

If your business uses a third-party scheduling tool as standard practice, you can use that scheduling tool as an alternative to the client acceptor. Typically, third-party scheduling tools start client programs directly by using operating system commands. To configure a third-party scheduling tool, see the product documentation.

Procedure

To configure and start the client scheduler by using the client acceptor, follow the instructions for the operating system that is installed on the client node:

AIX® and Oracle Solaris

a. From the backup-archive client GUI, click Edit > Client Preferences.
b. Click the Web Client tab.
c. In the Managed Services Options field, click Schedule. If you also want the client acceptor to manage the web client, click the Both option.
d. To ensure that the scheduler can start unattended, in the dsm.sys file, set the passwordaccess option to `generate`.
e. To store the client node password, issue the following command and enter the client node password when prompted:

```
dsmc query sess
```

f. Start the client acceptor by issuing the following command on the command line:

```
/usr/bin/dsmcad
```

g. To enable the client acceptor to start automatically after a system restart, add the following entry to the system startup file (typically, /etc/inittab):

```
tsm::once:/usr/bin/dsmcad > /dev/null 2>&1 # Client Acceptor Daemon
```

Linux

a. From the backup-archive client GUI, click Edit > Client Preferences.
b. Click the Web Client tab.
c. In the Managed Services Options field, click Schedule. If you also want the client acceptor to manage the web client, click the Both option.
d. To ensure that the scheduler can start unattended, in the dsm.sys file, set the passwordaccess option to `generate`.
e. To store the client node password, issue the following command and enter the client node password when prompted:

```
dsmc query sess
```

f. Start the client acceptor by logging in with the root user ID and issuing the following command:

```
service dsmcad start
```

g. To enable the client acceptor to start automatically after a system restart, add the service by issuing the following command at a shell prompt:

```
# chkconfig --add dsmcad
```

MAC OS X

a. In the backup-archive client GUI, click Edit > Client Preferences.
b. To ensure that the scheduler can start unattended, click Authorization, select Password Generate, and click Apply.
c. To specify how services are managed, click Web Client, select Schedule, click Apply, and click OK.
d. To ensure that the generated password is saved, restart the backup-archive client.
e. Use the IBM Spectrum Protect Tools for Administrators application to start the client acceptor.

Windows

a. In the backup-archive client GUI, click Utilities > Setup Wizard > Help me configure the Client Scheduler. Click Next.
b. Read the information on the Scheduler Wizard page and click Next.
c. On the Scheduler Task page, select Install a new or additional scheduler and click Next.
d. On the Scheduler Name and Location page, specify a name for the client scheduler that you are adding. Then, select Use the Client Acceptor daemon (CAD) to manage the scheduler and click Next.
e. Enter the name that you want to assign to this client acceptor. The default name is Client Acceptor. Click Next.
f. Complete the configuration by stepping through the wizard.
g. Update the client options file, dsm.opt, and set the passwordaccess option to generate.
h. To store the client node password, issue the following command at the command prompt:

```
dsmc query sess
```

Enter the client node password when prompted.
i. Start the client acceptor service from the Services Control page. For example, if you used the default name, start the Client Acceptor service. Do not start the scheduler service that you specified on the Scheduler Name and Location page. The scheduler service is started and stopped automatically by the client acceptor service as needed.

Configuring client/server communications through a firewall

If a client must communicate with a server through a firewall, you must enable client/server communications through the firewall.

Before you begin

If you used the Add Client wizard to register a client, find the option values in the client options file that you obtained during that process. You can use the values to specify ports.

About this task

Attention: Do not configure a firewall in a way that might cause termination of sessions that are in use by a server or storage agent. Termination of a valid session can cause unpredictable results. Processes and sessions might appear to stop due to input/output errors. To help exclude sessions from timeout restrictions, configure known ports for IBM Spectrum Protect™ components. Ensure that the KEEPALIVE server option remains set to the default value of YES. In this way, you can help to ensure that client/server communication is uninterrupted. For instructions about setting the KEEPALIVE server option, see KEEPALIVE.

Procedure

Open the following ports to allow access through the firewall:

TCP/IP port for the backup-archive client, command-line administrative client, and the client scheduler
: Specify the port by using the tcpport option in the client options file. The tcpport option in the client options file must match the TCPPORT option in the server options file. The default value is 1500. If you decide to use a value other than the default, specify a number in the range 1024 - 32767.

HTTP port to enable communication between the web client and remote workstations
: Specify the port for the remote workstation by setting the httpport option in the client options file of the remote workstation. The default value is 1581.

TCP/IP ports for the remote workstation
: The default value of 0 (zero) causes two free port numbers to be randomly assigned to the remote workstation. If you do not want the port numbers to be randomly assigned, specify values by setting the webports option in the client options file of the remote workstation.

TCP/IP port for administrative sessions
: Specify the port on which the server waits for requests for administrative client sessions. The value of the client tcpadminport option must match the value of the TCPADMINPORT server option. In this way, you can secure administrative sessions within a private network.

Managing client operations

You can evaluate and resolve errors that are related to a backup-archive client by using the Operations Center, which provides suggestions for resolving errors. For errors on other types of clients, you must examine the error logs on the client and review the product documentation.

About this task

In some cases, you can resolve client errors by stopping and starting the client acceptor. If client nodes or administrator IDs are locked, you can resolve the issue by unlocking the client node or administrator ID, and then resetting the password.

For detailed instructions about identifying and resolving client errors, see Resolving client problems.

- Evaluating errors in client error logs
  You can resolve client errors by obtaining suggestions from the Operations Center or by reviewing error logs on the client.
- Stopping and restarting the client acceptor
  If you change the configuration of your solution, you must restart the client acceptor on all client nodes where a backup-archive client is installed.
- Resetting passwords
  If a password for a client node or an administrator ID is lost or forgotten, you can reset the password. Multiple attempts to access the system with an incorrect password can cause a client node or administrator ID to be locked. You can take steps to resolve the issue.
- Modifying the scope of a client backup
  When you set up client backup operations, the preferred practice is to exclude objects that you do not require. For example, you typically want to exclude temporary files from a backup operation.

Evaluating errors in client error logs

You can resolve client errors by obtaining suggestions from the Operations Center or by reviewing error logs on the client.

Before you begin

To resolve errors in a backup-archive client on a Linux or Windows operating system, ensure that the client management service is installed and started. For installation instructions, see Installing the client management service. For instructions about verifying the installation, see Verifying that the client management service is installed correctly.

Procedure

To diagnose and resolve client errors, take one of the following actions:

- If the client management service is installed on the client node, complete the following steps:
  1. On the Operations Center Overview page, click Clients and select the client.
  2. Click Details.
  3. On the client Summary page, click the Diagnosis tab.
  4. Review the retrieved log messages.
     Tips:
     - To show or hide the Client Logs pane, double-click the Client Logs bar.
     - To resize the Client Logs pane, click and drag the Client Logs bar.

     If suggestions are displayed on the Diagnosis page, select a suggestion. In the Client Logs pane, client log messages to which the suggestion relates are highlighted.
  5. Use the suggestions to resolve the problems that are indicated by the error messages.
     Tip: Suggestions are provided for only a subset of client messages.
- If the client management service is not installed on the client node, review the error logs for the installed client.

Stopping and restarting the client acceptor

If you change the configuration of your solution, you must restart the client acceptor on all client nodes where a backup-archive client is installed.

About this task

In some cases, you can resolve client scheduling problems by stopping and restarting the client acceptor. The client acceptor must be running to ensure that scheduled operations can occur on the client. For example, if you change the IP address or domain name of the server, you must restart the client acceptor.

Procedure

Follow the instructions for the operating system that is installed on the client node:

AIX and Oracle Solaris

- To stop the client acceptor, complete the following steps:
  a. Determine the process ID for the client acceptor by issuing the following command on the command line:

     ```
     ps -ef | grep dsmcad
     ```

     Review the output. In the following sample output, 6764 is the process ID for the client acceptor:

     ```
     root  6764     1   0 16:26:35 ?           0:00 /usr/bin/dsmcad
     ```

  b. Issue the following command on the command line:

     ```
     kill -9 PID
     ```

     where *PID* specifies the process ID for the client acceptor.
- To start the client acceptor, issue the following command on the command line:

  ```
  /usr/bin/dsmcad
  ```

Linux

- To stop the client acceptor (and not restart it), issue the following command:

  ```
  # service dsmcad stop
  ```

- To stop and restart the client acceptor, issue the following command:

```
# service dsmcad restart
```

MAC OS X

Click Applications > Utilities > Terminal.

- To stop the client acceptor, issue the following command:

  ```
  /bin/launchctl unload -w com.ibm.tivoli.dsmcad
  ```

- To start the client acceptor, issue the following command:

  ```
  /bin/launchctl load -w com.ibm.tivoli.dsmcad
  ```

Windows

- To stop the client acceptor service, complete the following steps:
  a. Click Start > Administrative Tools > Services.
  b. Double-click the client acceptor service.
  c. Click Stop and OK.
- To restart the client acceptor service, complete the following steps:
  a. Click Start > Administrative Tools > Services.
  b. Double-click the client acceptor service.
  c. Click Start and OK.

Related reference:
Resolving client scheduling problems

Resetting passwords

If a password for a client node or an administrator ID is lost or forgotten, you can reset the password. Multiple attempts to access the system with an incorrect password can cause a client node or administrator ID to be locked. You can take steps to resolve the issue.

Procedure

To resolve password issues, take one of the following actions:

- If a backup-archive client is installed on a client node, and the password is lost or forgotten, complete the following steps:
  1. Generate a new password by issuing the UPDATE NODE command:

     ```
     update node node_name new_password forcepwreset=yes
     ```

     where *node_name* specifies the client node and *new_password* specifies the password that you assign.
  2. Inform the client node owner about the changed password. When the owner of the client node logs in with the specified password, a new password is generated automatically. That password is unknown to users to enhance security.
     Tip: The password is generated automatically if you previously set the passwordaccess option to `generate` in the client options file.
- If an administrator is locked out because of password issues, complete the following steps:
  1. To provide the administrator with access to the server, issue the UNLOCK ADMIN command. For instructions, see UNLOCK ADMIN (Unlock an administrator).
  2. Set a new password by using the UPDATE ADMIN command:

     ```
     update admin admin_name new_password forcepwreset=yes
     ```

     where *admin_name* specifies the name of the administrator and *new_password* specifies the password that you assign.
- If a client node is locked, complete the following steps:
  1. Determine why the client node is locked and whether it must be unlocked. For example, if the client node is decommissioned, the client node is being removed from the production environment. You cannot reverse the decommission operation, and the client node remains locked. A client node also might be locked if the client data is the subject of a legal investigation.
  2. If you must unlock a client node, use the UNLOCK NODE command. For instructions, see UNLOCK NODE (Unlock a client node).

3. Generate a new password by issuing the UPDATE NODE command:

   ```
   update node node_name new_password forcepwreset=yes
   ```

   where *node_name* specifies the name of the node and *new_password* specifies the password that you assign.
4. Inform the client node owner about the changed password. When the owner of the client node logs in with the specified password, a new password is generated automatically. That password is unknown to users to enhance security.
   Tip: The password is generated automatically if you previously set the passwordaccess option to `generate` in the client options file.

Modifying the scope of a client backup

When you set up client backup operations, the preferred practice is to exclude objects that you do not require. For example, you typically want to exclude temporary files from a backup operation.

About this task

When you exclude unnecessary objects from backup operations, you get better control of the amount of storage space that is required for backup operations, and the cost of storage. Depending on your licensing package, you also might be able to limit licensing costs.

Procedure

How you modify the scope of backup operations depends on the product that is installed on the client node:

- For a backup-archive client, you can create an include-exclude list to include or exclude a file, groups of files, or directories from backup operations. To create an include-exclude list, follow the instructions in Creating an include-exclude list.

  To ensure consistent use of an include-exclude list for all clients of one type, you can create a client option set on the server that contains the required options. Then, you assign the client option set to each of the clients of the same type. For details, see Controlling client operations through client option sets.

- For a backup-archive client, you can specify the objects to include in an incremental backup operation by using the domain option. Follow the instructions in Domain client option.
- For other products, to define which objects are included in and excluded from backup operations, follow the instructions in the product documentation.

Managing client upgrades

When a fix pack or interim fix becomes available for a client, you can upgrade the client to take advantage of product improvements. Servers and clients can be upgraded at different times and can be at different levels with some restrictions.

Before you begin

1. Review the client/server compatibility requirements in technote 1053218. If your solution includes servers or clients at a level that is earlier than V7.1, review the guidelines to ensure that client backup and archive operations are not disrupted.
2. Verify system requirements for the client in IBM Spectrum Protect™ Supported Operating Systems.
3. If the solution includes storage agents or library clients, review the information about storage-agent and library-client compatibility with servers that are configured as library managers. See technote 1302789.

   If you plan to upgrade a library manager and a library client, you must upgrade the library manager first.

Procedure

To upgrade the software, complete the instructions that are listed in the following table.

Software	Link to instructions
IBM Spectrum Protect backup-archive client	• Upgrading the backup-archive client

Software	Link to instructions
IBM Spectrum Protect Snapshot	• Installing and upgrading IBM Spectrum Protect Snapshot for UNIX and Linux • Installing and upgrading IBM Spectrum Protect Snapshot for VMware • Installing and upgrading IBM Spectrum Protect Snapshot for Windows
IBM Spectrum Protect for Databases	• Upgrading Data Protection for SQL Server • Data Protection for Oracle installation • Installing, upgrading, and migrating IBM Spectrum Protect for Mail: Data Protection for Microsoft Exchange Server
IBM Spectrum Protect for Enterprise Resource Planning	• Upgrading IBM Spectrum Protect for Enterprise Resource Planning: Data Protection for SAP for DB2® • Upgrading IBM Spectrum Protect for Enterprise Resource Planning: Data Protection for SAP for Oracle
IBM Spectrum Protect for Mail	• Installation of Data Protection for IBM Domino on a UNIX, AIX, or Linux system (V7.1.0) • Installation of Data Protection for IBM Domino on a Windows system (V7.1.0) • Installing, upgrading, and migrating IBM Spectrum Protect for Mail: Data Protection for Microsoft Exchange Server
IBM Spectrum Protect for Virtual Environments	• Installing and upgrading Data Protection for VMware • Installing Data Protection for Microsoft Hyper-V

Decommissioning a client node

If a client node is no longer required, you can start a process to remove it from the production environment. For example, if a workstation was backing up data to the IBM Spectrum Protect™ server, but the workstation is no longer used, you can decommission the workstation.

About this task

When you start the decommission process, the server locks the client node to prevent it from accessing the server. Files that belong to the client node are gradually deleted, and then the client node is deleted. You can decommission the following types of client nodes:

Application client nodes
: Application client nodes include email servers, databases, and other applications. For example, any of the following applications can be an application client node:

  - IBM Spectrum Protect Snapshot
  - IBM Spectrum Protect for Databases
  - IBM Spectrum Protect for Enterprise Resource Planning
  - IBM Spectrum Protect for Mail
  - IBM Spectrum Protect for Virtual Environments

System client nodes
: System client nodes include workstations, network-attached storage (NAS) file servers, and API clients.

Virtual machine client nodes
: Virtual machine client nodes consist of an individual guest host within a hypervisor. Each virtual machine is represented as a file space.

The simplest method for decommissioning a client node is to use the Operations Center. The decommission process runs in the background. If the client is configured to replicate client data, the Operations Center automatically removes the client from replication on the source and target replication servers before it decommissions the client.
Tip: Alternatively, you can decommission a client node by issuing the DECOMMISSION NODE or DECOMMISSION VM command. You might want to use this method in the following cases:

- To schedule the decommission process for the future or to run a series of commands by using a script, specify the decommission process to run in the background.
- To monitor the decommission process for debugging purposes, specify the decommission process to run in the foreground. If you run the process in the foreground, you must wait for the process to be completed before you continue with other tasks.

Procedure

Take one of the following actions:

- To decommission a client in the background by using the Operations Center, complete the following steps:
  1. On the Operations Center Overview page, click Clients and select the client.
  2. Click More > Decommission.
- To decommission a client node by using an administrative command, take one of the following actions:
  - To decommission an application or system client node in the background, issue the DECOMMISSION NODE command. For example, if the client node is named AUSTIN, issue the following command:

    ```
    decommission node austin
    ```

  - To decommission an application or system client node in the foreground, issue the DECOMMISSION NODE command and specify the `wait=yes` parameter. For example, if the client node is named AUSTIN, issue the following command:

    ```
    decommission node austin wait=yes
    ```

  - To decommission a virtual machine in the background, issue the DECOMMISSION VM command. For example, if the virtual machine is named AUSTIN, the file space is 7, and the file space name is specified by the file space ID, issue the following command:

    ```
    decommission vm austin 7 nametype=fsid
    ```

    If the virtual machine name includes one or more spaces, enclose the name in double quotation marks. For example:

    ```
    decommission vm "austin 2" 7 nametype=fsid
    ```

  - To decommission a virtual machine in the foreground, issue the DECOMMISSION VM command and specify the `wait=yes` parameter. For example, issue the following command:

    ```
    decommission vm austin 7 nametype=fsid wait=yes
    ```

    If the virtual machine name includes one or more spaces, enclose the name in double quotation marks. For example:

    ```
    decommission vm "austin 2" 7 nametype=fsid wait=yes
    ```

What to do next

Watch for error messages, which might be displayed in the user interface or in the command output, immediately after you run the process.

You can verify that the client node is decommissioned:

1. On the Operations Center Overview page, click Clients.
2. In the Clients table, in the At risk column, review the state:
   - A DECOMMISSIONED state specifies that the node is decommissioned.
   - A null value specifies that the node is not decommissioned.
   - A PENDING state specifies that the node is being decommissioned, or the decommission process failed.

   Tip: If you want to determine the status of a pending decommission process, issue the following command:

   ```
   query process
   ```

3. Review the command output:
   - If status is provided for the decommission process, the process is in progress. For example:

     ```
     query process

      Process     Process Description           Process Status
       Number
     --------     --------------------     -----------------------------------------
     ```

```
      3          DECOMMISSION NODE        Number of backup objects deactivated
                                          for node NODE1: 8 objects deactivated.
```

- If no status is provided for the decommission process, and you did not receive an error message, the process is incomplete. A process can be incomplete if files that are associated with the node are not yet deactivated. After the files are deactivated, run the decommission process again.
- If no status is provided for the decommission process, and you receive an error message, the process failed. Run the decommission process again.

DECOMMISSION NODE (Decommission a client node)
DECOMMISSION VM (Decommission a virtual machine)

Deactivating data to free storage space

In some cases, you can deactivate data that is stored on the IBM Spectrum Protect™ server. When you run the deactivation process, any backup data that was stored before the specified date and time is deactivated and will be deleted as it expires. In this way, you can free space on the server.

About this task

Some application clients always save data to the server as active backup data. Because active backup data is not managed by inventory expiration policies, the data is not deleted automatically, and uses server storage space indefinitely. To free the storage space that is used by obsolete data, you can deactivate the data.

When you run the deactivation process, all active backup data that was stored before the specified date becomes inactive. The data is deleted as it expires and cannot be restored. The deactivation feature applies only to application clients that protect Oracle databases.

Procedure

1. From the Operations Center Overview page, click Clients.
2. In the Clients table, select one or more clients and click More > Clean Up.
   Command-line method: Deactivate data by using the DEACTIVATE DATA command.

Related reference:
DEACTIVATE DATA (Deactivate data for a client node)

Managing data storage

Manage your data for efficiency and add supported devices and media to the server to store client data.

- Auditing a storage pool container
  Audit a storage pool container to check for inconsistencies between database information and a container in a storage pool.
- Managing inventory capacity
  Manage the capacity of the database, active log, and archive logs to ensure that the inventory is sized for the tasks, based on the status of the logs.
- Managing memory and processor usage
  Ensure that you manage memory requirements and processor usage to ensure that the server can complete data processes such as backup and data deduplication. Consider the impact on performance when you complete certain processes.
- Tuning scheduled activities
  Schedule maintenance tasks daily to ensure that your solution operates correctly. By tuning your solution, you maximize server resources and effectively use different functions available within your solution.

Related reference:
Types of storage pools

Auditing a storage pool container

Audit a storage pool container to check for inconsistencies between database information and a container in a storage pool.

About this task

You audit a storage pool container in the following situations:

- When you issue the QUERY DAMAGED command and a problem is detected
- When the server displays messages about damaged data extents
- Your hardware reports an issue and error messages that are associated with the storage pool container are displayed

Procedure

1. To audit a storage pool container, issue the AUDIT CONTAINER command. For example, issue the following command to audit a container, 000000000000076c.dcf:

   ```
   audit container c:\tsm-storage\07\000000000000076c.dcf
   ```

2. Review the output from the ANR4891I message for information about any damaged data extents.

What to do next

If you detect problems with the storage pool container, you can restore data based on your configuration. Issue the AUDIT CONTAINER command and specify the container name.

Related reference:
AUDIT CONTAINER (Verify the consistency of database information for a directory-container storage pool)
QUERY DAMAGED (Query damaged data in a directory-container or cloud-container storage pool)

Managing inventory capacity

Manage the capacity of the database, active log, and archive logs to ensure that the inventory is sized for the tasks, based on the status of the logs.

Before you begin

The active and archive logs have the following characteristics:

- The active log can be a maximum size of 512 GB. For more information about sizing the active log for your system, see Planning the storage arrays.
- The archive log size is limited to the size of the file system that it is installed on. The archive log size is not maintained at a predefined size like the active log. Archive log files are automatically deleted after they are no longer needed.

As a best practice, you can optionally create an archive failover log to store archive log files when the archive log directory is full.

Check the Operations Center to determine the component of the inventory that is full. Ensure that you stop the server before you increase the size of one of the inventory components.

Procedure

- To increase the size of the database, complete the following steps:
  - Create one or more directories for the database on separate drives or file systems.
  - Issue the EXTEND DBSPACE command to add the directory or directories to the database. The directories must be accessible to the instance user ID of the database manager. By default, data is redistributed across all database directories and space is reclaimed.
    Tips:
    - The time that is needed to complete redistribution of data and reclaiming of space is variable, depending on the size of your database. Make sure that you plan adequately.
    - Ensure that the directories that you specify are the same size as existing directories to ensure a consistent degree of parallelism for database operations. If one or more directories for the database are smaller than the others, they reduce the potential for optimized parallel prefetching and distribution of the database.
  - Halt and restart the server to fully use the new directories.
  - Reorganize the database if necessary. Index and table reorganization for the server database can help to avoid unexpected database growth and performance issues. For more information about reorganizing the database, see technote 1683633.

- To decrease the size of the database for V7.1 servers and later, issue the following DB2® commands from the server instance directory:
  Restriction: The commands can increase I/O activity, and might affect server performance. To minimize performance problems, wait until one command is completed before you issue the next command. The DB2 commands can be issued when the server is running.

  ```
  db2 connect to tsmdb1
  db2 set schema tsmdb1
  db2 ALTER TABLESPACE USERSPACE1 REDUCE MAX
  db2 ALTER TABLESPACE IDXSPACE1 REDUCE MAX
  db2 ALTER TABLESPACE LARGEIDXSPACE1 REDUCE MAX
  db2 ALTER TABLESPACE LARGESPACE1 REDUCE MAX
  db2 ALTER TABLESPACE REPLTBLSPACE1 REDUCE MAX
  db2 ALTER TABLESPACE REPLIDXSPACE1 REDUCE MAX
  db2 ALTER TABLESPACE ARCHOBJDATASPACE REDUCE MAX
  db2 ALTER TABLESPACE ARCHOBJIDXSPACE REDUCE MAX
  db2 ALTER TABLESPACE BACKOBJDATASPACE REDUCE MAX
  db2 ALTER TABLESPACE BACKOBJIDXSPACE REDUCE MAX
  db2 ALTER TABLESPACE BFABFDATASPACE REDUCE MAX
  db2 ALTER TABLESPACE BFABFIDXSPACE REDUCE MAX
  db2 ALTER TABLESPACE BFBFEXTDATASPACE REDUCE MAX
  db2 ALTER TABLESPACE BFBFEXTIDXSPACE REDUCE MAX
  db2 ALTER TABLESPACE DEDUPTBLSPACE1 REDUCE MAX
  db2 ALTER TABLESPACE DEDUPIDXSPACE1 REDUCE MAX
  db2 ALTER TABLESPACE DEDUPTBLSPACE2 REDUCE MAX
  db2 ALTER TABLESPACE DEDUPIDXSPACE2 REDUCE MAX
  db2 ALTER TABLESPACE DEDUPTBLSPACE3 REDUCE MAX
  db2 ALTER TABLESPACE DEDUPIDXSPACE3 REDUCE MAX
  db2 ALTER TABLESPACE DEDUPTBLSPACE4 REDUCE MAX
  db2 ALTER TABLESPACE DEDUPIDXSPACE4 REDUCE MAX
  db2 ALTER TABLESPACE DEDUPTBLSPACE5 REDUCE MAX
  db2 ALTER TABLESPACE DEDUPIDXSPACE5 REDUCE MAX
  ```

- To increase or decrease the size of the active log, complete the following steps:
  1. Ensure that the location for the active log has enough space for the increased log size. If a log mirror exists, its location must also have enough space for the increased log size.
  2. Halt the server.
  3. In the dsmserv.opt file, update the ACTIVELOGSIZE option to the new size of the active log, in megabytes.
     The size of an active log file is based on the value of the ACTIVELOGSIZE option. Guidelines for space requirements are in the following table:

     Table 1. How to estimate volume and file space requirements

ACTIVELOGSize option value	**Reserve this much free space in the active log directory, in addition to the ACTIVELOGSize space**
16 GB - 128 GB	5120 MB
129 GB - 256 GB	10240 MB
257 GB - 512 GB	20480 MB

     To change the active log to its maximum size of 512 GB, enter the following server option:

     ```
     activelogsize 524288
     ```

  4. If you plan to use a new active log directory, update the directory name that is specified in the ACTIVELOGDIRECTORY server option. The new directory must be empty and must be accessible to the user ID of the database manager.
  5. Restart the server.
- Compress the archive logs to reduce the amount of space that is required for storage. Enable dynamic compression of the archive log by issuing the following command:

  ```
  setopt archlogcompress yes
  ```

  Restriction: Use caution when you enable the ARCHLOGCOMPRESS server option on systems with sustained high volume usage and heavy workloads. Enabling this option in this system environment can cause delays in archiving log files from the active log file system to the archive log file system. This delay can cause the active log file system to run out of space. Be sure to monitor the available space in the active log file system after archive log compression is enabled. If the active log directory file system usage nears out of space conditions, the ARCHLOGCOMPRESS server option must be disabled. You can use the SETOPT command to disable archive log compression immediately without halting the server.

Related reference:
ACTIVELOGSIZE server option
EXTEND DBSPACE (Increase space for the database)
SETOPT (Set a server option for dynamic update)

Managing memory and processor usage

Ensure that you manage memory requirements and processor usage to ensure that the server can complete data processes such as backup and data deduplication. Consider the impact on performance when you complete certain processes.

Before you begin

- Ensure that your configuration uses the required hardware and software. For more information, see IBM Spectrum Protect™ Supported Operating Systems.
- For more information about managing resources such as the database and recovery log, see Planning the storage arrays.
- Add more system memory to determine whether there is a performance improvement. Monitor memory usage regularly to determine whether more memory is required.

Procedure

1. Release memory from the file system cache where possible.
2. To manage the system memory that is used by each server on a system, use the DBMEMPERCENT server option. Limit the percentage of system memory that can be used by the database manager of each server. If all servers are equally important, use the same value for each server. If one server is a production server and other servers are test servers, set the value for the production server to a higher value than the test servers.
3. Set the user data limit and private memory for the database to ensure that private memory is not exhausted. Exhausting private memory can result in errors, less than optimal performance, and instability.

Tuning scheduled activities

Schedule maintenance tasks daily to ensure that your solution operates correctly. By tuning your solution, you maximize server resources and effectively use different functions available within your solution.

Procedure

1. Monitor system performance regularly to ensure that backup and maintenance tasks are completing successfully. For more information about monitoring, see Monitoring a single-site disk solution.
2. If the monitoring information shows that the server workload increased, you might need to review the planning information. Review whether the capacity of the system is adequate in the following cases:
    - The number of clients increases
    - The amount of data that is being backed up increases
    - The amount of time that is available for backups changes
3. Determine whether your solution has performance issues. Review the client schedules to check whether tasks are completing within the scheduled time frame:
    a. On the Clients page of the Operations Center, select the client.
    b. Click Details.
    c. From the client Summary page, review the Backed up and Replicated activity to identify any risks.

    Adjust the time and frequency of client backup operations, if necessary.
4. Schedule enough time for the following maintenance tasks to complete successfully within a 24-hour period:
    a. Back up the database
    b. Run expiration to remove client backups and archive file copies from server storage.

Securing the IBM Spectrum Protect server

Secure the IBM Spectrum Protect™ server and data by controlling access to servers and client nodes, encrypting data, and maintaining secure access levels and passwords.

- Security concepts
  You can protect IBM Spectrum Protect from security risks by using communication protocols, securing passwords, and providing different access levels for administrators.
- Managing administrators
  An administrator who has system authority can complete any task with the IBM Spectrum Protect server, including assigning authority levels to other administrators. To complete some tasks, you must be granted authority by being assigned one or more authority levels.
- Changing password requirements
  You can change the minimum password limit, password length, password expiration, and enable or disable authentication for IBM Spectrum Protect.
- Securing the server on the system
  Protect the system where the IBM Spectrum Protect server runs to prevent unauthorized access.

Security concepts

You can protect IBM Spectrum Protect™ from security risks by using communication protocols, securing passwords, and providing different access levels for administrators.

Transport Layer Security

You can use the Secure Sockets Layer (SSL) or the Transport Layer Security (TLS) protocol to provide transport layer security for a secure connection between servers, clients, and storage agents. If you send data between the server, client, and storage agent, use SSL or TLS to encrypt the data.

Tip: Any IBM Spectrum Protect documentation that indicates "SSL" or to "select SSL" applies to TLS.

SSL is provided by the Global Security Kit (GSKit) that is installed with the IBM Spectrum Protect server that the server, client, and storage agent use.

Restriction: Do not use the SSL or TLS protocols for communications with a DB2® database instance that is used by any IBM Spectrum Protect servers.

Each server, client, or storage agent that enables SSL must use a trusted self-signed certificate or obtain a unique certificate that is signed by a certificate authority (CA). You can use your own certificates or purchase certificates from a CA. Either certificate must be installed and added to the key database on the IBM Spectrum Protect server, client, or storage agent. The certificate is verified by the SSL client or server that requests or initiates the SSL communication. Some CA certificates are preinstalled in the key databases, by default.

SSL is set up independently on the IBM Spectrum Protect server, client, and storage agent.

Authority levels

With each IBM Spectrum Protect server, different administrative authority levels are available that determine the tasks that an administrator can complete.

After registration, an administrator must be granted authority by being assigned one or more administrative authority levels. An administrator with system authority can complete any task with the server and assign authority levels to other administrators by using the GRANT AUTHORITY command. Administrators with policy, storage, or operator authority can complete subsets of tasks.

An administrator can register other administrator IDs, grant levels of authority to them, rename IDs, remove IDs, and lock and unlock them from the server.

An administrator can control access to specific client nodes for root user IDs and non-root user IDs. By default, a non-root user ID cannot back up data on the node. Use the UPDATE NODE command to change the node settings to enable backup.

Passwords

By default, the server automatically uses password authentication. With password authentication, all users must enter a password when they access the server.

Use Lightweight Directory Access Protocol (LDAP) to apply stricter requirements for passwords. For more information, see Managing passwords and logon procedures (V7.1.1).

Table 1. Password authentication characteristics

Characteristic	More information
Case-sensitivity	Not case-sensitive.
Default password expiration	90 days. The expiration period begins when an administrator ID or client node is first registered to the server. If the password is not changed within this period, the password must be changed the next time that the user accesses the server.
Invalid password attempts	You can set a limit on consecutive invalid password attempts for all client nodes. When the limit is exceeded, the server locks the node.
Password length	The administrator can specify a minimum length.

Session security

Session security is the level of security that is used for communication among IBM Spectrum Protect client nodes, administrative clients, and servers and is set by using the SESSIONSECURITY parameter.

The SESSIONSECURITY parameter can be set to one of the following values:

- The STRICT value enforces the highest level of security for communication between IBM Spectrum Protect servers, nodes, and administrators.
- The TRANSITIONAL value specifies that the existing communication protocol is used while you update your IBM Spectrum Protect software to V8.1.2 or later. This is the default. When SESSIONSECURITY=TRANSITIONAL, stricter security settings are automatically enforced as higher versions of the TLS protocol are used and as the software is updated to V8.1.2 or later. After a node, administrator, or server meets the requirements for the STRICT value, session security is automatically updated to the STRICT value, and the entity can no longer authenticate by using a previous version of the client or earlier TLS protocols.

For more information about the SESSIONSECURITY parameter values, see the following commands.

Table 2. Commands used to set the SESSIONSECURITY parameter

Entity	Command
Client nodes	• REGISTER NODE • UPDATE NODE
Administrators	• REGISTER ADMIN • UPDATE ADMIN
Servers	• DEFINE SERVER • UPDATE SERVER

Administrators that authenticate by using the DSMADMC command, DSMC command, or dsm program cannot authenticate by using an earlier version after authenticating by using V8.1.2 or later. To resolve authentication issues for administrators, see the following tips:
Tips:

- Ensure that all IBM Spectrum Protect software that the administrator account uses to log on is upgraded to V8.1.2 or later. If an administrator account logs on from multiple systems, ensure that the server's certificate is installed on each system.
- After an administrator authenticates to a V8.1.2 or later server by using a V8.1.2 or later client, the administrator can authenticate only on clients or servers that are using V8.1.2 or later. An administrator command can be issued from any system.
- If necessary, create a separate administrator account to use only with clients and servers that are using V8.1.1 or earlier software.

Enforce the highest level of security for communication with the IBM Spectrum Protect server by ensuring that all nodes, administrators, and servers use STRICT session security. You can use the SELECT command to determine which servers, nodes, and administrators are using TRANSITIONAL session security and should be updated to use STRICT session security.

Related tasks:
Securing communications

Managing administrators

An administrator who has system authority can complete any task with the IBM Spectrum Protect™ server, including assigning authority levels to other administrators. To complete some tasks, you must be granted authority by being assigned one or more authority levels.

Procedure

Complete the following tasks to modify administrator settings.

Task	Procedure
Add an administrator.	To add an administrator, ADMIN1, with system authority and specify a password, complete the following steps: a. Register the administrator and specify Pa$#$twO as the password by issuing the following command: `register admin admin1 Pa$#$twO` b. Grant system authority to the administrator by issuing the following command: `grant authority admin1 classes=system`
Change administrative authority.	Change the authority level for an administrator, ADMIN1. • Grant system authority to the administrator by issuing the following command: `grant authority admin1 classes=system` • Revoke system authority for the administrator by issuing the following command: `revoke authority admin1 classes=system`
Remove administrators.	Remove an administrator, ADMIN1, from accessing the IBM Spectrum Protect server by issuing the following command: `remove admin admin1`
Temporarily prevent access to the server.	Lock or unlock an administrator by using the LOCK ADMIN or UNLOCK ADMIN command.

Changing password requirements

You can change the minimum password limit, password length, password expiration, and enable or disable authentication for IBM Spectrum Protect™.

About this task

By enforcing password authentication and managing password restrictions, you protect your data and your servers from potential security risks.

Procedure

Complete the following tasks to change password requirements for IBM Spectrum Protect servers.

Table 1. Authentication tasks for IBM Spectrum Protect servers

Task	Procedure
Set a limit for invalid password attempts.	a. On the Servers page in the Operations Center, select the server. b. Click Details, and then click the Properties tab. c. Set the number of invalid attempts in the Invalid sign-on attempt limit field. The default value at installation is 0.
Set a minimum length for passwords.	a. On the Servers page in the Operations Center, select the server. b. Click Details and then click the Properties tab. c. Set the number of characters in the Minimum password length field.
Set the expiration period for passwords.	a. On the Servers page in the Operations Center, select the server. b. Click Details and then click the Properties tab. c. Set the number of days in the Password common expiration field.
Disable password authentication.	By default, the server automatically uses password authentication. With password authentication, all users must enter a password to access the server. You can disable password authentication only for passwords that authenticate with the server (LOCAL). By disabling password authentication, you increase the security risk for the server.
Set a default authentication method.	Issue the SET DEFAULTAUTHENTICATION command. For example, to use the server as the default authentication method, issue the following command: `set defaultauthentication local` To update one client node to authenticate with the server, include `AUTHENTICATION=LOCAL` in the UPDATE NODE command: `update node authentication=local`

Authenticating IBM Spectrum Protect users by using an LDAP server

Managing passwords and logon procedures (V7.1.1)

Securing the server on the system

Protect the system where the IBM Spectrum Protect™ server runs to prevent unauthorized access.

Procedure

Ensure that unauthorized users cannot access the directories for the server database and the server instance. Keep the access settings for these directories that you configured during implementation.

- Restricting user access to the server
  Authority levels determine what an administrator can do with the IBM Spectrum Protect server. An administrator with system authority can complete any task with the server. Administrators with policy, storage, or operator authority can complete subsets of tasks.

- Limiting access through port restrictions
  Limit access to the server by applying port restrictions.

Restricting user access to the server

Authority levels determine what an administrator can do with the IBM Spectrum Protect™ server. An administrator with system authority can complete any task with the server. Administrators with policy, storage, or operator authority can complete subsets of tasks.

Procedure

1. After you register an administrator by using the REGISTER ADMIN command, use the GRANT AUTHORITY command to set the administrator's authority level. For details about setting and changing authority, see Managing administrators.
2. To control the authority of an administrator to complete some tasks, use the following two server options:
   a. You can select the authority level that an administrator must have to issue QUERY and SELECT commands with the QUERYAUTH server option. By default, no authority level is required. You can change the requirement to one of the authority levels, including system.
   b. You can specify that system authority is required for commands that cause the server to write to an external file with the REQSYSAUTHOUTFILE server option. By default, system authority is required for such commands.
3. You can restrict data backup on a client node to only root user IDs or authorized users. For example, to limit backups to the root user ID, issue the REGISTER NODE or UPDATE NODE command and specify the BACKUPINITIATION=root parameter:

   ```
   update node backupinitiation=root
   ```

Limiting access through port restrictions

Limit access to the server by applying port restrictions.

About this task

You might have to restrict access to specific servers, based on your security requirements. The IBM Spectrum Protect™ server can be configured to listen on four TCP/IP ports: two that can be used for either regular TCP/IP protocols or Secure Sockets Layer (SSL)/Transport Layer Security (TLS) protocols and two that can be used only for the SSL/TLS protocol.

Procedure

You can set the server options to specify the port that you require, as listed in Table 1.

Table 1. Server options and port access

Server option	Port access
TCPPORT	Specifies the port number on which the server TCP/IP communication driver is to wait for requests for client sessions. This port listens for both TCP/IP and SSL-enabled sessions. The default value is 1500.
TCPADMINPORT	Specifies the port number on which the server TCP/IP communication driver is to wait for requests for sessions other than client sessions. This port listens for both TCP/IP and SSL-enabled sessions. The default is the value of TCPPORT. Use this option to separate administrative client traffic from regular client traffic that uses the TCPPORT and SSLTCPPORT options.
SSLTCPPORT	Specifies the SSL TCP/IP port address for a server. This port listens for SSL-enabled sessions only. A default port value is not available.
SSLTCPADMINPORT	Specifies the port address on which the server TCP/IP communication driver waits for requests for SSL-enabled sessions. A default port value is not available. Use this option to separate administrative client traffic from regular client traffic that uses the TCPPORT and SSLTCPPORT options.

Stopping and starting the server

Before you complete maintenance or reconfiguration tasks, stop the server. Then, start the server in maintenance mode. When you are finished with the maintenance or reconfiguration tasks, restart the server in production mode.

Before you begin

You must have system or operator privilege to stop and start the IBM Spectrum Protect™ server.

- Stopping the server
  Before you stop the server, prepare the system by ensuring that all database backup operations are completed, and all other processes and sessions are ended. In this way, you can safely shut down the server and ensure that data is protected.
- Starting the server for maintenance or reconfiguration tasks
  Before you begin server maintenance or reconfiguration tasks, start the server in maintenance mode. When you start the server in maintenance mode, you disable operations that might disrupt your maintenance or reconfiguration tasks.

Stopping the server

Before you stop the server, prepare the system by ensuring that all database backup operations are completed, and all other processes and sessions are ended. In this way, you can safely shut down the server and ensure that data is protected.

About this task

When you issue the HALT command to stop the server, the following actions occur:

- All processes and client node sessions are canceled.
- All current transactions are stopped. (The transactions will be rolled back when the server is restarted.)

Procedure

To prepare the system and stop the server, complete the following steps:

1. Prevent new client node sessions from starting by issuing the DISABLE SESSIONS command:

   ```
   disable sessions all
   ```

2. Determine whether any client node sessions or processes are in progress by completing the following steps:
   a. On the Overview page of the Operations Center, view the Activity area for the total numbers of processes and sessions that are currently active. If numbers differ significantly from the usual numbers that are displayed during your daily storage-management routine, view other status indicators in the Operations Center to check whether there is a problem.
   b. View the graph in the Activity area to compare the amount of network traffic over the following periods:
      - The current period, that is, the most recent 24-hour period
      - The previous period, that is, the 24 hours before the current period

      If the graph for the previous period represents the expected amount of traffic, significant differences on the graph for the current period might indicate a problem.
   c. On the Servers page, select a server for which you want to view processes and sessions, and click Details. If the server is not registered as a hub or spoke server in the Operations Center, obtain information about processes by using administrative commands. Issue the QUERY PROCESS command to query processes and obtain information about sessions by issuing the QUERY SESSION command.
3. Wait until the client node sessions are completed or cancel them. To cancel processes and sessions, complete the following steps:
   - On the Servers page, select a server for which you want to view processes and sessions, and click Details.
   - Click the Active Tasks tab, and select one or more processes, sessions, or a combination of both that you want to cancel.
   - Click Cancel.
   - If the server is not registered as a hub or spoke server in the Operations Center, cancel sessions by using administrative commands. Issue the CANCEL SESSION command to cancel a session and cancel processes by using the CANCEL PROCESS command.
     Tip: If the process that you want to cancel is waiting for a tape volume to be mounted, the mount request is canceled. For example, if you issue an EXPORT, IMPORT, or MOVE DATA command, the command might initiate a

process that requires a tape volume to be mounted. However, if a tape volume is being mounted by an automated library, the cancel operation might not take effect until the mount process is complete. Depending on your system environment, this could take several minutes.

4. Stop the server by issuing the HALT command:

```
halt
```

Starting the server for maintenance or reconfiguration tasks

Before you begin server maintenance or reconfiguration tasks, start the server in maintenance mode. When you start the server in maintenance mode, you disable operations that might disrupt your maintenance or reconfiguration tasks.

About this task

Start the server in maintenance mode by running the DSMSERV utility with the MAINTENANCE parameter.

The following operations are disabled in maintenance mode:

- Administrative command schedules
- Client schedules
- Reclamation of storage space on the server
- Inventory expiration
- Migration of storage pools

In addition, clients are prevented from starting sessions with the server.
Tips:

- You do not have to edit the server options file, dsmserv.opt, to start the server in maintenance mode.
- While the server is running in maintenance mode, you can manually start the storage-space reclamation, inventory expiration, and storage-pool migration processes.

Procedure

To start the server in maintenance mode, issue the following command:

```
dsmserv maintenance
```

Tip: To view a video about starting the server in maintenance mode, see Starting a server in maintenance mode.

What to do next

To resume server operations in production mode, complete the following steps:

1. Shut down the server by issuing the HALT command:

```
halt
```

2. Start the server by using the method that you use in production mode. Follow the instructions for your operating system:
   - AIX Starting the server instance
   - Linux Starting the server instance
   - Windows Starting the server instance

Operations that were disabled during maintenance mode are reenabled.

Planning to upgrade the server

When a fix pack or interim fix becomes available, you can upgrade the IBM Spectrum Protect™ server to take advantage of product improvements. Servers and clients can be upgraded at different times. Ensure that you complete the planning steps before you upgrade the server.

About this task

Follow these guidelines:

- The preferred method is to upgrade the server by using the installation wizard. After you start the wizard, in the IBM Installation Manager window, click the Update icon; do not click the Install or Modify icon.
- If upgrades are available for both the server component and the Operations Center component, select the check boxes to upgrade both components.

Procedure

1. Review the list of fix packs and interim fixes. See technote 1239415.
2. Review product improvements, which are described in readme files.
   Tip: When you obtain the installation package file from the IBM Spectrum Protect support site, you can also access the readme file.
3. Ensure that the version that you upgrade your server to is compatible with other components, such as storage agents and library clients. See technote 1302789.
4. If your solution includes servers or clients at a level that is earlier than V7.1, review the guidelines to ensure that client backup and archive operations are not disrupted. See technote 1053218.
5. Review the upgrade instructions. Ensure that you back up the server database, the device configuration information, and the volume history file.

What to do next

To install a fix pack or interim fix, follow the instructions for your operating system:

- AIX Installing an IBM Spectrum Protect server fix pack
- Linux Installing an IBM Spectrum Protect server fix pack
- Windows Installing an IBM Spectrum Protect server fix pack

Upgrade and Migration Process - Frequently Asked Questions

Preparing for an outage or system update

Prepare IBM Spectrum Protect™ to maintain your system in a consistent state during a planned power outage or system update.

About this task

Ensure that you schedule activities regularly to manage, protect, and maintain the server.

Procedure

1. Cancel processes and sessions that are in progress by completing the following steps:
   a. In the Operations Center, on the Servers page, select a server for which you want to view processes and sessions, and click Details.
   b. Click the Active Tasks tab, and select one or more processes, sessions, or a combination of both that you want to cancel.
   c. Click Cancel.
2. Stop the server by issuing the HALT command:

   ```
   halt
   ```

   Tip: You can issue the halt command from the Operations Center by hovering over the Settings icon and clicking Command Builder. Then, select the server, type `halt`, and press Enter.

Implementing a disaster recovery plan

Implement a disaster recovery strategy to recover your applications if a disaster occurs and to ensure high server availability.

About this task

Determine your disaster recovery requirements by identifying the business priorities for client node recovery, the systems that you use to recover data, and whether client nodes have connectivity to a recovery server. Use replication and storage pool protection to protect data. You must also determine how often directory-container storage pools are protected.

- Completing recovery drills
  Schedule disaster recovery drills to prepare for audits that certify the recoverability of the IBM Spectrum Protect server and to ensure that data can be restored and operations can resume after an outage. A drill also helps you ensure that all data can be restored and operations resumed before a critical situation occurs.

Recovering from system outages

For IBM Spectrum Protect™ single-site disk solutions, you can recover the inventory locally only and restore the database to protect your data.

Procedure

Use one of the following methods to recover inventory to a local site, based on the type of information that is backed up.
Restriction: Because single-site disk solutions do not have a second copy of the storage pool, you cannot restore storage pools. To review the architecture of disk solutions, see Selecting an IBM Spectrum Protect solution.

Table 1. Scenarios for recovering from a disaster

Scenario	Procedure
Your system is inaccessible and you want to locally restore to an earlier version by using system tools.	• Use IBM Spectrum Protect to back up the server to another server. • Use operating system tools to back up and restore your system to an earlier version.
An outage or disaster occurs and you want to restore your data from backed up versions of the data.	• To back up a client, on the TSM Clients page of the Operations Center, select the clients that you want to back up, and click Back Up. • On the TSM Servers page of the Operations Center, select the server whose database you want to back up. Click Back Up, and follow the instructions in the Back Up Server Database window. To restore a storage pool from a backed-up version of the storage pool, you must restore the database. Issue the DSMSERV RESTORE DB command to restore the database and associated storage pools to a backed-up version.

- Restoring the database
  You might have to restore the IBM Spectrum Protect database after a disaster. You can restore the database to the most current state or to a specified point in time. You must have full, incremental, or snapshot database backup volumes to restore the database.

Multisite disk solution

This data protection solution provides replication at multiple sites so that each server protects data for the other site.

- Planning for a multisite disk data protection solution
  Plan for a multisite disk data protection solution with servers at two sites that use data deduplication and replication.
- Multisite disk implementation of a data protection solution
  The multisite disk solution is configured at two sites and uses data deduplication and replication.
- Monitoring a multisite disk solution
  After you implement a multisite disk solution with IBM Spectrum Protect, monitor the solution to ensure correct operation. By monitoring the solution daily and periodically, you can identify existing and potential issues. The information that you gather can be used to troubleshoot problems and optimize system performance.

- Managing operations for a multisite disk solution
  Use this information to manage operations for a multisite disk solution with IBM Spectrum Protect that includes a server and uses data deduplication for multiple locations.

Planning for a multisite disk data protection solution

Plan for a multisite disk data protection solution with servers at two sites that use data deduplication and replication.

Implementation methods

You can configure servers for a multisite disk solution in the following ways:

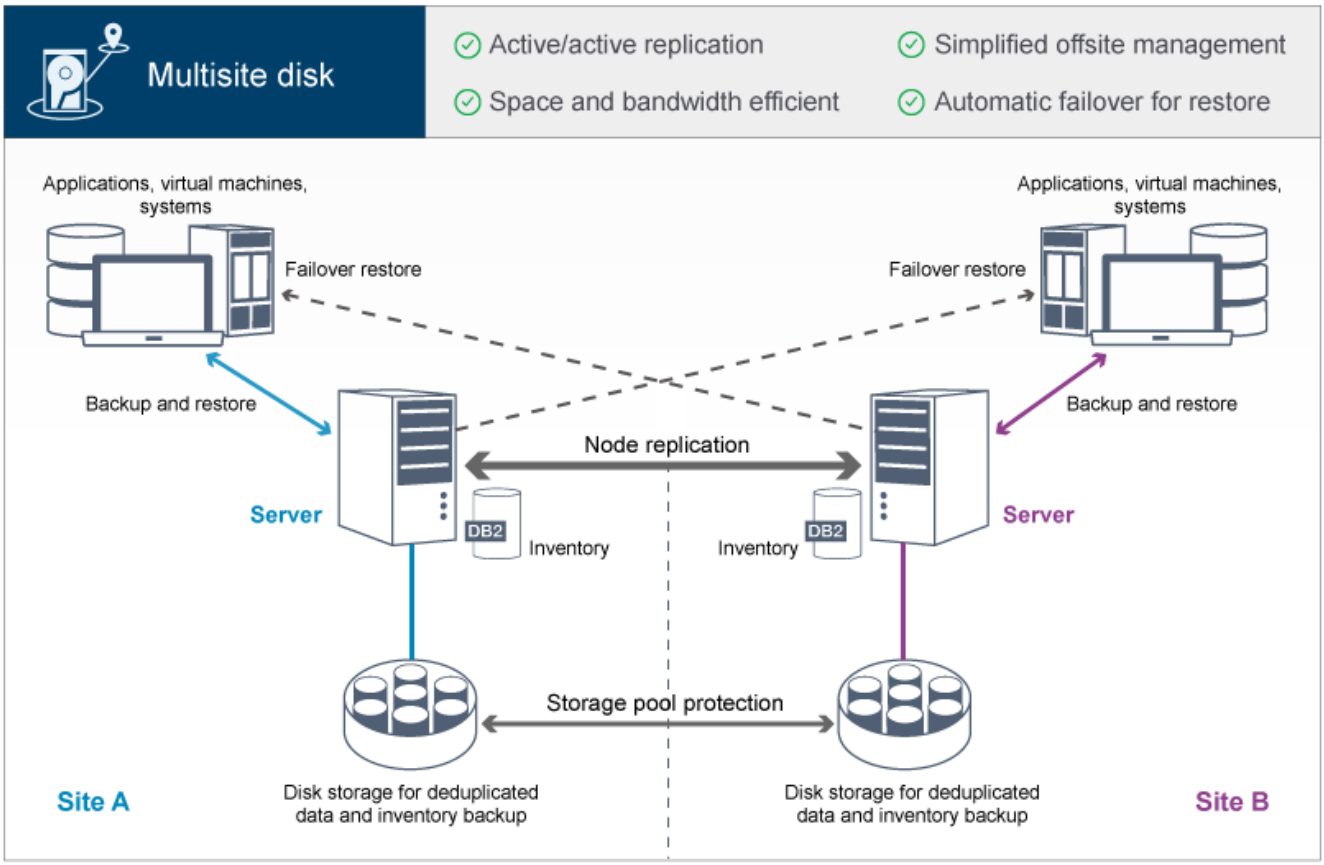
Configure servers by using the Operations Center and administrative commands
: You can configure a range of storage systems and the server software for your solution. Configuration tasks are completed by using wizards and options in the Operations Center and IBM Spectrum Protect™ commands. For information about getting started, see the Planning roadmap.

Configure the servers by using automated scripts
: For detailed guidance on configuration with specific IBM® Storwize® storage systems, and by using automated scripts to configure each server, see the IBM Spectrum Protect blueprints. The documentation and scripts are available on IBM developerWorks® at IBM Spectrum Protect Blueprints.

  The blueprint documentation does not include steps for installing and configuring the Operations Center, or setting up secure communications by using Transport Security Layer (TLS). Replication is configured by using commands after each server is set up. An option for using Elastic Storage Server, based on IBM Spectrum Scale™ technology, is included.

Planning roadmap

Plan for a multisite disk solution by reviewing the architecture layout in the following figure and then completing the roadmap tasks that follow the diagram.
Figure 1. Multisite disk solution



The following steps are required to plan properly for a multisite disk environment.

1. Select your system size.

2. Plan for the sites.
3. Meet system requirements for hardware and software.
4. Record values for your system configuration in the planning worksheets.
5. Plan for storage.
6. Plan for security.
    a. Plan for administrator roles.
    b. Plan for secure communications.
    c. Plan for storage of encrypted data.
    d. Plan for firewall access.

Selecting a system size

Select the size of the IBM Spectrum Protect™ server based on the amount of data that you manage and the systems to be protected.

About this task

You can use the information in the table to determine the size of the server that is required, based on the amount of data that you manage.

The following table describes the volume of data that a server manages. This amount includes all versions. The daily amount of data is how much new data you back up each day. Both the total managed data and daily amount of new data are measured as the size before any data reduction.

Table 1. Determining the size of the server

Total managed data	Daily amount of new data to back up	Required server size
48 TB - 192 TB	Up to 10 TB per day	Small
200 TB - 800 TB	10 - 20 TB per day	Medium
1000 TB - 4000 TB	20 - 100 TB per day	Large

The daily backup values in the table are based on test results with 128 MB sized objects, which are used by IBM Spectrum Protect for Virtual Environments. Workloads that consist of objects that are smaller than 128 KB might not be able to achieve these daily limits.

Planning the sites

Review use cases and evaluate the factors to provide the most efficient data protection for the multisite disk solution for IBM Spectrum Protect™.

Use cases

The multisite disk solution creates at least one copy of backed-up data. If the IBM Spectrum Protect servers are at separate locations, the backed-up replica is maintained offsite. Although your company might benefit from a multisite disk solution for various reasons, the most common reasons to use a multisite disk solution include the following replication scenarios:

Replication from the primary site to the disaster recovery site

In this scenario, data that is backed up from the primary site, Site A, is replicated to a server at the secondary, disaster recovery site, Site B. If a disaster occurs at Site A, such as failure of the server, you can use the server at Site B to recover systems. Alternatively, you can use the server at Site A to restore primary storage pool data at Site B, such as after a disk storage failure at Site B.

Mutual replication at two active sites

In this scenario, local data at each site is backed up by the servers at both Site A and Site B. Data that is backed up from Site A is replicated to Site B, and backed-up data from Site B is replicated to Site A. If data that was backed up is lost at Site A, you can use the server at Site B to recover storage pool data to the server at Site A. If Site A is no longer available, you can recover the replicated data for Site A to a new system at Site B. You must size the server resources to ensure that either server has sufficient capacity to back up and restore all client nodes as part of your disaster recovery plan.

Protect remote servers to the primary site

In this scenario, you configure remote servers that are relatively small to replicate data that is backed up to a larger server at the primary site. If bandwidth is limited, it might not be practical to restore systems to the remote sites. In this case, you might want to recover systems at the primary site before you replicate the backed-up data to the remote servers.

Factors to evaluate

Before you implement a multisite disk solution, evaluate the following factors:

Network bandwidth

The network must have sufficient bandwidth for the expected data transfers between nodes, for replication, and for the cross-site restore operations that are required for disaster recovery. Before you proceed with testing replication throughput, ensure that your network can handle the replication traffic. Calculate the required network bandwidth for the steady-state requirement by applying the guidelines in Estimating network bandwidth required for replication (V7.1.1).

The network connection is often a shared resource. Plan the time of day to schedule node replication to run to avoid a conflict with other resource users. Also, network controls might limit activity to only a portion of the bandwidth. There are no controls in IBM Spectrum Protect to restrict network usage.

Resources for the initial replication

To set up the data protection solution across two sites, you must replicate data initially from Site A to the target server at Site B. To ensure that the initial replication is successful, you must determine whether you have the network bandwidth, processor resources, and time available to replicate the data. You might have to plan for replicating the initial full backups across several days. If you cannot extend the schedule for the initial backups, you can replicate data from Site A to Site B without using the network. For example, you can export and import the backed-up data by using media or you can temporarily locate the source and target servers on the same site.

Daily data ingestion

For the multisite disk solution, the daily data ingestion and total data retention must be within the capacity of the configurations. For example, a large configuration has a data ingestion capacity of up to 100 TB per day, including node replication. In cases where the backup requirements exceed the capacity of a single server, you can configure a solution that uses multiple servers to achieve the required capacity.

Server configuration

The server configuration must meet or exceed the requirements for the multisite disk solution.

Single replica of backed-up data

The multisite disk solution is most efficient when a single, offsite copy of the backed-up data meets your data protection and risk mitigation requirements. In this case, the single copy of the data is maintained off-site at the location of a replication server.

System requirements for a multisite disk solution

System requirements for a multisite disk solution

After you select the IBM Spectrum Protect™ solution that best fits your data protection requirements, review the system requirements to plan for implementation of the data protection solution.

Ensure that your system meets the hardware and software prerequisites for the size of server that you plan to use.

- Hardware requirements
  Hardware requirements for your IBM Spectrum Protect solution are based on system size. Choose equivalent or better components than those items that are listed to ensure optimum performance for your environment.
- Software requirements
  Documentation for the IBM Spectrum Protect multisite disk solution includes installation and configuration tasks for the following operating systems. You must meet the minimum software requirements that are listed.

Related information:
IBM Spectrum Protect Supported Operating Systems

Hardware requirements

Hardware requirements for your IBM Spectrum Protect™ solution are based on system size. Choose equivalent or better components than those items that are listed to ensure optimum performance for your environment.

For a definition of system sizes, see Selecting a system size.

The following table includes minimum hardware requirements for the server and storage, based on the size of the server that you plan to build. If you are using local partitions (LPARs) or work partitions (WPARs), adjust the network requirements to take account of the partition sizes.

Hardware component	Small system	Medium system	Large system
Server processor	AIX 6 processor cores, 3.42 GHz or faster Linux Windows 12 processor cores, 1.9 GHz or faster	AIX 8 processor cores, 3.42 GHz or faster Linux Windows 16 processor cores, 2.0 GHz or faster	AIX 20 processor cores, 3.42 GHz Linux Windows 32 processor cores, 2.0 GHz or faster
Server memory	64 GB RAM	128 GB RAM	192 GB RAM
Network	• 10 GB Ethernet (1 port) • 8 GB Fibre Channel adapter (2 ports)	• 10 GB Ethernet (2 ports) • 8 GB Fibre Channel adapter (2 ports)	• 10 GB Ethernet (4 ports) • 8 GB Fibre Channel adapter (4 ports)
Storage	• 1.3 TB inventory, plus space for Operations Center records • 46 TB deduplicated directory-container storage pool	• 2 TB inventory, plus space for Operations Center records • 200 TB deduplicated directory-container storage pool	• 6 TB inventory, plus space for Operations Center records • 1000 TB deduplicated directory-container storage pool

Estimating database space requirements for the Operations Center

Hardware requirements for the Operations Center are included in the preceding table, except for the database and archive log space (inventory) that the Operations Center uses to hold records for managed clients.

If you do not plan to install the Operations Center on the same system as the server, you can estimate system requirements separately. To calculate system requirements for the Operations Center, see the system requirements calculator in technote 1641684.

Managing the Operations Center on the server is a workload that requires extra space for database operations. The amount of space depends on the number of clients that are monitored on a server. Review the following guidelines to estimate how much space your server requires.

Database space

The Operations Center uses approximately 1.2 GB of database space for every 1000 clients that are monitored on a server. For example, consider a hub server with 2000 clients that also manages three spoke servers, each with 1500 clients. This configuration has a total of 6500 clients across the four servers and requires approximately 8.4 GB of database space. This value is calculated by rounding the 6500 clients up to the next closest 1000, which is 7000:

```
7 x 1.2 GB=8.4 GB
```

Archive log space

The Operations Center uses approximately 8 GB of archive log space every 24 hours, for every 1000 clients. In the example of 6500 clients across the hub server and the spoke servers, 56 GB of archive log space is used over a 24-hour period for the hub server.

For each spoke server in the example, the archive log space that is used over 24 hours is approximately 16 GB. These estimates are based on the default status collection interval of 5 minutes. If you reduce the collection interval from once every 5 minutes to once every 3 minutes, the space requirements increase. The following examples show the approximate increase in the log space requirement with a collection interval of once every 3 minutes:

- Hub server: 56 GB to approximately 94 GB
- Each spoke server: 16 GB to approximately 28 GB

Increase the archive log space so that you have sufficient space available to support the Operations Center, without affecting the existing server operations.

Hardware requirements for the second server

If you are planning to set up your sites so that everything at the first site is replicated to the second site, hardware requirements are identical at both sites. If you want to only replicate a subset of data to your second site, storage and network requirements might be reduced.

Software requirements

Documentation for the IBM Spectrum Protect™ multisite disk solution includes installation and configuration tasks for the following operating systems. You must meet the minimum software requirements that are listed.

For information about software requirements for IBM® lin_tape device drivers, refer to the IBM Tape Device Drivers Installation and User's Guide.

AIX systems

Type of software	Minimum software requirements
Operating system	IBM AIX® 7.1 For more information about operating system requirements, see AIX: Minimum system requirements for AIX systems.
Gunzip utility	The gunzip utility must be available on your system before you install or upgrade the IBM Spectrum Protect server. Ensure that the gunzip utility is installed and the path to it is set in the PATH environment variable.
File system type	JFS2 file systems AIX systems can cache a large amount of file system data, which can reduce memory that is required for server and IBM DB2® processes. To avoid paging with the AIX server, use the rbrw mount option for the JFS2 file system. Less memory is used for the file system cache and more is available for IBM Spectrum Protect. Do not use the file system mount options, Concurrent I/O (CIO), and Direct I/O (DIO), for file systems that contain the IBM Spectrum Protect database, logs, or storage pool volumes. These options can cause performance degradation of many server operations. IBM Spectrum Protect and DB2 can still use DIO where it is beneficial to do so, but IBM Spectrum Protect does not require the mount options to selectively take advantage of these techniques.
Other software	Korn Shell (ksh)

Linux systems

Type of software	Minimum software requirements
Operating system	Red Hat Enterprise Linux 7 (x86_64)
Libraries	GNU C libraries, Version 2.3.3-98.38 or later that is installed on the IBM Spectrum Protect system. Red Hat Enterprise Linux Servers: • libaio • libstdc++.so.6 (32-bit and 64-bit packages are required) • numactl.x86_64

Type of software	Minimum software requirements
File system type	Format database-related file systems with ext3 or ext4. For storage pool-related file systems, use XFS.
Other software	Korn Shell (ksh)

Windows systems

Type of software	Minimum software requirements
Operating system	Microsoft Windows Server 2012 R2 (64-bit) or Windows Server 2016
File system type	NTFS
Other software	Windows 2012 R2 or Windows 2016 with .NET Framework 3.5 is installed and enabled. The following User Account Control policies must be disabled: • User Account Control: Admin Approval Mode for the Built-in Administrator account • User Account Control: Run all administrators in Admin Approval Mode

Setting AIX network options

Planning worksheets

Use the planning worksheets to record values that you use to set up your system and configure the IBM Spectrum Protect™ server. Use the best practice default values that are listed in the worksheets.

Each worksheet helps you prepare for different parts of the system configuration by using best practice values:

Server system preconfiguration
: Use the preconfiguration worksheets to plan for the file systems and directories that you create when you configure file systems for IBM Spectrum Protect during system setup. All directories that you create for the server must be empty.

Server configuration
: Use the configuration worksheets when you configure the server. Default values are suggested for most items, except where noted.

AIX®

Table 1. Worksheet for preconfiguration of an AIX server system

Item	Default value	Your value	Minimum directory size	Notes
TCP/IP port address for communications with the server	1500		Not applicable	Ensure that this port is available when you install and configure the operating system The port number can be a number in the range 1024 - 32767.
Directory for the server instance	/home/tsminst1/tsminst1		50 GB	If you change the value for the server instance directory from the default, also modify the DB2® instance owner value in Table 2.

Item	Default value	Your value	Minimum directory size	Notes
Directory for server installation	/		Available space that is required for the directory: 5 GB	
Directory for server installation	/usr		Available space that is required for the directory: 5 GB	
Directory for server installation	/var		Available space that is required for the directory: 5 GB	
Directory for server installation	/tmp		Available space that is required for the directory: 5 GB	
Directory for server installation	/opt		Available space that is required for the directory: 10 GB	
Directory for the active log	/tsminst1/TSMalog		• Small and medium: 140 GB • Large: 300 GB	When you create the active log during the initial configuration of the server, set the size to 128 GB.
Directory for the archive log	/tsminst1/TSMarchlog		• Small: 1 TB • Medium: 3 TB • Large: 4 TB	
Directories for the database	/tsminst1/TSMdbspace00 /tsminst1/TSMdbspace01 /tsminst1/TSMdbspace02 /tsminst1/TSMdbspace03 ...		Minimum total space for all directories: • Small: At least 1 TB • Medium: At least 2 TB • Large: At least 4 TB	Create a minimum number of file systems for the database, depending on the size of your system: • Small: At least 4 file systems • Medium: At least 4 file systems • Large: At least 8 file systems
Directories for storage	/tsminst1/TSMfile00 /tsminst1/TSMfile01 /tsminst1/TSMfile02 /tsminst1/TSMfile03 ...		Minimum total space for all directories: • Small: At least 38 TB • Medium: At least 180 TB • Large: At least 500 TB	Create a minimum number of file systems for storage, depending on the size of your system: • Small: At least 10 file systems • Medium: At least 20 file systems • Large: At least 40 file systems

Item	Default value	Your value	Minimum directory size	Notes
Directories for database backup	/tsminst1/TSMbkup00 /tsminst1/TSMbkup01 /tsminst1/TSMbkup02 /tsminst1/TSMbkup03		Minimum total space for all directories: • Small: At least 3 TB • Medium: At least 10 TB • Large: At least 16 TB	Create a minimum number of file systems for backing up the database, depending on the size of your system: • Small: At least 2 file systems • Medium: At least 4 file systems • Large: At least 4 file systems, but preferably 6 The first database backup directory is also used for the archive log failover directory and a second copy of the volume history and device configuration files.

Table 2. Worksheet for IBM Spectrum Protect configuration

Item	Default value	Your value	Notes
DB2 instance owner	tsminst1		If you changed the value for the server instance directory in Table 1 from the default, also modify the value for the DB2 instance owner.
DB2 instance owner password	passw0rd		Select a different value for the instance owner password than the default. Ensure that you record this value in a secure location.
Primary group for the DB2 instance owner	tsmsrvrs		
Server name	The default value for the server name is the system host name.		
Server password	passw0rd		Select a different value for the server password than the default. Ensure that you record this value in a secure location.
Administrator ID: user ID for the server instance	admin		
Administrator ID password	passw0rd		Select a different value for the administrator password than the default. Ensure that you record this value in a secure location.

Item	Default value	Your value	Notes
Schedule start time	22:00		The default schedule start time begins the client workload phase, which is predominantly the client backup and archive activities. During the client workload phase, server resources support client operations. Normally, these operations are completed during the nightly schedule window. Schedules for server maintenance operations are defined to begin 10 hours after the start of the client backup window.

Linux

Table 3. Worksheet for preconfiguration of a Linux server system

Item	Default value	Your value	Minimum directory size	Notes
TCP/IP port address for communications with the server	1500		Not applicable	Ensure that this port is available when you install and configure the operating system The port number can be a number in the range 1024 - 32767.
Directory for the server instance	/home/tsminst1/tsminst1		25 GB	If you change the value for the server instance directory from the default, also modify the DB2 instance owner value in Table 4.
Directory for the active log	/tsminst1/TSMalog		• Small and medium: 140 GB • Large: 300 GB	
Directory for the archive log	/tsminst1/TSMarchlog		• Small: 1 TB • Medium: 3 TB • Large: 4 TB	

Item	Default value	Your value	Minimum directory size	Notes
Directories for the database	/tsminst1/TSMdbspace00 /tsminst1/TSMdbspace01 /tsminst1/TSMdbspace02 /tsminst1/TSMdbspace03 ...		Minimum total space for all directories: • Small: At least 1 TB • Medium: At least 2 TB • Large: At least 4 TB	Create a minimum number of file systems for the database, depending on the size of your system: • Small: At least 4 file systems • Medium: At least 4 file systems • Large: At least 8 file systems
Directories for storage	/tsminst1/TSMfile00 /tsminst1/TSMfile01 /tsminst1/TSMfile02 /tsminst1/TSMfile03 ...		Minimum total space for all directories: • Small: At least 38 TB • Medium: At least 180 TB • Large: At least 500 TB	Create a minimum number of file systems for storage, depending on the size of your system: • Small: At least 10 file systems • Medium: At least 20 file systems • Large: At least 40 file systems
Directories for database backup	/tsminst1/TSMbkup00 /tsminst1/TSMbkup01 /tsminst1/TSMbkup02 /tsminst1/TSMbkup03		Minimum total space for all directories: • Small: At least 3 TB • Medium: At least 10 TB • Large: At least 16 TB	Create a minimum number of file systems for backing up the database, depending on the size of your system: • Small: At least 2 file systems • Medium: At least 4 file systems • Large: At least 4 file systems, but preferably 6 The first database backup directory is also used for the archive log failover directory and a second copy of the volume history and device configuration files.

Table 4. Worksheet for IBM Spectrum Protect configuration

Item	Default value	Your value	Notes

Item	Default value	Your value	Notes
DB2 instance owner	tsminst1		If you changed the value for the server instance directory in Table 3 from the default, also modify the value for the DB2 instance owner.
DB2 instance owner password	passw0rd		Select a different value for the instance owner password than the default. Ensure that you record this value in a secure location.
Primary group for the DB2 instance owner	tsmsrvrs		
Server name	The default value for the server name is the system host name.		
Server password	passw0rd		Select a different value for the server password than the default. Ensure that you record this value in a secure location.
Administrator ID: user ID for the server instance	admin		
Administrator ID password	passw0rd		Select a different value for the administrator password than the default. Ensure that you record this value in a secure location.
Schedule start time	22:00		The default schedule start time begins the client workload phase, which is predominantly the client backup and archive activities. During the client workload phase, server resources support client operations. Normally, these operations are completed during the nightly schedule window. Schedules for server maintenance operations are defined to begin 10 hours after the start of the client backup window.

Windows

Because many volumes are created for the server, configure the server by using the Windows feature of mapping disk volumes to directories rather than to drive letters.

For example, C:\tsminst1\TSMdbpsace00 is a mount point to a volume with its own space. The volume is mapped to a directory under the C: drive, but does not take up space from the C: drive. The exception is the server instance directory, C:\tsminst1, which can be a mount point or a regular directory.

Table 5. Worksheet for preconfiguration of a Windows server system

Item	Default value	Your value	Minimum directory size	Notes

Item	Default value	Your value	Minimum directory size	Notes
TCP/IP port address for communications with the server	1500		Not applicable	Ensure that this port is available when you install and configure the operating system The port number can be a number in the range 1024 - 32767.
Directory for the server instance	C:\tsminst1		25 GB	If you change the value for the server instance directory from the default, also modify the DB2 instance owner value in Table 6.
Directory for the active log	C:\tsminst1\TSMalog		• Small and medium: 140 GB • Large: 300 GB	
Directory for the archive log	C:\tsminst1\TSMarchlog		• Small: 1 TB • Medium: 3 TB • Large: 4 TB	
Directories for the database	C:\tsminst1\TSMdbspace00 C:\tsminst1\TSMdbspace01 C:\tsminst1\TSMdbspace02 C:\tsminst1\TSMdbspace03 ...		Minimum total space for all directories: • Small: At least 1 TB • Medium: At least 2 TB • Large: At least 4 TB	Create a minimum number of file systems for the database, depending on the size of your system: • Small: At least 4 file systems • Medium: At least 4 file systems • Large: At least 8 file systems
Directories for storage	C:\tsminst1\TSMfile00 C:\tsminst1\TSMfile01 C:\tsminst1\TSMfile02 C:\tsminst1\TSMfile03 ...		Minimum total space for all directories: • Small: At least 38 TB • Medium: At least 180 TB • Large: At least 500 TB	Create a minimum number of file systems for storage, depending on the size of your system: • Small: At least 10 file systems • Medium: At least 20 file systems • Large: At least 40 file systems

Item	Default value	Your value	Minimum directory size	Notes
Directories for database backup	C:\tsminst1\TSMbkup00 C:\tsminst1\TSMbkup01 C:\tsminst1\TSMbkup02 C:\tsminst1\TSMbkup03		Minimum total space for all directories: • Small: At least 3 TB • Medium: At least 10 TB • Large: At least 16 TB	Create a minimum number of file systems for backing up the database, depending on the size of your system: • Small: At least 2 file systems • Medium: At least 4 file systems • Large: At least 4 file systems, but preferably 6 The first database backup directory is also used for the archive log failover directory and a second copy of the volume history and device configuration files.

Table 6. Worksheet for IBM Spectrum Protect configuration

Item	Default value	Your value	Notes
DB2 instance owner	tsminst1		If you changed the value for the server instance directory in Table 5 from the default, also modify the value for the DB2 instance owner.
DB2 instance owner password	pAssW0rd		Select a different value for the instance owner password than the default. Ensure that you record this value in a secure location.
Server name	The default value for the server name is the system host name.		
Server password	passw0rd		Select a different value for the server password than the default. Ensure that you record this value in a secure location.
Administrator ID: user ID for the server instance	admin		
Administrator ID password	passw0rd		Select a different value for the administrator password than the default. Ensure that you record this value in a secure location.

Item	Default value	Your value	Notes
Schedule start time	22:00		The default schedule start time begins the client workload phase, which is predominantly the client backup and archive activities. During the client workload phase, server resources support client operations. Normally, these operations are completed during the nightly schedule window. Schedules for server maintenance operations are defined to begin 10 hours after the start of the client backup window.

Planning for storage

Choose the most effective storage technology for IBM Spectrum Protect™ components to ensure efficient server performance and operations.

Storage hardware devices have different capacity and performance characteristics, which determine how they can be used effectively with IBM Spectrum Protect. For general guidance on selecting the appropriate storage hardware and set up for your solution, review the following guidelines.

Database and active log

- Use a fast disk for the IBM Spectrum Protect database and active log, for example with the following characteristics:
  - High performance, 15k rpm disk with Fibre Channel or serial-attached SCSI (SAS) interface
  - Solid-state disk (SSD)
- Isolate the active log from the database unless you use SSD or flash hardware
- When you create arrays for the database, use RAID level 5

Storage pool

- You can use less expensive and slower disks for the storage pool
- The storage pool can share disks for the archive log and database backup storage
- Use RAID level 6 for storage pool arrays to add protection against double drive failures when you use large disk types

- Planning the storage arrays
  Prepare for disk storage configuration by planning for RAID arrays and volumes, according to the size of your IBM Spectrum Protect system.

Related reference:
Storage system requirements and reducing the risk of data corruption

Planning for security

Plan to protect the security of systems in the IBM Spectrum Protect™ solution with access and authentication controls, and consider encrypting data and password transmission.

- Planning for administrator roles
  Define the authority levels that you want to assign to administrators who have access to the IBM Spectrum Protect solution.
- Planning for secure communications
  Plan for protecting communications among the IBM Spectrum Protect solution components.
- Planning for storage of encrypted data
  Determine whether your company requires stored data to be encrypted, and choose the option that best suits your needs.

- Planning firewall access
  Determine the firewalls that are set and the ports that must be open for the IBM Spectrum Protect solution to work.

Planning for administrator roles

Define the authority levels that you want to assign to administrators who have access to the IBM Spectrum Protect™ solution.

You can assign one of the following levels of authority to administrators:

System
: Administrators with system authority have the highest level of authority. Administrators with this level of authority can complete any task. They can manage all policy domains and storage pools, and grant authority to other administrators.

Policy
: Administrators who have policy authority can manage all of the tasks that are related to policy management. This privilege can be unrestricted, or can be restricted to specific policy domains.

Storage
: Administrators who have storage authority can allocate and control storage resources for the server.

Operator
: Administrators who have operator authority can control the immediate operation of the server and the availability of storage media such as tape libraries and drives.

The scenarios in Table 1 provide examples about why you might want to assign varying levels of authority so that administrators can perform tasks:

Table 1. Scenarios for administrator roles

Scenario	Type of administrator ID to set up
An administrator at a small company manages the server and is responsible for all server activities.	• System authority: 1 administrator ID
An administrator for multiple servers also manages the overall system. Several other administrators manage their own storage pools.	• System authority on all servers: 1 administrator ID for the overall system administrator • Storage authority for designated storage pools: 1 administrator ID for each of the other administrators
An administrator manages 2 servers. Another person helps with the administration tasks. Two assistants are responsible for helping to ensure that important systems are backed up. Each assistant is responsible for monitoring the scheduled backups on one of the IBM Spectrum Protect servers.	• System authority on both servers: 2 administrator IDs • Operator authority: 2 administrator IDs for the assistants with access to the server that each person is responsible for

Planning for secure communications

Plan for protecting communications among the IBM Spectrum Protect™ solution components.

Determine the level of protection that is required for your data, based on regulations and business requirements under which your company operates.

If your business requires a high level of security for passwords and data transmission, plan on implementing secure communication with Transport Layer Security (TLS) or Secure Sockets Layer (SSL) protocols.

TLS and SSL provide secure communications between the server and client, but can affect system performance. To improve system performance, use TLS for authentication without encrypting object data. To specify whether the server uses TLS 1.2 for the entire session or only for authentication, see the SSL client option for client-to-server communication, and the UPDATE SERVER=SSL parameter for server-to-server communication. Beginning in V8.1.2, TLS is used for authentication by default. If you decide to use TLS to encrypt entire sessions, use the protocol only for sessions where it is necessary and add processor resources on the server to manage the increase in network traffic. You can also try other options. For example, some networking devices such as routers and switches provide the TLS or SSL function.

You can use TLS and SSL to protect some or all of the different possible communication paths, for example:

- Operations Center: browser to hub; hub to spoke
- Client to server

- Server to server: node replication

Related tasks:
Securing communications

Planning for storage of encrypted data

Determine whether your company requires stored data to be encrypted, and choose the option that best suits your needs.

If your company requires the data in storage pools to be encrypted, then you have the option of using IBM Spectrum Protect™ encryption, or an external device such as tape for encryption.

If you choose IBM Spectrum Protect to encrypt the data, extra computing resources are required at the client that might affect the performance of backup and restore processes.

Related information:
technote 1963635

Planning firewall access

Determine the firewalls that are set and the ports that must be open for the IBM Spectrum Protect™ solution to work.

Table 1 describes the ports that are used by the server, client, and Operations Center.

Table 1. Ports that are used by the server, client, and Operations Center

Item	Default	Direction	Description
Base port (TCPPORT)	1500	Outbound/inbound	Each server instance requires a unique port. You can specify an alternative port number instead of using the default. The TCPPORT option listens for both TCP/IP and SSL-enabled sessions from the client. For administrative client traffic, you can use the TCPADMINPORT and ADMINONCLIENTPORT options to set port values.
SSL-only port (SSLTCPPORT)	No default	Outbound/inbound	This port is used if you want to restrict communication on the port to SSL-enabled sessions only. To support both SSL and non-SSL communications, use the TCPPORT or TCPADMINPORT options.
SMB	45	Inbound/outbound	This port is used by configuration wizards that communicate by using native protocols with multiple hosts.
SSH	22	Inbound/outbound	This port is used by configuration wizards that communicate by using native protocols with multiple hosts.
SMTP	25	Outbound	This port is used to send email alerts from the server.
NDMP	No default	Inbound/outbound	The server must be able to open an outbound NDMP control port connection to the NAS device. The outbound control port is the Low-Level Address in the data mover definition for the NAS device. During an NDMP filer-to-server restore, the server must be able to open an outbound NDMP data connection to the NAS device. The data connection port that is used during a restore can be configured on the NAS device. During NDMP filer-to-server backups, the NAS device must be able to open outbound data connections to the server and the server must be able to accept inbound NDMP data connections. You can use the server option NDMPPORTRANGE to restrict the set of ports available for use as NDMP data connections. You can configure a firewall for connections to these ports.

Item	Default	Direction	Description
Replication	No default	Outbound/inbound	The port and protocol for the outbound port for replication are set by the DEFINE SERVER command that is used to set up replication. The inbound ports for replication are the TCP ports and SSL ports that the source server names in the DEFINE SERVER command.
Client schedule port	Client port: 1501	Outbound	The client listens on the port that is named and communicates the port number to the server. The server contacts the client if server prompted scheduling is used. You can specify an alternative port number in the client options file.
Long running sessions	KEEPALIVE setting: YES	Outbound	When the KEEPALIVE option is enabled, keepalive packets are sent during client-server sessions to prevent the firewall software from closing long-running, inactive connections.
Operations Center	HTTPS: 11090	Inbound	These ports are used for the Operations Center web browser. You can specify an alternative port number.
Client management service port	Client port: 9028	Inbound	The client management service port must be accessible from the Operations Center. Ensure that firewalls cannot prevent connections. The client management service uses the TCP port of the server for the client node for authentication by using an administrative session.

Multisite disk implementation of a data protection solution

The multisite disk solution is configured at two sites and uses data deduplication and replication.

Implementation roadmap

The following steps are required to set up a multisite disk environment.

1. Set up the system.
    a. Configure the storage hardware and set up storage arrays for your environment size.
    b. Install the server operating system.
    c. Configure multipath I/O.
    d. Create the user ID for the server instance.
    e. Prepare file systems for IBM Spectrum Protect.
2. Install the server and Operations Center.
3. Configure the server and Operations Center.
    a. Complete the initial configuration of the server.
    b. Set server options.
    c. Configure Secure Sockets Layer for the server and client.
    d. Configure the Operations Center.
    e. Register your IBM Spectrum Protect license.
    f. Configure data deduplication.
    g. Define data retention rules for your business.
    h. Define server maintenance schedules.
    i. Define client schedules.
4. Install and configure clients.
    a. Register and assign clients to schedules.
    b. Install and verify the client management service.
    c. Configure the Operations Center to use the client management service.
5. Configure the second server.
    a. Confgure for SSL communication between the hub and spoke server.
    b. Add the second server as a spoke.
    c. Enable replication.
6. Complete the implementation.

Setting up the system

To set up the system, you must first configure your disk storage hardware and the server system for IBM Spectrum Protect™.

- Configuring the storage hardware
  To configure your storage hardware, review general guidance for disk systems and IBM Spectrum Protect.
- Installing the server operating system
  Install the operating system on the server system and ensure that IBM Spectrum Protect server requirements are met. Adjust operating system settings as directed.
- Configuring multipath I/O
  You can enable and configure multipathing for disk storage. Use the documentation that is provided with your hardware for detailed instructions.
- Creating the user ID for the server
  Create the user ID that owns the IBM Spectrum Protect server instance. You specify this user ID when you create the server instance during initial configuration of the server.
- Preparing file systems for the server
  You must complete file system configuration for the disk storage to be used by the server.

Configuring the storage hardware

To configure your storage hardware, review general guidance for disk systems and IBM Spectrum Protect™.

Procedure

1. Provide a connection between the server and the storage devices by following these guidelines:
   - Use a switch or direct connection for Fibre Channel connections.
   - Consider the number of ports that are connected and account for the amount of bandwidth that is needed.
   - Consider the number of ports on the server and the number of host ports on the disk system that are connected.
2. Verify that device drivers and firmware for the server system, adapters, and operating system are current and at the recommended levels.
3. Configure storage arrays. Make sure that you planned properly to ensure optimal performance. See Planning for storage for more information.
4. Ensure that the server system has access to disk volumes that are created. Complete the following steps:
   a. If the system is connected to a Fibre Channel switch, zone the server to see the disks.
   b. Map all of the volumes to tell the disk system that this specific server is allowed to see each disk.

Related tasks:
Configuring storage

Installing the server operating system

Install the operating system on the server system and ensure that IBM Spectrum Protect™ server requirements are met. Adjust operating system settings as directed.

- Installing on AIX systems
  Complete the following steps to install AIX® on the server system.
- Installing on Linux systems
  Complete the following steps to install Linux x86_64 on the server system.
- Installing on Windows systems
  Install Microsoft Windows Server 2012 Standard Edition on the server system and prepare the system for installation and configuration of the IBM Spectrum Protect server.

Installing on AIX systems

Complete the following steps to install AIX® on the server system.

Procedure

1. Install AIX Version 7.1, TL4, SP2, or later according to the manufacturer instructions.
2. Configure your TCP/IP settings according to the operating system installation instructions.
3. Open the /etc/hosts file and complete the following actions:
   - Update the file to include the IP address and host name for the server. For example:

```
192.0.2.7  server.yourdomain.com  server
```

- Verify that the file contains an entry for localhost with an address of 127.0.0.1. For example:

```
127.0.0.1  localhost
```

4. Enable AIX I/O completion ports by issuing the following command:

```
chdev -l iocp0 -P
```

Server performance can be affected by the Olson time zone definition.

5. To optimize performance, change your system time zone format from Olson to POSIX. Use the following command format to update the time zone setting:

```
chtz=local_timezone,date/time,date/time
```

For example, if you lived in Tucson, Arizona, where Mountain Standard Time is used, you would issue the following command to change to the POSIX format:

```
chtz MST7MDT,M3.2.0/2:00:00,M11.1.0/2:00:00
```

6. Add an entry in the .profile of the instance user so that the following environment is set:

```
export MALLOCOPTIONS=multiheap:16
```

7. Set the system to create full application core files. Issue the following command:

```
chdev -l sys0 -a fullcore=true -P
```

8. For communications with the server and Operations Center, make sure that the following ports are open on any firewalls that might exist:
   - For communications with the server, open port 1500.
   - For secure communications with the Operations Center, open port 11090 on the hub server.

   If you are not using the default port values, make sure that the ports that you are using are open.

9. Enable TCP high-performance enhancements. Issue the following command:

```
no -p -o rfc1323=1
```

10. For optimal throughput and reliability, bond four 10 Gb Ethernet ports together. Use the System Management Interface Tool (SMIT) to bond the ports together by using Etherchannel. The following settings were used during testing:

```
mode            8023ad
auto_recovery   yes             Enable automatic recovery after failover
backup_adapter  NONE            Adapter used when whole channel fails
hash_mode       src_dst_port    Determines how outgoing adapter is chosen
interval        long            Determines interval value for IEEE
                                802.3ad mode
mode            8023ad          EtherChannel mode of operation
netaddr         0               Address to ping
noloss_failover yes             Enable lossless failover after ping
                                failure
num_retries     3               Times to retry ping before failing
retry_time      1               Wait time (in seconds) between pings
use_alt_addr    no              Enable Alternate EtherChannel Address
use_jumbo_frame no              Enable Gigabit Ethernet Jumbo Frames
```

11. Verify that user process resource limits, also known as *ulimits*, are set according to guidelines in Table 1. If ulimit values are not set correctly, you might experience server instability or a failure of the server to respond.

Table 1. User limits (ulimit) values

User limit type	Setting	Value	Command to query value
Maximum size of core files created	core	Unlimited	`ulimit -Hc`
Maximum size of a data segment for a process	data	Unlimited	`ulimit -Hd`
Maximum file size	fsize	Unlimited	`ulimit -Hf`

User limit type	Setting	Value	Command to query value
Maximum number of open files	nofile	65536	`ulimit -Hn`
Maximum amount of processor time in seconds	cpu	Unlimited	`ulimit -Ht`
Maximum number of user processes	nproc	16384	`ulimit -Hu`

If you need to modify any user limit values, follow the instructions in the documentation for your operating system.

Installing on Linux systems

Complete the following steps to install Linux x86_64 on the server system.

Before you begin

The operating system will be installed on the internal hard disks. Configure the internal hard disks by using a hardware RAID 1 array. For example, if you are configuring a small system, the two 300 GB internal disks are mirrored in RAID 1 so that a single 300 GB disk appears available to the operating system installer.

Procedure

1. Install Red Hat Enterprise Linux Version 7.1 or later, according to the manufacturer instructions. Obtain a bootable DVD that contains Red Hat Enterprise Linux Version 7.1 and start your system from this DVD. See the following guidance for installation options. If an item is not mentioned in the following list, leave the default selection.
   a. After you start the DVD, choose Install or upgrade an existing system from the menu.
   b. On the Welcome screen, select Test this media & install Red Hat Enterprise Linux 7.1.
   c. Select your language and keyboard preferences.
   d. Select your location to set the correct time zone.
   e. Select Software Selection and then on the next screen, select Server with GUI.
   f. From the installation summary page, click Installation Destination and verify the following items:
      - The local 300 GB disk is selected as the installation target.
      - Under Other Storage Options, Automatically configure partitioning is selected.

      Click Done.
   g. Click Begin Installation. After the installation starts, set the root password for your root user account.

   After the installation is completed, restart the system and log in as the root user. Issue the df command to verify your basic partitioning. For example, on a test system, the initial partitioning produced the following result:

```
[root@tvapp02]# df -h
Filesystem              Size  Used Avail Use% Mounted on
/dev/mapper/rhel-root    50G  3.0G   48G   6% /
devtmpfs                 32G     0   32G   0% /dev
tmpfs                    32G   92K   32G   1% /dev/shm
tmpfs                    32G  8.8M   32G   1% /run
tmpfs                    32G     0   32G   0% /sys/fs/cgroup
/dev/mapper/rhel-home   220G   37M  220G   1% /home
/dev/sda1               497M  124M  373M  25% /boot
```

2. Configure your TCP/IP settings according to the operating system installation instructions.
   For optimal throughput and reliability, consider bonding multiple network ports together. This can be accomplished by creating a Link Aggregation Control Protocol (LACP) network connection, which aggregates several subordinate ports into a single logical connection. The preferred method is to use a bond mode of 802.3ad, miimon setting of 100, and a xmit_hash_policy setting of layer3+4.
   Restriction: To use an LACP network connection, you must have a network switch that supports LACP.

   For additional instructions about configuring bonded network connections with Red Hat Enterprise Linux Version 7, see Create a Channel Bonding Interface.

3. Open the /etc/hosts file and complete the following actions:
   - Update the file to include the IP address and host name for the server. For example:

```
192.0.2.7  server.yourdomain.com  server
```

- Verify that the file contains an entry for localhost with an address of 127.0.0.1. For example:

```
127.0.0.1  localhost
```

4. Install components that are required for the server installation. Complete the following steps to create a Yellowdog Updater Modified (YUM) repository and install the prerequisite packages.
   a. Mount your Red Hat Enterprise Linux installation DVD to a system directory. For example, to mount it to the /mnt directory, issue the following command:

```
mount -t iso9660 -o ro /dev/cdrom /mnt
```

   b. Verify that the DVD mounted by issuing the mount command. You should see output similar to the following example:

```
/dev/sr0 on /mnt type iso9660
```

   c. Change to the YUM repository directory by issuing the following command:

```
cd /etc/yum/repos.d
```

   If the repos.d directory does not exist, create it.
   d. List directory contents:

```
ls rhel-source.repo
```

   e. Rename the original repo file by issuing the mv command. For example:

```
mv rhel-source.repo rhel-source.repo.orig
```

   f. Create a new repo file by using a text editor. For example, to use the vi editor, issue the following command:

```
vi rhel71_dvd.repo
```

   g. Add the following lines to the new repo file. The baseurl parameter specifies your directory mount point:

```
[rhel71_dvd]
name=DVD Redhat Enterprise Linux 7.1
baseurl=file:///mnt
enabled=1
gpgcheck=0
```

   h. Install the prerequisite package ksh.x86_64, by issuing the yum command. For example:

```
yum install ksh.x86_64
```

   Exception: You do not need to install the compat-libstdc++-33-3.2.3-69.el6.i686 and libstdc++.i686 libraries for Red Hat Enterprise Linux Version 7.1.
5. When the software installation is complete, you can restore the original YUM repository values by completing the following steps:
   a. Unmount the Red Hat Enterprise Linux installation DVD by issuing the following command:

```
unmount /mnt
```

   b. Change to the YUM repository directory by issuing the following command:

```
cd /etc/yum/repos.d
```

   c. Rename the repo file that you created:

```
mv rhel71_dvd.repo rhel71_dvd.repo.orig
```

   d. Rename the original file to the original name:

```
mv rhel-source.repo.orig rhel-source.repo
```

6. Determine whether kernel parameter changes are required. Complete the following steps:
   a. Use the sysctl -a command to list the parameter values.
   b. Analyze the results by using the guidelines in Table 1 to determine whether any changes are required.
   c. If changes are required, set the parameters in the /etc/sysctl.conf file. The file changes are applied when the system is started.

Tip: Automatically adjust kernel parameter settings and eliminate the need for manual updates to these settings. On Linux, the DB2® database software automatically adjusts interprocess communication (IPC) kernel parameter values to the preferred settings. For more information about kernel parameter settings, search for Linux kernel parameters in the IBM DB2 Version 11.1 Knowledge Center.

Table 1. Linux kernel parameter optimum settings

Parameter	Description
kernel.shmmni	The maximum number of segments.
kernel.shmmax	The maximum size of a shared memory segment (bytes). This parameter must be set before automatically starting the IBM Spectrum Protect™ server on system startup.
kernel.shmall	The maximum allocation of shared memory pages (pages).
kernel.sem There are four values for the kernel.sem parameter.	(SEMMSL) The maximum semaphores per array.
	(SEMMNS) The maximum semaphores per system.
	(SEMOPM) The maximum operations per semaphore call.
	(SEMMNI) The maximum number of arrays.
kernel.msgmni	The maximum number of system-wide message queues.
kernel.msgmax	The maximum size of messages (bytes).
kernel.msgmnb	The default maximum size of queue (bytes).
kernel.randomize_va_space	The kernel.randomize_va_space parameter configures the use of memory ASLR for the kernel. Disable ASLR because it can cause errors for the DB2 software. To learn more details about the Linux ASLR and DB2, see technote 1365583.
vm.swappiness	The vm.swappiness parameter defines whether the kernel can swap application memory out of physical random access memory (RAM). For more information about kernel parameters, see the DB2 product information.
vm.overcommit_memory	The vm.overcommit_memory parameter influences how much virtual memory the kernel permits allocating. For more information about kernel parameters, see the DB2 product information.

7. Open firewall ports to communicate with the server. Complete the following steps:
   a. Determine the zone that is used by the network interface. The zone is public, by default.
   Issue the following command:

   ```
   #  firewall-cmd --get-active-zones
   public
     interfaces: ens4f0
   ```

   b. To use the default port address for communications with the server, open TCP/IP port 1500 in the Linux firewall.
   Issue the following command:

   ```
   firewall-cmd --zone=public --add-port=1500/tcp --permanent
   ```

   If you want to use a value other than the default, you can specify a number in the range 1024 - 32767. If you open a port other than the default, you will need to specify that port when you run the configuration script.

   c. If you plan to use this system as a hub, open port 11090, which is the default port for secure (https) communications.
   Issue the following command:

```
firewall-cmd --zone=public --add-port=11090/tcp --permanent
```

d. Reload the firewall definitions for the changes to take effect.
Issue the following command:

```
firewall-cmd --reload
```

8. Verify that user process resource limits, also known as *ulimits*, are set according to guidelines in Table 2. If ulimit values are not set correctly, you might experience server instability or a failure of the server to respond.

Table 2. User limits (ulimit) values

User limit type	Setting	Value	Command to query value
Maximum size of core files created	core	Unlimited	`ulimit -Hc`
Maximum size of a data segment for a process	data	Unlimited	`ulimit -Hd`
Maximum file size	fsize	Unlimited	`ulimit -Hf`
Maximum number of open files	nofile	65536	`ulimit -Hn`
Maximum amount of processor time in seconds	cpu	Unlimited	`ulimit -Ht`
Maximum number of user processes	nproc	16384	`ulimit -Hu`

If you need to modify any user limit values, follow the instructions in the documentation for your operating system.

Installing on Windows systems

Install Microsoft Windows Server 2012 Standard Edition on the server system and prepare the system for installation and configuration of the IBM Spectrum Protect™ server.

Procedure

1. Install Microsoft Windows Server 2012 R2 Standard Edition, according to the manufacturer instructions.
2. Change the Windows account control policies by completing the following steps.
   a. Open the Local Security Policy editor by running secpol.msc.
   b. Click Local Policies > Security Options and ensure that the following User Account Control policies are disabled:
      - Admin Approval Mode for the Built-in Administrator account
      - Run all administrators in Admin Approval Mode
3. Configure your TCP/IP settings according to installation instructions for the operating system.
4. Apply Windows updates and enable optional features by completing the following steps:
   a. Apply the latest Windows 2012 R2 updates.
   b. Install and enable the Windows 2012 R2 feature Microsoft .NET Framework 3.5 from the Windows Server Manager.
   c. If required, update the FC and Ethernet HBA device drivers to newer levels.
   d. Install the multipath I/O driver that is appropriate for the disk system that you are using.
5. Open the default TCP/IP port, 1500, for communications with the IBM Spectrum Protect server. For example, issue the following command:

```
netsh advfirewall firewall add rule name="Backup server port 1500"
dir=in action=allow protocol=TCP localport=1500
```

6. On the Operations Center hub server, open the default port for secure (https) communications with the Operations Center. The port number is 11090. For example, issue the following command:

```
netsh advfirewall firewall add rule name="Operations Center port 11090"
dir=in action=allow protocol=TCP localport=11090
```

Configuring multipath I/O

You can enable and configure multipathing for disk storage. Use the documentation that is provided with your hardware for detailed instructions.

- AIX systems
- Linux systems
- Windows systems

AIX systems

Procedure

1. Determine the Fibre Channel port address that you must use for the host definition on the disk subsystem. Issue the lscfg command for every port.
   - On small and medium systems, issue the following commands:

     ```
     lscfg -vps -l fcs0 | grep "Network Address"
     lscfg -vps -l fcs1 | grep "Network Address"
     ```

   - On large systems, issue the following commands:

     ```
     lscfg -vps -l fcs0 | grep "Network Address"
     lscfg -vps -l fcs1 | grep "Network Address"
     lscfg -vps -l fcs2 | grep "Network Address"
     lscfg -vps -l fcs3 | grep "Network Address"
     ```

2. Ensure that the following AIX® file sets are installed:
   - devices.common.IBM.mpio.rte
   - devices.fcp.disk.array.rte
   - devices.fcp.disk.rte
3. Issue the cfgmgr command to have AIX rescan the hardware and discover available disks. For example:

   ```
   cfgmgr
   ```

4. To list the available disks, issue the following command:

   ```
   lsdev -Ccdisk
   ```

   You should see output similar to the following:

   ```
   hdisk0  Available 00-00-00 SAS Disk Drive
   hdisk1  Available 00-00-00 SAS Disk Drive
   hdisk2  Available 01-00-00 SAS Disk Drive
   hdisk3  Available 01-00-00 SAS Disk Drive
   hdisk4  Available 06-01-02 MPIO IBM 2076 FC Disk
   hdisk5  Available 07-01-02 MPIO IBM 2076 FC Disk
   ...
   ```

5. Use the output from the lsdev command to identify and list device IDs for each disk device.

   For example, a device ID could be `hdisk4`. Save the list of device IDs to use when you create file systems for the IBM Spectrum Protect™ server.

6. Correlate the SCSI device IDs to specific disk LUNs from the disk system by listing detailed information about all physical volumes in the system. Issue the following command:

   ```
   lspv -u
   ```

   On an IBM® Storwize® system, the following information is an example of what is shown for each device:

   ```
   hdisk4  00f8cf083fd97327  None  active
    3321360050763008101057800000000000030042145O3IBMfcp
   ```

   In the example, *600507630081010578000000000000030* is the UID for the volume, as reported by the Storwize management interface.
   To verify disk size in megabytes and compare the value with what is listed for the system, issue the following command:

   ```
   bootinfo -s hdisk4
   ```

Linux systems

Procedure

1. Edit the /etc/multipath.conf file to enable multipathing for Linux hosts. If the multipath.conf file does not exist, you can create it by issuing the following command:

   ```
   mpathconf --enable
   ```

   The following parameters were set in multipath.conf for testing on an IBM Storwize® system:

   ```
   defaults {
                user_friendly_names no
   }

   devices {
                device {
                            vendor "IBM "
                            product "2145"
                            path_grouping_policy group_by_prio
                            user_friendly_names no
                            path_selector "round-robin 0"
                            prio "alua"
                            path_checker "tur"
                            failback "immediate"
                            no_path_retry 5
                            rr_weight uniform
                            rr_min_io_rq "1"
                            dev_loss_tmo 120
              }
   }
   ```

2. Set the multipath option to start when the system is started. Issue the following commands:

   ```
   systemctl enable multipathd.service
   systemctl start multipathd.service
   ```

3. To verify that disks are visible to the operating system and are managed by multipath, issue the following command:

   ```
   multipath -l
   ```

4. Ensure that each device is listed and that it has as many paths as you expect. You can use size and device ID information to identify which disks are listed.
   For example, the following output shows that a 2 TB disk has two path groups and four active paths. The 2 TB size confirms that the disk corresponds to a pool file system. Use part of the long device ID number (12, in this example) to search for the volume on the disk-system management interface.

   ```
   [root@tapsrv01 code]# multipath -l
   36005076802810c509800000000000012 dm-43 IBM,2145
    size=2.0T features='1 queue_if_no_path' hwhandler='0' wp=rw
   |-+- policy='round-robin 0' prio=0 status=active
   | |- 2:0:1:18 sdcw 70:64   active undef running
   | `- 4:0:0:18 sdgb 131:112 active undef running
   `-+- policy='round-robin 0' prio=0 status=enabled
     |- 1:0:1:18 sdat 66:208  active undef running
     `- 3:0:0:18 sddy 128:0   active undef running
   ```

   a. If needed, correct disk LUN host assignments and force a bus rescan. For example:

      ```
      echo "- - -" > /sys/class/scsi_host/host0/scan
      echo "- - -" > /sys/class/scsi_host/host1/scan
      echo "- - -" > /sys/class/scsi_host/host2/scan
      ```

      You can also restart the system to rescan disk LUN host assignments.
   b. Confirm that disks are now available for multipath I/O by reissuing the multipath -l command.
5. Use the multipath output to identify and list device IDs for each disk device.

   For example, the device ID for your 2 TB disk is `36005076802810c509800000000000012`.

   Save the list of device IDs to use in the next step.

Windows systems

Procedure

1. Ensure that the Multipath I/O feature is installed. If needed, install additional vendor-specific multipath drivers.
2. To verify that disks are visible to the operating system and are managed by multipath I/O, issue the following command:

   ```
   c:\program files\IBM\SDDDSM\datapath.exe query device
   ```

3. Review the multipath output and ensure that each device is listed and that it has as many paths as you expect. You can use size and device serial information to identify which disks are listed.
   For example, by using part of the long device serial number (34, in this example) you can search for the volume on the disk-system management interface. The 2 TB size confirms that the disk corresponds to a storage pool file system.

   ```
   DEV#:   4  DEVICE NAME: Disk5 Part0   TYPE: 2145    POLICY: OPTIMIZED
   SERIAL: 600507630081010578000000000000034          LUN SIZE: 2.0TB
   ============================================================================
   Path#          Adapter/Hard Disk       State   Mode    Select  Errors
       0   Scsi Port2 Bus0/Disk5 Part0    OPEN    NORMAL       0       0
       1   Scsi Port2 Bus0/Disk5 Part0    OPEN    NORMAL   27176       0
       2   Scsi Port3 Bus0/Disk5 Part0    OPEN    NORMAL   28494       0
       3   Scsi Port3 Bus0/Disk5 Part0    OPEN    NORMAL       0       0
   ```

4. Create a list of disk device IDs by using the serial numbers that are returned from the multipath output in the previous step.

   For example, the device ID for your 2 TB disk is `600507630081010578000000000000034`

   Save the list of device IDs to use in the next step.

5. To bring new disks online and clear the read-only attribute, run diskpart.exe with the following commands. Repeat for each of the disks:

   ```
   diskpart
      select Disk 1
      online disk
      attribute disk clear readonly
      select Disk 2
      online disk
      attribute disk clear readonly
      < ... >
      select Disk 49
      online disk
      attribute disk clear readonly
      exit
   ```

Creating the user ID for the server

Create the user ID that owns the IBM Spectrum Protect™ server instance. You specify this user ID when you create the server instance during initial configuration of the server.

About this task

You can specify only lowercase letters (a-z), numerals (0-9), and the underscore character (_) for the user ID. The user ID and group name must comply with the following rules:

- The length must be 8 characters or fewer.
- The user ID and group name cannot start with *ibm*, *sql*, *sys*, or a numeral.
- The user ID and group name cannot be *user*, *admin*, *guest*, *public*, *local*, or any SQL reserved word.

Procedure

1. Use operating system commands to create a user ID.
   - AIX Linux Create a group and user ID in the home directory of the user that owns the server instance.

     For example, to create the user ID tsminst1 in group tsmsrvrs with a password of tsminst1, issue the following commands from an administrative user ID:

     AIX

```
mkgroup id=1001 tsmsrvrs
mkuser id=1002 pgrp=tsmsrvrs home=/home/tsminst1 tsminst1
passwd tsminst1
```

Linux

```
groupadd tsmsrvrs
useradd -d /home/tsminst1 -m -g tsmsrvrs -s /bin/bash tsminst1
passwd tsminst1
```

Log off, and then log in to your system. Change to the user account that you created. Use an interactive login program, such as telnet, so that you are prompted for the password and can change it if necessary.

- Windows Create a user ID and then add the new ID to the Administrators group. For example, to create the user ID tsminst1, issue the following command:

```
net user tsminst1 * /add
```

After you create and verify a password for the new user, add the user ID to the Administrators group by issuing the following commands:

```
net localgroup Administrators tsminst1 /add
net localgroup DB2ADMNS tsminst1 /add
```

2. Log off the new user ID.

Preparing file systems for the server

You must complete file system configuration for the disk storage to be used by the server.

- Preparing file systems on AIX systems
  You must create volume groups, logical volumes, and file systems for the server by using the AIX® Logical Volume Manager.
- Preparing file systems on Linux systems
  You must format ext4 or xfs file systems on each of the disk LUNs to be used by the IBM Spectrum Protect server.
- Preparing file systems on Windows systems
  You must format New Technology File System (NTFS) file systems on each of the disk LUNs to be used by the IBM Spectrum Protect server.

Preparing file systems on AIX systems

You must create volume groups, logical volumes, and file systems for the server by using the AIX® Logical Volume Manager.

Procedure

1. Increase the queue depth and maximum transfer size for all of the available *hdiskX* disks. Issue the following commands for each disk:

```
chdev -l hdisk4 -a max_transfer=0x100000
chdev -l hdisk4 -a queue_depth=32
chdev -l hdisk4 -a reserve_policy=no_reserve
chdev -l hdisk4 -a algorithm=round_robin
```

Do not run these commands for operating system internal disks, for example, *hdisk0*.

2. Create volume groups for the IBM Spectrum Protect™ database, active log, archive log, database backup, and storage pool. Issue the mkvg command, specifying the device IDs for corresponding disks that you previously identified.
For example, if the device names *hdisk4, hdisk5*, and *hdisk6* correspond to database disks, include them in the database volume group and so on.
System size: The following commands are based on the medium system configuration. For small and large systems, you must adjust the syntax as required.

```
mkvg -S -y tsmdb hdisk2 hdisk3 hdisk4
mkvg -S -y tsmactlog hdisk5
mkvg -S -y tsmarchlog hdisk6
mkvg -S -y tsmdbback hdisk7 hdisk8 hdisk9 hdisk10
mkvg -S -y tsmstgpool hdisk11 hdisk12 hdisk13 hdisk14 ... hdisk49
```

3. Determine the physical volume names and the number of free physical partitions to use when you create logical volumes. Issue the lsvg for each volume group that you created in the previous step.
   For example:

   ```
   lsvg -p tsmdb
   ```

   The output is similar to the following. The *FREE PPs* column represents the free physical partitions:

   ```
   tsmdb:
   PV_NAME  PV STATE   TOTAL PPs  FREE PPs  FREE DISTRIBUTION
   hdisk4   active     1631       1631      327..326..326..326..326
   hdisk5   active     1631       1631      327..326..326..326..326
   hdisk6   active     1631       1631      327..326..326..326..326
   ```

4. Create logical volumes in each volume group by using the mklv command. The volume size, volume group, and device names vary, depending on the size of your system and variations in your disk configuration.
   For example, to create the volumes for the IBM Spectrum Protect database on a medium system, issue the following commands:

   ```
   mklv -y tsmdb00 -t jfs2 -u 1 -x 1631 tsmdb 1631 hdisk2
   mklv -y tsmdb01 -t jfs2 -u 1 -x 1631 tsmdb 1631 hdisk3
   mklv -y tsmdb02 -t jfs2 -u 1 -x 1631 tsmdb 1631 hdisk4
   ```

5. Format file systems in each logical volume by using the crfs command.
   For example, to format file systems for the database on a medium system, issue the following commands:

   ```
   crfs -v jfs2 -d tsmdb00 -p rw -a logname=INLINE -a options=rbrw
    -a agblksize=4096 -m /tsminst1/TSMdbspace00 -A yes
   crfs -v jfs2 -d tsmdb01 -p rw -a logname=INLINE -a options=rbrw
    -a agblksize=4096 -m /tsminst1/TSMdbspace01 -A yes
   crfs -v jfs2 -d tsmdb02 -p rw -a logname=INLINE -a options=rbrw
    -a agblksize=4096 -m /tsminst1/TSMdbspace02 -A yes
   ```

6. Mount all of the newly created file systems by issuing the following command:

   ```
   mount -a
   ```

7. List all file systems by issuing the df command. Verify that file systems are mounted at the correct LUN and correct mount point. Also, verify the available space.
   The following example of command output shows that the amount of used space is typically 1%:

   ```
   tapsrv07> df -g /tsminst1/*
   Filesystem      GB blocks  Free     %Used   Iused   %Iused   Mounted on
   /dev/tsmact00   195.12     194.59   1%      4       1%       /tsminst1/TSMalog
   ```

8. Verify that the user ID you created in Creating the user ID for the server has read and write access to the directories for the IBM Spectrum Protect server.

Preparing file systems on Linux systems

You must format ext4 or xfs file systems on each of the disk LUNs to be used by the IBM Spectrum Protect™ server.

Procedure

1. Using the list of device IDs that you generated previously, issue the mkfs command to create and format a file system for each storage LUN device. Specify the device ID in the command. See the following examples. For the database, format ext4 file systems:

   ```
   mkfs -t ext4 -T largefile -m 2 /dev/mapper/36005076802810c509800000000000012
   ```

   For storage pool LUNs, format xfs file systems:

   ```
   mkfs -t xfs /dev/mapper/360050763008101057800000000002c3
   ```

   You might issue the mkfs command as many as 50 times, depending on how many different devices you have.

2. Create mount point directories for file systems.

Issue the mkdir command for each directory that you must create. Use the directory values that you recorded in the planning worksheets.

For example, to create the server instance directory by using the default value, issue the following command:

```
mkdir /tsminst1
```

Repeat the mkdir command for each file system.

3. Add an entry in the /etc/fstab file for each file system so that file systems are mounted automatically when the server is started.
   For example:

```
/dev/mapper/36005076802810c509800000000000012 /tsminst1/TSMdbspace00 ext4 defaults 0 0
```

4. Mount the file systems that you added to the /etc/fstab file by issuing the mount -a command.
5. List all file systems by issuing the df command. Verify that file systems are mounted at the correct LUN and correct mount point. Also, verify the available space.
   The following example on an IBM® Storwize® system shows that the amount of used space is typically 1%:

```
[root@tapsrv04 ~]# df -h /tsminst1/*
Filesystem                                      Size  Used Avail Use% Mounted on
/dev/mapper/3600507630081010578000000000000003 134G  188M 132G  1%   /tsminst1/TSMalog
```

6. Verify that the user ID you created in Creating the user ID for the server has read and write access to the directories for IBM Spectrum Protect.

Preparing file systems on Windows systems

You must format New Technology File System (NTFS) file systems on each of the disk LUNs to be used by the IBM Spectrum Protect™ server.

Procedure

1. Create mount point directories for file systems.
   Issue the md command for each directory that you must create. Use the directory values that you recorded in the planning worksheets. For example, to create the server instance directory by using the default value, issue the following command:

```
md c:\tsminst1
```

   Repeat the md command for each file system.
2. Create a volume for every disk LUN that is mapped to a directory under the server instance directory by using the Windows volume manager.

   Go to Server Manager > File and Storage Services and complete the following steps for each disk that corresponds to the LUN mapping that was created in the previous step:

   a. Bring the disk online.
   b. Initialize the disk to the GPT basic type, which is the default.
   c. Create a simple volume that occupies all of the space on the disk. Format the file system by using NTFS, and assign a label that matches the purpose of the volume, such as TSMfile00. Do not assign the new volume to a drive letter. Instead, map the volume to a directory under the instance directory, such as C:\tsminst1\TSMfile00.
      Tip: Determine the volume label and directory mapping labels based on the size of the disk that is reported.
3. Verify that file systems are mounted at the correct LUN and correct mount point. List all file systems by issuing the mountvol command and then review the output. For example:

```
\\?\Volume{8ffb9678-3216-474c-a021-20e420816a92}\
    C:\tsminst1\TSMdbspace00\
```

4. After the disk configuration is complete, restart the system.

What to do next

You can confirm the amount of free space for each volume by using Windows Explorer.

Installing the server and Operations Center

Use the IBM® Installation Manager graphical wizard to install the components.

- Installing on AIX and Linux systems
  Install the IBM Spectrum Protect™ server and the Operations Center on the first server system.
- Installing on Windows systems
  Install the IBM Spectrum Protect server and the Operations Center on the first server system.

Installing on AIX® and Linux systems

Install the IBM Spectrum Protect™ server and the Operations Center on the first server system.

Before you begin

Verify that the operating system is set to the language that you require. By default, the language of the operating system is the language of the installation wizard.

Procedure

1. AIX Verify that the required RPM files are installed on your system.

   See Installing prerequisite RPM files for the graphical wizard for details.

2. Before you download the installation package, verify that you have enough space to store the installation files when they are extracted from the product package. For space requirements, see the download document at technote 4042992.
3. Go to Passport Advantage® and download the package file to an empty directory of your choice.
4. Ensure that executable permission is set for the package. If necessary, change the file permissions by issuing the following command:

   ```
   chmod a+x package_name.bin
   ```

5. Extract the package by issuing the following command:

   ```
   ./package_name.bin
   ```

   where *package_name* is the name of the downloaded file.
6. AIX Ensure that the following command is enabled so that the wizards work properly:

   ```
   lsuser
   ```

   By default, the command is enabled.
7. Change to the directory where you placed the executable file.
8. Start the installation wizard by issuing the following command:

   ```
   ./install.sh
   ```

   When you select the packages to install, choose both the server and Operations Center.

What to do next

- If errors occur during the installation process, the errors are recorded in log files that are stored in the IBM Installation Manager logs directory.

  To view installation log files from the Installation Manager tool, click File > View Log. To collect these log files from the Installation Manager tool, click Help > Export Data for Problem Analysis.

- After you install the server and before you customize it for your use, go to the IBM Spectrum Protect support site. Click Support and downloads and apply any applicable fixes.

- Installing prerequisite RPM files for the graphical wizard
  RPM files are required for the IBM Installation Manager graphical wizard.

Installing on Windows systems

Install the IBM Spectrum Protect™ server and the Operations Center on the first server system.

Before you begin

Make sure that the following prerequisites are met:

- Verify that the operating system is set to the language that you require. By default, the language of the operating system is the language of the installation wizard.
- Ensure that the user ID that you plan to use during the installation is a user with local Administrator authority.

Procedure

1. Before you download the installation package, verify that you have enough space to store the installation files when they are extracted from the product package. For space requirements, see the download document at technote 4042993.
2. Go to Passport Advantage® and download the package file to an empty directory of your choice.
3. Change to the directory where you placed the executable file.
4. Double-click the executable file to extract to the current directory.
5. In the directory where the installation files were extracted, start the installation wizard by double-clicking the install.bat file. When you select the packages to install, choose both the server and Operations Center.

What to do next

- If errors occur during the installation process, the errors are recorded in log files that are stored in the IBM® Installation Manager logs directory.

  To view installation log files from the Installation Manager tool, click File > View Log. To collect these log files from the Installation Manager tool, click Help > Export Data for Problem Analysis.

- After you install the server and before you customize it for your use, go to the IBM Spectrum Protect support site. Click Support and downloads and apply any applicable fixes.

Other methods for installing IBM Spectrum Protect components

Configuring the server and the Operations Center

After you install the components, complete the configuration for the IBM Spectrum Protect™ server and the Operations Center.

- Configuring the server instance
  Use the IBM Spectrum Protect server instance configuration wizard to complete the initial configuration of the server.
- Installing the backup-archive client
  As a best practice, install the IBM Spectrum Protect backup-archive client on the server system so that the administrative command-line client and scheduler are available.
- Setting options for the server
  Review the server options file that is installed with the IBM Spectrum Protect server to verify that the correct values are set for your system.
- Configuring secure communications with Transport Layer Security
  To encrypt data and secure communications in your environment, Secure Sockets Layer (SSL) or Transport Layer Security (TLS) is enabled on the IBM Spectrum Protect server and backup-archive client. An SSL certificate is used to verify communication requests between the server and client.
- Configuring the Operations Center
  After you install the Operations Center, complete the following configuration steps to start managing your storage environment.
- Registering the product license
  To register your license for the IBM Spectrum Protect product, use the REGISTER LICENSE command.
- Configuring data deduplication
  Create a directory-container storage pool and at least one directory to use inline data deduplication.
- Defining data retention rules for your business
  After you create a directory-container storage pool for data deduplication, update the default server policy to use the new

storage pool. The Add Storage Pool wizard opens the Services page in the Operations Center to complete this task.

- Defining schedules for server maintenance activities
  Create schedules for each server maintenance operation by using the DEFINE SCHEDULE command in the Operations Center command builder.
- Defining client schedules
  Use the Operations Center to create schedules for client operations.

Configuring the server instance

Use the IBM Spectrum Protect™ server instance configuration wizard to complete the initial configuration of the server.

Before you begin

Ensure that the following requirements are met:
AIX Linux

- The system where you installed IBM Spectrum Protect must have the X Window System client. You must also be running an X Window System server on your desktop.
- The system must have the Secure Shell (SSH) protocol enabled. Ensure that the port is set to the default value, 22, and that the port is not blocked by a firewall. You must enable password authentication in the sshd_config file in the /etc/ssh/directory. Also, ensure that the SSH daemon service has access rights to connect to the system by using the *localhost* value.
- You must be able to log in to IBM Spectrum Protect with the user ID that you created for the server instance, by using the SSH protocol. When you use the wizard, you must provide this user ID and password to access that system.
- If you changed any settings in the preceding steps, restart the server before you proceed with the configuration wizard.

Windows Verify that the remote registry service is started by completing the following steps:

1. Click Start > Administrative Tools > Services. In the Services window, select Remote Registry. If it is not started, click Start.
2. Ensure that port 137, 139, and 445 are not blocked by a firewall:
   a. Click Start > Control Panel > Windows Firewall.
   b. Select Advanced Settings.
   c. Select Inbound Rules.
   d. Select New Rule.
   e. Create a port rule for TCP ports 137, 139, and 445 to allow connections for domain and private networks.
3. Configure the user account control by accessing the local security policy options and completing the following steps.
   a. Click Start > Administrative Tools > Local Security Policy. Expand Local Policies > Security Options.
   b. If not already enabled, enable the built-in administrator account by selecting Accounts: Administrator account status > Enable > OK.
   c. If not already disabled, disable user account control for all Windows administrators by selecting User Account Control: Run all administrators in Admin Approval Mode > Disable > OK.
   d. If not already disabled, disable the User Account Control for the built-in Administrator account by selecting User Account Control: Admin Approval Mode for the Built-in Administrator Account > Disable > OK.
4. If you changed any settings in the preceding steps, restart the server before you proceed with the configuration wizard.

About this task

The wizard can be stopped and restarted, but the server is not operational until the entire configuration process is complete.

Procedure

1. Start the local version of the wizard.
   - AIX Linux Open the dsmicfgx program in the /opt/tivoli/tsm/server/bin directory. This wizard can be only run as a root user.
   - Windows Click Start > All Programs > IBM Spectrum Protect > Configuration Wizard.
2. Follow the instructions to complete the configuration. Use the information that you recorded in Planning worksheets during IBM Spectrum Protect system set up to specify directories and options in the wizard.

   AIX Linux On the Server Information window, set the server to start automatically by using the instance user ID when the system boots.

   Windows By using the configuration wizard, the server is set to start automatically when rebooted.

Installing the backup-archive client

As a best practice, install the IBM Spectrum Protect™ backup-archive client on the server system so that the administrative command-line client and scheduler are available.

Procedure

To install the backup-archive client, follow the installation instructions for your operating system.

- Installing the UNIX and Linux backup-archive clients
- Installing the Windows backup-archive client

Setting options for the server

Review the server options file that is installed with the IBM Spectrum Protect™ server to verify that the correct values are set for your system.

Procedure

1. Go to the server instance directory and open the dsmserv.opt file.
2. Review the values in the following table and verify your server option settings, based on system size.

Server option	Small system value	Medium system value	Large system value
ACTIVELOGDIRECTORY	Directory path that was specified during configuration	Directory path that was specified during configuration	Directory path that was specified during configuration
ACTIVELOGSIZE	131072	131072	262144
ARCHLOGCOMPRESS	Yes	No	No
ARCHLOGDIRECTORY	Directory path that was specified during configuration	Directory path that was specified during configuration	Directory path that was specified during configuration
COMMMETHOD	TCPIP	TCPIP	TCPIP
COMMTIMEOUT	3600	3600	3600
DEDUPREQUIRESBACKUP	No	No	No
DEVCONFIG	devconf.dat	devconf.dat	devconf.dat
EXPINTERVAL	0	0	0
IDLETIMEOUT	60	60	60
MAXSESSIONS	250	500	1000
NUMOPENVOLSALLOWED	20	20	20
TCPADMINPORT	1500	1500	1500
TCPPORT	1500	1500	1500
VOLUMEHISTORY	volhist.dat	volhist.dat	volhist.dat

Update server option settings if necessary, to match the values in the table. To make updates, close the dsmserv.opt file and use the SETOPT command from the administrative command-line interface to set the options.
For example, to update the IDLETIMEOUT option to 60, issue the following command:

```
setopt idletimeout 60
```

3. To configure secure communications for the server, clients, and the Operations Center, verify the options in the following table.

Server option	All system sizes
SSLFIPSMODE	NO

Server option	All system sizes
TCPPORT	Specify the port number on which the server waits for requests for TCP/IP and SSL-enabled sessions from the client.
TCPADMINPORT	Specify the port address on which the server waits for requests for TCP/IP and SSL-enabled sessions from the command-line administrative client.

If any of the option values must be updated, edit the dsmserv.opt file by using the following guidelines:

- Remove the asterisk at the beginning of a line to enable an option.
- On each line, enter only one option and the specified value for the option.
- If an option occurs in multiple entries in the file, the server uses the last entry.

Save your changes and close the file. If you edit the dsmserv.opt file directly, you must restart the server for the changes to take effect.

SETOPT (Set a server option for dynamic update)

Configuring secure communications with Transport Layer Security

To encrypt data and secure communications in your environment, Secure Sockets Layer (SSL) or Transport Layer Security (TLS) is enabled on the IBM Spectrum Protect™ server and backup-archive client. An SSL certificate is used to verify communication requests between the server and client.

About this task

Beginning with IBM Spectrum Protect Version 8.1.2, SSL is enabled by default, and the IBM Spectrum Protect server and backup-archive client are automatically configured to communicate with each other by using the TLS 1.2 protocol.

As shown in the following figure, you can manually configure secure communications between the server and backup-archive client by setting options in the server and client options files, and then transferring the self-signed certificate that is generated on the server to the client. Alternatively, you can obtain and transfer a unique certificate that is signed by a certificate authority (CA).

For more information about configuring the server and clients for SSL or TLS communications, see Configuring storage agents, servers, clients, and the Operations Center to connect to the server by using SSL.

Configuring the Operations Center

After you install the Operations Center, complete the following configuration steps to start managing your storage environment.

Before you begin

When you connect to the Operations Center for the first time, you must provide the following information:

- Connection information for the server that you want to designate as a hub server
- Login credentials for an administrator ID that is defined for that server

Procedure

1. Designate the hub server. In a web browser, enter the following address:

   `https://hostname:secure_port/oc`

where:
    - *hostname* represents the name of the computer where the Operations Center is installed
    - *secure_port* represents the port number that the Operations Center uses for HTTPS communication on that computer

  For example, if your host name is tsm.storage.mylocation.com and you are using the default secure port for the Operations Center, which is 11090, the address is:

  ```
  https://tsm.storage.mylocation.com:11090/oc
  ```

  When you log in to the Operations Center for the first time, a wizard guides you through an initial configuration to set up a new administrator with system authority on the server.

2. Set up secure communications between the Operations Center and the hub server by configuring the Secure Sockets Layer (SSL) protocol.

   Follow the instructions in Securing communications between the Operations Center and the hub server.

3. Optional: To receive a daily email report that summarizes system status, configure your email settings in the Operations Center.

   Follow the instructions in Tracking system status by using email reports.

- Securing communications between the Operations Center and the hub server
  To secure communications between the Operations Center and the hub server, add the Transport Layer Security (TLS) certificate of the hub server to the truststore file of the Operations Center.

Registering the product license

To register your license for the IBM Spectrum Protect™ product, use the REGISTER LICENSE command.

About this task

Licenses are stored in enrollment certificate files, which contain licensing information for the product. The enrollment certificate files are on the installation media, and are placed on the server during installation. When you register the product, the licenses are stored in a NODELOCK file within the current directory.

Procedure

Register a license by specifying the name of the enrollment certificate file that contains the license. To use the Operations Center command builder for this task, complete the following steps.

1. Open the Operations Center.
2. Open the Operations Center command builder by hovering over the settings icon  and clicking Command Builder.
3. Issue the REGISTER LICENSE command. For example, to register a base IBM Spectrum Protect license, issue the following command:

   ```
   register license file=tsmbasic.lic
   ```

What to do next

Save the installation media that contains your enrollment certificate files. You might need to register your license again if, for example, one of the following conditions occur:

- The server is moved to a different computer.
- The NODELOCK file is corrupted. The server stores license information in the NODELOCK file, which is in the directory from which the server is started.
- Linux If you change the processor chip that is associated with the server on which the server is installed.

Related reference:
REGISTER LICENSE (Register a new license)

Configuring data deduplication

Create a directory-container storage pool and at least one directory to use inline data deduplication.

Before you begin

Use the storage pool directory information that you recorded in Planning worksheets for this task.

Procedure

1. Open the Operations Center.
2. On the Operations Center menu bar, hover over Storage.
3. From the list that is displayed, click Storage Pools.
4. Click the +Storage Pool button.
5. Complete the steps in the Add Storage Pool wizard:
    - To use inline data deduplication, select a Directory storage pool under Container-based storage.
    - When you configure directories for the directory-container storage pool, specify the directory paths that you created for storage during system setup.
6. After you configure the new directory-container storage pool, click Close & View Policies to update a management class and start using the storage pool.

Defining data retention rules for your business

After you create a directory-container storage pool for data deduplication, update the default server policy to use the new storage pool. The Add Storage Pool wizard opens the Services page in the Operations Center to complete this task.

Procedure

1. On the Services page of the Operations Center, select the STANDARD domain and click Details.
2. On the Summary page for the policy domain, click the Policy Sets tab. The Policy Sets page indicates the name of the active policy set and lists all of the management classes for that policy set.
3. Click the Configure toggle, and make the following changes:
    - Change the backup destination for the STANDARD management class to the directory-container storage pool.
    - Change the value for the Backups column to No limit.
    - Change the retention period. Set the Keep Extra Backups column to 30 days or more, depending on your business requirements.
4. Save your changes and click the Configure toggle again so that the policy set is no longer editable.
5. Activate the policy set by clicking Activate.

Related tasks:
Specifying rules for backing up and archiving client data

Defining schedules for server maintenance activities

Create schedules for each server maintenance operation by using the DEFINE SCHEDULE command in the Operations Center command builder.

About this task

Schedule server maintenance operations to run after client backup operations. You can control the timing of schedules by setting the start time in combination with the duration time for each operation.

The following example shows how you can schedule server maintenance processes in combination with the client backup schedule for a multisite disk solution.

Operation	Schedule
Client backup	Starts at 22:00.
Node replication	Starts at 08:00, or 10 hours after the beginning of the client backup.

Operation	Schedule
Processing for database and disaster recovery files	• Database backup starts at 11:00, or 13 hours after the beginning of the client backup. This process runs until completion. • Device configuration information and volume history backup starts at 17:00, or 6 hours after the start of the database backup. • Volume history deletion starts at 20:00, or 9 hours after the start of the database backup.
Inventory expiration	Starts at 12:00, or 14 hours after the beginning of the client backup window. This process runs until completion.

Procedure

After you configure the device class for the database backup operations, create schedules for database backup and other required maintenance operations by using the DEFINE SCHEDULE command. Depending on the size of your environment, you might need to adjust the start times for each schedule in the example.

1. Define a device class for the backup operations. For example, use the DEFINE DEVCLASS command to create a device class that is named DBBACK_FILEDEV:

   ```
   define devclass dbback_filedev devtype=file
     directory=db_backup_directories
   ```

   where *db_backup_directories* is a list of the directories that you created for the database backup.
   AIX Linux For example, if you have four directories for database backups, starting with /tsminst1/TSMbkup00, issue the following command:

   ```
   define devclass dbback_filedev devtype=file
     directory=/tsminst1/TSMbkup00,
     /tsminst1/TSMbkup01,/tsminst1/TSMbkup02,
     /tsminst1/TSMbkup03"
   ```

   Windows For example, if you have four directories for database backups, starting with C:\tsminst1\TSMbkup00, issue the following command:

   ```
   define devclass dbback_filedev devtype=file
     directory="c:\tsminst1\TSMbkup00,
     c:\tsminst1\TSMbkup01,c:\tsminst1\TSMbkup02,
     c:\tsminst1\TSMbkup03"
   ```

2. Set the device class for automatic database backup operations. Use the SET DBRECOVERY command to specify the device class that you created in the preceding step. For example, if the device class is dbback_filedev, issue the following command:

   ```
   set dbrecovery dbback_filedev
   ```

3. Create schedules for the maintenance operations by using the DEFINE SCHEDULE command. See the following table for the required operations with examples of the commands.
   Tip: You create the schedule for replication separately in a later step, when you use the Operations Center to configure replication.

Operation	Example command
Back up the database.	Create a schedule to run the BACKUP DB command. If you are configuring a small system, set the COMPRESS parameter to YES. For example, on a small system, issue the following command to create a backup schedule that uses the new device class: `define schedule DBBACKUP type=admin cmd="backup db devclass=dbback_filedev type=full numstreams=3 wait=yes compress=yes" active=yes desc="Back up the database." startdate=today starttime=11:00:00 duration=45 durunits=minutes`

Operation	Example command
Back up the device configuration information.	Create a schedule to run the BACKUP DEVCONFIG command: `define schedule DEVCONFIGBKUP type=admin cmd="backup devconfig filenames=devconfig.dat" active=yes desc="Backup the device configuration file." startdate=today starttime=17:00:00 duration=45 durunits=minutes`
Back up the volume history.	Create a schedule to run the BACKUP VOLHISTORY command: `define schedule VOLHISTBKUP type=admin cmd="backup volhistory filenames=volhist.dat" active=yes desc="Back up the volume history." startdate=today starttime=17:00:00 duration=45 durunits=minutes`
Remove older versions of database backups that are no longer required.	Create a schedule to run the DELETE VOLHISTORY command: `define schedule DELVOLHIST type=admin cmd="delete volhistory type=dbb todate=today-6 totime=now" active=yes desc="Remove old database backups." startdate=today starttime=20:00:00 duration=45 durunits=minutes`
Remove objects that exceed their allowed retention.	Create a schedule to run the EXPIRE INVENTORY command. Set the RESOURCE parameter based on the system size that you are configuring: ○ Small systems: 10 ○ Medium systems: 30 ○ Large systems: 40 For example, on a medium-sized system, issue the following command to create a schedule that is named EXPINVENTORY: `define schedule EXPINVENTORY type=admin cmd="expire inventory wait=yes resource=30 duration=120" active=yes desc="Remove expired objects." startdate=today starttime=12:00:00 duration=45 durunits=minutes`

What to do next

After you create schedules for the server maintenance tasks, you can view them in the Operations Center by completing the following steps:

1. On the Operations Center menu bar, hover over Servers.
2. Click Maintenance.

Related reference:
DEFINE SCHEDULE (Define a schedule for an administrative command)

Defining client schedules

Use the Operations Center to create schedules for client operations.

Procedure

1. On the Operations Center menu bar, hover over Clients.
2. Click Schedules.

3. Click +Schedule.
4. Complete the steps in the Create Schedule wizard. Set client backup schedules to start at 22:00, based on the server maintenance activities that you scheduled in Defining schedules for server maintenance activities.

Installing and configuring backup-archive clients

Following the successful setup of your IBM Spectrum Protect™ server system, install and configure client software to begin backing up data.

Procedure

To install the backup-archive client, follow the installation instructions for your operating system.

- Installing the UNIX and Linux backup-archive clients
- Installing the Windows backup-archive client

What to do next

Register and assign your clients to schedules.

- Registering and assigning clients to schedules
  Add and register your clients through the Operations Center by using the Add Client wizard.
- Installing the client management service
  Install the client management service for backup-archive clients that run on Linux and Windows operating systems. The client management service collects diagnostic information about backup-archive clients and makes the information available to the Operations Center for basic monitoring capability.

Registering and assigning clients to schedules

Add and register your clients through the Operations Center by using the Add Client wizard.

Before you begin

Determine whether the client requires an administrative user ID with client owner authority over the client node. To determine which clients require an administrative user ID, see technote 7048963.
Restriction: For some types of clients, the client node name and the administrative user ID must match. You cannot authenticate those clients by using the Lightweight Directory Access Protocol authentication method that was introduced in V7.1.7. For details about this authentication method, sometimes referred to as integrated mode, see Authenticating users by using an Active Directory database.

Procedure

To register a client, complete one of the following actions.

- If the client requires an administrative user ID, register the client by using the REGISTER NODE command and specify the USERID parameter:

  ```
  register node node_name password userid=node_name
  ```

  where *node_name* specifies the node name and *password* specifies the node password. For details, see Register a node.
- If the client does not require an administrative user ID, register the client by using the Operations Center Add Client wizard. Complete the following steps:
  a. On the Operations Center menu bar, click Clients.
  b. In the Clients table, click +Client.
  c. Complete the steps in the Add Client wizard:
     i. Specify that redundant data can be eliminated on both the client and server. In the Client-side data deduplication area, select the Enable check box.
     ii. In the Configuration window, copy the TCPSERVERADDRESS, TCPPORT, NODENAME, and DEDUPLICATION option values.
     Tip: Record the option values and keep them in a safe place. After you complete the client registration and install the software on the client node, use the values to configure the client.

iii. Follow the instructions in the wizard to specify the policy domain, schedule, and option set.
iv. Set how risks are displayed for the client by specifying the at-risk setting.
v. Click Add Client.

Installing the client management service

Install the client management service for backup-archive clients that run on Linux and Windows operating systems. The client management service collects diagnostic information about backup-archive clients and makes the information available to the Operations Center for basic monitoring capability.

Procedure

Install the client management service on the same computer as the backup-archive client by completing the following steps:

1. Download the installation package for the client management service from an IBM® download site such as IBM Passport Advantage® or IBM Fix Central. Look for a file name that is similar to `<version>-IBM_Spectrum_Protect-CMS-operating_system.bin`.
2. Create a directory on the client system that you want to manage, and copy the installation package there.
3. Extract the contents of the installation package file.
4. Run the installation batch file from the directory where you extracted the installation and associated files. This is the directory that you created in step 2.
5. To install the client management service, follow the instructions in the IBM Installation Manager wizard. If IBM Installation Manager is not already installed on the client system, you must select both IBM Installation Manager and IBM Spectrum Protect™ Client Management Services.

- Verifying that the client management service is installed correctly
  Before you use the client management service to collect diagnostic information about a backup-archive client, you can verify that the client management service is correctly installed and configured.
- Configuring the Operations Center to use the client management service
  If you did not use the default configuration for the client management service, you must configure the Operations Center to access the client management service.

Related tasks:
Configuring the client management service for custom client installations

Verifying that the client management service is installed correctly

Before you use the client management service to collect diagnostic information about a backup-archive client, you can verify that the client management service is correctly installed and configured.

Procedure

On the client system, at the command line, run the following commands to view the configuration of the client management service:

- On Linux client systems, issue the following command:

  ```
  client_install_dir/cms/bin/CmsConfig.sh list
  ```

  where *client_install_dir* is the directory where the backup-archive client is installed. For example, with the default client installation, issue the following command:

  ```
  /opt/tivoli/tsm/cms/bin/CmsConfig.sh list
  ```

  The output is similar to the following text:

  ```
  Listing CMS configuration

  server1.example.com:1500 NO_SSL HOSTNAME
  Capabilities: [LOG_QUERY]
      Opt Path: /opt/tivoli/tsm/client/ba/bin/dsm.sys

      Log File: /opt/tivoli/tsm/client/ba/bin/dsmerror.log
          en_US MM/dd/yyyy HH:mm:ss Windows-1252
  ```

```
    Log File: /opt/tivoli/tsm/client/ba/bin/dsmsched.log
        en_US MM/dd/yyyy HH:mm:ss Windows-1252
```

- On Windows client systems, issue the following command:

  ```
  client_install_dir\cms\bin\CmsConfig.bat list
  ```

  where *client_install_dir* is the directory where the backup-archive client is installed. For example, with the default client installation, issue the following command:

  ```
  C:\"Program Files"\Tivoli\TSM\cms\bin\CmsConfig.bat list
  ```

  The output is similar to the following text:

  ```
  Listing CMS configuration

  server1.example.com:1500 NO_SSL HOSTNAME
  Capabilities: [LOG_QUERY]
      Opt Path: C:\Program Files\Tivoli\TSM\baclient\dsm.opt

      Log File: C:\Program Files\Tivoli\TSM\baclient\dsmerror.log
          en_US MM/dd/yyyy HH:mm:ss Windows-1252

      Log File: C:\Program Files\Tivoli\TSM\baclient\dsmsched.log
          en_US MM/dd/yyyy HH:mm:ss Windows-1252
  ```

If the client management service is correctly installed and configured, the output displays the location of the error log file. The output text is extracted from the following configuration file:

- On Linux client systems:

  ```
  client_install_dir/cms/Liberty/usr/servers/cmsServer/client-configuration.xml
  ```

- On Windows client systems:

  ```
  client_install_dir\cms\Liberty\usr\servers\cmsServer\client-configuration.xml
  ```

If the output does not contain any entries, you must configure the client-configuration.xml file. For instructions to configure this file, see Configuring the client management service for custom client installations. You can use the CmsConfig verify command to verify that a node definition is correctly created in the client-configuration.xml file.

Configuring the Operations Center to use the client management service

If you did not use the default configuration for the client management service, you must configure the Operations Center to access the client management service.

Before you begin

Ensure that the client management service is installed and started on the client system. Verify whether the default configuration is used. The default configuration is not used if either of the following conditions is met:

- The client management service does not use the default port number, 9028.
- The backup-archive client is not accessed by the same IP address as the client system where the backup-archive client is installed. For example, a different IP address might be used in the following situations:
  - The computer system has two network cards. The backup-archive client is configured to communicate on one network, while the client management service communicates on the other network.
  - The client system is configured with the Dynamic Host Configuration Protocol (DHCP). As a result, the client system is dynamically assigned an IP address, which is saved on the server during the previous backup-archive client operation. When the client system is restarted, the client system might be assigned a different IP address. To ensure that the Operations Center can always find the client system, you specify a fully qualified domain name.

Procedure

To configure the Operations Center to use the client management service, complete the following steps:

1. On the Clients page of the Operations Center, select the client.

2. Click Details > Properties.
3. In the Remote diagnostics URL field in the General section, specify the URL for the client management service on the client system. The address must start with `https`. The following table shows examples of the remote diagnostics URL.

Type of URL	Example
With DNS host name and default port, 9028	https://server.example.com
With DNS host name and non-default port	https://server.example.com:1599
With IP address and non-default port	https://192.0.2.0:1599

4. Click Save.

What to do next

You can access client diagnostic information such as client log files from the Diagnosis tab in the Operations Center.

Configuring the second server

After you complete the configuration for the first server in your system, configure the second server.

Procedure

Complete the instructions in the following sections:

1. Configure a second server that is the same as the first server by completing the instructions in the following sections:
   a. Setting up the system
   b. Installing the server and Operations Center

      Only one server in the multisite disk solution is configured as the hub server, so you do not need to install the Operations Center on the second server. When you select the installation packages to install on the second server, do not select the Operations Center.

   c. Configuring the server and the Operations Center

      Skip the tasks for configuring the Operations Center.

   d. Installing and configuring backup-archive clients
2. Configuring SSL communications between the hub server and a spoke server
3. Adding the second server as a spoke
4. Enabling replication

Configuring SSL communications between the hub server and a spoke server

To secure communications between the hub server and a spoke server by using the Transport Layer Security (TLS) protocol, you must define the certificate of the spoke server to the hub server. You must also configure the Operations Center to monitor the spoke server.

Procedure

1. On the spoke server, change to the directory of the spoke server instance.
2. Specify the required cert256.arm certificate as the default certificate in the key database file of the spoke server. Issue the following command:

```
gsk8capicmd_64 -cert -setdefault -db cert.kdb -stashed
 -label "TSM Server SelfSigned SHA Key"
```

3. Verify the certificates in the key database file of the spoke server. Issue the following command:

```
gsk8capicmd_64 -cert -list -db cert.kdb -stashed
```

4. Securely transfer the cert256.arm file of the spoke server to the hub server.
5. On the hub server, change to the directory of the hub server instance.

6. Define the spoke server certificate to the hub server. Issue the following command from the hub server instance directory, where *spoke_servername* is the name of the spoke server, and *spoke_cert256.arm* is the file name of the spoke server certificate:

   ```
   gsk8capicmd_64 -cert -add -db cert.kdb -stashed -format ascii
    -label spoke_servername -file spoke_cert256.arm
   ```

   The spoke server does not require the hub server certificate for hub-to-spoke communication. However, other server configurations that require cross-defined servers do require the spoke server to have the hub server certificate.
7. Restart the hub server and the spoke server.
8. For the hub server, issue the DEFINE SERVER command, according to the following example:

   ```
   DEFINE SERVER spoke_servername HLA=spoke_address
    LLA=spoke_SSLTCPADMINPort SERVERPA=spoke_serverpassword
   ```

   Tip: By default, server communication is encrypted except when the server is sending or receiving object data. Object data is sent and received by using TCP/IP. By choosing not to encrypt the object data, server performance is similar to communication over a TCP/IP session and the session is secure. To encrypt all communication with the specified server, even when the server is sending and receiving object data, specify the SSL=YES parameter on the DEFINE SERVER command.
9. On the Operations Center menu bar, click Servers.

   In the table on the Servers page, the spoke server that you defined in step 8 typically has a status of "Unmonitored." Depending on the setting for the status refresh interval, you might not see the spoke server immediately.
10. Click the spoke server to highlight the item, and in the table menu bar, click Monitor Spoke.

Related reference:
DEFINE SERVER (Define a server for server-to-server communications)
QUERY OPTION (Query server options)

Adding the second server as a spoke

After you configure both servers in your environment, add the second server as a spoke to the hub server.

Procedure

1. Open the Operations Center.
2. In the Operations Center menu bar, click Servers.
3. Complete one of the following steps:
   - Click the server to highlight it, and in the table menu bar, click Monitor Spoke.
   - If the server that you want to add is not shown in the table, click +Spoke.
4. Complete the steps in the spoke configuration wizard.

Enabling replication

To protect your data, enable node replication in addition to protecting your storage pools.

Procedure

To enable node replication for all of the clients that are registered to the source server, complete the following steps

1. Open the Operations Center.
2. On the Operations Center menu bar, hover over Storage and click Replication.
3. On the Replication page, click +Server Pair.
4. Complete the steps in the Add Server Pair wizard:
   - Set the source server as the first server that you configured for the multisite disk solution. The target server is the second server.
   - Set the node replication schedule to start 10 hours after the client backup window, based on the server maintenance activities that you scheduled in Defining schedules for server maintenance activities.
   - The wizard sets up storage pool protection schedules for you, based on the amount of data that you are protecting and when client replication is scheduled.

What to do next

If you plan to set up mutual replication between the two sites, run the Add Server Pair wizard again and set the second server as the source and the first server as the target.

Completing the implementation

After the IBM Spectrum Protect™ solution is configured and running, test backup operations and set up monitoring to ensure that everything runs smoothly.

Procedure

1. Test backup operations to verify that your data is protected in the way that you expect.
    a. On the Clients page of the Operations Center, select the clients that you want to back up, and click Back Up.
    b. On the Servers page of the Operations Center, select the server for which you want to back up the database. Click Back Up, and follow the instructions in the Back Up Database window.
    c. Verify that the backup operations completed successfully with no warning or error messages.
    Tip: Alternatively, you can use the backup-archive client GUI to back up client data and you can backup the server database by issuing BACKUP DB command from an administrative command-line.
2. Set up monitoring for your solution by following the instructions in Monitoring a multisite disk solution.

Monitoring a multisite disk solution

After you implement a multisite disk solution with IBM Spectrum Protect™, monitor the solution to ensure correct operation. By monitoring the solution daily and periodically, you can identify existing and potential issues. The information that you gather can be used to troubleshoot problems and optimize system performance.

About this task

The preferred way to monitor a solution is by using the Operations Center, which provides overall and detailed system status in a graphical user interface. In addition, you can configure the Operations Center to generate a daily email report that summarizes system status.

In some cases, you might want to use advanced monitoring tools to complete specific monitoring or troubleshooting tasks.

Tip: If you plan to diagnose issues with backup-archive clients on Linux or Windows operating systems, install IBM Spectrum Protect client management services on each computer where a backup-archive client is installed. In this way, you can ensure that the Diagnose button is available in the Operations Center for diagnosing issues with backup-archive clients. To install the client management service, follow the instructions in Installing the client management service.

Procedure

1. Complete daily monitoring tasks. For instructions, see Daily monitoring checklist.
2. Complete periodic monitoring tasks. For instructions, see Periodic monitoring checklist.
3. To verify that your IBM Spectrum Protect solution complies with licensing requirements, follow the instructions in Verifying license compliance.
4. To set up Operations Center to generate email status reports, see Tracking system status by using email reports

What to do next

Resolve any issues that you detect. To resolve an issue by changing the configuration of your solution, follow the instructions in Managing operations for a multisite disk solution. The following resources are also available:

- To resolve performance issues, see Performance.
- To resolve other types of issues, see Troubleshooting.

Daily monitoring checklist

To ensure that you are completing the daily monitoring tasks for your IBM Spectrum Protect™ solution, review the daily monitoring checklist.

Complete the daily monitoring tasks from the Operations Center Overview page. You can access the Overview page by opening the Operations Center and clicking Overviews.

The following figure shows the location for completing each task.

Tip: To run administrative commands for advanced monitoring tasks, use the Operations Center command builder. The command builder provides a type-ahead function to guide you as you enter commands. To open the command builder, go to the Operations Center Overview page. On the menu bar, hover over the settings icon and click Command Builder.

The following table lists the daily monitoring tasks and provides instructions for completing each task.

Table 1. Daily monitoring tasks

Task	Basic procedures	Advanced procedures and troubleshooting information
1 Determine whether clients are at risk of being unprotected due to failed or missed backup operations.	To verify whether clients are at risk, in the Clients area, look for an At risk notification. To view details, click the Clients area. If you installed the client management service on a backup-archive client, you can view and analyze the client error and schedule logs by completing the following steps: 1. In the Clients table, select the client and click Details. 2. To diagnose an issue, click Diagnosis.	For clients that do not have the client management service installed, access the client system to review the client error logs.
2 Determine whether client-related or server-related errors require attention.	To determine the severity of any reported alerts, in the Alerts area, hover over the columns.	To view additional information about alerts, complete the following steps: 1. Click the Alerts area. 2. In the Alerts table, select an alert. 3. In the Activity Log pane, review the messages. The pane displays related messages that were issued before and after the selected alert occurred.

Task	Basic procedures	Advanced procedures and troubleshooting information
3 Determine whether servers that are managed by the Operations Center are available to provide data protection services to clients.	1. To verify whether servers are at risk, in the Servers area, look for an Unavailable notification. 2. To view additional information, click the Servers area. 3. Select a server in the Servers table and click Details.	Tip: If you detect an issue that is related to server properties, update the server properties: 1. In the Servers table, select a server and click Details. 2. To update server properties, click Properties.
4 Determine whether sufficient space is available for the server inventory, which consists of the server database, active log, and archive log.	1. Click the Servers area. 2. In the Status column of the table, view the status of the server and resolve any issues: ○ Normal Sufficient space is available for the server database, active log, and archive log. ○ Critical Insufficient space is available for the server database, active log, or archive log. You must add space immediately, or the data protection services that are provided by the server will be interrupted. ○ Warning The server database, active log, or archive log is running out of space. If this condition persists, you must add space. ○ Unavailable Status cannot be obtained. Ensure that the server is running, and that there are no network issues. This status is also shown if the monitoring administrator ID is locked or otherwise unavailable on the server. This ID is named IBM-OC-hub_server_name. ○ Unmonitored Unmonitored servers are defined to the hub server, but are not configured for management by the Operations Center. To configure an unmonitored server, select the server, and click Monitor Spoke.	You can also look for related alerts on the Alerts page. For additional instructions about troubleshooting, see Resolving server problems.

Task	Basic procedures	Advanced procedures and troubleshooting information
5 Verify server database backup operations.	To determine when a server was most recently backed up, complete the following steps: 1. Click the Servers area. 2. In the Servers table, review the Last Database Backup column.	To obtain more detailed information about backup operations, complete the following steps: 1. In the Servers table, select a row and click Details. 2. In the DB Backup area, hover over the check marks to review information about backup operations. If a database was not backed up recently (for example, in the last 24 hours), you can start a backup operation: 1. On the Operations Center Overview page, click the Servers area. 2. In the table, select a server and click Back Up. To determine whether the server database is configured for automatic backup operations, complete the following steps: 1. On the menu bar, hover over the settings icon  and click Command Builder. 2. Issue the QUERY DB command: `query db f=d` 3. In the output, review the `Full Device Class Name` field. If a device class is specified, the server is configured for automatic database backups.
6 Monitor other server maintenance tasks. Server maintenance tasks can include running administrative command schedules, maintenance scripts, and related commands.	To search for information about processes that failed because of server issues, complete the following steps: 1. Click Servers > Maintenance. 2. To obtain the two-week history of a process, view the History column. 3. To obtain more information about a scheduled process, hover over the check box that is associated with the process.	For more information about monitoring processes and resolving issues, see the Operations Center online help.
7 Verify that the amount of data that was recently sent to and from servers is within the expected range.	• To obtain an overview of activity in the last 24 hours, view the Activity area. • To compare activity in the last 24 hours with activity in the previous 24 hours, review the figures in the Current and Previous areas.	• If more data was sent to the server than you expected, determine which clients are backing up more data and investigate the cause. It is possible that client-side data deduplication is not working correctly. • If less data was sent to the server than you expected, investigate whether client backup operations are proceeding on schedule.

Task	Basic procedures	Advanced procedures and troubleshooting information
8 Verify that storage pools are available to back up client data.	1. If problems are indicated in the Storage & Data Availability area, click Pools to view the details: ○ If the Critical status is displayed, insufficient space is available in the storage pool, or its access status is unavailable. ○ If the Warning status is displayed, the storage pool is running out of space, or its access status is read-only. 2. To view the used, free, and total space for your selected storage pool, hover over the entries in the Capacity Used column.	To view the storage-pool capacity that was used over the past two weeks, select a row in the Storage Pools table and click Details.
9 Verify that storage devices are available for backup operations.	In the Storage & Data Availability area, in the Volumes section, under the capacity bars, review the status that is reported next to Devices. If a Critical or Warning status is displayed for any device, investigate the issue. To view details, click Devices.	Disk devices might have a critical or warning status for the following reasons: • For DISK device classes, volumes might be offline or have a read-only access status. The Disk Storage column of the Disk Devices table shows the state of volumes. • For FILE device classes that are not shared, directories might be offline. Also, insufficient free space might be available for allocating scratch volumes. The Disk Storage column of the Disk Devices table shows the state of directories. • For FILE device classes that are shared, drives might be unavailable. A drive is unavailable if it is offline, if it stopped responding to the server, or if its path is offline. Other columns of the Disk Devices table show the state of the drives and paths.

Task	Basic procedures	Advanced procedures and troubleshooting information
10 Monitor node replication processes.	1. To obtain the overall status of node replication processes, view the Replication area on the Operations Center Overview page. 2. To view information about each replicated server pair, click the Replication area. 3. To view the amount of data that was replicated over the last two weeks and the speed of replication, select a server pair and click Details. 4. To view replication information for a client, on the Operations Center Overview page, click Clients. View the information in the Replication Workload column.	For advanced monitoring, view information about running and ended node replication processes by using commands: 1. On the Operations Center Overview page, hover over the settings icon and click Command Builder. 2. Issue the QUERY REPLICATION command. For instructions, see QUERY REPLICATION (Query node replication processes). If the replication operation was completed successfully, the `Total Files To Replicate` value matches the `Total Files Replicated` value. To display messages that are related to a node replication process on a source or target replication server, complete the following steps: 1. On the Operations Center Overview page, click Servers. 2. Select the source or target replication server and click Details: ○ To view active tasks, click Active Tasks, select the task, and verify that the Running status is displayed. For details, view the related activity logs. ○ To view completed tasks, click Completed Tasks, select the task, and ensure that the Completed status is displayed. For details, view the related activity logs.

Periodic monitoring checklist

To help ensure that your solution operates correctly, complete the tasks in the periodic monitoring checklist. Schedule periodic tasks frequently enough so that you can detect potential issues before they become problematic.

Tip: To run administrative commands for advanced monitoring tasks, use the Operations Center command builder. The command builder provides a type-ahead function to guide you as you enter commands. To open the command builder, go to the Operations Center Overview page. On the menu bar, hover over the settings icon and click Command Builder.

Table 1. Periodic monitoring tasks

Task	Basic procedures	Advanced procedures and troubleshooting

Task	Basic procedures	Advanced procedures and troubleshooting
Monitor system performance.	Determine the length of time that is required for client backup operations: 1. On the Operations Center Overview page, click Clients. Find the server that is associated with the client. 2. Click Servers. Select the server and click Details. 3. To view the duration of completed tasks in the last 24 hours, click Completed Tasks. 4. To view the duration of tasks that were completed more than 24 hours ago, use the QUERY ACTLOG command. Follow the instructions in QUERY ACTLOG (Query the activity log). 5. If the duration of client backup operations is increasing and the reasons are not clear, investigate the cause. If you installed the client management service on a backup-archive client, you can diagnose performance issues for the backup-archive client by completing the following steps: 1. On the Operations Center Overview page, click Clients. 2. Select a backup-archive client and click Details. 3. To retrieve client logs, click Diagnosis.	For instructions about reducing the time that it takes for the client to back up data to the server, see Resolving common client performance problems. Look for performance bottlenecks. For instructions, see Identifying performance bottlenecks. For information about identifying and resolving other performance issues, see Performance.
Determine the disk savings that are provided by data deduplication.	1. On the Operations Center Overview page, click Pools. 2. Select a pool and click Quick Look. 3. In the Data Deduplication area, view the Space saved row.	For advanced monitoring, to obtain detailed statistics about the data-deduplication process for a specific directory-container storage pool or cloud-container storage pool, complete the following steps: 1. On the Operations Center Overview page, hover over the settings icon and click Command Builder. 2. Obtain a statistical report by issuing the GENERATE DEDUPSTATS command. Follow the instructions in GENERATE DEDUPSTATS (Generate data deduplication statistics for a directory-container storage pool). 3. View the statistical report by issuing the QUERY DEDUPSTATS command. Follow the instructions in QUERY DEDUPSTATS (Query data deduplication statistics).

Task	Basic procedures	Advanced procedures and troubleshooting
Verify that current backup files for device configuration and volume history information are saved.	Access your storage locations to ensure that the files are available. The preferred method is to save the backup files to two locations. To locate the volume history and device configuration files, complete the following steps: 1. On the Operations Center Overview page, hover over the settings icon  and click Command Builder. 2. To locate the volume history and device configuration files, issue the following commands: `query option volhistory` `query option devconfig` 3. In the output, review the Option Setting column to find the file locations. If a disaster occurs, both the volume history file and the device configuration file are required to restore the server database.	

Task	Basic procedures	Advanced procedures and troubleshooting
Determine whether sufficient space is available for the instance directory file system.	Verify that at least 20% of free space is available in the instance directory file system. Take the action that is appropriate for your operating system: • AIX To view available space in the file system, on the operating system command line, issue the following command: `df -g instance_directory` where *instance_directory* specifies the instance directory. • Linux To view available space in the file system, on the operating system command line, issue the following command: `df -h instance_directory` where *instance_directory* specifies the instance directory. • Windows In the Windows Explorer program, right-click the file system and click Properties. View the capacity information. The preferred location of the instance directory depends on the operating system where the server is installed: • AIX Linux /home/tsminst1/tsminst1 • Windows C:\tsminst1 Tip: If you completed a planning worksheet, the location of the instance directory is recorded in the worksheet.	
Identify unexpected client activity.	To monitor client activity to determine whether data volumes exceed expected amounts, complete the following steps: 1. On the Operations Center Overview page, click the Clients area. 2. To view activity over the past two weeks, double-click any client. 3. To view the number of bytes sent to the client, click the Properties tab. 4. In the Last Session area, view the Sent to client row.	When you double-click a client in the Clients table, the Activity over 2 Weeks area displays the amount of data that the client sent to the server each day.

Task	Basic procedures	Advanced procedures and troubleshooting
Monitor storage pool growth over time.	1. On the Operations Center Overview page, click the Pools area. 2. To view the capacity that was used over the last two weeks, select a pool and click Details.	Tips: • To specify the time period that must elapse before all deduplicated extents are removed from a directory-container storage pool or cloud-container storage pool after they are no longer referenced by the inventory, complete the following steps: 1. On the Storage Pools page of the Operations Center, select the storage pool. 2. Click Details > Properties. 3. Specify the duration in the `Delay period for container reuse` field. • To determine data deduplication performance for directory-container and cloud-container storage pools, use the GENERATE DEDUPSTATS command. • To view data deduplication statistics for a storage pool, complete the following steps: 1. On the Storage Pools page of the Operations Center, select the storage pool. 2. Click Details > Properties. Alternatively, use the QUERY EXTENTUPDATES command to display information about updates to data extents in directory-container or cloud-container storage pools. The command output can help you determine which data extents are no longer referenced and which ones are eligible to be deleted from the system. In the output, monitor the number of data extents that are eligible to be deleted from the system. This metric has a direct correlation to the amount of free space that will be available within the container storage pool. • To display the amount of physical space that is occupied by a file space after the removal of the data deduplication savings, use the select * from occupancy command. The command output includes the LOGICAL_MB value. LOGICAL_MB is the amount of space that is used by the file space.
Evaluate the timing of client schedules. Ensure that the start and end times of client schedules meet your business needs.	On the Operations Center Overview page, click Clients > Schedules. In the Schedules table, the Start column displays the configured start time for the scheduled operation. To see when the most recent operation was started, hover over the clock icon.	Tip: You can receive a warning message if a client operation runs longer than expected. Complete the following steps: 1. On the Operations Center Overview page, hover over Clients and click Schedules. 2. Select a schedule and click Details. 3. View the details of a schedule by clicking the blue arrow next to the row. 4. In the Run time alert field, specify the time when a warning message will be issued if the scheduled operation is not completed. 5. Click Save.

Task	Basic procedures	Advanced procedures and troubleshooting
Evaluate the timing of maintenance tasks. Ensure that the start and end times of maintenance tasks meet your business needs.	On the Operations Center Overview page, click Servers > Maintenance. In the Maintenance table, review the information in the Last Run Time column. To see when the last maintenance task was started, hover over the clock icon.	Tip: If a maintenance task is running too long, change the start time or the maximum run time. Complete the following steps: 1. On the Operations Center Overview page, hover over the settings icon and click Command Builder. 2. To change the start time or maximum run time for a task, issue the UPDATE SCHEDULE command. For instructions, see UPDATE SCHEDULE (Update a client schedule).

UPDATE STGPOOL (Update a storage pool)
QUERY EXTENTUPDATES (Query updated data extents)

Verifying license compliance

Verify that your IBM Spectrum Protect™ solution complies with the provisions of your licensing agreement. By verifying compliance regularly, you can track trends in data growth or processor value unit (PVU) usage. Use this information to plan for future license purchasing.

About this task

The method that you use to verify that your solution complies with license terms varies depending on the provisions of your IBM Spectrum Protect licensing agreement.

Front-end capacity licensing
: The front-end model determines license requirements based on the amount of primary data that is reported as being backed up by clients. Clients include applications, virtual machines, and systems.

Back-end capacity licensing
: The back-end model determines license requirements based on the terabytes of data that are stored in primary storage pools and repositories.
Tips:

- To ensure the accuracy of front-end and back-end capacity estimates, install the most recent version of the client software on each client node.
- The front-end and back-end capacity information in the Operations Center is for planning and estimation purposes.

PVU licensing
: The PVU model is based on the use of PVUs by server devices.
Important: The PVU calculations that are provided by IBM Spectrum Protect are considered estimates and are not legally binding. The PVU licensing information that is reported by IBM Spectrum Protect is not considered an acceptable substitute for the IBM® License Metric Tool.

For the most recent information about licensing models, see the information about product details and licenses at the IBM Spectrum Protect product family website. If you have questions or concerns about licensing requirements, contact your IBM Spectrum Protect software provider.

Procedure

To monitor license compliance, complete the steps that correspond to the provisions of your licensing agreement.
Tip: The Operations Center provides an email report that summarizes front-end and back-end capacity usage. Reports can be sent automatically to one or more recipients regularly. To configure and manage email reports, click Reports on the Operations Center menu bar.

Option	Description

Option	Description
Front-end model	a. On the Operations Center menu bar, hover over the settings icon and click Licensing. The front-end capacity estimate is displayed on the Front-end Usage page. b. If a value is displayed in the Not Reporting column, click the number to identify clients that did not report capacity usage. c. To estimate capacity for clients that did not report capacity usage, go to the following FTP site, which provides measuring tools and instructions: ftp://public.dhe.ibm.com/storage/tivoli-storage-management/front_end_capacity_measurement_tools To measure front-end capacity by script, complete the instructions in the most recently available licensing guide. d. Add the Operations Center estimate and any estimates that you obtained by using a script. e. Verify that the estimated capacity complies with your licensing agreement.
Back-end model	Restriction: If the source and target replication servers do not use the same policy settings, you cannot use the Operations Center to monitor back-end capacity usage for replicated clients. For information about how to estimate capacity usage for these clients, see technote 1656476. a. On the Operations Center menu bar, hover over the settings icon and click Licensing. b. Click the Back-end tab. c. Verify that the estimated amount of data complies with your licensing agreement.
PVU model	For information about how to assess compliance with PVU licensing terms, see Assessing compliance with the PVU licensing model.

Tracking system status by using email reports

Set up the Operations Center to generate email reports that summarize system status. You can configure a mail server connection, change report settings, and optionally create custom SQL reports.

Before you begin

Before you set up email reports, ensure that the following requirements are met:

- A Simple Mail Transfer Protocol (SMTP) host server is available to send and receive reports by email. The SMTP server must be configured as an open mail relay. You must also ensure that the IBM Spectrum Protect™ server that sends email messages has access to the SMTP server. If the Operations Center is installed on a separate computer, that computer does not require access to the SMTP server.
- To set up email reports, you must have system privilege for the server.
- To specify the recipients, you can enter one or more email addresses or administrator IDs. If you plan to enter an administrator ID, the ID must be registered on the hub server and must have an email address associated with it. To specify an email address for an administrator, use the EMAILADDRESS parameter of the UPDATE ADMIN command.

About this task

You can configure the Operations Center to send a general operations report, a license compliance report, and one or more custom reports, which use SQL SELECT statements to query managed servers.

Procedure

To set up and manage email reports, complete the following steps:

1. On the Operations Center menu bar, click Reports.
2. If an email server connection is not yet configured, click Configure Mail Server and complete the fields. After you configure the mail server, the general operations report and license compliance report are enabled.
3. To change report settings, select a report, click Details, and update the form.

4. Optional: To add a custom SQL report, click + Report, and complete the fields.
   Tip: To immediately run and send a report, select the report and click Send.

Results

Enabled reports are sent according to the specified settings.

UPDATE ADMIN (Update an administrator)

Managing operations for a multisite disk solution

Use this information to manage operations for a multisite disk solution with IBM Spectrum Protect™ that includes a server and uses data deduplication for multiple locations.

- Managing the Operations Center
  The Operations Center provides web and mobile access to status information about the IBM Spectrum Protect environment. You can use the Operations Center to monitor multiple servers and to complete some administrative tasks. The Operations Center also provides web access to the IBM Spectrum Protect command line.
- Protecting applications, virtual machines, and systems
  The server protects data for clients, which can include applications, virtual machines, and systems. To start protecting client data, register the client node with the server and select a backup schedule to protect the client data.
- Managing data storage
  Manage your data for efficiency and add supported devices and media to the server to store client data.
- Managing replication
  Use replication to recover data at a disaster recovery site and to maintain the same level of files on the source and target servers. You can manage replication at the node level. You can also protect data at the storage-pool level.
- Securing the server
  Secure the IBM Spectrum Protect server and data by controlling access to servers and client nodes, encrypting data, and maintaining secure access levels and passwords.
- Stopping and starting the server
  Before you complete maintenance or reconfiguration tasks, stop the server. Then, start the server in maintenance mode. When you are finished with the maintenance or reconfiguration tasks, restart the server in production mode.
- Planning to upgrade the server
  When a fix pack or interim fix becomes available, you can upgrade the IBM Spectrum Protect server to take advantage of product improvements. Servers and clients can be upgraded at different times. Ensure that you complete the planning steps before you upgrade the server.
- Preparing for an outage or system update
  Prepare IBM Spectrum Protect to maintain your system in a consistent state during a planned power outage or system update.
- Implementing a disaster recovery plan
  Implement a disaster recovery strategy to recover your applications if a disaster occurs and to ensure high server availability.
- Recovering from data loss or system outages
  You can use IBM Spectrum Protect to recover data that was lost when a disaster or system outage occurred. You can recover directory-container storage pools, client data, and databases.

Managing the Operations Center

The Operations Center provides web and mobile access to status information about the IBM Spectrum Protect™ environment. You can use the Operations Center to monitor multiple servers and to complete some administrative tasks. The Operations Center also provides web access to the IBM Spectrum Protect command line.

- Adding and removing spoke servers
  In a multiple-server environment, you can connect the other servers, called *spoke servers*, to the hub server.
- Starting and stopping the web server
  The web server of the Operations Center runs as a service and starts automatically. You might have to stop and start the web server, for example, to make configuration changes.
- Restarting the initial configuration wizard
  You might need to restart the initial configuration wizard of the Operations Center, for example, to make configuration changes.

- Changing the hub server
  You can use the Operations Center to remove the hub server of IBM Spectrum Protect, and configure another hub server.
- Restoring the configuration to the preconfiguration state
  If certain problems occur, you might want to restore the Operations Center configuration to the preconfigured state where the IBM Spectrum Protect servers are not defined as hub or spoke servers.

Adding and removing spoke servers

In a multiple-server environment, you can connect the other servers, called *spoke servers*, to the hub server.

About this task

The spoke servers send alerts and status information to the hub server. The Operations Center shows you a consolidated view of alerts and status information for the hub server and any spoke servers.

- Adding a spoke server
  After you configure the hub server for the Operations Center, you can add one or more spoke servers to the hub server.
- Removing a spoke server
  You can remove a spoke server from the Operations Center.

Adding a spoke server

After you configure the hub server for the Operations Center, you can add one or more spoke servers to the hub server.

Before you begin

Communication between the spoke server and the hub server must be secured by using the Transport Layer Security (TLS) protocol. To secure communication, add the certificate of the spoke server to the truststore file of the hub server.

Procedure

1. In the Operations Center menu bar, click Servers. The Servers page opens.

   In the table on the Servers page, a server might have a status of "Unmonitored." This status means that although an administrator defined this server to the hub server by using the DEFINE SERVER command, the server is not yet configured as a spoke server.

2. Complete one of the following steps:
   - Click the server to highlight it, and in the table menu bar, click Monitor Spoke.
   - If the server that you want to add is not shown in the table, and secure SSL/TLS communication is not required, click + Spoke in the table menu bar.
3. Provide the necessary information, and complete the steps in the spoke configuration wizard.
   Tip: If the event-record retention period of the server is less than 14 days, the period is automatically reset to 14 days if you configure the server as a spoke server.

Removing a spoke server

You can remove a spoke server from the Operations Center.

About this task

You might need to remove a spoke server in the following situations, for example:

- You want to move the spoke server from one hub server to another hub server.
- You want to decommission the spoke server.

Procedure

To remove the spoke server from the group of servers that are managed by the hub server, complete the following steps:

1. From the IBM Spectrum Protect™ command line, issue the following command on the hub server:

   ```
   QUERY MONITORSETTINGS
   ```

2. From the output of the command, copy the name that is in the Monitored Group field.
3. Issue the following command on the hub server, where *group_name* represents the name of the monitored group, and *member_name* represents the name of the spoke server:

   ```
   DELETE GRPMEMBER group_name member_name
   ```

4. Optional: If you want to move the spoke server from one hub server to another hub server, do **not** complete this step. Otherwise, you can disable alerting and monitoring on the spoke server by issuing the following commands on the spoke server:

   ```
   SET STATUSMONITOR OFF
   SET ALERTMONITOR OFF
   ```

5. Optional: If the spoke server definition is used for other purposes, such as enterprise configuration, command routing, storing virtual volumes, or library management, do **not** complete this step. Otherwise, you can delete the spoke server definition on the hub server by issuing the following command on the hub server:

   ```
   DELETE SERVER spoke_server_name
   ```

Starting and stopping the web server

The web server of the Operations Center runs as a service and starts automatically. You might have to stop and start the web server, for example, to make configuration changes.

Procedure

1. Stop the web server.
   - AIX From the */installation_dir*/ui/utils directory, where *installation_dir* represents the directory where the Operations Center is installed, issue the following command:

     ```
     ./stopserver.sh
     ```

   - Linux Issue the following command:

     ```
     service opscenter.rc stop
     ```

   - Windows From the Services window, stop the IBM Spectrum Protect™ Operations Center service.
2. Start the web server.
   - AIX From the */installation_dir*/ui/utils directory, where *installation_dir* represents the directory where the Operations Center is installed, issue the following command:

     ```
     ./startserver.sh
     ```

   - Linux Issue the following commands:

     Start the server:

     ```
     service opscenter.rc start
     ```

     Restart the server:

     ```
     service opscenter.rc restart
     ```

     Determine whether the server is running:

     ```
     service opscenter.rc status
     ```

   - Windows From the Services window, start the IBM Spectrum Protect Operations Center service.

Restarting the initial configuration wizard

You might need to restart the initial configuration wizard of the Operations Center, for example, to make configuration changes.

Before you begin

To change the following settings, use the Settings page in the Operations Center rather than restarting the initial configuration wizard:

- The frequency at which status data is refreshed
- The duration that alerts remain active, inactive, or closed
- The conditions that indicate that clients are at risk

The Operations Center help includes more information about how to change these settings.

About this task

To restart the initial configuration wizard, you must delete a properties file that includes information about the hub server connection. However, any alerting, monitoring, at-risk, or multiserver settings that were configured for the hub server are not deleted. These settings are used as the default settings in the configuration wizard when the wizard restarts.

Procedure

1. Stop the Operations Center web server.
2. On the computer where the Operations Center is installed, go to the following directory, where *installation_dir* represents the directory in which the Operations Center is installed:
   - AIX Linux *installation_dir*/ui/Liberty/usr/servers/guiServer
   - Windows *installation_dir*\ui\Liberty\usr\servers\guiServer

   For example:
   - AIX Linux /opt/tivoli/tsm/ui/Liberty/usr/servers/guiServer
   - Windows c:\Program Files\Tivoli\TSM\ui\Liberty\usr\servers\guiServer
3. In the guiServer directory, delete the serverConnection.properties file.
4. Start the Operations Center web server.
5. Open the Operations Center.
6. Use the configuration wizard to reconfigure the Operations Center. Specify a new password for the monitoring administrator ID.
7. On any spoke servers that were previously connected to the hub server, update the password for the monitoring administrator ID by issuing the following command from the IBM Spectrum Protect™ command-line interface:

   ```
   UPDATE ADMIN IBM-OC-hub_server_name new_password
   ```

   Restriction: Do not change any other settings for this administrator ID. After you specify the initial password, this password is managed automatically by the Operations Center.

Changing the hub server

You can use the Operations Center to remove the hub server of IBM Spectrum Protect™, and configure another hub server.

Procedure

1. Restart the initial configuration wizard of the Operations Center. As part of this procedure, you delete the existing hub server connection.
2. Use the wizard to configure the Operations Center to connect to the new hub server.

Related tasks:
Restarting the initial configuration wizard

Restoring the configuration to the preconfiguration state

If certain problems occur, you might want to restore the Operations Center configuration to the preconfigured state where the IBM Spectrum Protect™ servers are not defined as hub or spoke servers.

Procedure

To restore the configuration, complete the following steps:

1. Stop the Operations Center web server.
2. Unconfigure the hub server by completing the following steps:
   a. On the hub server, issue the following commands:

      ```
      SET MONITORINGADMIN ""
      SET MONITOREDSERVERGROUP ""
      SET STATUSMONITOR OFF
      SET ALERTMONITOR OFF
      REMOVE ADMIN IBM-OC-hub_server_name
      ```

      Tip: `IBM-OC-hub_server_name` represents the monitoring administrator ID that was automatically created when you initially configured the hub server.
   b. Reset the password for the hub server by issuing the following command on the hub server:

      ```
      SET SERVERPASSWORD ""
      ```

      Attention: Do not complete this step if the hub server is configured with other servers for other purposes, such as library sharing, exporting and importing of data, or node replication.
3. Unconfigure any spoke servers by completing the following steps:
   a. On the hub server, to determine whether any spoke servers remain as members of the server group, issue the following command:

      ```
      QUERY SERVERGROUP IBM-OC-hub_server_name
      ```

      Tip: `IBM-OC-hub_server_name` represents the name of the monitored server group that was automatically created when you configured the first spoke server. This server group name is also the same as the monitoring administrator ID that was automatically created when you initially configured the hub server.
   b. On the hub server, to delete spoke servers from the server group, issue the following command for each spoke server:

      ```
      DELETE GRPMEMBER IBM-OC-hub_server_name spoke_server_name
      ```

   c. After all spoke servers are deleted from the server group, issue the following commands on the hub server:

      ```
      DELETE SERVERGROUP IBM-OC-hub_server_name
      SET MONITOREDSERVERGROUP ""
      ```

   d. On each spoke server, issue the following commands:

      ```
      REMOVE ADMIN IBM-OC-hub_server_name
      SETOPT PUSHSTATUS NO
      SET ALERTMONITOR OFF
      SET STATUSMONITOR OFF
      ```

   e. On each spoke server, delete the definition of the hub server by issuing the following command:

      ```
      DELETE SERVER hub_server_name
      ```

      Attention: Do not complete this step if the definition is used for other purposes, such as library sharing, exporting and importing of data, or node replication.
   f. On the hub server, delete the definition of each spoke server by issuing the following command:

      ```
      DELETE SERVER spoke_server_name
      ```

      Attention: Do not complete this step if the server definition is used for other purposes, such as library sharing, exporting and importing of data, or node replication.
4. Restore the default settings on each server by issuing the following commands:

   ```
   SET STATUSREFRESHINTERVAL 5
   SET ALERTUPDATEINTERVAL 10
   SET ALERTACTIVEDURATION 480
   SET ALERTINACTIVEDURATION 480
   SET ALERTCLOSEDDURATION 60
   SET STATUSATRISKINTERVAL TYPE=AP INTERVAL=24
   SET STATUSATRISKINTERVAL TYPE=VM INTERVAL=24
   SET STATUSATRISKINTERVAL TYPE=SY INTERVAL=24
   SET STATUSSKIPASFAILURE YES TYPE=ALL
   ```

5. Restart the initial configuration wizard of the Operations Center.

Restarting the initial configuration wizard
Starting and stopping the web server

Protecting applications, virtual machines, and systems

The server protects data for clients, which can include applications, virtual machines, and systems. To start protecting client data, register the client node with the server and select a backup schedule to protect the client data.

- Adding clients
  After you implement a data protection solution with IBM Spectrum Protect, you can expand the solution by adding clients.
- Managing client operations
  You can evaluate and resolve errors that are related to a backup-archive client by using the Operations Center, which provides suggestions for resolving errors. For errors on other types of clients, you must examine the error logs on the client and review the product documentation.
- Managing client upgrades
  When a fix pack or interim fix becomes available for a client, you can upgrade the client to take advantage of product improvements. Servers and clients can be upgraded at different times and can be at different levels with some restrictions.
- Decommissioning a client node
  If a client node is no longer required, you can start a process to remove it from the production environment. For example, if a workstation was backing up data to the IBM Spectrum Protect server, but the workstation is no longer used, you can decommission the workstation.
- Deactivating data to free storage space
  In some cases, you can deactivate data that is stored on the IBM Spectrum Protect server. When you run the deactivation process, any backup data that was stored before the specified date and time is deactivated and will be deleted as it expires. In this way, you can free space on the server.

Adding clients

After you implement a data protection solution with IBM Spectrum Protect™, you can expand the solution by adding clients.

About this task

The procedure describes basic steps for adding a client. For more specific instructions about configuring clients, see the documentation for the product that you install on the client node. You can have the following types of client nodes:

Application client nodes
: Application client nodes include email servers, databases, and other applications. For example, any of the following applications can be an application client node:

  - IBM Spectrum Protect Snapshot
  - IBM Spectrum Protect for Databases
  - IBM Spectrum Protect for Enterprise Resource Planning
  - IBM Spectrum Protect for Mail
  - IBM Spectrum Protect for Virtual Environments

System client nodes
: System client nodes include workstations, network-attached storage (NAS) file servers, and API clients.

Virtual machine client nodes
: Virtual machine client nodes consist of an individual guest host within a hypervisor. Each virtual machine is represented as a file space.

Procedure

To add a client, complete the following steps:

1. Select the software to install on the client node and plan the installation. Follow the instructions in Selecting the client software and planning the installation.
2. Specify how to back up and archive client data. Follow the instructions in Specifying rules for backing up and archiving client data.
3. Specify when to back up and archive client data. Follow the instructions in Scheduling backup and archive operations.
4. To allow the client to connect to the server, register the client. Follow the instructions in Registering clients.

5. To start protecting a client node, install and configure the selected software on the client node. Follow the instructions in Installing and configuring clients.

Selecting the client software and planning the installation

Different types of data require different types of protection. Identify the type of data that you must protect and select the appropriate software.

About this task

The preferred practice is to install the backup-archive client on all client nodes so that you can configure and start the client acceptor on the client node. The client acceptor is designed to efficiently run scheduled operations.

The client acceptor runs schedules for the following products: the backup-archive client, IBM Spectrum Protect™ for Databases, IBM Spectrum Protect for Enterprise Resource Planning, IBM Spectrum Protect for Mail, and IBM Spectrum Protect for Virtual Environments. If you install a product for which the client acceptor does not run schedules, you must follow the configuration instructions in the product documentation to ensure that scheduled operations can occur.

Procedure

Based on your goal, select the products to install and review the installation instructions.
Tip: If you install the client software now, you must also complete the client configuration tasks that are described in Installing and configuring clients before you can use the client.

Goal	Product and description	Installation instructions
Protect a file server or workstation	The backup-archive client backs up and archives files and directories from file servers and workstations to storage. You can also restore and retrieve backup versions and archived copies of files.	• Backup-archive client requirements • Installing the UNIX and Linux backup-archive clients • Installing the Windows backup-archive client
Protect applications with snapshot backup and restore capabilities	IBM Spectrum Protect Snapshot protects data with integrated, application-aware snapshot backup and restore capabilities. You can protect data that is stored by IBM DB2® database software and SAP, Oracle, Microsoft Exchange, and Microsoft SQL Server applications.	• Installing and upgrading IBM Spectrum Protect Snapshot for UNIX and Linux • Installing and upgrading IBM Spectrum Protect Snapshot for VMware • Installing and upgrading IBM Spectrum Protect Snapshot for Windows
Protect an email application on an IBM Domino® server	IBM Spectrum Protect for Mail: Data Protection for IBM® Domino automates data protection so that backups are completed without shutting down IBM Domino servers.	• Installation of Data Protection for IBM Domino on a UNIX, AIX, or Linux system (V7.1.0) • Installation of Data Protection for IBM Domino on a Windows system (V7.1.0)
Protect an email application on a Microsoft Exchange server	IBM Spectrum Protect for Mail: Data Protection for Microsoft Exchange Server automates data protection so that backups are completed without shutting down Microsoft Exchange servers.	Installing, upgrading, and migrating IBM Spectrum Protect for Mail: Data Protection for Microsoft Exchange Server
Protect an IBM DB2 database	The application programming interface (API) of the backup-archive client can be used to back up DB2 data to the IBM Spectrum Protect server.	Installing the IBM Spectrum Protect backup-archive clients (UNIX, Linux, and Windows)
Protect an IBM Informix® database	The API of the backup-archive client can be used to back up Informix data to the IBM Spectrum Protect server.	Installing the IBM Spectrum Protect backup-archive clients (UNIX, Linux, and Windows)
Protect a Microsoft SQL database	IBM Spectrum Protect for Databases: Data Protection for Microsoft SQL Server protects Microsoft SQL data.	Installing Data Protection for SQL Server on Windows Server Core

Goal	Product and description	Installation instructions
Protect an Oracle database	IBM Spectrum Protect for Databases: Data Protection for Oracle protects Oracle data.	Data Protection for Oracle installation
Protect an SAP environment	IBM Spectrum Protect for Enterprise Resource Planning: Data Protection for SAP provides protection that is customized for SAP environments. The product is designed to improve the availability of SAP database servers and reduce administration workload.	• Installing IBM Spectrum Protect for Enterprise Resource Planning: Data Protection for SAP for DB2 • Installing IBM Spectrum Protect for Enterprise Resource Planning: Data Protection for SAP for Oracle
Protect a virtual machine	IBM Spectrum Protect for Virtual Environments provides protection that is tailored for Microsoft Hyper-V and VMware virtual environments. You can use IBM Spectrum Protect for Virtual Environments to create incremental forever backups that are stored on a centralized server, create backup policies, and restore virtual machines or individual files. Alternatively, use the backup-archive client to back up and restore a full VMware or Microsoft Hyper-V virtual machine. You can also back up and restore files or directories from a VMware virtual machine.	• Installing Data Protection for Microsoft Hyper-V • Installing and upgrading Data Protection for VMware • Installing the IBM Spectrum Protect backup-archive clients (UNIX, Linux, and Windows)

Tip: To use the client for space management, you can install IBM Spectrum Protect for Space Management or IBM Spectrum Protect HSM for Windows.

Specifying rules for backing up and archiving client data

Before you add a client, ensure that appropriate rules are specified for backing up and archiving the client data. During the client registration process, you assign the client node to a policy domain, which has the rules that control how and when client data is stored.

Before you begin

Determine how to proceed:

- If you are familiar with the policies that are configured for your solution and you know that they do not require changes, continue with Scheduling backup and archive operations.
- If you are not familiar with the policies, follow the steps in this procedure.

About this task

Policies affect how much data is stored over time, and how long data is retained and available for clients to restore. To meet objectives for data protection, you can update the default policy and create your own policies. A policy includes the following rules:

- How and when files are backed up and archived to server storage
- The number of copies of a file and the length of time copies are kept in server storage

During the client registration process, you assign a client to a *policy domain*. The policy for a specific client is determined by the rules in the policy domain to which the client is assigned. In the policy domain, the rules that are in effect are in the active *policy set*.

When a client backs up or archives a file, the file is bound to a management class in the active policy set of the policy domain. A *management class* is the key set of rules for managing client data. The backup and archive operations on the client use the settings in the default management class of the policy domain unless you further customize policy. A policy can be customized by defining more management classes and assigning their use through client options.

Client options can be specified in a local, editable file on the client system and in a client option set on the server. The options in the client option set on the server can override or add to the options in the local client option file.

Procedure

1. Review the policies that are configured for your solution by following the instructions in Viewing policies.
2. If you need to make minor changes to meet data retention requirements, follow the instructions in Editing policies.
3. Optional: If you need to create policy domains or make extensive changes to policies to meet data retention requirements, see Customizing policies.

Viewing policies

View policies to determine whether they must be edited to meet your requirements.

Procedure

1. To view the active policy set for a policy domain, complete the following steps:
   a. On the Services page of the Operations Center, select a policy domain and click Details.
   b. On the Summary page for the policy domain, click the Policy Sets tab.
2. To view inactive policy sets for a policy domain, complete the following steps:
   a. On the Policy Sets page, click the Configure toggle. You can now view and edit the policy sets that are inactive.
   b. Scroll through the inactive policy sets by using the forward and back arrows. When you view an inactive policy set, the settings that differentiate the inactive policy set from the active policy set are highlighted.
   c. Click the Configure toggle. The policy sets are no longer editable.

Editing policies

To change the rules that apply to a policy domain, edit the active policy set for the policy domain. You can also activate a different policy set for a domain.

Before you begin

Changes to policy can affect data retention. Ensure that you continue to back up data that is essential to your organization so that you can restore that data if a disaster occurs. Also, ensure that your system has sufficient storage space for planned backup operations.

About this task

You edit a policy set by changing one or more management classes within the policy set. If you edit the active policy set, the changes are not available to clients unless you reactivate the policy set. To make the edited policy set available to clients, activate the policy set.

Although you can define multiple policy sets for a policy domain, only one policy set can be active. When you activate a different policy set, it replaces the currently active policy set.

To learn about preferred practices for defining policies, see Customizing policies.

Procedure

1. On the Services page of the Operations Center, select a policy domain and click Details.
2. On the Summary page for the policy domain, click the Policy Sets tab.

   The Policy Sets page indicates the name of the active policy set and lists all of the management classes for that policy set.

3. Click the Configure toggle. The policy set is editable.
4. Optional: To edit a policy set that is not active, click the forward and back arrows to locate the policy set.
5. Edit the policy set by completing any of the following actions:

Option	Description

Option	Description
Add a management class	a. In the Policy Sets table, click +Management Class. b. To specify the rules for backing up and archiving data, complete the fields in the Add Management Class window. c. To make the management class the default management class, select the Make default check box. d. Click Add.
Delete a management class	In the Management Class column, click -. Tip: To delete the default management class, you must first assign a different management class as the default.
Make a management class the default management class	In the Default column for the management class, click the radio button. Tip: The default management class manages client files when another management class is not assigned to, or appropriate for managing, a file. To ensure that clients can always back up and archive files, choose a default management class that contains rules for both backing up and archiving files.
Modify a management class	To change the properties of a management class, update the fields in the table.

6. Click Save.
   Attention: When you activate a new policy set, data might be lost. Data that is protected under one policy set might not be protected under another policy set. Therefore, before you activate a policy set, ensure that the differences between the previous policy set and the new policy set do not cause data to be lost.
7. Click Activate. A summary of the differences between the active policy set and the new policy set is displayed. Ensure that the changes in the new policy set are consistent with your data retention requirements by completing the following steps:
   a. Review the differences between corresponding management classes in the two policy sets, and consider the consequences for client files. Client files that are bound to management classes in the active policy set will be bound to the management classes with the same names in the new policy set.
   b. Identify management classes in the active policy set that do not have counterparts in the new policy set, and consider the consequences for client files. Client files that are bound to these management classes will be managed by the default management class in the new policy set.
   c. If the changes to be implemented by the policy set are acceptable, select the I understand that these updates can cause data loss check box and click Activate.

Scheduling backup and archive operations

Before you register a new client with the server, ensure that a schedule is available to specify when backup and archive operations take place. During the registration process, you assign a schedule to the client.

Before you begin

Determine how to proceed:

- If you are familiar with the schedules that are configured for the solution and you know that they do not require modification, continue with Registering clients.
- If you are not familiar with the schedules or the schedules require modification, follow the steps in this procedure.

About this task

Typically, backup operations for all clients must be completed daily. Carefully schedule client and server workloads to achieve the best performance for your storage environment. To avoid the overlap of client and server operations, consider scheduling client backup and archive operations so that they run at night. If client and server operations overlap or are not given enough time and resources to be processed, you might experience decreased system performance, failed operations, and other issues.

Procedure

1. Review available schedules by hovering over Clients on the Operations Center menu bar. Click Schedules.
2. Optional: Modify or create a schedule by completing the following steps:

Option	Description

Option	Description
Modify a schedule	a. In the Schedules view, select the schedule and click Details. b. On the Schedule Details page, view details by clicking the blue arrows at the beginning of the rows. c. Modify the settings in the schedule, and click Save.
Create a schedule	In the Schedules view, click +Schedule and complete the steps to create a schedule.

3. Optional: To configure schedule settings that are not visible in the Operations Center, use a server command. For example, you might want to schedule a client operation that backs up a specific directory and assigns it to a management class other than the default.
    a. On the Overview page of the Operations Center, hover over the settings icon and click Command Builder.
    b. Issue the DEFINE SCHEDULE command to create a schedule or the UPDATE SCHEDULE command to modify a schedule. For details about the commands, see DEFINE SCHEDULE (Define a schedule for an administrative command) or UPDATE SCHEDULE (Update a client schedule).

Related tasks:
Tuning the schedule for daily operations

Registering clients

Register a client to ensure that the client can connect to the server, and the server can protect client data.

Before you begin

Determine whether the client requires an administrative user ID with client owner authority over the client node. To determine which clients require an administrative user ID, see technote 7048963.
Restriction: For some types of clients, the client node name and the administrative user ID must match. You cannot authenticate those clients by using the Lightweight Directory Access Protocol authentication method that was introduced in V7.1.7. For details about this authentication method, sometimes referred to as integrated mode, see Authenticating users by using an Active Directory database.

Procedure

To register a client, complete one of the following actions.

- If the client requires an administrative user ID, register the client by using the REGISTER NODE command and specify the USERID parameter:

  ```
  register node node_name password userid=node_name
  ```

  where *node_name* specifies the node name and *password* specifies the node password. For details, see Register a node.
- If the client does not require an administrative user ID, register the client by using the Operations Center Add Client wizard. Complete the following steps:
    a. On the Operations Center menu bar, click Clients.
    b. In the Clients table, click +Client.
    c. Complete the steps in the Add Client wizard:
        i. Specify that redundant data can be eliminated on both the client and server. In the Client-side data deduplication area, select the Enable check box.
        ii. In the Configuration window, copy the TCPSERVERADDRESS, TCPPORT, NODENAME, and DEDUPLICATION option values.
        Tip: Record the option values and keep them in a safe place. After you complete the client registration and install the software on the client node, use the values to configure the client.
        iii. Follow the instructions in the wizard to specify the policy domain, schedule, and option set.
        iv. Set how risks are displayed for the client by specifying the at-risk setting.
        v. Click Add Client.

Nodename option

Installing and configuring clients

To start protecting a client node, you must install and configure the selected software.

Procedure

If you already installed the software, start at step 2.

1. Take one of the following actions:
   - To install software on an application or client node, follow the instructions.

Software	Link to instructions
IBM Spectrum Protect™ backup-archive client	▪ Installing the UNIX and Linux backup-archive clients ▪ Installing the Windows backup-archive client For information about manual deployment of client updates from the server, see the following documents: ▪ For IBM Spectrum Protect 8.1.2 or later servers, see technote 2004596. ▪ For IBM® Tivoli® Storage Manager V7.1 servers and IBM Spectrum Protect V8.1.0 and V8.1.1 servers, see technote 1673299.
IBM Spectrum Protect for Databases	▪ Data Protection for Oracle installation ▪ Installing Data Protection for SQL Server on Windows Server Core
IBM Spectrum Protect for Mail	▪ Installation of Data Protection for IBM Domino on a UNIX, AIX, or Linux system (V7.1.0) ▪ Installation of Data Protection for IBM Domino on a Windows system (V7.1.0) ▪ Installing, upgrading, and migrating IBM Spectrum Protect for Mail: Data Protection for Microsoft Exchange Server
IBM Spectrum Protect Snapshot	▪ Installing and upgrading IBM Spectrum Protect Snapshot for UNIX and Linux ▪ Installing and upgrading IBM Spectrum Protect Snapshot for VMware ▪ Installing and upgrading IBM Spectrum Protect Snapshot for Windows
IBM Spectrum Protect for Enterprise Resource Planning	▪ Installing IBM Spectrum Protect for Enterprise Resource Planning: Data Protection for SAP for DB2® ▪ Installing IBM Spectrum Protect for Enterprise Resource Planning: Data Protection for SAP for Oracle

   - To install software on a virtual machine client node, follow the instructions for the selected backup type.

Backup type	Link to instructions
If you plan to create full VMware backups of virtual machines, install and configure the IBM Spectrum Protect backup-archive client.	▪ Installing the UNIX and Linux backup-archive clients ▪ Installing the Windows backup-archive client
If you plan to create incremental forever full backups of virtual machines, install and configure IBM Spectrum Protect for Virtual Environments and the backup-archive client on the same client node or on different client nodes.	▪ IBM Spectrum Protect for Virtual Environments online product documentation Tip: You can obtain the software for IBM Spectrum Protect for Virtual Environments and the backup-archive client in the IBM Spectrum Protect for Virtual Environments installation package.

2. To allow the client to connect to the server, add or update the values for the TCPSERVERADDRESS, TCPPORT, and NODENAME options in the client options file. Use the values that you recorded when you registered the client (Registering clients).
   - For clients that are installed on an AIX®, Linux, or Mac OS X operating system, add the values to the client system-options file, dsm.sys.
   - For clients that are installed on a Windows operating system, add the values to the dsm.opt file.

By default, the options files are in the installation directory.

3. If you installed a backup-archive client on a Linux or Windows operating system, install the client management service on the client. Follow the instructions in Installing the client management service.
4. Configure the client to run scheduled operations. Follow the instructions in Configuring the client to run scheduled operations.
5. Optional: Configure communications through a firewall. Follow the instructions in Configuring client/server communications through a firewall.
6. Run a test backup to verify that data is protected as you planned. For example, for a backup-archive client, complete the following steps:
    a. On the Clients page of the Operations Center, select the client that you want to back up, and click Back Up.
    b. Verify that the backup completes successfully and that there are no warning or error messages.
7. Monitor the results of the scheduled operations for the client in the Operations Center.

What to do next

To change what is getting backed up from the client, follow the instructions in Modifying the scope of a client backup.

Configuring the client to run scheduled operations

You must configure and start a client scheduler on the client node. The client scheduler enables communication between the client and server so that scheduled operations can occur. For example, scheduled operations typically include backing up files from a client.

About this task

The preferred method is to install the backup-archive client on all client nodes so that you can configure and start the client acceptor on the client node. The client acceptor is designed to efficiently run scheduled operations. The client acceptor manages the client scheduler so that the scheduler runs only when required:

- When it is time to query the server about the next scheduled operation
- When it is time to start the next scheduled operation

By using the client acceptor, you can reduce the number of background processes on the client and help to avoid memory retention problems.

The client acceptor runs schedules for the following products: the backup-archive client, IBM Spectrum Protect™ for Databases, IBM Spectrum Protect for Enterprise Resource Planning, IBM Spectrum Protect for Mail, and IBM Spectrum Protect for Virtual Environments. If you installed a product for which the client acceptor does not run schedules, follow the configuration instructions in the product documentation to ensure that scheduled operations can occur.

If your business uses a third-party scheduling tool as standard practice, you can use that scheduling tool as an alternative to the client acceptor. Typically, third-party scheduling tools start client programs directly by using operating system commands. To configure a third-party scheduling tool, see the product documentation.

Procedure

To configure and start the client scheduler by using the client acceptor, follow the instructions for the operating system that is installed on the client node:

AIX® and Oracle Solaris

a. From the backup-archive client GUI, click Edit > Client Preferences.
b. Click the Web Client tab.
c. In the Managed Services Options field, click Schedule. If you also want the client acceptor to manage the web client, click the Both option.
d. To ensure that the scheduler can start unattended, in the dsm.sys file, set the passwordaccess option to `generate`.
e. To store the client node password, issue the following command and enter the client node password when prompted:

```
dsmc query sess
```

f. Start the client acceptor by issuing the following command on the command line:

```
/usr/bin/dsmcad
```

g. To enable the client acceptor to start automatically after a system restart, add the following entry to the system startup file (typically, /etc/inittab):

```
tsm::once:/usr/bin/dsmcad > /dev/null 2>&1 # Client Acceptor Daemon
```

Linux

a. From the backup-archive client GUI, click Edit > Client Preferences.
b. Click the Web Client tab.
c. In the Managed Services Options field, click Schedule. If you also want the client acceptor to manage the web client, click the Both option.
d. To ensure that the scheduler can start unattended, in the dsm.sys file, set the passwordaccess option to `generate`.
e. To store the client node password, issue the following command and enter the client node password when prompted:

```
dsmc query sess
```

f. Start the client acceptor by logging in with the root user ID and issuing the following command:

```
service dsmcad start
```

g. To enable the client acceptor to start automatically after a system restart, add the service by issuing the following command at a shell prompt:

```
# chkconfig --add dsmcad
```

MAC OS X

a. In the backup-archive client GUI, click Edit > Client Preferences.
b. To ensure that the scheduler can start unattended, click Authorization, select Password Generate, and click Apply.
c. To specify how services are managed, click Web Client, select Schedule, click Apply, and click OK.
d. To ensure that the generated password is saved, restart the backup-archive client.
e. Use the IBM Spectrum Protect Tools for Administrators application to start the client acceptor.

Windows

a. In the backup-archive client GUI, click Utilities > Setup Wizard > Help me configure the Client Scheduler. Click Next.
b. Read the information on the Scheduler Wizard page and click Next.
c. On the Scheduler Task page, select Install a new or additional scheduler and click Next.
d. On the Scheduler Name and Location page, specify a name for the client scheduler that you are adding. Then, select Use the Client Acceptor daemon (CAD) to manage the scheduler and click Next.
e. Enter the name that you want to assign to this client acceptor. The default name is Client Acceptor. Click Next.
f. Complete the configuration by stepping through the wizard.
g. Update the client options file, dsm.opt, and set the passwordaccess option to generate.
h. To store the client node password, issue the following command at the command prompt:

```
dsmc query sess
```

Enter the client node password when prompted.
i. Start the client acceptor service from the Services Control page. For example, if you used the default name, start the Client Acceptor service. Do not start the scheduler service that you specified on the Scheduler Name and Location page. The scheduler service is started and stopped automatically by the client acceptor service as needed.

Configuring client/server communications through a firewall

If a client must communicate with a server through a firewall, you must enable client/server communications through the firewall.

Before you begin

If you used the Add Client wizard to register a client, find the option values in the client options file that you obtained during that process. You can use the values to specify ports.

About this task

Attention: Do not configure a firewall in a way that might cause termination of sessions that are in use by a server or storage agent. Termination of a valid session can cause unpredictable results. Processes and sessions might appear to stop due to input/output errors. To help exclude sessions from timeout restrictions, configure known ports for IBM Spectrum Protect™ components. Ensure that the KEEPALIVE server option remains set to the default value of YES. In this way, you can help to ensure that client/server communication is uninterrupted. For instructions about setting the KEEPALIVE server option, see KEEPALIVE.

Procedure

Open the following ports to allow access through the firewall:

TCP/IP port for the backup-archive client, command-line administrative client, and the client scheduler
: Specify the port by using the tcpport option in the client options file. The tcpport option in the client options file must match the TCPPORT option in the server options file. The default value is 1500. If you decide to use a value other than the default, specify a number in the range 1024 - 32767.

HTTP port to enable communication between the web client and remote workstations
: Specify the port for the remote workstation by setting the httpport option in the client options file of the remote workstation. The default value is 1581.

TCP/IP ports for the remote workstation
: The default value of 0 (zero) causes two free port numbers to be randomly assigned to the remote workstation. If you do not want the port numbers to be randomly assigned, specify values by setting the webports option in the client options file of the remote workstation.

TCP/IP port for administrative sessions
: Specify the port on which the server waits for requests for administrative client sessions. The value of the client tcpadminport option must match the value of the TCPADMINPORT server option. In this way, you can secure administrative sessions within a private network.

Managing client operations

You can evaluate and resolve errors that are related to a backup-archive client by using the Operations Center, which provides suggestions for resolving errors. For errors on other types of clients, you must examine the error logs on the client and review the product documentation.

About this task

In some cases, you can resolve client errors by stopping and starting the client acceptor. If client nodes or administrator IDs are locked, you can resolve the issue by unlocking the client node or administrator ID, and then resetting the password.

For detailed instructions about identifying and resolving client errors, see Resolving client problems.

- Evaluating errors in client error logs
  You can resolve client errors by obtaining suggestions from the Operations Center or by reviewing error logs on the client.
- Stopping and restarting the client acceptor
  If you change the configuration of your solution, you must restart the client acceptor on all client nodes where a backup-archive client is installed.
- Resetting passwords
  If a password for a client node or an administrator ID is lost or forgotten, you can reset the password. Multiple attempts to access the system with an incorrect password can cause a client node or administrator ID to be locked. You can take steps to resolve the issue.
- Modifying the scope of a client backup
  When you set up client backup operations, the preferred practice is to exclude objects that you do not require. For example, you typically want to exclude temporary files from a backup operation.

Evaluating errors in client error logs

You can resolve client errors by obtaining suggestions from the Operations Center or by reviewing error logs on the client.

Before you begin

To resolve errors in a backup-archive client on a Linux or Windows operating system, ensure that the client management service is installed and started. For installation instructions, see Installing the client management service. For instructions about verifying the installation, see Verifying that the client management service is installed correctly.

Procedure

To diagnose and resolve client errors, take one of the following actions:

- If the client management service is installed on the client node, complete the following steps:
  1. On the Operations Center Overview page, click Clients and select the client.
  2. Click Details.
  3. On the client Summary page, click the Diagnosis tab.
  4. Review the retrieved log messages.
     Tips:
     - To show or hide the Client Logs pane, double-click the Client Logs bar.
     - To resize the Client Logs pane, click and drag the Client Logs bar.

     If suggestions are displayed on the Diagnosis page, select a suggestion. In the Client Logs pane, client log messages to which the suggestion relates are highlighted.
  5. Use the suggestions to resolve the problems that are indicated by the error messages.
     Tip: Suggestions are provided for only a subset of client messages.
- If the client management service is not installed on the client node, review the error logs for the installed client.

Stopping and restarting the client acceptor

If you change the configuration of your solution, you must restart the client acceptor on all client nodes where a backup-archive client is installed.

About this task

In some cases, you can resolve client scheduling problems by stopping and restarting the client acceptor. The client acceptor must be running to ensure that scheduled operations can occur on the client. For example, if you change the IP address or domain name of the server, you must restart the client acceptor.

Procedure

Follow the instructions for the operating system that is installed on the client node:

AIX and Oracle Solaris

- To stop the client acceptor, complete the following steps:
  a. Determine the process ID for the client acceptor by issuing the following command on the command line:

     ```
     ps -ef | grep dsmcad
     ```

     Review the output. In the following sample output, 6764 is the process ID for the client acceptor:

     ```
     root  6764     1   0 16:26:35 ?           0:00 /usr/bin/dsmcad
     ```

  b. Issue the following command on the command line:

     ```
     kill -9 PID
     ```

     where *PID* specifies the process ID for the client acceptor.
- To start the client acceptor, issue the following command on the command line:

  ```
  /usr/bin/dsmcad
  ```

Linux

- To stop the client acceptor (and not restart it), issue the following command:

  ```
  # service dsmcad stop
  ```

- To stop and restart the client acceptor, issue the following command:

```
# service dsmcad restart
```

MAC OS X

Click Applications > Utilities > Terminal.

- To stop the client acceptor, issue the following command:

  ```
  /bin/launchctl unload -w com.ibm.tivoli.dsmcad
  ```

- To start the client acceptor, issue the following command:

  ```
  /bin/launchctl load -w com.ibm.tivoli.dsmcad
  ```

Windows

- To stop the client acceptor service, complete the following steps:
  a. Click Start > Administrative Tools > Services.
  b. Double-click the client acceptor service.
  c. Click Stop and OK.
- To restart the client acceptor service, complete the following steps:
  a. Click Start > Administrative Tools > Services.
  b. Double-click the client acceptor service.
  c. Click Start and OK.

Resolving client scheduling problems

Resetting passwords

If a password for a client node or an administrator ID is lost or forgotten, you can reset the password. Multiple attempts to access the system with an incorrect password can cause a client node or administrator ID to be locked. You can take steps to resolve the issue.

Procedure

To resolve password issues, take one of the following actions:

- If a backup-archive client is installed on a client node, and the password is lost or forgotten, complete the following steps:
  1. Generate a new password by issuing the UPDATE NODE command:

     ```
     update node node_name new_password forcepwreset=yes
     ```

     where *node_name* specifies the client node and *new_password* specifies the password that you assign.
  2. Inform the client node owner about the changed password. When the owner of the client node logs in with the specified password, a new password is generated automatically. That password is unknown to users to enhance security.
     Tip: The password is generated automatically if you previously set the passwordaccess option to `generate` in the client options file.
- If an administrator is locked out because of password issues, complete the following steps:
  1. To provide the administrator with access to the server, issue the UNLOCK ADMIN command. For instructions, see UNLOCK ADMIN (Unlock an administrator).
  2. Set a new password by using the UPDATE ADMIN command:

     ```
     update admin admin_name new_password forcepwreset=yes
     ```

     where *admin_name* specifies the name of the administrator and *new_password* specifies the password that you assign.
- If a client node is locked, complete the following steps:
  1. Determine why the client node is locked and whether it must be unlocked. For example, if the client node is decommissioned, the client node is being removed from the production environment. You cannot reverse the decommission operation, and the client node remains locked. A client node also might be locked if the client data is the subject of a legal investigation.
  2. If you must unlock a client node, use the UNLOCK NODE command. For instructions, see UNLOCK NODE (Unlock a client node).

3. Generate a new password by issuing the UPDATE NODE command:

   ```
   update node node_name new_password forcepwreset=yes
   ```

   where *node_name* specifies the name of the node and *new_password* specifies the password that you assign.
4. Inform the client node owner about the changed password. When the owner of the client node logs in with the specified password, a new password is generated automatically. That password is unknown to users to enhance security.
   Tip: The password is generated automatically if you previously set the passwordaccess option to `generate` in the client options file.

Modifying the scope of a client backup

When you set up client backup operations, the preferred practice is to exclude objects that you do not require. For example, you typically want to exclude temporary files from a backup operation.

About this task

When you exclude unnecessary objects from backup operations, you get better control of the amount of storage space that is required for backup operations, and the cost of storage. Depending on your licensing package, you also might be able to limit licensing costs.

Procedure

How you modify the scope of backup operations depends on the product that is installed on the client node:

- For a backup-archive client, you can create an include-exclude list to include or exclude a file, groups of files, or directories from backup operations. To create an include-exclude list, follow the instructions in Creating an include-exclude list.

  To ensure consistent use of an include-exclude list for all clients of one type, you can create a client option set on the server that contains the required options. Then, you assign the client option set to each of the clients of the same type. For details, see Controlling client operations through client option sets.

- For a backup-archive client, you can specify the objects to include in an incremental backup operation by using the domain option. Follow the instructions in Domain client option.
- For other products, to define which objects are included in and excluded from backup operations, follow the instructions in the product documentation.

Managing client upgrades

When a fix pack or interim fix becomes available for a client, you can upgrade the client to take advantage of product improvements. Servers and clients can be upgraded at different times and can be at different levels with some restrictions.

Before you begin

1. Review the client/server compatibility requirements in technote 1053218. If your solution includes servers or clients at a level that is earlier than V7.1, review the guidelines to ensure that client backup and archive operations are not disrupted.
2. Verify system requirements for the client in IBM Spectrum Protect™ Supported Operating Systems.
3. If the solution includes storage agents or library clients, review the information about storage-agent and library-client compatibility with servers that are configured as library managers. See technote 1302789.

   If you plan to upgrade a library manager and a library client, you must upgrade the library manager first.

Procedure

To upgrade the software, complete the instructions that are listed in the following table.

Software	Link to instructions
IBM Spectrum Protect backup-archive client	• Upgrading the backup-archive client

Software	Link to instructions
IBM Spectrum Protect Snapshot	• Installing and upgrading IBM Spectrum Protect Snapshot for UNIX and Linux • Installing and upgrading IBM Spectrum Protect Snapshot for VMware • Installing and upgrading IBM Spectrum Protect Snapshot for Windows
IBM Spectrum Protect for Databases	• Upgrading Data Protection for SQL Server • Data Protection for Oracle installation • Installing, upgrading, and migrating IBM Spectrum Protect for Mail: Data Protection for Microsoft Exchange Server
IBM Spectrum Protect for Enterprise Resource Planning	• Upgrading IBM Spectrum Protect for Enterprise Resource Planning: Data Protection for SAP for DB2® • Upgrading IBM Spectrum Protect for Enterprise Resource Planning: Data Protection for SAP for Oracle
IBM Spectrum Protect for Mail	• Installation of Data Protection for IBM Domino on a UNIX, AIX, or Linux system (V7.1.0) • Installation of Data Protection for IBM Domino on a Windows system (V7.1.0) • Installing, upgrading, and migrating IBM Spectrum Protect for Mail: Data Protection for Microsoft Exchange Server
IBM Spectrum Protect for Virtual Environments	• Installing and upgrading Data Protection for VMware • Installing Data Protection for Microsoft Hyper-V

Decommissioning a client node

If a client node is no longer required, you can start a process to remove it from the production environment. For example, if a workstation was backing up data to the IBM Spectrum Protect™ server, but the workstation is no longer used, you can decommission the workstation.

About this task

When you start the decommission process, the server locks the client node to prevent it from accessing the server. Files that belong to the client node are gradually deleted, and then the client node is deleted. You can decommission the following types of client nodes:

Application client nodes
: Application client nodes include email servers, databases, and other applications. For example, any of the following applications can be an application client node:

  - IBM Spectrum Protect Snapshot
  - IBM Spectrum Protect for Databases
  - IBM Spectrum Protect for Enterprise Resource Planning
  - IBM Spectrum Protect for Mail
  - IBM Spectrum Protect for Virtual Environments

System client nodes
: System client nodes include workstations, network-attached storage (NAS) file servers, and API clients.

Virtual machine client nodes
: Virtual machine client nodes consist of an individual guest host within a hypervisor. Each virtual machine is represented as a file space.

The simplest method for decommissioning a client node is to use the Operations Center. The decommission process runs in the background. If the client is configured to replicate client data, the Operations Center automatically removes the client from replication on the source and target replication servers before it decommissions the client.
Tip: Alternatively, you can decommission a client node by issuing the DECOMMISSION NODE or DECOMMISSION VM command. You might want to use this method in the following cases:

- To schedule the decommission process for the future or to run a series of commands by using a script, specify the decommission process to run in the background.
- To monitor the decommission process for debugging purposes, specify the decommission process to run in the foreground. If you run the process in the foreground, you must wait for the process to be completed before you continue with other tasks.

Procedure

Take one of the following actions:

- To decommission a client in the background by using the Operations Center, complete the following steps:
  1. On the Operations Center Overview page, click Clients and select the client.
  2. Click More > Decommission.
- To decommission a client node by using an administrative command, complete the following steps:
  1. Determine whether the client node is configured for node replication by issuing the QUERY NODE command. For example, if the client node is named AUSTIN, run the following command:

     ```
     query node austin format=detailed
     ```

     Review the Replication State output field.
  2. If the client node is configured for replication, remove the client node from replication by issuing the REMOVE REPLNODE command. For example, if the client node is named AUSTIN, issue the following command:

     ```
     remove replnode austin
     ```

  3. Take one of the following actions:
     - To decommission an application or system client node in the background, issue the DECOMMISSION NODE command. For example, if the client node is named AUSTIN, issue the following command:

       ```
       decommission node austin
       ```

     - To decommission an application or system client node in the foreground, issue the DECOMMISSION NODE command and specify the `wait=yes` parameter. For example, if the client node is named AUSTIN, issue the following command:

       ```
       decommission node austin wait=yes
       ```

     - To decommission a virtual machine in the background, issue the DECOMMISSION VM command. For example, if the virtual machine is named AUSTIN, the file space is 7, and the file space name is specified by the file space ID, issue the following command:

       ```
       decommission vm austin 7 nametype=fsid
       ```

       If the virtual machine name includes one or more spaces, enclose the name in double quotation marks. For example:

       ```
       decommission vm "austin 2" 7 nametype=fsid
       ```

     - To decommission a virtual machine in the foreground, issue the DECOMMISSION VM command and specify the `wait=yes` parameter. For example, issue the following command:

       ```
       decommission vm austin 7 nametype=fsid wait=yes
       ```

       If the virtual machine name includes one or more spaces, enclose the name in double quotation marks. For example:

       ```
       decommission vm "austin 2" 7 nametype=fsid wait=yes
       ```

What to do next

Watch for error messages, which might be displayed in the user interface or in the command output, immediately after you run the process.

You can verify that the client node is decommissioned:

1. On the Operations Center Overview page, click Clients.
2. In the Clients table, in the At risk column, review the state:
   - A DECOMMISSIONED state specifies that the node is decommissioned.

- A null value specifies that the node is not decommissioned.
- A PENDING state specifies that the node is being decommissioned, or the decommission process failed.

Tip: If you want to determine the status of a pending decommission process, issue the following command:

```
query process
```

3. Review the command output:
   - If status is provided for the decommission process, the process is in progress. For example:

```
query process

 Process     Process Description           Process Status
  Number
--------     --------------------     -------------------------------------------
       3          DECOMMISSION NODE        Number of backup objects deactivated
                                           for node NODE1: 8 objects deactivated.
```

   - If no status is provided for the decommission process, and you did not receive an error message, the process is incomplete. A process can be incomplete if files that are associated with the node are not yet deactivated. After the files are deactivated, run the decommission process again.
   - If no status is provided for the decommission process, and you receive an error message, the process failed. Run the decommission process again.

DECOMMISSION NODE (Decommission a client node)
DECOMMISSION VM (Decommission a virtual machine)
QUERY NODE (Query nodes)
REMOVE REPLNODE (Remove a client node from replication)

Deactivating data to free storage space

In some cases, you can deactivate data that is stored on the IBM Spectrum Protect™ server. When you run the deactivation process, any backup data that was stored before the specified date and time is deactivated and will be deleted as it expires. In this way, you can free space on the server.

About this task

Some application clients always save data to the server as active backup data. Because active backup data is not managed by inventory expiration policies, the data is not deleted automatically, and uses server storage space indefinitely. To free the storage space that is used by obsolete data, you can deactivate the data.

When you run the deactivation process, all active backup data that was stored before the specified date becomes inactive. The data is deleted as it expires and cannot be restored. The deactivation feature applies only to application clients that protect Oracle databases.

Procedure

1. From the Operations Center Overview page, click Clients.
2. In the Clients table, select one or more clients and click More > Clean Up.
   Command-line method: Deactivate data by using the DEACTIVATE DATA command.

Related reference:
DEACTIVATE DATA (Deactivate data for a client node)

Managing data storage

Manage your data for efficiency and add supported devices and media to the server to store client data.

- Auditing a storage pool container
  Audit a storage pool container to check for inconsistencies between database information and a container in a storage pool.
- Managing inventory capacity
  Manage the capacity of the database, active log, and archive logs to ensure that the inventory is sized for the tasks, based on the status of the logs.

- Managing memory and processor usage
  Ensure that you manage memory requirements and processor usage to ensure that the server can complete data processes such as backup and data deduplication. Consider the impact on performance when you complete certain processes.
- Tuning scheduled activities
  Schedule maintenance tasks daily to ensure that your solution operates correctly. By tuning your solution, you maximize server resources and effectively use different functions available within your solution.

Related reference:
Types of storage pools

Auditing a storage pool container

Audit a storage pool container to check for inconsistencies between database information and a container in a storage pool.

About this task

You audit a storage pool container in the following situations:

- When you issue the QUERY DAMAGED command and a problem is detected
- When the server displays messages about damaged data extents
- Your hardware reports an issue and error messages that are associated with the storage pool container are displayed

Procedure

1. To audit a storage pool container, issue the AUDIT CONTAINER command. For example, issue the following command to audit a container, 000000000000076c.dcf:

   ```
   audit container c:\tsm-storage\07\000000000000076c.dcf
   ```

2. Review the output from the ANR4891I message for information about any damaged data extents.

What to do next

If you detect problems with the storage pool container, you can restore data based on your configuration. You can repair the contents in the storage pool by using the REPAIR STGPOOL command.
Restriction: You can repair the contents of the storage pool only if you protected the storage pool by using the PROTECT STGPOOL command.
Related reference:
AUDIT CONTAINER (Verify the consistency of database information for a directory-container storage pool)
QUERY DAMAGED (Query damaged data in a directory-container or cloud-container storage pool)

Managing inventory capacity

Manage the capacity of the database, active log, and archive logs to ensure that the inventory is sized for the tasks, based on the status of the logs.

Before you begin

The active and archive logs have the following characteristics:

- The active log can be a maximum size of 512 GB. For more information about sizing the active log for your system, see Planning the storage arrays.
- The archive log size is limited to the size of the file system that it is installed on. The archive log size is not maintained at a predefined size like the active log. Archive log files are automatically deleted after they are no longer needed.

As a best practice, you can optionally create an archive failover log to store archive log files when the archive log directory is full.

Check the Operations Center to determine the component of the inventory that is full. Ensure that you stop the server before you increase the size of one of the inventory components.

Procedure

- To increase the size of the database, complete the following steps:
  - Create one or more directories for the database on separate drives or file systems.
  - Issue the EXTEND DBSPACE command to add the directory or directories to the database. The directories must be accessible to the instance user ID of the database manager. By default, data is redistributed across all database directories and space is reclaimed.
    Tips:
    - The time that is needed to complete redistribution of data and reclaiming of space is variable, depending on the size of your database. Make sure that you plan adequately.
    - Ensure that the directories that you specify are the same size as existing directories to ensure a consistent degree of parallelism for database operations. If one or more directories for the database are smaller than the others, they reduce the potential for optimized parallel prefetching and distribution of the database.
  - Halt and restart the server to fully use the new directories.
  - Reorganize the database if necessary. Index and table reorganization for the server database can help to avoid unexpected database growth and performance issues. For more information about reorganizing the database, see technote 1683633.
- To decrease the size of the database for V7.1 servers and later, issue the following DB2® commands from the server instance directory:
  Restriction: The commands can increase I/O activity, and might affect server performance. To minimize performance problems, wait until one command is completed before you issue the next command. The DB2 commands can be issued when the server is running.

```
db2 connect to tsmdb1
db2 set schema tsmdb1
db2 ALTER TABLESPACE USERSPACE1 REDUCE MAX
db2 ALTER TABLESPACE IDXSPACE1 REDUCE MAX
db2 ALTER TABLESPACE LARGEIDXSPACE1 REDUCE MAX
db2 ALTER TABLESPACE LARGESPACE1 REDUCE MAX
db2 ALTER TABLESPACE REPLTBLSPACE1 REDUCE MAX
db2 ALTER TABLESPACE REPLIDXSPACE1 REDUCE MAX
db2 ALTER TABLESPACE ARCHOBJDATASPACE REDUCE MAX
db2 ALTER TABLESPACE ARCHOBJIDXSPACE REDUCE MAX
db2 ALTER TABLESPACE BACKOBJDATASPACE REDUCE MAX
db2 ALTER TABLESPACE BACKOBJIDXSPACE REDUCE MAX
db2 ALTER TABLESPACE BFABFDATASPACE REDUCE MAX
db2 ALTER TABLESPACE BFABFIDXSPACE REDUCE MAX
db2 ALTER TABLESPACE BFBFEXTDATASPACE REDUCE MAX
db2 ALTER TABLESPACE BFBFEXTIDXSPACE REDUCE MAX
db2 ALTER TABLESPACE DEDUPTBLSPACE1 REDUCE MAX
db2 ALTER TABLESPACE DEDUPIDXSPACE1 REDUCE MAX
db2 ALTER TABLESPACE DEDUPTBLSPACE2 REDUCE MAX
db2 ALTER TABLESPACE DEDUPIDXSPACE2 REDUCE MAX
db2 ALTER TABLESPACE DEDUPTBLSPACE3 REDUCE MAX
db2 ALTER TABLESPACE DEDUPIDXSPACE3 REDUCE MAX
db2 ALTER TABLESPACE DEDUPTBLSPACE4 REDUCE MAX
db2 ALTER TABLESPACE DEDUPIDXSPACE4 REDUCE MAX
db2 ALTER TABLESPACE DEDUPTBLSPACE5 REDUCE MAX
db2 ALTER TABLESPACE DEDUPIDXSPACE5 REDUCE MAX
```

- To increase or decrease the size of the active log, complete the following steps:
  1. Ensure that the location for the active log has enough space for the increased log size. If a log mirror exists, its location must also have enough space for the increased log size.
  2. Halt the server.
  3. In the dsmserv.opt file, update the ACTIVELOGSIZE option to the new size of the active log, in megabytes.
     The size of an active log file is based on the value of the ACTIVELOGSIZE option. Guidelines for space requirements are in the following table:

Table 1. How to estimate volume and file space requirements

ACTIVELOGSize option value	**Reserve this much free space in the active log directory, in addition to the ACTIVELOGSize space**
16 GB - 128 GB	5120 MB
129 GB - 256 GB	10240 MB
257 GB - 512 GB	20480 MB

     To change the active log to its maximum size of 512 GB, enter the following server option:

```
activelogsize 524288
```

4. If you plan to use a new active log directory, update the directory name that is specified in the ACTIVELOGDIRECTORY server option. The new directory must be empty and must be accessible to the user ID of the database manager.
5. Restart the server.

- Compress the archive logs to reduce the amount of space that is required for storage. Enable dynamic compression of the archive log by issuing the following command:

  ```
  setopt archlogcompress yes
  ```

  Restriction: Use caution when you enable the ARCHLOGCOMPRESS server option on systems with sustained high volume usage and heavy workloads. Enabling this option in this system environment can cause delays in archiving log files from the active log file system to the archive log file system. This delay can cause the active log file system to run out of space. Be sure to monitor the available space in the active log file system after archive log compression is enabled. If the active log directory file system usage nears out of space conditions, the ARCHLOGCOMPRESS server option must be disabled. You can use the SETOPT command to disable archive log compression immediately without halting the server.

ACTIVELOGSIZE server option
EXTEND DBSPACE (Increase space for the database)
SETOPT (Set a server option for dynamic update)

Managing memory and processor usage

Ensure that you manage memory requirements and processor usage to ensure that the server can complete data processes such as backup and data deduplication. Consider the impact on performance when you complete certain processes.

Before you begin

- Ensure that your configuration uses the required hardware and software. For more information, see IBM Spectrum Protect™ Supported Operating Systems.
- For more information about managing resources such as the database and recovery log, see Planning the storage arrays.
- Add more system memory to determine whether there is a performance improvement. Monitor memory usage regularly to determine whether more memory is required.

Procedure

1. Release memory from the file system cache where possible.
2. To manage the system memory that is used by each server on a system, use the DBMEMPERCENT server option. Limit the percentage of system memory that can be used by the database manager of each server. If all servers are equally important, use the same value for each server. If one server is a production server and other servers are test servers, set the value for the production server to a higher value than the test servers.
3. Set the user data limit and private memory for the database to ensure that private memory is not exhausted. Exhausting private memory can result in errors, less than optimal performance, and instability.

Tuning scheduled activities

Schedule maintenance tasks daily to ensure that your solution operates correctly. By tuning your solution, you maximize server resources and effectively use different functions available within your solution.

Procedure

1. Monitor system performance regularly to ensure that client backup and server maintenance tasks are completing successfully. Follow the instructions in Monitoring a multisite disk solution.
2. Optional: If the monitoring information shows that the server workload increased, review the planning information. Review whether the capacity of the system is adequate in the following cases:
   - The number of clients increases
   - The amount of data that is being backed up increases
   - The amount of time that is available for backups changes
3. Determine whether your solution is performing at the level you expect. Review the client schedules to check whether tasks are completing within the scheduled time frame:
   a. On the Clients page of the Operations Center, select the client.

b. Click Details.
c. From the client Summary page, review the Backed up and Replicated activity to identify any risks.

Adjust the time and frequency of client backup operations, if necessary.

4. Schedule enough time for the following maintenance tasks to complete successfully within a 24-hour period:
   a. Protect storage pools.
   b. Replicate node data.
   c. Back up the database.
   d. Run expiration processing to remove client backups and archive file copies from server storage.

   Tip: Schedule maintenance tasks to start at an appropriate time and in the correct sequence. For example, schedule replication tasks after client backups complete successfully.

- Moving clients from one server to another
  To avoid running out of space on a server or to resolve workload issues, you might have to move client nodes from one server to another.

Related concepts:
Performance
Related tasks:
Defining schedules for server maintenance activities
Deduplicating data (V7.1.1)

Managing replication

Use replication to recover data at a disaster recovery site and to maintain the same level of files on the source and target servers. You can manage replication at the node level. You can also protect data at the storage-pool level.

- Replication compatibility
  Before you set up replication operations with IBM Spectrum Protect, you must ensure that the source and target replication servers are compatible for replication.
- Enabling node replication
  You can enable node replication to protect your data.
- Protecting data in directory-container storage pools
  Protect data in directory-container storage pools to reduce node replication time and to enable repair of data in directory-container storage pools.
- Modifying replication settings
  Modify replication settings in the Operations Center. Change settings such as the number of replication sessions, replication rules, the data that you want to replicate, the replication schedule, and the replication workload.
- Setting different retention policies for the source server and target server
  You can set policies on the target replication server that manage the replicated client-node data differently than on the source server. For example, you can maintain a different number of versions of files on the source and the target servers.

Replication compatibility

Before you set up replication operations with IBM Spectrum Protect™, you must ensure that the source and target replication servers are compatible for replication.

Table 1. Replication compatibility of server versions

Source replication server version	Compatible versions for the target replication server
V6.3.0 - V6.3.2	V6.3.0 - V6.3.2
V6.3.3	V6.3.3 or later V6.3 levels
V6.3.4 or later V6.3 levels	V6.3.4 or later
V7.1	V7.1 or later
V7.1.1	V7.1 or later
V7.1.3	V7.1.3 or later
V7.1.4	V7.1.3 or later
V7.1.5	V7.1.3 or later

Source replication server version	Compatible versions for the target replication server
V7.1.6	V7.1.3 or later
V7.1.7	V7.1.3 or later
V8.1	V7.1.3 or later
V8.1.1	V7.1.3 or later
V8.1.2	V7.1.3 or later

Enabling node replication

You can enable node replication to protect your data.

Before you begin

Ensure that the source and target servers are compatible for replication.

About this task

Replicate the client node to replicate all client data, including metadata. By default, node replication is disabled when you start the server for the first time.
Tips:

- To reduce replication processing time, protect the storage pool before you replicate client nodes. When node replication is started, the data extents that are already replicated through storage pool protection are skipped.
- Replication requires increased amounts of memory and sufficient bandwidth to complete processing. Size the database and its logs to ensure that transactions can complete.

Procedure

To enable node replication, complete the following steps in the Operations Center:

a. On the Servers page, click Details.
b. On the Details page, click Properties.
c. In the Replication section, select Enabled in the Outbound replication field.
d. Click Save.

What to do next

Complete the following actions:

1. To verify that replication was successful, review the Daily monitoring checklist.
2. Linux If the IBM Spectrum Protect server replicates nodes to a remote server, determine whether Aspera® Fast Adaptive Secure Protocol (FASP®) technology can improve data throughput to the remote server. Follow the instructions in Determining whether Aspera FASP technology can optimize data transfer in your system environment.

Replication compatibility

Protecting data in directory-container storage pools

Protect data in directory-container storage pools to reduce node replication time and to enable repair of data in directory-container storage pools.

Before you begin

Ensure that at least one directory-container storage pool exists on the target replication server. When you enable replication in the Operations Center, you can schedule storage pool protection. To configure replication and enable storage pool protection, complete the following steps:

1. On the Operations Center menu bar, hover over Storage and click Replication.
2. On the Replication page, click Server Pair.
3. Complete the steps in the Add Server Pair wizard.

About this task

Protecting a directory-container storage pool backs up data extents to another storage pool, and can improve performance for node replication. When node replication is started, the data extents that are already backed up through storage pool protection are skipped, which reduces the replication processing time. You can schedule the protection of storage pools several times a day to keep up with changes to data.

By protecting a storage pool, you do not use resources that replicate existing data and metadata, which improves server performance. You must use directory-container storage pools if you want to protect and back up the storage pool only.

Alternative protection strategy: As an alternative to using replication, you can protect data in directory-container storage pools by copying the data to container-copy storage pools. Data in container-copy storage pools is stored on tape volumes. Tape copies that are stored offsite provide additional disaster recovery protection in a replicated environment.

Procedure

1. Alternatively, to enable storage pool protection, you can use the PROTECT STGPOOL command from the source server to back up data extents in a directory-container storage pool. For example, to protect a directory-container storage pool that is named POOL1 issue the following command:

   ```
   protect stgpool pool1
   ```

   As part of the operation of the PROTECT STGPOOL command, damaged extents in the target storage pool are repaired. To be repaired, extents must already be marked as damaged on the target server. For example, an AUDIT CONTAINER command might identify damage in the target storage pool before the PROTECT STGPOOL command is issued.
2. Optional: If damaged extents were repaired in the target storage pool and you protect multiple source storage pools in one target storage pool, complete the following steps to ensure a complete repair:
   a. Issue the PROTECT STGPOOL command for all source storage pools to repair as much of the damage as possible.
   b. Issue the PROTECT STGPOOL command again for all source storage pools. For this second operation, use the FORCERECONCILE=YES parameter. This step ensures that any repairs from other source pools are properly recognized for all source storage pools.

Results

If a directory-container storage pool is protected, you can repair the storage pool if damage occurs, by using the REPAIR STGPOOL command.
Restriction: If you replicate client nodes but do not protect the directory-container storage pool, you cannot repair the storage pool.

What to do next

Complete the following actions:

1. To view replication workload status, follow the instructions in the Daily monitoring checklist.
2. Linux If the IBM Spectrum Protect server replicates nodes to a remote server, determine whether Aspera® Fast Adaptive Secure Protocol (FASP®) technology can improve data throughput to the remote server. Follow the instructions in Determining whether Aspera FASP technology can optimize data transfer in your system environment.

Modifying replication settings

Modify replication settings in the Operations Center. Change settings such as the number of replication sessions, replication rules, the data that you want to replicate, the replication schedule, and the replication workload.

About this task

You might need to customize your replication settings in the following scenarios:

- Changes to data priorities
- Changes to replication rules
- Requirement for a different server to be the target server
- Scheduled processes that negatively affect server performance

Procedure

Use the Operations Center to modify replication settings.

Task	Procedure
Change a replication rule.	a. On the Servers page, click Details. b. On the Details page, click Properties. c. In the Replication section, choose the replication rule that you want to apply: Default archive rule, Default backup rule, or Default space-management rule. d. Click Save.
Specify the duration that replication records are retained.	a. On the Servers page, click Details. b. On the Details page, click Properties. c. In the Replication section, enter the number of days that replication records must be retained in the Retain replication history field. Alternatively, select the Do not retain check box if you do not require replication records. d. Click Save.
Specify a target replication server.	a. On the Servers page, click Details. b. On the Details page, click Properties. c. In the Replication section, specify the target server. d. Click Save.
Cancel a replication process.	a. On the Servers page, click Active tasks. b. Select the process or session that you want to cancel. c. Click Cancel.

Setting different retention policies for the source server and target server

You can set policies on the target replication server that manage the replicated client-node data differently than on the source server. For example, you can maintain a different number of versions of files on the source and the target servers.

Procedure

1. From the source replication server, validate the replication configuration and verify that the source replication server can communicate with the target replication server by issuing the VALIDATE REPLICATION command. For example, validate the configuration by using the name of one client node that is being replicated:

   ```
   validate replication node1 verifyconnection=yes
   ```

2. From the source replication server, issue the VALIDATE REPLPOLICY command to review the differences between the policies on the source and target replication servers. For example, to display the differences between the policies on the source server and the target server, CVT_SRV2, issue the following command from the source server:

   ```
   validate replpolicy cvt_srv2
   ```

3. Update the policies on the target server if necessary.
   Tip: You can use the Operations Center to modify the policies on the target server. Follow the instructions in Editing policies.
   For example, to maintain inactive versions of files for a shorter time on the target server than on the source server, reduce the Backups setting in the management classes that apply to replicated client data.
4. Enable the target replication server to use its policies to manage the replicated client-node data by issuing the SET DISSIMILARPOLICIES command on the source server. For example, to enable the policies on the target replication server, CVT_SRV2, issue the following command on the source server:

   ```
   set dissimilarpolicies cvt_srv2 on
   ```

   The next time that the replication process runs, the policies on the target replication server are used to manage the replicated client-node data.
   Tip: If you configure replication by using the Operations Center and the policies on the source and target replication servers do not match, the policy that is specified for the source replication server is used. If you enabled the policies on the target replication server by using the SET DISSIMILARPOLICIES command, the policy that is specified for the target replication server is used. If the target replication server does not have the policy that is used by the node on the source replication server, the STANDARD policy is used.

Related reference:
EXPORT POLICY (Export policy information)

Securing the server

Secure the IBM Spectrum Protect™ server and data by controlling access to servers and client nodes, encrypting data, and maintaining secure access levels and passwords.

- Security concepts
  You can protect IBM Spectrum Protect from security risks by using communication protocols, securing passwords, and providing different access levels for administrators.
- Managing administrators
  An administrator who has system authority can complete any task with the IBM Spectrum Protect server, including assigning authority levels to other administrators. To complete some tasks, you must be granted authority by being assigned one or more authority levels.
- Changing password requirements
  You can change the minimum password limit, password length, password expiration, and enable or disable authentication for IBM Spectrum Protect.
- Securing IBM Spectrum Protect on the system
  Protect the system where the IBM Spectrum Protect server runs to prevent unauthorized access.

Security concepts

You can protect IBM Spectrum Protect™ from security risks by using communication protocols, securing passwords, and providing different access levels for administrators.

Transport Layer Security

You can use the Secure Sockets Layer (SSL) or the Transport Layer Security (TLS) protocol to provide transport layer security for a secure connection between servers, clients, and storage agents. If you send data between the server, client, and storage agent, use SSL or TLS to encrypt the data.

Tip: Any IBM Spectrum Protect documentation that indicates "SSL" or to "select SSL" applies to TLS.

SSL is provided by the Global Security Kit (GSKit) that is installed with the IBM Spectrum Protect server that the server, client, and storage agent use.

Restriction: Do not use the SSL or TLS protocols for communications with a DB2® database instance that is used by any IBM Spectrum Protect servers.

Each server, client, or storage agent that enables SSL must use a trusted self-signed certificate or obtain a unique certificate that is signed by a certificate authority (CA). You can use your own certificates or purchase certificates from a CA. Either certificate must be installed and added to the key database on the IBM Spectrum Protect server, client, or storage agent. The certificate is verified by the SSL client or server that requests or initiates the SSL communication. Some CA certificates are preinstalled in the key databases, by default.

SSL is set up independently on the IBM Spectrum Protect server, client, and storage agent.

Authority levels

With each IBM Spectrum Protect server, different administrative authority levels are available that determine the tasks that an administrator can complete.

After registration, an administrator must be granted authority by being assigned one or more administrative authority levels. An administrator with system authority can complete any task with the server and assign authority levels to other administrators by using the GRANT AUTHORITY command. Administrators with policy, storage, or operator authority can complete subsets of tasks.

An administrator can register other administrator IDs, grant levels of authority to them, rename IDs, remove IDs, and lock and unlock them from the server.

An administrator can control access to specific client nodes for root user IDs and non-root user IDs. By default, a non-root user ID cannot back up data on the node. Use the UPDATE NODE command to change the node settings to enable backup.

Passwords

By default, the server automatically uses password authentication. With password authentication, all users must enter a password when they access the server.

Use Lightweight Directory Access Protocol (LDAP) to apply stricter requirements for passwords. For more information, see Managing passwords and logon procedures (V7.1.1).

Table 1. Password authentication characteristics

Characteristic	More information
Case-sensitivity	Not case-sensitive.
Default password expiration	90 days. The expiration period begins when an administrator ID or client node is first registered to the server. If the password is not changed within this period, the password must be changed the next time that the user accesses the server.
Invalid password attempts	You can set a limit on consecutive invalid password attempts for all client nodes. When the limit is exceeded, the server locks the node.
Password length	The administrator can specify a minimum length.

Session security

Session security is the level of security that is used for communication among IBM Spectrum Protect client nodes, administrative clients, and servers and is set by using the SESSIONSECURITY parameter.

The SESSIONSECURITY parameter can be set to one of the following values:

- The STRICT value enforces the highest level of security for communication between IBM Spectrum Protect servers, nodes, and administrators.
- The TRANSITIONAL value specifies that the existing communication protocol is used while you update your IBM Spectrum Protect software to V8.1.2 or later. This is the default. When SESSIONSECURITY=TRANSITIONAL, stricter security settings are automatically enforced as higher versions of the TLS protocol are used and as the software is updated to V8.1.2 or later. After a node, administrator, or server meets the requirements for the STRICT value, session security is automatically updated to the STRICT value, and the entity can no longer authenticate by using a previous version of the client or earlier TLS protocols.

For more information about the SESSIONSECURITY parameter values, see the following commands.

Table 2. Commands used to set the SESSIONSECURITY parameter

Entity	Command
Client nodes	• REGISTER NODE • UPDATE NODE
Administrators	• REGISTER ADMIN • UPDATE ADMIN
Servers	• DEFINE SERVER • UPDATE SERVER

Administrators that authenticate by using the DSMADMC command, DSMC command, or dsm program cannot authenticate by using an earlier version after authenticating by using V8.1.2 or later. To resolve authentication issues for administrators, see the following tips:
Tips:

- Ensure that all IBM Spectrum Protect software that the administrator account uses to log on is upgraded to V8.1.2 or later. If an administrator account logs on from multiple systems, ensure that the server's certificate is installed on each system.
- After an administrator authenticates to a V8.1.2 or later server by using a V8.1.2 or later client, the administrator can authenticate only on clients or servers that are using V8.1.2 or later. An administrator command can be issued from any system.
- If necessary, create a separate administrator account to use only with clients and servers that are using V8.1.1 or earlier software.

Enforce the highest level of security for communication with the IBM Spectrum Protect server by ensuring that all nodes, administrators, and servers use STRICT session security. You can use the SELECT command to determine which servers, nodes, and administrators are using TRANSITIONAL session security and should be updated to use STRICT session security.

Related tasks:
Securing communications

Managing administrators

An administrator who has system authority can complete any task with the IBM Spectrum Protect™ server, including assigning authority levels to other administrators. To complete some tasks, you must be granted authority by being assigned one or more authority levels.

Procedure

Complete the following tasks to modify administrator settings.

Task	Procedure
Add an administrator.	To add an administrator, ADMIN1, with system authority and specify a password, complete the following steps: a. Register the administrator and specify Pa$#$twO as the password by issuing the following command: `register admin admin1 Pa$#$twO` b. Grant system authority to the administrator by issuing the following command: `grant authority admin1 classes=system`

Task	Procedure
Change administrative authority.	Change the authority level for an administrator, ADMIN1. • Grant system authority to the administrator by issuing the following command: `grant authority admin1 classes=system` • Revoke system authority for the administrator by issuing the following command: `revoke authority admin1 classes=system`
Remove administrators.	Remove an administrator, ADMIN1, from accessing the IBM Spectrum Protect server by issuing the following command: `remove admin admin1`
Temporarily prevent access to the server.	Lock or unlock an administrator by using the LOCK ADMIN or UNLOCK ADMIN command.

Changing password requirements

You can change the minimum password limit, password length, password expiration, and enable or disable authentication for IBM Spectrum Protect™.

About this task

By enforcing password authentication and managing password restrictions, you protect your data and your servers from potential security risks.

Procedure

Complete the following tasks to change password requirements for IBM Spectrum Protect servers.

Table 1. Authentication tasks for IBM Spectrum Protect servers

Task	Procedure
Set a limit for invalid password attempts.	a. On the Servers page in the Operations Center, select the server. b. Click Details, and then click the Properties tab. c. Set the number of invalid attempts in the Invalid sign-on attempt limit field. The default value at installation is 0.
Set a minimum length for passwords.	a. On the Servers page in the Operations Center, select the server. b. Click Details and then click the Properties tab. c. Set the number of characters in the Minimum password length field.
Set the expiration period for passwords.	a. On the Servers page in the Operations Center, select the server. b. Click Details and then click the Properties tab. c. Set the number of days in the Password common expiration field.

Task	Procedure
Disable password authentication.	By default, the server automatically uses password authentication. With password authentication, all users must enter a password to access the server. You can disable password authentication only for passwords that authenticate with the server (LOCAL). By disabling password authentication, you increase the security risk for the server.
Set a default authentication method.	Issue the SET DEFAULTAUTHENTICATION command. For example, to use the server as the default authentication method, issue the following command: `set defaultauthentication local` To update one client node to authenticate with the server, include `AUTHENTICATION=LOCAL` in the UPDATE NODE command: `update node authentication=local`

Related concepts:

Authenticating IBM Spectrum Protect users by using an LDAP server

Managing passwords and logon procedures (V7.1.1)

Securing IBM Spectrum Protect on the system

Protect the system where the IBM Spectrum Protect™ server runs to prevent unauthorized access.

Procedure

Ensure that unauthorized users cannot access the directories for the server database and the server instance. Keep the access settings for these directories that you configured during implementation.

- Restricting user access to the server
  Authority levels determine what an administrator can do with the IBM Spectrum Protect server. An administrator with system authority can complete any task with the server. Administrators with policy, storage, or operator authority can complete subsets of tasks.
- Limiting access through port restrictions
  Limit access to the server by applying port restrictions.

Restricting user access to the server

Authority levels determine what an administrator can do with the IBM Spectrum Protect™ server. An administrator with system authority can complete any task with the server. Administrators with policy, storage, or operator authority can complete subsets of tasks.

Procedure

1. After you register an administrator by using the REGISTER ADMIN command, use the GRANT AUTHORITY command to set the administrator's authority level. For details about setting and changing authority, see Managing administrators.
2. To control the authority of an administrator to complete some tasks, use the following two server options:
   a. You can select the authority level that an administrator must have to issue QUERY and SELECT commands with the QUERYAUTH server option. By default, no authority level is required. You can change the requirement to one of the authority levels, including system.
   b. You can specify that system authority is required for commands that cause the server to write to an external file with the REQSYSAUTHOUTFILE server option. By default, system authority is required for such commands.
3. You can restrict data backup on a client node to only root user IDs or authorized users. For example, to limit backups to the root user ID, issue the REGISTER NODE or UPDATE NODE command and specify the BACKUPINITIATION=root parameter:

   ```
   update node backupinitiation=root
   ```

Limiting access through port restrictions

Limit access to the server by applying port restrictions.

About this task

You might have to restrict access to specific servers, based on your security requirements. The IBM Spectrum Protect™ server can be configured to listen on four TCP/IP ports: two that can be used for either regular TCP/IP protocols or Secure Sockets Layer (SSL)/Transport Layer Security (TLS) protocols and two that can be used only for the SSL/TLS protocol.

Procedure

You can set the server options to specify the port that you require, as listed in Table 1.

Table 1. Server options and port access

Server option	Port access
TCPPORT	Specifies the port number on which the server TCP/IP communication driver is to wait for requests for client sessions. This port listens for both TCP/IP and SSL-enabled sessions. The default value is 1500.
TCPADMINPORT	Specifies the port number on which the server TCP/IP communication driver is to wait for requests for sessions other than client sessions. This port listens for both TCP/IP and SSL-enabled sessions. The default is the value of TCPPORT. Use this option to separate administrative client traffic from regular client traffic that uses the TCPPORT and SSLTCPPORT options.
SSLTCPPORT	Specifies the SSL TCP/IP port address for a server. This port listens for SSL-enabled sessions only. A default port value is not available.
SSLTCPADMINPORT	Specifies the port address on which the server TCP/IP communication driver waits for requests for SSL-enabled sessions. A default port value is not available. Use this option to separate administrative client traffic from regular client traffic that uses the TCPPORT and SSLTCPPORT options.

Planning firewall access

Stopping and starting the server

Before you complete maintenance or reconfiguration tasks, stop the server. Then, start the server in maintenance mode. When you are finished with the maintenance or reconfiguration tasks, restart the server in production mode.

Before you begin

You must have system or operator privilege to stop and start the IBM Spectrum Protect™ server.

- Stopping the server
  Before you stop the server, prepare the system by ensuring that all database backup operations are completed, and all other processes and sessions are ended. In this way, you can safely shut down the server and ensure that data is protected.
- Starting the server for maintenance or reconfiguration tasks
  Before you begin server maintenance or reconfiguration tasks, start the server in maintenance mode. When you start the server in maintenance mode, you disable operations that might disrupt your maintenance or reconfiguration tasks.

Stopping the server

Before you stop the server, prepare the system by ensuring that all database backup operations are completed, and all other processes and sessions are ended. In this way, you can safely shut down the server and ensure that data is protected.

About this task

When you issue the HALT command to stop the server, the following actions occur:

- All processes and client node sessions are canceled.
- All current transactions are stopped. (The transactions will be rolled back when the server is restarted.)

Procedure

To prepare the system and stop the server, complete the following steps:

1. Prevent new client node sessions from starting by issuing the DISABLE SESSIONS command:

   ```
   disable sessions all
   ```

2. Determine whether any client node sessions or processes are in progress by completing the following steps:
   a. On the Overview page of the Operations Center, view the Activity area for the total numbers of processes and sessions that are currently active. If numbers differ significantly from the usual numbers that are displayed during your daily storage-management routine, view other status indicators in the Operations Center to check whether there is a problem.
   b. View the graph in the Activity area to compare the amount of network traffic over the following periods:
      - The current period, that is, the most recent 24-hour period
      - The previous period, that is, the 24 hours before the current period

      If the graph for the previous period represents the expected amount of traffic, significant differences on the graph for the current period might indicate a problem.
   c. On the Servers page, select a server for which you want to view processes and sessions, and click Details. If the server is not registered as a hub or spoke server in the Operations Center, obtain information about processes by using administrative commands. Issue the QUERY PROCESS command to query processes and obtain information about sessions by issuing the QUERY SESSION command.
3. Wait until the client node sessions are completed or cancel them. To cancel processes and sessions, complete the following steps:
   - On the Servers page, select a server for which you want to view processes and sessions, and click Details.
   - Click the Active Tasks tab, and select one or more processes, sessions, or a combination of both that you want to cancel.
   - Click Cancel.
   - If the server is not registered as a hub or spoke server in the Operations Center, cancel sessions by using administrative commands. Issue the CANCEL SESSION command to cancel a session and cancel processes by using the CANCEL PROCESS command.
     Tip: If the process that you want to cancel is waiting for a tape volume to be mounted, the mount request is canceled. For example, if you issue an EXPORT, IMPORT, or MOVE DATA command, the command might initiate a process that requires a tape volume to be mounted. However, if a tape volume is being mounted by an automated library, the cancel operation might not take effect until the mount process is complete. Depending on your system environment, this could take several minutes.
4. Stop the server by issuing the HALT command:

   ```
   halt
   ```

Starting the server for maintenance or reconfiguration tasks

Before you begin server maintenance or reconfiguration tasks, start the server in maintenance mode. When you start the server in maintenance mode, you disable operations that might disrupt your maintenance or reconfiguration tasks.

About this task

Start the server in maintenance mode by running the DSMSERV utility with the MAINTENANCE parameter.

The following operations are disabled in maintenance mode:

- Administrative command schedules
- Client schedules
- Reclamation of storage space on the server
- Inventory expiration
- Migration of storage pools

In addition, clients are prevented from starting sessions with the server.

Tips:

- You do not have to edit the server options file, dsmserv.opt, to start the server in maintenance mode.
- While the server is running in maintenance mode, you can manually start the storage-space reclamation, inventory expiration, and storage-pool migration processes.

Procedure

To start the server in maintenance mode, issue the following command:

```
dsmserv maintenance
```

Tip: To view a video about starting the server in maintenance mode, see Starting a server in maintenance mode.

What to do next

To resume server operations in production mode, complete the following steps:

1. Shut down the server by issuing the HALT command:

   ```
   halt
   ```

2. Start the server by using the method that you use in production mode. Follow the instructions for your operating system:
   - AIX Starting the server instance
   - Linux Starting the server instance
   - Windows Starting the server instance

Operations that were disabled during maintenance mode are reenabled.

Planning to upgrade the server

When a fix pack or interim fix becomes available, you can upgrade the IBM Spectrum Protect™ server to take advantage of product improvements. Servers and clients can be upgraded at different times. Ensure that you complete the planning steps before you upgrade the server.

About this task

Follow these guidelines:

- The preferred method is to upgrade the server by using the installation wizard. After you start the wizard, in the IBM Installation Manager window, click the Update icon; do not click the Install or Modify icon.
- If upgrades are available for both the server component and the Operations Center component, select the check boxes to upgrade both components.

Procedure

1. Review the list of fix packs and interim fixes. See technote 1239415.
2. Review product improvements, which are described in readme files.
   Tip: When you obtain the installation package file from the IBM Spectrum Protect support site, you can also access the readme file.
3. Ensure that the version that you upgrade your server to is compatible with other components, such as storage agents and library clients. See technote 1302789.
4. If your solution includes servers or clients at a level that is earlier than V7.1, review the guidelines to ensure that client backup and archive operations are not disrupted. See technote 1053218.
5. Review the upgrade instructions. Ensure that you back up the server database, the device configuration information, and the volume history file.

What to do next

To install a fix pack or interim fix, follow the instructions for your operating system:

- AIX Installing an IBM Spectrum Protect server fix pack
- Linux Installing an IBM Spectrum Protect server fix pack

- Windows Installing an IBM Spectrum Protect server fix pack

Upgrade and Migration Process - Frequently Asked Questions

Preparing for an outage or system update

Prepare IBM Spectrum Protect™ to maintain your system in a consistent state during a planned power outage or system update.

About this task

Ensure that you schedule activities regularly to manage, protect, and maintain the server.

Procedure

1. Cancel processes and sessions that are in progress by completing the following steps:
   a. In the Operations Center, on the Servers page, select a server for which you want to view processes and sessions, and click Details.
   b. Click the Active Tasks tab, and select one or more processes, sessions, or a combination of both that you want to cancel.
   c. Click Cancel.
2. Stop the server by issuing the HALT command:

   ```
   halt
   ```

   Tip: You can issue the halt command from the Operations Center by hovering over the Settings icon and clicking Command Builder. Then, select the server, type `halt`, and press Enter.

Implementing a disaster recovery plan

Implement a disaster recovery strategy to recover your applications if a disaster occurs and to ensure high server availability.

About this task

Determine your disaster recovery requirements by identifying the business priorities for client node recovery, the systems that you use to recover data, and whether client nodes have connectivity to a recovery server. Use replication and storage pool protection to protect data. You must also determine how often directory-container storage pools are protected.

- Completing recovery drills
  Schedule disaster recovery drills to prepare for audits that certify the recoverability of the IBM Spectrum Protect server and to ensure that data can be restored and operations can resume after an outage. A drill also helps you ensure that all data can be restored and operations resumed before a critical situation occurs.

Recovering from data loss or system outages

You can use IBM Spectrum Protect™ to recover data that was lost when a disaster or system outage occurred. You can recover directory-container storage pools, client data, and databases.

Before you begin

Schedule client and server workloads to achieve the best performance for your storage environment. Issue the PROTECT STGPOOL and REPLICATE NODE commands as part of the schedule. Protect the storage pool before you replicate the client node. When node replication is started, the data extents that are already replicated through storage pool protection are skipped, which reduces replication processing time.

Procedure

Use the following recovery methods based on the component that you must recover.

Component to recover	Procedure	More information

Component to recover	Procedure	More information
Directory-container storage pool	To recover directory-container storage pools, complete the following steps: a. Scan for damaged data extents in the directory-container storage pool by using the AUDIT CONTAINER command and specifying the ACTION=SCANALL parameter. b. Repair damaged data extents in the directory-container storage pool by using the REPAIR STGPOOL command. Restriction: You can repair a storage pool only if the storage pool is protected. c. Remove damaged data extents by using the AUDIT CONTAINER command and specifying the ACTION=REMOVEDAMAGED parameter.	Repairing storage pools
Client data	Prerequisites: • The source replication server, the target replication server, and the client must be at the V7.1 level or later. If any of the servers are at an earlier level, automatic failover is disabled and you must rely on manual failover. Manually configure the client to automatically fail over to the target server for data recovery. If you enabled the client for automated client failover, you can recover the data by using automatic failover function. You can verify that the usereplicationfailover option is either not in the client options file or is set to `yes`. Recover data from the target server when the source server is unavailable due to an outage by using automatic failover. Tip: • Use the SET FAILOVERHLADDRESS command to specify the IP address for the replication server during failover, if the address is different from the IP address that is specified for the replication process.	• Recovering damaged data from a replicated copy • SET FAILOVERHLADDRESS (Set a failover high level address)

Component to recover	Procedure	More information
Database	Prerequisites: • To restore the database after a disaster, you must have a copy of the current device configuration file. The device configuration file cannot be recreated. • Ensure that you have a backed up version of the database. Restore the IBM Spectrum Protect database to the most current state or to a specific point in time by using the DSMSERV RESTORE DB server utility.	DSMSERV RESTORE DB (Restore the database)

- Restoring the database
  You might have to restore the IBM Spectrum Protect database after a disaster. You can restore the database to the most current state or to a specified point in time. You must have full, incremental, or snapshot database backup volumes to restore the database.
- Recovering damaged data from a replicated copy
  If a source replication server is unavailable, you can recover damaged data from a replicated copy that is stored on the target replication server.
- Repairing storage pools
  If a disaster or system outage occurred, you can repair deduplicated data extents in a directory-container storage pool.

Related reference:
AUDIT CONTAINER (Verify the consistency of database information for a directory-container storage pool)
DSMSERV RESTORE DB (Restore the database)

Restoring the database

You might have to restore the IBM Spectrum Protect™ database after a disaster. You can restore the database to the most current state or to a specified point in time. You must have full, incremental, or snapshot database backup volumes to restore the database.

Before you begin

If the database and recovery log directories are lost, re-create them before you issue the DSMSERV RESTORE DB server utility. For example, use the following commands: AIX Linux

```
mkdir /tsmdb001
mkdir /tsmdb002
mkdir /tsmdb003
mkdir /activelog
mkdir /archlog
mkdir /archfaillog
```

Windows

```
mkdir e:\tsm\db001
mkdir f:\tsm\db001
mkdir g:\tsm\db001
mkdir h:\tsm\activelog
mkdir i:\tsm\archlog
mkdir j:\tsm\archfaillog
```

Restrictions:

- To restore the database to its latest version, you must locate the archive log directory. If you are cannot locate the directory, you can restore the database only to a point in time.

- You cannot use Secure Sockets Layer (SSL) for database restore operations.
- If the release level of the database backup is different from the release level of the server that is being restored, you cannot restore the server database. For example, if you are using a Version 8.1 server and you try to restore a Version 7.1 database, an error occurs.

About this task

Point-in-time restore operations are typically used for situations such as disaster recovery or to remove the effects of errors that can cause inconsistencies in the database. To recover the database to the time when the database was lost, recover the database to its latest version.

Procedure

Use the DSMSERV RESTORE DB server utility to restore the database. Depending on the version of the database that you want to restore, choose one of the following methods:

- Restore a database to its latest version. For example, use the following command:

  ```
  dsmserv restore db
  ```

- Restore a database to a point in time. For example, to restore the database to a backup series that was created on 19 April 2015, use the following command:

  ```
  dsmserv restore db todate=04/19/2015
  ```

What to do next

If you restored the database and directory-container storage pools exist on the server, you must identify inconsistencies between the database and the file system.

1. If you restored the database to a point in time and you did not delay reuse of the directory-container storage pool, you must audit all the containers. To audit all containers, issue the following command:

   ```
   audit container stgpool
   ```

2. If the server cannot identify containers on the system, complete the following steps to display a list of containers:
   a. From an administrative client, issue the following command:

      ```
      select container_name from containers
      ```

   b. From the file system, issue the following command for the storage pool directory on the source server:
      Tip: The storage pool directory is displayed in the command output:
      AIX Linux

      ```
      [root@source]$ ls -l
      ```

      Windows

      ```
      c:\source_stgpooldir\00>dir
      ```

   c. Compare the containers that are listed on the file system and the server.
   d. Issue the AUDIT CONTAINER command and specify the container that is missing from the server output. Specify the ACTION=REMOVEDAMAGED parameter to delete the container.
   e. To ensure that the containers are deleted on the file system, review the messages that are displayed.

Related tasks:
Replicating client node data after a database restore (V7.1.1)
Related reference:
AUDIT CONTAINER (Verify the consistency of database information for a directory-container storage pool)
DSMSERV RESTORE DB (Restore the database)

Recovering damaged data from a replicated copy

If a source replication server is unavailable, you can recover damaged data from a replicated copy that is stored on the target replication server.

Before you begin

The server name that you specify with the SET REPLSERVER command must match the name of an existing server definition. It must also be the name of the server to be used as the target replication server. If the server name specified by this command does not match the server name of an existing server definition, the command fails.
Tip:

- Use care when you change or remove a target replication server. If you change a target replication server, client-node data that is replicated is sent to a different target replication server. If you remove a target replication server, client node data is not replicated.

Procedure

1. Verify the replication status of the data on the target server. The replication status indicates whether the most recent backup was replicated to the secondary server.
2. Restore data from a target replication server by setting the source replication server as the target replication server. For example, if you want to set the source replication server as the target replication server, server1, issue the following command:

   ```
   set replserver server1
   ```

What to do next

When you restore the IBM Spectrum Protect™ database on a source replication server, replication is automatically disabled. Before you re-enable replication, determine whether copies of data that are on the target replication server are needed.

Related tasks:
Replicating client node data after a database restore (V7.1.1)

Repairing storage pools

If a disaster or system outage occurred, you can repair deduplicated data extents in a directory-container storage pool.

Before you begin

Identify inconsistencies between the database and the directory-container storage pool by using the AUDIT CONTAINER command. By identifying the damaged data extents in the directory-container storage pool, you can determine what data extents to repair.

Before you repair a storage pool, ensure that the storage pool is protected by using the PROTECT STGPOOL command.

Procedure

1. To repair a directory-container storage pool, use the REPAIR STGPOOL command. For example, to repair a storage pool, STGPOOL1, issue the following command:

   ```
   repair stgpool stgpool1
   ```

2. If the damaged storage pool is specified as a target storage pool on the PROTECT STGPOOL command for one or more source storage pools, issue the PROTECT STGPOOL command for all source storage pools.
3. To ensure that all damaged data is identified and repaired from other source storage pools, issue the PROTECT STGPOOL command again from all source storage pools and specify the FORCERECONCILE=YES parameter.
4. To remove objects that refer to damaged data, issue the AUDIT CONTAINER command and specify the ACTION=REMOVEDAMAGED parameter.
5. If the damaged storage pool is a target storage pool for node replication from one or more source servers, issue the REPLICATE NODE command again from all source servers.
6. When the damage is repaired, issue the PROTECT STGPOOL command to ensure that the storage pool is protected to another directory-container storage pool.

What to do next

Ensure that no damaged data extents are displayed in the output by using the QUERY DAMAGED command.

Related reference:
Repairing and recovering data
AUDIT CONTAINER (Verify the consistency of database information for a directory-container storage pool)
QUERY DAMAGED (Query damaged data in a directory-container or cloud-container storage pool)

Tape solution

This data protection solution provides storage to tape media, a flexible and affordable option for long-term data retention.

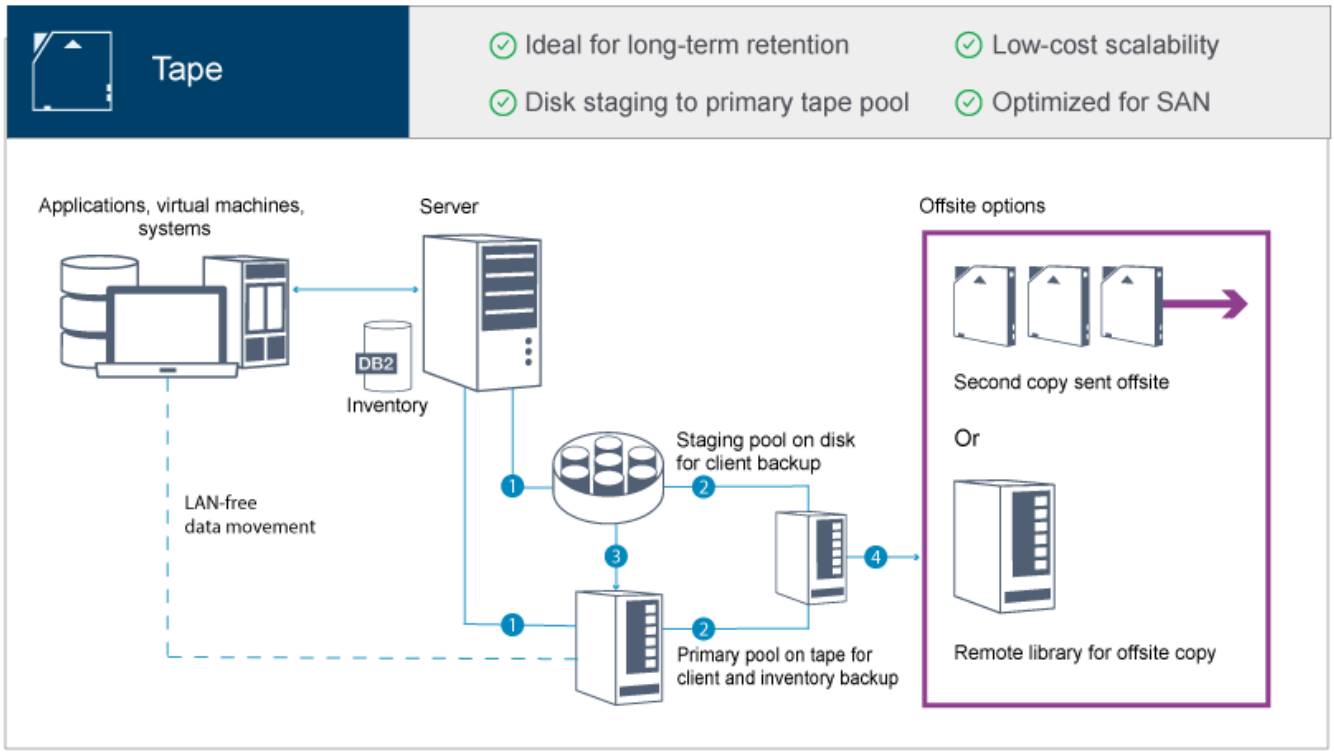
- Planning for a tape-based data protection solution
  Plan for a data protection solution that includes disk-to-disk-to-tape and disk-to-tape backup operations to optimize storage.
- Implementation of a tape-based data protection solution
  Implement the tape-based solution, which uses disk-to-disk-to-tape backup and disk staging to optimize storage. By implementing the tape solution, you can enable long-term data retention and achieve low-cost scalability.
- Monitoring a tape solution
  After you implement an IBM Spectrum Protect tape-based solution, monitor the solution to ensure correct operation. By monitoring the solution daily and periodically, you can identify existing and potential issues. The information that you gather can be used to troubleshoot problems and optimize system performance.
- Managing operations for a tape solution
  Use this information to manage operations for a tape implementation for an IBM Spectrum Protect server.

Planning for a tape-based data protection solution

Plan for a data protection solution that includes disk-to-disk-to-tape and disk-to-tape backup operations to optimize storage.

Planning roadmap

Plan for the tape solution by reviewing the architecture layout in Figure 1 and then completing the roadmap tasks that follow the diagram.
Figure 1. Tape solution



In this data protection configuration, the server uses both disk and tape storage hardware. Storage pool staging is used, in which client data is initially stored in disk storage pools and then later migrated to tape storage pools. For disaster recovery, tape

volumes can be stored offsite. Offsite options include physically moving a second copy offsite by a courier or electronically vaulting copies offsite to a remote library.

Tip: The described solution does not include node replication. However, if you want to use node replication to back up a storage pool from disk to disk, ensure that the replication operation is completed before data is migrated from disk to tape. You can also use node replication to back up a storage pool on a local tape device to a copy storage pool on a local tape device.
To plan for a tape-based solution, complete the following tasks:

1. Meet system requirements for hardware and software.
2. Record values for your system configuration in the planning worksheets.
3. Plan for disk storage.
4. Plan for tape storage.
5. Plan for security.

Tape planning requirements

Before you implement a tape solution, review the general guidelines about system requirements. Determine whether to back up data to disk or tape, or a combination of both.

Network bandwidth
: The network must have sufficient bandwidth for the expected data transfers between the client and the server, and for the cross-site restore operations that are required for disaster recovery. Use a storage area network (SAN) for data transfers among the server, disk devices, and tape devices. For more information, see Hardware requirements.

Data migration
: Migrate all data from disk to tape daily. Specify a FILE device class for disk-based storage pools. Schedule migration to control when processing occurs. To prevent automatic migration based on the migration threshold, specify a value of 100 for the HIGHMIG parameter and 0 for the LOWMIG parameter when you issue the DEFINE STGPOOL command. You must keep at least 20% of the tape drives available for restore operations. To use up to 80% of available tape drives and improve throughput performance, specify the MIGPROCESS parameter.
Consider the following information based on the type of data that is migrated:

  - Use tape to back up data from clients that have large objects, such as databases.
    Tip: Check with your tape-drive manufacturer for guidance about the size of the database that is suitable to write to tape.
  - Use disk to back up data from clients that have smaller objects.
  - To back up data directly to tape, use LAN-free data movement. For more information, see Configuring LAN-free data movement.
  - Do not back up virtual machines to tape. Use a separate disk-based storage pool that does not migrate to a tape-based storage pool. For more information about virtual machine support, see technote 1239546.

Storage pool capacity
: Maintain enough storage pool capacity to allow for 2 days of client backups and a buffer of 20%. You might have to schedule full backups over a few days to ensure that you have enough storage pool space.

Tape drives
: Review the manufacturer specifications and estimate the capacity of a tape drive. Determine the amount of space that is required for backup and migration operations. Reserve 20% of tape drives for restore operations.

Related reference:
MIGRATE STGPOOL (Migrate storage pool to next storage pool)

System requirements for a tape-based solution

Hardware and software requirements are provided for a tape-based storage solution that has a data ingestion rate of 14 TB per hour.

Review the information to determine the hardware and software requirements for your storage environment. You might have to make adjustments based on your system size.

- Hardware requirements
  Hardware requirements for your IBM Spectrum Protect™ solution are based on system size. Choose equivalent or better components than those items that are listed to ensure optimum performance for your environment.

- Software requirements
  Documentation for the IBM Spectrum Protect tape-based solution includes installation and configuration tasks for IBM® AIX®, Linux, and Microsoft Windows operating systems. You must meet the minimum software requirements that are listed.

Hardware requirements

Hardware requirements for your IBM Spectrum Protect™ solution are based on system size. Choose equivalent or better components than those items that are listed to ensure optimum performance for your environment.

For more information about planning disk devices, see Planning for disk storage.

For more information about planning tape devices, see Planning for tape storage.

The following table includes minimum hardware requirements for the server and storage. If you are using local partitions (LPARs) or work partitions (WPARs), adjust the network requirements to take account of the partition sizes. The figures in the table are based on a data ingestion rate of 14 TB per hour.

Hardware component	**System requirements**
Server processor	AIX 8 processor cores, 3.42 GHz or faster. For example, use a POWER8® processor-based server. Linux Windows 16 processor cores, 2.0 GHz or faster. For example, use an Intel Xeon processor.
Server memory	64 GB RAM.
Network	The following sizing manages approximately 14 TB of data per hour: • 10 Gb Ethernet (a minimum of four ports) • 8 Gb Fibre Channel adapter (a minimum of four ports) The number of ports depends on the percentage of daily data ingestion to disk storage pools versus tape storage. Use separate Fibre Channel adapters for tape and disk data.

Hardware component	System requirements
Storage	Disk Based on the amount of data that you are writing to disk, specify the number of disks that you require. Ensure that the sequential input/output (I/O) throughput of the storage area network (SAN) matches the I/O throughput for the network in the previous row. For example, if you must back up 10 TB of data in a four-hour window, the throughput is approximately 700 MB per second. In this case, the server requires a front-end network (client-to-server path) that supports a minimum throughput of 700 MB per second. The back-end SAN (the server-to-storage device path) also must support a minimum throughput of 700 MB per second. To calculate the required disk speed, use the following formulas: `(Total amount of daily data ingestion -` `amount of daily data ingestion directly to tape) ÷` `(Number of hours for daily client backup operations) =` `Megabytes of data ingestion to disk per hour` `(Megabytes of data ingestion to disk per hour) ÷` `(3600 seconds per hour) =` `Megabytes of data ingestion per second` `that must be supported by the disk technology` Tape Select the tape technology that best fits your business requirements. For example, use IBM Linear Tape-Open (LTO) or IBM TS1150 tape drives. Ensure that you have sufficient mount points for client backup operations and for migration. For more information about planning tape storage, see Planning for tape storage. For a list of supported tape devices, see IBM® Support Portal for IBM Spectrum Protect. Tip: To optimize data movement, use LAN-free data movement.
SAN I/O adapters	Segregate disk and tape I/O. For more information about selecting an adapter, see the documentation for Brocade hardware products and for IBM Storwize® storage solutions. Disk Use at least two adapters. Tape Use at least two adapters.

Estimating space requirements for the Operations Center

Hardware requirements for the Operations Center are included in the preceding table, except for the database and archive log space (inventory) that the Operations Center uses to hold records for managed clients.

If you do not plan to install the Operations Center on the same system as the IBM Spectrum Protect server, you can estimate system requirements separately. To calculate system requirements for the Operations Center, see the system requirements calculator in technote 1641684.

Managing the Operations Center on the IBM Spectrum Protect server is a workload that requires extra space for database operations on both the hub server and any spoke servers. The amount of space on the hub server for the archive log is larger if the hub server is monitoring one or more spoke servers. Review the following guidelines to estimate how much space your IBM Spectrum Protect server requires.

Database space for the Operations Center

The Operations Center uses approximately 4.4 GB of database space for every 1000 clients that are monitored on that server. This calculation applies to both hub servers and spoke servers within a configuration.

For example, consider a hub server with 2000 clients that also manages three spoke servers, each with 1000 clients. This configuration has a total of 5000 clients across the four servers. Each of the spoke servers requires 4.4 GB of database space. If the spoke servers are at IBM Spectrum Protect Version 8.1.2 or later, the hub server requires 8.8 GB of database space for monitoring only its 2000 clients:

```
(4.4 GB x 2) = 8.8 GB
```

Database space for managed data

Managed data is the amount of data that is protected, including the amount of data for all retained versions.

- For client types that perform incremental-forever backups, the following formula can be used to estimate the total managed data:

  ```
  Front-end + (front-end × change rate × (retention - 1))
  ```

  For example, if you back up 100 TB of front-end data, use a 30-day retention period, and have a 5% change rate, calculate your total managed data by using the following figures:

  ```
  100 TB + (100 TB × 0.05 × (30-1)) = 245 TB total managed data
  ```

- For client types that perform full backups every day, the following formula can be used to estimate the total managed data:

  ```
  Front-end × retention × (1 + change rate)
  ```

  For example, if you back up 10 TB of front-end data, use a 30-day retention period, and have a 3% change rate, calculate your total managed data by using the following figures:

  ```
  10 TB × 30 × (1 + .03) = 309 TB total managed data
  ```

  Unstructured data, average object size: 4 MB

  Structured data, average object size: 128 MB

  Unstructured data, number of objects =

  ```
  (245 TB × 1024 × 1024) / 4 MB = 64225280
  ```

  Structured data, number of objects =

  ```
  (309 TB × 1024 × 1024) / 128 MB = 2531328
  ```

  Total number of objects: 66756608

  Managed data cost (1 KB per object) =

  ```
  (66756608 KB) / (1024 × 1024) = 63.66 GB
  ```

  Plan for 20% of additional space so that database systems are not at 100% capacity:

  ```
  Database total physical storage requirements =
  (managed data space + Operations Center space) × (1.20)
  ```

  For this example, you would calculate the space by using the following figures:

  ```
  (66.33 GB + 8.4 GB) × 1.20 = 76.41 GB
  ```

Archive log space

The Operations Center uses approximately 18 GB of archive log space every 24 hours, per server, for every 1000 clients monitored on that server. Additionally, for every 1000 clients that are monitored on spoke servers, additional archive log space is used on the hub server. For spoke servers at V8.1.2 or later, this added amount is 1.2 GB of archive log space on the hub server per 1000 clients monitored every 24 hours.

For example, consider a hub server with 2000 clients that also manages three spoke servers, each with 1000 clients. This configuration has a total of 5000 clients across the four servers. You can calculate the archive log space for the hub server by using the following formula:

```
((18 GB x 2) + (1.2 GB x 3)) = 39.6 GB of archive log space
```

These estimates are based on the default status collection interval of 5 minutes. If you reduce the collection interval from once every 5 minutes to once every 3 minutes, the space requirements increase. The following examples show the approximate increase in the log space requirements with a collection interval of once every 3 minutes for a configuration in which V8.1.2 or later spoke servers are monitored:

- Hub server: In the range 39.6 GB - 66 GB

- Each spoke server: In the range 18 GB - 30 GB

Allocate archive log space so that you can support the Operations Center without affecting server operations.

Software requirements

Documentation for the IBM Spectrum Protect™ tape-based solution includes installation and configuration tasks for IBM® AIX®, Linux, and Microsoft Windows operating systems. You must meet the minimum software requirements that are listed.

For information about software requirements for IBM lin_tape device drivers, refer to the IBM Tape Device Drivers Installation and User's Guide.

AIX systems

Type of software	Minimum software requirements
Operating system	IBM AIX 7.1 For more information about operating system requirements, see AIX: Minimum system requirements for AIX systems.
Gunzip utility	The gunzip utility must be available on your system before you install or upgrade the IBM Spectrum Protect server. Ensure that the gunzip utility is installed and the path to it is set in the PATH environment variable.
File system type	JFS2 file systems AIX systems can cache a large amount of file system data, which can reduce memory that is required for server and IBM DB2® processes. To avoid paging with the AIX server, use the rbrw mount option for the JFS2 file system. Less memory is used for the file system cache and more is available for IBM Spectrum Protect. Do not use the file system mount options, Concurrent I/O (CIO), and Direct I/O (DIO), for file systems that contain the IBM Spectrum Protect database, logs, or storage pool volumes. These options can cause performance degradation of many server operations. IBM Spectrum Protect and DB2 can still use DIO where it is beneficial to do so, but IBM Spectrum Protect does not require the mount options to selectively take advantage of these techniques.
Other software	Korn Shell (ksh)

Linux systems

Type of software	Minimum software requirements
Operating system	Red Hat Enterprise Linux 7 (x86_64)
Libraries	GNU C libraries, Version 2.3.3-98.38 or later that is installed on the IBM Spectrum Protect system. Red Hat Enterprise Linux Servers: • libaio • libstdc++.so.6 (32-bit and 64-bit packages are required) • numactl.x86_64
File system type	Format database-related file systems with ext3 or ext4. For storage pool-related file systems, use XFS.
Other software	Korn Shell (ksh)

Windows systems

Type of software	Minimum software requirements
Operating system	Microsoft Windows Server 2012 R2 (64-bit) or Windows Server 2016

Type of software	Minimum software requirements
File system type	NTFS
Other software	Windows 2012 R2 or Windows 2016 with .NET Framework 3.5 is installed and enabled. The following User Account Control policies must be disabled: • User Account Control: Admin Approval Mode for the Built-in Administrator account • User Account Control: Run all administrators in Admin Approval Mode

Planning worksheets

Use the planning worksheets to record values that you use to set up your system and configure the IBM Spectrum Protect™ server. Use the best practice default values that are listed in the worksheets.

Each worksheet helps you prepare for different parts of the system configuration by using best practice values:

Server system preconfiguration
: Use the preconfiguration worksheets to plan for the file systems and directories that you create when you configure file systems for IBM Spectrum Protect during system setup. All directories that you create for the server must be empty.

Server configuration
: Use the configuration worksheets when you configure the server. Default values are suggested for most items, except where noted.

Table 1. Worksheet for preconfiguration of a server system

Item	Default value	Your value	Minimum directory size	More information
TCP/IP port address for communications with the server	1500		Not applicable.	Ensure that this port is available when you install and configure the operating system. The port number can be a number in the range 1024 - 32767.
Directory for the server instance	AIX Linux /home/tsminst1/tsminst1 Windows C:\tsminst1		AIX 50 GB. Linux Windows 25 GB.	If you change the value for the server instance directory from the default, also modify the DB2® instance owner value in Table 2.
Directory for server installation	• AIX Linux / • Windows C:		AIX Available space that is required for the directory: 5 GB. Linux Windows Minimum space that is required for the directory: 30 GB	
Directory for server installation	/usr		AIX Available space that is required for the directory: 5 GB.	
Directory for server installation	AIX /var		AIX Available space that is required for the directory: 5 GB.	

Item	Default value	Your value	Minimum directory size	More information
Directory for server installation	AIX /tmp		AIX Available space that is required for the directory: 5 GB.	
Directory for server installation	AIX /opt		AIX Available space that is required for the directory: 10 GB.	
Directory for the active log	AIX Linux /tsminst1/TSMalog Windows C:\tsminst1\TSMalog		128 GB.	When you create the active log during the initial configuration of the server, set the size to 128 GB.

Create four file systems for the database.
Directories for storage	AIX Linux /tsminst1/TSMfile00 /tsminst1/TSMfile01 /tsminst1/TSMfile02 /tsminst1/TSMfile03 ... Windows C:\tsminst1\TSMfile00 C:\tsminst1\TSMfile01 C:\tsminst1\TSMfile02 C:\tsminst1\TSMfile03 ...		Determine the minimum total capacity for all directories by using the following calculation: `Daily percentage of ingested data that is written to disk + 20% = Minimum total capacity`	The preferred method is to define at least one directory for each tape device.

Table 2. Worksheet for IBM Spectrum Protect configuration

Item	Default value	Your value	More information
DB2 instance owner	tsminst1		If you changed the value for the server instance directory in Table 1 from the default, also modify the value for the DB2 instance owner.
DB2 instance owner password	AIX Linux passw0rd Windows pAssW0rd		Select a different value for the instance owner password than the default. Ensure that you record this value in a secure location.
Primary group for the DB2 instance owner	AIX Linux tsmsrvrs		
Server name	The default value for the server name is the system host name.		

Item	Default value	Your value	More information
Server password	passw0rd		Select a different value for the server password than the default. Ensure that you record this value in a secure location.
Administrator ID: user ID for the server instance	admin		
Administrator ID password	passw0rd		Select a different value for the administrator password than the default. Ensure that you record this value in a secure location.
Schedule start time	23:00		The default schedule start time begins the client workload phase, which is predominantly the client backup and archive activities. During the client workload phase, server resources support client operations. Normally, these operations are completed during the nightly schedule window. Schedules for server maintenance operations are defined to begin 10 hours after the start of the client backup window. In this guide, the suggested time to start client backup operations is 23:00.

Table 3. Worksheet for tape configuration

Item	Default value	Your value	More information
Robotic device files	IBM® devices with an IBM tape device driver: • AIX /dev/smcX • Linux /dev/IBMchangerX • Windows ChangerX Non-IBM devices with an IBM Spectrum Protect device driver: • AIX /dev/lbX • Linux /dev/tsmscsi/lbX • Windows lbA.B.C.D		To manually define the library device files, use the following commands: • DEFINE LIBRARY • DEFINE DRIVE • DEFINE PATH For SCSI, you can use the PERFORM LIBACTION command to define all drives and their paths for a single library in one step. To use this command to define all drives and paths, the SANDISCOVERY option must be supported and enabled.

Item	Default value	Your value	More information
Tape drives	IBM devices with an IBM tape device driver: • AIX /dev/rmtX • Linux /dev/IBMtapeX • Windows TapeX Non-IBM devices with an IBM Spectrum Protect device driver: • AIX /dev/mtX • Linux /dev/tsmscsi/mtX • Windows mtA.B.C.D		

Planning for disk storage

Choose the most effective storage technology for IBM Spectrum Protect™ components to ensure efficient server performance and operations.

Storage hardware devices have different capacity and performance characteristics, which determine how they can be used effectively with IBM Spectrum Protect. For general guidance about selecting the appropriate storage hardware and setup for your solution, review the following guidelines.

Database, active log, and archive log

- Use a solid-state disk (SSD) or a fast, 15,000 rpm disk for the IBM Spectrum Protect database and active log.
- When you create arrays for the database, use RAID level 5.
- Use separate disks for archive log and database backup storage.

Storage pool
Use RAID level 6 for storage pool arrays to add protection against double drive failures when you use large disk types.

- Planning the storage arrays
  Prepare for disk storage configuration by planning for RAID arrays and volumes, according to the size of your IBM Spectrum Protect system.

Planning for tape storage

Determine which tape devices to use and how to configure them. To optimize system performance, plan to use fast, high-capacity tape devices. Provision enough tape drives to meet your business requirements.

- Supported tape devices and libraries
  The server can use a wide range of tape devices and libraries. Select tape devices and libraries that meet your business requirements.
- Supported tape device configurations
  Review the information about local area networks (LAN) and storage area networks (SAN). To optimize data movement, plan to configure LAN-free data movement. In addition, consider whether to use library sharing.
- Required definitions for tape storage devices
  Before the IBM Spectrum Protect™ server can use a tape device, you must configure the device to the operating system and to the server. As part of the planning process, determine which definitions are required for your tape storage devices.
- Planning the storage pool hierarchy
  Plan the storage pool hierarchy to ensure that data is migrated daily from disk to tape. The migration releases space on the disk device and moves the data to tape for long-term retention. In this way, you can take advantage of the scalability, cost efficiency, and security features of tape storage.
- Offsite data storage
  To facilitate data recovery and as part of your disaster recovery strategy, store tape copies offsite.

Supported tape devices and libraries

The server can use a wide range of tape devices and libraries. Select tape devices and libraries that meet your business requirements.

For a list of supported devices and valid device class formats, see the website for your operating system:

- AIX Windows Supported devices for AIX and Windows
- Linux Supported devices for Linux

For more information about storage devices and storage objects, see Types of storage devices.

Each device that is defined to IBM Spectrum Protect™ is associated with one *device class*. The device class specifies the device type and media management information, such as recording format, estimated capacity, and labeling prefixes.

A *device type* identifies a device as a member of a group of devices that share similar media characteristics. For example, the LTO device type applies to all generations of LTO tape drives.

A device class for a tape drive must also specify a library. A *physical library* is a collection of one or more drives that share similar media-mounting requirements. That is, the drive can be mounted by an operator or by an automated mounting mechanism.

A *library object definition* specifies the library type and other characteristics that are associated with that library type.

The following table lists the preferred library types for an IBM Spectrum Protect Version 8.1.2 tape solution.

Table 1. Library types for an IBM Spectrum Protect 8.1.2 tape solution

Library type	Description	More information
SCSI	A SCSI library is controlled through a SCSI interface, attached either directly to the server's host by using SCSI cabling or by a storage area network. A robot or other mechanism automatically handles tape volume mounts and dismounts. If you create different drive types for a SCSI library, you create multiple logical libraries that cannot be split between different types of drives. A SCSI library can contain drives of mixed technologies, including LTO Ultrium and digital linear tape (DLT) drives. For example: • The Oracle StorageTek L700 library • The IBM® 3592 tape device	Configuring libraries for use by a server Restrictions apply when you mix different generations of media and drives. For more information, see: • Mixing generations of 3592 drives and media in a single library • Mixing LTO drives and media in a library
Shared	Shared libraries are logical libraries that are represented by SCSI. The library is controlled by the IBM Spectrum Protect server that is configured as a library manager. IBM Spectrum Protect servers that use the SHARED library type are library clients to the library manager server. Shared libraries reference a library manager.	

Supported tape device configurations

Review the information about local area networks (LAN) and storage area networks (SAN). To optimize data movement, plan to configure LAN-free data movement. In addition, consider whether to use library sharing.

Select the device configuration that meets your business requirements.

- LAN-based and LAN-free data movement
  You can move data between clients and storage devices that are attached to a local area network (LAN), or to storage devices that are attached to a storage area network (SAN), known as LAN-free data movement.
- Library sharing
  You can optimize the efficiency of your tape solution by configuring library sharing. Library sharing allows multiple IBM Spectrum Protect™ servers to use the same tape library and drives on a storage area network (SAN) and to improve backup and recovery performance and tape hardware utilization.

- LAN-free data movement
  IBM Spectrum Protect provides the capability for a client, through a storage agent, to directly back up and restore data to a tape library on a SAN. This type of data movement is also known as LAN-free data movement.
- Mixed device types in libraries
  IBM Spectrum Protect supports mixing different device types within a single automated library, if the library can distinguish among the different media for the different device types. To simplify the configuration process, do not plan to mix different device types within a library. If you must mix device types, review the restrictions.

LAN-based and LAN-free data movement

You can move data between clients and storage devices that are attached to a local area network (LAN), or to storage devices that are attached to a storage area network (SAN), known as LAN-free data movement.

In a conventional LAN configuration, one or more tape libraries are associated with a single IBM Spectrum Protect™ server. LAN-free data movement makes LAN bandwidth available for other uses and decreases the load on the IBM Spectrum Protect server.

In a LAN configuration, client data, email, terminal connection, application program, and device control information must be handled by the same network. Device control information and client backup and restore data flow across the LAN.

A SAN is a dedicated storage network that can improve system performance.

By using IBM Spectrum Protect in a SAN, you benefit from the following functions:

- Sharing storage devices among multiple IBM Spectrum Protect servers.
  Restriction: A storage device with the GENERICTAPE device type cannot be shared among servers.
- Moving IBM Spectrum Protect client data directly to storage devices (LAN-free data movement) by configuring a storage agent on the client system.

In a SAN, you can share tape drives and libraries that are supported by the IBM Spectrum Protect server, including most SCSI tape devices.

When IBM Spectrum Protect servers share a SCSI tape, one server, the *library manager*, owns and controls the device. The storage agents, along with other IBM Spectrum Protect servers that share this library are *library clients*. A library client requests shared library resources, such as drives or media, from the library manager, but uses the resources independently. The library manager coordinates the access to these resources. IBM Spectrum Protect servers that are defined as library clients use server-to-server communications to contact the library manager and request device service. Data moves over the SAN between each server and the storage device.
Requirement: If you define a library manager server that is shared with the IBM Spectrum Protect server, the SANDISCOVERY option must be set to ON. By default, this option is set to OFF.
IBM Spectrum Protect servers use the following features when sharing an automated library:

Partitioning of the volume inventory
: The inventory of media volumes in the shared library is partitioned among servers. Either one server owns a particular volume, or the volume is in the global scratch pool. No server owns the scratch pool.

Serialized drive access
: Only one server accesses each tape drive at a time. Drive access is serialized. IBM Spectrum Protect controls drive access so that servers do not dismount other servers' volumes or write to drives where other servers mount their volumes.

Serialized mount access
: The library autochanger completes a single mount or dismount operation at a time. The library manager completes all mount operations to provide this serialization.

Library sharing

You can optimize the efficiency of your tape solution by configuring library sharing. Library sharing allows multiple IBM Spectrum Protect™ servers to use the same tape library and drives on a storage area network (SAN) and to improve backup and recovery performance and tape hardware utilization.

When IBM Spectrum Protect servers share a library, one server is set up as the library manager and controls library operations such as mount and dismount. The library manager also controls volume ownership and the library inventory. Other servers are set up as library clients and use server-to-server communications to contact the library manager and request resources.

Library clients must be at the same or an earlier version than the library manager server. A library manager cannot support library clients that are at a later version. For more information, see Storage-agent and library-client compatibility with an IBM Spectrum

Protect server.

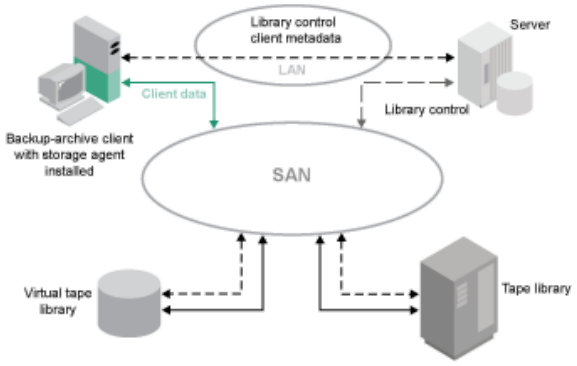
LAN-free data movement

IBM Spectrum Protect™ provides the capability for a client, through a storage agent, to directly back up and restore data to a tape library on a SAN. This type of data movement is also known as LAN-free data movement.

Restriction: Centera storage devices cannot be targets for LAN-free operations.

Figure 1 shows a SAN configuration in which a client directly accesses a tape to read or write data.

Figure 1. LAN-free data movement



LAN-free data movement requires the installation of a storage agent on the client system. The server maintains the database and recovery log, and acts as the library manager to control device operations. The storage agent on the client handles the data transfer to the device on the SAN. This implementation frees up bandwidth on the LAN that would otherwise be used for client data movement.

Mixed device types in libraries

IBM Spectrum Protect™ supports mixing different device types within a single automated library, if the library can distinguish among the different media for the different device types. To simplify the configuration process, do not plan to mix different device types within a library. If you must mix device types, review the restrictions.

Libraries with this capability are models that have built-in mixed drives, or that support the addition of mixed drives. For information about specific models, see the manufacturer's documentation. To learn about libraries that were tested on IBM Spectrum Protect with mixed device types, see the information for your operating system:

- IBM Spectrum Protect Supported Devices for AIX®, HP-UX, Solaris, and Windows

- IBM Spectrum Protect Supported Devices for Linux

For example, you can have LTO Ultrium drives and IBM TS4500 drives in a single library that is defined to the IBM Spectrum Protect server.

- Different media generations in a library
  The IBM Spectrum Protect server allows mixed device types in an automated library, but the mixing of different generations of the same type of drive is generally not supported. New drives cannot write to the older media formats, and old drives cannot read new formats. LTO Ultrium drives are an exception to this rule.
- Mixed media and storage pools
  You can optimize the efficiency of your tape solution by not mixing media formats in a storage pool. Instead of mixing formats, map each unique media format to a separate storage pool by using its own device class. This restriction also applies to LTO formats.

Different media generations in a library

The IBM Spectrum Protect™ server allows mixed device types in an automated library, but the mixing of different generations of the same type of drive is generally not supported. New drives cannot write to the older media formats, and old drives cannot read new formats. LTO Ultrium drives are an exception to this rule.

If the new drive technology cannot write to media that is formatted by older generation drives, the older media must be marked read-only to avoid problems for server operations. Also, the older drives must be removed from the library, or the definitions of the older drives must be removed from the server. For example, the IBM Spectrum Protect server does not support the use of Oracle StorageTek 9940A drives with 9940B drives in combination with other device types in a single library.

In general, IBM Spectrum Protect does not support mixing generations of LTO Ultrium drives and media. However, the following mixtures are supported:

- LTO Ultrium Generation 3 (LTO-3) with LTO Ultrium Generation 4 (LTO-4)
- LTO Ultrium Generation 4 (LTO-4) with LTO Ultrium Generation 5 (LTO-5)
- LTO Ultrium Generation 5 (LTO-5) with LTO Ultrium Generation 6 (LTO-6)
- LTO Ultrium Generation 6 (LTO-6) with LTO Ultrium Generation 7 (LTO-7)

The server supports these mixtures because the different drives can read and write to the different media. If you plan to upgrade all drives to Generation 4 (or Generation 5, 6, or 7), you must delete all existing LTO Ultrium drive definitions and the paths that are associated with them. Then, you can define the new Generation 4 (or Generation 5, 6, or 7) drives and paths.

Restrictions that apply to mixing LTO Ultrium tape drives and media

- LTO-5 drives can read only LTO-3 media. If you are mixing LTO-3 with LTO-5 drives and media in a single library, you must mark the LTO-3 media as read-only. You must check out all LTO-3 scratch volumes.
- LTO-6 drives can read only LTO-4 media. If you are mixing LTO-4 with LTO-6 drives and media in a single library, you must mark the LTO-4 media as read-only. You must check out all LTO-4 scratch volumes.
- LTO-7 drives can read only LTO-5 media. If you are mixing LTO-5 with LTO-7 drives and media in a single library, you must mark the LTO-5 media as read-only. You must check out all LTO-5 scratch volumes.

Restrictions that apply to mixed generation LTO Ultrium tape drives in a library
: You must use tape cartridges that are an earlier generation than the tape drive. A later generation tape drive can read and write data to an earlier generation tape cartridge. For an example, if a library has LTO-7 and LTO-6 tape drives, you must use LTO-6 tape cartridges. Both the LTO-7 and LTO-6 tape drives can read and write data to LTO-6 tape cartridges.

Restrictions that apply to mixed generation LTO Ultrium tape cartridges in a library
: You must use a tape cartridge that is the same generation as the tape drive, or one generation earlier. For example, if a library has LTO-7 tape drives, you can use LTO-7 tape cartridges or mixed LTO-7 and LTO-6 tape cartridges. If this library has LTO-7, LTO-6, and LTO-5 tape cartridges, you must change the access mode to READONLY for the LTO-5 tape cartridges.

To learn about additional considerations when you mix LTO Ultrium generations, see Defining LTO device classes.

When you use IBM Spectrum Protect, you cannot mix drives that are 3592, TS1130, TS1140, TS1150, and later drive generations. Use one of three special configurations. For details, see Defining 3592 device classes.

If you plan to encrypt volumes in a library, do not mix media generations in the library.

Mixed media and storage pools

You can optimize the efficiency of your tape solution by not mixing media formats in a storage pool. Instead of mixing formats, map each unique media format to a separate storage pool by using its own device class. This restriction also applies to LTO formats.

Multiple storage pools and their device classes of different types can point to the same library that can support them as described in Different media generations in a library.

You can migrate to a new generation of a media type within the same storage pool by following these steps:

1. Replace all older drives with the newer generation drives within the library. The drives should be mixed.
2. Mark the existing volumes with the older formats read-only if the new drive cannot append those tapes in the old format. If the new drive can write to the existing media in their old format, this is not necessary, but Step 1 is still required. If it is necessary to keep different drive generations that are read but not write compatible within the same library, use separate storage pools for each.

Required definitions for tape storage devices

Before the IBM Spectrum Protect™ server can use a tape device, you must configure the device to the operating system and to the server. As part of the planning process, determine which definitions are required for your tape storage devices.

Tip: You can use the PERFORM LIBACTION command to simplify the process when you add devices to SCSI and VTL library types.

Table 1 summarizes the definitions that are required for different device types.

Table 1. Required definitions for storage devices

Device	Device types	Required definitions			
		Library	**Drive**	**Path**	**Device class**
Magnetic disk	DISK	—	—	—	Yes [1]
	FILE [2]	—	—	—	Yes
	AIX Windows CENTERA Linux CENTERA [3]	—	—	—	Yes
Tape	• 3590 • 3592 • DLT • LTO • NAS • VOLSAFE AIX Windows GENERICTAPE ECARTRIDGE [4]	Yes	Yes	Yes	Yes
Removable media (file system)	REMOVABLEFILE	Yes	Yes	Yes	Yes

1. The DISK device class exists at installation and cannot be changed.
2. FILE libraries, drives, and paths are required for sharing with storage agents.
3. Linux The CENTERA device type is available only for Linux x86_64 systems.
4. The ECARTRIDGE device type is for Oracle StorageTek cartridge tape drives such as 9840 and T10000 drives.

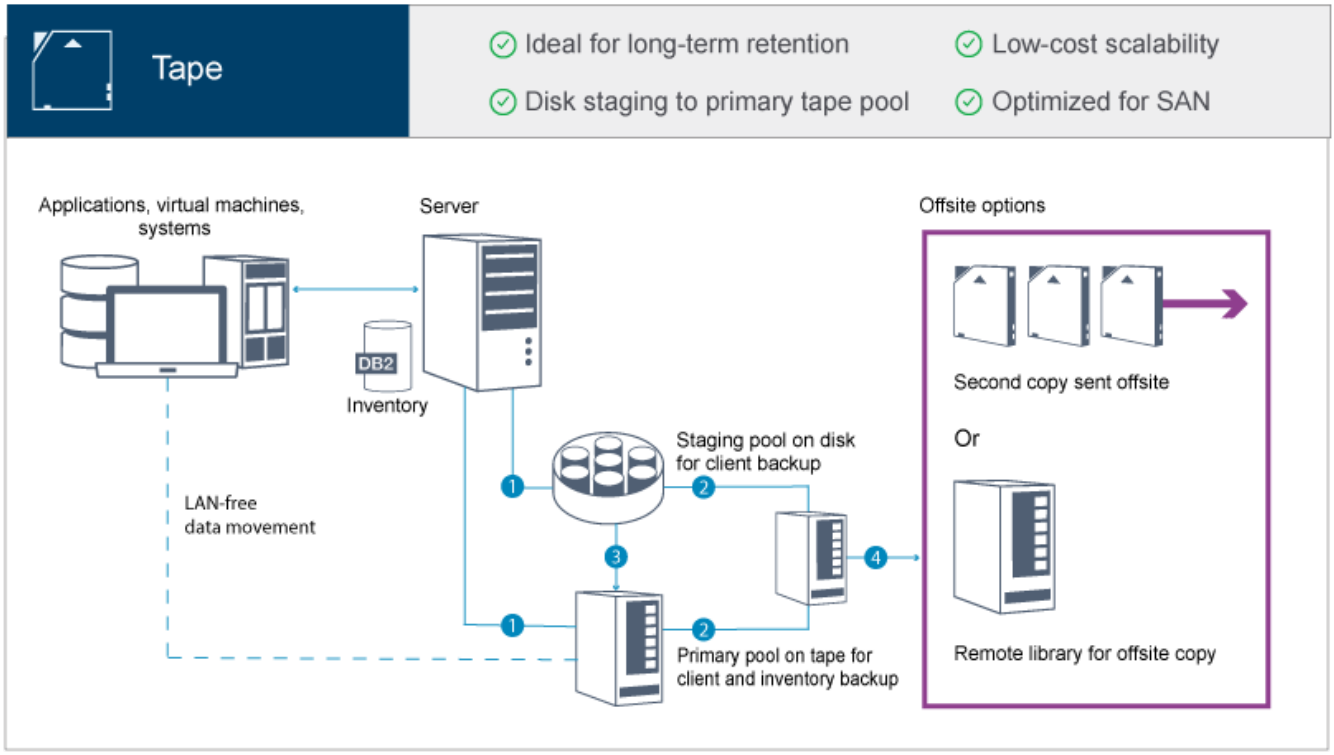
Planning the storage pool hierarchy

Plan the storage pool hierarchy to ensure that data is migrated daily from disk to tape. The migration releases space on the disk device and moves the data to tape for long-term retention. In this way, you can take advantage of the scalability, cost efficiency, and security features of tape storage.

Before you begin

The storage pool hierarchy helps to manage the flow of data. To understand the data flow, review Figure 1.

Figure 1. Tape solution



The following steps correspond to the numbers in the figure:

1. The server receives data from clients (applications, virtual machines, or systems) and stores the data on primary storage pools. Depending on the client type, the data is stored on a primary storage pool on disk or tape.
2. The data on disk and tape is backed up to a copy storage pool on tape.
3. Data in the primary storage pool on disk is migrated daily to the primary storage pool on tape.
4. Data from the copy storage pool on tape is moved offsite to support long-term retention and disaster recovery.

Procedure

To plan the storage pool hierarchy, answer the following questions:

a. Which clients should back up data to disk, and which clients should back up data to tape?
   - The preferred method is to back up clients that host large objects, such as databases, to tape.
   - The preferred method is to back up all other clients to disk.
   - Virtual machine (VM) clients can be backed up to disk or tape. The preferred method is to back up a VM client to a separate disk storage pool, which is not migrated to tape. If you must migrate a VM client to tape, create a smaller disk storage pool to hold the VMware control files. This smaller disk storage pool cannot be allowed to migrate to tape. For more information about backing up a VM client to tape, see Tape media guidelines and technote 1239546.

   Tip: If many clients must back up data to a single storage pool, consider using a storage pool on disk because you can specify many mount points. You can specify a maximum value of 999 for the MAXNUMMP parameter on the REGISTER NODE command.

b. What are the considerations for specifying the capacity of disk-based storage pools?

   At minimum, plan enough capacity to store data from a single day of backup operations. The preferred method is to plan enough capacity to store data from two days' worth of backup operations and add a 20% buffer.

c. What are the considerations for specifying the device class for the disk-based storage pool?

   The preferred method is to specify a FILE device class. Set the MOUNTLIMIT parameter to 4000. Also, ensure that the node has a sufficiently high number of mount points, which you can specify by using the MAXNUMMP parameter on the REGISTER NODE command.

d. Should data deduplication be specified for the disk storage pool?

No, because the data is stored on disk for only one day before the data is migrated to tape.

e. Should automatic migration of data be specified based on a migration threshold?

No. Instead, plan to schedule daily migration by using the MIGRATE STGPOOL command. (To prevent automatic migration based on the migration threshold, specify a value of 100 for the HIGHMIG parameter and 0 for the LOWMIG parameter when you issue the DEFINE STGPOOL command.)

f. Should a migration delay be specified?

The preferred method is to specify migration from disk to tape daily, and not specify a migration delay, which requires additional planning. For more information about migration delays, see Migrating files in a storage pool hierarchy.

g. How can the number of tape drives be calculated?
   i. Determine the native data transfer rate of the drive by reviewing the manufacturer's documentation. To obtain an estimate of the sustained data transfer rate in your storage environment, subtract 30% from the native data transfer rate.
   ii. Calculate the required rate of data ingestion by the server. Then, divide that figure by the sustained data transfer rate of a single tape device. The result is the minimum number of drives to support data ingestion.
   iii. Calculate the number of mount points that are required by clients that back up data to tape, including those clients that use multiple sessions. You can distribute the mount points over the backup window, keeping in mind that clients are likely backing up large objects, which might use most of the window.
   iv. Calculate the performance requirements *and* mount points that are required for maintenance tasks, such as disk-to-tape migration and tape-to-tape copies. By backing up data to tape, you can avoid migration processing, but making tape-to-tape copies will double the tape drive requirement.
   v. Calculate the number of additional drives that might be required, for example:
      - If a tape drive malfunctions, the issue impacts the number of available mount points and the ingestion rate. Consider provisioning spare drives. For example, if you require five tape drives for normal operations, consider provisioning two spare drives.
      - Restore and retrieve operations might require additional tape drives if you plan to run the operations simultaneously with data ingestion and maintenance operations. If necessary, provision additional tape drives and ensure that they are unused when you start the restore or retrieve operations.

h. What alternatives are available for optimizing restore operations?
   You can use collocation to improve system performance and optimize data organization. Collocation can reduce the number of volumes that must be accessed when a large amount of data must be restored:
   - For disk-based storage pools, the preferred method is to use collocation by node. The server stores the data for the node on as few volumes as possible.
   - For tape-based storage pools, the preferred method is to use collocation by group. Collocation by group results in a reduction of unused tape capacity, which allows for more collocated data on individual tapes.

   For more information about collocation, see Optimizing operations by enabling collocation of client files.
   If you are an experienced system administrator, you might plan additional actions to optimize restore operations. See Optimizing restore operations for clients, File backup techniques, and MOVE NODEDATA (Move data by node in a sequential access storage pool).

Offsite data storage

To facilitate data recovery and as part of your disaster recovery strategy, store tape copies offsite.

Use the disaster recovery manager (DRM) function to configure and automatically generate a disaster recovery plan that contains the information, scripts, and procedures that are required to automatically restore the server and recover client data after a disaster. Choose from one of the following offsite data storage options as a disaster recovery strategy to protect tape copies:

Offsite vaulting from a single production site
: Storage volumes, such as tape cartridges and media volumes, are vaulted at an offsite location. A courier transports the data from the offsite storage facility to the recovery site. If a disaster occurs, the volumes are sent back to the production site after hardware and the IBM Spectrum Protect™ server are restored.

Offsite vaulting with a recovery site
: A courier moves storage volumes from the production site to an offsite storage facility. By having a dedicated recovery site, you can reduce recovery time compared to the single production site. However, this option increases the cost of disaster recovery because more hardware and software must be maintained. For example, the recovery site must have compatible tape devices and IBM Spectrum Protect server software. Before the production site can be recovered, the hardware and software at the recovery site must be set up and running.

Electronic vaulting
: To use electronic vaulting as a disaster recovery strategy, the recovery site must have a running IBM Spectrum Protect server. Critical data is vaulted electronically from the production site to the recovery site. DRM is also used for offsite vaulting of noncritical data. Electronic vaulting moves critical data offsite faster and more frequently than traditional courier methods. Recovery time is reduced because critical data is already stored at the recovery site. However, because the recovery site runs continuously, the cost of the disaster recovery strategy is more expensive than offsite vaulting.

Related concepts:
Preparing for and recovering from a disaster by using DRM

Planning for security

Plan to protect the security of systems in the IBM Spectrum Protect™ solution with access and authentication controls, and consider encrypting data and password transmission.

- Planning for administrator roles
  Define the authority levels that you want to assign to administrators who have access to the IBM Spectrum Protect solution.
- Planning for secure communications
  Plan for protecting communications among the IBM Spectrum Protect solution components.
- Planning for storage of encrypted data
  Determine whether your company requires stored data to be encrypted, and choose the method that best suits your needs.
- Planning firewall access
  Determine the firewalls that are set and the ports that must be open for the IBM Spectrum Protect solution to work.

Planning for administrator roles

Define the authority levels that you want to assign to administrators who have access to the IBM Spectrum Protect™ solution.

You can assign one of the following levels of authority to administrators:

System
: Administrators with system authority have the highest level of authority. Administrators with this level of authority can complete any task. They can manage all policy domains and storage pools, and grant authority to other administrators.

Policy
: Administrators who have policy authority can manage all of the tasks that are related to policy management. This privilege can be unrestricted, or can be restricted to specific policy domains.

Storage
: Administrators who have storage authority can allocate and control storage resources for the server.

Operator
: Administrators who have operator authority can control the immediate operation of the server and the availability of storage media such as tape libraries and drives.

The scenarios in Table 1 provide examples about why you might want to assign varying levels of authority so that administrators can perform tasks:

Table 1. Scenarios for administrator roles

Scenario	Type of administrator ID to set up
An administrator at a small company manages the server and is responsible for all server activities.	• System authority: 1 administrator ID
An administrator for multiple servers also manages the overall system. Several other administrators manage their own storage pools.	• System authority on all servers: 1 administrator ID for the overall system administrator • Storage authority for designated storage pools: 1 administrator ID for each of the other administrators
An administrator manages 2 servers. Another person helps with the administration tasks. Two assistants are responsible for helping to ensure that important systems are backed up. Each assistant is responsible for monitoring the scheduled backups on one of the IBM Spectrum Protect servers.	• System authority on both servers: 2 administrator IDs • Operator authority: 2 administrator IDs for the assistants with access to the server that each person is responsible for

Related tasks:
Managing administrators

Planning for secure communications

Plan for protecting communications among the IBM Spectrum Protect™ solution components.

Determine the level of protection that is required for your data, based on regulations and business requirements under which your company operates.

If your business requires a high level of security for passwords and data transmission, plan on implementing secure communication with Transport Layer Security (TLS) or Secure Sockets Layer (SSL) protocols.

TLS and SSL provide secure communications between the server and client, but can affect system performance. To improve system performance, use TLS for authentication without encrypting object data. To specify whether the server uses TLS 1.2 for the entire session or only for authentication, see the SSL client option for client-to-server communication, and the UPDATE SERVER=SSL parameter for server-to-server communication. Beginning in V8.1.2, TLS is used for authentication by default. If you decide to use TLS to encrypt entire sessions, use the protocol only for sessions where it is necessary and add processor resources on the server to manage the increase in network traffic. You can also try other options. For example, some networking devices such as routers and switches provide the TLS or SSL function.

You can use TLS and SSL to protect some or all of the different possible communication paths, for example:

- Operations Center: browser to hub; hub to spoke
- Client to server
- Server to server: node replication

Related tasks:
Configuring secure communications with Transport Layer Security

Planning for storage of encrypted data

Determine whether your company requires stored data to be encrypted, and choose the method that best suits your needs.

Table 1. Selecting a data encryption method

Business requirement	Encryption method	Additional information
Protect data at the client level.	IBM Spectrum Protect™ client encryption	You can encrypt data at the file level by using an include/exclude list. In this way, you can maintain a high degree of control over which data is encrypted. Extra computing resources are required at the client that might affect the performance of backup and restore processes. For more information about this method, see IBM Spectrum Protect client encryption.
Protect data in storage pool volumes on a tape drive.	Application method	When you use the Application method, IBM Spectrum Protect manages the encryption keys to protect data in storage pool volumes. You must take extra care to secure database backups because the encryption keys are stored in the server database. Without access to database backups and matching encryption keys, you cannot restore your data. You cannot use this method to encrypt database backups, exported data, or backup sets. For more information about the Application method, see Tape encryption methods.
Protect data on a tape drive.	Library method	When you use the Library method, the library manages encryption keys. You can encrypt both data in storage pools and other data on a tape drive. You can control which volumes are encrypted by using their bar code serial numbers. For more information about the Library method, see Tape encryption methods.
Protect data on a tape drive.	System method	When you use the System method, a device driver or the AIX operating system manages encryption. This encryption method is available only on the AIX® operating system. You can encrypt both data in storage pools and other data on a tape drive. For more information about the System method, see Tape encryption methods.

Planning firewall access

Determine the firewalls that are set and the ports that must be open for the IBM Spectrum Protect™ solution to work.

Table 1 describes the ports that are used by the server, client, and Operations Center.

Table 1. Ports that are used by the server, client, and Operations Center

Item	Default	Direction	Description
Base port (TCPPORT)	1500	Outbound/inbound	Each server instance requires a unique port. You can specify an alternative port number. The TCPPORT option listens for both TCP/IP and SSL-enabled sessions from the client. You can use the TCPADMINPORT option and ADMINONCLIENTPORT option to set port values for administrative client traffic.
SSL-only port (SSLTCPPORT)	No default	Outbound/inbound	This port is used if you want to restrict communication on the port to SSL-enabled sessions only. A server can support both SSL and non-SSL communication by using the TCPPORT or TCPADMINPORT options.
SMB	45	Inbound/outbound	This port is used by configuration wizards that communicate by using native protocols with multiple hosts.
SSH	22	Inbound/outbound	This port is used by configuration wizards that communicate by using native protocols with multiple hosts.
SMTP	25	Outbound	This port is used to send email alerts from the server.
Replication	No default	Outbound/inbound	The port and protocol for the outbound port for replication are set by the DEFINE SERVER command that is used to set up replication. The inbound ports for replication are the TCP ports and SSL ports are specified for the source server on the DEFINE SERVER command.
Client schedule port	Client port: 1501	Outbound	The client listens on the port that is named and communicates the port number to the server. The server contacts the client if server prompted scheduling is used. You can specify an alternative port number in the client options file.
Long-running sessions	KEEPALIVE setting: YES	Outbound	When the KEEPALIVE option is enabled, keepalive packets are sent during client/server sessions to prevent the firewall software from closing long-running, inactive connections.
Operations Center	HTTPS: 11090	Inbound	These ports are used for the Operations Center web browser. You can specify an alternative port number.
Client management service port	Client port: 9028	Inbound	If you plan to use IBM Spectrum Protect client management services, the client management service port must be accessible from the Operations Center. Ensure that firewalls cannot prevent connections. The client management service uses the TCP port of the server for the client node for authentication by using an administrative session.

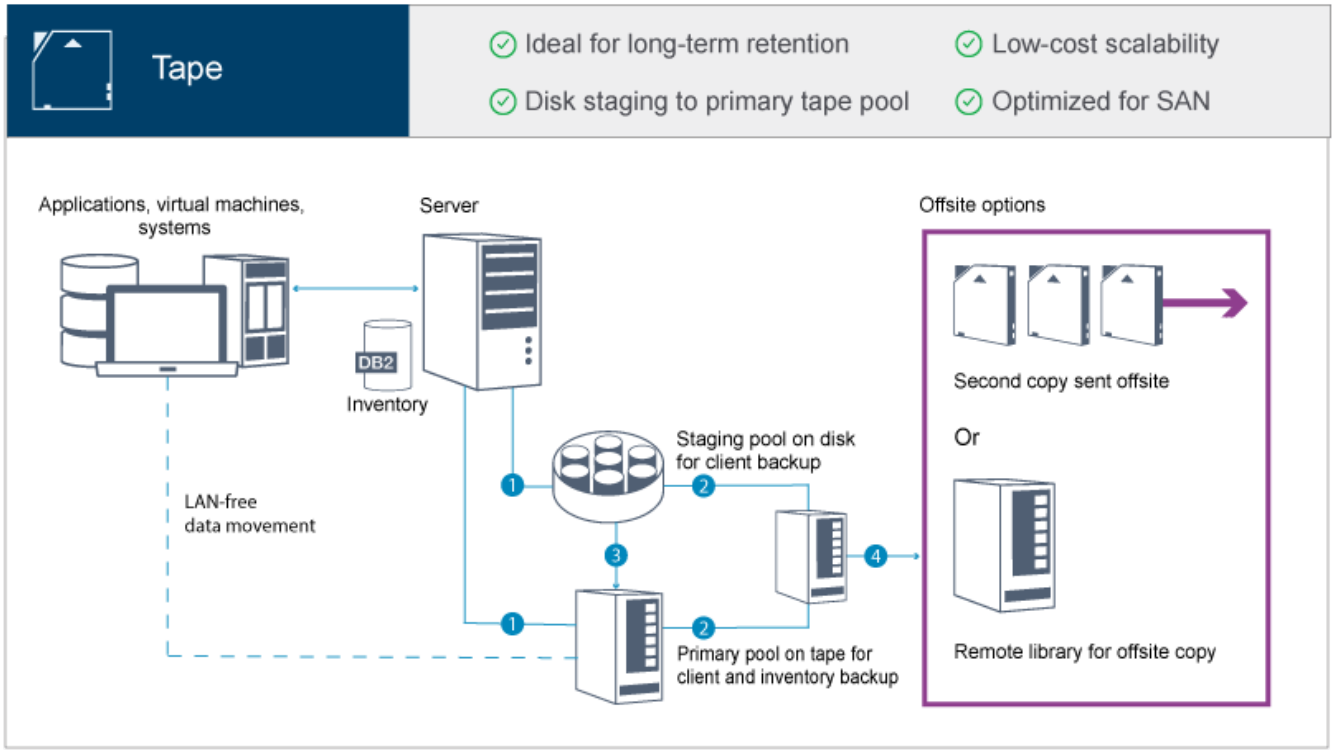
DEFINE SERVER (Define a server for server-to-server communications)

TCPADMINPORT server option

TCPPORT server option

Implementation of a tape-based data protection solution

Implement the tape-based solution, which uses disk-to-disk-to-tape backup and disk staging to optimize storage. By implementing the tape solution, you can enable long-term data retention and achieve low-cost scalability.



Tip: The described solution does not include node replication. However, if you want to use node replication to back up a storage pool from disk to disk, ensure that the replication operation is completed before data is migrated from disk to tape. You can also use node replication to back up a storage pool on a local tape device to a copy storage pool on a local tape device.

Implementation roadmap

The following steps are required to set up a tape-based solution.

1. Set up the system.
2. Install the server and the Operations Center.
3. Configure the server and the Operations Center.
4. Attach tape devices for the server.
5. Configure tape libraries for use by the server.
6. Set up a storage pool hierarchy.
7. Install and configure clients.
8. Configure LAN-free data movement.
9. Select an encryption method and configure encryption.
10. Set up tape storage operations.
11. Complete the implementation.

Setting up the system

To set up the system, you must first configure your disk storage hardware and the server system for IBM Spectrum Protect™.

About this task

Tip: Procedures for setting up the server and the disk storage system are described. To get started with setting up tape devices, see Attaching tape devices for the server.

- Configuring the storage hardware
  To optimize disk storage, review the guidelines for setting up disk storage with IBM Spectrum Protect. Then, provide a connection between the server and the disk storage devices and complete other configuration tasks.
- Installing the server operating system
  Install the operating system on the server system and ensure that IBM Spectrum Protect server requirements are met. Adjust operating system settings as directed.
- Configuring multipath I/O
  You can enable and configure multipathing for disk storage. Use the documentation that is provided with your hardware for

detailed instructions.

- Creating the user ID for the server
  Create the user ID that owns the IBM Spectrum Protect server instance. You specify this user ID when you create the server instance during initial configuration of the server.
- Preparing file systems for the server
  You must complete file system configuration for the disk storage to be used by the server.

Configuring the storage hardware

To optimize disk storage, review the guidelines for setting up disk storage with IBM Spectrum Protect. Then, provide a connection between the server and the disk storage devices and complete other configuration tasks.

Before you begin

For guidelines about setting up disk storage, see Checklist for storage pools on DISK or FILE

Procedure

1. Provide a connection between the server and the storage devices by following these guidelines:
   - Use a switch or direct connection for Fibre Channel connections.
   - Consider the number of ports that are connected and account for the amount of bandwidth that is needed.
   - Consider the number of ports on the server and the number of host ports on the disk system that are connected.
2. Verify that device drivers and firmware for the server system, adapters, and operating system are current and at the recommended levels.
3. Configure storage arrays. Make sure that you planned properly to ensure optimal performance. For more information, see Planning for disk storage.
4. Ensure that the server system has access to disk volumes that are created. Complete the following steps:
   a. If the system is connected to a Fibre Channel switch, zone the server to see the disks.
   b. Map all of the volumes to tell the disk system that this specific server is allowed to see each disk.
5. Ensure that tape and disk devices use different Host Bus Adapter (HBA) ports. Control tape and disk I/O by using the SAN.

Related tasks:
Configuring multipath I/O

Installing the server operating system

Install the operating system on the server system and ensure that IBM Spectrum Protect™ server requirements are met. Adjust operating system settings as directed.

- Installing on AIX systems
  Complete the following steps to install AIX® on the server system.
- Installing on Linux systems
  Complete the following steps to install Linux x86_64 on the server system.
- Installing on Windows systems
  Install Microsoft Windows Server 2012 Standard Edition on the server system and prepare the system for installation and configuration of the IBM Spectrum Protect server.

Installing on AIX systems

Complete the following steps to install AIX® on the server system.

Procedure

1. Install AIX Version 7.1, TL4, SP2, or later according to the manufacturer instructions.
2. Configure your TCP/IP settings according to the operating system installation instructions.
3. Open the /etc/hosts file and complete the following actions:
   - Update the file to include the IP address and host name for the server. For example:

```
192.0.2.7  server.yourdomain.com  server
```

- Verify that the file contains an entry for localhost with an address of 127.0.0.1. For example:

  ```
  127.0.0.1  localhost
  ```

4. Enable AIX I/O completion ports by issuing the following command:

   ```
   chdev -l iocp0 -P
   ```

   Server performance can be affected by the Olson time zone definition.
5. To optimize performance, change your system time zone format from Olson to POSIX. Use the following command format to update the time zone setting:

   ```
   chtz=local_timezone,date/time,date/time
   ```

   For example, if you lived in Tucson, Arizona, where Mountain Standard Time is used, you would issue the following command to change to the POSIX format:

   ```
   chtz MST7MDT,M3.2.0/2:00:00,M11.1.0/2:00:00
   ```

6. Add an entry in the .profile of the instance user so that the following environment is set:

   ```
   export MALLOCOPTIONS=multiheap:16
   ```

7. Set the system to create full application core files. Issue the following command:

   ```
   chdev -l sys0 -a fullcore=true -P
   ```

8. For communications with the server and Operations Center, make sure that the following ports are open on any firewalls that might exist:
   - For communications with the server, open port 1500.
   - For secure communications with the Operations Center, open port 11090 on the hub server.

   If you are not using the default port values, make sure that the ports that you are using are open.

9. Enable TCP high-performance enhancements. Issue the following command:

   ```
   no -p -o rfc1323=1
   ```

10. For optimal throughput and reliability, bond four 10 Gb Ethernet ports together. Use the System Management Interface Tool (SMIT) to bond the ports together by using Etherchannel. The following settings were used during testing:

    ```
    mode            8023ad
    auto_recovery   yes             Enable automatic recovery after failover
    backup_adapter  NONE            Adapter used when whole channel fails
    hash_mode       src_dst_port    Determines how outgoing adapter is chosen
    interval        long            Determines interval value for IEEE
                                    802.3ad mode
    mode            8023ad          EtherChannel mode of operation
    netaddr         0               Address to ping
    noloss_failover yes             Enable lossless failover after ping
                                    failure
    num_retries     3               Times to retry ping before failing
    retry_time      1               Wait time (in seconds) between pings
    use_alt_addr    no              Enable Alternate EtherChannel Address
    use_jumbo_frame no              Enable Gigabit Ethernet Jumbo Frames
    ```

11. Verify that user process resource limits, also known as *ulimits*, are set according to guidelines in Table 1. If ulimit values are not set correctly, you might experience server instability or a failure of the server to respond.

Table 1. User limits (ulimit) values

User limit type	Setting	Value	Command to query value
Maximum size of core files created	core	Unlimited	`ulimit -Hc`
Maximum size of a data segment for a process	data	Unlimited	`ulimit -Hd`
Maximum file size	fsize	Unlimited	`ulimit -Hf`
Maximum number of open files	nofile	65536	`ulimit -Hn`

User limit type	Setting	Value	Command to query value
Maximum amount of processor time in seconds	cpu	Unlimited	`ulimit -Ht`
Maximum number of user processes	nproc	16384	`ulimit -Hu`

If you need to modify any user limit values, follow the instructions in the documentation for your operating system.

Installing on Linux systems

Complete the following steps to install Linux x86_64 on the server system.

Before you begin

The operating system will be installed on the internal hard disks. Configure the internal hard disks by using a hardware RAID 1 array. For example, if you are configuring a small system, the two 300 GB internal disks are mirrored in RAID 1 so that a single 300 GB disk appears available to the operating system installer.

Procedure

1. Install Red Hat Enterprise Linux Version 7.1 or later, according to the manufacturer instructions. Obtain a bootable DVD that contains Red Hat Enterprise Linux Version 7.1 and start your system from this DVD. See the following guidance for installation options. If an item is not mentioned in the following list, leave the default selection.
   a. After you start the DVD, choose Install or upgrade an existing system from the menu.
   b. On the Welcome screen, select Test this media & install Red Hat Enterprise Linux 7.1.
   c. Select your language and keyboard preferences.
   d. Select your location to set the correct time zone.
   e. Select Software Selection and then on the next screen, select Server with GUI.
   f. From the installation summary page, click Installation Destination and verify the following items:
      - The local 300 GB disk is selected as the installation target.
      - Under Other Storage Options, Automatically configure partitioning is selected.

      Click Done.
   g. Click Begin Installation. After the installation starts, set the root password for your root user account.

   After the installation is completed, restart the system and log in as the root user. Issue the df command to verify your basic partitioning. For example, on a test system, the initial partitioning produced the following result:

```
[root@tvapp02]# df -h
Filesystem             Size  Used Avail Use% Mounted on
/dev/mapper/rhel-root   50G  3.0G   48G   6% /
devtmpfs                32G     0   32G   0% /dev
tmpfs                   32G   92K   32G   1% /dev/shm
tmpfs                   32G  8.8M   32G   1% /run
tmpfs                   32G     0   32G   0% /sys/fs/cgroup
/dev/mapper/rhel-home  220G   37M  220G   1% /home
/dev/sda1              497M  124M  373M  25% /boot
```

2. Configure your TCP/IP settings according to the operating system installation instructions.
   For optimal throughput and reliability, consider bonding multiple network ports together. This can be accomplished by creating a Link Aggregation Control Protocol (LACP) network connection, which aggregates several subordinate ports into a single logical connection. The preferred method is to use a bond mode of 802.3ad, miimon setting of 100, and a xmit_hash_policy setting of layer3+4.
   Restriction: To use an LACP network connection, you must have a network switch that supports LACP.

   For additional instructions about configuring bonded network connections with Red Hat Enterprise Linux Version 7, see Create a Channel Bonding Interface.

3. Open the /etc/hosts file and complete the following actions:
   - Update the file to include the IP address and host name for the server. For example:

     ```
     192.0.2.7  server.yourdomain.com  server
     ```

   - Verify that the file contains an entry for localhost with an address of 127.0.0.1. For example:

     ```
     127.0.0.1  localhost
     ```

4. Install components that are required for the server installation. Complete the following steps to create a Yellowdog Updater Modified (YUM) repository and install the prerequisite packages.
    a. Mount your Red Hat Enterprise Linux installation DVD to a system directory. For example, to mount it to the /mnt directory, issue the following command:

    ```
    mount -t iso9660 -o ro /dev/cdrom /mnt
    ```

    b. Verify that the DVD mounted by issuing the mount command. You should see output similar to the following example:

    ```
    /dev/sr0 on /mnt type iso9660
    ```

    c. Change to the YUM repository directory by issuing the following command:

    ```
    cd /etc/yum/repos.d
    ```

    If the repos.d directory does not exist, create it.
    d. List directory contents:

    ```
    ls rhel-source.repo
    ```

    e. Rename the original repo file by issuing the mv command. For example:

    ```
    mv rhel-source.repo rhel-source.repo.orig
    ```

    f. Create a new repo file by using a text editor. For example, to use the vi editor, issue the following command:

    ```
    vi rhel71_dvd.repo
    ```

    g. Add the following lines to the new repo file. The baseurl parameter specifies your directory mount point:

    ```
    [rhel71_dvd]
    name=DVD Redhat Enterprise Linux 7.1
    baseurl=file:///mnt
    enabled=1
    gpgcheck=0
    ```

    h. Install the prerequisite package ksh.x86_64, by issuing the yum command. For example:

    ```
    yum install ksh.x86_64
    ```

    Exception: You do not need to install the compat-libstdc++-33-3.2.3-69.el6.i686 and libstdc++.i686 libraries for Red Hat Enterprise Linux Version 7.1.
5. When the software installation is complete, you can restore the original YUM repository values by completing the following steps:
    a. Unmount the Red Hat Enterprise Linux installation DVD by issuing the following command:

    ```
    unmount /mnt
    ```

    b. Change to the YUM repository directory by issuing the following command:

    ```
    cd /etc/yum/repos.d
    ```

    c. Rename the repo file that you created:

    ```
    mv rhel71_dvd.repo rhel71_dvd.repo.orig
    ```

    d. Rename the original file to the original name:

    ```
    mv rhel-source.repo.orig rhel-source.repo
    ```

6. Determine whether kernel parameter changes are required. Complete the following steps:
    a. Use the sysctl -a command to list the parameter values.
    b. Analyze the results by using the guidelines in Table 1 to determine whether any changes are required.
    c. If changes are required, set the parameters in the /etc/sysctl.conf file. The file changes are applied when the system is started.

Tip: Automatically adjust kernel parameter settings and eliminate the need for manual updates to these settings. On Linux, the DB2® database software automatically adjusts interprocess communication (IPC) kernel parameter values to the preferred settings. For more information about kernel parameter settings, search for Linux kernel parameters in the IBM DB2 Version 11.1 Knowledge Center.

Table 1. Linux kernel parameter optimum settings

Parameter	Description
kernel.shmmni	The maximum number of segments.
kernel.shmmax	The maximum size of a shared memory segment (bytes). This parameter must be set before automatically starting the IBM Spectrum Protect™ server on system startup.
kernel.shmall	The maximum allocation of shared memory pages (pages).
kernel.sem There are four values for the kernel.sem parameter.	(SEMMSL) The maximum semaphores per array.
	(SEMMNS) The maximum semaphores per system.
	(SEMOPM) The maximum operations per semaphore call.
	(SEMMNI) The maximum number of arrays.
kernel.msgmni	The maximum number of system-wide message queues.
kernel.msgmax	The maximum size of messages (bytes).
kernel.msgmnb	The default maximum size of queue (bytes).
kernel.randomize_va_space	The kernel.randomize_va_space parameter configures the use of memory ASLR for the kernel. Disable ASLR because it can cause errors for the DB2 software. To learn more details about the Linux ASLR and DB2, see technote 1365583.
vm.swappiness	The vm.swappiness parameter defines whether the kernel can swap application memory out of physical random access memory (RAM). For more information about kernel parameters, see the DB2 product information.
vm.overcommit_memory	The vm.overcommit_memory parameter influences how much virtual memory the kernel permits allocating. For more information about kernel parameters, see the DB2 product information.

7. Open firewall ports to communicate with the server. Complete the following steps:
   a. Determine the zone that is used by the network interface. The zone is public, by default.
      Issue the following command:

      ```
      #  firewall-cmd --get-active-zones
      public
        interfaces: ens4f0
      ```

   b. To use the default port address for communications with the server, open TCP/IP port 1500 in the Linux firewall.
      Issue the following command:

      ```
      firewall-cmd --zone=public --add-port=1500/tcp --permanent
      ```

      If you want to use a value other than the default, you can specify a number in the range 1024 - 32767. If you open a port other than the default, you will need to specify that port when you run the configuration script.

   c. If you plan to use this system as a hub, open port 11090, which is the default port for secure (https) communications.
      Issue the following command:

      ```
      firewall-cmd --zone=public --add-port=11090/tcp --permanent
      ```

   d. Reload the firewall definitions for the changes to take effect.
      Issue the following command:

```
firewall-cmd --reload
```

8. Verify that user process resource limits, also known as *ulimits*, are set according to guidelines in Table 2. If ulimit values are not set correctly, you might experience server instability or a failure of the server to respond.

Table 2. User limits (ulimit) values

User limit type	Setting	Value	Command to query value
Maximum size of core files created	core	Unlimited	`ulimit -Hc`
Maximum size of a data segment for a process	data	Unlimited	`ulimit -Hd`
Maximum file size	fsize	Unlimited	`ulimit -Hf`
Maximum number of open files	nofile	65536	`ulimit -Hn`
Maximum amount of processor time in seconds	cpu	Unlimited	`ulimit -Ht`
Maximum number of user processes	nproc	16384	`ulimit -Hu`

If you need to modify any user limit values, follow the instructions in the documentation for your operating system.

Installing on Windows systems

Install Microsoft Windows Server 2012 Standard Edition on the server system and prepare the system for installation and configuration of the IBM Spectrum Protect™ server.

Procedure

1. Install Microsoft Windows Server 2012 R2 Standard Edition, according to the manufacturer instructions.
2. Change the Windows account control policies by completing the following steps.
   a. Open the Local Security Policy editor by running secpol.msc.
   b. Click Local Policies > Security Options and ensure that the following User Account Control policies are disabled:
      - Admin Approval Mode for the Built-in Administrator account
      - Run all administrators in Admin Approval Mode
3. Configure your TCP/IP settings according to installation instructions for the operating system.
4. Apply Windows updates and enable optional features by completing the following steps:
   a. Apply the latest Windows 2012 R2 updates.
   b. Install and enable the Windows 2012 R2 feature Microsoft .NET Framework 3.5 from the Windows Server Manager.
   c. If required, update the FC and Ethernet HBA device drivers to newer levels.
   d. Install the multipath I/O driver that is appropriate for the disk system that you are using.
5. Open the default TCP/IP port, 1500, for communications with the IBM Spectrum Protect server. For example, issue the following command:

```
netsh advfirewall firewall add rule name="Backup server port 1500"
dir=in action=allow protocol=TCP localport=1500
```

6. On the Operations Center hub server, open the default port for secure (https) communications with the Operations Center. The port number is 11090. For example, issue the following command:

```
netsh advfirewall firewall add rule name="Operations Center port 11090"
dir=in action=allow protocol=TCP localport=11090
```

Configuring multipath I/O

You can enable and configure multipathing for disk storage. Use the documentation that is provided with your hardware for detailed instructions.

- AIX systems
  Complete the following steps to enable and configure multipathing for disk storage.
- Linux systems
  Complete the following steps to enable and configure multipathing for disk storage.

- Windows systems
  Complete the following steps to enable and configure multipathing for disk storage.

AIX systems

Complete the following steps to enable and configure multipathing for disk storage.

Procedure

1. Determine the Fibre Channel port address that you must use for the host definition on the disk subsystem. Issue the lscfg command for every port.
   - On small and medium systems, issue the following commands:

     ```
     lscfg -vps -l fcs0 | grep "Network Address"
     lscfg -vps -l fcs1 | grep "Network Address"
     ```

   - On large systems, issue the following commands:

     ```
     lscfg -vps -l fcs0 | grep "Network Address"
     lscfg -vps -l fcs1 | grep "Network Address"
     lscfg -vps -l fcs2 | grep "Network Address"
     lscfg -vps -l fcs3 | grep "Network Address"
     ```

2. Ensure that the following AIX® file sets are installed:
   - devices.common.IBM.mpio.rte
   - devices.fcp.disk.array.rte
   - devices.fcp.disk.rte
3. Issue the cfgmgr command to have AIX rescan the hardware and discover available disks. For example:

   ```
   cfgmgr
   ```

4. To list the available disks, issue the following command:

   ```
   lsdev -Ccdisk
   ```

   You should see output similar to the following:

   ```
   hdisk0  Available 00-00-00 SAS Disk Drive
   hdisk1  Available 00-00-00 SAS Disk Drive
   hdisk2  Available 01-00-00 SAS Disk Drive
   hdisk3  Available 01-00-00 SAS Disk Drive
   hdisk4  Available 06-01-02 MPIO IBM 2076 FC Disk
   hdisk5  Available 07-01-02 MPIO IBM 2076 FC Disk
   ...
   ```

5. Use the output from the lsdev command to identify and list device IDs for each disk device.

   For example, a device ID could be `hdisk4`. Save the list of device IDs to use when you create file systems for the IBM Spectrum Protect™ server.

6. Correlate the SCSI device IDs to specific disk LUNs from the disk system by listing detailed information about all physical volumes in the system. Issue the following command:

   ```
   lspv -u
   ```

   On an IBM® Storwize® system, the following information is an example of what is shown for each device:

   ```
   hdisk4  00f8cf083fd97327  None  active
    3321360050763008101057800000000000003004214503IBMfcp
   ```

   In the example, *600507630081010578000000000000030* is the UID for the volume, as reported by the Storwize management interface.
   To verify disk size in megabytes and compare the value with what is listed for the system, issue the following command:

   ```
   bootinfo -s hdisk4
   ```

Linux systems

Complete the following steps to enable and configure multipathing for disk storage.

Procedure

1. Edit the /etc/multipath.conf file to enable multipathing for Linux hosts. If the multipath.conf file does not exist, you can create it by issuing the following command:

   ```
   mpathconf --enable
   ```

   The following parameters were set in multipath.conf for testing on an IBM Storwize® system:

   ```
   defaults {
                user_friendly_names no
   }

   devices {
                device {
                            vendor "IBM "
                            product "2145"
                            path_grouping_policy group_by_prio
                            user_friendly_names no
                            path_selector "round-robin 0"
                            prio "alua"
                            path_checker "tur"
                            failback "immediate"
                            no_path_retry 5
                            rr_weight uniform
                            rr_min_io_rq "1"
                            dev_loss_tmo 120
               }
   }
   ```

2. Set the multipath option to start when the system is started. Issue the following commands:

   ```
   systemctl enable multipathd.service
   systemctl start multipathd.service
   ```

3. To verify that disks are visible to the operating system and are managed by multipath, issue the following command:

   ```
   multipath -l
   ```

4. Ensure that each device is listed and that it has as many paths as you expect. You can use size and device ID information to identify which disks are listed.
   For example, the following output shows that a 2 TB disk has two path groups and four active paths. The 2 TB size confirms that the disk corresponds to a pool file system. Use part of the long device ID number (12, in this example) to search for the volume on the disk-system management interface.

   ```
   [root@tapsrv01 code]# multipath -l
   36005076802810c509800000000000012 dm-43 IBM,2145
    size=2.0T features='1 queue_if_no_path' hwhandler='0' wp=rw
   |-+- policy='round-robin 0' prio=0 status=active
   | |- 2:0:1:18 sdcw 70:64   active undef running
   | `- 4:0:0:18 sdgb 131:112 active undef running
   `-+- policy='round-robin 0' prio=0 status=enabled
     |- 1:0:1:18 sdat 66:208  active undef running
     `- 3:0:0:18 sddy 128:0   active undef running
   ```

   a. If needed, correct disk LUN host assignments and force a bus rescan. For example:

      ```
      echo "- - -" > /sys/class/scsi_host/host0/scan
      echo "- - -" > /sys/class/scsi_host/host1/scan
      echo "- - -" > /sys/class/scsi_host/host2/scan
      ```

      You can also restart the system to rescan disk LUN host assignments.
   b. Confirm that disks are now available for multipath I/O by reissuing the multipath -l command.
5. Use the multipath output to identify and list device IDs for each disk device.

   For example, the device ID for your 2 TB disk is `36005076802810c509800000000000012`.

   Save the list of device IDs to use in the next step.

Windows systems

Complete the following steps to enable and configure multipathing for disk storage.

Procedure

1. Ensure that the Multipath I/O feature is installed. If needed, install additional vendor-specific multipath drivers.
2. To verify that disks are visible to the operating system and are managed by multipath I/O, issue the following command:

   ```
   c:\program files\IBM\SDDDSM\datapath.exe query device
   ```

3. Review the multipath output and ensure that each device is listed and that it has as many paths as you expect. You can use size and device serial information to identify which disks are listed.
   For example, by using part of the long device serial number (34, in this example) you can search for the volume on the disk-system management interface. The 2 TB size confirms that the disk corresponds to a storage pool file system.

   ```
   DEV#:   4  DEVICE NAME: Disk5 Part0   TYPE: 2145    POLICY: OPTIMIZED
   SERIAL: 600507630081010578000000000000034          LUN SIZE: 2.0TB
   ============================================================================
   Path#          Adapter/Hard Disk       State    Mode    Select  Errors
       0   Scsi Port2 Bus0/Disk5 Part0    OPEN     NORMAL       0       0
       1   Scsi Port2 Bus0/Disk5 Part0    OPEN     NORMAL   27176       0
       2   Scsi Port3 Bus0/Disk5 Part0    OPEN     NORMAL   28494       0
       3   Scsi Port3 Bus0/Disk5 Part0    OPEN     NORMAL       0       0
   ```

4. Create a list of disk device IDs by using the serial numbers that are returned from the multipath output in the previous step.

   For example, the device ID for your 2 TB disk is `600507630081010578000000000000034`

   Save the list of device IDs to use in the next step.

5. To bring new disks online and clear the read-only attribute, run diskpart.exe with the following commands. Repeat for each of the disks:

   ```
   diskpart
      select Disk 1
      online disk
      attribute disk clear readonly
      select Disk 2
      online disk
      attribute disk clear readonly
      < ... >
      select Disk 49
      online disk
      attribute disk clear readonly
      exit
   ```

Creating the user ID for the server

Create the user ID that owns the IBM Spectrum Protect™ server instance. You specify this user ID when you create the server instance during initial configuration of the server.

About this task

You can specify only lowercase letters (a-z), numerals (0-9), and the underscore character (_) for the user ID. The user ID and group name must comply with the following rules:

- The length must be 8 characters or fewer.
- The user ID and group name cannot start with *ibm*, *sql*, *sys*, or a numeral.
- The user ID and group name cannot be *user*, *admin*, *guest*, *public*, *local*, or any SQL reserved word.

Procedure

1. Use operating system commands to create a user ID.
   - AIX Linux Create a group and user ID in the home directory of the user that owns the server instance.

For example, to create the user ID tsminst1 in group tsmsrvrs with a password of tsminst1, issue the following commands from an administrative user ID:

AIX

```
mkgroup id=1001 tsmsrvrs
mkuser id=1002 pgrp=tsmsrvrs home=/home/tsminst1 tsminst1
passwd tsminst1
```

Linux

```
groupadd tsmsrvrs
useradd -d /home/tsminst1 -m -g tsmsrvrs -s /bin/bash tsminst1
passwd tsminst1
```

Log off, and then log in to your system. Change to the user account that you created. Use an interactive login program, such as telnet, so that you are prompted for the password and can change it if necessary.

- Windows Create a user ID and then add the new ID to the Administrators group. For example, to create the user ID tsminst1, issue the following command:

```
net user tsminst1 * /add
```

After you create and verify a password for the new user, add the user ID to the Administrators group by issuing the following commands:

```
net localgroup Administrators tsminst1 /add
net localgroup DB2ADMNS tsminst1 /add
```

2. Log off the new user ID.

Preparing file systems for the server

You must complete file system configuration for the disk storage to be used by the server.

- Preparing file systems on AIX systems
  You must create volume groups, logical volumes, and file systems for the server by using the AIX® Logical Volume Manager.
- Preparing file systems on Linux systems
  You must format ext4 or xfs file systems on each of the disk LUNs to be used by the IBM Spectrum Protect server.
- Preparing file systems on Windows systems
  You must format New Technology File System (NTFS) file systems on each of the disk LUNs to be used by the IBM Spectrum Protect server.

Preparing file systems on AIX systems

You must create volume groups, logical volumes, and file systems for the server by using the AIX® Logical Volume Manager.

Procedure

1. Increase the queue depth and maximum transfer size for all of the available *hdiskX* disks. Issue the following commands for each disk:

```
chdev -l hdisk4 -a max_transfer=0x100000
chdev -l hdisk4 -a queue_depth=32
chdev -l hdisk4 -a reserve_policy=no_reserve
chdev -l hdisk4 -a algorithm=round_robin
```

   Do not run these commands for operating system internal disks, for example, *hdisk0*.
2. Create volume groups for the IBM Spectrum Protect™ database, active log, archive log, database backup, and storage pool. Issue the mkvg command, specifying the device IDs for corresponding disks that you previously identified.
   For example, if the device names *hdisk4, hdisk5*, and *hdisk6* correspond to database disks, include them in the database volume group and so on.
   System size: The following commands are based on the medium system configuration. For small and large systems, you must adjust the syntax as required.

```
mkvg -S -y tsmdb hdisk2 hdisk3 hdisk4
mkvg -S -y tsmactlog hdisk5
```

```
mkvg -S -y tsmarchlog hdisk6
mkvg -S -y tsmdbback hdisk7 hdisk8 hdisk9 hdisk10
mkvg -S -y tsmstgpool hdisk11 hdisk12 hdisk13 hdisk14 ... hdisk49
```

3. Determine the physical volume names and the number of free physical partitions to use when you create logical volumes. Issue the lsvg for each volume group that you created in the previous step.
   For example:

   ```
   lsvg -p tsmdb
   ```

   The output is similar to the following. The *FREE PPs* column represents the free physical partitions:

   ```
   tsmdb:
   PV_NAME  PV STATE   TOTAL PPs  FREE PPs  FREE DISTRIBUTION
   hdisk4   active     1631       1631      327..326..326..326..326
   hdisk5   active     1631       1631      327..326..326..326..326
   hdisk6   active     1631       1631      327..326..326..326..326
   ```

4. Create logical volumes in each volume group by using the mklv command. The volume size, volume group, and device names vary, depending on the size of your system and variations in your disk configuration.
   For example, to create the volumes for the IBM Spectrum Protect database on a medium system, issue the following commands:

   ```
   mklv -y tsmdb00 -t jfs2 -u 1 -x 1631 tsmdb 1631 hdisk2
   mklv -y tsmdb01 -t jfs2 -u 1 -x 1631 tsmdb 1631 hdisk3
   mklv -y tsmdb02 -t jfs2 -u 1 -x 1631 tsmdb 1631 hdisk4
   ```

5. Format file systems in each logical volume by using the crfs command.
   For example, to format file systems for the database on a medium system, issue the following commands:

   ```
   crfs -v jfs2 -d tsmdb00 -p rw -a logname=INLINE -a options=rbrw
    -a agblksize=4096 -m /tsminst1/TSMdbspace00 -A yes
   crfs -v jfs2 -d tsmdb01 -p rw -a logname=INLINE -a options=rbrw
    -a agblksize=4096 -m /tsminst1/TSMdbspace01 -A yes
   crfs -v jfs2 -d tsmdb02 -p rw -a logname=INLINE -a options=rbrw
    -a agblksize=4096 -m /tsminst1/TSMdbspace02 -A yes
   ```

6. Mount all of the newly created file systems by issuing the following command:

   ```
   mount -a
   ```

7. List all file systems by issuing the df command. Verify that file systems are mounted at the correct LUN and correct mount point. Also, verify the available space.
   The following example of command output shows that the amount of used space is typically 1%:

   ```
   tapsrv07> df -g /tsminst1/*
   Filesystem      GB blocks  Free     %Used   Iused   %Iused   Mounted on
   /dev/tsmact00   195.12     194.59   1%      4       1%       /tsminst1/TSMalog
   ```

8. Verify that the user ID that you created in Creating the user ID for the server has read and write access to the directories for the server.

Preparing file systems on Linux systems

You must format ext4 or xfs file systems on each of the disk LUNs to be used by the IBM Spectrum Protect™ server.

Procedure

1. Using the list of device IDs that you generated previously, issue the mkfs command to create and format a file system for each storage LUN device. Specify the device ID in the command. See the following examples. For the database, format ext4 file systems:

   ```
   mkfs -t ext4 -T largefile -m 2 /dev/mapper/36005076802810c509800000000000012
   ```

   For storage pool LUNs, format xfs file systems:

   ```
   mkfs -t xfs /dev/mapper/360050763008101057800000000002c3
   ```

   You might issue the mkfs command as many as 50 times, depending on how many different devices you have.

2. Create mount point directories for file systems.

   Issue the mkdir command for each directory that you must create. Use the directory values that you recorded in the planning worksheets.

   For example, to create the server instance directory by using the default value, issue the following command:

   ```
   mkdir /tsminst1
   ```

   Repeat the mkdir command for each file system.
3. Add an entry in the /etc/fstab file for each file system so that file systems are mounted automatically when the server is started.
   For example:

   ```
   /dev/mapper/36005076802810c509800000000000012 /tsminst1/TSMdbspace00 ext4 defaults 0 0
   ```

4. Mount the file systems that you added to the /etc/fstab file by issuing the mount -a command.
5. List all file systems by issuing the df command. Verify that file systems are mounted at the correct LUN and correct mount point. Also, verify the available space.
   The following example on an IBM® Storwize® system shows that the amount of used space is typically 1%:

   ```
   [root@tapsrv04 ~]# df -h /tsminst1/*
   Filesystem                                      Size  Used Avail Use% Mounted on
   /dev/mapper/3600507630081010578000000000000003 134G  188M 132G  1%   /tsminst1/TSMalog
   ```

6. Verify that the user ID that you created in Creating the user ID for the server has read and write access to the directories for the IBM Spectrum Protect server.

Preparing file systems on Windows systems

You must format New Technology File System (NTFS) file systems on each of the disk LUNs to be used by the IBM Spectrum Protect™ server.

Procedure

1. Create mount point directories for file systems.
   Issue the md command for each directory that you must create. Use the directory values that you recorded in the planning worksheets. For example, to create the server instance directory by using the default value, issue the following command:

   ```
   md c:\tsminst1
   ```

   Repeat the md command for each file system.
2. Create a volume for every disk LUN that is mapped to a directory under the server instance directory by using the Windows volume manager.

   Go to Server Manager > File and Storage Services and complete the following steps for each disk that corresponds to the LUN mapping that was created in the previous step:

   a. Bring the disk online.
   b. Initialize the disk to the GPT basic type, which is the default.
   c. Create a simple volume that occupies all of the space on the disk. Format the file system by using NTFS, and assign a label that matches the purpose of the volume, such as TSMfile00. Do not assign the new volume to a drive letter. Instead, map the volume to a directory under the instance directory, such as C:\tsminst1\TSMfile00.
      Tip: Determine the volume label and directory mapping labels based on the size of the disk that is reported.
3. Verify that file systems are mounted at the correct LUN and correct mount point. List all file systems by issuing the mountvol command and then review the output. For example:

   ```
   \\?\Volume{8ffb9678-3216-474c-a021-20e420816a92}\
     C:\tsminst1\TSMdbspace00\
   ```

4. After the disk configuration is complete, restart the system.

What to do next

You can confirm the amount of free space for each volume by using Windows Explorer.

Installing the server and Operations Center

Use the IBM® Installation Manager graphical wizard to install the components.

- Installing on AIX and Linux systems
  Install the IBM Spectrum Protect™ server and the Operations Center on the same system.
- Installing on Windows systems
  Install the IBM Spectrum Protect server and the Operations Center on the same system.

Installing on AIX® and Linux systems

Install the IBM Spectrum Protect™ server and the Operations Center on the same system.

Before you begin

Verify that the operating system is set to the language that you require. By default, the language of the operating system is the language of the installation wizard.

Procedure

1. AIX Verify that the required RPM files are installed on your system.

   See Installing prerequisite RPM files for the graphical wizard for details.

2. Before you download the installation package, verify that you have enough space to store the installation files when they are extracted from the product package. For space requirements, see the download document at technote 4042992.
3. Go to Passport Advantage® and download the package file to an empty directory of your choice.
4. Ensure that executable permission is set for the package. If necessary, change the file permissions by issuing the following command:

   ```
   chmod a+x package_name.bin
   ```

5. Extract the package by issuing the following command:

   ```
   ./package_name.bin
   ```

   where *package_name* is the name of the downloaded file.
6. AIX Ensure that the following command is enabled so that the wizards work properly:

   ```
   lsuser
   ```

   By default, the command is enabled.
7. Change to the directory where you placed the executable file.
8. Start the installation wizard by issuing the following command:

   ```
   ./install.sh
   ```

   When you select the packages to install, choose both the server and Operations Center.

What to do next

- If errors occur during the installation process, the errors are recorded in log files that are stored in the IBM Installation Manager logs directory.

  To view installation log files from the Installation Manager tool, click File > View Log. To collect these log files from the Installation Manager tool, click Help > Export Data for Problem Analysis.

- After you install the server and before you customize it for your use, go to the IBM Spectrum Protect support site. Click Support and downloads and apply any applicable fixes.

- Installing prerequisite RPM files for the graphical wizard
  RPM files are required for the IBM Installation Manager graphical wizard.

Installing on Windows systems

Install the IBM Spectrum Protect™ server and the Operations Center on the same system.

Before you begin

Make sure that the following prerequisites are met:

- Verify that the operating system is set to the language that you require. By default, the language of the operating system is the language of the installation wizard.
- Ensure that the user ID that you plan to use during the installation is a user with local Administrator authority.

Procedure

1. Before you download the installation package, verify that you have enough space to store the installation files when they are extracted from the product package. For space requirements, see the download document at technote 4042993.
2. Go to Passport Advantage® and download the package file to an empty directory of your choice.
3. Change to the directory where you placed the executable file.
4. Double-click the executable file to extract to the current directory.
5. In the directory where the installation files were extracted, start the installation wizard by double-clicking the install.bat file. When you select the packages to install, choose both the server and Operations Center.

What to do next

- If errors occur during the installation process, the errors are recorded in log files that are stored in the IBM® Installation Manager logs directory.

  To view installation log files from the Installation Manager tool, click File > View Log. To collect these log files from the Installation Manager tool, click Help > Export Data for Problem Analysis.

- After you install the server and before you customize it for your use, go to the IBM Spectrum Protect support site. Click Support and downloads and apply any applicable fixes.

Configuring the server and the Operations Center

After you install the components, complete the configuration for the IBM Spectrum Protect™ server and the Operations Center.

- Configuring the server instance
  Use the IBM Spectrum Protect server instance configuration wizard to complete the initial configuration of the server.
- Installing the backup-archive client
  As a best practice, install the IBM Spectrum Protect backup-archive client on the server system so that the administrative command-line client and scheduler are available.
- Setting options for the server
  Review the server options file that is installed with the IBM Spectrum Protect server to verify that the correct values are set for your system.
- Security concepts
  You can protect IBM Spectrum Protect from security risks by using communication protocols, securing passwords, and providing different access levels for administrators.
- Configuring the Operations Center
  After you install the Operations Center, complete the following configuration steps to start managing your storage environment.
- Registering the product license
  To register your license for the IBM Spectrum Protect product, use the REGISTER LICENSE command.
- Defining data retention rules for your business
  After you create a directory-container storage pool for data deduplication, update the default server policy to use the new storage pool. The Add Storage Pool wizard opens the Services page in the Operations Center to complete this task.
- Defining schedules for server maintenance activities
  Create schedules for each server maintenance operation by using the DEFINE SCHEDULE command in the Operations Center command builder.
- Defining client schedules
  Use the Operations Center to create schedules for client operations.

Configuring the server instance

Use the IBM Spectrum Protect™ server instance configuration wizard to complete the initial configuration of the server.

Before you begin

Ensure that the following requirements are met:
AIX Linux

- The system where you installed IBM Spectrum Protect must have the X Window System client. You must also be running an X Window System server on your desktop.
- The system must have the Secure Shell (SSH) protocol enabled. Ensure that the port is set to the default value, 22, and that the port is not blocked by a firewall. You must enable password authentication in the sshd_config file in the /etc/ssh/directory. Also, ensure that the SSH daemon service has access rights to connect to the system by using the *localhost* value.
- You must be able to log in to IBM Spectrum Protect with the user ID that you created for the server instance, by using the SSH protocol. When you use the wizard, you must provide this user ID and password to access that system.
- If you changed any settings in the preceding steps, restart the server before you proceed with the configuration wizard.

Windows Verify that the remote registry service is started by completing the following steps:

1. Click Start > Administrative Tools > Services. In the Services window, select Remote Registry. If it is not started, click Start.
2. Ensure that port 137, 139, and 445 are not blocked by a firewall:
    a. Click Start > Control Panel > Windows Firewall.
    b. Select Advanced Settings.
    c. Select Inbound Rules.
    d. Select New Rule.
    e. Create a port rule for TCP ports 137, 139, and 445 to allow connections for domain and private networks.
3. Configure the user account control by accessing the local security policy options and completing the following steps.
    a. Click Start > Administrative Tools > Local Security Policy. Expand Local Policies > Security Options.
    b. If not already enabled, enable the built-in administrator account by selecting Accounts: Administrator account status > Enable > OK.
    c. If not already disabled, disable user account control for all Windows administrators by selecting User Account Control: Run all administrators in Admin Approval Mode > Disable > OK.
    d. If not already disabled, disable the User Account Control for the built-in Administrator account by selecting User Account Control: Admin Approval Mode for the Built-in Administrator Account > Disable > OK.
4. If you changed any settings in the preceding steps, restart the server before you proceed with the configuration wizard.

About this task

The wizard can be stopped and restarted, but the server is not operational until the entire configuration process is complete.

Procedure

1. Start the local version of the wizard.
    - AIX Linux Open the dsmicfgx program in the /opt/tivoli/tsm/server/bin directory. This wizard can be only run as a root user.
    - Windows Click Start > All Programs > IBM Spectrum Protect > Configuration Wizard.
2. Follow the instructions to complete the configuration. Use the information that you recorded in Planning worksheets during IBM Spectrum Protect system setup to specify directories and options in the wizard.

    AIX Linux On the Server Information window, set the server to start automatically by using the instance user ID when the system boots.

    Windows By using the configuration wizard, the server is set to start automatically when rebooted.

Installing the backup-archive client

As a best practice, install the IBM Spectrum Protect™ backup-archive client on the server system so that the administrative command-line client and scheduler are available.

Procedure

To install the backup-archive client, follow the installation instructions for your operating system.

- Installing the UNIX and Linux backup-archive clients
- Installing the Windows backup-archive client

Setting options for the server

Review the server options file that is installed with the IBM Spectrum Protect™ server to verify that the correct values are set for your system.

Procedure

1. Go to the server instance directory and open the dsmserv.opt file.
2. Review the values in the following table and verify your server option settings, based on system size.

Server option	Value
ACTIVELOGDIRECTORY	Directory path that was specified during configuration
ACTIVELOGSIZE	131072
ARCHLOGCOMPRESS	No
ARCHLOGDIRECTORY	Directory path that was specified during configuration
COMMMETHOD	TCPIP
COMMTIMEOUT	3600
DEVCONFIG	devconf.dat
EXPINTERVAL	0
IDLETIMEOUT	60
MAXSESSIONS	500
NUMOPENVOLSALLOWED	20
TCPADMINPORT	1500
TCPPORT	1500
VOLUMEHISTORY	volhist.dat

Update server option settings if necessary, to match the values in the table. To make updates, close the dsmserv.opt file and use the SETOPT command from the administrative command-line interface to set the options.
For example, to update the IDLETIMEOUT option to 60, issue the following command:

```
setopt idletimeout 60
```

3. To configure secure communications for the server, clients, and the Operations Center, verify the options in the following table.

Server option	All system sizes
SSLDISABLELEGACYTLS	YES
SSLFIPSMODE	NO
SSLTCPPORT	Specify the SSL port number. The server TCP/IP communication driver waits for requests on this port for SSL-enabled sessions from the client.
SSLTCPADMINPORT	Specify the port address on which the server waits for requests for SSL-enabled sessions from the command-line administrative client.
SSLTLS12	YES

If any of the option values must be updated, edit the dsmserv.opt file by using the following guidelines:
   - Remove the asterisk at the beginning of a line to enable an option.

- On each line, enter only one option and the specified value for the option.
- If an option occurs in multiple entries in the file, the server uses the last entry.

Save your changes and close the file. If you edit the dsmserv.opt file directly, you must restart the server for the changes to take effect.

Security concepts

You can protect IBM Spectrum Protect™ from security risks by using communication protocols, securing passwords, and providing different access levels for administrators.

Transport Layer Security

You can use the Secure Sockets Layer (SSL) or the Transport Layer Security (TLS) protocol to provide transport layer security for a secure connection between servers, clients, and storage agents. If you send data between the server, client, and storage agent, use SSL or TLS to encrypt the data.

Tip: Any IBM Spectrum Protect documentation that indicates "SSL" or to "select SSL" applies to TLS.

SSL is provided by the Global Security Kit (GSKit) that is installed with the IBM Spectrum Protect server that the server, client, and storage agent use.

Restriction: Do not use the SSL or TLS protocols for communications with a DB2® database instance that is used by any IBM Spectrum Protect servers.

Each server, client, or storage agent that enables SSL must use a trusted self-signed certificate or obtain a unique certificate that is signed by a certificate authority (CA). You can use your own certificates or purchase certificates from a CA. Either certificate must be installed and added to the key database on the IBM Spectrum Protect server, client, or storage agent. The certificate is verified by the SSL client or server that requests or initiates the SSL communication. Some CA certificates are preinstalled in the key databases, by default.

SSL is set up independently on the IBM Spectrum Protect server, client, and storage agent.

Authority levels

With each IBM Spectrum Protect server, different administrative authority levels are available that determine the tasks that an administrator can complete.

After registration, an administrator must be granted authority by being assigned one or more administrative authority levels. An administrator with system authority can complete any task with the server and assign authority levels to other administrators by using the GRANT AUTHORITY command. Administrators with policy, storage, or operator authority can complete subsets of tasks.

An administrator can register other administrator IDs, grant levels of authority to them, rename IDs, remove IDs, and lock and unlock them from the server.

An administrator can control access to specific client nodes for root user IDs and non-root user IDs. By default, a non-root user ID cannot back up data on the node. Use the UPDATE NODE command to change the node settings to enable backup.

Passwords

By default, the server automatically uses password authentication. With password authentication, all users must enter a password when they access the server.

Use Lightweight Directory Access Protocol (LDAP) to apply stricter requirements for passwords. For more information, see Managing passwords and logon procedures (V7.1.1).

Table 1. Password authentication characteristics

Characteristic	More information
Case-sensitivity	Not case-sensitive.

Characteristic	More information
Default password expiration	90 days. The expiration period begins when an administrator ID or client node is first registered to the server. If the password is not changed within this period, the password must be changed the next time that the user accesses the server.
Invalid password attempts	You can set a limit on consecutive invalid password attempts for all client nodes. When the limit is exceeded, the server locks the node.
Password length	The administrator can specify a minimum length.

Session security

Session security is the level of security that is used for communication among IBM Spectrum Protect client nodes, administrative clients, and servers and is set by using the SESSIONSECURITY parameter.

The SESSIONSECURITY parameter can be set to one of the following values:

- The STRICT value enforces the highest level of security for communication between IBM Spectrum Protect servers, nodes, and administrators.
- The TRANSITIONAL value specifies that the existing communication protocol is used while you update your IBM Spectrum Protect software to V8.1.2 or later. This is the default. When SESSIONSECURITY=TRANSITIONAL, stricter security settings are automatically enforced as higher versions of the TLS protocol are used and as the software is updated to V8.1.2 or later. After a node, administrator, or server meets the requirements for the STRICT value, session security is automatically updated to the STRICT value, and the entity can no longer authenticate by using a previous version of the client or earlier TLS protocols.

For more information about the SESSIONSECURITY parameter values, see the following commands.

Table 2. Commands used to set the SESSIONSECURITY parameter

Entity	Command
Client nodes	• REGISTER NODE • UPDATE NODE
Administrators	• REGISTER ADMIN • UPDATE ADMIN
Servers	• DEFINE SERVER • UPDATE SERVER

Administrators that authenticate by using the DSMADMC command, DSMC command, or dsm program cannot authenticate by using an earlier version after authenticating by using V8.1.2 or later. To resolve authentication issues for administrators, see the following tips:
Tips:

- Ensure that all IBM Spectrum Protect software that the administrator account uses to log on is upgraded to V8.1.2 or later. If an administrator account logs on from multiple systems, ensure that the server's certificate is installed on each system.
- After an administrator authenticates to a V8.1.2 or later server by using a V8.1.2 or later client, the administrator can authenticate only on clients or servers that are using V8.1.2 or later. An administrator command can be issued from any system.
- If necessary, create a separate administrator account to use only with clients and servers that are using V8.1.1 or earlier software.

Enforce the highest level of security for communication with the IBM Spectrum Protect server by ensuring that all nodes, administrators, and servers use STRICT session security. You can use the SELECT command to determine which servers, nodes, and administrators are using TRANSITIONAL session security and should be updated to use STRICT session security.

- Configuring secure communications with Transport Layer Security
  To encrypt data and secure communications in your environment, Secure Sockets Layer (SSL) or Transport Layer Security

(TLS) is enabled on the IBM Spectrum Protect server and backup-archive client. An SSL certificate is used to verify communication requests between the server and client.

Related tasks:
Securing communications

Configuring the Operations Center

After you install the Operations Center, complete the following configuration steps to start managing your storage environment.

Before you begin

When you connect to the Operations Center for the first time, you must provide the following information:

- Connection information for the server that you want to designate as a hub server
- Login credentials for an administrator ID that is defined for that server

Procedure

1. Designate the hub server. In a web browser, enter the following address:

   `https://hostname:secure_port/oc`

   where:
   - *hostname* represents the name of the computer where the Operations Center is installed
   - *secure_port* represents the port number that the Operations Center uses for HTTPS communication on that computer

   For example, if your host name is tsm.storage.mylocation.com and you are using the default secure port for the Operations Center, which is 11090, the address is:

   `https://tsm.storage.mylocation.com:11090/oc`

   When you log in to the Operations Center for the first time, a wizard guides you through an initial configuration to set up a new administrator with system authority on the server.

2. Set up secure communications between the Operations Center and the hub server by configuring the Secure Sockets Layer (SSL) protocol.

   Follow the instructions in Securing communications between the Operations Center and the hub server.

3. Optional: To receive a daily email report that summarizes system status, configure your email settings in the Operations Center.

   Follow the instructions in Tracking system status by using email reports.

- Securing communications between the Operations Center and the hub server
  To secure communications between the Operations Center and the hub server, add the Transport Layer Security (TLS) certificate of the hub server to the truststore file of the Operations Center.

Registering the product license

To register your license for the IBM Spectrum Protect™ product, use the REGISTER LICENSE command.

About this task

Licenses are stored in enrollment certificate files, which contain licensing information for the product. The enrollment certificate files are on the installation media, and are placed on the server during installation. When you register the product, the licenses are stored in a NODELOCK file within the current directory.

Procedure

Register a license by specifying the name of the enrollment certificate file that contains the license. To use the Operations Center command builder for this task, complete the following steps.

1. Open the Operations Center.
2. Open the Operations Center command builder by hovering over the settings icon and clicking Command Builder.
3. Issue the REGISTER LICENSE command. For example, to register a base IBM Spectrum Protect license, issue the following command:

```
register license file=tsmbasic.lic
```

What to do next

Save the installation media that contains your enrollment certificate files. You might need to register your license again if, for example, one of the following conditions occur:

- The server is moved to a different computer.
- The NODELOCK file is corrupted. The server stores license information in the NODELOCK file, which is in the directory from which the server is started.
- Linux If you change the processor chip that is associated with the server on which the server is installed.

Defining data retention rules for your business

After you create a directory-container storage pool for data deduplication, update the default server policy to use the new storage pool. The Add Storage Pool wizard opens the Services page in the Operations Center to complete this task.

Procedure

1. On the Services page of the Operations Center, select the STANDARD domain and click Details.
2. On the Summary page for the policy domain, click the Policy Sets tab. The Policy Sets page indicates the name of the active policy set and lists all of the management classes for that policy set.
3. Click the Configure toggle, and make the following changes:
    - Change the backup destination for the STANDARD management class to the directory-container storage pool.
    - Change the value for the Backups column to No limit.
    - Change the retention period. Set the Keep Extra Backups column to 30 days or more, depending on your business requirements.
4. Save your changes and click the Configure toggle again so that the policy set is no longer editable.
5. Activate the policy set by clicking Activate.

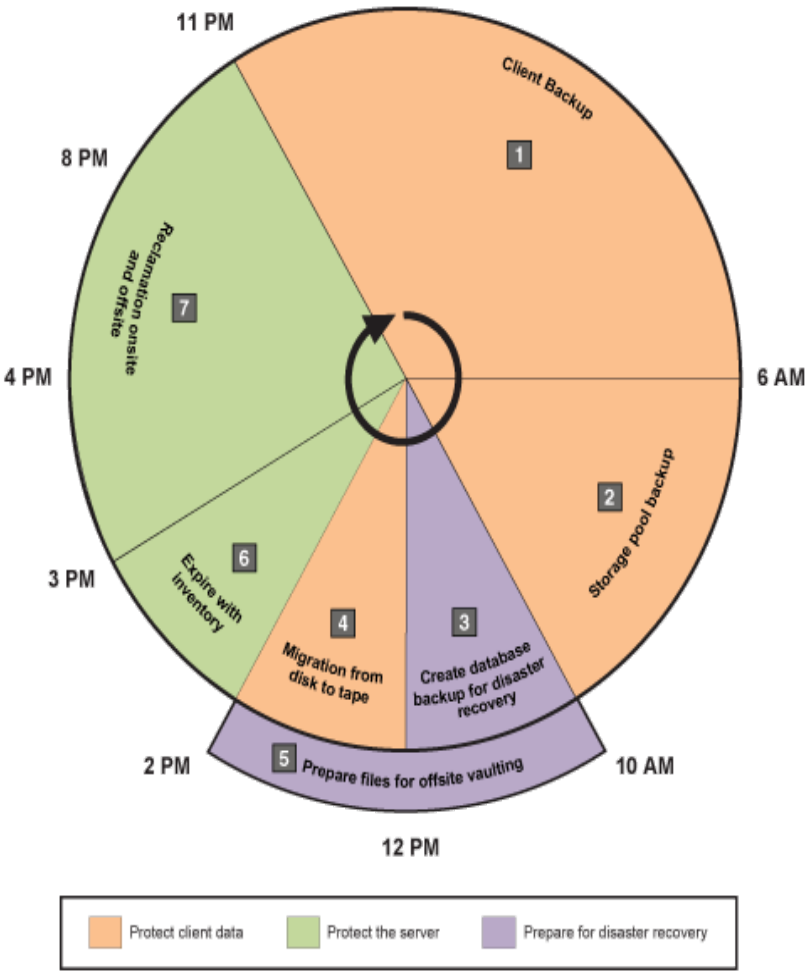
Defining schedules for server maintenance activities

Create schedules for each server maintenance operation by using the DEFINE SCHEDULE command in the Operations Center command builder.

About this task

Schedule server maintenance operations to run after client backup operations. You can control the timing of schedules by setting the start time in combination with the duration time for each operation.

The following figure provides an example of how to plan maintenance operations.
Figure 1. Daily schedule of server operations for a tape solution



The following table shows how you can schedule server maintenance processes in combination with the client backup schedule for a tape solution.

Operation	Schedule
Client backup	Starts at 11 PM.
Storage pool backup	Starts at 6 AM.
Processing for database and disaster recovery files	• The database backup operation starts at 10 AM, or 11 hours after the beginning of the client backup operation. This process runs until completion. • Device configuration information and volume history backup operations start at 5 PM, or 7 hours after the start of the database backup operation. • Volume history deletion starts at 8 PM, or 10 hours after the start of the database backup operation.
Preparation of files for offsite vaulting	Starts at 10 AM, at the same time as processing for the database and disaster recovery files.
Migration from disk to tape	Starts at 12 PM, or 2 hours after the start of the database backup operation.
Inventory expiration	Starts at 2 PM, or 15 hours after the beginning of the client backup operation. This process runs until completion.
Space reclamation	Starts at 3 PM, or 16 hours after the beginning of the client backup operation.

Procedure

After you configure the device class for the database backup operations, create schedules for database backup and other required maintenance operations by using the DEFINE SCHEDULE command. Depending on the size of your environment, you might need to adjust the start times for each schedule in the example.

1. Define a device class for the backup operation before you create the schedule for database backups. Use the DEFINE DEVCLASS command to create a device class that is named LTOTAPE:

   ```
   define devclass ltotape devtype=lto library=ltolib
   ```

2. Set the device class for automatic database backups. Use the SET DBRECOVERY command to specify the device class that you created for the database backup in the preceding step. For example, if the device class is LTOTAPE, issue the following command:

   ```
   set dbrecovery ltotape
   ```

3. Create schedules for the maintenance operations by using the DEFINE SCHEDULE command. See the following table for the required operations with examples of the commands.

Operation	Example commands and additional information
Back up storage pools.	Create a schedule to run the BACKUP STGPOOL command. For example, issue the following command to create a backup schedule for a primary storage pool that is named PRIMARY_POOL. The pool will be backed up to a copy storage pool, COPYSTG: `define schedule BACKUPSTGPOOL type=administrative cmd="backup stgpool primary_pool copystg" active=yes starttime=06:00 period=1`
Back up the database.	Create a schedule to run the BACKUP DB command. For example, issue the following command to create a backup schedule that uses the new device class: `define schedule DBBACKUP type=admin cmd="backup db devclass=ltotape type=full numstreams=3 wait=yes compress=yes" active=yes desc="Back up the database." startdate=today starttime=10:00:00 duration=45 durunits=minutes`
Replicate nodes.	Optionally, use node replication to protect client data by backing the data up to a secondary server. For instructions, see Replicating client data to another server. Ensure that node replication is completed before migration operations begin.

Operation	Example commands and additional information
Migrate data from disk to tape daily.	Create a schedule for storage pool migration. For example, if a disk storage pool is named DISKPOOL and the next storage pool is TAPEPOOL, you can schedule storage pool migration by issuing the following command: `define schedule stgpool_migration type=administrative cmd="migrate stgpool diskpool lomig=0" active=yes description="migrate disk storagepool to tapepool" startdate=today starttime=12:00 duration=2 durunits=hours period=1 perunits=days` To maximize throughput, you can specify the number of parallel processes to use for migrating files by completing the following steps: a. For the tape storage pool, ensure that collocation is enabled. To verify whether collocation is enabled, run the QUERY STGPOOL command. Verify that a value of `GROUP`, `NODE`, or `FILESPACE` is specified in the `COLLOCATE` field. If a value of `GROUP`, `NODE`, or `FILESPACE` is not specified, use the UPDATE STGPOOL command to specify `COLLOCATE=GROUP`, `COLLOCATE=NODE`, or `COLLOCATE=FILESPACE`, depending on your system configuration. b. For the disk storage pool, use the DEFINE STGPOOL or UPDATE STGPOOL command to specify a value for the MIGPROCESS parameter. For example, if you have 12 tape drives, specify `MIGPROCESS=10`. In this way, a maximum of 10 tape drives are used for migration processes. Two drives are reserved for other tasks, such as restore, database backup, and client backup operations.
Prepare files for offsite vaulting.	a. Move tape volumes offsite by following the instructions in Moving backup media. b. Create the disaster recovery plan file by issuing the PREPARE command on the source server: `prepare` c. Ensure that all volumes that are required for disaster recovery are included in the recovery plan file. For more information, see Preparing for and recovering from a disaster by using DRM.
Back up the device configuration information.	Create a schedule to run the BACKUP DEVCONFIG command: `define schedule DEVCONFIGBKUP type=admin cmd="backup devconfig filenames=devconfig.dat" active=yes desc="Backup the device configuration file." startdate=today starttime=17:00:00 duration=45 durunits=minutes`
Back up the volume history.	Create a schedule to run the BACKUP VOLHISTORY command: `define schedule VOLHISTBKUP type=admin cmd="backup volhistory filenames=volhist.dat" active=yes desc="Back up the volume history." startdate=today starttime=17:00:00 duration=45 durunits=minutes`

Operation	Example commands and additional information
Remove older versions of database backups that are no longer required.	Create a schedule to run the DELETE VOLHISTORY command: `define schedule DELVOLHIST type=admin cmd="delete volhistory` `  type=dbb todate=today-6 totime=now" active=yes desc="Remove` `  old database backups." startdate=today starttime=20:00:00` `  duration=45 durunits=minutes`
Remove objects that exceed their allowed retention.	Create a schedule to run the EXPIRE INVENTORY command. Set the RESOURCE parameter based on the system size that you are configuring to be equal to the number of processor cores that you specified for your system. For example, issue the following command to create a schedule that is named EXPINVENTORY: `define schedule EXPINVENTORY type=admin cmd="expire inventory` `  wait=yes resource=8 duration=120" active=yes desc="Remove expired` `  objects." startdate=today starttime=14:00:00 duration=1` `  durunits=hours`
Reclaim space.	Create a schedule to run the RECLAIM STGPOOL command. For example, issue the following command to create a schedule that is named RECLAIM: `define schedule RECLAIM type=admin cmd="reclaim stgpool` `tapepool duration=60" startdate=today starttime=15:00:00 duration=5` `  durunits=hours` Tip: To maximize throughput, you can specify the number of parallel processes to use for reclaiming space. Update the tape storage pool by using the UPDATE STGPOOL command and specify a value for the RECLAIMPROCESS parameter. For example, if you have 12 tape drives, specify `RECLAIMPROCESS=5`. Because two drives are used for each reclamation process, the total number of drives that can be used for reclamation is 10. Two drives are reserved for backup operations.

What to do next

After you create schedules for the server maintenance tasks, you can view them in the Operations Center by completing the following steps:

1. On the Operations Center menu bar, hover over Servers.
2. Click Maintenance.

- Moving backup media
  To recover from a disaster, you need database backup volumes, copy storage pool volumes, and additional files. To stay prepared for a disaster, you must complete daily tasks.

Related reference:
UPDATE STGPOOL (Update a storage pool)
DEFINE SCHEDULE (Define a schedule for an administrative command)
DEFINE STGPOOL (Define a volume in a storage pool)

Defining client schedules

Use the Operations Center to create schedules for client operations.

Procedure

1. On the Operations Center menu bar, hover over Clients.
2. Click Schedules.
3. Click +Schedule.
4. Complete the steps in the Create Schedule wizard. Set client backup schedules to start at 22:00, based on the server maintenance activities that you scheduled in Defining schedules for server maintenance activities.

Attaching tape devices for the server

Before the server can use a tape device, you must attach the device to your server system and install the appropriate tape device driver.

About this task

To optimize system performance, use fast, high-capacity tape devices. Provision enough tape drives to meet your business requirements.

Attach tape devices on their own host bus adapter (HBA), not shared with other devices types such as disk. IBM® tape drives have some special requirements for HBAs and associated drivers.

- AIX Linux Attaching an automated library device to your system
  You can attach an automated library device to your system to store your data on tapes.
- Selecting a tape device driver
  To use tape devices with IBM Spectrum Protect™ you must install the appropriate tape device driver.
- AIX Linux Special file names for tape devices
  A special file name for a tape device is required for the IBM Spectrum Protect server to work with tape, medium changer, or removable media devices.
- Installing and configuring tape device drivers
  Before you can use tape devices with IBM Spectrum Protect, you must install the correct tape device driver.

Attaching an automated library device to your system

You can attach an automated library device to your system to store your data on tapes.

About this task

Before you attach an automated library device, consider the following restrictions:

- Attached devices must be on their own Host Bus Adapter (HBA).
- An HBA must not be shared with other device types, such as a disk.
- For multiport Fibre Channel HBAs, devices must be attached on their own port. These ports must not be shared with other device types.
- IBM® tape drives have some special requirements on HBA and associated drivers. For more information about devices, see the website for your operating system:
  - IBM Spectrum Protect™ Supported Devices for AIX®
  - IBM Spectrum Protect Supported Devices for Linux and Windows

Procedure

To use the Fibre Channel (FC) adapter, complete the following steps:

1. Install the FC adapter and associated drivers.
2. Install the appropriate device drivers for attached medium changer devices.

- AIX Linux Setting the library mode
  For the IBM Spectrum Protect server to access a SCSI library, the tape device must be set for the appropriate mode.

Related concepts:
Selecting a tape device driver

Selecting a tape device driver

To use tape devices with IBM Spectrum Protect™ you must install the appropriate tape device driver.

- IBM tape device drivers
  IBM® tape device drivers are available for most IBM labeled tape devices.
- IBM Spectrum Protect tape device drivers
  The IBM Spectrum Protect server provides tape device drivers.

Related reference:
Installing and configuring tape device drivers

IBM tape device drivers

IBM® tape device drivers are available for most IBM labeled tape devices.

You can download IBM tape device drivers from the Fix Central website:

1. Go to the Fix Central website: Fix Central website.
2. Click Select product.
3. Select System Storage for the Product Group menu.
4. Select Tape systems for the System Storage menu.
5. Select Tape drivers and software for the Tape systems menu.
6. Select Tape device drivers for the Tape drivers and software menu. In addition to tape drivers, you also get access to tools such as the IBM Tape Diagnostic Tool (ITDT).
7. Select your operating system for the Platform menu.

AIX | Windows

For the most up-to-date list of devices and operating-system levels that are supported by IBM tape device drivers, see the IBM Spectrum Protect™ Supported Devices website at Supported devices for AIX and Windows.

Linux

For the most up-to-date list of tape devices and operating-system levels that are supported by IBM tape device drivers, see the IBM Spectrum Protect Supported Devices website at Supported devices for Linux.

IBM tape device drivers support only some Linux kernel levels. For information about supported kernel levels, see the Fix Central website.

IBM Spectrum Protect tape device drivers

The IBM Spectrum Protect™ server provides tape device drivers.

An IBM Spectrum Protect tape device driver is installed with the server.

AIX

You can use the generic SCSI tape device driver that is provided by the IBM® AIX® operating system to work with tape devices that are not supported by the IBM Spectrum Protect device driver. If the AIX generic SCSI tape device driver is used, the GENERICTAPE device class must be set to the device type that is specified in the DEFINE DEVCLASS command.

For the following tape devices, you can choose whether to install the IBM Spectrum Protect tape device driver or the native device driver for your operating system:

- ECART
- LTO (not from IBM)

All SCSI-attached libraries that contain tape drives from the list must use the IBM Spectrum Protect changer driver.

Tape device drivers that are acquired from other hardware vendors can be used if they are associated with the GENERICTAPE device class. Generic device drivers are not supported in write-one read-many (WORM) device classes.

Linux

You can use the IBM Spectrum Protect Passthru device driver. IBM Spectrum Protect Passthru device drivers require the Linux SCSI generic (sg) device driver along with the Linux operating system to install the kernels.

For example, you can install the IBM Spectrum Protect Passthru device driver for the following tape devices:

- ECART
- LTO (not from IBM)

All SCSI-attached libraries that contain tape drives that are not IBM labeled from the list must also use the IBM Spectrum Protect Passthru device driver.

You cannot use the generic SCSI tape (st) device driver that is provided by the Linux operating system. Therefore, the GENERICTAPE device type is not supported for the DEFINE DEVCLASS command.

Windows You can select a Windows Hardware Qualification Lab certified native device driver instead of the IBM Spectrum Protect device driver. The Windows Hardware Qualification Lab certified native device driver can be used only for devices that have a non-IBM label and for non-IBM tape drives. For the Windows Hardware Qualification Lab certified native device driver, you can select either the IBM Spectrum Protect SCSI passthru device driver or the Windows native tape device driver. If the SCSI passthru device driver is used, the device class on the DEFINE DEVCLASS command cannot be GENERICTAPE. If the native device driver is used, the device class must be GENERICTAPE.

Special file names for tape devices

A special file name for a tape device is required for the IBM Spectrum Protect™ server to work with tape, medium changer, or removable media devices.

AIX
When a device is configured successfully, a logical file name is returned. Table 1 specifies the name of the device, also called a special file name, that corresponds to the drive or library. You can use the SMIT operating system command to get the device special file name. In the examples, *x* specifies an integer, 0 or greater.

Table 1. Device examples

Device	Device example	Logical file name
Tape drives that can be used by the IBM Spectrum Protect device driver	/dev/mt*x*	mt*x*
Tape drives that can be used by the IBM tape device driver	/dev/rmt*x*	rmt*x*
Tape drives that can be used by the IBM AIX® generic tape device driver	/dev/rmt*x*	rmt*x*
Library devices that can be used by the IBM Spectrum Protect device driver	/dev/lb*x*	lb*x*
Library devices that can be used by the IBM tape device driver	/dev/smc*x*	smc*x*

Linux
When a device is configured successfully, a logical file name is returned. Table 2 specifies the name of the device, also called the special file name, that corresponds to the drive or library. In the examples, *x* specifies an integer, 0 or greater.

Table 2. Device examples

Device	Device example	Logical file name
Tape drives that can be used by the IBM Spectrum Protect passthru device driver	/dev/tsmscsi/mt*x*	mt*x*
Tape drives that can be used by the IBM lin_tape device driver	/dev/IBMtape*x*	IBMtape*x*
Library devices that can be used by the IBM Spectrum Protect passthru device driver	/dev/tsmscsi/lb*x*	lb*x*
Library devices that can be used by the IBM lin_tape device driver	/dev/IBMchanger*x*	IBMchanger*x*

Windows
When a device is configured successfully, a logical file name is returned. Table 3 specifies the name of the device, also called the special file name, that corresponds to the drive or library. In the examples, *a*, *b*, *c*, *d*, and *x* specify an integer, 0 or greater, where:

- *a* specifies the target ID.
- *b* specifies the LUN.
- *c* specifies the SCSI bus ID.
- *d* specifies the port ID.

Table 3. Device examples

Device	Device example	Converted device name
Tape drives that are supported by the IBM Spectrum Protect device driver	mt*a.b.c.d*	mt*a.b.c.d*
Tape drives that are supported by the IBM Spectrum Protect passthru device driver	mt*a.b.c.d*	mt*a.b.c.d*
Tape drives that are supported by the IBM device driver	Tape*x*	mt*a.b.c.d*
Library devices that are supported by the IBM Spectrum Protect device driver	lb.*a.b.c.d*	lb*a.b.c.d*
Library devices that are supported by the IBM Spectrum Protect passthru device driver	lb*a.b.c.d*	lb*a.b.c.d*
Library devices that are supported by the IBM device driver	Changer*x*	lb*a.b.c.d*

Installing and configuring tape device drivers

Before you can use tape devices with IBM Spectrum Protect™, you must install the correct tape device driver.

IBM Spectrum Protect supports all devices that are supported by IBM® tape device drivers. However, IBM Spectrum Protect does not support all the operating-system levels that are supported by IBM tape device drivers.

- Installing and configuring IBM device drivers for IBM tape devices
  Install and configure an IBM tape device driver to use an IBM tape device.
- AIX Configuring tape device drivers on AIX systems
  Review the instructions to install and configure non-IBM tape device drivers on AIX® systems.
- Linux Configuring tape device drivers on Linux systems
  Review the following topics when you install and configure tape device drivers on Linux systems.
- Windows Configuring tape device drivers on Windows systems
  Review the instructions to install and configure drivers for tape devices and libraries on Windows systems.

Installing and configuring IBM device drivers for IBM tape devices

Install and configure an IBM® tape device driver to use an IBM tape device.

About this task

For instructions about installing and configuring IBM tape device drivers, see the *IBM Tape Device Drivers Installation and User's Guide*.

AIX After you complete the installation procedure in the *IBM Tape Device Drivers Installation and User's Guide*, different messages are issued, depending on the device driver that you are installing. If you are installing the device driver for an IBM tape drive or library, the following messages are returned:

```
rmtx Available
```

or

```
smcx Available
```

Note the value of x, which is assigned by the IBM tape device driver. To determine the special file name of your device, issue one of the following commands:

- For tape drives, `ls -l /dev/rmt*`
- For tape libraries, `ls -l /dev/smc*`

The file name might have more characters at the end to indicate different operating characteristics, but these characters are not needed by IBM Spectrum Protect™. For IBM device drivers, use the base file name in the DEVICE parameter of the DEFINE PATH command to assign a device to a drive (/dev/rmtx) or a library (/dev/smcx).
After you install the device driver, you can use the System Management Interface Tool (SMIT) to configure non-IBM tape drives and tape libraries. Complete the following steps:

1. Run the SMIT program.
2. Click Devices.

3. Click IBM Spectrum Protect Devices.
4. Click Fibre Channel SAN Attached devices.
5. Click Discover Devices Supported by IBM Spectrum Protect. Wait for the discovery process to be completed.
6. Go back to the Fibre Channel SAN Attached devices menu, and click List Attributes of a Discovered Device.

Linux After you complete the installation procedure in the *IBM Tape Device Drivers Installation and User's Guide*, different messages are issued, depending on the device driver that you are installing. If you are installing the device driver for an IBM LTO or 3592 device, the following messages are returned:

```
IBMtapex Available
```

or

```
IBMChangerx Available
```

Note the value of x, which is assigned by the IBM tape device driver. To determine the special file name of your device, issue one of the following commands:

- For tape drives, `ls -l /dev/IBMtape*`
- For tape libraries, `ls -l /dev/IBMChange*`

The file name might have more characters at the end to indicate different operating characteristics, but these characters are not needed by IBM Spectrum Protect. For IBM device drivers, use the base file name in the DEVICE parameter of the DEFINE PATH command to assign a device to a drive (/dev/IBMtapex) or a library (/dev/IBMChangerx).
Restriction: The device type of this class must not be GENERICTAPE.
Windows For Windows operating systems, IBM Spectrum Protect provides two device drivers:

Passthru device driver
: If the tape device manufacturer provides a SCSI device driver, install the IBM Spectrum Protect passthru device driver.

SCSI device driver for tape devices
: If the tape device manufacturer does not provide a SCSI device driver, install the IBM Spectrum Protect SCSI device driver for tape devices. The driver file name is tsmscsi64.sys.

For instructions about installing and configuring IBM tape device drivers, see the *IBM Tape Device Drivers Installation and User's Guide*. After you install the IBM tape device driver, the server specifies a special file name, Tape*X*, for IBM tape drives, or Changer*Y*, for IBM medium changers. For an IBM Spectrum Protect SCSI device driver or an IBM Spectrum Protect passthru device driver, you can issue the Windows operating system command, regedit, to verify the device special file name and driver.
The IBM Spectrum Protect server also provides a utility to check the device for the Windows operating system. The utility, tsmdlst, is packaged with the server package. To use the utility, complete the following steps:

1. Ensure that the host bus adapter application programming interface (API) is installed.
2. To obtain device information from the host system, type:

   ```
   tsmdlst
   ```

- AIX Linux Multipath I/O access with IBM tape devices
  Multipath I/O is a technique that uses different paths to access the same physical device, for example through multiple host bus adapters (HBA) or switches. The use of the multipath technique helps to ensure that a single point of failure does not occur.

Related concepts:
Multipath I/O access with IBM tape devices
AIX

Configuring tape device drivers on AIX systems

Review the instructions to install and configure non-IBM® tape device drivers on AIX® systems.

About this task

For instructions about installing and configuring IBM tape device drivers, see the *IBM Tape Device Drivers Installation and User's Guide*.

- AIX SCSI and Fibre Channel devices
  The IBM Spectrum Protect device definition menus and prompts in SMIT allow for the management of both SCSI and Fibre

Channel (FC) attached devices.

- AIX Configuring IBM Spectrum Protect device drivers for autochangers
  Use the following procedure to configure IBM Spectrum Protect device drivers for autochangers for non-IBM libraries.
- AIX Configuring IBM Spectrum Protect device drivers for tape drives
  Use the following procedure to configure IBM Spectrum Protect device drivers for autochangers for vendor-acquired libraries.
- AIX Configuring Fibre Channel SAN-attached devices
  To configure a Fibre Channel SAN-attached device, complete the procedure.

AIX

SCSI and Fibre Channel devices

The IBM Spectrum Protect™ device definition menus and prompts in SMIT allow for the management of both SCSI and Fibre Channel (FC) attached devices.

The main menu for IBM Spectrum Protect has two options:

SCSI attached devices
: Use this option to configure SCSI devices that are connected to a SCSI adapter in the host.

Fibre channel system area network (SAN) attached devices
: Use this option to configure devices that are connected to an FC adapter in the host. Choose one of the following attributes:

  List attributes of a discovered device
  : Lists attributes of a device that is known to the current ODM database.

    - FC Port ID:

      The 24-bit FC Port ID(N(L)_Port or F(L)_Port). This is the address identifier that is unique within the associated topology where the device is connected. In the switch or fabric environments, it can be determined by the switch, with the upper 2 bytes, which are not zero. In a Private Arbitrated Loop, it is the Arbitrated Loop Physical Address(AL_PA), with the upper 2 bytes being zero. Consult with your FC vendors to find out how an AL_PA or a Port ID is assigned.

    - Mapped LUN ID:

      An FC to SCSI bridge (also, called a converter, router, or gateway) box. Consult with your bridge vendors about how LUNs are mapped. You should not change LUN Mapped IDs.

    - WW Name:

      The worldwide name of the port to which the device is attached. It is the 64-bit unique identifier that is assigned by vendors of FC components such as bridges or native FC devices. Consult with your FC vendors to find out the WWN of a port.

    - Product ID:

      The product ID of a device. Consult with your device vendors to determine the product ID.

Discover devices supported by IBM Spectrum Protect
: This option discovers devices on an FC SAN that are supported by IBM Spectrum Protect and makes them available. If a device is added to or removed from an existing SAN environment, rediscover devices by selecting this option. Devices must be discovered first so that current values of device attributes are shown in the List Attributes of a Discovered Device option. Supported devices on FC SAN are tape drives, and autochangers. The IBM Spectrum Protect device driver ignores all other device types, such as disk.

Remove all defined devices
: This option removes all FC SAN-attached IBM Spectrum Protect devices whose state is `DEFINED` in the ODM database. If necessary, rediscover devices by selecting the `Discover Devices Supported by IBM Spectrum Protect` option after the removal of all defined devices.

Remove a device
: This option removes a single FC SAN-attached IBM Spectrum Protect device whose state is `DEFINED` in the ODM database. If necessary, rediscover the device by selecting the `Discover Devices Supported by IBM Spectrum Protect` option after removal of a defined device.

AIX

Configuring IBM Spectrum Protect device drivers for autochangers

Use the following procedure to configure IBM Spectrum Protect™ device drivers for autochangers for non-IBM libraries.

Procedure

Run the SMIT program to configure the device driver for each autochanger or robot:

1. Select Devices.
2. Select IBM Spectrum Protect Devices.
3. Select Library/MediumChanger.
4. Select Add a Library/MediumChanger.
5. Select the IBM Spectrum Protect-SCSI-LB for any IBM Spectrum Protect supported library.
6. Select the parent adapter to which you are connecting the device. This number is listed in the form: 00-0X, where X is the slot number location of the SCSI adapter card.
7. When prompted, enter the CONNECTION address of the device that you are installing. The connection address is a two-digit number. The first digit is the SCSI ID (the value you recorded on the worksheet). The second digit is the device's SCSI logical unit number (LUN), which is usually zero, unless otherwise noted. The SCSI ID and LUN must be separated by a comma (,). For example, a connection address of `4,0` has a SCSI ID=4 and a LUN=0.
8. Click DO.

   You receive a message (logical file name) of the form `lbX Available`. Note the value of X, which is a number that is assigned automatically by the system. Use this information to complete the Device Name field on your worksheet.

   For example, if the message is `lb0 Available`, the Device Name field is /dev/lb0 on the worksheet. Always use the /dev/ prefix with the name provided by SMIT.

AIX

Configuring IBM Spectrum Protect device drivers for tape drives

Use the following procedure to configure IBM Spectrum Protect™ device drivers for autochangers for vendor-acquired libraries.

Procedure

Important: IBM Spectrum Protect cannot overwrite *tar* or *dd* tapes, but *tar* or *dd* can overwrite IBM Spectrum Protect tapes. Restriction: Tape drives can be shared only when the drive is not defined or the server is not started. The MKSYSB command does not work when both IBM Spectrum Protect and AIX® are sharing the same drive or drives. To use the operating system's native tape device driver with a SCSI drive, the device must be configured to AIX first and then configured to IBM Spectrum Protect. See your AIX documentation regarding these native device drivers.

Run the SMIT program to configure the device driver for each drive (including drives in libraries) as follows:

1. Select Devices.
2. Select IBM Spectrum Protect Devices.
3. Select Tape Drive.
4. Select Add a Tape Drive.
5. Select the IBM Spectrum Protect-SCSI-MT for any supported tape drive.
6. Select the adapter to which you are connecting the device. This number is listed in the form: 00-0X, where X is the slot number location of the SCSI adapter card.
7. When prompted, enter the CONNECTION address of the device you are installing. The connection address is a two-digit number. The first digit is the SCSI ID (the value you recorded on the worksheet). The second digit is the device's SCSI logical unit number (LUN), which is usually zero, unless otherwise noted. The SCSI ID and LUN must be separated by a comma (,). For example, a connection address of `4,0` has a SCSI ID=4 and a LUN=0.
8. Click DO. You receive a message:

   If you are configuring the device driver for a tape device (other than an IBM® tape drive), you receive a message (logical file name) of the form `mtX Available`. Note the value of X, which is a number that is assigned automatically by the system. Use this information to complete the Device Name field on the worksheet.

   For example, if the message is `mt0 Available`, the Device Name field is /dev/mt0 on the worksheet. Always use the /dev/ prefix with the name provided by SMIT.

AIX

Configuring Fibre Channel SAN-attached devices

To configure a Fibre Channel SAN-attached device, complete the procedure.

Procedure

1. Run the SMIT program.
2. Select Devices.
3. Select IBM Spectrum Protect™ Devices.
4. Select Fibre Channel SAN Attached devices.
5. Select Discover Devices Supported by IBM Spectrum Protect. The discovery process can take some time.
6. Go back to the Fibre Channel menu, and select List Attributes of a Discovered Device.
7. Note the three-character device identifier, which you use when you define a path to the device to IBM Spectrum Protect. For example, if a tape drive has the identifier `mt2`, specify /dev/mt2 as the device name.

Linux

Configuring tape device drivers on Linux systems

Review the following topics when you install and configure tape device drivers on Linux systems.

- Linux Configuring IBM Spectrum Protect passthru drivers for tape devices and libraries
  To use the IBM Spectrum Protect Linux Passthru driver, you must complete the following steps.
- Linux Installing zSeries Linux Fibre Channel adapter (zfcp) device drivers
  The zSeries Linux Fibre Channel adapter (zfcp) device driver is a special adapter driver on the IBM® zSeries system.
- Linux Information about your system's SCSI devices
  Information about the devices seen by your system is available in the file */proc/scsi/scsi*. This file contains a list of every detected SCSI device.
- Linux Preventing tape labels from being overwritten
  The IBM Spectrum Protect Passthru device driver uses the Linux SCSI generic device driver (sg) to control and operate tape devices that are attached on the system. If the Linux generic SCSI tape device driver (st) is loaded to the kernel and configures attached tape devices, conflicts can arise over how a device is managed because the generic sg driver and the st driver can both control the same device.

Linux

Configuring IBM Spectrum Protect passthru drivers for tape devices and libraries

To use the IBM Spectrum Protect™ Linux Passthru driver, you must complete the following steps.

Procedure

1. Verify that the device is connected to your system, and is powered on and active.
2. Verify that the device is correctly detected by your system by issuing this command:

   ```
   cat /proc/scsi/scsi
   ```

3. Ensure that both the IBM Spectrum Protect device driver package (tsmscsi) and the storage server package are installed.
4. There are two driver configuration methods available in the IBM Spectrum Protect device driver package: autoconf and tsmscsi. Both of these methods complete the following tasks:
   - Load the Linux SCSI generic driver (sg) to the kernel.
   - Create necessary special files for the Passthru driver.
   - Create device information files for tape devices (/dev/tsmscsi/mtinfo) and libraries (/dev/tsmscsi/lbinfo).
5. Run the configuration method that you prefer (autoconf or tsmscsi) for the IBM Spectrum Protect Passthru driver.
   - To run the autoconf configuration method, issue the following command:

     ```
     autoconf
     ```

   - To run the tsmscsi configuration method, complete the following steps:

a. Copy the two sample configuration files that are in the installation directory from *mt.conf.smp* and *lb.conf.smp* to *mt.conf* and *lb.conf*, respectively.
b. Edit the mt.conf and lb.conf files. Add one stanza (as shown in the example at the start of the file) for each SCSI target, ID, and LUN combination. Each combination of SCSI target, ID, and LUN entries correspond to a tape drive or library you want configured. Make sure that the files meet these requirements:
   - Remove the example that is at the start of the files.
   - There must be a new line between each stanza.
   - There must be one new line after the last stanza.
   - Ensure that there are no number signs (#) in either file.
c. Run the tsmscsi script from the device driver installation directory.

6. Verify that the device is configured properly by viewing the text files for tape devices (/dev/tsmscsi/mtinfo) and libraries (/dev/tsmscsi/lbinfo).
7. Determine the special file names for the tape drives and libraries:
   - To determine the names for tape devices, issue the following command:

     ```
     > ls  /dev/tsmscsi/mt*
     ```

   - To determine the names for libraries, issue the following command:

     ```
     > ls  /dev/tsmscsi/lb*
     ```

   This information helps you identify which of the /dev/tsmscsi/mtx and /dev/tsmscsi/lbx special file names to provide the server when you issue a DEFINE PATH command.

What to do next

If you restart the host system, you must rerun the autoconf or tsmscsi script to reconfigure IBM Spectrum Protect devices. If you restart the IBM Spectrum Protect server instance, you do not have to reconfigure devices. In general, the Linux SCSI generic driver is preinstalled to the kernel. To verify that the driver is in the kernel, issue the following command:

```
> lsmod | grep sg
```

If the driver is not in the kernel, issue the modprobe sg command to load the sg driver into the kernel.

Linux

Installing zSeries Linux Fibre Channel adapter (zfcp) device drivers

The zSeries Linux Fibre Channel adapter (zfcp) device driver is a special adapter driver on the IBM® zSeries system.

About this task

IBM Spectrum Protect™ and IBM tape device drivers can run on zSeries platforms with Linux operating systems in 64-bit environments, and support most original equipment manufacturer (OEM) and IBM tape devices with Fibre Channel interfaces.

For more information about the zfcp driver, see the IBM Redpaper™, *Getting Started with zSeries Fibre Channel Protocol*, which is available at IBM Redbooks®.

Procedure

1. Load the qdio module.
2. Install the zfcp driver.
3. Map the Fibre Channel Protocol (FCP) and configure the zfcp driver.
4. Install and configure the IBM tape device driver.

Linux

Information about your system's SCSI devices

Information about the devices seen by your system is available in the file */proc/scsi/scsi*. This file contains a list of every detected SCSI device.

The following device information is available: the host number, channel number, SCSI ID, Logical Unit number, vendor, firmware level, type of device, and the SCSI mode. For example, if a system contains some StorageTek and IBM® libraries, a SAN Gateway,

and some Quantum DLT drives, the */proc/scsi/scsi* file will look similar to this:

```
Attached devices:
Host: scsi2 Channel: 00 Id: 00 Lun: 00
  Vendor:  STK    Model: 9738     Rev: 2003
  Type:  Medium Changer        ANSI SCSI revision: 02
Host: scsi2 Channel: 00 Id: 01 Lun: 02
  Vendor:  PATHLIGHT Model: SAN Gateway     Rev: 32aC
  Type: Unknown         ANSI SCSI revision: 03
Host: scsi2 Channel: 00 Id: 01 Lun: 02
  Vendor:  QUANTUM  Model: DLT7000     Rev: 2560
  Type:  Sequential-Access         ANSI SCSI revision: 02
Host: scsi2 Channel: 00 Id: 01 Lun: 04
  Vendor: IBM     Model: 7337     Rev: 1.63
  Type:  Medium Changer         ANSI SCSI revision: 02
```

Linux

Preventing tape labels from being overwritten

The IBM Spectrum Protect™ Passthru device driver uses the Linux SCSI generic device driver (sg) to control and operate tape devices that are attached on the system. If the Linux generic SCSI tape device driver (st) is loaded to the kernel and configures attached tape devices, conflicts can arise over how a device is managed because the generic sg driver and the st driver can both control the same device.

About this task

If the st driver controls devices that are used by IBM Spectrum Protect, IBM Spectrum Protect internal tape labels can be overwritten and data can be lost. If an application uses the st driver to control devices and the non-rewind option is not specified, tapes are automatically rewound following completion of an operation. The auto-rewind operation relocates the tape header position to the beginning of the tape. If the tape remains loaded in the drive, the next non-IBM Spectrum Protect write operation overwrites the IBM Spectrum Protect tape label because the label is at the beginning of the tape.

To prevent IBM Spectrum Protect labels from being overwritten, which can result in data loss, ensure that only the IBM Spectrum Protect Passthru driver controls devices that are used by IBM Spectrum Protect. Remove the st driver from the kernel or, if the driver is used by some applications on the system, delete the special files that correspond to IBM Spectrum Protect devices so that the st driver can no longer control them.

If you are using the IBM tape device driver to control devices on your system, you might encounter the same issues with device driver control conflicts. Review your IBM tape documentation to determine how to resolve this issue and prevent data loss.

Remove the st driver

If no other applications on the system use st devices, remove the st driver from the kernel. Issue the following command to unload the st driver:

```
rmmod st
```

Delete device special files that correspond to IBM Spectrum Protect devices

If there are applications that require use of the st driver, delete the special files that correspond to IBM Spectrum Protect devices. These special files are generated by the st driver. When they are eliminated, the st driver can no longer control the corresponding IBM Spectrum Protect devices. Device special file names for tape drives appear in the /dev/ directory. Their names have the form /dev/[n]st[0-1024][l][m][a].

List the st drive special file names and IBM Spectrum Protect device special file names by using the ls command. Based on the output of the device sequences, you can find devices in the st devices list matching those in the IBM Spectrum Protect devices list. The rm command can then be used to delete st devices.

Issue the following commands to list the st and IBM Spectrum Protect devices:

```
ls -l /dev/*st*
ls -l /dev/tsmscsi/mt*
```

Delete the st devices with the `rm` command:

```
rm /dev/*st*
```

Windows

Configuring tape device drivers on Windows systems

Review the instructions to install and configure drivers for tape devices and libraries on Windows systems.

- Windows Preparing to use the IBM Spectrum Protect passthru driver for tape devices and libraries
  To use the IBM Spectrum Protect Windows passthru device driver for tape devices and libraries, you must install the driver and obtain the device names for the server to use.
- Windows Configuring the IBM Spectrum Protect SCSI driver for tape devices and libraries
  If the manufacturer of a tape drive or tape library does not provide a SCSI device driver, you must install the IBM Spectrum Protect SCSI device driver.

Windows

Preparing to use the IBM Spectrum Protect passthru driver for tape devices and libraries

To use the IBM Spectrum Protect™ Windows passthru device driver for tape devices and libraries, you must install the driver and obtain the device names for the server to use.

Before you begin

1. Determine whether the manufacturer of the tape device or tape library provides a device driver.
2. If the manufacturer provides a device driver package, download the package and install it.
3. Configure the SCSI device driver by following the manufacturer's instructions.

Procedure

1. Install the IBM Spectrum Protect passthru device driver.
2. Obtain the device names that the server must use by taking one of the following actions:
   - On the server, run the QUERY SAN command. The output shows all devices names and their associated device serial numbers.
   - In the server directory, run the tsmdlst.exe utility. The output shows all devices names, their associated serial numbers, and associated device locations.
   - At the Windows system command prompt, run the regedit command. From the output, obtain the device file names based on the device locations. The location consists of the port ID, SCSI bus ID, LUN ID, and SCSI target ID. The IBM Spectrum Protect device file name has a format of mt*A*.*B*.*C*.*C* for tape drives and lb*A*.*B*.*C*.*D* for tape libraries, where:
     - *A* is the SCSI target ID.
     - *B* is the LUN ID.
     - *C* is the SCSI bus ID.
     - *D* is the port ID.

Windows

Configuring the IBM Spectrum Protect SCSI driver for tape devices and libraries

If the manufacturer of a tape drive or tape library does not provide a SCSI device driver, you must install the IBM Spectrum Protect™ SCSI device driver.

About this task

The IBM Spectrum Protect SCSI device driver file name is tsmscsi64.sys.

Procedure

1. Locate the device in the Device Manager console (devmgmt.msc) and select it. Tape drives are listed under Tape drives, and medium changers are under Medium Changers.
2. Configure the device for use by the tsmscsi64.sys device driver:
   a. Right-click the device and click Update Driver Software.

b. Click Browse my computer for driver software.
3. Click Let me pick from a list of device drivers on my computer.
4. Click Next.
5. Select the appropriate option:
   a. For a tape drive, select IBM Spectrum Protect for Tape Drives.
   b. For a medium changer, select IBM Spectrum Protect for Medium Changers.
6. Click Next.
7. Click Close.
8. Verify that the device was configured correctly for the tsmscsi64 device driver:
   a. Right-click on the device and click Properties.
   b. Click the Driver tab and Driver Details. The Driver Details window shows the device driver that is controlling the device.

Configuring libraries for use by a server

To use a library or libraries for storage for an IBM Spectrum Protect™ server, you must first set up the devices on the server system.

Before you begin

1. Attach devices to the server hardware. Follow the instructions in Attaching an automated library device to your system.
2. Select the tape device drivers. Follow the instructions in Selecting a tape device driver.
3. Install and configure the tape device drivers. Follow the instructions in Installing and configuring tape device drivers.
4. Determine the device names that are needed to define the library to the server. Follow the instructions in Special file names for tape devices.

Procedure

1. Define the library and the path from the server to the library. Follow the instructions in Defining libraries.
2. Define the drives in the library. Follow the instructions in Defining drives.

   For SCSI libraries, you can use the PERFORM LIBACTION command to define drives and paths for a library in one step, instead of completing both steps 2 and 3. To use the PERFORM LIBACTION command to define drives and paths for a library, the SANDISCOVERY option must be supported and enabled.

3. Define a path from the server to each drive by using the DEFINE PATH command.
4. Define a device class. Follow the instructions in Defining tape device classes.

   Device classes specify the recording formats for drives and classify them according to type. Use the default value, FORMAT=DRIVE as the recording format only if all the drives that are associated with the device class can read and write to all of the media.

   For example, you have a mix of Ultrium Generation 3 and Ultrium Generation 4 drives, but you have only Ultrium Generation 3 media. You can specify FORMAT=DRIVE because both the Generation 4 and Generation 3 drives can read from and write to Generation 3 media.
5. Define a storage pool by using the DEFINE STGPOOL command.
   Consider the following key choices for defining storage pools:
   - Scratch volumes are empty volumes that are available for use. If you specify a value for the maximum number of scratch volumes in the storage pool, the server can choose from the scratch volumes available in the library.

     If you do not allow scratch volumes, you must complete the extra step of explicitly defining each volume to be used in the storage pool. Also, specify the MAXSCRATCH=0 parameter when you define the storage pool so that scratch volumes are not used.

   - The default setting for primary storage pools is collocation by group. The default for copy storage pools and active-data pools is disablement of collocation. The server uses *collocation* to keep all files that belong to a group of client nodes, a single client node, a client file space, or a group of client file spaces on a minimal number of volumes. If collocation is disabled for a storage pool and clients begin storing data, you cannot easily change the data in the pool so that it is collocated.
6. Check in and label library volumes. Follow the instructions in Checking volumes into an automated library and Labeling tape volumes.

Ensure that enough volumes in the library are available to the server. Keep enough labeled volumes on hand so that you do not run out during an operation such as client backup. Label extra scratch volumes for any potential recovery operations that you might have later.

The procedures for checking in and labeling volumes are the same whether the library contains drives of a single device type, or drives of multiple device types. You can use the CHECKIN LIBVOLUME command to check in volumes that are already labeled. Or, if you want to label and check in volumes with one step, issue the LABEL LIBVOLUME command.

Libraries with multiple device types: If your library has drives of multiple device types, and you defined two libraries to the IBM Spectrum Protect server, the two defined libraries represent one physical library. You must check in tape volumes separately to each defined library. Ensure that you check in volumes to the correct IBM Spectrum Protect library.

What to do next

Verify your device definitions to ensure that everything is configured correctly. Use a QUERY command to review information about each storage object.

When you review the results of the QUERY DRIVE command, verify that the device type for the drive is what you expect. If a path is not defined, the drive device type is listed as UNKNOWN and if the wrong path is used, GENERIC_TAPE or another device type is shown. This step is especially important when you are using mixed media.

Optionally, configure library sharing. Follow the instructions in Configuring library sharing.

- Defining tape devices
  Before you can back up or migrate data to tape, you must define a tape device to the IBM Spectrum Protect.
- Configuring library sharing
  Multiple IBM Spectrum Protect servers can share storage devices by using a storage area network (SAN). You set up one server as the library manager and the other servers as library clients.

Related reference:
CHECKIN LIBVOLUME (Check a storage volume into a library)
DEFINE STGPOOL (Define a volume in a storage pool)
LABEL LIBVOLUME (Label a library volume)
PERFORM LIBACTION (Define or delete all drives and paths for a library)

Defining tape devices

Before you can back up or migrate data to tape, you must define a tape device to the IBM Spectrum Protect™.

- Defining libraries and drives
  A tape library can include one or more tape drives. Learn how to define libraries, drives, and paths to the IBM Spectrum Protect server.
- Defining tape device classes
  A device class defines a set of characteristics that are used by a set of volumes that can be created in a storage pool. You must define a device class for a tape device to ensure that the server can use the device.

Defining libraries and drives

A tape library can include one or more tape drives. Learn how to define libraries, drives, and paths to the IBM Spectrum Protect™ server.

- Defining libraries
  Before you can use a drive, you must define the library to which the drive belongs.
- Defining drives
  To inform the server about a drive that can be used to access storage volumes, issue the DEFINE DRIVE command, followed by the DEFINE PATH command.

Defining libraries

Before you can use a drive, you must define the library to which the drive belongs.

Procedure

1. Define the library by using the DEFINE LIBRARY command.

   For example, if you have an IBM TS3500 tape library, you can define a library that is named ROBOTMOUNT by using the following command:

   ```
   define library robotmount libtype=scsi
   ```

   If you require library sharing or LAN-free data movement, see the following information:
   - Configuring library sharing
   - Configuring LAN-free data movement
2. Define a path from the server to the library by using the DEFINE PATH command. When you specify the DEVICE parameter, enter the device special file name. This name is required by the server to communicate with tape drives, medium changer, and removable media devices. For more information about device special file names, see Special file names for tape devices. AIX

   ```
   define path server1 robotmount srctype=server desttype=library
    device=/dev/lb0
   ```

   Linux

   ```
   define path server1 robotmount srctype=server desttype=library
    device=/dev/tsmscsi/lb0
   ```

   Windows

   ```
   define path server1 robotmount srctype=server desttype=library
    device=lb0.0.1.0
   ```

- Defining SCSI libraries on a SAN
  For a library type of SCSI on a SAN, the server can track the library's serial number. With the serial number, the server can confirm the identity of the device when you define the path or when the server uses the device.

Related reference:
DEFINE LIBRARY (Define a library)
DEFINE PATH (Define a path)

Defining drives

To inform the server about a drive that can be used to access storage volumes, issue the DEFINE DRIVE command, followed by the DEFINE PATH command.

Before you begin

A *drive object* represents a drive mechanism within a library that uses removable media. For devices with multiple drives, including automated libraries, you must define each drive separately and associate it with a library. Drive definitions can include such information as the element address for drives in SCSI, how often a tape drive is cleaned, and whether the drive is online.

IBM Spectrum Protect™ supports tape drives that can be stand-alone or that can be part of an automated library. The preferred method is to configure the tape solution by using automated libraries.

About this task

When you issue the DEFINE DRIVE command, you must provide some or all of the following information:

Library name
: The name of the library in which the drive is located.

Drive name
: The name that is assigned to the drive.

Serial number
: The serial number of the drive. The serial number parameter applies only to drives in SCSI. With the serial number, the server can confirm the identity of the device when you define the path or when the server uses the device.

You can specify the serial number if you choose. The default is to enable the server to obtain the serial number from the drive itself at the time that the path is defined. If you specify the serial number, the server confirms that the serial number is correct when you define the path to the drive. When you define the path, you can set the AUTODETECT=YES parameter to enable the server to correct the serial number if the number that it detects does not match what you entered when you defined the drive. As a best practice, specify the AUTODETECT=YES parameter to automatically update the serial number for the drive in the database when the path is defined.

Depending on the capabilities of the drive, the server might not be able to automatically detect the serial number. In this case, the server does not record a serial number for the device, and is not able to confirm the identity of the device when you define the path or when the server uses the device. See Impacts of device changes on the SAN.

Element address
: The element address of the drive. The ELEMENT parameter applies only to drives in SCSI libraries. The element address is a number that indicates the physical location of a drive within an automated library. The server needs the element address to connect the physical location of the drive to the drive's SCSI address. The server can obtain the element address from the drive when you define the path, or you can specify the element number when you define the drive. As a best practice, specify the ELEMENT=AUTODETECT parameter for the server to automatically detect the element number when the path to the drive is defined.

  Depending on the capabilities of the library, the server might not be able to automatically detect the element address. In this case, you must supply the element address when you define the drive, if the library has more than one drive. To obtain the element address, go to the IBM® Support Portal for IBM Spectrum Protect.

Tip: IBM tape device drivers and non-IBM tape device drivers generate different device files and formats:

- For IBM, device names begin with rmt followed by an integer, for example, /dev/rmt0.
- For IBM Spectrum Protect tape device drivers, tape device names begin with mt followed by an integer, for example /dev/mt0.

You must use the correct device file when you define a path.

Procedure

1. Assign a drive to a library by issuing the DEFINE DRIVE command.
2. To make the drive usable by the server, issue the DEFINE PATH command.

   For examples about configuring libraries, paths, and drives, see Example: Configure a SCSI or virtual tape library with a single drive device type and Example: Configure a SCSI or virtual tape library with multiple drive device types.

Defining tape device classes

A device class defines a set of characteristics that are used by a set of volumes that can be created in a storage pool. You must define a device class for a tape device to ensure that the server can use the device.

Before you begin

You must define libraries and drives to the server before you define device classes.

About this task

For a list of supported devices and valid device class formats, see the IBM Spectrum Protect™ Supported Devices website for your operating system:

- AIX Windows Supported devices for AIX and Windows
- Linux Supported devices for Linux

You can define multiple device classes for each device type. For example, you might want to specify different attributes for different storage pools that use the same type of tape drive. Variations might be required that are not specific to the device, but rather to how you want to use the device (for example, mount retention or mount limit).

Guidelines:

- One device class can be associated with multiple storage pools, but each storage pool is associated with only one device class.

- SCSI libraries can include tape drives of more than one device type. When you define the device class in this environment, you must declare a value for the FORMAT parameter.

  For more information, see Mixed device types in libraries.

Procedure

To define a device class, use the DEFINE DEVCLASS command with the DEVTYPE parameter, which assigns a device type to the device class.

Results

If you include the DEVCONFIG option in the dsmserv.opt file, the files that you specify with that option are automatically updated with the results of the DEFINE DEVCLASS, UPDATE DEVCLASS, and DELETE DEVCLASS commands.

- Defining LTO device classes
  To prevent problems when you mix different generations of LTO drives and media in a single library, review the restrictions. Also, review the restrictions for LTO drive encryption.
- Defining 3592 device classes
  Device class definitions for 3592, TS1130, TS1140, TS1150, and later devices include parameters for faster volume-access speeds and drive encryption. To prevent problems when mixing different generations of 3592 and TS1130 and later drives in a library, review the guidelines.

Related reference:
DEFINE DEVCLASS (Define a device class)
QUERY DEVCLASS (Display information on one or more device classes)
UPDATE DEVCLASS (Update a device class)

Defining LTO device classes

To prevent problems when you mix different generations of LTO drives and media in a single library, review the restrictions. Also, review the restrictions for LTO drive encryption.

- Mixing LTO drives and media in a library
  When you mix different generations of LTO drives and media, you must consider the read/write capabilities of each generation. The preferred method is to configure a different device class for each generation of media.
- Mount limits in LTO mixed-media environments
  In a mixed-media library, in which multiple device classes point to the same library, compatible drives are shared between storage pools. Ensure that you set an appropriate value for the MOUNTLIMIT parameter in each of the device classes.
- Enabling and disabling drive encryption for LTO Generation 4 or later tape drives
  IBM Spectrum Protect™ supports the three types of drive encryption that are available with LTO Generation 4 or later drives: Application, System, and Library. These methods are defined through the hardware.

Mixing LTO drives and media in a library

When you mix different generations of LTO drives and media, you must consider the read/write capabilities of each generation. The preferred method is to configure a different device class for each generation of media.

About this task

If you are considering mixing different generations of LTO media and drives, review the following restrictions:

Table 1. Read/write capabilities for different generations of LTO drives

Drives	Generation 1 media	Generation 2 media	Generation 3 media	Generation 4 media	Generation 5 media	Generation 6 media	Generation 7 media
Generation 1	Read/write access	n/a	n/a	n/a	n/a	n/a	n/a
Generation 2	Read/write access	Read/write access	n/a	n/a	n/a	n/a	n/a

Drives	Generation 1 media	Generation 2 media	Generation 3 media	Generation 4 media	Generation 5 media	Generation 6 media	Generation 7 media
Generation 3	Read-only access	Read/write access	Read/write access	n/a	n/a	n/a	n/a
Generation 4	n/a	Read-only access	Read/write access	Read/write access	n/a	n/a	n/a
Generation 5	n/a	n/a	Read-only access	Read/write access	Read/write access	n/a	n/a
Generation 6	n/a	n/a	n/a	Read-only access	Read/write access	Read/write access	n/a
Generation 7	n/a	n/a	n/a	n/a	Read access	Read/write access	Read/write access

Example

If you are mixing different types of drives and media, configure different device classes: one for each type of media. To specify the media type, use the FORMAT parameter in each of the device class definitions. (Do not specify FORMAT=DRIVE.) For example, if you are mixing Ultrium Generation 5 and Ultrium Generation 6 drives, specify FORMAT=ULTRIUM5C (or ULTRIUM5) for the Ultrium Generation 5 device class, and FORMAT=ULTRIUM6C (or ULTRIUM6) for the Ultrium Generation 6 device class.

In this example, both device classes can point to the same library with Ultrium Generation 5 and Ultrium Generation 6 drives. The drives are shared between the two storage pools. One storage pool uses the first device class and Ultrium Generation 5 media exclusively. The other storage pool uses the second device class and Ultrium Generation 6 media exclusively. Because the two storage pools share a single library, Ultrium Generation 5 media can be mounted on Ultrium Generation 6 drives as they become available during mount point processing.

If you mix older read-only media generations with newer read/write media in a single library, you must mark the read-only media as read-only and check out all read-only scratch media. For example, if you are mixing Ultrium Generation 4 with Ultrium Generation 6 drives and media in a single library, you must mark the Generation 4 media as read-only. In addition, you must check out all Generation 4 scratch volumes.

Mount limits in LTO mixed-media environments

In a mixed-media library, in which multiple device classes point to the same library, compatible drives are shared between storage pools. Ensure that you set an appropriate value for the MOUNTLIMIT parameter in each of the device classes.

For example, in a mixed media library that contains Ultrium Generation 1 and Ultrium Generation 2 drives and media, Ultrium Generation 1 media can be mounted in Ultrium Generation 2 drives.

Consider the example of a mixed library that consists of the following drives and media:

- Four LTO Ultrium Generation 1 drives and LTO Ultrium Generation 1 media
- Four LTO Ultrium Generation 2 drives and LTO Ultrium Generation 2 media

You created the following device classes:

- LTO Ultrium Generation 1 device class LTO1CLASS specifying FORMAT=ULTRIUMC
- LTO Ultrium Generation 2 device class LTO2CLASS specifying FORMAT=ULTRIUM2C

You also created the following storage pools:

- LTO Ultrium Generation 1 storage pool LTO1POOL based on device class LTO1CLASS
- LTO Ultrium Generation 2 storage pool LTO2POOL based on device class LTO2CLASS

The number of mount points available for use by each storage pool is specified in the device class by using the MOUNTLIMIT parameter. The MOUNTLIMIT parameter in the LTO2CLASS device class must be set to 4 to match the number of available drives that can mount only LTO2 media. The MOUNTLIMIT parameter in the LTO1CLASS device class must be set to a value that is greater than the number of available drives (5 or possibly 6) to adjust for the fact that Ultrium Generation 1 media can be mounted in Ultrium Generation 2 drives. The optimal value for MOUNTLIMIT depends on workload and storage pool access patterns.

Monitor and adjust the MOUNTLIMIT setting to suit changing workloads. If the MOUNTLIMIT for LTO1POOL is set too high, mount requests for the LTO2POOL might be delayed or fail because the Ultrium Generation 2 drives are used to satisfy Ultrium Generation 1 mount requests. In the worst scenario, too much competition for Ultrium Generation 2 drives might cause mounts for Generation 2 media to fail with the following message:

```
ANR8447E No drives are currently available in the library.
```

If the MOUNTLIMIT value for LTO1POOL is not set high enough, mount requests that might be satisfied by LTO Ultrium Generation 2 drives are delayed.
Restriction: Restrictions apply when you mix Ultrium Generation 1 with Ultrium Generation 2 or Generation 3 drives because of how mount points are allocated. For example, processes that require multiple mount points that include both Ultrium Generation 1 and Ultrium Generation 2 volumes might try to reserve Ultrium Generation 2 drives only, even when one mount can be satisfied by an available Ultrium Generation 1 drive. Processes that behave in this manner include the MOVE DATA and BACKUP STGPOOL commands. These processes wait until the required number of mount points can be satisfied with Ultrium Generation 2 drives.

BACKUP STGPOOL (Back up primary storage pool data to a copy storage pool)
DEFINE DEVCLASS (Define a device class)
MOVE DATA (Move files on a storage pool volume)

Enabling and disabling drive encryption for LTO Generation 4 or later tape drives

IBM Spectrum Protect™ supports the three types of drive encryption that are available with LTO Generation 4 or later drives: Application, System, and Library. These methods are defined through the hardware.

About this task

The DRIVEENCRYPTION parameter on the DEFINE DEVCLASS command specifies whether drive encryption is allowed for IBM and HP LTO Generation 4 or later, Ultrium 4, and Ultrium 4C formats. This parameter ensures IBM Spectrum Protect compatibility with hardware encryption settings for empty volumes. You cannot use this parameter for storage pool volumes that are full or are filling.

IBM Spectrum Protect supports the Application method of encryption with IBM and HP LTO-4 or later drives. Only IBM LTO-4 or later supports the System and Library methods. The Library method of encryption can be used only if your system hardware (for example, IBM TS3500) supports it.

Restriction: You cannot use drive encryption with write-once, read-many (WORM) media.

The Application method is defined through the hardware. To use the Application method, in which IBM Spectrum Protect generates and manages encryption keys, set the DRIVEENCRYPTION parameter to ON. This action enables data encryption for empty volumes. If the parameter is set to ON and the hardware is configured for another encryption method, backup operations fail.

Procedure

The following simplified example shows the steps that you would take to enable and disable data encryption for empty volumes in a storage pool:

1. Define a library by issuing the DEFINE LIBRARY command:

   ```
   define library 3584 libtype=SCSI
   ```

2. Define a device class, LTO_ENCRYPT, by issuing the DEFINE DEVCLASS command and specifying IBM Spectrum Protect as the key manager:

   ```
   define devclass lto_encrypt library=3584 devtype=lto driveencryption=on
   ```

3. Define a storage pool by issuing the DEFINE STGPOOL command:

   ```
   define stgpool lto_encrypt_pool lto_encrypt
   ```

4. To disable encryption on new volumes, set the DRIVEENCRYPTION parameter to OFF. The default value is ALLOW. Drive encryption for empty volumes is allowed if another method of encryption is enabled.

Tape encryption methods

Defining 3592 device classes

Device class definitions for 3592, TS1130, TS1140, TS1150, and later devices include parameters for faster volume-access speeds and drive encryption. To prevent problems when mixing different generations of 3592 and TS1130 and later drives in a library, review the guidelines.

- Mixing generations of 3592 drives and media in a single library
  For optimal performance, do not mix generations of 3592 media in a single library. Media problems can result when different drive generations are mixed. For example, IBM Spectrum Protect™ might not be able to read a volume's label.
- Controlling data-access speeds for 3592 volumes
  You can optimize the storage capacity and improve data-access speeds when you create volumes. By partitioning data into storage pools that have volumes, you can specify the scale capacity percentage to provide maximum storage capacity, or to provide fast access to the volume.
- Enabling and disabling 3592 Generation 2 and later drive encryption
  With IBM Spectrum Protect, you can use the following types of drive encryption with drives that are 3592 Generation 2 and later: Application, System, and Library. These methods are defined through the hardware.

Mixing generations of 3592 drives and media in a single library

For optimal performance, do not mix generations of 3592 media in a single library. Media problems can result when different drive generations are mixed. For example, IBM Spectrum Protect™ might not be able to read a volume's label.

About this task

The following table shows read/write interoperability for drive generations.

Drives	Generation 1 format	Generation 2 format	Generation 3 format	Generation 4 format	Generation 5 format
Generation 1	Read/write access	n/a	n/a	n/a	n/a
Generation 2	Read/write access	Read/write access	n/a	n/a	n/a
Generation 3	Read-only access	Read/write access	Read/write access	n/a	n/a
Generation 4	n/a	Read only	Read/write access	Read/write access	n/a
Generation 5	n/a	n/a	Read access	Read/write access	Read/write access

If you must mix generations of drives in a library, review the example and restrictions to help prevent problems.

Table 1. Mixing generations of drives

Library type	Example and restrictions

Library type	Example and restrictions
SCSI	Define a new storage pool and device class for the latest drive generation. For example, suppose that you have a storage pool and device class for 3592-2. The storage pool contains all the media that were written in Generation 2 format. Suppose that the value of the FORMAT parameter in the device class definition is set to 3952-2 (not DRIVE). You add Generation 3 drives to the library. Complete the following steps: 1. In the new device-class definition for the Generation 3 drives, set the value of the FORMAT parameter to 3592-3 or 3592-3C. Do not specify DRIVE. 2. In the definition of the storage pool that is associated with Generation 2 drives, update the MAXSCRATCH parameter to 0, for example: `update stgpool genpool2 maxscratch=0` This method allows both generations to use their optimal format and minimizes potential media problems that can result from mixing generations. However, it does not resolve all media issues. For example, competition for mount points and mount failures might result. (To learn more about mount point competition in the context of 3592 drives and media, see Defining 3592 device classes.) Restriction: The following list describes media restrictions: • CHECKIN LIBVOL: The issue is using the CHECKLABEL=YES option. If the label is written in a Generation 3 or later format, and you specify the CHECKLABEL=YES option, drives of previous generations fail by using this command. To avoid the issue, specify CHECKLABEL=BARCODE. • LABEL LIBVOL: When the server tries to use drives of a previous generation to read the label that is written in a Generation 3 or later format, the LABEL LIBVOL command fails unless OVERWRITE=YES is specified. Verify that the media that is being labeled with OVERWRITE=YES does not have any active data. • CHECKOUT LIBVOL: When IBM Spectrum Protect verifies the label (CHECKLABEL=YES) as a Generation 3 or later format, and read drives of previous generations, the command fails. To avoid this issue, specify CHECKLABEL=NO.

CHECKIN LIBVOLUME (Check a storage volume into a library)
CHECKOUT LIBVOLUME (Check a storage volume out of a library)
LABEL LIBVOLUME (Label a library volume)
UPDATE STGPOOL (Update a storage pool)

Controlling data-access speeds for 3592 volumes

You can optimize the storage capacity and improve data-access speeds when you create volumes. By partitioning data into storage pools that have volumes, you can specify the scale capacity percentage to provide maximum storage capacity, or to provide fast access to the volume.

About this task

To reduce media capacity, specify the SCALECAPACITY parameter when you define the device class by using the DEFINE DEVCLASS command or when you update the device class by using the UPDATE DEVCLASS command.

Specify a percentage value of 20, 90, or 100. A value of 20 percent provides the fastest access time, and 100 percent provides the largest storage capacity. For example, if you specify a scale capacity of 20 for a 3592 device class without compression, a 3592 volume in that device class would store 20 percent of its full capacity of 300 GB, or about 60 GB.

Scale capacity takes effect only when data is first written to a volume. Updates to the device class for scale capacity do not affect volumes that already have data written to them until the volume is returned to scratch status.

Related reference:
DEFINE DEVCLASS (Define a device class)
UPDATE DEVCLASS (Update a device class)

Enabling and disabling 3592 Generation 2 and later drive encryption

With IBM Spectrum Protect™, you can use the following types of drive encryption with drives that are 3592 Generation 2 and later: Application, System, and Library. These methods are defined through the hardware.

About this task

The DRIVEENCRYPTION parameter on the DEFINE DEVCLASS command specifies whether drive encryption is allowed for drives that are 3592 Generation 2 and later. Use this parameter to ensure IBM Spectrum Protect compatibility with hardware encryption settings for empty volumes. You cannot use this parameter for storage pool volumes that are full or are filling.

- To use the Application method, in which IBM Spectrum Protect generates and manages encryption keys, set the DRIVEENCRYPTION parameter to ON. This enables the encryption of data for empty volumes. If the parameter is set to ON and if the hardware is configured for another encryption method, backup operations fail.
- To use the Library or System methods of encryption, set the parameter to ALLOW. This specifies that IBM Spectrum Protect is not the key manager for drive encryption, but allows the hardware to encrypt the volume's data through one of the other methods. Specifying this parameter does not automatically encrypt volumes. Data can be encrypted only by specifying the ALLOW parameter and configuring the hardware to use one of these methods.

The DRIVEENCRYPTION parameter is optional. The default value is to allow the Library or System methods of encryption.

Procedure

The following simplified example shows how to encrypt data for empty volumes in a storage pool, by using IBM Spectrum Protect as the key manager:

1. Define a library by issuing the DEFINE LIBRARY command. For example, issue the following command:

   ```
   define library 3584 libtype=SCSI
   ```

2. Define a device class, 3592_ENCRYPT, by issuing the DEFINE DEVCLASS command and specifying the value ON for the DRIVEENCRYPTION parameter. For example, issue the following command:

   ```
   define devclass 3592_encrypt library=3584 devtype=3592 driveencryption=on
   ```

3. Define a storage pool. For example, issue the following command:

   ```
   define stgpool 3592_encrypt_pool 3592_encrypt
   ```

What to do next

To disable any method of encryption on new volumes, set the DRIVEENCRYPTION parameter to OFF. If the hardware is configured to encrypt data through either the Library or System method and DRIVEENCRYPTION is set to OFF, backup operations fail.

Configuring library sharing

Multiple IBM Spectrum Protect™ servers can share storage devices by using a storage area network (SAN). You set up one server as the library manager and the other servers as library clients.

Before you begin

Ensure that your systems meet licensing requirements for library sharing. An entitlement for IBM Spectrum Protect for SAN is required for each IBM Spectrum Protect server that is configured as a library client or a library manager in a SAN environment.

About this task

With LAN-free data movement, IBM Spectrum Protect client systems can directly access storage devices that are defined to an IBM Spectrum Protect server. Storage agents are installed and configured on the client systems to perform the data movement.

To set up library sharing, you must define one IBM Spectrum Protect server as the library manager for your shared library configuration. Then, you define other IBM Spectrum Protect servers as library clients that communicate and request storage

resources from the library manager. The library manager server must be at the same version or a later version as the server or servers that are defined as library clients.

Procedure

To complete the following steps to share library resources on a SAN among IBM Spectrum Protect servers, complete the following steps:

1. Set up server-to-server communications.

   To share a storage device on a SAN, define servers to each other by using the cross-define function. Each server must have a unique name.

2. Define a shared library and set up tape devices on the server systems.

   Use the procedure that is described in Configuring libraries for use by a server to define a library for use in the shared environment. Modify the procedure to define the library as shared, by specifying the SHARED=YES parameter for the DEFINE LIBRARY command.

3. Define the library manager server.
4. Define the shared library on the server that is the library client.
5. From the library manager server, define paths from the library client to each drive that the library client can access. The device name must reflect the way that the library client system recognizes the tape device. A path from the library manager to each tape drive must be defined in order for the library client to use the drive.

   To avoid problems, ensure that all drive path definitions that are defined for the library manager are also defined for each library client.

   For example, if the library manager defines three tape drives, the library client must also define three tape drives. To limit the number of tape drives that a library client can use at a time, use the MOUNTLIMIT parameter of the device class on the library client.
6. Define device classes for the shared library.

   The preferred method is to make the device class names the same on both servers to avoid confusion when you define multiple device classes with the same device type and library parameters. Some operations, such as database backup, use the device class name to identify the data for backup.

   The device class parameters that are specified on the library manager override the parameters that are specified for the library client. If the device class names are different, the library manager uses the parameters that are specified in a device class that matches the device type that is specified for the library client.

7. Define a storage pool for the shared library.
8. Repeat the steps to configure another server as a library client.

AIX | Linux

Example: Library sharing for AIX and Linux servers

To learn how to set up a SCSI library sharing environment for servers that run on AIX® or Linux systems, review the sample procedure.

About this task

In this example, a library manager server named ASTRO and a library client named JUDY are configured. To help clarify where each step is performed, the commands are preceded by the server name from which the command is issued. Most commands are issued from the library client.

For SCSI libraries, define the library by specifying the libtype=scsi parameter.

Procedure

1. To set up ASTRO as the library manager server, define a shared SCSI library named SANGROUP. For example:

   ```
   astro> define library sangroup libtype=scsi shared=yes
   ```

   Then complete the rest of the steps as described in Example: Configure a SCSI or virtual tape library with a single drive device type to configure the library.
   Tip: You can use the PERFORM LIBACTION command to define drives and paths for a library in one step.
2. Define ASTRO as the library manager server by issuing the DEFINE SERVER command.

   ```
   judy> define server astro serverpassword=secret hladdress=192.0.2.24
    lladdress=1777 crossdefine=yes
   ```

3. Define the shared library SANGROUP by issuing the DEFINE LIBRARY command. You must use the library manager server name in the PRIMARYLIBMANAGER parameter, and use `LIBTYPE=SHARED`.

   ```
   judy> define library sangroup libtype=shared primarylibmanager=astro
   ```

   Ensure that the library name is the same as the library name on the library manager.
4. Define paths from the library manager, ASTRO, to two drives in the shared library by issuing the DEFINE PATH command.
   AIX

   ```
   astro> define path judy drivea srctype=server desttype=drive
    library=sangroup device=/dev/rmt6
   astro> define path judy driveb srctype=server desttype=drive
    library=sangroup device=/dev/rmt7
   ```

   Linux

   ```
   astro> define path judy drivea srctype=server desttype=drive
    library=sangroup device=/dev/IBMtape6
   astro> define path judy driveb srctype=server desttype=drive
    library=sangroup device=/dev/IBMtape7
   ```

5. Define all device classes that are associated with the shared library. AIX

   ```
   judy> define devclass tape library=sangroup devtype=lto
   ```

   Linux

   ```
   judy> define devclass tape library=sangroup devtype=lto
   ```

   The following parameters for the device class definition must be the same on the library client and the library manager:
   - LIBRARY
   - DRIVEENCRYPTION
   - WORM
   - FORMAT
6. Define a storage pool that is named BACKTAPE for the shared library to use. Issue the DEFINE STGPOOL command.

   ```
   judy> define stgpool backtape tape maxscratch=50
   ```

What to do next

Repeat the procedure to define more library clients to your library manager.
Related reference:

DEFINE LIBRARY (Define a library)
DEFINE PATH (Define a path)
DEFINE STGPOOL (Define a volume in a storage pool)
Windows

Example: Library sharing for Windows servers

To learn how to set up a library sharing environment for servers that run on Windows systems, review the sample procedure.

About this task

In this example, a library manager server named ASTRO and a library client named JUDY are configured.

For SCSI libraries, define the library by specifying the libtype=scsi parameter.

- Windows Setting up the library manager server
  You must set up the library manager server in order to configure the IBM Spectrum Protect servers to share SAN-connected devices.
- Windows Setting up the library client servers
  You must set up one or more library client servers to configure the IBM Spectrum Protect servers to share SAN-connected devices.

Windows

Setting up the library manager server

You must set up the library manager server in order to configure the IBM Spectrum Protect™ servers to share SAN-connected devices.

Procedure

The following procedure is an example of how to set up an IBM Spectrum Protect server that is named ASTRO as a library manager:

1. Ensure that the library manager server is running:
   a. Start the Windows Services Management Console (services.msc).
   b. Select the service. For example, `TSM Server1`.
   c. If the service is not running, right-click the service name and click Start.
2. Obtain the library and drive information for the shared library device:
   a. Run the `tsmdlst.exe` utility. The utility is in the \Program Files\Tivoli\TSM\server directory.
3. Define a library whose library type is SCSI. For example:

   ```
   define library sangroup libtype=scsi shared=yes
   ```

   This example uses the default for the library's serial number, which is to have the server obtain the serial number from the library itself at the time that the path is defined. Depending on the capabilities of the library, the server might not be able to automatically detect the serial number. In this case, the server does not record a serial number for the device, and is not able to confirm the identity of the device when you define the path or when the server uses the device.

4. Define the path from the server to the library.

   ```
   define path astro sangroup srctype=server desttype=library
    device=lb0.0.0.2
   ```

   If you did not include the serial number when you defined the library, the server now queries the library to obtain this information. If you did include the serial number when you defined the library, the server verifies what you defined and issues a message if there is a mismatch.

5. Define the drives in the library.

   ```
   define drive sangroup drivea
   define drive sangroup driveb
   ```

   This example uses the default for the drive's serial number, which is to have the server obtain the serial number from the drive itself at the time that the path is defined. Depending on the capabilities of the drive, the server might not be able to automatically detect the serial number. In this case, the server does not record a serial number for the device, and is not able to confirm the identity of the device when you define the path or when the server uses the device.

This example also uses the default for the drive's element address, which is to have the server obtain the element number from the drive itself at the time that the path is defined.

The element address is a number that indicates the physical location of a drive within an automated library. The server needs the element address to connect the physical location of the drive to the drive's SCSI address. You can have the server obtain the element number from the drive itself at the time that the path is defined, or you can specify the element number when you define the drive.

Depending on the capabilities of the library, the server might not be able to automatically detect the element address. In this case, you must supply the element address when you define the drive. Element numbers for many libraries are available at IBM® Support Portal for IBM Spectrum Protect.

6. Define the path from the server to each of the drives.

```
define path astro drivea srctype=server desttype=drive library=sangroup
 device=mt0.1.0.2
define path astro driveb srctype=server desttype=drive library=sangroup
 device=mt0.2.0.2
```

If you did not include the serial number or element address when you defined the drive, the server now queries the drive or the library to obtain this information.

7. Define at least one device class.

```
define devclass tape devtype=dlt library=sangroup
```

8. Check in the library inventory. The following example checks all volumes into the library inventory as scratch volumes. The server uses the name on the bar code label as the volume name.

```
checkin libvolume sangroup search=yes status=scratch
 checklabel=barcode
```

9. Set up a storage pool for the shared library with a maximum of 50 scratch volumes.

```
define stgpool backtape tape
 description='storage pool for shared sangroup' maxscratch=50
```

Windows

Setting up the library client servers

You must set up one or more library client servers to configure the IBM Spectrum Protect™ servers to share SAN-connected devices.

Before you begin

Ensure that a library manager server is defined.

About this task

You must define the library manager server. Use the following procedure as an example of how to set up an IBM Spectrum Protect server that is named JUDY as a library client.

Procedure

1. Ensure that the library manager server is running:
   a. Start the Windows Services Management Console (services.msc).
   b. Select the service. For example, `TSM Server1`.

c. If the service is not running, right-click and select Start.

2. Obtain the library and drive information for the shared library device:
   a. Run the `tsmdlst.exe` utility. The utility is in the \Program Files\Tivoli\TSM\server directory.
3. Define the shared library, SANGROUP, and identify the library manager. Ensure that the library name is the same as the library name on the library manager.

   ```
   define library sangroup libtype=shared primarylibmanager=astro
   ```

4. Define the paths from the library client server to each of the drives by issuing commands on the administrative client:

   ```
   define path judy drivea srctype=server desttype=drive library=sangroup
    device=mt0.1.0.3
    define path judy driveb srctype=server desttype=drive library=sangroup
    device=mt0.2.0.3
   ```

5. Define at least one device class by issuing commands from the library client:

   ```
   define devclass tape devtype=dlt mountretention=1 mountwait=10
   library=sangroup
   ```

   Set the parameters for the device class the same on the library client as on the library manager. Making the device class names the same on both servers is also a good practice, but is not required.

   The device class parameters that are specified on the library manager server override those specified for the library client. This is true whether or not the device class names are the same on both servers. If the device class names are different, the library manager uses the parameters specified in a device class that matches the device type specified for the library client.

   If a library client requires a setting that is different from what is specified in the library manager's device class (for example, a different mount limit), complete the following steps:

   a. Create an additional device class on the library manager server. Specify the parameter settings that you want the library client to use.
   b. Create a device class on the library client with the same name and device type as the new device class you created on the library server.
6. Define the storage pool, BACKTAPE, that will use the shared library:

   ```
   define stgpool backtape tape
   description='storage pool for shared sangroup' maxscratch=50
   ```

7. Repeat this procedure to define additional servers as library clients.

DEFINE STGPOOL (Define a volume in a storage pool)

Setting up a storage pool hierarchy

As part of the implementation process, you must set up a storage pool hierarchy. Set up at least one primary storage pool on disk and one primary storage pool on tape. Ensure that data is migrated from disk to tape daily.

Before you begin

1. Ensure that you reviewed the information in Planning the storage pool hierarchy.
2. Ensure that appropriate rules, also known as *policies*, are specified for backing up client data. Follow the instructions in Specifying rules for backing up and archiving client data.
3. Ensure that a policy is assigned to each node. For instructions about assigning a policy when you register a node, see Registering clients.

Procedure

To set up a storage pool hierarchy, complete the following steps:

1. Define a primary storage pool for the tape device by issuing the DEFINE STGPOOL command.

For example, define a primary storage pool, TAPE1, with a device class of LTO, and enable group collocation. Set the maximum number of scratch volumes that the server can request for this storage pool to 999. Issue the following command:

```
define stgpool tape1 lto pooltype=primary collocate=group
maxscratch=999
```

2. Define the drives, paths, and libraries for the primary storage pool on tape. Follow the instructions in Defining tape devices.
3. Define a primary storage pool for the disk device by issuing the DEFINE STGPOOL command.

   For example, define a storage pool, DISK1, with a device class of FILE. Ensure that data can be migrated to the tape storage pool, TAPE1, but prevent automatic migration by specifying 100 for the HIGHMIG parameter and 0 for the LOWMIG parameter. Prevent reclamation by specifying 100 for the RECLAIM parameter. Enable node collocation. Set the maximum number of scratch volumes that the server can request for this storage pool to 9999. Use the MIGPROCESS parameter to specify the number of migration processes. The value of the MIGPROCESS parameter should equal the number of drives in the library minus the number of drives that are reserved for restore operations. Issue the following command:

   ```
   define stgpool disk1 file pooltype=primary nextstgpool=tape1
   highmig=100 lowmig=0 reclaim=100 collocate=node maxscratch=9999 migprocess=5
   ```

   For more information about how to set up migration from disk to tape, see Migrating disk storage pools.

What to do next

A storage pool hierarchy includes only primary storage pools. After you set up the storage pool hierarchy, complete the following steps:

1. Create a copy storage pool on a tape device. For instructions, see DEFINE STGPOOL (Define a copy storage pool assigned to sequential access devices).
2. Back up the tape-based primary storage pool to the copy storage pool by using the BACKUP STGPOOL command. For instructions, see BACKUP STGPOOL (Back up primary storage pool data to a copy storage pool).
3. To ensure that data can be recoved in a disaster, set up a procedure for moving tape volumes from the copy storage pool to an offsite location. For instructions, see Preparing for and recovering from a disaster by using DRM.

DEFINE STGPOOL (Define a volume in a storage pool)

Protecting applications, virtual machines, and systems

The server protects data for clients, which can include applications, virtual machines, and systems.

- Adding clients
  Following the successful setup of your IBM Spectrum Protect™ server, install and configure client software to begin backing up data.

Configuring LAN-free data movement

You can configure the IBM Spectrum Protect™ client and server so that the client, through a storage agent, can move data directly to storage on a SAN. This function, called LAN-free data movement, is provided by the IBM Spectrum Protect for SAN product.

Procedure

To configure LAN-free data movement, complete the following steps. For details, see the documentation for IBM Spectrum Protect for SAN.

1. Verify the network connection.
2. Establish communications among the client, storage agent, and the server.
3. Install and configure software on client systems.
4. Configure devices on the server for the storage agent to access.
5. Configure IBM Spectrum Protect policies for LAN-free data movement for the client.
6. If you are using shared FILE storage, install and configure IBM® TotalStorage SAN File System or IBM Spectrum Scale™.

Windows Restriction: If an IBM Spectrum Scale volume is formatted by an AIX® server, the Windows system uses TCP/IP to transfer data and not the storage area network.

7. Define paths from the storage agent to drives.
8. Start the storage agent and verify the LAN-free configuration.

What to do next

To help you tune the use of your LAN and SAN resources, you can control the path that data transfers take for clients with the capability of LAN-free data movement. Control the path by using the UPDATE NODE command. For each client, you can select one of the following settings for data read and write operations. Specify data read operations by using the DATAREADPATH parameter and data write operations by using the DATAWRITEPATH parameter. The parameter is optional. The default value is ANY.

LAN (LAN path only)
Specify the LAN value if either of the following conditions is true:

- You want to back up or restore a small amount of data.
- The client does not have SAN connectivity.

LANFREE (LAN-free path only)
Specify the LANFREE value if the client and server are on the same SAN, and any of the following conditions are true:

- You want to back up or restore a large amount of data.
- You want to offload the server processing load to the client.
- You want to relieve LAN congestion.

ANY (Any available path)
A LAN-free path is used if one is available. If a LAN-free path is unavailable, the data is moved by using the LAN.

- Validating your LAN-free configuration
  After you configure an IBM Spectrum Protect client for LAN-free data movement, you can verify the configuration and server definitions by using the VALIDATE LANFREE command.

Tape encryption methods

Deciding on the encryption method to use depends on how you want to manage your data.

It is critical to secure client data, especially when that data is sensitive. To ensure that data in onsite and offsite volumes is protected, IBM tape encryption technology is available.

IBM tape technology supports different methods of drive encryption for the following devices:

- IBM 3592 Generation 2 and Generation 3
- IBM Linear Tape-Open (LTO) Generation 4 and Generation 5

The methods of drive encryption that you can use with IBM Spectrum Protect™ are set up at the hardware level. IBM Spectrum Protect cannot control or change which encryption method is used in the hardware configuration. If the hardware is set up for the Application method, IBM Spectrum Protect can turn encryption on or off depending on the DRIVEENCRYPTION value on the device class.

To encrypt all data in a particular logical library or to encrypt data on more than just storage pool volumes, use the Library or System method. If the encryption key manager is set up to share keys, the Library and System methods can share the encryption key, which allows the two methods to be interchanged. IBM Spectrum Protect cannot share or use encryption keys between the Application method and either the Library or the System methods of encryption.

Table 1. Encryption methods

Encryption method	Description

Encryption method	Description
Application encryption	With application-managed encryption, you can create dedicated storage pools that contain encrypted volumes only. This way, you can use storage pool hierarchies and policies to manage the way data is encrypted. Encryption keys are managed by the application, in this case, IBM Spectrum Protect. IBM Spectrum Protect generates and stores the keys in the server database. Data is encrypted during write operations, when the encryption key is passed from the server to the drive. Data is decrypted for read operations. To encrypt storage pool volumes and eliminate some encryption processing on your system, enable the Application method. Use application-managed encryption only for storage pool volumes. Other volumes, such as backup-set tapes, export volumes, and database backups, are not encrypted by using the Application method. Requirement: When application encryption is enabled, you must take extra care to secure database backups because the encryption keys that are used to encrypt and decrypt data are stored in the server database. To restore your data, you must have the correct database backup and corresponding encryption keys to access your information. Ensure that you back up the database frequently and safeguard the backups to prevent data loss or theft. Anyone who has access to both the database backup and the encryption keys has access to your data.
Library encryption	With library-managed encryption, you can control which volumes are encrypted by using their serial numbers. You can specify a range or set of volumes to encrypt. Encryption keys are managed by the library. Keys are stored in an encryption key manager and provided to the drive. If you set up the hardware to use library-managed encryption, you can use this method by issuing the DEFINE DEVCLASS command and specifying the DRIVEENCRYPTION=ALLOW parameter. Restriction: Only certain IBM libraries support IBM LTO-4 and later encryption. For details, see Configuring tape drive encryption.
System encryption	System-managed encryption is available only on the AIX® operating system. Encryption keys that are provided to the drive are managed by the device driver or operating system and stored in an encryption key manager. If the hardware is set up to use system encryption, you can use this method by issuing the DEFINE DEVCLASS command and specifying the DRIVEENCRYPTION=ALLOW parameter.

To determine whether a volume is encrypted and which method was used, issue the QUERY VOLUME command and specify the FORMAT=DETAILED parameter.

- Configuring tape drive encryption
  You can use drive encryption to protect tapes that contain critical or sensitive data, for example, tapes that contain confidential financial information. Drive encryption can be useful when you move tapes from the IBM Spectrum Protect server environment to an onsite or offsite location.

Controlling tape storage operations

Device class definitions for tapes include parameters that allow you to control storage operations.

- How IBM Spectrum Protect fills volumes
  The DEFINE DEVCLASS command has an optional ESTCAPACITY parameter that indicates the estimated capacity for sequential volumes that are associated with the device class. IBM Spectrum Protect™ uses the estimated capacity of volumes to determine the estimated capacity of a storage pool, and the estimated percent utilized.
- Specifying the estimated capacity of tape volumes
  IBM Spectrum Protect also uses estimated capacity to determine when to begin the reclamation of storage pool volumes.
- Specifying recording formats for tape media
  You can specify the recording format that is used by IBM Spectrum Protect to write data to tape media. If you plan to mix generations of drives, or different drive types, within a library, you must specify a recording format for each drive generation and each drive type. In this way, the server can differentiate between the drive generations and drive types.
- Associating library objects with device classes
  A library contains the drives that can be used to mount the volume. Only one library can be associated with a device class. However, multiple device classes can reference the same library.
- Controlling media-mount operations for tape devices
  By using device class definitions, you can control the number of mounted volumes, the amount of time a volume remains mounted, and the amount of time that the IBM Spectrum Protect server waits for a drive to become available.
- Preempting operations
  The server can preempt server or client operations for a higher priority operation when a mount point is in use and no others are available, or access to a specific volume is required. When an operation is preempted, it is canceled.
- Impacts of device changes on the SAN
  The SAN environment can shift dramatically due to device or cabling changes. The dynamic nature of the SAN can cause static definitions to fail or become unpredictable.
- Windows Displaying device information
  You can display information about devices that are connected to the server by using the device information utility (tsmdlst).
- Write-once, read-many tape media
  Write-once, read-many (WORM) media help to prevent accidental or deliberate deletion of critical data. However, IBM Spectrum Protect imposes certain restrictions and guidelines to follow when you use WORM media.
- Windows Troubleshooting problems with devices
  You can troubleshoot errors that occur when you configure or use devices with IBM Spectrum Protect.

How IBM Spectrum Protect fills volumes

The DEFINE DEVCLASS command has an optional ESTCAPACITY parameter that indicates the estimated capacity for sequential volumes that are associated with the device class. IBM Spectrum Protect™ uses the estimated capacity of volumes to determine the estimated capacity of a storage pool, and the estimated percent utilized.

If the ESTCAPACITY parameter is not specified, IBM Spectrum Protect uses a default value that is based on the recording format that is specified for the device class by using the FORMAT parameter.

If you specify an estimated capacity that exceeds the actual capacity of the volume in the device class, IBM Spectrum Protect updates the estimated capacity of the volume when the volume becomes full. When IBM Spectrum Protect reaches the end of the volume, it updates the capacity to match the amount that is written to the volume.

You can either accept the default estimated capacity for the device class, or explicitly specify an estimated capacity. An accurate estimated capacity value is not required, but is useful. IBM Spectrum Protect uses the estimated capacity of volumes to determine the estimated capacity of a storage pool, and the estimated percent that is used. You might want to change the estimated capacity if on or both of the following conditions are true:

- The default estimated capacity is inaccurate because of data compression.
- You have volumes of nonstandard size.

Related reference:
DEFINE DEVCLASS (Define a device class)
UPDATE DEVCLASS (Update a device class)

Specifying the estimated capacity of tape volumes

IBM Spectrum Protect™ also uses estimated capacity to determine when to begin the reclamation of storage pool volumes.

About this task

For tape device classes, the default values selected by the server depend on the recording format that is used to write data to the volume. You can either accept the default for a device type or specify a value.

To specify estimated capacity for tape volumes, use the ESTCAPACITY parameter when you define the device class or update its definition.

Related reference:
DEFINE DEVCLASS (Define a device class)
UPDATE DEVCLASS (Update a device class)

Specifying recording formats for tape media

You can specify the recording format that is used by IBM Spectrum Protect™ to write data to tape media. If you plan to mix generations of drives, or different drive types, within a library, you must specify a recording format for each drive generation and each drive type. In this way, the server can differentiate between the drive generations and drive types.

About this task

To specify a recording format, use the FORMAT parameter when you define the device class or update its definition.

If all drives associated with that device class are identical, specify FORMAT=DRIVE. The server selects the highest format that is supported by the drive on which a volume is mounted.

If some drives associated with the device class support a higher density format than others, specify a format that is compatible with all drives.

If drives in a single SCSI library use different tape technologies (for example, DLT and LTO Ultrium), specify a unique value for the FORMAT parameter in each device class definition.

For a configuration example, see Example: Configure a SCSI or virtual tape library with multiple drive device types.

The recording format that the server uses for a volume is selected when data is first written to the volume. Updating the FORMAT parameter does not affect media that already contain data until those media are rewritten from the beginning. This process might happen after a volume is reclaimed or deleted, or after all of the data on the volume expires.

Related reference:
DEFINE DEVCLASS (Define a device class)
UPDATE DEVCLASS (Update a device class)

Associating library objects with device classes

A library contains the drives that can be used to mount the volume. Only one library can be associated with a device class. However, multiple device classes can reference the same library.

About this task

To associate a device class with a library, use the LIBRARY parameter when you define a device class or update its definition.

Related reference:
DEFINE DEVCLASS (Define a device class)
UPDATE DEVCLASS (Update a device class)

Controlling media-mount operations for tape devices

By using device class definitions, you can control the number of mounted volumes, the amount of time a volume remains mounted, and the amount of time that the IBM Spectrum Protect™ server waits for a drive to become available.

- Controlling the number of simultaneously mounted volumes
  When you set a mount limit for a device class, you must consider the number of storage devices that are connected to your

system. You must also consider whether you use the simultaneous-write function, whether you associate multiple device classes with a single library, and the number of processes that run at the same time.

- Controlling the amount of time that a volume remains mounted
  You can control the amount of time that a mounted volume remains mounted after its last I/O activity. If a volume is used frequently, you can improve performance by setting a longer mount retention period to avoid unnecessary mount and dismount operations.
- Controlling the amount of time that the server waits for a drive
  You can specify the maximum amount of time, in minutes, that the IBM Spectrum Protect server waits for a drive to become available for the current mount request.

Controlling the number of simultaneously mounted volumes

When you set a mount limit for a device class, you must consider the number of storage devices that are connected to your system. You must also consider whether you use the simultaneous-write function, whether you associate multiple device classes with a single library, and the number of processes that run at the same time.

About this task

When you select a mount limit for a device class, consider the following issues:

- How many storage devices are connected to your system?

  Do not specify a mount limit value that is greater than the number of associated available drives in your installation. If the server tries to mount as many volumes as specified by the mount limit and no drives are available for the required volume, an error occurs and client sessions might end. (This restriction does not apply when the DRIVES parameter is specified.)

  If you are sharing library resources on a SAN among IBM Spectrum Protect™ servers, you must limit the number of tape drives that a library client can use at a time. To allow multiple library client servers use a library simultaneously specify the MOUNTLIMIT parameter when you define or update the device class on the library client. For more information about configuring library sharing, see Configuring library sharing.

- Are you using the simultaneous-write function to primary storage pools, copy storage pools, and active-data pools?

  Specify a mount limit value that provides enough mount points to support writing data simultaneously to the primary storage pool and all associated copy storage pools and active-data pools.

- Are you associating multiple device classes with a single library?

  A device class that is associated with a library can use any drive in the library that is compatible with the device class' device type. Because you can associate more than one device class with a library, a single drive in the library can be used by more than one device class. IBM Spectrum Protect ensures that two operations cannot use the same drive simultaneously by using two different device classes.

- How many IBM Spectrum Protect processes do you want to run at the same time, by using devices in this device class?

  IBM Spectrum Protect automatically cancels some processes to run other, higher priority processes. If the server is using all available drives in a device class to complete higher priority processes, lower-priority processes must wait until a drive becomes available. For example, IBM Spectrum Protect cancels the process for a client that backs up directly to tape if the drive is needed for a server migration or tape reclamation process. IBM Spectrum Protect cancels a tape reclamation process if the drive is needed for a client restore operation. For more information, see Preempting operations.

  If processes are often canceled by other processes, consider whether you can make more drives available for IBM Spectrum Protect use. Otherwise, review your scheduling of operations to reduce the contention for drives.

  This consideration also applies to the simultaneous-write function. You must have enough drives available to allow for a successful simultaneous-write operation.

  To specify the maximum number of volumes that can be simultaneously mounted, use the MOUNTLIMIT parameter when you define the device class or update its definition.

Related reference:
DEFINE DEVCLASS (Define a device class)
UPDATE DEVCLASS (Update a device class)

Controlling the amount of time that a volume remains mounted

You can control the amount of time that a mounted volume remains mounted after its last I/O activity. If a volume is used frequently, you can improve performance by setting a longer mount retention period to avoid unnecessary mount and dismount operations.

About this task

If mount operations are being handled by manual, operator-assisted activities, you might want to specify a long mount retention period. For example, if only one operator supports your entire operation on a weekend, then define a long mount retention period so that the operator is not being asked to mount volumes every few minutes.

To control the amount of time a mounted volume remains mounted, use the MOUNTRETENTION parameter when you define the device class or update its definition. For example, if the mount retention value is 60, and a mounted volume remains idle for 60 minutes, the server dismounts the volume.

While IBM Spectrum Protect™ has a volume mounted, the drive is allocated to IBM Spectrum Protect and cannot be used for anything else. If you need to free the drive for other uses, you can cancel IBM Spectrum Protect operations that are using the drive and then dismount the volume. For example, you can cancel server migration or backup operations. For information on how to cancel processes and dismount volumes, see Managing server requests for volumes

Related reference:
DEFINE DEVCLASS (Define a device class)
UPDATE DEVCLASS (Update a device class)

Controlling the amount of time that the server waits for a drive

You can specify the maximum amount of time, in minutes, that the IBM Spectrum Protect™ server waits for a drive to become available for the current mount request.

About this task

To control the wait time for a drive to become available for a mount request, use the MOUNTWAIT parameter when you define or update a device class.

Related reference:
DEFINE DEVCLASS (Define a device class)
UPDATE DEVCLASS (Update a device class)

Preempting operations

The server can preempt server or client operations for a higher priority operation when a mount point is in use and no others are available, or access to a specific volume is required. When an operation is preempted, it is canceled.

You can use the QUERY MOUNT command to see the status of the volume for the mount point.

By default, preemption is enabled on the server. To disable preemption, specify the NOPREEMPT option in the server options file. If you specify this option, the BACKUP DB command, and the export and import commands are the only operations that can preempt other operations.

- Mount point preemption
  If a high-priority operation requires a mount point that is in a specific device class and all the mount points in the device class are in use, the high-priority operation can preempt a mount point from a lower-priority operation.
- Volume access preemption
  If a high-priority operation requires access to a specific volume and that volume is in use, the high-priority operation can preempt the lower-priority operation for that volume.

Related reference:
BACKUP DB (Back up the database)
QUERY MOUNT (Display information on mounted sequential access volumes)

Mount point preemption

If a high-priority operation requires a mount point that is in a specific device class and all the mount points in the device class are in use, the high-priority operation can preempt a mount point from a lower-priority operation.

Mount points can be preempted only when the device class of the operation preempting and the operation that is being preempted is the same.

The following high-priority operations can preempt other operations for a mount point.

- Database backup operations
- Retrieve, restore, or HSM recall operations that are initiated by clients
- Restore operations by using a remote data mover
- Export operations
- Import operations
- Operations to generate backup sets

The following server operations cannot preempt other operations or be preempted:

- Audit a volume
- Restore data from a copy or active-data pool
- Prepare a recovery plan file
- Store data by using a remote data mover

The following operations can be preempted and are listed in order of priority, from highest priority to lowest priority. The server selects the lowest priority operation to preempt, for example, identify duplicates.

- Replicate nodes
- Back up data to a copy storage pool
- Copy active data to an active data pool
- Move data on a storage pool volume
- Migrate data from disk to sequential media
- Migrate data from sequential media to sequential media
- Back up, archive, or HSM migrate operations that are initiated by clients
- Reclaim volumes in a sequential-access storage pool
- Identify duplicates

Volume access preemption

If a high-priority operation requires access to a specific volume and that volume is in use, the high-priority operation can preempt the lower-priority operation for that volume.

For example, if a restore request requires access to a volume in use by a reclamation operation and a drive is available, the reclamation operation is canceled.

The following high-priority operations can preempt operations for access to a specific volume:

- Database backup operations
- Retrieve, restore, or HSM recall operations that are initiated by clients
- Restore operations by using a remote data mover
- Export operations
- Import operations
- Operations to generate backup sets

The following operations cannot preempt other operations or be preempted:

- Audit volume
- Restore data from a copy or active-data pool
- Prepare a recovery plan
- Store data by using a remote data mover

The following operations can be preempted, and are listed in order of priority, from highest priority to lowest priority. The server selects the lowest priority operation to preempt, for example, identify duplicates.

- Replicate nodes
- Back up data to a copy storage pool
- Copy active data to an active data pool
- Move data on a storage pool volume
- Migrate data from disk to sequential media
- Migrate data from sequential media to sequential media
- Back up, archive, or HSM migrate data that is initiated by client
- Reclaim volumes in a sequential-access storage pool
- Identify duplicates

Impacts of device changes on the SAN

The SAN environment can shift dramatically due to device or cabling changes. The dynamic nature of the SAN can cause static definitions to fail or become unpredictable.

Device IDs that are assigned by the SAN and known to the server or storage agent can be altered due to bus resets or other environmental changes. For example, the server might know a device X as *rmt0* (on AIX®), based on the original path specification to the server and original configuration of the LAN. However, some event in the SAN, for example, the addition of new device Y, causes device X to be assigned *rmt1*. When the server tries to access device X by using *rmt0*, either the access fails or the wrong target device is accessed. The server attempts to recover from changes to devices on the SAN by using device serial numbers to confirm the identity of devices it contacts.

When you define a drive or library, you have the option of specifying the serial number for that device. If you do not specify the serial number when you define the device, the server obtains the serial number when you define the path for the device. In either case, the server then has the device serial number in its database and can use it to confirm the identity of a device for operations.

When the server uses drives and libraries on a SAN, the server attempts to verify that the correct device is used. The server contacts the device by using the device name in the path that you defined for it. The server then requests the serial number from the device, and compares that serial number with the serial number that is stored in the server database for that device.

If the serial number does not match, the server begins the process of discovery on the SAN, attempting to find the device with the matching serial number. If the server finds the device with the matching serial number, it corrects the definition of the path in the server's database by updating the device name in that path. The server issues a message with information about the change that is made to the device. Then, the server proceeds to use the device.

To determine when device changes on the SAN affect the IBM Spectrum Protect™ server, you can monitor the activity log for messages. The following messages are related to serial numbers:

- ANR8952 through ANR8958
- ANR8961 through ANR8968
- ANR8974 through ANR8975

Restriction: Some devices cannot report their serial numbers to applications such as the IBM Spectrum Protect server. If the server cannot obtain the serial number from a device, the server cannot help the system to recover from a device location change on the SAN.

Windows

Displaying device information

You can display information about devices that are connected to the server by using the device information utility (tsmdlst).

Before you begin

- Ensure that the HBA API is installed. The HBA API is required to run the device information utility.
- Ensure that the tape device driver is installed and configured.

Procedure

1. From a command prompt, change to the `server` subdirectory of the server installation directory, for example, C:\Program Files\Tivoli\TSM\server.
2. Run the tsmdlst.exe executable file.

Related reference:
QUERY SAN (Query the devices on the SAN)
tsmdlst (Display information about devices)

Write-once, read-many tape media

Write-once, read-many (WORM) media help to prevent accidental or deliberate deletion of critical data. However, IBM Spectrum Protect™ imposes certain restrictions and guidelines to follow when you use WORM media.

You can use the following types of WORM media with IBM Spectrum Protect:

- IBM® 3592, all supported generations
- IBM LTO-3 and all supported generations
- HP LTO-3 and all supported generations
- Quantum LTO-3 and all supported generations
- Quantum SDLT 600, Quantum DLT V4, and Quantum DLT S4
- StorageTek VolSafe
- Sony AIT50 and AIT100

Tips:

- A storage pool can consist of either WORM or RW media, but not both.
- To avoid wasting tape after a restore or import operation, do not use WORM tapes for database backup or export operations.

- WORM-capable drives
  To use WORM media in a library, all the drives in the library must be WORM-capable. A mount will fail if a WORM cartridge is mounted in a read/write (RW) drive.
- Check-in of WORM media
  The type of WORM media determines whether the media label needs to be read during check-in.
- Restrictions on WORM media
  You cannot use prelabeled WORM media with the LTO or ECARTRIDGE device class.
- Mount failures with WORM media
  If WORM tape media are loaded into a drive for a read-write (RW) device-class mount, it will cause a mount failure. Similarly, if RW tape media are loaded into a drive for a WORM device-class mount, the mount will fail.
- Relabeling WORM media
  You cannot relabel a WORM cartridge if it contains data. This applies to Sony AIT WORM, LTO WORM, SDLT WORM, DLT WORM, and IBM 3592 cartridges. The label on a VolSafe volume should be overwritten only once and only if the volume does not contain usable, deleted, or expired data.
- Removing private WORM volumes from a library
  If you perform an action on a WORM volume (for example, if you delete file spaces) and the server does not mark the volume as full, the volume is returned to scratch status. If a WORM volume is not marked as full and you delete it from a storage pool, the volume remains private. To remove a private WORM volume from a library, you must issue the CHECKOUT LIBVOLUME command.
- Creation of DLT WORM volumes
  DLT WORM volumes can be converted from read/write (RW) volumes.
- Support for short and normal 3592 WORM tapes
  IBM Spectrum Protect supports both short and normal 3592 WORM tapes. For best results, define them in separate storage pools
- Querying a device class for the WORM-parameter setting
  You can determine the setting of the WORM parameter for a device class by using the QUERY DEVCLASS command. The output contains a field, labeled WORM, and a value (YES or NO).

WORM-capable drives

To use WORM media in a library, all the drives in the library must be WORM-capable. A mount will fail if a WORM cartridge is mounted in a read/write (RW) drive.

However, a WORM-capable drive can be used as a RW drive if the WORM parameter in the device class is set to NO. Any type of library can have both WORM and RW media if *all* of the drives are WORM enabled. The only exception to this rule is NAS-attached libraries in which WORM tape media cannot be used.

Related reference:
DEFINE DEVCLASS (Define a device class)
UPDATE DEVCLASS (Update a device class)

Check-in of WORM media

The type of WORM media determines whether the media label needs to be read during check-in.

Library changers cannot identify the difference between standard read/write (RW) tape media and the following types of WORM tape media:

- VolSafe
- Sony AIT
- LTO
- SDLT
- DLT

To determine the type of WORM media that is being used, a volume must be loaded into a drive. Therefore, when you check in one of these types of WORM volumes, you must use the CHECKLABEL=YES option on the CHECKIN LIBVOLUME command.

If they provide support for WORM media, IBM® 3592 library changers can detect whether a volume is WORM media without loading the volume into a drive. Specifying CHECKLABEL=YES is not required. Verify with your hardware vendors that your 3592 drives and libraries provide the required support.

Related reference:
CHECKIN LIBVOLUME (Check a storage volume into a library)

Restrictions on WORM media

You cannot use prelabeled WORM media with the LTO or ECARTRIDGE device class.

You cannot use WORM media with IBM Spectrum Protect™ specified as the drive-encryption key manager for the following drives:

- IBM® LTO-5, LTO-6, and later
- HP LTO-5, LTO-6, and later
- Oracle StorageTek T10000B
- Oracle StorageTek T10000C
- Oracle StorageTek T10000D

Mount failures with WORM media

If WORM tape media are loaded into a drive for a read-write (RW) device-class mount, it will cause a mount failure. Similarly, if RW tape media are loaded into a drive for a WORM device-class mount, the mount will fail.

Relabeling WORM media

You cannot relabel a WORM cartridge if it contains data. This applies to Sony AIT WORM, LTO WORM, SDLT WORM, DLT WORM, and IBM® 3592 cartridges. The label on a VolSafe volume should be overwritten only once and only if the volume does not contain usable, deleted, or expired data.

Issue the LABEL LIBVOLUME command only once for VolSafe volumes. You can guard against overwriting the label by using the OVERWRITE=NO option on the LABEL LIBVOLUME command.

Related reference:
LABEL LIBVOLUME (Label a library volume)

Removing private WORM volumes from a library

If you perform an action on a WORM volume (for example, if you delete file spaces) and the server does not mark the volume as full, the volume is returned to scratch status. If a WORM volume is not marked as full and you delete it from a storage pool, the

volume remains private. To remove a private WORM volume from a library, you must issue the CHECKOUT LIBVOLUME command.

Related reference:
CHECKOUT LIBVOLUME (Check a storage volume out of a library)

Creation of DLT WORM volumes

DLT WORM volumes can be converted from read/write (RW) volumes.

If you have SDLT-600, DLT-V4, or DLT-S4 drives and you want to enable them for WORM media, upgrade the drives by using V30 or later firmware available from Quantum. You can also use DLTIce software to convert unformatted RW volumes or blank volumes to WORM volumes.

In SCSI libraries, the IBM Spectrum Protect™ server creates scratch DLT WORM volumes automatically when the server cannot locate any scratch WORM volumes in a library's inventory. The server converts available unformatted or blank RW scratch volumes or empty RW private volumes to scratch WORM volumes. The server also rewrites labels on newly created WORM volumes by using the label information on the existing RW volumes.

Support for short and normal 3592 WORM tapes

IBM Spectrum Protect™ supports both short and normal 3592 WORM tapes. For best results, define them in separate storage pools

Querying a device class for the WORM-parameter setting

You can determine the setting of the WORM parameter for a device class by using the QUERY DEVCLASS command. The output contains a field, labeled WORM, and a value (YES or NO).

Related reference:
QUERY DEVCLASS (Display information on one or more device classes)
Windows

Troubleshooting problems with devices

You can troubleshoot errors that occur when you configure or use devices with IBM Spectrum Protect™.

About this task

Use Table 1 to find a solution to the device-related problem.

Table 1. Resolving device problems

Symptom	Problem	Solution
Conflicts with other applications.	IBM Spectrum Protect requires a storage area network to share devices.	Set up a storage area network. Attention: Data loss can occur if multiple IBM Spectrum Protect servers use the same device. Define or use a device with only one IBM Spectrum Protect server. AIX Linux Other applications can access IBM Spectrum Protect devices, by using a SCSI tape driver.
Labeling fails.	A device for labeling volumes cannot be used at the same time that the server uses the device for other processes.	You cannot overwrite existing volumes in a storage pool. You must resolve any hardware issues before you label a volume.
	Incorrect or incomplete license registration.	Register the license for the device support that was purchased.

Symptom	Problem	Solution
Conflicts among device drivers.	IBM Spectrum Protect issues messages about I/O errors when you define or use a sequential access device.	Windows device drivers and drivers that are provided by other applications can interfere with the IBM Spectrum Protect device driver if the IBM Spectrum Protect driver is not started first. To check on the order that device drivers are started by the system, complete the following steps: 1. Click Control Panel. 2. Click Devices. Device drivers and their startup types are listed.
I/O errors	When you try to define or use a tape device, there might be device-driver conflicts. Windows device drivers and drivers that are provided by other applications can interfere with the IBM Spectrum Protect device driver if it is not started first.	

Completing the implementation

After the IBM Spectrum Protect™ solution is configured and running, test backup operations and set up monitoring to ensure that everything runs smoothly.

Procedure

1. Test backup operations to verify that your data is protected in the way that you expect.
   a. On the Clients page of the Operations Center, select the clients that you want to back up, and click Back Up.
   b. On the Servers page of the Operations Center, select the server for which you want to back up the database. Click Back Up, and follow the instructions in the Back Up Database window.
   c. Verify that the backup operations completed successfully with no warning or error messages.
   Tip: Alternatively, you can use the backup-archive client GUI to back up client data and you can backup the server database by issuing BACKUP DB command from an administrative command-line.
2. Set up monitoring for your solution by following the instructions in Monitoring a tape solution.

Monitoring a tape solution

After you implement an IBM Spectrum Protect™ tape-based solution, monitor the solution to ensure correct operation. By monitoring the solution daily and periodically, you can identify existing and potential issues. The information that you gather can be used to troubleshoot problems and optimize system performance.

About this task

The preferred way to monitor a solution is by using the Operations Center, which provides overall and detailed system status in a graphical user interface. In addition, you can configure the Operations Center to generate email reports that summarize system status.

Procedure

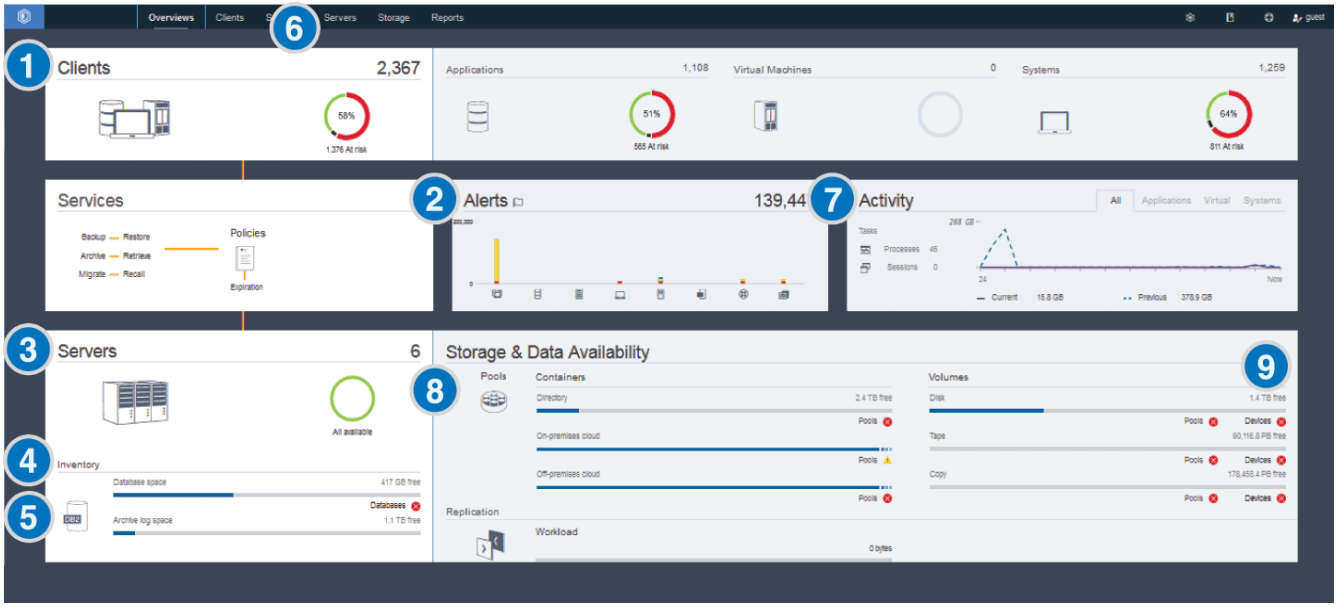
1. Complete daily monitoring tasks. For instructions, see Daily monitoring checklist.
2. Complete periodic monitoring tasks. For instructions, see Periodic monitoring checklist.
3. Verify that your system complies with licensing requirements. For instructions, see Verifying license compliance.
4. Optional: Set up email reports of system status. For instructions, see Tracking system status by using email reports

Daily monitoring checklist

To ensure that you are completing the daily monitoring tasks for your IBM Spectrum Protect™ solution, review the daily monitoring checklist.

Complete the daily monitoring tasks from the Operations Center Overview page. You can access the Overview page by opening the Operations Center and clicking Overviews.

The following figure shows the location for completing each task.



Tip: To run administrative commands for advanced monitoring tasks, use the Operations Center command builder. The command builder provides a type-ahead function to guide you as you enter commands. To open the command builder, go to the Operations Center Overview page. On the menu bar, hover over the settings icon and click Command Builder.

The following table lists the daily monitoring tasks and provides instructions for completing each task.

Table 1. Daily monitoring tasks

Task	Basic procedures	Advanced procedures and troubleshooting information
1 Determine whether clients are at risk of being unprotected due to failed or missed backup operations.	To verify whether clients are at risk, in the Clients area, look for an At risk notification. To view details, click the Clients area. If you installed the client management service on a backup-archive client, you can view and analyze the client error and schedule logs by completing the following steps: 1. In the Clients table, select the client and click Details. 2. To diagnose an issue, click Diagnosis.	For clients that do not have the client management service installed, access the client system to review the client error logs.
2 Determine whether client-related or server-related errors require attention.	To determine the severity of any reported alerts, in the Alerts area, hover over the columns.	To view additional information about alerts, complete the following steps: 1. Click the Alerts area. 2. In the Alerts table, select an alert. 3. In the Activity Log pane, review the messages. The pane displays related messages that were issued before and after the selected alert occurred.

Task	Basic procedures	Advanced procedures and troubleshooting information
3 Determine whether servers that are managed by the Operations Center are available to provide data protection services to clients.	1. To verify whether servers are at risk, in the Servers area, look for an Unavailable notification. 2. To view additional information, click the Servers area. 3. Select a server in the Servers table and click Details.	Tip: If you detect an issue that is related to server properties, update the server properties: 1. In the Servers table, select a server and click Details. 2. To update server properties, click Properties.
4 Determine whether sufficient space is available for the server inventory, which consists of the server database, active log, and archive log.	1. Click the Servers area. 2. In the Status column of the table, view the status of the server and resolve any issues: ○ Normal Sufficient space is available for the server database, active log, and archive log. ○ Critical Insufficient space is available for the server database, active log, or archive log. You must add space immediately, or the data protection services that are provided by the server will be interrupted. ○ Warning The server database, active log, or archive log is running out of space. If this condition persists, you must add space. ○ Unavailable Status cannot be obtained. Ensure that the server is running, and that there are no network issues. This status is also shown if the monitoring administrator ID is locked or otherwise unavailable on the server. This ID is named IBM-OC-hub_server_name. ○ Unmonitored Unmonitored servers are defined to the hub server, but are not configured for management by the Operations Center. To configure an unmonitored server, select the server, and click Monitor Spoke.	You can also look for related alerts on the Alerts page. For additional instructions about troubleshooting, see Resolving server problems.

Task	Basic procedures	Advanced procedures and troubleshooting information
5 Verify server database backup operations.	To determine when a server was most recently backed up, complete the following steps: 1. Click the Servers area. 2. In the Servers table, review the Last Database Backup column.	To obtain more detailed information about backup operations, complete the following steps: 1. In the Servers table, select a row and click Details. 2. In the DB Backup area, hover over the check marks to review information about backup operations. If a database was not backed up recently (for example, in the last 24 hours), you can start a backup operation: 1. On the Operations Center Overview page, click the Servers area. 2. In the table, select a server and click Back Up. To determine whether the server database is configured for automatic backup operations, complete the following steps: 1. On the menu bar, hover over the settings icon  and click Command Builder. 2. Issue the QUERY DB command: `query db f=d` 3. In the output, review the `Full Device Class Name` field. If a device class is specified, the server is configured for automatic database backups.
6 Monitor other server maintenance tasks. Server maintenance tasks can include running administrative command schedules, maintenance scripts, and related commands.	To search for information about processes that failed because of server issues, complete the following steps: 1. Click Servers > Maintenance. 2. To obtain the two-week history of a process, view the History column. 3. To obtain more information about a scheduled process, hover over the check box that is associated with the process.	For more information about monitoring processes and resolving issues, see the Operations Center online help.
7 Verify that the amount of data that was recently sent to and from servers is within the expected range.	• To obtain an overview of activity in the last 24 hours, view the Activity area. • To compare activity in the last 24 hours with activity in the previous 24 hours, review the figures in the Current and Previous areas.	• If more data was sent to the server than you expected, determine which clients are backing up more data and investigate the cause. It is possible that client-side data deduplication is not working correctly. • If less data was sent to the server than you expected, investigate whether client backup operations are proceeding on schedule.

Task	Basic procedures	Advanced procedures and troubleshooting information
8 Verify that storage pools are available to back up client data.	1. If problems are indicated in the Storage & Data Availability area, click Pools to view the details: ○ If the Critical status is displayed, insufficient space is available in the storage pool, or its access status is unavailable. ○ If the Warning status is displayed, the storage pool is running out of space, or its access status is read-only. 2. To view the used, free, and total space for your selected storage pool, hover over the entries in the Capacity Used column.	To view the storage-pool capacity that was used over the past two weeks, select a row in the Storage Pools table and click Details.
9 Verify that storage devices are available for backup operations.	In the Storage & Data Availability area, in the Volumes section, under the capacity bars, review the status that is reported next to Devices. If a Critical or Warning status is displayed for any device, investigate the issue. To view details, click Devices.	Tape devices might have a warning or critical status if drives are unavailable. A drive is unavailable if it is offline, if it stopped responding to the server, or if its path is offline. A tape device might also have a critical status if the library is offline. Other columns of the Tape Devices table show the state of the library robotics, drives, and paths. To resolve issues with tape drives that have a critical state, you can take the drive offline if you need to use it for another activity, such as maintenance. To take a drive offline, complete the following steps: 1. On the Operations CenterStorage page, and select Tape Devices. 2. To view more information about a tape library, select a row and click Details. 3. To take a drive offline, select the tape drive and click Offline. For tape backup operations, verify that sufficient scratch tapes are available. If you are not certain whether the number of available scratch tapes is sufficient, open the details notebook to view tape usage and an estimate of scratch tape availability. To open the details notebook, select a library in the table and click Details.

Periodic monitoring checklist

To help ensure that operations run correctly, complete the tasks in the periodic monitoring checklist. Schedule periodic tasks frequently enough so that you can detect potential issues before they become problematic.

Tip: To run administrative commands for advanced monitoring tasks, use the Operations Center command builder. The command builder provides a type-ahead function to guide you as you enter commands. To open the command builder, go to the Operations Center Overview page. On the menu bar, hover over the settings icon and click Command Builder.

Table 1. Periodic monitoring tasks

Task	Basic procedures	Advanced procedures and troubleshooting

Task	Basic procedures	Advanced procedures and troubleshooting
Monitor system performance.	Determine the length of time that is required for client backup operations: 1. On the Operations Center Overview page, click Clients. Find the server that is associated with the client. 2. Click Servers. Select the server and click Details. 3. To view the duration of completed tasks in the last 24 hours, click Completed Tasks. 4. To view the duration of tasks that were completed more than 24 hours ago, use the QUERY ACTLOG command. For information about this command, see QUERY ACTLOG (Query the activity log). 5. If the duration of client backup operations is increasing and the reasons are not clear, investigate the cause. If you installed the client management service on a backup-archive client, you can diagnose performance issues for the backup-archive client by completing the following steps: 1. On the Operations Center Overview page, click Clients. 2. Select a backup-archive client and click Details. 3. To retrieve client logs, click Diagnosis.	Limit the time for client backup operations to 8 - 12 hours. Ensure that client schedules do not overlap with server maintenance tasks. For instructions about reducing the time that it takes for the client to back up data to the server, see Resolving common client performance problems. Look for performance bottlenecks. For instructions, see Identifying performance bottlenecks. For information about identifying and resolving other performance issues, see Performance.

Task	Basic procedures	Advanced procedures and troubleshooting
Verify that current backup files for device configuration and volume history information are saved.	Access your storage locations to ensure that the files are available. The preferred method is to save the backup files to two locations. To locate the volume history and device configuration files, complete the following steps: 1. On the Operations Center Overview page, hover over the settings icon and click Command Builder. 2. To locate the volume history and device configuration files, issue the following commands: `query option volhistory` `query option devconfig` 3. In the output, review the Option Setting column to find the file locations. If a disaster occurs, both the volume history file and the device configuration file are required to restore the server database.	

Task	Basic procedures	Advanced procedures and troubleshooting
Determine whether sufficient space is available in the directory for the server instance.	Verify that at least 50 GB of free space is available in the directory for the server instance. Take the action that is appropriate for your operating system: • AIX To view available space in the file system, on the operating system command line, issue the following command: `df -g instance_directory` where *instance_directory* specifies the instance directory. • Linux To view available space in the file system, on the operating system command line, issue the following command: `df -h instance_directory` where *instance_directory* specifies the instance directory. • Windows In the Windows Explorer program, right-click the file system and click Properties. View the capacity information. The preferred location of the instance directory depends on the operating system where the server is installed: • AIX Linux /home/tsminst1/tsminst1 • Windows C:\tsminst1 Tip: If you completed a planning worksheet, the location of the instance directory is recorded in the worksheet.	
Identify unexpected client activity.	To monitor client activity to determine whether data volumes exceed expected amounts, complete the following steps: 1. On the Operations Center Overview page, click the Clients area. 2. To view activity over the past two weeks, double-click any client. 3. To view the number of bytes sent to the client, click the Properties tab. 4. In the Last Session area, view the Sent to client row.	When you double-click a client in the Clients table, the Activity over 2 Weeks area displays the amount of data that the client sent to the server each day.

Task	Basic procedures	Advanced procedures and troubleshooting
Monitor storage pool growth over time.	1. On the Operations Center Overview page, click the Pools area. 2. To view the capacity that was used over the last two weeks, select a pool and click Details.	Tips: • To specify the time period that must elapse before all deduplicated extents are removed from a directory-container storage pool or cloud-container storage pool after they are no longer referenced by the inventory, complete the following steps: 1. On the Storage Pools page of the Operations Center, select the storage pool. 2. Click Details > Properties. 3. Specify the duration in the `Delay period for container reuse` field. • To determine data deduplication performance for directory-container and cloud-container storage pools, use the GENERATE DEDUPSTATS command. • To view data deduplication statistics for a storage pool, complete the following steps: 1. On the Storage Pools page of the Operations Center, select the storage pool. 2. Click Details > Properties. Alternatively, use the QUERY EXTENTUPDATES command to display information about updates to data extents in directory-container or cloud-container storage pools. The command output can help you determine which data extents are no longer referenced and which ones are eligible to be deleted from the system. In the output, monitor the number of data extents that are eligible to be deleted from the system. This metric has a direct correlation to the amount of free space that is available within the container storage pool. • To display the amount of physical space that is occupied by a file space after the removal of the data deduplication savings, use the select * from occupancy command. The command output includes the LOGICAL_MB value. LOGICAL_MB is the amount of space that is used by the file space.
Monitor and maintain tape devices.	Monitor your environment for hardware errors on tape drives and tape libraries. For instructions, see Monitoring tape alert messages for hardware errors. Monitor media compatibility to prevent errors on tape drives. For instructions, see Preventing errors caused by media incompatibility. Monitor cleaning messages for tape drives. For instructions, see Operations with cleaner cartridges.	

Task	Basic procedures	Advanced procedures and troubleshooting
Evaluate the timing of client schedules. Ensure that the start and end times of client schedules do not overlap with server maintenance tasks. Limit the time for client backup operations to 8 - 12 hours.	On the Operations Center Overview page, click Clients > Schedules. In the Schedules table, the Start column displays the configured start time for the scheduled operation. To see when the most recent operation was started, hover over the clock icon.	Tip: You can receive a warning message if a client operation runs longer than expected. Complete the following steps: 1. On the Operations Center Overview page, hover over Clients and click Schedules. 2. Select a schedule and click Details. 3. View the details of a schedule by clicking the blue arrow next to the row. 4. In the Run time alert field, specify the time when a warning message will be issued if the scheduled operation is not completed. 5. Click Save.
Evaluate the timing of maintenance tasks. Ensure that the start and end times of maintenance tasks do not overlap with client schedules.	On the Operations Center Overview page, click Servers > Maintenance. In the Maintenance table, review the information in the Last Run Time column. To see when the last maintenance task was started, hover over the clock icon.	The preferred method is to ensure that each maintenance task runs to completion before the next maintenance task starts. Examples of maintenance tasks include inventory expiration, copying of storage pools, space reclamation, and database backup. Tip: If a maintenance task is running too long, change the start time or the maximum runtime. Complete the following steps: 1. On the Operations Center Overview page, hover over the settings icon and click Command Builder. 2. To change the start time or maximum runtime for a task, issue the UPDATE SCHEDULE command. For information about this command, see UPDATE SCHEDULE (Update a client schedule).

- Monitoring tape alert messages for hardware errors
  Tape alert messages are generated by tape and library devices to report hardware errors. These messages help to determine problems that are not related to the IBM Spectrum Protect server.
- Preventing errors caused by media incompatibility
  By monitoring and resolving media compatibility issues, you can prevent errors in an IBM Spectrum Protect tape-based solution. A new drive might have a limited ability to use media formats that are supported by a previous version of the drive. Often, a new drive can read but not write to the previous media format.
- Operations with cleaner cartridges
  To ensure that tape drives are cleaned when necessary, and to avoid issues with tape storage, follow the guidelines.

Monitoring tape alert messages for hardware errors

Tape alert messages are generated by tape and library devices to report hardware errors. These messages help to determine problems that are not related to the IBM Spectrum Protect™ server.

About this task

A log page is created and can be retrieved at any time or at a specific time such as when a drive is dismounted.

A tape alert message can have one of the following severity levels:

- Informational (for example, trying to load a cartridge type that is not supported)
- Warning (for example, a hardware failure is predicted)
- Critical (for example, there is a problem with the tape and data is at risk)

Tape alert messages are turned off by default.

Procedure

- To enable tape alert messages, issue the SET TAPEALERTMSG command and specify the ON value: `set tapealertmsg on`
- To check whether tape alert messages are enabled, issue the QUERY TAPEALERTMSG command: `query tapealertmsg`

Preventing errors caused by media incompatibility

By monitoring and resolving media compatibility issues, you can prevent errors in an IBM Spectrum Protect™ tape-based solution. A new drive might have a limited ability to use media formats that are supported by a previous version of the drive. Often, a new drive can read but not write to the previous media format.

About this task

By default, existing volumes with a status of `FILLING` remain in that state after a drive upgrade. In some cases, you might want to continue to use a previous drive to fill these volumes. This preserves read/write capability for the existing volumes until they are reclaimed. If you choose to upgrade all of the drives in a library, verify that the media formats are supported by the new hardware. Unless you plan to use only the most current media with your new drive, you need to be aware of any compatibility issues. For migration instructions, see Migrating data to upgraded drives.

To use a new drive with media that it can read but not write to, issue the UPDATE VOLUME command to set the access for those volumes to read-only. This prevents errors that are caused by read/write incompatibility. For example, a new drive might eject media that is written in a format that the drive does not support as soon as the media is loaded into the drive. Or a new drive might fail the first write command to media partially written in a format that the drive does not support.

When data on the read-only media expires and the volume is reclaimed, replace it with media that is fully compatible with the new drive. Errors can be generated if a new drive is unable to correctly calibrate a volume that is written when you use a previous format. To avoid this problem, ensure that the original drive is in good working order and at current microcode levels.

Operations with cleaner cartridges

To ensure that tape drives are cleaned when necessary, and to avoid issues with tape storage, follow the guidelines.

Monitoring the cleaning process
: If a cleaner cartridge is checked in to a library, and a drive must be cleaned, the server dismounts the data volume and runs the cleaning operation. If the cleaning operation fails or is canceled, or if no cleaner cartridge is available, you might not be aware that the drive needs cleaning. Monitor cleaning messages for these problems to ensure that drives are cleaned as needed. If necessary, issue the CLEAN DRIVE command to have the server try the cleaning again, or manually load a cleaner cartridge into the drive.

Using multiple cleaner cartridges
: The server uses a cleaner cartridge for the number of cleanings that you specify when you check in the cleaner cartridge. If you check in two or more cleaner cartridges, the server uses only one of the cartridges until the designated number of cleanings for that cartridge is reached. Then, the server uses the next cleaner cartridge. If you check in two or more cleaner cartridges and issue two or more CLEAN DRIVE commands concurrently, the server uses multiple cartridges at the same time and decrements the remaining cleanings on each cartridge.

Related reference:
- AUDIT LIBRARY (Audit volume inventories in an automated library)

- QUERY LIBVOLUME (Query a library volume)

Verifying license compliance

Verify that your IBM Spectrum Protect™ solution complies with the provisions of your licensing agreement. By verifying compliance regularly, you can track trends in data growth or processor value unit (PVU) usage. Use this information to plan for future license purchasing.

About this task

The method that you use to verify that your solution complies with license terms varies depending on the provisions of your IBM Spectrum Protect licensing agreement.

Front-end capacity licensing
: The front-end model determines license requirements based on the amount of primary data that is reported as being backed up by clients. Clients include applications, virtual machines, and systems.

Back-end capacity licensing
: The back-end model determines license requirements based on the terabytes of data that are stored in primary storage pools and repositories.
Tips:

- To ensure the accuracy of front-end and back-end capacity estimates, install the most recent version of the client software on each client node.
- The front-end and back-end capacity information in the Operations Center is for planning and estimation purposes.

PVU licensing
: The PVU model is based on the use of PVUs by server devices.
Important: The PVU calculations that are provided by IBM Spectrum Protect are considered estimates and are not legally binding. The PVU licensing information that is reported by IBM Spectrum Protect is not considered an acceptable substitute for the IBM® License Metric Tool.

For the most recent information about licensing models, see the information about product details and licenses at the IBM Spectrum Protect product family website. If you have questions or concerns about licensing requirements, contact your IBM Spectrum Protect software provider.

Procedure

To monitor license compliance, complete the steps that correspond to the provisions of your licensing agreement.
Tip: The Operations Center provides an email report that summarizes front-end and back-end capacity usage. Reports can be sent automatically to one or more recipients regularly. To configure and manage email reports, click Reports on the Operations Center menu bar.

Option	Description
Front-end model	a. On the Operations Center menu bar, hover over the settings icon and click Licensing. The front-end capacity estimate is displayed on the Front-end Usage page. b. If a value is displayed in the Not Reporting column, click the number to identify clients that did not report capacity usage. c. To estimate capacity for clients that did not report capacity usage, go to the following FTP site, which provides measuring tools and instructions: ftp://public.dhe.ibm.com/storage/tivoli-storage-management/front_end_capacity_measurement_tools To measure front-end capacity by script, complete the instructions in the most recently available licensing guide. d. Add the Operations Center estimate and any estimates that you obtained by using a script. e. Verify that the estimated capacity complies with your licensing agreement.
Back-end model	Restriction: If the source and target replication servers do not use the same policy settings, you cannot use the Operations Center to monitor back-end capacity usage for replicated clients. For information about how to estimate capacity usage for these clients, see technote 1656476. a. On the Operations Center menu bar, hover over the settings icon and click Licensing. b. Click the Back-end tab. c. Verify that the estimated amount of data complies with your licensing agreement.

Option	Description
PVU model	For information about how to assess compliance with PVU licensing terms, see Assessing compliance with the PVU licensing model.

Tracking system status by using email reports

Set up the Operations Center to generate email reports that summarize system status. You can configure a mail server connection, change report settings, and optionally create custom SQL reports.

Before you begin

Before you set up email reports, ensure that the following requirements are met:

- A Simple Mail Transfer Protocol (SMTP) host server is available to send and receive reports by email. The SMTP server must be configured as an open mail relay. You must also ensure that the IBM Spectrum Protect™ server that sends email messages has access to the SMTP server. If the Operations Center is installed on a separate computer, that computer does not require access to the SMTP server.
- To set up email reports, you must have system privilege for the server.
- To specify the recipients, you can enter one or more email addresses or administrator IDs. If you plan to enter an administrator ID, the ID must be registered on the hub server and must have an email address associated with it. To specify an email address for an administrator, use the EMAILADDRESS parameter of the UPDATE ADMIN command.

About this task

You can configure the Operations Center to send a general operations report, a license compliance report, and one or more custom reports, which use SQL SELECT statements to query managed servers.

Procedure

To set up and manage email reports, complete the following steps:

1. On the Operations Center menu bar, click Reports.
2. If an email server connection is not yet configured, click Configure Mail Server and complete the fields. After you configure the mail server, the general operations report and license compliance report are enabled.
3. To change report settings, select a report, click Details, and update the form.
4. Optional: To add a custom SQL report, click + Report, and complete the fields.
   Tip: To immediately run and send a report, select the report and click Send.

Results

Enabled reports are sent according to the specified settings.

What to do next

The general operations report includes an attachment. To find more detailed information, expand the sections in the attachment.

If you cannot view the image in a report, you might be using an email client that converts HTML to another format. For information about restrictions, see the Operations Center online help.

Managing operations for a tape solution

Use this information to manage operations for a tape implementation for an IBM Spectrum Protect™ server.

- Managing the Operations Center
  The Operations Center provides web and mobile access to status information about the IBM Spectrum Protect environment.
- Managing client operations
  You can resolve client errors, manage client upgrades, and decommission client nodes that are no longer required. To free storage space on the server, you can deactivate obsolete data that is stored by application clients.

- Managing data storage
  Manage your data for efficiency and add supported devices and media to the server to store client data.
- Managing tape devices
  Routine tape operations include preparing tape volumes for use, controlling how and when volumes are reused, and ensuring that sufficient volumes are available. You also must respond to operator requests and manage libraries, drives, disks, paths, and data movers.
- Managing tape drives
  You can query, update, and delete tape drives. You can also clean tape drives and configure tape drive encryption and data validation.
- Securing the IBM Spectrum Protect server
  Secure the IBM Spectrum Protect server and data by controlling access to servers and client nodes, encrypting data, and maintaining secure access levels and passwords.
- Stopping and starting the server
  Before you complete maintenance or reconfiguration tasks, stop the server. Then, start the server in maintenance mode. When you are finished with the maintenance or reconfiguration tasks, restart the server in production mode.
- Planning to upgrade the server
  When a fix pack or interim fix becomes available, you can upgrade the IBM Spectrum Protect server to take advantage of product improvements. Servers and clients can be upgraded at different times. Ensure that you complete the planning steps before you upgrade the server.
- Preparing for an outage or system update
  Prepare IBM Spectrum Protect to maintain your system in a consistent state during a planned power outage or system update.
- Preparing for and recovering from a disaster by using DRM
  IBM Spectrum Protect provides a disaster recovery manager (DRM) function to recover your server and client data during a disaster.

Managing the Operations Center

The Operations Center provides web and mobile access to status information about the IBM Spectrum Protect™ environment.

About this task

You can use the Operations Center to monitor multiple servers and to complete some administrative tasks. The Operations Center also provides web access to the IBM Spectrum Protect command line. For more information about managing the Operations Center, see Managing the Operations Center.

Managing client operations

You can resolve client errors, manage client upgrades, and decommission client nodes that are no longer required. To free storage space on the server, you can deactivate obsolete data that is stored by application clients.

About this task

In some cases, you can resolve client errors by stopping and starting the client acceptor. If client nodes or administrator IDs are locked, you can resolve the issue by unlocking the client node or administrator ID, and then resetting the password.

For detailed instructions about identifying and resolving client errors, see Resolving client problems.

For instructions about adding clients, see Protecting applications, virtual machines, and systems.

- Evaluating errors in client error logs
  You can resolve client errors by obtaining suggestions from the Operations Center or by reviewing error logs on the client.
- Stopping and restarting the client acceptor
  If you change the configuration of your solution, you must restart the client acceptor on all client nodes where a backup-archive client is installed.
- Resetting passwords
  If a password for a client node or an administrator ID is lost or forgotten, you can reset the password. Multiple attempts to access the system with an incorrect password can cause a client node or administrator ID to be locked. You can take steps to resolve the issue.
- Managing client upgrades
  When a fix pack or interim fix becomes available for a client, you can upgrade the client to take advantage of product

improvements. Servers and clients can be upgraded at different times and can be at different levels with some restrictions.

- Decommissioning a client node
  If a client node is no longer required, you can start a process to remove it from the production environment. For example, if a workstation was backing up data to the IBM Spectrum Protect server, but the workstation is no longer used, you can decommission the workstation.
- Deactivating data to free storage space
  In some cases, you can deactivate data that is stored on the IBM Spectrum Protect server. When you run the deactivation process, any backup data that was stored before the specified date and time is deactivated and will be deleted as it expires. In this way, you can free space on the server.

Evaluating errors in client error logs

You can resolve client errors by obtaining suggestions from the Operations Center or by reviewing error logs on the client.

Before you begin

Optionally, to resolve errors in a backup-archive client on a Linux or Windows operating system, ensure that the client management service is installed and started. For installation instructions, see Installing the client management service.

Procedure

To diagnose and resolve client errors, take one of the following actions:

- If the client management service is installed on the client node, complete the following steps:
  1. On the Operations Center Overview page, click Clients and select the client.
  2. Click Details.
  3. On the client Summary page, click the Diagnosis tab.
  4. Review the retrieved log messages.
     Tips:
     - To show or hide the Client Logs pane, double-click the Client Logs bar.
     - To resize the Client Logs pane, click and drag the Client Logs bar.

     If suggestions are displayed on the Diagnosis page, select a suggestion. In the Client Logs pane, client log messages to which the suggestion relates are highlighted.
  5. Use the suggestions to resolve the problems that are indicated by the error messages.
     Tip: Suggestions are provided for only a subset of client messages.
- If the client management service is not installed on the client node, review the error logs for the installed client.

Stopping and restarting the client acceptor

If you change the configuration of your solution, you must restart the client acceptor on all client nodes where a backup-archive client is installed.

About this task

In some cases, you can resolve client scheduling problems by stopping and restarting the client acceptor. The client acceptor must be running to ensure that scheduled operations can occur on the client. For example, if you change the IP address or domain name of the server, you must restart the client acceptor.

Procedure

Follow the instructions for the operating system that is installed on the client node:

AIX and Oracle Solaris

- To stop the client acceptor, complete the following steps:
  a. Determine the process ID for the client acceptor by issuing the following command on the command line:

     ```
     ps -ef | grep dsmcad
     ```

     Review the output. In the following sample output, 6764 is the process ID for the client acceptor:

```
root   6764     1    0 16:26:35 ?           0:00 /usr/bin/dsmcad
```

b. Issue the following command on the command line:

```
kill -9 PID
```

where *PID* specifies the process ID for the client acceptor.

- To start the client acceptor, issue the following command on the command line:

```
/usr/bin/dsmcad
```

Linux

- To stop the client acceptor (and not restart it), issue the following command:

```
# service dsmcad stop
```

- To stop and restart the client acceptor, issue the following command:

```
# service dsmcad restart
```

MAC OS X

Click Applications > Utilities > Terminal.

- To stop the client acceptor, issue the following command:

```
/bin/launchctl unload -w com.ibm.tivoli.dsmcad
```

- To start the client acceptor, issue the following command:

```
/bin/launchctl load -w com.ibm.tivoli.dsmcad
```

Windows

- To stop the client acceptor service, complete the following steps:
  a. Click Start > Administrative Tools > Services.
  b. Double-click the client acceptor service.
  c. Click Stop and OK.
- To restart the client acceptor service, complete the following steps:
  a. Click Start > Administrative Tools > Services.
  b. Double-click the client acceptor service.
  c. Click Start and OK.

Resolving client scheduling problems

Resetting passwords

If a password for a client node or an administrator ID is lost or forgotten, you can reset the password. Multiple attempts to access the system with an incorrect password can cause a client node or administrator ID to be locked. You can take steps to resolve the issue.

Procedure

To resolve password issues, take one of the following actions:

- If a backup-archive client is installed on a client node, and the password is lost or forgotten, complete the following steps:
  1. Generate a new password by issuing the UPDATE NODE command:

     ```
     update node node_name new_password forcepwreset=yes
     ```

     where *node_name* specifies the client node and *new_password* specifies the password that you assign.
  2. Inform the client node owner about the changed password. When the owner of the client node logs in with the specified password, a new password is generated automatically. That password is unknown to users to enhance security.
     Tip: The password is generated automatically if you previously set the passwordaccess option to `generate` in the client options file.

- If an administrator is locked out because of password issues, complete the following steps:
  1. To provide the administrator with access to the server, issue the UNLOCK ADMIN command. For instructions, see UNLOCK ADMIN (Unlock an administrator).
  2. Set a new password by using the UPDATE ADMIN command:

     ```
     update admin admin_name new_password forcepwreset=yes
     ```

     where *admin_name* specifies the name of the administrator and *new_password* specifies the password that you assign.
- If a client node is locked, complete the following steps:
  1. Determine why the client node is locked and whether it must be unlocked. For example, if the client node is decommissioned, the client node is being removed from the production environment. You cannot reverse the decommission operation, and the client node remains locked. A client node also might be locked if the client data is the subject of a legal investigation.
  2. If you must unlock a client node, use the UNLOCK NODE command. For instructions, see UNLOCK NODE (Unlock a client node).
  3. Generate a new password by issuing the UPDATE NODE command:

     ```
     update node node_name new_password forcepwreset=yes
     ```

     where *node_name* specifies the name of the node and *new_password* specifies the password that you assign.
  4. Inform the client node owner about the changed password. When the owner of the client node logs in with the specified password, a new password is generated automatically. That password is unknown to users to enhance security.
     Tip: The password is generated automatically if you previously set the passwordaccess option to `generate` in the client options file.

Managing client upgrades

When a fix pack or interim fix becomes available for a client, you can upgrade the client to take advantage of product improvements. Servers and clients can be upgraded at different times and can be at different levels with some restrictions.

Before you begin

1. Review the client/server compatibility requirements in technote 1053218. If your solution includes servers or clients at a level that is earlier than V7.1, review the guidelines to ensure that client backup and archive operations are not disrupted.
2. Verify system requirements for the client in IBM Spectrum Protect™ Supported Operating Systems.
3. If the solution includes storage agents or library clients, review the information about storage-agent and library-client compatibility with servers that are configured as library managers. See technote 1302789.

   If you plan to upgrade a library manager and a library client, you must upgrade the library manager first.

Procedure

To upgrade the software, complete the instructions that are listed in the following table.

Software	Link to instructions
IBM Spectrum Protect backup-archive client	• Upgrading the backup-archive client
IBM Spectrum Protect Snapshot	• Installing and upgrading IBM Spectrum Protect Snapshot for UNIX and Linux • Installing and upgrading IBM Spectrum Protect Snapshot for VMware • Installing and upgrading IBM Spectrum Protect Snapshot for Windows
IBM Spectrum Protect for Databases	• Upgrading Data Protection for SQL Server • Data Protection for Oracle installation • Installing, upgrading, and migrating IBM Spectrum Protect for Mail: Data Protection for Microsoft Exchange Server

Software	Link to instructions
IBM Spectrum Protect for Enterprise Resource Planning	• Upgrading IBM Spectrum Protect for Enterprise Resource Planning: Data Protection for SAP for DB2® • Upgrading IBM Spectrum Protect for Enterprise Resource Planning: Data Protection for SAP for Oracle
IBM Spectrum Protect for Mail	• Installation of Data Protection for IBM Domino on a UNIX, AIX, or Linux system (V7.1.0) • Installation of Data Protection for IBM Domino on a Windows system (V7.1.0) • Installing, upgrading, and migrating IBM Spectrum Protect for Mail: Data Protection for Microsoft Exchange Server
IBM Spectrum Protect for Virtual Environments	• Installing and upgrading Data Protection for VMware • Installing Data Protection for Microsoft Hyper-V

Decommissioning a client node

If a client node is no longer required, you can start a process to remove it from the production environment. For example, if a workstation was backing up data to the IBM Spectrum Protect™ server, but the workstation is no longer used, you can decommission the workstation.

About this task

When you start the decommission process, the server locks the client node to prevent it from accessing the server. Files that belong to the client node are gradually deleted, and then the client node is deleted. You can decommission the following types of client nodes:

Application client nodes
: Application client nodes include email servers, databases, and other applications. For example, any of the following applications can be an application client node:

  - IBM Spectrum Protect Snapshot
  - IBM Spectrum Protect for Databases
  - IBM Spectrum Protect for Enterprise Resource Planning
  - IBM Spectrum Protect for Mail
  - IBM Spectrum Protect for Virtual Environments

System client nodes
: System client nodes include workstations, network-attached storage (NAS) file servers, and API clients.

Virtual machine client nodes
: Virtual machine client nodes consist of an individual guest host within a hypervisor. Each virtual machine is represented as a file space.

The simplest method for decommissioning a client node is to use the Operations Center. The decommission process runs in the background. If the client is configured to replicate client data, the Operations Center automatically removes the client from replication on the source and target replication servers before it decommissions the client.
Tip: Alternatively, you can decommission a client node by issuing the DECOMMISSION NODE or DECOMMISSION VM command. You might want to use this method in the following cases:

- To schedule the decommission process for the future or to run a series of commands by using a script, specify the decommission process to run in the background.
- To monitor the decommission process for debugging purposes, specify the decommission process to run in the foreground. If you run the process in the foreground, you must wait for the process to be completed before you continue with other tasks.

Procedure

Take one of the following actions:

- To decommission a client in the background by using the Operations Center, complete the following steps:
  1. On the Operations Center Overview page, click Clients and select the client.
  2. Click More > Decommission.
- To decommission a client node by using an administrative command, take one of the following actions:
  - To decommission an application or system client node in the background, issue the DECOMMISSION NODE command. For example, if the client node is named AUSTIN, issue the following command:

    ```
    decommission node austin
    ```

  - To decommission an application or system client node in the foreground, issue the DECOMMISSION NODE command and specify the `wait=yes` parameter. For example, if the client node is named AUSTIN, issue the following command:

    ```
    decommission node austin wait=yes
    ```

  - To decommission a virtual machine in the background, issue the DECOMMISSION VM command. For example, if the virtual machine is named AUSTIN, the file space is 7, and the file space name is specified by the file space ID, issue the following command:

    ```
    decommission vm austin 7 nametype=fsid
    ```

    If the virtual machine name includes one or more spaces, enclose the name in double quotation marks. For example:

    ```
    decommission vm "austin 2" 7 nametype=fsid
    ```

  - To decommission a virtual machine in the foreground, issue the DECOMMISSION VM command and specify the `wait=yes` parameter. For example, issue the following command:

    ```
    decommission vm austin 7 nametype=fsid wait=yes
    ```

    If the virtual machine name includes one or more spaces, enclose the name in double quotation marks. For example:

    ```
    decommission vm "austin 2" 7 nametype=fsid wait=yes
    ```

What to do next

Watch for error messages, which might be displayed in the user interface or in the command output, immediately after you run the process.

You can verify that the client node is decommissioned:

1. On the Operations Center Overview page, click Clients.
2. In the Clients table, in the At risk column, review the state:
   - A DECOMMISSIONED state specifies that the node is decommissioned.
   - A null value specifies that the node is not decommissioned.
   - A PENDING state specifies that the node is being decommissioned, or the decommission process failed.

   Tip: If you want to determine the status of a pending decommission process, issue the following command:

   ```
   query process
   ```

3. Review the command output:
   - If status is provided for the decommission process, the process is in progress. For example:

     ```
     query process

      Process     Process Description           Process Status
       Number
     --------     --------------------     -------------------------------------------
            3          DECOMMISSION NODE        Number of backup objects deactivated
                                                for node NODE1: 8 objects deactivated.
     ```

   - If no status is provided for the decommission process, and you did not receive an error message, the process is incomplete. A process can be incomplete if files that are associated with the node are not yet deactivated. After the files are deactivated, run the decommission process again.
   - If no status is provided for the decommission process, and you receive an error message, the process failed. Run the decommission process again.

DECOMMISSION NODE (Decommission a client node)

DECOMMISSION VM (Decommission a virtual machine)

Deactivating data to free storage space

In some cases, you can deactivate data that is stored on the IBM Spectrum Protect™ server. When you run the deactivation process, any backup data that was stored before the specified date and time is deactivated and will be deleted as it expires. In this way, you can free space on the server.

About this task

Some application clients always save data to the server as active backup data. Because active backup data is not managed by inventory expiration policies, the data is not deleted automatically, and uses server storage space indefinitely. To free the storage space that is used by obsolete data, you can deactivate the data.

When you run the deactivation process, all active backup data that was stored before the specified date becomes inactive. The data is deleted as it expires and cannot be restored. The deactivation feature applies only to application clients that protect Oracle databases.

Procedure

1. From the Operations Center Overview page, click Clients.
2. In the Clients table, select one or more clients and click More > Clean Up.
   Command-line method: Deactivate data by using the DEACTIVATE DATA command.

Related reference:
DEACTIVATE DATA (Deactivate data for a client node)

Managing data storage

Manage your data for efficiency and add supported devices and media to the server to store client data.

- Managing inventory capacity
  Manage the capacity of the database, active log, and archive logs to ensure that the inventory is sized for the tasks, based on the status of the logs.
- Tuning scheduled activities
  Schedule maintenance tasks daily to ensure that your solution operates correctly. By tuning your solution, you maximize server resources and effectively use different functions available within your solution.
- Optimizing operations by enabling collocation of client files
  Collocation of client files reduces the number of volume mounts that are required when users restore, retrieve, or recall many files from a storage pool. Collocation thus reduces the amount of time that is required for these operations.

Related reference:
Types of storage pools

Managing inventory capacity

Manage the capacity of the database, active log, and archive logs to ensure that the inventory is sized for the tasks, based on the status of the logs.

Before you begin

The active and archive logs have the following characteristics:

- The active log can be a maximum size of 512 GB. For more information about sizing the active log for your system, see Planning the storage arrays.
- The archive log size is limited to the size of the file system that it is installed on. The archive log size is not maintained at a predefined size like the active log. Archive log files are automatically deleted after they are no longer needed.

As a best practice, you can optionally create an archive failover log to store archive log files when the archive log directory is full.

Check the Operations Center to determine the component of the inventory that is full. Ensure that you stop the server before you increase the size of one of the inventory components.

Procedure

- To increase the disk space for the database, complete the following steps:
  - Create one or more directories for the database on separate drives or file systems.
  - Issue the EXTEND DBSPACE command to add the directory or directories to the database. The directories must be accessible to the instance user ID of the database manager. By default, data is redistributed across all database directories and space is reclaimed.
    Tips:
    - The time that is needed to complete redistribution of data and reclaiming of space is variable, depending on the size of your database. Make sure that you plan adequately.
    - Ensure that the directories that you specify are the same size as existing directories to ensure a consistent degree of parallelism for database operations. If one or more directories for the database are smaller than the others, they reduce the potential for optimized parallel prefetching and distribution of the database.
  - Halt and restart the server to fully use the new directories.
  - Reorganize the database if necessary. Index and table reorganization for the server database can help to avoid unexpected database growth and performance issues. For more information about reorganizing the database, see technote 1683633.
- To decrease the size of the database for V7.1 servers and later, see the information in technote 1683633.
  Restriction: The commands can increase I/O activity, and might affect server performance. To minimize performance problems, wait until one command is completed before you issue the next command. The DB2® commands can be issued when the server is running.
- To increase or decrease the size of the active log, complete the following steps:
  1. Ensure that the location for the active log has enough space for the increased log size.
  2. Halt the server.
  3. In the dsmserv.opt file, update the ACTIVELOGSIZE option to the new size of the active log, in megabytes.
     The size of an active log file is based on the value of the ACTIVELOGSIZE option. Guidelines for space requirements are in the following table:

     Table 1. How to estimate volume and file space requirements

ACTIVELOGSize option value	Reserve this much free space in the active log directory, in addition to the ACTIVELOGSize space
16 GB - 128 GB	5120 MB
129 GB - 256 GB	10240 MB
257 GB - 512 GB	20480 MB

     To change the active log to its maximum size of 512 GB, enter the following server option:

     ```
     activelogsize 524288
     ```

  4. If you plan to use a new active log directory, update the directory name that is specified in the ACTIVELOGDIRECTORY server option. The new directory must be empty and must be accessible to the user ID of the database manager.
  5. Restart the server.
- Compress the archive logs to reduce the amount of space that is required for storage. Enable dynamic compression of the archive log by issuing the following command:

  ```
  setopt archlogcompress yes
  ```

  Restriction: Use caution when you enable the ARCHLOGCOMPRESS server option on systems with sustained high volume usage and heavy workloads. Enabling this option in this system environment can cause delays in archiving log files from the active log file system to the archive log file system. This delay can cause the active log file system to run out of space. Be sure to monitor the available space in the active log file system after archive log compression is enabled. If the active log directory file system usage nears out of space conditions, the ARCHLOGCOMPRESS server option must be disabled. You can use the SETOPT command to disable archive log compression immediately without halting the server.

Related reference:
ACTIVELOGSIZE server option
EXTEND DBSPACE (Increase space for the database)
SETOPT (Set a server option for dynamic update)

Tuning scheduled activities

Schedule maintenance tasks daily to ensure that your solution operates correctly. By tuning your solution, you maximize server resources and effectively use different functions available within your solution.

Procedure

1. Monitor system performance regularly to ensure that backup and maintenance tasks are completing successfully. For more information about monitoring, see Monitoring a tape solution.
2. If the monitoring information shows that the server workload increased, you might need to review the planning information. Review whether the capacity of the system is adequate in the following cases:
   - The number of clients increases
   - The amount of data that is being backed up increases
   - The amount of time that is available for backups changes
3. Determine whether your solution has performance issues. Review the client schedules to check whether tasks are completing within the scheduled time frame:
   a. On the Clients page of the Operations Center, select the client.
   b. Click Details.
   c. From the client Summary page, review the Backed up and Replicated activity to identify any risks.

   Adjust the time and frequency of client backup operations, if necessary.
4. Schedule enough time for the following maintenance tasks to complete successfully within a 24-hour period:
   a. Back up the database
   b. Run expiration to remove client backups and archive file copies from server storage.

Deduplicating data (V7.1.1)

Optimizing operations by enabling collocation of client files

Collocation of client files reduces the number of volume mounts that are required when users restore, retrieve, or recall many files from a storage pool. Collocation thus reduces the amount of time that is required for these operations.

About this task

With collocation enabled, the server tries to keep files on a minimal number of sequential-access storage volumes. The files can belong to a single client node, a group of client nodes, a client file space, or a group of file spaces. You can set collocation for each sequential-access storage pool when you define or update the pool.

Figure 1 shows an example of collocation by client node with three clients, each having a separate volume that contains that client's data.

Figure 1. Example of collocation enabled by node

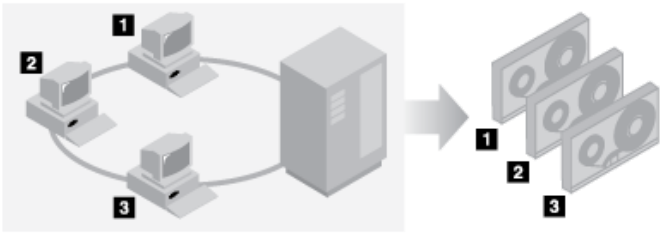

Figure 2 shows an example of collocation by group of client nodes. Three groups are defined, and the data for each group is stored on separate volumes.

Figure 2. Example of collocation enabled by node collocation group

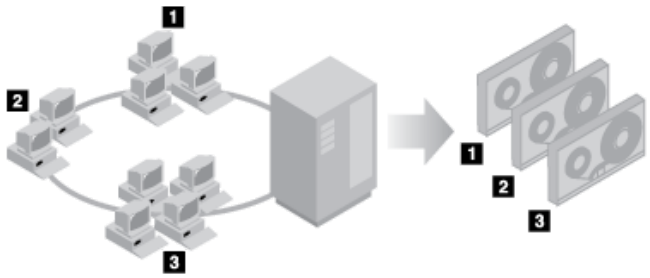

Figure 3 shows an example of collocation by file space group. Six groups are defined. Each group contains data from file spaces that belong to a single node. The data for each group is stored on a separate volume.

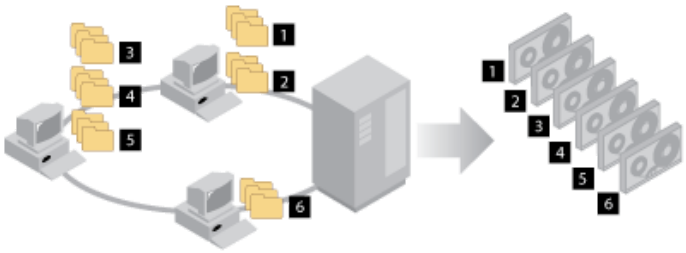
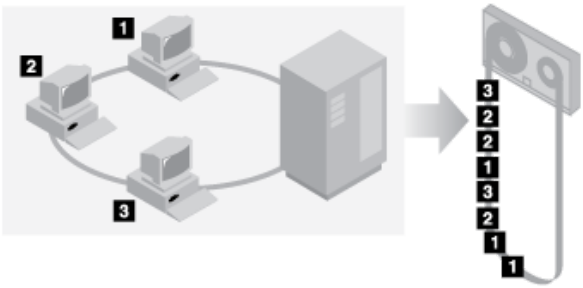
Figure 3. Example of collocation enabled by file space collocation group



When collocation is disabled, the server tries to use all available space on each volume before it selects a new volume. While this process provides better use of individual volumes, user files can become scattered across many volumes. Figure 4 shows an example of collocation that is disabled, with three clients that share space on single volume.

Figure 4. Example of collocation disabled



With collocation disabled, more media mount operations might be required to mount volumes when users restore, retrieve, or recall many files.

Collocation by group is the IBM Spectrum Protect™ system default for primary sequential-access storage pools. The default for copy storage pools is no collocation.

- Effects of collocation on operations
  The effect of collocation on resources and system performance depends on the type of operation that is being run.
- Selecting volumes with collocation enabled
  Volume selection depends on whether collocation is by group, node, or file space.
- Selecting volumes with collocation disabled
  When collocation is disabled, the server attempts to use all available space in a storage volume before it accesses another volume.
- Collocation settings
  After you define a storage pool, you can change the collocation setting by updating the storage pool. The change in collocation for the pool does not affect files that are already stored in the pool.
- Collocation of copy storage pools
  Using collocation on copy storage pools requires special consideration. Collocation of copy storage pools, especially by node or file space, results in more partially filled volumes and potentially unnecessary offsite reclamation activity.

- Planning for and enabling collocation
  Understanding the effects of collocation can help reduce the number of media mounts, make better use of space on sequential volumes, and improve the efficiency of server operations.

Effects of collocation on operations

The effect of collocation on resources and system performance depends on the type of operation that is being run.

Table 1 summarizes the effects of collocation on operations.

Table 1. Effect of collocation on operations

Operation	Collocation enabled	Collocation disabled
Backing up, archiving, or migrating client files	More media mounts to collocate files.	Fewer media mounts are required.
Restoring, retrieving, or recalling client files	Large numbers of files can be restored, retrieved, or recalled more quickly because files are on fewer volumes.	Multiple mounts of media might be required for a single user because files might be spread across multiple volumes. More than one user's files can be stored on the same sequential-access storage volume. For example, if two users try to recover a file that is on the same volume, the second user is forced to wait until the first user's files are recovered.
Storing data on tape	The server attempts to use all available tape volumes to separate user files before it uses all available space on every tape volume.	The server attempts to use all available space on each tape volume before the server use another tape volume.
Media mount operations	More mount operations are required when user files are backed up, archived, or migrated from client nodes directly to sequential-access volumes. More mount operations are required during reclamation and storage pool migration. More volumes are managed because volumes are not fully used.	More mount operations are required during restore, retrieve, and recall of client files.
Generating backup sets	Less time is spent searching database entries, and fewer mount operations are required.	More time is spent searching database entries and fewer mount operations are required.

When collocation is enabled for a group, single client node, or file space, all the data that belongs to the group, the node, or the file space is moved or copied by one server process. For example, if data is collocated by group, all data for all nodes that belong to the same collocation group is migrated by the same process.

When collocating data, the IBM Spectrum Protect™ server tries to keep files together on a minimal number of sequential-access storage volumes. However, when the server is backing up data to volumes in a sequential-access storage pool, the backup process has priority over collocation settings. As a result, the server completes the backup operation, but might not be able to collocate the data.

For example, suppose that you are collocating by node and you specify that a node can use two mount points on the server. Suppose also that the data that is backed up from the node can easily fit on one tape volume. During backup, the server might mount two tape volumes, and the node's data might be distributed across two tapes, rather than one. If you enable collocation, the following server operations use one server process:

- Moving data from random-access and sequential-access volumes
- Moving node data from sequential-access volumes
- Backing up a random-access or sequential-access storage pool

- Restoring a sequential-access storage pool
- Reclaiming space in a sequential-access storage pool or offsite volumes
- Migrating data from a random-access storage pool

When you migrate data from a random-access disk storage pool to a sequential-access storage pool, and collocation is by node or file space, nodes or file spaces are automatically selected for migration based on the amount of data to be migrated. The node or file space with the most data is migrated first. If collocation is by group, all nodes in the storage pool are evaluated to determine which node has the most data. The node with the most data is migrated first along with all the data for all the nodes that belong to that collocation group. This process occurs, regardless of how much data is stored in the file spaces of nodes and regardless of whether the low migration threshold was reached.

However, when you migrate collocated data from a sequential-access storage pool to another sequential-access storage pool, the server orders the volumes according to the date when the volume was last accessed. The volume with the earliest access date is migrated first, and the volume with the latest access date is migrated last.

One reason to collocate by group is that individual client nodes often do not have sufficient data to fill high-capacity tape volumes. Collocating data by groups of nodes can reduce unused tape capacity by putting more collocated data on individual tapes. Also, collocating data by groups of file spaces reduces the unused tape to a greater degree.

The data that belongs to all the nodes in the same collocation group are migrated by the same process. Therefore, collocation by group can reduce the number of times that a volume to be migrated must be mounted. Collocation by group can also minimize database scanning and reduce tape passes during data transfer from one sequential-access storage pool to another.

Selecting volumes with collocation enabled

Volume selection depends on whether collocation is by group, node, or file space.

Table 1 shows how the IBM Spectrum Protect™ server selects the first volume when collocation is enabled for a storage pool at the client-node, collocation-group, and file-space level.

Table 1. How the server selects volumes when collocation is enabled

Volume Selection Order	When collocation is by group	When collocation is by node	When collocation is by file space
1	A volume that already contains files from the collocation group to which the client belongs	A volume that already contains files from the same client node	A volume that already contains files from the same file space of that client node
2	An empty predefined volume	An empty predefined volume	An empty predefined volume
3	An empty scratch volume	An empty scratch volume	An empty scratch volume
4	A volume with the most available free space among volumes that already contain data	A volume with the most available free space among volumes that already contain data	A volume that contains data from the same client node
5	Not applicable	Not applicable	A volume with the most available free space among volumes that already contain data

When the server must continue to store data on a second volume, it uses the following selection order to acquire more space:

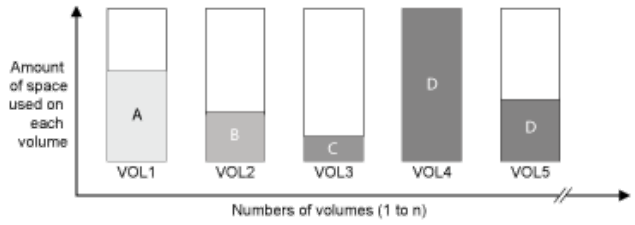
1. An empty predefined volume
2. An empty scratch volume
3. A volume with the most available free space among volumes that already contain data
4. Any available volume in the storage pool

When collocation is by client node or file space, the server tries to provide the best use of individual volumes and minimizes file mixing from different clients or file spaces on volumes. This configuration is depicted in Figure 1, which shows that volume selection is *horizontal*, where all available volumes are used before all available space on each volume is used. A, B, C, and D represent files from four different client nodes.
Tips:

1. If collocation is by node and the node has multiple file spaces, the server does not attempt to collocate those file spaces.

2. If collocation is by file space and a node has multiple file spaces, the server attempts to put data for different file spaces on different volumes.

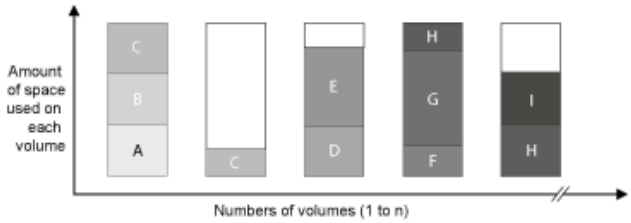
Figure 1. Using all available sequential-access storage volumes with collocation enabled at the node or file space level



Collocation can be by file space group or node group. When collocation is by node group (node collocation group), the server tries to collocate data from nodes that belong to the same collocation group. A file space collocation group uses the same methods as a node collocation group, but can use more space because of the granularity of file space sizes. As shown in Figure 2, data for the following groups of nodes was collocated:

- Group 1 consists of nodes A, B, and C
- Group 2 consists of nodes D and E
- Group 3 consists of nodes F, G, H, and I

Whenever possible, the IBM Spectrum Protect server collocates data that belongs to a group of nodes on a single tape, as represented by Group 2 in the figure. Data for a single node can also be spread across several tapes that are associated with a group (Group 1 and 2). If the nodes in the collocation group have multiple file spaces, the server does not attempt to collocate those file spaces.
Figure 2. Using all available sequential-access storage volumes with collocation enabled at the group level



Normally, the IBM Spectrum Protect server always writes data to the current filling volume for the operation that is running. However, occasionally you might notice more than one filling volume in a collocated storage pool. Having more than one filling volume in a collocated storage pool can occur if different server processes or client sessions try to store data into the collocated pool at the same time. In this situation, IBM Spectrum Protect allocates a volume for each process or session that needs a volume so that both operations are completed as quickly as possible.

Selecting volumes with collocation disabled

When collocation is disabled, the server attempts to use all available space in a storage volume before it accesses another volume.

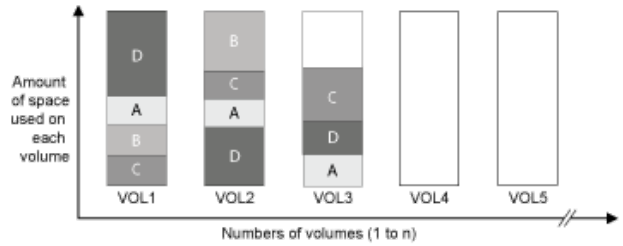
When you store client files in a sequential-access storage pool where collocation is disabled, the server selects a volume by using the following selection order:

1. A previously used sequential volume with available space (a volume with the most amount of data is selected first)
2. An empty volume

When the server needs to continue to store data on a second volume, it attempts to select an empty volume. If no empty volume exists, the server attempts to select any remaining available volume in the storage pool.

Figure 1 shows that volume use is vertical when collocation is disabled. In this example, fewer volumes are used because the server attempts to use all available space by mixing client files on individual volumes. A, B, C, and D represent files from four different client nodes.

Figure 1. Using all available space on sequential-access volumes with collocation disabled



Collocation settings

After you define a storage pool, you can change the collocation setting by updating the storage pool. The change in collocation for the pool does not affect files that are already stored in the pool.

For example, if collocation is off for a storage pool and you turn it on, from then on client files that are stored in the pool are collocated. Files that were previously stored in the storage pool are not moved to collocate them. As volumes are reclaimed, the data in the pool tends to become more collocated. You can also use the MOVE DATA or MOVE NODEDATA commands to move data to new volumes to increase collocation. Moving data to new volumes causes an increase in the processing time and the volume mount activity.
Tip: A mount wait can occur or take longer than usual when collocation by file space is enabled and a node has a volume that contains multiple file spaces. If a volume is eligible to receive data, IBM Spectrum Protect™ waits for that volume.

Collocation of copy storage pools

Using collocation on copy storage pools requires special consideration. Collocation of copy storage pools, especially by node or file space, results in more partially filled volumes and potentially unnecessary offsite reclamation activity.

Primary storage pools play a different recovery role than copy storage pools. Normally, you use primary storage pools to recover data to clients directly. In a disaster, when both clients and the server are lost, you might use offsite copy storage pool volumes to recover the primary storage pools. The types of recovery scenarios can help you to determine whether to use collocation on your copy storage pools.

Collocation typically results in partially filled volumes when you collocate by node or by file space. However, partially filled volumes are less prevalent when you collocate by group. Partially filled volumes might be acceptable for primary storage pools because the volumes remain available and can be filled during the next migration process. However, partially filled volumes might be unacceptable for copy storage pools whose storage pool volumes are taken offsite immediately. If you use collocation for copy storage pools, you must make the following decisions:

- Taking more partially filled volumes offsite, which increases the reclamation activity when the reclamation threshold is lowered or reached.
- Leaving these partially filled volumes onsite until they fill and risk not having an offsite copy of the data on these volumes.
- Whether to collocate by group to use as much tape capacity as possible.

When collocation is disabled for a copy storage pool, typically only a few partially filled volumes remain after data is backed up to the copy storage pool.

Consider your options carefully before you use collocation for copy storage pools, and whether to use simultaneous write. If you do not use simultaneous write and you use collocation for your primary storage pools, you might want to disable collocation for copy storage pools. Collocation of copy storage pools might be desirable if you have few clients with each of them having large amounts of incremental backup data each day. For collocation with simultaneous write, you must ensure that the collocation settings are identical for the primary storage pools and copy storage pools.

Planning for and enabling collocation

Understanding the effects of collocation can help reduce the number of media mounts, make better use of space on sequential volumes, and improve the efficiency of server operations.

About this task

Table 1 lists the four collocation options that you can specify on the DEFINE STGPOOL and UPDATE STGPOOL commands. The table also shows the effects of collocation on data that belongs to nodes that are and are not members of collocation groups.

Table 1. Collocation options and the effects on node data

Collocation option	If a node is not defined as a member of a collocation group	If a node is defined as a member of a collocation group
No	The data for the node is not collocated.	The data for the node is not collocated.
Group	The server stores the data for the node on as few volumes in the storage pool as possible.	The server stores the data for the node and for other nodes that belong to the same collocation group on as few volumes as possible.
Node	The server stores the data for the node on as few volumes as possible.	The server stores the data for the node on as few volumes as possible.
File space	The server stores the data for the node's file space on as few volumes as possible. If a node has multiple file spaces, the server stores the data for different file spaces on different volumes in the storage pool.	The server stores the data for the node's file space on as few volumes as possible. If a node has multiple file spaces, the server stores the data for different file spaces on different volumes in the storage pool.

Table 2. Collocation group options and effects on file space data

Collocation option	If a file space is not defined as a member of a collocation group	If a file space is defined as a member of a collocation group
No	The data for the file space is not collocated.	The data for the file space is not collocated.
Group	The server stores the data for the file space on as few volumes in the storage pool as possible.	The server stores the data for the file space and other file spaces that belong to the same collocation group on as few volumes as possible.
Node	The server stores the data for the node on as few volumes as possible.	The server stores the data for the node on as few volumes as possible.
File space	The server stores the data for the node's file space on as few volumes as possible. If a node has multiple file spaces, the server stores the data for different file spaces on different volumes in the storage pool.	The server stores the data for the file spaces on as few volumes as possible. If a node has multiple file spaces, the server stores the data for different file spaces on different volumes in the storage pool.

Procedure

To determine whether and how to collocate data, complete the following steps:

1. Determine how to organize data, whether by client node, group of client nodes, or file space. To collocate by group, you must decide how to group nodes:
   - If the goal is to save space, you might want to group small nodes together to better use tapes.
   - If the goal is potentially faster client restores, group nodes together so that they fill as many tapes as possible. By grouping nodes together, the individual node data is distributed across two or more tapes and that more tapes can be mounted simultaneously during a multi-session no-query restore operation.
   - If the goal is to departmentalize data, you can group nodes by department.
2. To collocate groups, complete the following steps:
   a. Define collocation groups with the DEFINE COLLOCGROUP command.
   b. Add client nodes to the collocation groups with the DEFINE COLLOCMEMBER command.

   The following query commands are available to help in collocating groups:

   QUERY COLLOCGROUP
   : Displays the collocation groups that are defined on the server.

   QUERY NODE
   : Displays the collocation group, if any, to which a node belongs.

   QUERY NODEDATA
   : Displays information about the data for one or more nodes in a sequential-access storage pool.

   QUERY STGPOOL
   : Displays information about the location of client data in a sequential-access storage pool and the amount of space a node occupies in a volume.

You can also use IBM Spectrum Protect™ server scripts or PerlL scripts to display information that can be useful in defining collocation groups.

3. Specify how data must be collocated in a storage pool by issuing the DEFINE STGPOOL or UPDATE STGPOOL command and specifying the COLLOCATE parameter.

What to do next

Tip: To reduce the number of media mounts, use space on sequential volumes more efficiently, and enable collocation, complete the following steps:

- Define a storage pool hierarchy and policy to require that backed-up, archived, or space-managed files are initially stored in disk storage pools.

  When files are migrated from a disk storage pool, the server attempts to migrate all files that belong to the client node or collocation group that is using the most disk space in the storage pool. This process works well with the collocation option because the server tries to place all of the files from a particular client on the same sequential-access storage volume.

- Use scratch volumes for sequential-access storage pools to allow the server to select new volumes for collocation.
- Specify the client option COLLOCATEBYFILESPEC to limit the number of tapes to which objects associated with one file specification are written. This collocation option makes collocation by the server more efficient; it does not override collocation by file space or collocation by node.

Managing tape devices

Routine tape operations include preparing tape volumes for use, controlling how and when volumes are reused, and ensuring that sufficient volumes are available. You also must respond to operator requests and manage libraries, drives, disks, paths, and data movers.

- Preparing removable media
  You must prepare removable media before it can be used to store data. Typical preparation tasks include labeling and checking in volumes.
- Managing volume inventory
  You can manage volume inventory by controlling the server's access to volumes, by reusing tapes, and by reusing volumes that are used for database backup and export operations. You can also manage inventory by maintaining a supply of scratch volumes.
- Partially written volumes
  Partially written volumes are always private volumes, even if their status was scratch before the server mounted them. The server tracks the original status of scratch volumes and returns them to scratch status when they are empty.
- Operations with shared libraries
  Shared libraries are logical libraries that are represented physically by SCSI libraries. The physical library is controlled by the IBM Spectrum Protect server that is configured as a library manager. IBM Spectrum Protect servers that use the SHARED library type are library clients to the IBM Spectrum Protect library manager server.
- Managing server requests for volumes
  IBM Spectrum Protect displays requests and status messages to all administrative command-line clients that are started in console mode. These request messages often have a time limit. Successful server operations must be completed within the time limit that is specified; otherwise, the operation times out.

Preparing removable media

You must prepare removable media before it can be used to store data. Typical preparation tasks include labeling and checking in volumes.

About this task

When IBM Spectrum Protect™ accesses a removable media volume, it verifies the volume name in the label header to ensure that the correct volume is accessed.

Tape volumes must be labeled before the server can use them.

Procedure

To prepare a volume for use, complete the following steps:

1. Label the volume by issuing the LABEL LIBVOLUME command.
2. For automated libraries, check the volume into the library. For instructions, see Checking volumes into an automated library,
   Tip: When you use the LABEL LIBVOLUME command with drives in an automated library, you can label and check in the volumes with one command.
3. If the storage pool cannot contain scratch volumes (`MAXSCRATCH=0`), identify the volume to IBM Spectrum Protect by name so that the volume can be accessed later.

   If the storage pool can contain scratch volumes (MAXSCRATCH is set to a non-zero value), skip this step.

- Labeling tape volumes
  You must label tape volumes before the server can use them.
- Checking volumes into an automated library
  You can check in a volume to an automated library by using the CHECKIN LIBVOLUME command.

Labeling tape volumes

You must label tape volumes before the server can use them.

About this task

For automated libraries, you are prompted to insert the volume in the entry/exit slot of the library. If no convenience input/output (I/O) station is available, insert the volume into an empty slot. You can label the volumes when you check them in or before you check them in.

Procedure

To label tape volumes before you check them in, complete the following steps:

1. Label tape volumes by issuing the LABEL LIBVOLUME command. For example, to name a library volume VOLUME1 in a library that is named LIBRARY 1, issue the following command:

   ```
   label libvolume library1 volume1
   ```

   Requirement: At least one drive must be available. The drive cannot be used by another IBM Spectrum Protect™ process. If a drive is idle, the drive is considered to be unavailable.
2. To overwrite an existing label, specify the `OVERWRITE=YES` parameter. By default, the LABEL LIBVOLUME command does not overwrite an existing label.

- Labeling volumes in a SCSI library
  You can label volumes individually or use IBM Spectrum Protect to search the library for volumes and label the found volumes.

Related tasks:
Labeling new volumes by using AUTOLABEL
Related reference:
LABEL LIBVOLUME (Label a library volume)

Checking volumes into an automated library

You can check in a volume to an automated library by using the CHECKIN LIBVOLUME command.

Before you begin

To automatically label tapes before you check them in, issue the DEFINE LIBRARY command and specify the AUTOLABEL=YES parameter. By using the AUTOLABEL parameter, you eliminate the need to prelabel a set of tapes.

About this task

Each volume that is used by a server for any purpose must have a unique name. This requirement applies to all volumes, whether the volumes are used for storage pools, or used for operations such as database backup or export. The requirement also applies to volumes that are in different libraries but that are used by the same server.

Tips:

- Do not use a single library for volumes that have bar code labels and volumes that do not have bar code labels. Bar code scanning can take a long time for unlabeled volumes.
- The server accepts only tapes that are labeled with IBM® standard labels.
- Any volume that has a bar code that begins with `CLN` is treated as a cleaning tape.
- If a volume has an entry in volume history, you cannot check it in as a scratch volume.

Procedure

1. To check a storage volume into a library, issue the CHECKIN LIBVOLUME command.
   Tip: The command always runs as a background process. Wait for the CHECKIN LIBVOLUME process to complete processing before you define volumes, or the defining process fails. You can save time by checking in volumes as part of the labeling operation.
2. Name the library and specify whether the volume is a private volume or a scratch volume. Depending on whether you use scratch volumes or private volumes, complete one of the following steps:
   - If you use only scratch volumes, ensure that enough scratch volumes are available. For example, you might need to label more volumes. As volumes are used, you might also need to increase the number of scratch volumes that are allowed in the storage pool that you defined for this library.
   - If you want to use private volumes in addition to or instead of scratch volumes in the library, define volumes to the storage pool by using the DEFINE VOLUME command. You must label and check in the volumes that you define.

- Checking a single volume into a SCSI library
  You can check in a single volume by issuing the CHECKIN LIBVOLUME command and specifying the SEARCH=NO parameter. IBM Spectrum Protect™ requests that the mount operator load the volume into the entry/exit port of the library.
- Checking in volumes from library storage slots
  When you have many volumes to check in and you want to avoid issuing a CHECKIN LIBVOLUME command for each volume, you can search storage slots for new volumes. The server finds volumes that have not yet been added to the volume inventory.
- Checking in volumes from library entry/exit ports
  You can search all slots of bulk entry/exit ports for labeled volumes and the server can check them in automatically.
- Checking in volumes by using library bar code readers
  You can save time when you check in volumes to libraries that have bar code readers by using the characters on the bar code labels as names for the volumes.
- Checking in volumes by using a bar code reader
  You can save time when you check in volumes by using a bar code reader, if your library has one.
- Checking volumes into a full library with swapping
  If no empty slots are available in the library when you are checking in volumes, the check-in operation fails unless you enable *swapping*. If you enable swapping and the library is full, the server selects a volume to eject and then checks in the volume that you requested.
- Windows Private volumes and scratch volumes
  To optimize tape storage, review the information about private volumes and scratch volumes. Use private volumes and scratch volumes appropriately.
- Windows Element addresses for library storage slots
  An element address is a number that indicates the physical location of a storage slot or drive within an automated library.

Related tasks:
Labeling tape volumes

Checking a single volume into a SCSI library

You can check in a single volume by issuing the CHECKIN LIBVOLUME command and specifying the SEARCH=NO parameter. IBM Spectrum Protect™ requests that the mount operator load the volume into the entry/exit port of the library.

Procedure

1. Issue the CHECKIN LIBVOLUME command.

For example, to check in volume VOL001, enter the following command:

```
checkin libvolume tapelib vol001 search=no status=scratch
```

2. Respond to the prompt from the server.
   - If the library has an entry/exit port, you are prompted to insert a tape into the entry/exit port.
   - If the library does not have an entry/exit port, you are prompted to insert a tape into one of the slots in the library. Element addresses identify these slots. For example, the server finds that the first empty slot is at element address 5. The following message is returned:

     ```
     ANR8306I 001: Insert 8MM volume VOL001 R/W in slot with element
     address 5 of library TAPELIB within 60 minutes; issue 'REPLY' along
     with the request ID when ready.
     ```

     If you do not know the location of element address 5 in the library, check the worksheet for the device. To find the worksheet, review the documentation for your library. After you insert the volume as requested, respond to the message from an IBM Spectrum Protect administrative client. Issue the REPLY command, followed by the request number (the number at the beginning of the mount request) for example:

     ```
     reply 1
     ```

     Tip: Element addresses are sometimes numbered starting with a number other than 1. Check the worksheet to be sure. If no worksheet is listed for your device in IBM® Support Portal for IBM Spectrum Protect, see the documentation for your library.

If you specify a wait time of 0 by using the optional WAITTIME parameter on the CHECKIN LIBVOLUME command, a REPLY command is not required. The default wait time is 60 minutes.

Checking in volumes from library storage slots

When you have many volumes to check in and you want to avoid issuing a CHECKIN LIBVOLUME command for each volume, you can search storage slots for new volumes. The server finds volumes that have not yet been added to the volume inventory.

Procedure

1. Open the library and place the new volumes in unused slots. For example, for a SCSI device, open the library access door, place all of the new volumes in unused slots, and close the door.
2. If the volumes are not labeled, use the LABEL LIBVOLUME command to label the volume.
3. Issue the CHECKIN LIBVOLUME command with the SEARCH=YES parameter.

Related reference:
CHECKIN LIBVOLUME (Check a storage volume into a library)

Checking in volumes from library entry/exit ports

You can search all slots of bulk entry/exit ports for labeled volumes and the server can check them in automatically.

Before you begin

Issue the LABEL LIBVOLUME command to label volumes that are not labeled.

About this task

For SCSI libraries, the server scans all of the entry/exit ports in the library for volumes. If a volume is found that contains a valid volume label, it is checked in automatically.

Procedure

Issue the CHECKIN LIBVOLUME command and specify the SEARCH=BULK parameter.

- To load a tape in a drive and read the label, specify the CHECKLABEL=YES parameter. After the server reads the label, the server moves the tape from the drive to a storage slot.
- To have the server use the bar code reader to verify external labels on tapes, specify the CHECKLABEL=BARCODE parameter. When bar code reading is enabled, the server reads the label and moves the tape from the entry/exit port to a

storage slot.

Checking in volumes by using library bar code readers

You can save time when you check in volumes to libraries that have bar code readers by using the characters on the bar code labels as names for the volumes.

About this task

The server reads the bar code labels and uses the information to write the internal media labels. For volumes that have no bar code labels, the server mounts the volumes in a drive and attempts to read the internal, recorded label.

Procedure

Issue the CHECKIN LIBVOLUME command with the CHECKLABEL=BARCODE parameter. For example, to use a bar code reader to search a library that is named TAPELIB and check in a scratch tape, issue the following command:

```
checkin libvolume tapelib search=yes status=scratch checklabel=barcode
```

Checking in volumes by using a bar code reader

You can save time when you check in volumes by using a bar code reader, if your library has one.

About this task

When you check in a volume, you can specify whether the media labels are read during check-in processing. When label-checking is on, IBM Spectrum Protect™ mounts each volume to read the internal label and checks in a volume only if it is correctly labeled. Label-checking can prevent future errors when volumes are used in storage pools, but also increases processing time at check-in.

If a volume has no bar code label, IBM Spectrum Protect mounts the volumes in a drive and attempts to read the recorded label.

Procedure

To check in volumes by using a bar code reader, issue the CHECKIN LIBVOLUME command and specify CHECKLABEL=BARCODE. For example, to use the bar code reader to check in all volumes as scratch volumes in a library that is named TAPELIB, issue the following command:

```
checkin libvolume tapelib search=yes status=scratch checklabel=barcode
```

Related tasks:
Preparing removable media
Related reference:
CHECKIN LIBVOLUME (Check a storage volume into a library)

Checking volumes into a full library with swapping

If no empty slots are available in the library when you are checking in volumes, the check-in operation fails unless you enable *swapping*. If you enable swapping and the library is full, the server selects a volume to eject and then checks in the volume that you requested.

About this task

The server selects the volume to eject by checking first for any available scratch volume, then for the volume that is least frequently mounted. The server ejects the volume that it selects for the swap operation from the library and replaces the ejected volume with the volume that is being checked in.

Procedure

To swap volumes if an empty library slot is not available to check in a volume, issue the CHECKIN LIBVOLUME command and specify the SWAP=YES parameter. For example, to check in a volume that is named `VOL1` into a library that is named AUTO and

specify swapping, issue the following command:

```
checkin libvolume auto vol1 swap=yes
```

Related tasks:
Managing a full library with an overflow location
Related reference:
CHECKIN LIBVOLUME (Check a storage volume into a library)

Private volumes and scratch volumes

To optimize tape storage, review the information about private volumes and scratch volumes. Use private volumes and scratch volumes appropriately.

Private volumes cannot be overwritten when a scratch mount is requested. You cannot check in a volume with scratch status when that volume is used by a storage pool, to export data, to back up a database or to back up to a backup set volume.

Partially written volumes are always private volumes. Volumes have a status of either scratch or private, but when IBM Spectrum Protect™ stores data on them, their status becomes private.

Table 1. Private volume and scratch volume uses

Type of volume	When to use
Private volumes	Use private volumes to regulate the volumes that are used by individual storage pools, and to manually control the volumes. To define private volumes, issue the DEFINE VOLUME command. For database restore, memory dumps, or loads, or for server import operations, you must specify private volumes.
Scratch volumes	In some cases, you can simplify volume management by using scratch volumes. You can use scratch volumes in the following circumstances: • When you do not need to define each storage pool volume. • When you want to take advantage of the automation of robotic devices. • When different storage pools share an automated library, and the storage pools can dynamically acquire volumes from the scratch volumes in the library. The volumes do not have to be preallocated to the storage pools.

Related tasks:
Changing the status of a volume in an automated library

CHECKIN LIBVOLUME (Check a storage volume into a library)
DELETE VOLUME (Delete a storage pool volume)

Element addresses for library storage slots

An element address is a number that indicates the physical location of a storage slot or drive within an automated library.

If a library has entry/exit ports, you can add and remove media by using the ports. If no entry/exit port exists, you must load tapes into storage slots.

If you load tapes into storage slots, you must reply to mount requests that identify storage slots with element addresses. If you specify a wait time of 0 on the CHECKIN LIBVOLUME command or the LABEL LIBVOLUME command, you do not need to reply to a mount request.

For element addresses, see the device manufacturer's documentation or go to the IBM® Support Portal for IBM Spectrum Protect™ and search for element addresses.

CHECKIN LIBVOLUME (Check a storage volume into a library)
LABEL LIBVOLUME (Label a library volume)

Managing volume inventory

You can manage volume inventory by controlling the server's access to volumes, by reusing tapes, and by reusing volumes that are used for database backup and export operations. You can also manage inventory by maintaining a supply of scratch volumes.

About this task

Each volume that is used by a server must have a unique name, whether the volumes are used for storage pools, or used for operations such as database backup or export. Volumes that are in different libraries but that are used by the same server must also have a unique name.

- Controlling access to volumes
  You can use different methods to control access to volumes.
- Reusing tapes
  To ensure an adequate supply of tapes, you can expire old files, reclaim volumes, and delete volumes that reach end of life. You can also maintain a supply of scratch volumes.
- Maintaining a supply of scratch volumes
  You must set the maximum number of scratch volumes for a storage pool high enough for the expected usage.
- AIX Linux Maintaining a supply of volumes in a library that contains WORM media
  For libraries that contain Write Once Read Many (WORM) media, you can prevent cancellation of data storage transactions by maintaining a supply of scratch or new private volumes in the library. Canceled transactions can cause WORM media to be wasted.
- Manage the volume inventory in automated libraries
  The IBM Spectrum Protect™ server uses a library volume inventory to track scratch and private volumes that are available in an automated library. You must ensure that the inventory is consistent with the volumes that are physically in the library.

Controlling access to volumes

You can use different methods to control access to volumes.

Procedure

To control access to volumes, take any of the following actions:

- To prevent the server from mounting a volume, issue the UPDATE VOLUME command and specify the ACCESS=UNAVAILABLE parameter.
- To make volumes unavailable and send them offsite for protection, use a copy storage pool or an active-data storage pool.
- You can back up primary storage pools to a copy storage pool and then send the copy storage pool volumes offsite.
- You can copy active versions of client backup data to active-data storage pools, and then send the volumes offsite.
- You can track copy storage pool volumes and active-data pool volumes by changing their access mode to offsite, and updating the volume history to identify their location.

Related reference:
UPDATE VOLUME (Update a storage pool volume)

Reusing tapes

To ensure an adequate supply of tapes, you can expire old files, reclaim volumes, and delete volumes that reach end of life. You can also maintain a supply of scratch volumes.

About this task

Over time, media age, and you might not need some of the backup data that is stored on the media. You can define server policies to determine how many backup versions are retained and how long they are retained. You can use expiration processing to delete files that you no longer require. You can keep the data that you require on the media. When you no longer require the data, you can then reclaim and reuse the media.

Procedure

1. Delete unnecessary client data by regularly running expiration processing. Expiration processing deletes data that is no longer valid either because it exceeds the retention specifications in the policy or because users or administrators deleted the active versions of the data.
2. Reuse volumes in storage pools by running reclamation processing.

   Reclamation processing consolidates any unexpired data by moving it from multiple volumes onto fewer volumes. The media can then be returned to the storage pool and reused.

3. Reuse volumes that contain outdated database backups or exported data that is no longer required by deleting volume history.

   Before the server can reuse volumes that are tracked in the volume history, you must delete the volume information from the volume history file by issuing the DELETE VOLHISTORY command.

   Tip: If your server uses the disaster recovery manager (DRM) function, the volume information is automatically deleted during MOVE DRMEDIA command processing.
4. Determine when tape volumes reach end of life. You can use the server to display statistics about volumes, including the number of write operations that are completed on the media and the number of write errors. Private volumes and scratch volumes display the following statistical data:

   Private volumes
   : For media initially defined as private volumes, the server maintains this statistical data, even as the volume is reclaimed. You can compare the information with the number of write operations and write errors that are recommended by the manufacturer.

   Scratch volumes
   : For media initially defined as scratch volumes, the server overwrites this statistical data each time the volumes are reclaimed.

5. Reclaim any valid data from volumes that reach end of life. If the volumes are in automated libraries, check them out of the volume inventory. Delete private volumes from the database with the DELETE VOLUME command.
6. Ensure that volumes are available for tape rotation so that the storage pool does not run out of space. You can use the Operations Center to monitor the availability of scratch volumes. Ensure that the number of scratch volumes is high enough to meet demand. For more information, see Maintaining a supply of volumes in a library that contains WORM media.
   WORM media: Write Once Read Many (WORM) drives can waste media when the server cancels transactions because volumes are unavailable to complete the backup operation. After the server writes to WORM volumes, the space on the volumes cannot be reused, even if the transactions are canceled (for example, if a backup is canceled because of a shortage of media in the device). To minimize wasted WORM media, complete the following actions:
   a. Ensure that the maximum number of scratch volumes for the device storage pool is at least equal to the number of storage slots in the library.
   b. Check enough volumes into the device's volume inventory for the expected load.

   If most backup operations are for small files, controlling the transaction size can affect how WORM platters are used. Smaller transactions mean that less space is wasted when a transaction such as a backup operation must be canceled. Transaction size is controlled by a server option, TXNGROUPMAX, and a client option, TXNBYTELIMIT.

Maintaining a supply of scratch volumes

You must set the maximum number of scratch volumes for a storage pool high enough for the expected usage.

About this task

When you define a storage pool, you must specify the maximum number of scratch volumes that the storage pool can use. The server automatically requests a scratch volume when needed. When the number of scratch volumes that the server is using for the storage pool exceeds the specified maximum, the storage pool can run out of space.

Procedure

When a storage pool needs more than the maximum number of scratch volumes, you can take one or both of the following actions:

1. Increase the maximum number of scratch volumes by issuing the UPDATE STGPOOL command and specifying the MAXSCRATCH parameter.
2. Make volumes available for reuse by running expiration processing and reclamation to consolidate data onto fewer volumes.
    a. Issue the EXPIRE INVENTORY command to run expiration processing.
    Tip: By default this process automatically runs every day. You can also specify the EXPINTERVAL server option in the server options file, dsmserv.opt, to run expiration processing automatically. A value of 0 means that you must use the EXPIRE INVENTORY command to run expiration processing.
    b. Issue the RECLAIM STGPOOL command to run reclamation processing.
    Tip: You can also specify reclamation thresholds when you define the storage pool by using the DEFINE STGPOOL command and specifying the RECLAIMPROCESS parameter.

What to do next

If you need more volumes for future backup operations, label more scratch volumes by using the LABEL LIBVOLUME command.
Related tasks:
Maintaining a supply of scratch volumes in an automated library

EXPIRE INVENTORY (Manually start inventory expiration processing)
LABEL LIBVOLUME (Label a library volume)
RECLAIM STGPOOL (Reclaim volumes in a sequential-access storage pool)
UPDATE STGPOOL (Update a storage pool)

Maintaining a supply of volumes in a library that contains WORM media

For libraries that contain Write Once Read Many (WORM) media, you can prevent cancellation of data storage transactions by maintaining a supply of scratch or new private volumes in the library. Canceled transactions can cause WORM media to be wasted.

About this task

IBM Spectrum Protect™ cancels a transaction if volumes, either private or scratch, are unavailable to complete the data storage operation. After IBM Spectrum Protect begins a transaction by writing to a WORM volume, the written space on the volume cannot be reused, even if the transaction is canceled.

For example, if you have WORM volumes that hold 2.6 GB each and a client starts to back up a 12 GB file. If IBM Spectrum Protect cannot acquire a fifth scratch volume after four volumes are full, IBM Spectrum Protect cancels the backup operation. The four volumes that IBM Spectrum Protect already filled cannot be reused.

To minimize cancellation of transactions, you must have enough volumes available in the library to manage expected client operations such as backups.

Procedure

1. Ensure that the storage pool that is associated with the library has sufficient scratch volumes. Issue the UPDATE STGPOOL command and specify the MAXSCRATCH parameter.
2. To manage the expected load, check in a sufficient number of scratch or private volumes to the library by issuing the CHECKIN LIBVOLUME command.
3. To control transaction size, specify the TXNGROUPMAX server option and the TXNBYTELIMIT client option. If your clients tend to store small files, controlling the transaction size can affect how WORM volumes are used. Smaller transactions waste less space when a transaction such as a backup must be canceled.

Manage the volume inventory in automated libraries

The IBM Spectrum Protect™ server uses a library volume inventory to track scratch and private volumes that are available in an automated library. You must ensure that the inventory is consistent with the volumes that are physically in the library.

The library volume inventory is separate from the inventory of volumes for each storage pool. To add a volume to a library volume inventory, you check in a volume to that IBM Spectrum Protect library.

A list of volumes in the library volume inventory might not be identical to a list of volumes in the storage pool inventory for the device. For example, you can check in scratch volumes to the library but you cannot define them to a storage pool. If scratch volumes are not selected for backup operations, you can define private volumes to a storage pool but you cannot check them into the volume inventory for the device.

To ensure that the volume inventory for the server library remains accurate, check out volumes to physically remove the volumes from a SCSI library. When you check out a volume that is used by a storage pool, the volume remains in the storage pool. If you must mount the volume when it is checked out, a message to the mount operator's console is displayed with a request to check in the volume. If the check-in operation is unsuccessful, the server marks the volume as unavailable.

When a volume is in the library volume inventory, you can change the status of the volume from scratch to private.

To check whether the volume inventory for the server library is consistent with the volumes that are physically in the library, you can audit the library. The inventory can become inaccurate if volumes are moved in and out of the library without informing the server by using volume check-in or check-out operations.

- Changing the status of a volume in an automated library
  You can change the status of a volume from private to scratch or from scratch to private.
- Removing volumes from an automated library
  You can remove volumes from an automated library if you exported data to a volume and want to import the data to another system. You might also want to remove volumes to create space for new volumes.
- Maintaining a supply of scratch volumes in an automated library
  When you define a storage pool that is associated with an automated library, you can specify a maximum number of scratch volumes equal to the physical capacity of the library. If the server is using a greater number of scratch volumes for the storage pool, you must ensure that enough volumes are available.
- Managing a full library with an overflow location
  As the demand for storage grows, the number of volumes that you need for a storage pool might exceed the physical capacity of an automated library. To make space available for new volumes and to monitor existing volumes, you can define an overflow location for a storage pool.
- Auditing the volume inventory in a library
  You can audit an automated library to ensure that the library volume inventory is consistent with the volumes that are physically in the library. You might want to audit a library if the library volume inventory is distorted due to manual movement of volumes in the library or to database problems.

Related tasks:
Checking volumes into an automated library
Related reference:
AUDIT LIBRARY (Audit volume inventories in an automated library)

Changing the status of a volume in an automated library

You can change the status of a volume from private to scratch or from scratch to private.

Procedure

To change the status of a volume, issue the UPDATE LIBVOLUME command. For example, to change the status of a volume that is named VOL1 to a private volume, issue the following command:

```
update libvolume lib1 vol1 status=private
```

Restrictions:

- You cannot change the status of a volume from private to scratch if the volume belongs to a storage pool or is defined in the volume history file.
- Private volumes must be administrator-defined volumes with either no data or invalid data. They cannot be partially written volumes that contain active data. Volume statistics are lost when volume statuses are modified.

Removing volumes from an automated library

You can remove volumes from an automated library if you exported data to a volume and want to import the data to another system. You might also want to remove volumes to create space for new volumes.

About this task

By default, the server mounts the volume that you check out and verifies the internal label. When the label is verified, the server removes the volume from the library volume inventory, and then moves it to the entry/exit port or convenience I/O station of the library. If the library does not have an entry/exit port, the server requests that the mount operator remove the volume from a slot or device within the library.

Procedure

- To remove a volume from an automated library, issue the CHECKOUT LIBVOLUME command.
- For automated libraries with multiple entry/exit ports, issue the CHECKOUT LIBVOLUME command and specify the REMOVE=BULK parameter. The server ejects the volume to the next available entry/exit port.

What to do next

If you check out a volume that is defined in a storage pool and the server must access the volume later, the server requests that the volume be checked in. To return volumes to a library, issue the CHECKIN LIBVOLUME command.

Related reference:

CHECKIN LIBVOLUME (Check a storage volume into a library)

CHECKOUT LIBVOLUME (Check a storage volume out of a library)

Maintaining a supply of scratch volumes in an automated library

When you define a storage pool that is associated with an automated library, you can specify a maximum number of scratch volumes equal to the physical capacity of the library. If the server is using a greater number of scratch volumes for the storage pool, you must ensure that enough volumes are available.

Procedure

If the number of scratch volumes that the server is using for the storage pool exceeds the number that is specified in the storage pool definition, complete the following steps:

1. Add scratch volumes to the library by issuing the CHECKIN LIBVOLUME command.
   Tip: You might have to use an overflow location to move volumes out of the library to make room for these scratch volumes. For more information, see Managing a full library with an overflow location.
2. Increase the maximum number of scratch volumes that can be added to a storage pool by issuing the UPDATE STGPOOL command and specifying the MAXSCRATCH parameter.

What to do next

You might need more volumes for future recovery operations, so consider labeling and setting aside extra scratch volumes.

Related tasks:

Maintaining a supply of scratch volumes

Managing a full library with an overflow location

As the demand for storage grows, the number of volumes that you need for a storage pool might exceed the physical capacity of an automated library. To make space available for new volumes and to monitor existing volumes, you can define an overflow location for a storage pool.

About this task

The server tracks the volumes that are moved to the overflow area and makes storage slots available for new volumes.

Procedure

1. Create a volume overflow location. Define or update the storage pool that is associated with the automated library by issuing the DEFINE STGPOOL or UPDATE STGPOOL command and specifying the OVFLOCATION parameter. For example, to create an overflow location that is named `ROOM2948` for a storage pool that is named `ARCHIVEPOOL`, issue the following command:

   ```
   update stgpool archivepool ovflocation=Room2948
   ```

2. When you need to create space in the library for scratch volumes, move full volumes to the overflow location by issuing the MOVE MEDIA command. For example, to move all full volumes in the specified storage pool out of the library, issue the following command:

   ```
   move media * stgpool=archivepool
   ```

3. Check in scratch volumes as needed.
   Restriction: If a volume has an entry in the volume history file, you cannot check it in as a scratch volume. For more information, see Checking volumes into an automated library.
4. Identify the empty scratch tapes in the overflow location by issuing the QUERY MEDIA command. For example, issue the following command:

   ```
   query media * stg=* whereovflocation=Room2948 wherestatus=empty
   ```

5. If the server requests additional volumes, locate and check in volumes from the overflow location.

   To find volumes in an overflow location, issue the QUERY MEDIA command. You can also use the QUERY MEDIA command to generate commands by checking in volumes.

   For example, to list the volumes in the overflow location, and at the same time generate the commands to check those volumes into the library, issue a command that is similar to the following example:

   ```
   query media format=cmd stgpool=archivepool whereovflocation=Room2948
   cmd="checkin libvol autolib &vol status=private"
   cmdfilename="\storage\move\media\checkin.vols"
   ```

   Tips:
   - Mount requests from the server include the location of the volumes.
   - To specify the number of days that must elapse before the volumes are eligible for processing, issue the UPDATE STGPOOL command and specify the REUSEDELAY parameter.
   - The file that contains the generated commands can be run by using the IBM Spectrum Protect™ MACRO command.

MOVE MEDIA (Move sequential-access storage pool media)
QUERY MEDIA (Query sequential-access storage pool media)
UPDATE STGPOOL (Update a storage pool)

Auditing the volume inventory in a library

You can audit an automated library to ensure that the library volume inventory is consistent with the volumes that are physically in the library. You might want to audit a library if the library volume inventory is distorted due to manual movement of volumes in the library or to database problems.

Procedure

1. Ensure that no volumes are mounted in the library drives. If any volumes are mounted in the IDLE state, issue the DISMOUNT VOLUME command to dismount them.

2. Audit the volume inventory by issuing the AUDIT LIBRARY command. Take one of the following actions:
   - If the library has a bar code reader, you can save time by using the bar code reader to identify volumes. For example, to audit the TAPELIB library by using its bar code reader, issue the following command:

     ```
     audit library tapelib checklabel=barcode
     ```

   - If the library does not have a bar code reader, issue the AUDIT LIBRARY command without specifying CHECKLABEL=BARCODE. The server mounts each volume to verify the label. After the label is verified, the server completes auditing any remaining volumes.

Results

The server deletes missing volumes from the inventory and updates the locations of volumes that moved since the last audit.

Restriction: The server cannot add new volumes to the inventory during an audit operation.

Related tasks:
Labeling tape volumes

Related reference:
AUDIT LIBRARY (Audit volume inventories in an automated library)
DISMOUNT VOLUME (Dismount a volume by volume name)

Partially written volumes

Partially written volumes are always private volumes, even if their status was scratch before the server mounted them. The server tracks the original status of scratch volumes and returns them to scratch status when they are empty.

Except for volumes in automated libraries, the server is unaware of a scratch volume until after the volume is mounted. Then, the volume status changes to private, and the volume is automatically defined as part of the storage pool for which the mount request was made.

Related tasks:
Changing the status of a volume in an automated library

Operations with shared libraries

Shared libraries are logical libraries that are represented physically by SCSI libraries. The physical library is controlled by the IBM Spectrum Protect™ server that is configured as a library manager. IBM Spectrum Protect servers that use the SHARED library type are library clients to the IBM Spectrum Protect library manager server.

The library client contacts the library manager when the library manager starts and the storage device initializes, or after a library manager is defined to a library client. The library client confirms that the contacted server is the library manager for the named library device. The library client also compares drive definitions with the library manager for consistency. The library client contacts the library manager for each of the following operations:

Volume mount
: A library client sends a request to the library manager for access to a particular volume in the shared library device. For a scratch volume, the library client does not specify a volume name. If the library manager cannot access the requested volume, or if scratch volumes are unavailable, the library manager denies the mount request. If the mount is successful, the library manager returns the name of the drive where the volume is mounted.

Volume release
: When a library client no longer needs to access a volume, it notifies the library manager that the volume can be returned to a scratch volume. The library manager database is updated with the new location for the volume, which is now in the inventory of the library server. The volume is deleted from the volume inventory of the library client.

Table 1 shows the interaction between library clients and the library manager in processing IBM Spectrum Protect operations.

Table 1. How SAN-enabled servers process IBM Spectrum Protect operations

Operation (Command)	Library manager	Library client

Operation (Command)	Library manager	Library client
Query library volumes (QUERY LIBVOLUME)	Displays the volumes that are checked into the library. For private volumes, the owner server is also displayed.	Not applicable.
Check in and check out library volumes (CHECKIN LIBVOLUME, CHECKOUT LIBVOLUME)	Sends the commands to the library device.	Not applicable. When a check-in operation is required because of a client restore operation, a request is sent to the library manager server.
Move media and move DRM media (MOVE MEDIA, MOVE DRMEDIA)	Valid only for volumes that are used by the library manager server.	Requests that the library manager server completes the operation. Generates a check-out process on the library manager server.
Audit library inventory (AUDIT LIBRARY)	Synchronizes the inventory with the library device.	Synchronizes the inventory with the library manager server.
Label a library volume (LABEL LIBVOLUME)	Labels and checks in volumes.	Not applicable.
Dismount a volume (DISMOUNT VOLUME)	Sends the request to the library device.	Requests that the library manager server completes the operation.
Query a volume (QUERY VOLUME)	Checks whether the volume is owned by the requesting library client and checks whether the volume is in the library device.	Requests that the library manager server completes the operation.

Managing server requests for volumes

IBM Spectrum Protect™ displays requests and status messages to all administrative command-line clients that are started in console mode. These request messages often have a time limit. Successful server operations must be completed within the time limit that is specified; otherwise, the operation times out.

About this task

For automated libraries, use the CHECKIN LIBVOLUME and LABEL LIBVOLUME commands to insert cartridges into slots. If you specify a value for the WAITTIME parameter, a reply message is displayed. If the value of the parameter is 0, no reply is required. When you issue the CHECKOUT LIBVOLUME command, you must insert cartridges into slots and, in all cases, a reply message is displayed.

Procedure

The following table provides information about how to handle different server media tasks.

Task	Details
Use the administrative client for mount messages	The server sends mount request status messages to the server console and to all administrative command-line clients in mount mode or console mode. To start an administrative command-line client in mount mode, issue the dsmadmc -mountmode command on the administrative command-line client.
Receive messages about automated libraries	You can view mount messages and error messages about automated libraries on administrative command-line clients in mount mode or console mode. Mount messages are sent to the library and not to an operator. Messages about problems with the library are sent to the mount message queue.
Get information about pending operator requests	To get information about pending operator requests, issue the QUERY REQUEST command or view the mount message queue on an administrative command-line client that is started in mount mode. When you issue the QUERY REQUEST command, the server displays requested actions and the amount of time that is remaining before the requests time out.
Reply to operator requests	When the server requires an explicit reply to a completed mount request, use the REPLY command. The *request_number* parameter specifies the request identification number that tells the server which pending operator request is completed. This three-digit number is always displayed as part of the request message.
Cancel an operator request	To cancel a mount request for a library, issue the CANCEL REQUEST command. For most requests that are associated with automated SCSI libraries, an operator must complete a hardware or system action to cancel the requested mount. For such requests, the CANCEL REQUEST command is not accepted by the server. The CANCEL REQUEST command must include the request identification number. This number is included in the request message. If you want to mark the requested volume as UNAVAILABLE, issue the CANCEL REQUEST command and specify the PERMANENT parameter. If you specify the PERMANENT parameter, the server does not try to mount the requested volume again. This is useful if, for example, the volume is at a remote site or is otherwise unavailable.
Respond to a volume check-in request	If the server cannot find a particular volume to mount in an automated library, the server requests that the operator check in the volume. If the requested volume is available, place the volume in the library and check it in. For more information, see Checking volumes into an automated library. If the requested volume is unavailable, update the access mode of the volume by issuing the UPDATE VOLUME command and specifying the ACCESS=UNAVAILABLE parameter. Then, cancel the check-in request by using the CANCEL REQUEST command. Do not cancel the client process that caused the request. Use the QUERY REQUEST command to obtain the ID of the request that you want to cancel. If you do not respond to the check-in request from the server within the mount-wait period that is specified for the device class for the storage pool, the server marks the volume as unavailable.
Determine which volumes are mounted	For a report about all volumes that are currently mounted for use by the server, issue the QUERY MOUNT command. The report shows which volumes are mounted, which drives accessed them, and whether the volumes are in use.

Task	Details
Dismount idle volumes	When a volume is idle, the server keeps it mounted for a time that is specified by the mount retention parameter for the device class. Using a mount retention value can reduce the access time when volumes are used repeatedly. To dismount an idle volume from the drive where it is mounted, issue the DISMOUNT VOLUME command. For information about setting mount retention times, see Controlling the amount of time that a volume remains mounted.

Related reference:
QUERY REQUEST (Query one or more pending mount requests)

Managing tape drives

You can query, update, and delete tape drives. You can also clean tape drives and configure tape drive encryption and data validation.

- Updating drives
  You can change the attributes of a drive definition to take a drive offline or reconfigure it.
- Data validation during read/write operations to tape
  To validate data and identify data that is corrupted, you can use a feature that is called logical block protection. If you use logical block protection, IBM Spectrum Protect inserts a cyclic redundancy check (CRC) value at the end of each logical block of data while it is written to tape.
- Cleaning tape drives
  You can use the server to manage tape-drive cleaning. The server can control how tape drives in SCSI libraries are cleaned.
- Tape drive replacement
  If you replace a drive in a tape library that is defined to IBM Spectrum Protect, you must delete the drive and path definitions for the old drive and define the new drive and path.

Updating drives

You can change the attributes of a drive definition to take a drive offline or reconfigure it.

About this task

You can change the following attributes of a drive:

- The element address, if the drive is in a SCSI
- The cleaning frequency
- The drive status: online or offline

Restriction: If a drive is in use, you cannot change the element number or the device name. For instructions about taking drives offline, see Taking tape drives offline.
If a volume is mounted in the drive but the volume is idle, it can be explicitly dismounted. For instructions about dismounting idle volumes, see Managing server requests for volumes.

Procedure

- Change the element address of a drive by issuing the UPDATE DRIVE command. For example, in a library that is named AUTO, change the element address of DRIVE3 to 119 by issuing the following command:

  ```
  update drive auto drive3 element=119
  ```

- Change the device name of a drive by issuing the UPDATE PATH command. For example, to change the device name of a drive that is named DRIVE3, issue the following command: AIX

  ```
  update path server1 drive3 srctype=server desttype=drive library=scsilib
   device=/dev/rmt0
  ```

  Linux

```
update path server1 drive3 srctype=server desttype=drive library=scsilib
 device=/dev/IBMtape0
```

Windows

```
update path server1 drive3 srctype=server desttype=drive library=scsilib
   device=mt3.0.0.0
```

- Taking tape drives offline
  You can take a tape drive offline while it is in use. For example, you might take a drive offline to complete maintenance.

Related reference:
UPDATE DRIVE (Update a drive)
UPDATE PATH (Change a path)

Data validation during read/write operations to tape

To validate data and identify data that is corrupted, you can use a feature that is called logical block protection. If you use logical block protection, IBM Spectrum Protect™ inserts a cyclic redundancy check (CRC) value at the end of each logical block of data while it is written to tape.

With logical block protection, you can identify errors that occur when data is written to tape and during data transfer from the tape drive to IBM Spectrum Protect through the storage area network. Drives that support logical block protection validate data during read and write operations. The IBM Spectrum Protect server validates data during read operations.

If validation by the drive fails during write operations, the failure can indicate that data was corrupted during transfer to tape. In this case, the IBM Spectrum Protect server fails the write operation. You must restart the operation to continue. If validation by the drive fails during read operations, the failure can indicate that the tape media is corrupted. If validation by the IBM Spectrum Protect server fails during read operations, the failure can indicate that data was corrupted during transfer from the tape drive, and the server tries the operation again. If validation fails consistently, the IBM Spectrum Protect server issues an error message that indicates hardware or connection problems.

If logical block protection is disabled on a tape drive, or the drive does not support logical block protection, the IBM Spectrum Protect server can read protected data. However, the data is not validated.

Logical block protection is superior to the CRC validation that you can specify when you define or update a storage pool. When you specify CRC validation for a storage pool, data is validated only during volume auditing operations. Errors are identified after the data is written to tape.

Restrictions:

- You cannot use logical block protection for sequential data such as backup sets and database backups.
- CRC checking impacts performance because more processor usage is required on both the client and server to calculate and compare CRC values.
- For a scratch volume, if you specify logical block protection for read/write operations (LBPROTECT=READWRITE), do not change the parameter value at any time after data is written to the volume. Changing the parameter value during the life of the volume on the IBM Spectrum Protect server is not supported.

- Drives that support logical block protection
  Logical block protection is available only for 3592, LTO, and ECARTRIDGE device types. Capable 3592 drives include IBM TS1130, TS1140, and later generations. Capable LTO drives include IBM LTO-5 and supported LTO-6 drives. Capable Oracle StorageTek drives include drives with the T10000C and T10000D format.
- Enabling and disabling logical block protection
  You can specify logical block protection for read and write operations, or only for write operations. You can also disable logical block protection. By default, logical block protection is disabled because of performance effects that result from cyclic redundancy check (CRC) validation on the server and the tape drive.
- Read/write operations to volumes with logical block protection
  Read/write operations to empty or filling volumes depend on whether the volumes have logical block protection. Protected and unprotected data blocks cannot be mixed on the same volume.
- Storage pool management in a tape library
  To mix protected and unprotected data in a library, you must create different device classes and different storage pools to separate the data. If a device class is associated with protected data, you can specify logical block protection for read and write operations or for write operations only.

Drives that support logical block protection

Logical block protection is available only for 3592, LTO, and ECARTRIDGE device types. Capable 3592 drives include IBM TS1130, TS1140, and later generations. Capable LTO drives include IBM LTO-5 and supported LTO-6 drives. Capable Oracle StorageTek drives include drives with the T10000C and T10000D format.

The following table shows the media and the formats that you can use with drives that support logical block protection.

Drive	Tape media	Drive formats
IBM TS1130	3592 Generation 2	3592-3 and 3592-3C
IBM TS1140	3592 Generation 2 3592 Generation 3	Generation 2: 3592-3 and 3592-3C Generation 3: 3592-4 and 3592-4C
IBM TS1150	3592 Generation 3 3592 Generation 4	Generation 4: 3592-5 and 3592-5C
IBM LTO-5	LTO-5	Ultrium 5 and Ultrium 5C
IBM LTO-6	LTO-6 LTO-5	Ultrium 6 and Ultrium 6C Ultrium 5 and Ultrium 5C
IBM LTO-7	LTO-7 LTO-6	Ultrium 7 and Ultrium 7C Ultrium 6 and Ultrium 6C
Oracle T10000C	Oracle StorageTek T10000 T2	T10000C and T10000C-C
Oracle T10000D	Oracle StorageTek T10000 T2	T10000D and T10000D-C

Tips:

- To enable logical block protection for a tape volume and then reuse the volume to back up data, you must enable logical block protection for the device class and the drive.
- If you have a 3592, LTO, or Oracle StorageTek drive that is not capable of logical block protection, you can upgrade the drive with firmware that provides logical block protection.

Logical block protection is available for drives that are in SCSI libraries. For the most current information about support for logical block protection, see technote 1568108.

To use logical block protection for write operations, all drives in the library must support logical block protection. If a drive is not capable of logical block protection, volumes that have read/write access are not mounted. However, the server can use the drive to mount volumes that have read-only access. The protected data is read and validated by the IBM Spectrum Protect™ server if logical block protection is enabled for read/write operations.

Enabling and disabling logical block protection

You can specify logical block protection for read and write operations, or only for write operations. You can also disable logical block protection. By default, logical block protection is disabled because of performance effects that result from cyclic redundancy check (CRC) validation on the server and the tape drive.

About this task

Read/write operations to empty or filling volumes depend on whether the volumes have logical block protection. Protected and unprotected data blocks cannot be mixed on the same volume. If you change the setting for logical block protection, the change applies only to empty volumes. Filling and full volumes maintain their status of logical block protection until they are empty and ready to be refilled. For example, if you disable logical block protection and the server selects a volume that is associated with a device class that has logical block protection, the server continues writing protected data to the volume.
Restriction: Logical block protection is available only for certain device types. For more information, see Drives that support logical block protection.

Procedure

1. To enable logical block protection for the 3592, LTO, and ECARTRIDGE device types, issue the DEFINE DEVCLASS or the UPDATE DEVCLASS command and specify the LBPROTECT parameter. For example, to specify logical block protection during read and write operations for a 3592 device class that is named 3592_lbprotect, issue the following command:

   ```
   define devclass 3592_lbprotect library=3594 lbprotect=readwrite
   ```

   Tips:
   - If you update the value of the LBPROTECT parameter from NO to READWRITE or WRITEONLY and the server selects a filling volume without logical block protection for write operations, the server issues a message each time the volume is mounted. The message indicates that data is written to the volume without logical block protection. To prevent this message from displaying or to have IBM Spectrum Protect™ write data only with logical block protection, update the access of filling volumes without logical block protection to read-only.
   - To improve performance, do not specify the CRCDATA parameter on the DEFINE STGPOOL or UPDATE STGPOOL command.
   - When data is validated during read operations by both the drive and by the IBM Spectrum Protect server, it can slow server performance during restore and retrieve operations. To reduce the time that is required for restore and retrieve operations, change the setting of the LBPROTECT parameter from READWRITE to WRITEONLY. After data is restored or retrieved, you can reset the LBPROTECT parameter to READWRITE.
2. To disable logical block protection, issue the DEFINE DEVCLASS or the UPDATE DEVCLASS command and specify the LBPROTECT=NO parameter.
   Restriction: If logical block protection is disabled, the server does not write to an empty tape with logical block protection. However, if a filling volume with logical block protection is selected, the server continues to write to the volume with logical block protection. To prevent the server from writing to tapes with logical block protection, change the access of filling volumes with logical block protection to read-only. When data is read, the CRC results are not checked by the drive or server.

   If a disaster occurs and the disaster recovery site does not have drives that support logical block protection, you must specify the LBPROTECT=NO parameter. If the tape drives are used for write operations, you must change the volume access for volumes with protected data to read-only to prevent the server from using the volumes.

   If the server must enable logical block protection, the server issues an error message that indicates that the drive does not support logical block protection.

What to do next

To determine whether a volume has logical block protection, issue the QUERY VOLUME command and review the value in the `Logical Block Protection` field.

Related reference:
DEFINE DEVCLASS (Define a device class)
DEFINE STGPOOL (Define a volume in a storage pool)
QUERY VOLUME (Query storage pool volumes)
UPDATE DEVCLASS (Update a device class)
UPDATE STGPOOL (Update a storage pool)

Read/write operations to volumes with logical block protection

Read/write operations to empty or filling volumes depend on whether the volumes have logical block protection. Protected and unprotected data blocks cannot be mixed on the same volume.

If you use the UPDATE DEVCLASS command to change the setting for logical block protection, the change applies only to empty volumes. Filling and full volumes maintain their status of logical block protection until they are empty and ready to be refilled.

For example, suppose that you change the value of the LBPROTECT parameter from READWRITE to NO. If the server selects a volume that is associated with the device class and that has logical block protection, the server continues writing protected data to the volume.

Tips:

- If a drive does not support logical block protection, volumes with logical block protection for write operations cannot be mounted. To prevent the server from mounting the protected volumes for write operations, change the volume access to

read-only. Also, disable logical block protection to prevent the server from enabling the feature on the tape drive.
- If a drive does not support logical block protection, and logical block protection is disabled, the server reads data from protected volumes. However, the data is not validated by the server and the tape drive.

QUERY VOLUME (Query storage pool volumes)
UPDATE DEVCLASS (Update a device class)

Storage pool management in a tape library

To mix protected and unprotected data in a library, you must create different device classes and different storage pools to separate the data. If a device class is associated with protected data, you can specify logical block protection for read and write operations or for write operations only.

To define device classes and storage pools for a TS3500 library that has LTO-5 drives, for protected and unprotected data, you can issue a series of commands as shown in the following example:

```
define library 3584 libtype=scsi
define devclass lbprotect library=3584 devicetype=lto lbprotect=readwrite
define devclass normal library=3584 devicetype=lto lbprotect=no
define stgpool lbprotect_pool lbprotect maxscratch=10
define stgpool normal_pool normal maxscratch=10
```

Related reference:
DEFINE DEVCLASS (Define a device class)
DEFINE LIBRARY (Define a library)
DEFINE STGPOOL (Define a volume in a storage pool)

Cleaning tape drives

You can use the server to manage tape-drive cleaning. The server can control how tape drives in SCSI libraries are cleaned.

About this task

You must have system privilege or unrestricted storage privilege to clean tape drives. For automated libraries, you can automate cleaning by specifying the frequency of cleaning operations and checking a cleaner cartridge into the library volume inventory. IBM Spectrum Protect™ mounts the cleaner cartridge as specified. There are special considerations if you plan to use server-controlled drive cleaning with a SCSI library that provides automatic drive cleaning support in its device hardware.

Tip: If an automated tape library supports library-drive cleaning, ensure that the feature is enabled.

You can prevent premature wear on the read/write heads of drives by using the library cleaning functions that are available from your device manufacturer.

Drives and libraries from manufacturers differ in how they manage cleaner cartridges, and how they report the presence of a cleaner cartridge in a drive. The device driver might not be able to open a drive that contains a cleaner cartridge. Sense codes and error codes that are issued by devices for drive cleaning vary. Library-drive cleaning is usually not known to applications. Therefore, IBM Spectrum Protect might not always detect the cleaner cartridges in drives and might not be able to determine when cleaning begins.

Some devices require a small amount of idle time between mount requests to start drive cleaning. However, IBM Spectrum Protect tries to minimize the idle time for a drive. The result might be to prevent the library drive cleaning from functioning effectively. If this happens, use IBM Spectrum Protect to control drive cleaning. You can set the frequency to match the cleaning recommendations from the manufacturer.

- Methods for cleaning tape drives
  Over time, the read heads on tapes can get dirty, which can cause read and write operations to fail. To prevent these issues, enable tape cleaning. You can enable tape cleaning from the drive or from IBM Spectrum Protect.
- Configuring the server for drive cleaning in an automated library
  When you configure server-controlled drive cleaning in an automated library, you can specify how often you want the drives to be cleaned.
- Resolving errors that are related to drive cleaning
  While moving cartridges within a library, you might place a data cartridge where a cleaner cartridge should be. Review the

process that the server completes and the messages that are issued so that you can resolve the issue.

Methods for cleaning tape drives

Over time, the read heads on tapes can get dirty, which can cause read and write operations to fail. To prevent these issues, enable tape cleaning. You can enable tape cleaning from the drive or from IBM Spectrum Protect™.

You can choose to use the library-drive cleaning method or the IBM Spectrum Protect drive-cleaning method, but not both. Some SCSI libraries provide automatic drive cleaning. Select the library-drive cleaning method if it is available. If it is unavailable or causes issues, use IBM Spectrum Protect to control library drive cleaning.

Library drive-cleaning method

The library drive-cleaning method provides several advantages for automated tape libraries that use this function:

- Reduces the burden on the IBM Spectrum Protect administrator to physically manage cartridge cleaning.
- Improves cleaning cartridge usage rates. Most tape libraries track the number of times that drives can be cleaned based on hardware indicators. IBM Spectrum Protect uses a raw count.
- Reduces unnecessary cleaning. Modern tape drives do not have to be cleaned at fixed intervals and can detect and request when cleaning is required.

Manufacturers who provide a library drive-cleaning method recommend its use to prevent premature wear on the read/write heads of the drives. Drives and libraries from different manufacturers differ in how they manage cleaner cartridges and how they report the presence of a cleaner cartridge in a drive. The device driver might not be able to open a drive that contains a cleaner cartridge. Sense codes and error codes that are issued by devices for drive cleaning vary. Library drive cleaning is usually transparent to all applications. However, IBM Spectrum Protect might not always detect cleaner cartridges in drives and might not be able to determine when cleaning begins.

IBM Spectrum Protect drive cleaning method

Some devices require a small amount of idle time between mount requests to start drive cleaning. However, IBM Spectrum Protect tries to minimize the idle time for a drive. The result might be to prevent the library drive cleaning from functioning effectively. If this happens, try using IBM Spectrum Protect to control drive cleaning. Set the frequency to match the cleaning recommendations from the manufacturer.

If IBM Spectrum Protect controls the drive-cleaning process, disable the library drive-cleaning function to prevent problems. If the library drive-cleaning function is enabled, some devices automatically move any cleaner cartridge that is found in the library to slots in the library that are dedicated to cleaner cartridges. You cannot check a cleaner cartridge into the IBM Spectrum Protect library inventory until you disable the library drive-cleaning function.

To enable cleaning from the drive, follow the instructions that are provided by the drive manufacturer. To enable cleaning by using IBM Spectrum Protect, see Configuring the server for drive cleaning in an automated library.

Configuring the server for drive cleaning in an automated library

When you configure server-controlled drive cleaning in an automated library, you can specify how often you want the drives to be cleaned.

Before you begin

Determine how often the drive must be cleaned. This step is required so that you can specify an appropriate value for the CLEANFREQUENCY parameter on the DEFINE DRIVE or UPDATE DRIVE command. For example, to clean a drive after 100 GB of data is processed on the drive, you would specify CLEANFREQUENCY=100.

For guidelines about cleaning frequency, see the drive manufacturer's documentation. If the documentation provides guidelines for cleaning frequency in terms of hours of use, convert the value to a gigabyte value by completing the following steps:

1. Use the bytes-per-second value for the drive to determine a gigabytes-per-hour value.
2. Multiply the gigabytes-per-hour value by the recommended hours of use between cleanings.
3. Use the result as the cleaning frequency value.

You can either specify a value for the CLEANFREQUENCY parameter or specify ASNEEDED to clean the drive as needed. Restrictions:

1. For IBM® 3592 drives, you must specify a numerical value for the CLEANFREQUENCY parameter. By using the cleaning frequency that is listed in the product documentation, you will not overclean the drives.
2. The CLEANFREQUENCY=ASNEEDED parameter value does not work for all tape drives. To determine whether a drive supports this function, see the information for your operating system:
   - AIX Windows Supported devices for AIX and Windows
   - Linux Supported devices for Linux

   In the technote, click the drive name to view detailed information. If the ASNEEDED value is not supported, specify the number of gigabytes.

Procedure

To configure server-controlled drive cleaning in an automated library, complete the following steps:

Define or update the drives in the library, by using the CLEANFREQUENCY parameter in the DEFINE DRIVE or UPDATE DRIVE command. For example, to clean a drive that is named DRIVE1 after 100 GB of data is processed, issue the following command:

```
update drive autolib1 drive1 cleanfrequency=100
```

Results

After the cleaner cartridge is checked in, the server mounts the cleaner cartridge in a drive when the drive needs cleaning. The server uses that cleaner cartridge for the number of specified cleanings. For more information, see Operations with cleaner cartridges.

What to do next

Check the cleaner cartridge into the library volume inventory by following the instructions in Checking a cleaner cartridge into a library.

- Checking a cleaner cartridge into a library
  To enable automatic tape-drive cleaning, you must check a cleaner cartridge into the volume inventory of the automated library.
- Operations with cleaner cartridges
  To ensure that tape drives are cleaned when necessary, and to avoid issues with tape storage, follow the guidelines.

Related reference:
DEFINE DRIVE (Define a drive to a library)
UPDATE DRIVE (Update a drive)

Checking a cleaner cartridge into a library

To enable automatic tape-drive cleaning, you must check a cleaner cartridge into the volume inventory of the automated library.

About this task

When you check a cleaner cartridge into a library, ensure that it is correctly identified to the server as a cleaner cartridge. Ensure that a cleaner cartridge is not in a slot that is detected by the search process. Errors and delays of 15 minutes or more might indicate that a cleaner cartridge is improperly placed.

The preferred method is to check in cleaner cartridges individually. If you have to check in both data cartridges and cleaner cartridges, place the data cartridges in the library and check them in first. Then, check the cleaner cartridge in to the library.

Procedure

To check a cleaner cartridge into a library, issue the CHECKIN LIBVOLUME command. For example, to check in a cleaner cartridge that is named AUTOLIB1, issue the following command:

```
checkin libvolume autolib1 cleanv status=cleaner cleanings=10
 checklabel=no
```

The server requests that the cartridge is placed in the entry/exit port, or into a specific slot.

Related reference:

CHECKIN LIBVOLUME (Check a storage volume into a library)

Operations with cleaner cartridges

To ensure that tape drives are cleaned when necessary, and to avoid issues with tape storage, follow the guidelines.

Monitoring the cleaning process

If a cleaner cartridge is checked in to a library, and a drive must be cleaned, the server dismounts the data volume and runs the cleaning operation. If the cleaning operation fails or is canceled, or if no cleaner cartridge is available, you might not be aware that the drive needs cleaning. Monitor cleaning messages for these problems to ensure that drives are cleaned as needed. If necessary, issue the CLEAN DRIVE command to have the server try the cleaning again, or manually load a cleaner cartridge into the drive.

Using multiple cleaner cartridges

The server uses a cleaner cartridge for the number of cleanings that you specify when you check in the cleaner cartridge. If you check in two or more cleaner cartridges, the server uses only one of the cartridges until the designated number of cleanings for that cartridge is reached. Then, the server uses the next cleaner cartridge. If you check in two or more cleaner cartridges and issue two or more CLEAN DRIVE commands concurrently, the server uses multiple cartridges at the same time and decrements the remaining cleanings on each cartridge.

AUDIT LIBRARY (Audit volume inventories in an automated library)
CHECKIN LIBVOLUME (Check a storage volume into a library)
CLEAN DRIVE (Clean a drive)
LABEL LIBVOLUME (Label a library volume)
QUERY LIBVOLUME (Query a library volume)

Resolving errors that are related to drive cleaning

While moving cartridges within a library, you might place a data cartridge where a cleaner cartridge should be. Review the process that the server completes and the messages that are issued so that you can resolve the issue.

When a drive needs cleaning, the server loads what its database shows as a cleaner cartridge into the drive. The drive then moves to a READY state, and IBM Spectrum Protect™ detects that the cartridge is a data cartridge. The server completes the following steps:

1. The server attempts to read the internal tape label of the data cartridge.
2. The server ejects the cartridge from the drive and moves it back to the home slot of the cleaner cartridge within the library. If the eject operation fails, the server marks the drive offline and issues a message that the cartridge is still in the drive.
3. The server checks out the cleaner cartridge to avoid selecting it for another drive cleaning request. The cleaner cartridge remains in the library but no longer appears in the IBM Spectrum Protect library inventory.
4. By using the internal tape label, the server checks the volume name against the current library inventory, storage pool volumes, and the volume history file.
    - If the volume name is not found in the library inventory, a data cartridge might be checked in as a cleaner cartridge by mistake. When the volume is checked out, you do not have to take further action.
    - If the volume name is found in the library inventory, the server issues messages that manual intervention and a library audit are required. To resolve the issue, follow the instructions in Auditing the volume inventory in a library.

Tape drive replacement

If you replace a drive in a tape library that is defined to IBM Spectrum Protect™, you must delete the drive and path definitions for the old drive and define the new drive and path.

Replacing drive and path definitions is required even if you are exchanging one drive for another of the same type, with the same logical address, physical address, SCSI ID, and port number. Device alias names can change when you change your drive connections.

If the new drive is an upgrade that supports a new media format, you might be required to define a new logical library, device class, and storage pool. Procedures for setting up a policy for a new drive in a multiple-drive library vary, depending on the types of drives and media in the library.

- Deleting tape drives
  You can delete tape drives from a library. For example, you can delete a drive that you no longer use, or a drive that you want to replace.
- Replacing drives with others of the same type
  To add a drive that supports the same media formats as the drive it replaces, you must define a new drive and path.
- Migrating data to upgraded drives
  If you upgrade all of the tape drives in a library, you can preserve your existing policy definitions to migrate and expire existing data, and you can use the new drives to store data.

Deleting tape drives

You can delete tape drives from a library. For example, you can delete a drive that you no longer use, or a drive that you want to replace.

Procedure

1. Stop the IBM Spectrum Protect™ server and shut down the operating system.
2. Remove the old drive and follow the manufacturer's instructions to install the new drive.
3. Restart the operating system and the IBM Spectrum Protect server.
4. Delete the path from the server to the drive. For example, to delete a path from SERVER1 to LIB1, issue the following command:

   ```
   delete path server1 lib1 srctype=server desttype=drive
   ```

5. Delete the drive definition. For example, issue the following command to delete a drive that is named DLT1 from a library device that is named LIB1:

   ```
   delete drive lib1 dlt1
   ```

Related reference:
DELETE DRIVE (Delete a drive from a library)
DELETE PATH (Delete a path)

Replacing drives with others of the same type

To add a drive that supports the same media formats as the drive it replaces, you must define a new drive and path.

About this task

If a library includes only one model of drive and you want to replace a drive, you must replace the drive with the same model drive. If a library includes mixed models of drives and you want to replace a drive, you can replace the drive with any model drive that exists in the library.

Procedure

1. Delete the path and drive definitions for the old drive. For example, to delete a drive that is named DRIVE1 from a library that is named LIB1, enter the following command:

   ```
   delete path server2 drive1 srctype=server desttype=drive library=lib1
   delete drive lib1 drive1
   ```

2. Power off the library, remove the original drive, replace it with the new drive, and power on the library.
3. Refresh the host system to ensure that the system detects the new drive.
4. Define the new drive and path. For example, to define a new drive, DRIVE2, and a path to it from SERVER2, if you are using the IBM Spectrum Protect™ device driver, enter the following commands:

   AIX

   ```
   define drive lib1 drive2
   define path server2 drive2 srctype=server desttype=drive library=lib1
      device=/dev/mt0
   ```

   Linux

```
define drive lib1 drive2
define path server2 drive2 srctype=server desttype=drive library=lib1
   device=/dev/tsmscsi/mt0
```

Windows

```
define drive lib1 drive2
define path server2 drive2 srctype=server desttype=drive library=lib1
   device=mt3.0.0.1
```

Tip: You can use your existing library, device class, and storage pool definitions.

Related reference:
DELETE DRIVE (Delete a drive from a library)
DELETE PATH (Delete a path)

Migrating data to upgraded drives

If you upgrade all of the tape drives in a library, you can preserve your existing policy definitions to migrate and expire existing data, and you can use the new drives to store data.

Before you begin

The following scenario assumes that you already have a primary storage pool for a DISK device class that is named POOL1.

Procedure

1. To migrate data to a storage pool that is created for the new drives, specify the NEXTSTGPOOL parameter. For example, to migrate data from an existing storage pool, POOL1, to the new storage pool, POOL2, issue the following command:

   ```
   update stgpool pool1 nextstgpool=pool2
   ```

2. Update the management-class definitions to store data in the DISK storage pool by using the UPDATE MGMTCLASS command.

Related reference:
DEFINE STGPOOL (Define a volume in a storage pool)
UPDATE MGMTCLASS (Update a management class)
UPDATE STGPOOL (Update a storage pool)

Securing the IBM Spectrum Protect server

Secure the IBM Spectrum Protect™ server and data by controlling access to servers and client nodes, encrypting data, and maintaining secure access levels and passwords.

- Managing administrators
  An administrator who has system authority can complete any task with the IBM Spectrum Protect server, including assigning authority levels to other administrators. To complete some tasks, you must be granted authority by being assigned one or more authority levels.
- Changing password requirements
  You can change the minimum password limit, password length, password expiration, and enable or disable authentication for IBM Spectrum Protect.
- Securing the server on the system
  Protect the system where the IBM Spectrum Protect server runs to prevent unauthorized access.

Managing administrators

An administrator who has system authority can complete any task with the IBM Spectrum Protect™ server, including assigning authority levels to other administrators. To complete some tasks, you must be granted authority by being assigned one or more authority levels.

Procedure

Complete the following tasks to modify administrator settings.

Task	Procedure
Add an administrator.	To add an administrator, ADMIN1, with system authority and specify a password, complete the following steps: a. Register the administrator and specify Pa$#$twO as the password by issuing the following command: `register admin admin1 Pa$#$twO` b. Grant system authority to the administrator by issuing the following command: `grant authority admin1 classes=system`
Change administrative authority.	Change the authority level for an administrator, ADMIN1. • Grant system authority to the administrator by issuing the following command: `grant authority admin1 classes=system` • Revoke system authority for the administrator by issuing the following command: `revoke authority admin1 classes=system`
Remove administrators.	Remove an administrator, ADMIN1, from accessing the IBM Spectrum Protect server by issuing the following command: `remove admin admin1`
Temporarily prevent access to the server.	Lock or unlock an administrator by using the LOCK ADMIN or UNLOCK ADMIN command.

Related concepts:
Planning for administrator roles

Changing password requirements

You can change the minimum password limit, password length, password expiration, and enable or disable authentication for IBM Spectrum Protect™.

About this task

By enforcing password authentication and managing password restrictions, you protect your data and your servers from potential security risks.

Procedure

Complete the following tasks to change password requirements for IBM Spectrum Protect servers.

Table 1. Authentication tasks for IBM Spectrum Protect servers

Task	Procedure
Set a limit for invalid password attempts.	a. On the Servers page in the Operations Center, select the server. b. Click Details, and then click the Properties tab. c. Set the number of invalid attempts in the Invalid sign-on attempt limit field. The default value at installation is 0.

Task	Procedure
Set a minimum length for passwords.	a. On the Servers page in the Operations Center, select the server. b. Click Details and then click the Properties tab. c. Set the number of characters in the Minimum password length field.
Set the expiration period for passwords.	a. On the Servers page in the Operations Center, select the server. b. Click Details and then click the Properties tab. c. Set the number of days in the Password common expiration field.
Disable password authentication.	By default, the server automatically uses password authentication. With password authentication, all users must enter a password to access the server. You can disable password authentication only for passwords that authenticate with the server (LOCAL). By disabling password authentication, you increase the security risk for the server.
Set a default authentication method.	Issue the SET DEFAULTAUTHENTICATION command. For example, to use the server as the default authentication method, issue the following command: `set defaultauthentication local` To update one client node to authenticate with the server, include `AUTHENTICATION=LOCAL` in the UPDATE NODE command: `update node authentication=local`

Securing the server on the system

Protect the system where the IBM Spectrum Protect™ server runs to prevent unauthorized access.

Procedure

Ensure that unauthorized users cannot access the directories for the server database and the server instance. Keep the access settings for these directories that you configured during implementation.

- Restricting user access to the server
  Authority levels determine what an administrator can do with the IBM Spectrum Protect server. An administrator with system authority can complete any task with the server. Administrators with policy, storage, or operator authority can complete subsets of tasks.

Stopping and starting the server

Before you complete maintenance or reconfiguration tasks, stop the server. Then, start the server in maintenance mode. When you are finished with the maintenance or reconfiguration tasks, restart the server in production mode.

Before you begin

You must have system or operator privilege to stop and start the IBM Spectrum Protect™ server.

- Stopping the server
  Before you stop the server, prepare the system by ensuring that all database backup operations are completed, and all other processes and sessions are ended. In this way, you can safely shut down the server and ensure that data is protected.

- Starting the server for maintenance or reconfiguration tasks
  Before you begin server maintenance or reconfiguration tasks, start the server in maintenance mode. When you start the server in maintenance mode, you disable operations that might disrupt your maintenance or reconfiguration tasks.

Stopping the server

Before you stop the server, prepare the system by ensuring that all database backup operations are completed, and all other processes and sessions are ended. In this way, you can safely shut down the server and ensure that data is protected.

About this task

When you issue the HALT command to stop the server, the following actions occur:

- All processes and client node sessions are canceled.
- All current transactions are stopped. (The transactions will be rolled back when the server is restarted.)

Procedure

To prepare the system and stop the server, complete the following steps:

1. Prevent new client node sessions from starting by issuing the DISABLE SESSIONS command:

   ```
   disable sessions all
   ```

2. Determine whether any client node sessions or processes are in progress by completing the following steps:
   a. On the Overview page of the Operations Center, view the Activity area for the total numbers of processes and sessions that are currently active. If numbers differ significantly from the usual numbers that are displayed during your daily storage-management routine, view other status indicators in the Operations Center to check whether there is a problem.
   b. View the graph in the Activity area to compare the amount of network traffic over the following periods:
      - The current period, that is, the most recent 24-hour period
      - The previous period, that is, the 24 hours before the current period

      If the graph for the previous period represents the expected amount of traffic, significant differences on the graph for the current period might indicate a problem.
   c. On the Servers page, select a server for which you want to view processes and sessions, and click Details. If the server is not registered as a hub or spoke server in the Operations Center, obtain information about processes by using administrative commands. Issue the QUERY PROCESS command to query processes and obtain information about sessions by issuing the QUERY SESSION command.
3. Wait until the client node sessions are completed or cancel them. To cancel processes and sessions, complete the following steps:
   - On the Servers page, select a server for which you want to view processes and sessions, and click Details.
   - Click the Active Tasks tab, and select one or more processes, sessions, or a combination of both that you want to cancel.
   - Click Cancel.
   - If the server is not registered as a hub or spoke server in the Operations Center, cancel sessions by using administrative commands. Issue the CANCEL SESSION command to cancel a session and cancel processes by using the CANCEL PROCESS command.
     Tip: If the process that you want to cancel is waiting for a tape volume to be mounted, the mount request is canceled. For example, if you issue an EXPORT, IMPORT, or MOVE DATA command, the command might initiate a process that requires a tape volume to be mounted. However, if a tape volume is being mounted by an automated library, the cancel operation might not take effect until the mount process is complete. Depending on your system environment, this could take several minutes.
4. Stop the server by issuing the HALT command:

   ```
   halt
   ```

Starting the server for maintenance or reconfiguration tasks

Before you begin server maintenance or reconfiguration tasks, start the server in maintenance mode. When you start the server in maintenance mode, you disable operations that might disrupt your maintenance or reconfiguration tasks.

About this task

Start the server in maintenance mode by running the DSMSERV utility with the MAINTENANCE parameter.

The following operations are disabled in maintenance mode:

- Administrative command schedules
- Client schedules
- Reclamation of storage space on the server
- Inventory expiration
- Migration of storage pools

In addition, clients are prevented from starting sessions with the server.
Tips:

- You do not have to edit the server options file, dsmserv.opt, to start the server in maintenance mode.
- While the server is running in maintenance mode, you can manually start the storage-space reclamation, inventory expiration, and storage-pool migration processes.

Procedure

To start the server in maintenance mode, issue the following command:

```
dsmserv maintenance
```

Tip: To view a video about starting the server in maintenance mode, see Starting a server in maintenance mode.

What to do next

To resume server operations in production mode, complete the following steps:

1. Shut down the server by issuing the HALT command:

   ```
   halt
   ```

2. Start the server by using the method that you use in production mode. Follow the instructions for your operating system:
   - AIX Starting the server instance
   - Linux Starting the server instance
   - Windows Starting the server instance

Operations that were disabled during maintenance mode are reenabled.

Planning to upgrade the server

When a fix pack or interim fix becomes available, you can upgrade the IBM Spectrum Protect™ server to take advantage of product improvements. Servers and clients can be upgraded at different times. Ensure that you complete the planning steps before you upgrade the server.

About this task

Follow these guidelines:

- The preferred method is to upgrade the server by using the installation wizard. After you start the wizard, in the IBM Installation Manager window, click the Update icon; do not click the Install or Modify icon.
- If upgrades are available for both the server component and the Operations Center component, select the check boxes to upgrade both components.

Procedure

1. Review the list of fix packs and interim fixes. See technote 1239415.
2. Review product improvements, which are described in readme files.
   Tip: When you obtain the installation package file from the IBM Spectrum Protect support site, you can also access the readme file.

3. Ensure that the version that you upgrade your server to is compatible with other components, such as storage agents and library clients. See technote 1302789.
4. If your solution includes servers or clients at a level that is earlier than V7.1, review the guidelines to ensure that client backup and archive operations are not disrupted. See technote 1053218.
5. Review the upgrade instructions. Ensure that you back up the server database, the device configuration information, and the volume history file.

What to do next

To install a fix pack or interim fix, follow the instructions for your operating system:

- AIX Installing an IBM Spectrum Protect server fix pack
- Linux Installing an IBM Spectrum Protect server fix pack
- Windows Installing an IBM Spectrum Protect server fix pack

Related information:
Upgrade and Migration Process - Frequently Asked Questions

Preparing for an outage or system update

Prepare IBM Spectrum Protect™ to maintain your system in a consistent state during a planned power outage or system update.

About this task

Ensure that you schedule activities regularly to manage, protect, and maintain the server. For information about scheduling activities such as backing up the database, backing up the device configuration file, and backing up the volume history, see Defining schedules for server maintenance activities.

Procedure

1. Cancel processes and sessions that are in progress by completing the following steps:
   a. In the Operations Center, on the Servers page, select a server for which you want to view processes and sessions, and click Details.
   b. Click the Active Tasks tab, and select one or more processes, sessions, or a combination of both that you want to cancel.
   c. Click Cancel.
2. Stop the server by issuing the HALT command:

   ```
   halt
   ```

   Tip: You can issue the halt command from the Operations Center by hovering over the Settings icon and clicking Command Builder. Then, select the server, type `halt`, and press Enter.

HALT (Shut down the server)

Preparing for and recovering from a disaster by using DRM

IBM Spectrum Protect™ provides a disaster recovery manager (DRM) function to recover your server and client data during a disaster.

DRM tracks the movement of offsite media and registers that information in the IBM Spectrum Protect database. DRM consolidates plans, scripts, and other information in a plan file that is required to recover the IBM Spectrum Protect server when a disaster or unplanned outage occurs.
Restriction: DRM is only available in the IBM Spectrum Protect Extended Edition product.

- Disaster recovery plan file
  The disaster recovery plan file contains the information that is required to recover an IBM Spectrum Protect server to the point in time of the last database backup operation that was completed before the plan was created.
- Recovering the server and client data by using DRM
  Use the disaster recovery manager (DRM) function to recover the IBM Spectrum Protect server and client data when a disaster occurs.

- Running a disaster recovery drill
  Schedule disaster recovery drills to prepare for audits that certify the recoverability of the IBM Spectrum Protect server and to ensure that data can be restored and operations can resume after an outage. A drill also helps you ensure that all data can be restored and operations resumed before a critical situation occurs.
- Restoring the database
  If you have the disaster recovery manager (DRM) function enabled and you followed the procedure to prepare for a disaster, you can restore the database after a disaster. If you do not have DRM configured, you can still restore the database, provided that you have the required backup files.

Disaster recovery plan file

The disaster recovery plan file contains the information that is required to recover an IBM Spectrum Protect™ server to the point in time of the last database backup operation that was completed before the plan was created.

The plan is organized into stanzas, which you can separate into multiple files. Each stanza has a begin statement and an end statement.

Table 1. Stanzas in the disaster recovery plan file

Stanza	Information in the stanza
SERVER.REQUIREMENTS	Identifies the database and recovery log storage requirements for the server.
RECOVERY.INSTRUCTIONS.GENERAL	Identifies site-specific instructions that the administrator enters in the file that is identified by the prefix RECOVERY.INSTRUCTIONS.GENERAL. The instructions include the recovery strategy, key contact names, an overview of key applications that are backed up by this server, and other relevant recovery instructions.
RECOVERY.INSTRUCTIONS.OFFSITE	Contains instructions that the administrator enters in the file that is identified by the prefix RECOVERY.INSTRUCTIONS.OFFSITE. The instructions describe the name and location of the offsite vault, and how to contact the vault administrator (for example, a name and phone number).
RECOVERY.INSTRUCTIONS.INSTALL	Contains instructions that the administrator enters in the file that is identified by the prefix RECOVERY.INSTRUCTIONS.INSTALL. The instructions describe how to rebuild the base server and provide the location of the system image backup copies.
RECOVERY.INSTRUCTIONS.DATABASE	Contains instructions that the administrator enters in the file that is identified by the prefix RECOVERY.INSTRUCTIONS.DATABASE. The instructions describe how to prepare for the database recovery. For example, you might enter instructions about how to initialize or load the backup volumes for an automated library. No sample of this stanza is provided.
RECOVERY.INSTRUCTIONS.STGPOOL	Contains instructions that the administrator enters in the file that is identified by the prefix RECOVERY.INSTRUCTIONS.STGPOOL. The instructions include the names of your software applications and the copy storage pool names that contain the backups of these applications. No sample of this stanza is provided.
RECOVERY.VOLUMES.REQUIRED	Provides a list of the database backup and copy storage pool volumes that are required to recover the server. A database backup volume is included if it is part of the most recent database backup series. A copy storage pool volume is included if it is not empty and not marked destroyed.

Stanza	Information in the stanza
RECOVERY.DEVICES.REQUIRED	Provides details about the devices that are required to read the backup volumes.
RECOVERY.SCRIPT.DISASTER.RECOVERY.MODE	Contains a script with the commands that are required to recover the server.
RECOVERY.SCRIPT.NORMAL.MODE	Contains a script with the commands that are required to restore the server primary storage pools.
DB.STORAGEPATHS	Identifies the directories for the IBM Spectrum Protect database.
LICENSE.REGISTRATION	Contains a macro to register your server licenses.
COPYSTGPOOL.VOLUMES.AVAILABLE	Contains a macro to mark copy storage pool volumes that were moved offsite and then moved back onsite. You can use the information as a guide and issue the administrative commands. Alternatively, copy, modify, and run the macro to a file. This macro is started by the RECOVERY.SCRIPT.DISASTER.RECOVERY.MODE script.
COPYSTGPOOL.VOLUMES.DESTROYED	Contains a macro to mark copy storage pool volumes as unavailable if the volumes were onsite at the time of the disaster. These volumes are considered offsite and have not been destroyed in a disaster. You can use the information as a guide and issue the administrative commands from a command line, or you can copy, modify, and run the macro to a file. This macro is started by the RECOVERY.SCRIPT.DISASTER.RECOVERY.MODE script.
PRIMARY.VOLUMES.DESTROYED	Contains a macro to mark primary storage pool volumes as destroyed if the volumes were onsite at the time of disaster. You can use the information as a guide and run the administrative commands from a command line, or you can copy, modify, and run the macro to a file. This macro is started by the RECOVERY.SCRIPT.DISASTER.RECOVERY.MODE script.
PRIMARY.VOLUMES.REPLACEMENT	Contains a macro to identify replacement primary storage pool volumes. You can use the information as a guide and run the administrative commands from a command line, or you can copy, modify, and run the macro to a file. This macro is started by the RECOVERY.SCRIPT.DISASTER.RECOVERY.MODE script.
STGPOOLS.RESTORE	Contains a macro to restore the primary storage pools. You can use the stanza as a guide and run the administrative commands from a command line. You can also copy, modify, and run it to a file. This macro is started by the RECOVERY.SCRIPT.NORMAL.MODE script.
VOLUME.HISTORY.FILE	Contains a copy of the volume history information when the recovery plan was created. The DSMSERV RESTORE DB utility uses the volume history file to determine what volumes are needed to restore the database. The volume history file is used by the RECOVERY.SCRIPT.DISASTER.RECOVERY.MODE script.
DEVICE.CONFIGURATION.FILE	Contains a copy of the server device configuration information when the recovery plan was created. The DSMSERV RESTORE DB utility uses the device configuration file to read the database backup volumes. The device configuration file is used by the RECOVERY.SCRIPT.DISASTER.RECOVERY.MODE script.
DSMSERV.OPT.FILE	Contains a copy of the server options file. This stanza is used by the RECOVERY.SCRIPT.DISASTER.RECOVERY.MODE script.
LICENSE.INFORMATION	Contains a copy of the latest license audit results and the server license terms.

Stanza	Information in the stanza
MACHINE.GENERAL.INFORMATION	Provides information for the server machine, such as its location, which is needed to rebuild the server machine. This stanza is included in the plan file if the machine information is saved in the database by using the DEFINE MACHINE command and specifying the ADSMSERVER=YES.
MACHINE.RECOVERY.INSTRUCTIONS	Provides the recovery instructions about the server machine. This stanza is included in the plan file if the machine recovery instructions are saved in the database.
MACHINE.RECOVERY.CHARACTERISTICS	Provides the hardware and software characteristics for the server machine. This stanza is included in the plan file if the machine characteristics are saved in the database.
MACHINE.RECOVERY.MEDIA	Provides information about the media that are required for rebuilding the machine that contains the server. This stanza is included in the plan file if recovery media information is saved in the database and it is associated with the machine that contains the server.

Recovering the server and client data by using DRM

Use the disaster recovery manager (DRM) function to recover the IBM Spectrum Protect™ server and client data when a disaster occurs.

Before you begin

IBM Spectrum Protect is set up to use the Secure Sockets Layer (SSL) protocol for client/server authentication. When you start the server, a digital certificate file, cert.kdb, is created as part of the process. This file includes the server's public key, which allows the client to encrypt data. The digital certificate file cannot be stored in the server database because the Global Security Kit (GSKit) requires a separate file in a certain format.

The master encryption key is stored in a new GSKit-managed key database, dsmkeydb.kdb. If the server has an existing master encryption key, the master encryption key is migrated from the dsmserv.pwd file to the key database, dsmkeydb.kdb. Keep backup copies of the dsmkeydb.kdb and dsmkeydb.sth files. You can configure the BACKUP DB command to back up the master encryption key, or you can manually back up the dsmkeydb.kdb and dsmkeydb.sth files yourself.

1. Keep backup copies of the cert.kdb, cert.sth, and cert256.arm files.
2. If both the original certificate files and any copies are lost or corrupted, generate new certificate files.

Procedure

1. Get the latest recovery plan.
2. Review the recovery steps that are described in the RECOVERY.INSTRUCTIONS.GENERAL stanza of the plan.
3. Separate the stanzas of the plan file into individual files for general preliminary instructions, IBM Spectrum Protect server recovery scripts, and client recovery instructions.
4. Retrieve all required recovery volumes (as listed in the plan) from the vault.
5. Review the device configuration file to ensure that the hardware configuration at the recovery site is the same as the original site. Any differences must be updated in the device configuration file. The following example configuration changes require updates to the configuration information:
    - Different device names.
    - For automated libraries, the requirement of manually placing the database backup volumes in the automated library and updating the configuration information to identify the element within the library. This allows the server to locate the required database backup volumes.
6. Set up replacement hardware for the IBM Spectrum Protect server, including the operating system and the IBM Spectrum Protect base release installation.
7. Run the IBM Spectrum Protect server recovery scripts from the recovery plan. The RECOVERY.SCRIPT.DISASTER.RECOVERY.MODE and RECOVERY.SCRIPT.NORMAL.MODE stanzas contain executable command files that can be used to drive the recovery of the IBM Spectrum Protect server by calling other command files that were generated in the plan. The RECOVERY.SCRIPT.DISASTER.RECOVERY.MODE script recovers the server to the point where clients can begin restores directly from the copy storage pool volumes.

8. Restore the primary storage pools by using the RECOVERY.SCRIPT.NORMAL.MODE script.
9. Start client restore operations in order of highest priority, as defined in your high-level planning.

What to do next

The IBM Spectrum Protect server can now be used for normal server operations. Ensure that all required operations are scheduled. For instructions, see Defining schedules for server maintenance activities and Scheduling backup and archive operations.

Related tasks:

Repairing and recovering data in directory-container storage pools

Related reference:

PREPARE (Create a recovery plan file)

Running a disaster recovery drill

Schedule disaster recovery drills to prepare for audits that certify the recoverability of the IBM Spectrum Protect™ server and to ensure that data can be restored and operations can resume after an outage. A drill also helps you ensure that all data can be restored and operations resumed before a critical situation occurs.

Before you begin

Complete the following tasks:

- Schedule activities regularly to manage, protect, and maintain the server. For more information about scheduling activities, see Defining schedules for server maintenance activities. Ensure that you schedule the following tasks:
  - Backing up the database.
  - Moving media offsite.
  - Backing up the device configuration file, the volume history file, and the dsmserv.opt server options file.
  - **Optional:** Issuing the PREPARE command to create the disaster recovery plan file.

  Tip:

  When you issue the PREPARE command, the IBM Spectrum Protectdisaster recovery manager (DRM) function creates one copy of the disaster recovery plan file.

  You can manage offsite disaster recovery without using DRM, however, DRM helps to consolidate plans, scripts, and other information that is required during disaster recovery.

  Create multiple copies of the plan for safekeeping. For example, keep copies in print, on a USB flash drive, on disk space that is located offsite, or on a remote server. The disaster recovery plan file is moved offsite daily with the tapes. For more information about DRM, see Preparing for and recovering from a disaster by using DRM.

- Configure the following resources at the disaster recovery site:
  1. A recovery IBM Spectrum Protect server. The server at the disaster recovery site must be at the same level as the server on the production site.
  2. A tape library to store the media that is shipped from the production site. For more information about offsite recovery locations, see Offsite data storage.
  3. Disk storage space for the database, archive log, active logs, and storage pools.
  4. Clients to test restore operations.

About this task

Test the disaster recovery plan and the IBM Spectrum Protect server recoverability often, in an environment that is similar to the production environment.

Procedure

1. Ensure that tapes are available onsite. Issue the QUERY LIBVOLUME command to identify volumes that are checked into an automated library.
2. Back up the database to the onsite tapes by completing the following steps:
   a. On the Servers page of the Operations Center, select the server whose database you want to back up.
   b. Click Back Up, and follow the instructions in the Back Up Database window.
3. Copy the following files to the home directory of the server at the recovery site:

    - Disaster recovery plan file
    - Volume history file
    - Device configuration file
    - Optional: dsmserv.opt server options file
4. Move the tape to the offsite recovery location.
5. Restore the server database by using the DSMSERV RESTORE DB utility on the recovery server. For more information about restoring the server database, see Restoring the database.
6. Issue the UPDATE VOLUME command and specify the ACCESS=DESTROYED parameter to indicate that an entire volume must be restored.
7. On the recovery server, restore the storage pool volumes by using the RESTORE STGPOOL command.

What to do next

Ensure that you can access the data in the library by auditing a tape volume in the restored storage pool to verify that the data is consistent. Issue the AUDIT VOLUME command to audit a tape volume. For faster performance, audit restored data only.

Related tasks:

Auditing the volume inventory in a library

Related reference:

AUDIT VOLUME (Verify database information for a storage pool volume)

DSMSERV RESTORE DB (Restore the database)

RESTORE STGPOOL (Restore storage pool data)

Restoring the database

If you have the disaster recovery manager (DRM) function enabled and you followed the procedure to prepare for a disaster, you can restore the database after a disaster. If you do not have DRM configured, you can still restore the database, provided that you have the required backup files.

Before you begin

If the database and recovery log directories are lost, re-create them before you run the DSMSERV RESTORE DB server utility.

About this task

You can restore the database to its most current state or to a specified point in time. To recover the database to the time when the database was lost, recover the database to its latest version.

Restrictions:

- To restore the database to its latest version, you must locate the archive log directory. If you cannot locate the directory, you can restore the database only to a point in time.
- You cannot use the Secure Sockets Layer (SSL) protocol for database restore operations.
- If the release level of the database backup is different from the release level of the server that is being restored, you cannot restore the server database. For example, if you are using a Version 8.1 server and you try to restore a V7.1 database, an error occurs.

Procedure

Use the DSMSERV RESTORE DB server utility to restore the database. Depending on the version of the database that you want to restore, choose one of the following methods:

- Restore a database to its latest version. For example, use the following command:

  ```
  dsmserv restore db
  ```

- Restore a database to a point in time. For example, to restore the database to a backup series that was created on 19 April 2017, use the following command:

  ```
  dsmserv restore db todate=04/19/2017
  ```

Version 7 what's new videos

Operations Center updates

New features are available in IBM Spectrum Protect™ Operations Center Version 8.1.2. By using the updated Operations Center, you can back up data to Microsoft Azure cloud storage and benefit from enhanced security enforcement.

The following enhancements were made to the Operations Center:

- You can use the Add Storage Pool wizard to create cloud-container storage pools that use Microsoft Azure, a cloud-based object storage system, to back up data.
- The Operations Center now provides enhanced security by enforcing the use of Transport Layer Security (TLS) 1.2 encryption for communication between the Operations Center and the hub server.

For more information about these enhancements, see the Operations Center help.

IBM Spectrum Protect server updates

New features and other changes are available in the IBM Spectrum Protect™ Version 8.1.2 server.

- Back up data to Microsoft Azure, a cloud-based object storage system
  With IBM Spectrum Protect Version 8.1.2, you can configure cloud-container storage pools to use Microsoft Azure, a cloud-based object storage system, to back up and restore data.
- Encrypt client data in a directory-container storage pool
  IBM Spectrum Protect Version 8.1.2 provides enhanced protection for client data. If you used an earlier release of IBM Spectrum Protect to write client data to a directory-container storage pool, you can encrypt the existing client data in the storage pool. You can also enable encryption of new client data before it is written to the storage pool.
- Back up a NAS file server to a directory-container storage pool
  With IBM Spectrum Protect Version 8.1.2, you can back up a file system that belongs to a network-attached storage (NAS) file server to a directory-container storage pool. By using directory-container storage pools, you can reduce the cost of storage hardware, improve server performance, and enhance security.
- Install IBM Spectrum Protect on the Linux on Power Systems (little endian) operating system
  You can install IBM Spectrum Protect Version 8.1.2 on the Linux on Power Systems™ (little endian) operating system. Limited support for this operating system was introduced in V8.1.1, and full support is introduced in V8.1.2. After you install and configure the V8.1.2 server on Linux on Power Systems (little endian), you can back up data to disk devices, cloud object storage, and tape devices.
- Protect your storage environment with an improved security protocol
  IBM Spectrum Protect Version 8.1.2 provides an improved security protocol.
- Optimize security with the automatically generated master encryption key
  Beginning with IBM Spectrum Protect Version 8.1.2, a master encryption key is automatically generated when you start the server if the master encryption key did not previously exist.
- Configure a storage environment by using the Tape Solution Guide
  The documentation set is updated to include the *IBM Spectrum Protect Tape Solution Guide*. By following the instructions in the guide, you can configure a tape-based solution that optimizes storage and supports disaster recovery by ensuring that data is securely backed up to an offsite location.
- Schedule automatic updates for backup-archive clients
  With IBM Spectrum Protect Version 8.1.2, you can schedule deployment of software updates to systems that already have the backup-archive client installed.
- Upgrade your IBM Spectrum Protect server to V8.1.2 before you upgrade clients
  Upgrade your IBM Spectrum Protect servers to Version 8.1.2 before you upgrade the backup-archive clients.
- Deprecated and discontinued server options, commands, and parameters
  Some server options, commands, and parameters are deprecated or no longer available, beginning with IBM Spectrum Protect Version 8.1.2. The behavior of some parameters and options has changed.

Back up data to Microsoft Azure, a cloud-based object storage system

With IBM Spectrum Protect™ Version 8.1.2, you can configure cloud-container storage pools to use Microsoft Azure, a cloud-based object storage system, to back up and restore data.

By configuring cloud-container storage pools to use Azure, you can simplify storage management and secure data by using encryption.

Related tasks:
Preparing for Azure
Configuring a cloud-container storage pool
Related reference:
DEFINE STGPOOL (Define a cloud-container storage pool)
UPDATE STGPOOL (Update a cloud-container storage pool)

Encrypt client data in a directory-container storage pool

IBM Spectrum Protect™ Version 8.1.2 provides enhanced protection for client data. If you used an earlier release of IBM Spectrum Protect to write client data to a directory-container storage pool, you can encrypt the existing client data in the storage pool. You can also enable encryption of new client data before it is written to the storage pool.

To enable encryption for an existing directory-container storage pool, issue the UPDATE STGPOOL command and specify ENCRYPT=YES. To enable encryption for a new directory-container storage pool, define the storage pool by using the DEFINE STGPOOL command and specify ENCRYPT=YES.

Related tasks:
Configuring a directory-container storage pool for data storage

Related reference:
DEFINE STGPOOL (Define a directory-container storage pool)
UPDATE STGPOOL (Update a directory-container storage pool)

Back up a NAS file server to a directory-container storage pool

With IBM Spectrum Protect™ Version 8.1.2, you can back up a file system that belongs to a network-attached storage (NAS) file server to a directory-container storage pool. By using directory-container storage pools, you can reduce the cost of storage hardware, improve server performance, and enhance security.

Directory-container storage pools offer the following advantages:

- You can enable inline data deduplication to eliminate duplicate data while it is written to the storage pool. In this way, you can reduce the need for offline reorganization, improve server performance, and lower costs.
- You can enable inline compression to reduce the amount of space that data occupies.
- You can enable encryption to encrypt client data before it is written to the storage pool.
- You can protect data by using the PROTECT STGPOOL command. You can store a copy of the data in another directory-container storage pool on a target replication server or on tape in a container-copy storage pool. To restore damaged data, you can run the REPAIR STGPOOL command.

Related tasks:
Protecting NAS file servers

Linux

Install IBM Spectrum Protect on the Linux on Power Systems (little endian) operating system

You can install IBM Spectrum Protect™ Version 8.1.2 on the Linux on Power Systems™ (little endian) operating system. Limited support for this operating system was introduced in V8.1.1, and full support is introduced in V8.1.2. After you install and configure the V8.1.2 server on Linux on Power Systems (little endian), you can back up data to disk devices, cloud object storage, and tape devices.

The installation packages include the server and license, device driver tools, the Operations Center, and the storage agent. The following restrictions apply:

- You cannot set up a clustered environment.
- You cannot use the QUERY SAN command or the SANDISCOVERY server option to detect devices on a storage area network when the devices are connected to a host bus adapter (HBA) card that is configured by using the N_Port ID Virtualization (NPIV) method.
- You cannot optimize data transfer to remote servers by enabling Aspera® Fast Adaptive Protocol (FASP®) technology.
- You cannot set up automated cartridge system library software (ACSLS) libraries.

Related tasks:
Linux: Installing the server

Linux: Minimum Linux on Power Systems™ (little endian) server requirements

Protect your storage environment with an improved security protocol

IBM Spectrum Protect™ Version 8.1.2 provides an improved security protocol.

To protect your storage environment from security threats, IBM Spectrum Protect has an improved security protocol that uses Transport Layer Security (TLS) 1.2 to encrypt all communication between the server, storage agent, and clients. A new SESSIONSECURITY parameter determines whether an administrator, node, or server must use the most secure settings to communicate with an IBM Spectrum Protect server. IBM Spectrum Protect servers, clients, and storage agents that use V8.12 or later software are automatically configured to communicate with each other by using the Secure Sockets Layer (SSL) protocol. Certificates are distributed automatically.

For a detailed description of the SESSIONSECURITY parameter, see the command topics for registering and updating administrator IDs, nodes, and servers. For the latest information about V8.1.2 security updates, see technote 2004844.

Security concepts

Optimize security with the automatically generated master encryption key

Beginning with IBM Spectrum Protect™ Version 8.1.2, a master encryption key is automatically generated when you start the server if the master encryption key did not previously exist.

The newly generated master encryption key is stored in a new key database, dsmkeydb.kdb. If the server has an existing master encryption key, the key is migrated from the dsmserv.pwd file to the new key database. The automatic generation of the master encryption key and its storage in the new key database are designed to enhance system security. Server certificates are still stored in the cert.kdb key database and accessed by the stash file cert.sth.

You must protect both the key databases (cert.kdb and dsmkeydb.kdb) and the stash files (cert.sth and dsmkeydb.sth) that provide access to each of the key databases. By default, the BACKUP DB command protects the master encryption key, but you must remember the database backup password to restore the database. The IBM Spectrum Protect server dsmserv.pwd file, which was used to store the master encryption key in previous releases, is no longer used.

Recovering data by using DRM

Configure a storage environment by using the Tape Solution Guide

The documentation set is updated to include the *IBM Spectrum Protect™ Tape Solution Guide*. By following the instructions in the guide, you can configure a tape-based solution that optimizes storage and supports disaster recovery by ensuring that data is securely backed up to an offsite location.

The guide provides instructions for completing the following tasks:

- Plan and implement a data protection solution that uses one or more tape storage devices to back up data
- Monitor an IBM Spectrum Protect tape solution
- Manage tape devices and tape drives
- Recover data after a disaster or unplanned outage

Schedule automatic updates for backup-archive clients

With IBM Spectrum Protect™ Version 8.1.2, you can schedule deployment of software updates to systems that already have the backup-archive client installed.

You can use IBM Spectrum Protect server commands to schedule updates for one or more backup-archive clients. The updates can be fix packs or new releases. This feature was available in previous releases of IBM Spectrum Protect, but an improved procedure is available for V8.1.2.

For more information about automatically deploying client updates from the server, see the following documents:

- For IBM Spectrum Protect V8.1.2 or later servers, see technote 2004596.
- For IBM® Tivoli® Storage Manager V7.1 servers and IBM Spectrum Protect V8.1.0 and V8.1.1 servers, see technote 1673299.

Upgrade your IBM Spectrum Protect server to V8.1.2 before you upgrade clients

Upgrade your IBM Spectrum Protect™ servers to Version 8.1.2 before you upgrade the backup-archive clients.

If you do not upgrade your servers first, communication between servers and clients might be interrupted.

Deprecated and discontinued server options, commands, and parameters

Some server options, commands, and parameters are deprecated or no longer available, beginning with IBM Spectrum Protect™ Version 8.1.2. The behavior of some parameters and options has changed.

Due to security protocol changes, the following updates were made in the product:

- Two SSL-related parameters, VALIDATEPROTOCOL and SSLREQUIRED, are deprecated and ignored. These parameters are replaced by the SESSIONSECURITY parameter.
- Four SSL-related server options, USETLS12, SSLTLS12, SSLHIDELEGACY, and SSLDISABLELEGACYTLS, are no longer available.
- The behavior of the SSL parameter on the DEFINE SERVER and UPDATE SERVER commands changed. SSL is now used to encrypt some communication with the server even if you specify SSL=NO.
- The behavior of the TCPPORT and TCPADMINPORT options changed. The port number that is specified in the TCPPORT or TCPADMINPORT option now listens for and accepts both TCP/IP and SSL-enabled sessions. You are no longer required to specify the SSLTCPPORT or SSLTCPADMINPORT option to allow SSL-enabled sessions from the client.
- The SET AUTHENTICATION, SET REGISTRATION, DELETE KEYRING, QUERY SSLKEYRINGPW, and SET SSLKEYRINGPW commands are no longer available.

  IBM Spectrum Protect device support for V8.1 is available. Compatibility, installation, and other getting-started issues are addressed.

Release notes for IBM Spectrum Protect server Version 8.1

The IBM Spectrum Protect™ server V8.1 is available. Compatibility, installation, and other getting-started issues are addressed.

Contents

Description

IBM Spectrum Protect provides automated, centrally scheduled, policy-managed backup, archive, and space-management capabilities for file servers, workstations, virtual machines, and applications.

An authorized program analysis report (APAR) is a request for the correction of a defect in a supported release of a program supplied by IBM. For a list of resolved APARs, see APARs fixed in IBM Spectrum Protect server Version 8.1.

Announcement

The announcement for the IBM Spectrum Protect V8.1 family of products includes the following information:

- Detailed product description, including descriptions of new functions
- Product-positioning statement
- International compatibility information

To search for the product announcement, complete the following steps:

1. Go to the product announcement website.
2. In the Search for field, enter the product identifier (PID) for your product. The PID for IBM Spectrum Protect is 5725-W98.
3. In the Information Type field, select Announcement letters, and click Search.
4. From the Search in list, select Product Number.
5. Optional: In the Refine Your Search pane on the left side of the window, select the country where you reside.
6. In the Sort by section, select Newest first.

Compatibility with earlier versions

For compatibility with earlier versions, see the IBM Spectrum Protect Server-Client Compatibility and Upgrade Considerations.

System requirements

For system requirement information, see the IBM Spectrum Protect Supported Operating Systems.

Installing and upgrading IBM Spectrum Protect

For server installation instructions, see the procedure for your operating system:

IBM AIX®
: Installing the server

Linux
: Installing the server

Microsoft Windows
: Installing the server

For upgrade instructions, see Upgrading to V8.1.

Updates, limitations, and known problems

Updates describe new product information or new product features that become available after product release. Updates, limitations, and known issues are documented in the form of technotes in the support knowledge base of the IBM® Support Portal. By searching the knowledge base, you can find workarounds or solutions to known issues.

Updates

REGISTER NODE command no longer creates an administrative user ID by default

Beginning with IBM Spectrum Protect V8.1, the REGISTER NODE command does not automatically create an administrative user ID that matches the node name. This product update can affect the process of registering client nodes, including but not limited to IBM Spectrum Protect backup-archive client nodes. In some cases, you might have to create an administrative user ID by specifying the USERID parameter on the REGISTER NODE command. For information about the types of clients that are affected, see technote 7048963.

To search for the latest updates, see Updates for IBM Spectrum Protect V8.1.

Limitations and known problems

At the time of publication, there were no limitations or known problems.

To search for the latest limitations and known problems, which might include additional items, see Limitations and known problems for IBM Spectrum Protect V8.1.

Release notes for Operations Center Version 8.1

The Operations Center is a web-based interface that you can use to manage your IBM Spectrum Protect™ environment. The release notes give you access to the product announcement, known issues, system requirements, installation instructions, and updates.

Contents

Description

You can use the Operations Center to take the following actions:

- Identify potential issues with your IBM Spectrum Protect environment
- Monitor key aspects of the storage environment: alerts, clients, servers, policies, storage pools, and storage devices
- Register clients
- Add servers to be monitored
- Back up clients, server databases, and storage pools
- Start storage pool migration and reclamation
- Assign alerts to administrators, and close alerts
- View and cancel server processes and client sessions
- Change client, server, storage pool, and storage device settings
- Create and manage client schedules and view administrative schedules
- Convert primary storage pools to container storage pools
- Copy data from directory-container storage pools to tape
- Configure replication
- Modify policy settings
- Decommission clients and deactivate data
- Create email reports
- View front-end and back-end capacity usage to monitor license compliance
- Issue commands to IBM Spectrum Protect servers

An authorized program analysis report (APAR) is a request for the correction of a defect in a supported release of a program supplied by IBM. For a list of resolved APARs, see APARs fixed in IBM Spectrum Protect Operations Center Version 8.1.

Announcement

The Operations Center is part of the IBM Spectrum Protect V8.1 family of products. The announcement for these products includes the following information:

- Detailed product description, including descriptions of new functions
- Product-positioning statement
- International compatibility information

To search for the product announcement, complete the following steps:

1. Go to the product announcement website.
2. In the Search for field, enter the product identifier (PID) for your product. The PID for IBM Spectrum Protect is 5725-W98.
3. In the Information Type field, select Announcement letters, and click Search.
4. From the Search in list, select Product Number.
5. Optional: In the Refine Your Search pane on the left side of the window, select the country where you reside.
6. In the Sort by section, select Newest first.

Compatibility with the IBM Spectrum Protect server

For compatibility information, see IBM Spectrum Protect server and Operations Center compatibility.

System requirements

For system requirements, see IBM Spectrum Protect Operations Center software and hardware requirements.

Installing or upgrading the Operations Center

For installation instructions, or to upgrade an existing version of the Operations Center, see Installing and upgrading the Operations Center.

Updates, limitations, and known issues

Updates describe new product information or new product features that become available after product release. Updates, limitations, and known issues are documented in the form of technotes in the support knowledge base of the IBM® Support Portal. By searching the knowledge base, you can find workarounds or solutions to known issues.

Updates

For the latest list of updates, see Search results for updates to Operations Center V8.1.

Limitations and known issues

- For a list of limitations and known issues, see Limitations and known issues with Operations Center V8.1.
- To search for additional issues that might become known after the product release, see Search results for known issues with Operations Center V8.1.

Release notes for IBM Spectrum Protect device support Version 8.1

IBM Spectrum Protect™ device support for V8.1 is available. Compatibility, installation, and other getting-started issues are addressed.

Contents

Description

This document includes information about IBM Spectrum Protect V8.1 device drivers.

An authorized program analysis report (APAR) is a request for the correction of a defect in a supported release of a program supplied by IBM. For a list of resolved APARs, see APARs Fixed in IBM Spectrum Protect device driver Version 8.1.

Announcement

IBM Spectrum Protect device support for V8.1 is announced as part of the IBM Spectrum Protect family of products announcement. The announcement for these products includes the following information:

- Detailed product description, including descriptions of new functions
- Product-positioning statement
- International compatibility information

To search for the product announcement, complete the following steps:

1. Go to the product announcement website.
2. In the Search for field, enter the product identifier (PID) for your product. The PID for IBM Spectrum Protect is 5725-W98.
3. In the Information Type field, select Announcement letters, and click Search.
4. From the Search in list, select Product Number.
5. Optional: In the Refine Your Search pane on the left side of the window, select the country where you reside.
6. In the Sort by section, select Newest first.

Supported devices

For information about supported devices and hardware for IBM AIX® and Microsoft Windows systems, see Supported devices for AIX and Windows.

For information about supported devices and hardware for Linux systems, see Supported devices for Linux.

Device driver requirements

Host bus adapter requirements
: For best results, connect tape drives and tape libraries to the system on their own host bus adapter. Do not share the host bus adapter with other device types, such as DISK or CD.

Maximum number of devices that are supported by IBM Spectrum Protect device drivers
: For information about the maximum number of devices that IBM Spectrum Protect device drivers can support on each operating system, see technote 1364225.

Serial Attached SCSI (SAS) device support
: SAS devices can be used on some operating systems and architectures. For information about operating systems and architectures for SAS devices, see technote 1396706.

Running the IBM Spectrum Protect passthru driver with a non-root user ID on Linux operating systems
: For information about how a non-root user can use devices with the IBM Spectrum Protect passthru driver on Linux, see technote 1321130. Use option -g or -a of the device autoconf utility to ensure that non-root users can use devices that are configured with the IBM Spectrum Protect passthru driver. Use option -g to add read and write permissions for groups to the SCSI generic driver (sg) device files. Use option -a to add read and write permissions for all users to the sg device files.

Library information

- IBM Spectrum Protect Extended Edition is required for a library with greater than four drives or greater than 48 storage slots.
- The element addresses of the storage slots might not directly correspond to the storage slot numbers. This fact is important because the IBM Spectrum Protect server always references storage slots by element addresses, not storage slot numbers. For element addresses, see the library configuration page for each library.
- For a library with multiple drives, a drive element address is required for the DEFINE and UPDATE DRIVE commands. However, if the library reports drive serial numbers, you can specify ELEMENT=AUTODETECT, and the element address is not required.
- For the procedure to configure the autochanger and each drive in the library separately, see Configuring and managing storage devices.

Updates, limitations, and known problems

Updates

Some devices that were supported by previous releases of IBM Spectrum Protect are no longer supported by the IBM Spectrum Protect V8.1 server. For the latest list of supported devices, see the following links:

- Supported devices for AIX and Windows
- Supported devices for Linux

To search for the latest updates, limitations, and known problems, which might include additional items, see Updates, limitations, and known problems for IBM Spectrum Protect V8.1 device support.

Readme files for Version 8.1 server components

Readme files for Version 8.1 fix packs are published in the IBM Software Support website. Updates might be available for server components, including the server itself, device support, and the Operations Center.

View IBM Spectrum Protect™ server V8.1 fix pack readme files

Installing and upgrading

- Implementing an IBM Spectrum Protect solution
  If you are deploying a new IBM Spectrum Protect server environment, consider implementing a best practice configuration.
- Installing and upgrading the server
  The IBM Spectrum Protect server provides backup, archive, and space management services to clients. You can install or upgrade individual or multiple servers in your enterprise network.
- Installing and upgrading the Operations Center
  The Operations Center is the web-based interface for managing your storage environment.

Implementing an IBM Spectrum Protect solution

If you are deploying a new IBM Spectrum Protect™ server environment, consider implementing a best practice configuration.

IBM Spectrum Protect solution documentation is available to help you select a best practice solution, based on your business needs and then install, configure, monitor, and operate that solution.

For details, see Selecting an IBM Spectrum Protect solution.

Availability of features by operating system

Most IBM Spectrum Protect™ features are available on all operating systems that are supported for the server.

In the following table, a check mark indicates that a feature is available.

Table 1. Availability of IBM Spectrum Protect features by operating system

Feature	IBM® AIX®	Linux x86_64	Linux on System z®	Linux on Power Systems™ (little endian)	Microsoft Windows
Aspera® Fast Adaptive Secure Protocol (FASP®) technology: Optimize data transfer to a remote server.		✓			
Cloud storage by using Amazon Simple Storage Service (Amazon S3) technology.	✓	✓		✓	✓
Cloud storage by using IBM Cloud Object Storage technology.	✓	✓		✓	✓

Feature	IBM® AIX®	Linux x86_64	Linux on System z®	Linux on Power Systems™ (little endian)	Microsoft Windows
Cloud storage by using IBM SoftLayer® (IBM Bluemix®) technology.	✓	✓		✓	✓
Cloud storage by using Microsoft Azure technology.	✓	✓		✓	✓
Cloud storage by using OpenStack Swift technology.	✓	✓		✓	✓
Data deduplication: Use *inline data deduplication* to eliminate duplicate data while the data is written to a directory-container storage pool or cloud-container storage pool. By using inline data deduplication, you reduce the need for offline reorganization and can improve server performance and lower the cost of storage hardware.	✓	✓	✓	✓	✓
Data deduplication: Use *postprocess data deduplication* to eliminate duplicate data from sequential-access disk storage pools. This option can result in longer processing times because the server must identify the data, and then remove it from the storage pool.	✓	✓	✓	✓	✓
Disaster recovery manager (DRM): Prepare a plan for recovering your server and client data if a disaster occurs.	✓	✓	✓	✓	✓
Inline data compression: Compress data as it is written to a cloud-container or directory-container storage pool to reduce the amount of space that the data occupies.	✓	✓	✓	✓	✓
Lightweight Directory Access Protocol (LDAP) authentication: Authenticate users to an Active Directory database on an LDAP server.	✓	✓	✓	✓	✓
Node replication: Incrementally copy data that belongs to backup-archive client nodes from one server to another.	✓	✓	✓	✓	✓
Operations Center: Monitor and manage the storage environment by using the Operations Center, a web-based user interface.	✓	✓	✓	✓	✓

Feature	IBM® AIX®	Linux x86_64	Linux on System z®	Linux on Power Systems™ (little endian)	Microsoft Windows
Protection of directory-container storage pools: Protect data in directory-container storage pools by using the PROTECT STGPOOL command. You can store a copy of the data in another directory-container storage pool on a target replication server, or store a copy on tape in a container-copy storage pool on the same server.	✓	✓	✓	✓	✓
Storage pool encryption: Encrypt data in cloud-container storage pools.	✓	✓		✓	✓
Storage pool encryption: Encrypt data in directory-container storage pools.	✓	✓	✓	✓	✓
Tape storage: Store data on tape, which provides a flexible and affordable option for long-term data retention.	✓	✓	✓	✓	✓
Transport Layer Security (TLS) 1.2 protocol: Secure communications by using TLS 1.2.	✓	✓	✓	✓	✓

Installing and upgrading the server

The IBM Spectrum Protect™ server provides backup, archive, and space management services to clients. You can install or upgrade individual or multiple servers in your enterprise network.

- Installing the server on AIX systems
- Installing the server on Linux systems
- Installing the server on Windows systems
- Upgrading the server

AIX: Installing the server

Installation of the server includes planning, installation, and initial configuration.

- AIX: Planning to install the server
  Install the server software on the computer that manages storage devices and install the client software on every workstation that transfers data to IBM Spectrum Protect™ server-managed storage.
- AIX: Installing the server components
  To install the Version 8.1.2 server components, you can use the installation wizard, the command line in console mode, or silent mode.
- AIX: Taking the first steps after you install IBM Spectrum Protect
  After you install Version 8.1.2, prepare for the configuration. Using the configuration wizard is the preferred method of configuring the IBM Spectrum Protect instance.
- AIX: Installing an IBM Spectrum Protect server fix pack
  IBM Spectrum Protect maintenance updates, which are also referred to as fix packs, bring your server up to the current maintenance level.
- AIX: Reverting from Version 8.1.2 to a previous server
  If you must revert to the previous version of the server after an upgrade, you must have a full database backup from your original version. You must also have the server installation media for your original version and key configuration files. Carefully follow the preparation steps before you upgrade the server. By doing so, it might be possible to revert to the previous version of the IBM Spectrum Protect server with minimal loss of data.

- AIX: Reference: DB2 commands for IBM Spectrum Protect server databases
  Use this list as reference when you are directed to issue DB2® commands by IBM® support.
- AIX: Uninstalling IBM Spectrum Protect
  You can use the following procedures to uninstall IBM Spectrum Protect. Before you remove IBM Spectrum Protect, ensure that you do not lose your backup and archive data.

AIX: Planning to install the server

Install the server software on the computer that manages storage devices and install the client software on every workstation that transfers data to IBM Spectrum Protect™ server-managed storage.

- AIX: What you should know first
  Before installing IBM Spectrum Protect, be familiar with your operating systems, storage devices, communication protocols, and system configurations.
- AIX: What you should know about security before you install or upgrade the server
  Before you install IBM Spectrum Protect V8.1.2 or later, review information about the enhanced security features and the requirements for updating your environment.
- AIX: Planning for optimal performance
  Before you install the IBM Spectrum Protect server, evaluate the characteristics and configuration of the system to ensure that the server is set up for optimal performance.
- AIX AIX: Minimum system requirements for AIX systems
  Before you install an IBM Spectrum Protect server on an AIX operating system on a system without data deduplication, review the hardware and software requirements.
- AIX AIX: Compatibility of the IBM Spectrum Protect server with other DB2 products on the system
  You can install other products that deploy and use DB2® products on the same system as the IBM Spectrum Protect Version 8.1.2 server, with some limitations.
- AIX: IBM Installation Manager
  IBM Spectrum Protect uses IBM® Installation Manager, which is an installation program that can use remote or local software repositories to install or update many IBM products.
- AIX: Worksheets for planning details for the server
  You can use the worksheets to help you plan the amount and location of storage needed for the IBM Spectrum Protect server. You can also use them to keep track of names and user IDs.
- AIX: Capacity planning
  Capacity planning for IBM Spectrum Protect includes managing resources such as the database, the recovery log and the shared resource area. To maximize resources as part of capacity planning, you must estimate space requirements for the database and the recovery log. The shared resource area must have enough space available for each installation or upgrade.
- AIX: Server naming best practices
  Use these descriptions as a reference when you install or upgrade an IBM Spectrum Protect server.
- AIX: Installation directories
  Installation directories for the IBM Spectrum Protect server include the server, DB2, device, language, and other directories. Each one contains several additional directories.

AIX: What you should know first

Before installing IBM Spectrum Protect™, be familiar with your operating systems, storage devices, communication protocols, and system configurations.

Server maintenance releases, client software, and publications are available from the IBM® Support Portal.

AIX Restriction: You can install and run the Version 8.1.2 server on a system that already has DB2® installed on it, whether DB2 was installed independently or as part of some other application, with some restrictions. For details, see the compatibility with other DB2 products topic.

Experienced DB2 administrators can choose to perform advanced SQL queries and use DB2 tools to monitor the database. Do not, however, use DB2 tools to change DB2 configuration settings from those that are preset by IBM Spectrum Protect, or alter the DB2 environment for IBM Spectrum Protect in other ways, such as with other products. The V8.1.2 server has been built and tested extensively using the data definition language (DDL) and database configuration that the server deploys.

Attention: Do not alter the DB2 software that is installed with IBM Spectrum Protect installation packages and fix packs. Do not install or upgrade to a different version, release, or fix pack of DB2 software because doing so can damage the database.

AIX: What you should know about security before you install or upgrade the server

Before you install IBM Spectrum Protect™ V8.1.2 or later, review information about the enhanced security features and the requirements for updating your environment.

About this task

Security enhancements that were introduced in V8.12 and later enforce stricter security settings. To ensure that communication between servers and clients is not interrupted when you install or upgrade IBM Spectrum Protect software to V8.1.2, follow the procedure.

Procedure

1. Install or upgrade the IBM Spectrum Protect servers to 8.1.2 or later.
2. Install or upgrade the backup-archive clients. For more information, see Installing and configuring clients.
   For information about scheduling deployment of client updates from the server, see the following documents:
   - For IBM Spectrum Protect 8.1.2 or later servers, see technote 2004596.
   - For IBM® Tivoli® Storage Manager V7.1 servers and IBM Spectrum Protect V8.1.0 and V8.1.1 servers, see technote 1673299.
3. Configure the options for backup-archive clients. For more information, see Upgrading the IBM Spectrum Protect Server and the IBM Spectrum Protect Client.

AIX: Planning for optimal performance

Before you install the IBM Spectrum Protect™ server, evaluate the characteristics and configuration of the system to ensure that the server is set up for optimal performance.

Procedure

1. Review AIX: What you should know first.
2. Review each of the following sub-sections.

- AIX: Planning for the server hardware and the operating system
  Use the checklist to verify that the system where the server is installed meets requirements for hardware and software configuration.
- AIX: Planning for the server database disks
  Use the checklist to verify that the system where the server is installed meets requirements for hardware and software configuration.
- AIX: Planning for the server recovery log disks
  Use the checklist to verify that the system where the server is installed meets requirements for hardware and software configuration.
- AIX: Planning for directory-container and cloud-container storage pools
  Review how your directory-container and cloud-container storage pools are set up to ensure optimal performance.
- AIX: Planning for storage pools in DISK or FILE device classes
  Use the checklist to review how your disk storage pools are set up. This checklist includes tips for storage pools that use DISK or FILE device classes.
- AIX: Planning for the correct type of storage technology
  Storage devices have different capacity and performance characteristics. These characteristics affect which devices are better for use with IBM Spectrum Protect.
- AIX: Applying best practices to the server installation
  Typically, hardware configuration and selection have the most significant effect on the performance of an IBM Spectrum Protect solution. Other factors that affect performance are the operating system selection and configuration, and the configuration of IBM Spectrum Protect.

AIX: Planning for the server hardware and the operating system

Use the checklist to verify that the system where the server is installed meets requirements for hardware and software configuration.

Question	Tasks, characteristics, options, or settings	More information
Does the operating system and hardware meet or exceed requirements? • Number and speed of processors • System memory • Supported operating system level	If you are using the minimum required amount of memory, you can support a minimal workload. You can experiment by adding more system memory to determine whether the performance is improved. Then, decide whether you want to keep the system memory dedicated to the server. Test the memory variations by using the entire daily cycle of the server workload. If you run multiple servers on the system, add the requirements for each server to get the requirements for the system. AIX Restriction: Do not use Active Memory™ Expansion (AME). When you use AME, DB2® software uses 4 KB pages instead of 64 KB pages. Each 4 KB page must be decompressed when accessed, and compressed when not needed. When the compression or decompression occurs, DB2 and the server wait for access to the page, which degrades the server performance.	Review operating system requirements at technote 1243309. Additionally, review the guidance in Tuning tasks for operating systems and other applications. For more information about requirements when these features are in use, see the following topics: • Checklist for data deduplication • Checklist for node replication For more information about sizing requirements for the server and storage, see the IBM Spectrum Protect™ Blueprint.
Are disks configured for optimal performance?	The amount of tuning that can be done for different disk systems varies. Ensure that the appropriate queue depths and other disk system options are set.	For more information, see the following topics: • "Planning for server database disks" • "Planning for server recovery log disks" • "Planning for storage pools in DISK or FILE device classes"

Question	Tasks, characteristics, options, or settings	More information
Does the server have enough memory?	Heavier workloads and advanced features such as data deduplication and node replication require more than the minimum system memory that is specified in the system requirements document. For databases that are not enabled for data deduplication, use the following guidelines to specify memory requirements: • For databases less than 500 GB, you need 16 GB of memory. • For databases with a size of 500 GB - 1 TB, you need 24 GB of memory. • For databases with a size of 1 TB - 1.5 TB, you need 32 GB of memory. • For databases greater than 1.5 TB, you need 40 GB of memory. Ensure that you allocate extra space for the active log and the archive log for replication processing.	For more information about requirements when these features are in use, see the following topics: • Checklist for data deduplication • Checklist for node replication • Memory requirements
Does the system have enough host bus adapters (HBAs) to handle the data operations that the IBM Spectrum Protect server must run simultaneously?	Understand what operations require use of HBAs at the same time. For example, a server must store 1 GB/sec of backup data while also doing storage pool migration that requires 0.5 GB/sec capacity to complete. The HBAs must be able to handle all of the data at the speed required.	See Tuning HBA capacity.
Is network bandwidth greater than the planned maximum throughput for backups?	Network bandwidth must allow the system to complete operations such as backups in the time that is allowed or that meets service level commitments. For node replication, network bandwidth must be greater than the planned maximum throughput.	For more information, see the following topics: • Tuning network performance • Checklist for node replication

Question	Tasks, characteristics, options, or settings	More information
Are you using a preferred file system for IBM Spectrum Protect server files?	Use a file system that ensures optimal performance and data availability. The server uses direct I/O with file systems that support the feature. Using direct I/O can improve throughput and reduce processor use. The following list identifies the preferred file system: • AIX AIX®Use the JFS2 file system with the rbrw option.	For more information, see Configuring the operating system for disk performance.
Are you planning to configure enough paging space?	Paging space, or swap space, extends the memory that is available for processing. When the amount of free RAM in the system is low, programs or data that is not in use are moved from memory to paging space. This action releases memory for other activities, such as database operations. AIX Use a minimum of 32 GB of paging space or 50% of your RAM, whichever value is larger.	

AIX: Planning for the server database disks

Use the checklist to verify that the system where the server is installed meets requirements for hardware and software configuration.

Question	Tasks, characteristics, options, or settings	More information

Question	Tasks, characteristics, options, or settings	More information
Is the database on fast, low-latency disks?	Do not use the following drives for the IBM Spectrum Protect™ database: • Nearline SAS (NL-SAS) • Serial Advanced Technology Attachment (SATA) • Parallel Advanced Technology Attachment (PATA) Do not use internal disks that are included by default in most server hardware. Enterprise-grade solid-state disks (SSD), with Fibre Channel or SAS interface, offer the best performance. If you plan to use the data deduplication functions of IBM Spectrum Protect, focus on disk performance in terms of I/O operations per second (IOPS).	For more information, see Checklist for data deduplication.
Is the database stored on disks or LUNs that are separate from disks or LUNs that are used for the active log, archive log, and storage pool volumes?	Separation of the server database from other server components helps reduce contention for the same resources by different operations that must run at the same time. Tip: The database and the archive log can share an array when you use solid-state drive (SSD) technology.	
If you are using RAID, do you know how to select the optimal RAID level for your system? Are you defining all LUNs with the same size and type of RAID?	When a system must do large numbers of writes, RAID 10 outperforms RAID 5. However, RAID 10 requires more disks than RAID 5 for the same amount of usable storage. If your disk system is RAID, define all your LUNs with the same size and type of RAID. For example, do not mix 4+1 RAID 5 with 4+2 RAID 6.	
If an option to set the strip size or segment size is available, are you planning to optimize the size when you configure the disk system?	If you can set the strip size or segment size, use 64 KB or 128 KB sizes on disk systems for the database.	The block size that is used for the database varies depending on the table space. Most table spaces use 8 KB blocks, but some use 32 KB blocks.

Question	Tasks, characteristics, options, or settings	More information
Are you planning to create at least four directories, also called storage paths, on four separate LUNs for the database? Create one directory per distinct array on the subsystem. If you have fewer than three arrays, create a separate LUN volume within the array.	Heavier workloads and use of some features require more database storage paths than the minimum requirements. Server operations such as data deduplication drive a high number of input/output operations per second (IOPS) for the database. Such operations perform better when the database has more directories. For server databases that are larger than 2 TB or are expected to grow to that size, use eight directories. Consider planned growth of the system when you determine how many storage paths to create. The server uses the higher number of storage paths more effectively if the storage paths are present when the server is first created. Use the *DB2_PARALLEL_IO* variable to force parallel I/O to occur on table spaces that have one container, or on table spaces that have containers on more than one physical disk. If you do not set the *DB2_PARALLEL_IO* variable, I/O parallelism is equal to the number of containers that are used by the table space. For example, if a table space spans four containers, the level of I/O parallelism that is used is 4.	For more information, see the following topics: • Checklist for data deduplication • Checklist for node replication For help with forecasting growth when the server deduplicates data, see technote 1596944. For the most recent information about database size, database reorganization, and performance considerations for IBM Spectrum Protect servers, see technote 1683633. For information about setting the *DB2_PARALLEL_IO* variable, see Recommended settings for IBM DB2 registry variables.
Are all directories for the database the same size?	Directories that are all the same size ensure a consistent degree of parallelism for database operations. If one or more directories for the database are smaller than the others, they reduce the potential for optimized parallel prefetching. This guideline also applies if you must add storage paths after the initial configuration of the server.	
Are you planning to raise the queue depth of the database LUNs on AIX® systems?	The default queue depth is often too low.	See Configuring AIX systems for disk performance.

AIX: Planning for the server recovery log disks

Use the checklist to verify that the system where the server is installed meets requirements for hardware and software configuration.

Question	Tasks, characteristics, options, or settings	More information
Are the active log and archive log stored on disks or LUNs that are separate from what is used for the database and storage pool volumes?	Ensure that the disks where you place the active log are not used for other server or system purposes. Do not place the active log on disks that contain the server database, the archive log, or system files such as page or swap space.	Separation of the server database, active log, and archive log helps to reduce contention for the same resources by different operations that must run at the same time.

Question	Tasks, characteristics, options, or settings	More information
Are the logs on disks that have nonvolatile write cache?	Nonvolatile write cache allows data to be written to the logs as fast as possible. Faster write operations for the logs can improve performance for server operations.	
Are you setting the logs to a size that adequately supports the workload?	If you are not sure about the workload, use the largest size that you can. Active log The maximum size is 512 GB, set with the ACTIVELOGSIZE server option. Ensure that there is at least 8 GB of free space on the active log file system after the fixed size active logs are created. Archive log The size of the archive log is limited by the size of the file system on which it is located, and not by a server option. Make the archive log at least as large as the active log.	• For log sizing details, see the recovery log information in technote 1421060. • For information about sizing when you use data deduplication, see Checklist for data deduplication.
Are you defining an archive failover log? Are you placing this log on a disk that is separate from the archive log?	The archive failover log is for emergency use by the server when the archive log becomes full. Slower disks can be used for the archive failover log.	Use the ARCHFAILOVERLOGDIRECTORY server option to specify the location of the archive failover log. Monitor the usage of the directory for the archive failover log. If the archive failover log must be used by the server, the space for the archive log might not be large enough.
If you are mirroring the active log, are you using only one type of mirroring?	You can mirror the log by using one of the following methods. Use only one type of mirroring for the log. • Use the MIRRORLOGDIRECTORY option that is available for the IBM Spectrum Protect™ server to specify a mirror location. • Use software mirroring, such as Logical Volume Manager (LVM) on AIX®. • Use mirroring in the disk system hardware.	If you mirror the active log, ensure that the disks for both the active log and the mirror copy have equal speed and reliability. For more information, see Configuring and tuning the recovery log.

AIX: Planning for directory-container and cloud-container storage pools

Review how your directory-container and cloud-container storage pools are set up to ensure optimal performance.

Question	Tasks, characteristics, options, or settings	More information

Question	Tasks, characteristics, options, or settings	More information
Measured in terms of input/output operations per second (IOPS), are you using fast disk storage for the IBM Spectrum Protect™ database?	Use a high-performance disk for the database. Use solid-state drive technology for data deduplication processing. Ensure that the database has a minimum capability of 3000 IOPS. For each TB of data that is backed up daily (before data deduplication), add 1000 IOPS to this minimum. For example, an IBM Spectrum Protect server that is ingesting 3 TB of data per day would need 6000 IOPS for the database disks: `3000 IOPS minimum + 3000 (3 TB x 1000 IOPS) = 6000 IOPS`	For recommendations about disk selection, see "Planning for server database disks". For more information about IOPS, see the IBM Spectrum Protect Blueprints.
Do you have enough memory for the size of your database?	Use a minimum of 40 GB of system memory for IBM Spectrum Protect servers, with a database size of 100 GB, that are deduplicating data. If the retained capacity of backup data grows, the memory requirement might need to be higher. Monitor memory usage regularly to determine whether more memory is required. Use more system memory to improve caching of database pages. The following memory size guidelines are based on the daily amount of new data that you back up: • 128 GB of system memory for daily backups of data, where the database size is 1 - 2 TB • 192 GB of system memory for daily backups of data, where the database size is 2 - 4 TB	Memory requirements

Question	Tasks, characteristics, options, or settings	More information
Have you properly sized the storage capacity for the database active log and archive log?	Configure the server to have a minimum active log size of 128 GB by setting the ACTIVELOGSIZE server option to a value of 131072. The suggested starting size for the archive log is 1 TB. The size of the archive log is limited by the size of the file system on which it is located, and not by a server option. Ensure that there is at least 10% extra disk space for the file system than the size of the archive log. Use a directory for the database archive logs with an initial free capacity of at least 1 TB. Specify the directory by using the ARCHLOGDIRECTORY server option. Define space for the archive failover log by using the ARCHFAILOVERLOGDIRECTORY server option.	For more information about sizing for your system, see the IBM Spectrum Protect Blueprints.
Is compression enabled for the archive log and database backups?	Enable the ARCHLOGCOMPRESS server option to save storage space. This compression option is different from inline compression. Inline compression is enabled by default with IBM Spectrum Protect V7.1.5 and later. Restriction: Do not use this option if the amount of backed up data exceeds 6 TB per day.	For more information about compression for your system, see the IBM Spectrum Protect Blueprints.
Are the IBM Spectrum Protect database and logs on separate disk volumes (LUNs)? Is the disk that is used for the database configured according to best practices for a transactional database?	The database must not share disk volumes with IBM Spectrum Protect database logs or storage pools, or with any other application or file system.	For more information about server database and recovery log configuration, see Server database and recovery log configuration and tuning.
Are you using a minimum of eight (2.2 GHz or equivalent) processor cores for each IBM Spectrum Protect server that you plan to use with data deduplication?	If you are planning to use client-side data deduplication, verify that client systems have adequate resources available during a backup operation to complete data deduplication processing. Use a processor that is at least the minimum equivalent of one 2.2 GHz processor core per backup process with client-side data deduplication.	• Effective planning and use of deduplication • IBM Spectrum Protect Blueprints

Question	Tasks, characteristics, options, or settings	More information
Did you allocate enough storage space for the database?	For a rough estimate, plan for 100 GB of database storage for every 50 TB of data that is to be protected in deduplicated storage pools. *Protected data* is the amount of data before data deduplication, including all versions of objects stored. As a best practice, define a new container storage pool exclusively for data deduplication. Data deduplication occurs at the storage-pool level, and all data within a storage pool, except encrypted data, is deduplicated.	
Have you estimated storage pool capacity to configure enough space for the size of your environment?	You can estimate capacity requirements for a deduplicated storage pool by using the following technique: 1. Estimate the base size of the source data. 2. Estimate the daily backup size by using an estimated change and growth rate. 3. Determine retention requirements. 4. Estimate the total amount of source data by factoring in the base size, daily backup size, and retention requirements. 5. Apply the deduplication ratio factor. 6. Apply the compression ratio factor. 7. Round up the estimate to consider transient storage pool usage.	For an example of using this technique, see Effective planning and use of deduplication.
Have you distributed disk I/O over many disk devices and controllers?	Use arrays that consist of as many disks as possible, which is sometimes referred to as wide striping. Ensure that you use one database directory per distinct array on the subsystem. Set the *DB2_PARALLEL_IO* registry variable to enable parallel I/O for each table space used if the containers in the table space span multiple physical disks. When I/O bandwidth is available and the files are large, for example 1 MB, the process of finding duplicates can occupy the resources of an entire processor. When files are smaller, other bottlenecks can occur. Specify eight or more file systems for the deduplicated storage pool device class so that I/O is distributed across as many LUNs and physical devices as possible.	For guidelines about setting up storage pools, see "Planning for storage pools in DISK or FILE device classes". For information about setting the *DB2_PARALLEL_IO* variable, see Recommended settings for IBM DB2 registry variables.

Question	Tasks, characteristics, options, or settings	More information
Have you scheduled daily operations based on your backup strategy?	The best practice sequence of operations is in the following order: 1. Client backup 2. Storage pool protection 3. Node replication 4. Database backup 5. Expire inventory	• Scheduling data deduplication and node replication processes • Daily operations for directory-container storage pools
Do you have enough storage to manage the DB2® lock list?	If you deduplicate data that includes large files or large numbers of files concurrently, the process can result in insufficient storage space. When the lock list storage is insufficient, backup failures, data management process failures, or server outages can occur. File sizes greater than 500 GB that are processed by data deduplication are most likely to deplete storage space. However, if many backup operations use client-side data deduplication, this problem can also occur with smaller-sized files.	For information about tuning the DB2 LOCKLIST parameter, see Tuning server-side data deduplication.
Is sufficient bandwidth available to transfer data to an IBM Spectrum Protect server?	To transfer data to an IBM Spectrum Protect server, use client-side or server-side data deduplication and compression to reduce the bandwidth that is required. Use a V7.1.5 server or higher to use inline compression and use a V7.1.6 or later client to enable enhanced compression processing.	For more information, see the enablededup client option.
Have you determined how many storage pool directories to assign to each storage pool?	Assign directories to a storage pool by using the DEFINE STGPOOLDIRECTORY command. Create multiple storage pool directories and ensure that each directory is backed up to a separate disk volume (LUN).	

Question	Tasks, characteristics, options, or settings	More information
Did you allocate enough disk space in the cloud-container storage pool?	To prevent backup failures, ensure that the local directory has enough space. Use the following list as a guide for optimal disk space: • For serial-attached SCSI (SAS) and spinning disk, calculate the amount of new data that is expected after daily data reduction (compression and data deduplication). Allocate up to 100 percent of that amount, in terabytes, for disk space. • Provide 3 TB for flash-based storage systems with fast network connections to on-premises, high-performance cloud systems. • Provide 5 TB for solid-state drive (SSD) systems with fast network connections to high-performance cloud systems.	
Did you select the appropriate type of local storage?	Ensure that data transfers from local storage to cloud finish before the next backup cycle starts. Tip: Data is removed from local storage soon after it moves to the cloud. Use the following guidelines: • Use flash or SSD for large systems that have high-performing cloud systems. Ensure that you have a dedicated 10 GB wide area network (WAN) link with a high-speed connection to the object storage. For example, use flash or SSD if you have a dedicated 10 GB WAN link plus a high-speed connection to either an IBM® Cloud Object Storage location or to an Amazon Simple Storage Service (Amazon S3) data center. • Use larger capacity 15000 rpm SAS disks for these scenarios: ◦ Medium-sized systems ◦ Slower cloud connections, for example, 1 GB ◦ When you use IBM Cloud Object Storage as your service provider across several regions • For SAS or spinning disk, calculate the amount of new data that is expected after daily data reduction (compression and data deduplication). Allocate up to 100 percent of that amount for disk space, in terabytes.	

AIX: Planning for storage pools in DISK or FILE device classes

Use the checklist to review how your disk storage pools are set up. This checklist includes tips for storage pools that use DISK or FILE device classes.

Question	Tasks, characteristics, options, or settings	More information
Can the storage pool LUNs sustain throughput rates for 256 KB sequential reads and writes to adequately handle the workload within the time constraints?	When you are planning for peak loads, consider all the data that you want the server to read or write to the disk storage pools simultaneously. For example, consider the peak flow of data from client backup operations and server data-movement operations such as migration that run at the same time. The IBM Spectrum Protect™ server reads and writes to storage pools predominantly in 256 KB blocks. If the disk system includes the capability, configure the disk system for optimal performance with sequential read/write operations rather than random read/write operations.	For more information, see Analyzing the basic performance of disk systems.
Is the disk configured to use read and write cache?	Use more cache for better performance.	
For storage pools that use FILE device classes, have you determined a good size to use for the storage pool volumes?	Review the information in Optimal number and size of volumes for storage pools that use disk. If you do not have the information to estimate a size for FILE device class volumes, start with volumes that are 50 GB.	Typically, problems arise more frequently when the volumes are too small. Few problems are reported when volumes are larger than needed. When you determine the volume size to use, as a precaution choose a size that might be larger than necessary.
For storage pools that use FILE device classes, are you using preallocated volumes?	Scratch volumes can cause file fragmentation. To ensure that a storage pool does not run out of volumes, set the MAXSCRATCH parameter to a value greater than zero.	Use the DEFINE VOLUME server command to preallocate volumes in the storage pool. Use the DEFINE STGPOOL or UPDATE STGPOOL server command to set the MAXSCRATCH parameter.
For storage pools that use FILE device classes, have you compared the maximum number of client sessions to the number of volumes that are defined?	Always maintain enough usable volumes in the storage pools to allow for the expected peak number of client sessions that run at one time. The volumes might be scratch volumes, empty volumes, or partly filled volumes.	For storage pools that use FILE device classes, only one session or process can write to a volume at the same time.

Question	Tasks, characteristics, options, or settings	More information
For storage pools that use FILE device classes, have you set the MOUNTLIMIT parameter of the device class to a value that is high enough to account for the number of volumes that might be mounted in parallel?	For storage pools that use data deduplication, the MOUNTLIMIT parameter is typically in the range of 500 - 1000. Set the value for MOUNTLIMIT to the maximum number of mount points that are needed for all active sessions. Consider parameters that affect the maximum number of mount points that are needed: • The MAXSESSIONS server option, which is the maximum number of IBM Spectrum Protect sessions that can run concurrently. • The MAXNUMMP parameter, which sets the maximum number of mount points that each client node can use. For example, if the maximum number of client node backup sessions is typically 100 and each of the nodes has `MAXNUMMP=2`, multiply 100 nodes by the 2 mount points for each node to get the value of 200 for the MOUNTLIMIT parameter.	Use the REGISTER NODE or UPDATE NODE server command to set the MAXNUMMP parameter for client nodes.
For storage pools that use DISK device classes, have you determined how many storage pool volumes to put on each file system?	How you configure the storage for a storage pool that uses a DISK device class depends on whether you are using RAID for the disk system. If you are not using RAID, then configure one file system per physical disk, and define one storage pool volume for each file system. If you are using RAID 5 with *n* + 1 volumes, configure the storage in one of the following ways: • Configure *n* file systems on the LUN and define one storage pool volume per file system. • Configure one file system and *n* storage pool volumes for the LUN.	For an example layout that follows this guideline, see Sample layout of server storage pools.
Did you create your storage pools to distribute I/O across multiple file systems?	Ensure that each file system is on a different LUN on the disk system. Typically, having 10 - 30 file systems is a good goal, but ensure that the file systems are no smaller than approximately 250 GB.	For details, see the following topics: • Tuning disk storage for the server • Tuning and configuring storage pools and volumes

AIX: Planning for the correct type of storage technology

Storage devices have different capacity and performance characteristics. These characteristics affect which devices are better for use with IBM Spectrum Protect™.

Procedure

Review the following table to help you to choose the correct type of storage technology for the storage resources that the server requires.

Table 1. Storage technology types for IBM Spectrum Protect storage requirements

Storage technology type	Database	Active log	Archive log and archive failover log	Storage pools
Solid-state disk (SSD)	Place the database on SSD in the following circumstances: • You are using IBM Spectrum Protect data deduplication. • You are backing up more than 8 TB of new data daily.	If you place the IBM Spectrum Protect database on an SSD, as a best practice, place the active log on an SSD. If space is not available, use high-performance disk instead.	Save SSDs for use with the database and active log. The archive log and archive failover logs can be placed on slower storage technology types.	Save SSDs for use with the database and active log. Storage pools can be placed on slower storage technology types.
High-performance disk with the following characteristics: • **15k rpm disk** • **Fibre Channel or serial-attached SCSI (SAS) interface**	Use high-performance disks in the following circumstances: • The server does not do data deduplication. • The server does not do node replication. Isolate the server database from its logs and storage pools, and from data for other applications.	Use high-performance disks in the following circumstances: • The server does not do data deduplication. • The server does not do node replication. For performance and availability, isolate the active log from the server database, archive logs, and storage pools.	You can use high-performance disks for the archive log and archive failover logs. For availability, isolate these logs from the database and active log.	Use high-performance disks for storage pools in the following circumstances: • Data is frequently read. • Data is frequently written. For performance and availability, isolate storage pool data from the server database and logs, and from data for other applications.
Medium-performance or high-performance disk with the following characteristics: • **10k rpm disk** • **Fibre Channel or SAS interface**	If the disk system has a mix of disk technologies, use the faster disks for the database and active log. Isolate the server database from its logs and storage pools, and from data for other applications.	If the disk system has a mix of disk technologies, use the faster disks for the database and active log. For performance and availability, isolate the active log from the server database, archive logs, and storage pools.	You can use medium-performance or high-performance disk for the archive log and archive failover logs. For availability, isolate these logs from the database and active log.	Use medium-performance or high-performance disk for storage pools in the following circumstances: • Data is frequently read. • Data is frequently written. For performance and availability, isolate storage pool data from the server database and logs, and from data for other applications.

Storage technology type	Database	Active log	Archive log and archive failover log	Storage pools
SATA, network-attached storage	Do not use this storage for the database. Do not place the database on XIV storage systems.	Do not use this storage for the active log.	Use of this slower storage technology is acceptable because these logs are written once and infrequently read.	Use this slower storage technology in the following circumstances: • Data is infrequently written, for example written once. • Data is infrequently read. .
Tape and virtual tape				Use for long-term retention or if data is infrequently used.

AIX: Applying best practices to the server installation

Typically, hardware configuration and selection have the most significant effect on the performance of an IBM Spectrum Protect™ solution. Other factors that affect performance are the operating system selection and configuration, and the configuration of IBM Spectrum Protect.

Procedure

- The following best practices are the most important for optimal performance and problem prevention.
- Review the table to determine the best practices that apply to your environment.

Best practice	More information
Use fast disks for the server database. Enterprise-grade solid-state disks (SSD), with Fibre Channel or SAS interface, offer the best performance.	Use fast, low-latency disks for the database. Using SSD is essential if you are using data deduplication and node replication. Avoid Serial Advanced Technology Attachment (SATA) and Parallel Advanced Technology Attachment (PATA) disks. For details and more tips, see the following topics: ◦ "Planning for server database disks" ◦ "Planning for the correct type of storage technology"
Ensure that the server system has enough memory.	Review operating system requirements in technote 1243309. Heavier workloads require more than the minimum requirements. Advanced features such as data deduplication and node replication can require more than the minimum memory that is specified in the system requirements document. If you plan to run multiple instances, each instance requires the memory that is listed for one server. Multiply the memory for one server by the number of instances that are planned for the system.

Best practice	More information
Separate the server database, the active log, the archive log, and disk storage pools from each other.	Keep all IBM Spectrum Protect storage resources on separate disks. Keep storage pool disks separate from the disks for the server database and logs. Storage pool operations can interfere with database operations when both are on the same disks. Ideally, the server database and logs are also separated from each other. For details and more tips, see the following topics: ○ "Planning for server database disks" ○ "Planning for server recovery log disks" ○ "Planning for storage pools in DISK or FILE device classes"
Use at least four directories for the server database. For larger servers or servers that use advanced features, use eight directories.	Place each directory on a LUN that is isolated from other LUNs and from other applications. A server is considered to be large if its database is larger than 2 TB or is expected to grow to that size. Use eight directories for such servers. See "Planning for server database disks".
If you are using data deduplication, node replication, or both, follow the guidelines for database configuration and other items.	Configure the server database according to the guidelines, because the database is extremely important to how well the server runs when these features are being used. For details and more tips, see the following topics: ○ Checklist for data deduplication ○ Checklist for node replication
For storage pools that use FILE type device classes, follow the guidelines for the size of storage pool volumes. Typically, 50 GB volumes are best.	Review the information in Optimal number and size of volumes for storage pools that use disk to help you to determine volume size. Configure storage pool devices and file systems based on throughput requirements, not only on capacity requirements. Isolate the storage devices that are used by IBM Spectrum Protect from other applications that have high I/O, and ensure that there is enough throughput to that storage. For more details, see Checklist for storage pools on DISK or FILE.
Schedule IBM Spectrum Protect client operations and server maintenance activities to avoid or minimize overlap of operations.	For more details, see the following topics: ○ Tuning the schedule for daily operations ○ Checklist for server configuration
Monitor operations constantly.	By monitoring, you can find problems early and more easily identify causes. Keep records of monitoring reports for up to a year to help you identify trends and plan for growth. See Monitoring and maintaining the environment for performance.

AIX: Minimum system requirements for AIX systems

Before you install an IBM Spectrum Protect™ server on an AIX operating system on a system without data deduplication, review the hardware and software requirements.

Hardware and software requirements for the IBM Spectrum Protect server installation

These tables list the minimum hardware and software requirements for the installation of an IBM Spectrum Protect server. Use these requirements as a starting point for systems without data deduplication. The optimal IBM Spectrum Protect environment is set up with data deduplication by using the IBM Spectrum Protect Blueprints. For the most current information about system requirements, see technote 1243309.

Hardware requirements

Table 1 describes the minimum hardware requirements for the server. If the server does not meet the minimum requirements, the installation fails. For more details about planning disk space, see AIX: Capacity planning.

Table 1. Hardware requirements

Type of hardware	Hardware requirements
Hardware	An appropriately configured POWER5 or later systems computer (64-bit)
Disk space	The following minimum values for disk space: • 5 GB for the installation directory • 512 MB for the /var directory • 2 GB for the /tmp directory • 128 MB in the home directory for the root user. • 2 GB for the shared resources area In case a problem arises and any diagnosis is needed, it is optimal to have temporary or other space available on the system for a first failure data capture (FFDC) log or for other temporary uses such as for collecting trace logs. Significant additional disk space is required for database and log files. The size of the database depends on the number of client files to be stored and the method by which the server manages them. The default active log space is 16 GB, the minimum that is needed for most workloads and configurations. When you create the active log, you need at least 64 GB to run replication. If replication and data deduplication are both being used, create an active log of 128 GB. Allocate at least three times the default active log space for the archive log (48 GB). Ensure that you have sufficient resources if you are using data deduplication or expect a heavy client workload. For optimal performance and to facilitate I/O, specify at least two equally sized containers or Logical Unit Numbers (LUNs) for the database. In addition, each active log and archive log needs its own container or LUN. Ensure that you see AIX: Capacity planning for more details about disk space.
Memory	The following are the minimum system memory requirements for servers with databases up to 500 GB, with daily ingestion of no more than 200 GB per day: • 16 GB for standard server operations without data deduplication and node replication • 24 GB for data deduplication or node replication • 32 GB for node replication with data deduplication For more specific memory requirements for larger databases and higher ingestion capability, see the IBM Spectrum Protect server memory tuning table. For more specific memory requirements when you are using data deduplication, see the IBM Spectrum Protect Blueprint for your operating system.

Software requirements

Table 2 describes the minimum software requirements that are needed for a server on an AIX® system.

Table 2. Software requirements

Type of software	Minimum software requirements

Type of software	Minimum software requirements
Operating system	AIX 6.1 running in a 64-bit kernel environment with the following additional requirements: • AIX 6.1 TL 7 and SP6. • Minimum C++ runtime level with the xlC.rte 12.1.0.1 or later file sets. The file set is automatically upgraded if the level is earlier than 12.1.0.1. The file set is included in the June 2008 fix pack package for IBM® C++ Runtime Environment Components for AIX. AIX 7.1 running in a 64-bit kernel environment. • AIX 7.1 TL 4 and SP2. • Minimum C++ runtime level with the xlC.rte 12.1.0.1 or later file sets. The file set is automatically upgraded if the level is earlier than 12.1.0.1. The file set is included in the June 2008 fix pack package for IBM C++ Runtime Environment Components for AIX. AIX 7.2 running in a 64-bit kernel environment. • AIX 7.2 TL 0 and SP2. • Minimum C++ runtime level with the xlC.rte 13.1.3.1 or later file sets. The file set is automatically upgraded if the level is earlier than 13.1.3.1. For the latest recommendations about AIX maintenance levels, see technote 21165448 To use the N_Port ID Virtualization (NPIV) facility, ensure that you have the following minimum requirements: • Virtual I/O Server 2.1.2 or later • AIX 7.1 or later • An HBA adapter supported by the corresponding AIX and Virtual I/O Server
Communication protocol	A configured communication method.
Processing	Asynchronous I/O must be enabled.
Device drivers	The IBM Spectrum Protect device driver is required for non-IBM drives and tape libraries. The IBM Spectrum Protect device driver package contains device driver tools and ACSLS daemons. For the IBM 3590, 3592, or the Ultrium tape library or drives, the IBM device drivers are required. Install the most current device drivers. You can locate IBM driver packages at Fix Central. Configure the device drivers before you use the server with tape devices.
Gunzip utility	The gunzip utility must be available on your system before you install or upgrade the server. Ensure that the gunzip utility is installed and the path to it is set in the PATH environment variable.
Other software	Korn Shell (ksh) is required. Configure the I/O completion ports (IOCP) on the operating system. To authenticate IBM Spectrum Protect users with a Lightweight Directory Access Protocol (LDAP) server, you must use one of the following directory servers: • Microsoft Active Directory (Windows Server 2012, Windows Server 2012 R2) • IBM Security Directory Server V6.3 • IBM Security Directory Server V6.4

AIX

AIX: Compatibility of the IBM Spectrum Protect server with other DB2 products on the system

You can install other products that deploy and use DB2® products on the same system as the IBM Spectrum Protect™ Version 8.1.2 server, with some limitations.

To install and use other products that use a DB2 product on the same system as the IBM Spectrum Protect server, ensure that the following criteria are met:

Table 1. Compatibility of the IBM Spectrum Protect server with other DB2 products on the system

Criterion	Instructions
Version level	The other products that use a DB2 product must use DB2 version 9 or later. DB2 products include product encapsulation and segregation support beginning with Version 9. Starting with this version, you can run multiple copies of DB2 products, at different code levels, on the same system. For details, see the information about multiple DB2 copies in the DB2 product information.
User IDs and directories	Ensure that the user IDs, fence user IDs, installation location, other directories, and related information are not shared across DB2 installations. Your specifications must be different from the IDs and locations that you used for the IBM Spectrum Protect server installation and configuration. If you used the dsmicfgx wizard to configure the server, these are values that you entered when running the wizard. If you used the manual configuration method, review the procedures that you used if necessary to recall the values that were used for the server.
Resource allocation	Consider the resources and capability of the system compared to the requirements for both the IBM Spectrum Protect server and the other applications that use the DB2 product. To provide sufficient resources for the other DB2 applications, you might have to change the IBM Spectrum Protect server settings so that the server uses less system memory and resources. Similarly, if the workloads for the other DB2 applications compete with the IBM Spectrum Protect server for processor or memory resources, the performance of the server in handling the expected client workload or other server operations might be adversely affected. To segregate resources and provide more capability for the tuning and allocation of processor, memory, and other system resources for multiple applications, consider using logical partition (LPAR), workload partition (WPAR), or other virtual workstation support. For example, run a DB2 application on its own virtualized system.

AIX: IBM Installation Manager

IBM Spectrum Protect™ uses IBM® Installation Manager, which is an installation program that can use remote or local software repositories to install or update many IBM products.

If the required version of IBM Installation Manager is not already installed, it is automatically installed or upgraded when you install IBM Spectrum Protect. It must remain installed on the system so that IBM Spectrum Protect can be updated or uninstalled later as needed.

The following list contains explanations of some terms that are used in IBM Installation Manager:

Offering
: An installable unit of a software product.

  The IBM Spectrum Protect offering contains all of the media that IBM Installation Manager requires to install IBM Spectrum Protect.

Package
: The group of software components that are required to install an offering.
  The IBM Spectrum Protect package contains the following components:

  - IBM Installation Manager installation program
  - IBM Spectrum Protect offering

Package group
: A set of packages that share a common parent directory.

  The default package group for the IBM Spectrum Protect package is `IBM Installation Manager`.

Repository
: A remote or local storage area for data and other application resources.

  The IBM Spectrum Protect package is stored in a repository on IBM Fix Central.

Shared resources directory
: A directory that contains software files or plug-ins that are shared by packages.

  IBM Installation Manager stores installation-related files in the shared resources directory, including files that are used for rolling back to a previous version of IBM Spectrum Protect.

AIX: Worksheets for planning details for the server

You can use the worksheets to help you plan the amount and location of storage needed for the IBM Spectrum Protect™ server. You can also use them to keep track of names and user IDs.

Item	Space required	Number of directories	Location of directories
The database			
Active log			
Archive log			
Optional: Log mirror for the active log			
Optional: Secondary archive log (failover location for archive log)			

Item	Names and user IDs	Location
The *instance user ID* for the server, which is the ID you use to start and run the IBM Spectrum Protect server		
The *home directory* for the server, which is the directory that contains the instance user ID		
The database instance name		
The *instance directory* for the server, which is a directory that contains files specifically for this server instance (the server options file and other server-specific files)		
The server name, use a unique name for each server		

AIX: Capacity planning

Capacity planning for IBM Spectrum Protect™ includes managing resources such as the database, the recovery log and the shared resource area. To maximize resources as part of capacity planning, you must estimate space requirements for the database and the recovery log. The shared resource area must have enough space available for each installation or upgrade.

- AIX: Estimating space requirements for the database
  To estimate space requirements for the database, you can use the maximum number of files that can be in server storage at one time or you can use storage pool capacity.
- AIX: Recovery log space requirements
  In IBM Spectrum Protect, the term *recovery log* comprises the active log, the archive log, the active log mirror, and the archive failover log. The amount of space that you require for the recovery log depends on various factors, including, for example, the amount of client activity with the server.
- AIX: Monitoring space utilization for the database and recovery logs
  To determine the amount of used and available active log space, you issue the QUERY LOG command. To monitor space utilization in the database and recovery logs, you can also check the activity log for messages.

- AIX: Deleting installation rollback files
  You can delete certain installation files that were saved during the installation process to free space in the shared resource directory. For example, files that might have been required for a rollback operation are types of files that you can delete.

AIX: Estimating space requirements for the database

To estimate space requirements for the database, you can use the maximum number of files that can be in server storage at one time or you can use storage pool capacity.

About this task

Consider using at least 25 GB for the initial database space. Provision file system space appropriately. A database size of 25 GB is adequate for a test environment or a library-manager-only environment. For a production server supporting client workloads, the database size is expected to be larger. If you use random-access disk (DISK) storage pools, more database and log storage space is needed than for sequential-access storage pools.

The maximum size of the IBM Spectrum Protect™ database is 6 TB.

For information about sizing the database in a production environment that is based on the number of files and on storage pool size, see the following topics.

- AIX: Estimating database space requirements based on the number of files
  If you can estimate the maximum number of files that might be in server storage at a time, you can use that number to estimate space requirements for the database.
- AIX: Estimating database space requirements based on storage pool capacity
  To estimate database space requirements based on storage pool capacity, use a ratio of 1 - 5%. For example, if you require 200 TB of storage pool capacity, the size of your database is expected to be 2 - 10 TB. As a general rule, make your database as large as possible to prevent running out of space. If you run out of database space, server operations and client-store operations can fail.
- AIX: The database manager and temporary space
  The IBM Spectrum Protect server database manager manages and allocates system memory and disk space for the database. The amount of database space you require depends on the amount of system memory available and the server workload.

AIX: Estimating database space requirements based on the number of files

If you can estimate the maximum number of files that might be in server storage at a time, you can use that number to estimate space requirements for the database.

About this task

To estimate space requirements that is based on the maximum number of files in server storage, use the following guidelines:

- 600 - 1000 bytes for each stored version of a file, including image backups.
  Restriction: The guideline does not include space that is used during data deduplication.
- 100 - 200 bytes for each cached file, copy storage pool file, active-data pool file, and deduplicated file.
- Additional space is required for database optimization to support varying data-access patterns and to support server back-end processing of the data. The amount of extra space is equal to 50% of the estimate for the total number of bytes for file objects.

In the following example for a single client, the calculations are based on the maximum values in the preceding guidelines. The examples do not take into account that you might use file aggregation. In general, when you aggregate small files, it reduces the amount of required database space. File aggregation does not affect space-managed files.

Procedure

1. Calculate the number of file versions. Add each of the following values to obtain the number of file versions:
   a. Calculate the number of backed-up files. For example, as many as 500,000 client files might be backed up at a time. In this example, storage policies are set to keep up to three copies of backed up files:

```
500,000 files * 3 copies = 1,500,000 files
```

b. Calculate the number of archive files. For example, as many as 100,000 client files might be archived copies.
c. Calculate the number of space-managed files. For example, as many as 200,000 client files might be migrated from client workstations.

Using 1000 bytes per file, the total amount of database space that is required for the files that belong to the client is 1.8 GB:

```
(1,500,000 + 100,000 + 200,000) * 1000 = 1.8 GB
```

2. Calculate the number of cached files, copy storage-pool files, active-data pool files, and deduplicated files:
   a. Calculate the number of cached copies. For example, caching is enabled in a 5 GB disk storage pool. The high migration threshold of the pool is 90% and the low migration threshold of the pool is 70%. Thus, 20% of the disk pool, or 1 GB, is occupied by cached files.
   If the average file size is about 10 KB, approximately 100,000 files are in cache at any one time:

   ```
   100,000 files * 200 bytes = 19 MB
   ```

   b. Calculate the number of copy storage-pool files. All primary storage pools are backed up to the copy storage pool:

   ```
   (1,500,000 + 100,000 + 200,000) * 200 bytes = 343 MB
   ```

   c. Calculate the number of active storage-pool files. All the active client-backup data in primary storage pools is copied to the active-data storage pool. Assume that 500,000 versions of the 1,500,000 backup files in the primary storage pool are active:

   ```
   500,000 * 200 bytes = 95 MB
   ```

   d. Calculate the number of deduplicated files. Assume that a deduplicated storage pool contains 50,000 files:

   ```
   50,000 * 200 bytes = 10 MB
   ```

   Based on the preceding calculations, about 0.5 GB of extra database space is required for the client's cached files, copy storage-pool files, active-data pool files, and deduplicated files.
3. Calculate the amount of extra space that is required for database optimization. To provide optimal data access and management by the server, extra database space is required. The amount of extra database space is equal to 50% of the total space requirements for file objects.

   ```
   (1.8 + 0.5) * 50% = 1.2 GB
   ```

4. Calculate the total amount of database space that is required for the client. The total is approximately 3.5 GB:

   ```
   1.8 + 0.5 + 1.2 = 3.5 GB
   ```

5. Calculate the total amount of database space that is required for all clients. If the client that was used in the preceding calculations is typical and you have 500 clients, for example, you can use the following calculation to estimate the total amount of database space that is required for all clients:

   ```
   500 * 3.5 = 1.7 TB
   ```

Results

Tip: In the preceding examples, the results are estimates. The actual size of the database might differ from the estimate because of factors such as the number of directories and the length of the path and file names. Periodically monitor your database and adjust its size as necessary.

What to do next

During normal operations, the IBM Spectrum Protect™ server might require temporary database space. This space is needed for the following reasons:

- To hold the results of sorting or ordering that are not already being kept and optimized in the database directly. The results are temporarily held in the database for processing.
- To give administrative access to the database through one of the following methods:
  - A DB2® open database connectivity (ODBC) client
  - An Oracle Java™ database connectivity (JDBC) client
  - Structured Query Language (SQL) to the server from an administrative-client command line

Consider using an extra 50 GB of temporary space for every 500 GB of space for file objects and optimization. See the guidelines in the following table. In the example that is used in the preceding step, a total of 1.7 TB of database space is required for file objects and optimization for 500 clients. Based on that calculation, 200 GB is required for temporary space. The total amount of required database space is 1.9 TB.

Database size	Minimum temporary-space requirement
< 500 GB	50 GB
≥ 500 GB and < 1 TB	100 GB
≥ 1 TB and < 1.5 TB	150 GB
≥ 1.5 and < 2 TB	200 GB
≥ 2 and < 3 TB	250 - 300 GB
≥ 3 and < 4 TB	350 - 400 GB

AIX: Estimating database space requirements based on storage pool capacity

To estimate database space requirements based on storage pool capacity, use a ratio of 1 - 5%. For example, if you require 200 TB of storage pool capacity, the size of your database is expected to be 2 - 10 TB. As a general rule, make your database as large as possible to prevent running out of space. If you run out of database space, server operations and client-store operations can fail.

AIX: The database manager and temporary space

The IBM Spectrum Protect™ server database manager manages and allocates system memory and disk space for the database. The amount of database space you require depends on the amount of system memory available and the server workload.

The database manager sorts data in a specific sequence, according to the SQL statement that you issue to request the data. Depending on the workload on the server, and if there is more data than the database manager can manage, the data (that is ordered in sequence) is allocated to temporary disk space. Data is allocated to temporary disk space when there is a large result set. The database manager dynamically manages the memory that is used when data is allocated to temporary disk space.

For example, expiration processing can produce a large result set. If there is not enough system memory on the database to store the result set, some of the data is allocated to temporary disk space. During expiration processing, if a node or file space are selected that are too large to process, the database manager cannot sort the data in memory. The database manager must use temporary space to sort data.

To run database operations, consider adding more database space for the following scenarios:

- The database has a small amount of space and the server operation that requires temporary space uses the remaining free space.
- The file spaces are large, or the file spaces have an assigned policy that creates many file versions.
- The IBM Spectrum Protect server must run with limited memory. The database uses the IBM Spectrum Protect server main memory to run database operations. However, if there is insufficient memory available, the IBM Spectrum Protect server allocates temporary space on disk to the database. For example, if 10G of memory is available and database operations require 12G of memory, the database uses temporary space.
- An `out of database space` error is displayed when you deploy an IBM Spectrum Protect server. Monitor the server activity log for messages that are related to database space.

Important: Do not change the DB2 software that is installed with the IBM Spectrum Protect installation packages and fix packs. Do not install or upgrade to a different version, release, or fix pack, of DB2 software to avoid damage to the database.

AIX: Recovery log space requirements

In IBM Spectrum Protect™, the term *recovery log* comprises the active log, the archive log, the active log mirror, and the archive failover log. The amount of space that you require for the recovery log depends on various factors, including, for example, the amount of client activity with the server.

- AIX: Active and archive log space
  When you estimate space requirements for active and archive logs, include some extra space for contingencies such as occasional heavy workloads and failovers.
- AIX: Active-log mirror space
  The active log can be mirrored so that the mirrored copy can be used if the active log files cannot be read. There can be only one active log mirror.
- AIX: Archive-failover log space
  The archive failover log is used by the server if the archive log directory runs out of space.

AIX: Active and archive log space

When you estimate space requirements for active and archive logs, include some extra space for contingencies such as occasional heavy workloads and failovers.

In IBM Spectrum Protect™ servers V7.1 and later, the active log can be a maximum size of 512 GB. The archive log size is limited to the size of the file system that it is installed on.

Use the following general guidelines when you estimate the size of the active log:

- The suggested starting size for the active log is 16 GB.
- Ensure that the active log is at least large enough for the amount of concurrent activity that the server typically handles. As a precaution, try to anticipate the largest amount of work that the server manages at one time. Provision the active log with extra space that can be used if needed. Consider using 20% of extra space.
- Monitor used and available active log space. Adjust the size of the active log as needed, depending upon factors such as client activity and the level of server operations.
- Ensure that the directory that holds the active log is as large as, or larger than, the size of the active log. A directory that is larger than the active log can accommodate failovers, if they occur.
- Ensure that the file system that contains the active log directory has at least 8 GB of free space for temporary log movement requirements.

The suggested starting size for the archive log is 48 GB.

The archive log directory must be large enough to contain the log files that are generated since the previous full backup. For example, if you perform a full backup of the database every day, the archive log directory must be large enough to hold the log files for all the client activity that occurs during 24 hours. To recover space, the server deletes obsolete archive log files after a full backup of the database. If the archive log directory becomes full and a directory for archive failover logs does not exist, log files remain in the active log directory. This condition can cause the active log directory to fill up and stop the server. When the server restarts, some of the existing active-log space is released.

After the server is installed, you can monitor archive log utilization and the space in the archive log directory. If the space in the archive log directory fills up, it can cause the following problems:

- The server is unable to perform full database backups. Investigate and resolve this problem.
- Other applications write to the archive log directory, exhausting the space that is required by the archive log. Do not share archive log space with other applications including other IBM Spectrum Protect servers. Ensure that each server has a separate storage location that is owned and managed by that specific server.

- AIX: Example: Estimating active and archive log sizes for basic client-store operations
  Basic client-store operations include backup, archive, and space management. Log space must be sufficient to handle all store transactions that are in progress at one time.
- AIX: Example: Estimating active and archive log sizes for clients that use multiple sessions
  If the client option RESOURCEUTILIZATION is set to a value that is greater than the default, the concurrent workload for the server increases.
- AIX: Example: Estimating active and archive log sizes for simultaneous write operations
  If client backup operations use storage pools that are configured for simultaneous write, the amount of log space that is required for each file increases.
- AIX: Example: Estimating active and archive log sizes for basic client store operations and server operations
  Migration of data in server storage, identification processes for data deduplication, reclamation, and expiration might run concurrently with client store operations. Administrative tasks such as administrative commands or SQL queries from administrative clients can also run concurrently with client store operations. Server operations and administrative tasks that run concurrently can increase the active log space that is required.
- AIX: Example: Estimating active and archive log sizes under conditions of extreme variation
  Problems with running out of active log space can occur if you have many transactions that complete quickly and some

transactions that take much longer to complete. A typical case occurs when many workstation or file-server backup sessions are active and a few very large database server-backup sessions are active. If this situation applies to your environment, you might need to increase the size of the active log so that the work completes successfully.

- AIX: Example: Estimating archive log sizes with full database backups
  The IBM Spectrum Protect server deletes unnecessary files from the archive log only when a full database backup occurs. Consequently, when you estimate the space that is required for the archive log, you must also consider the frequency of full database backups.
- AIX: Example: Estimating active and archive log sizes for data deduplication operations
  If you deduplicate data, you must consider its effects on space requirements for active and archive logs.

AIX: Example: Estimating active and archive log sizes for basic client-store operations

Basic client-store operations include backup, archive, and space management. Log space must be sufficient to handle all store transactions that are in progress at one time.

To determine the sizes of the active and archive logs for basic client-store operations, use the following calculation:

```
number of clients  x  files stored during each transaction
  x  log space needed for each file
```

This calculation is used in the example in the following table.

Table 1. Basic client-store operations

Item	Example values	Description
Maximum number of client nodes that back up, archive, or migrate files concurrently at any time	300	The number of client nodes that back up, archive, or migrate files every night.
Files stored during each transaction	4096	The default value of the server option TXNGROUPMAX is 4096.
Log space that is required for each file	3053 bytes	The value of 3053 bytes for each file in a transaction represents the log bytes that are needed when backing up files from a Windows client where the file names are 12 - 120 bytes. This value is based on the results of tests performed under laboratory conditions. The tests consisted of backup-archive clients performing backup operations to a random-access disk (DISK) storage pool. DISK pools result in more log use than sequential-access storage pools. Consider a value larger than 3053 bytes if the data being stored has file names that are longer than 12 - 120 bytes.
Active log: Suggested size	19.5 GB [1]	Use the following calculation to determine the size of the active log. One GB equals 1,073,741,824 bytes. `(300 clients x 4096 files stored during each transaction x 3053 bytes for each file) ÷ 1,073,741,824 bytes = 3.5 GB` Increase that amount by the suggested starting size of 16 GB: `3.5 + 16 = 19.5 GB`
Archive log: Suggested size	58.5 GB [1]	Because of the requirement to be able to store archive logs across three server database-backup cycles, multiply the estimate for the active log by 3 to estimate the total archive log requirement. `3.5 x 3 = 10.5 GB` Increase that amount by the suggested starting size of 48 GB: `10.5 + 48 = 58.5 GB`

Item	Example values	Description
[1] The example values in this table are used only to illustrate how the sizes for active logs and archive logs are calculated. In a production environment that does not use deduplication, 16 GB is the suggested minimum size for an active log. The suggested minimum size for an archive log in a production environment that does not use deduplication is 48 GB. If you substitute values from your environment and the results are larger than 16 GB and 48 GB, use your results to size the active log and archive log. Monitor your logs and adjust their size if necessary.		

AIX: Example: Estimating active and archive log sizes for clients that use multiple sessions

If the client option RESOURCEUTILIZATION is set to a value that is greater than the default, the concurrent workload for the server increases.

To determine the sizes of the active and archive logs when clients use multiple sessions, use the following calculation:

```
number of clients  x  sessions for each client  x  files stored
  during each transaction  x  log space needed for each file
```

This calculation is used in the example in the following table.

Table 1. Multiple client sessions

Item	Example values		Description
Maximum number of client nodes that back up, archive, or migrate files concurrently at any time	300	1000	The number of client nodes that back up, archive, or migrate files every night.
Possible sessions for each client	3	3	The setting of the client option RESOURCEUTILIZATION is larger than the default. Each client session runs a maximum of three sessions in parallel.
Files stored during each transaction	4096	4096	The default value of the server option TXNGROUPMAX is 4096.
Log space that is required for each file	3053	3053	The value of 3053 bytes for each file in a transaction represents the log bytes needed when backing up files from a Windows client where the file names are 12 - 120 bytes. This value is based on the results of tests performed under laboratory conditions. Tests consisted of clients performing backup operations to a random-access disk (DISK) storage pool. DISK pools result in more log use than sequential-access storage pools. Consider a value larger than 3053 bytes if the data being stored has file names that are longer than 12 - 120 bytes.

Item	Example values		Description
Active log: Suggested size	26.5 GB [1]	51 GB [1]	The following calculation was used for 300 clients. One GB equals 1,073,741,824 bytes. `(300 clients x 3 sessions for each client x 4096 files stored during each transaction x 3053 bytes for each file) ÷ 1,073,741,824 = 10.5 GB` Increase that amount by the suggested starting size of 16 GB: `10.5 + 16 = 26.5 GB` The following calculation was used for 1000 clients. One GB equals 1,073,741,824 bytes. `(1000 clients x 3 sessions for each client x 4096 files store during each transaction x 3053 bytes for each file) ÷ 1,073,741,824 = 35 GB` Increase that amount by the suggested starting size of 16 GB: `35 + 16 = 51 GB`
Archive log: Suggested size	79.5 GB [1]	153 GB [1]	Because of the requirement to be able to store archive logs across three server-database backup cycles, the estimate for the active log is multiplied by 3: `10.5 x 3 = 31.5 GB` `35 x 3 = 105 GB` Increase those amounts by the suggested starting size of 48 GB: `31.5 + 48 = 79.5 GB` `105 + 48 = 153 GB`

[1] The example values in this table are used only to illustrate how the sizes for active logs and archive logs are calculated. In a production environment that does not use deduplication, 16 GB is the suggested minimum size for an active log. The suggested minimum size for an archive log in a production environment that does not use deduplication is 48 GB. If you substitute values from your environment and the results are larger than 16 GB and 48 GB, use your results to size the active log and archive log.

Monitor your active log and adjust its size if necessary.

AIX: Example: Estimating active and archive log sizes for simultaneous write operations

If client backup operations use storage pools that are configured for simultaneous write, the amount of log space that is required for each file increases.

The log space that is required for each file increases by about 200 bytes for each copy storage pool that is used for a simultaneous write operation. In the example in the following table, data is stored to two copy storage pools in addition to a primary storage pool. The estimated log size increases by 400 bytes for each file. If you use the suggested value of 3053 bytes of log space for each file, the total number of required bytes is 3453.

This calculation is used in the example in the following table.

Table 1. Simultaneous write operations

Item	Example values	Description
Maximum number of client nodes that back up, archive, or migrate files concurrently at any time	300	The number of client nodes that back up, archive, or migrate files every night.
Files stored during each transaction	4096	The default value of the server option TXNGROUPMAX is 4096.

Item	Example values	Description
Log space that is required for each file	3453 bytes	3053 bytes plus 200 bytes for each copy storage pool. The value of 3053 bytes for each file in a transaction represents the log bytes that are needed when backing up files from a Windows client where the file names are 12 - 120 bytes. This value is based on the results of tests performed under laboratory conditions. The tests consisted of backup-archive clients performing backup operations to a random-access disk (DISK) storage pool. DISK pools result in more log use than sequential-access storage pools. Consider a value larger than 3053 bytes if the data being stored has file names that are longer than 12 - 120 bytes.
Active log: Suggested size	20 GB [1]	Use the following calculation to determine the size of the active log. One GB equals 1,073,741,824 bytes. `(300 clients x 4096 files stored during each transaction x 3453 bytes for each file) ÷ 1,073,741,824 bytes = 4.0 GB` Increase that amount by the suggested starting size of 16 GB: `4 + 16 = 20 GB`
Archive log: Suggested size	60 GB [1]	Because of the requirement to be able to store archive logs across three server database-backup cycles, multiply the estimate for the active log by 3 to estimate the archive log requirement: `4 GB x 3 = 12 GB` Increase that amount by the suggested starting size of 48 GB: `12 + 48 = 60 GB`
[1] The example values in this table are used only to illustrate how the sizes for active logs and archive logs are calculated. In a production environment that does not use deduplication, 16 GB is the suggested minimum size for an active log. The suggested minimum size for an archive log in a production environment that does not use deduplication is 48 GB. If you substitute values from your environment and the results are larger than 16 GB and 48 GB, use your results to size the active log and archive log. Monitor your logs and adjust their size if necessary.		

AIX: Example: Estimating active and archive log sizes for basic client store operations and server operations

Migration of data in server storage, identification processes for data deduplication, reclamation, and expiration might run concurrently with client store operations. Administrative tasks such as administrative commands or SQL queries from administrative clients can also run concurrently with client store operations. Server operations and administrative tasks that run concurrently can increase the active log space that is required.

For example, migration of files from the random-access (DISK) storage pool to a sequential-access disk (FILE) storage pool uses approximately 110 bytes of log space for each file that is migrated. For example, suppose that you have 300 backup-archive clients and each one of them backs up 100,000 files every night. The files are initially stored on DISK and then migrated to a FILE storage pool. To estimate the amount of active log space that is required for the data migration, use the following calculation. The number of clients in the calculation represents the maximum number of client nodes that back up, archive, or migrate files concurrently at any time.

```
300 clients  x 100,000 files for each client   x  110 bytes =  3.1 GB
```

Add this value to the estimate for the size of the active log that calculated for basic client store operations.

AIX: Example: Estimating active and archive log sizes under conditions of extreme variation

Problems with running out of active log space can occur if you have many transactions that complete quickly and some transactions that take much longer to complete. A typical case occurs when many workstation or file-server backup sessions are active and a few very large database server-backup sessions are active. If this situation applies to your environment, you might need to increase the size of the active log so that the work completes successfully.

AIX: Example: Estimating archive log sizes with full database backups

The IBM Spectrum Protect™ server deletes unnecessary files from the archive log only when a full database backup occurs. Consequently, when you estimate the space that is required for the archive log, you must also consider the frequency of full database backups.

For example, if a full database backup occurs once a week, the archive log space must be able to contain the information in the archive log for a full week.

The difference in archive log size for daily and full database backups is shown in the example in the following table.

Table 1. Full database backups

Item	Example values	Description
Maximum number of client nodes that back up, archive, or migrate files concurrently at any time	300	The number of client nodes that back up, archive, or migrate files every night.
Files stored during each transaction	4096	The default value of the server option TXNGROUPMAX is 4096.
Log space that is required for each file	3453 bytes	3053 bytes for each file plus 200 bytes for each copy storage pool. The value of 3053 bytes for each file in a transaction represents the log bytes needed when backing up files from a Windows client where the file names are 12 - 120 bytes. This value is based on the results of tests performed under laboratory conditions. Tests consisted of clients performing backup operations to a random-access disk (DISK) storage pool. DISK pools result in more log use than sequential-access storage pools. Consider a value larger than 3053 bytes if the data being stored has file names that are longer than 12 - 120 bytes.
Active log: Suggested size	20 GB [1]	Use the following calculation to determine the size of the active log. One GB equals 1,073,741,824 bytes. `(300 clients x 4096 files per transaction x 3453 bytes per file) ÷ 1,073,741,824 bytes = 4.0 GB` Increase that amount by the suggested starting size of 16 GB: `4 + 16 = 20 GB`
Archive log: Suggested size with a full database backup every day	60 GB [1]	Because of the requirement to be able to store archive logs across three backup cycles, multiply the estimate for the active log by 3 to estimate the total archive log requirement: `4 GB x 3 = 12 GB` Increase that amount by the suggested starting size of 48 GB: `12 + 48 = 60 GB`

Item	Example values	Description
Archive log: Suggested size with a full database every week	132 GB [1]	Because of the requirement to be able to store archive logs across three server database-backup cycles, multiply the estimate for the active log by 3 to estimate the total archive log requirement. Multiply the result by the number of days between full database backups: `(4 GB x 3 ) x 7 = 84 GB` Increase that amount by the suggested starting size of 48 GB: `84 + 48 = 132 GB`

[1] The example values in this table are used only to illustrate how the sizes for active logs and archive logs are calculated. In a production environment that does not use deduplication, 16 GB is the suggested minimum size for an active log. The suggested starting size for an archive log in a production environment that does not use deduplication is 48 GB. If you substitute values from your environment and the results are larger than 16 GB and 48 GB, use your results to size the active log and archive log.

Monitor your logs and adjust their size if necessary.

AIX: Example: Estimating active and archive log sizes for data deduplication operations

If you deduplicate data, you must consider its effects on space requirements for active and archive logs.

The following factors affect requirements for active and archive log space:

The amount of deduplicated data
: The effect of data deduplication on the active log and archive log space depends on the percentage of data that is eligible for deduplication. If the percentage of data that can be deduplicated is relatively high, more log space is required.

The size and number of extents
: Approximately 1,500 bytes of active log space are required for each extent that is identified by a duplicate-identification process. For example, if 250,000 extents are identified by a duplicate-identification process, the estimated size of the active log is 358 MB:

```
250,000 extents identified during each process x 1,500 bytes
 for each extent = 358 MB
```

Consider the following scenario. Three hundred backup-archive clients back up 100,000 files each night. This activity creates a workload of 30,000,000 files. The average number of extents for each file is two. Therefore, the total number of extents is 60,000,000, and the space requirement for the archive log is 84 GB:

```
60,000,000 extents x 1,500 bytes for each extent = 84 GB
```

A duplicate-identification process operates on aggregates of files. An aggregate consists of files that are stored in a given transaction, as specified by the TXNGROUPMAX server option. Suppose that the TXNGROUPMAX server option is set to the default of 4096. If the average number of extents for each file is two, the total number of extents in each aggregate is 8192, and the space required for the active log is 12 MB:

```
8192 extents in each aggregate x 1500 bytes for each extent =
   12 MB
```

The timing and number of the duplicate-identification processes
: The timing and number of duplicate-identification processes also affects the size of the active log. Using the 12 MB active-log size that was calculated in the preceding example, the concurrent load on the active log is 120 MB if 10 duplicate-identification processes are running in parallel:

```
12 MB for each process x 10 processes = 120 MB
```

File size
: Large files that are processed for duplicate identification can also affect the size of the active log. For example, suppose that a backup-archive client backs up an 80 GB, file-system image. This object can have a high number of duplicate extents if, for example, the files included in the file system image were backed up incrementally. For example, assume that a file

system image has 1.2 million duplicate extents. The 1.2 million extents in this large file represent a single transaction for a duplicate-identification process. The total space in the active log that is required for this single object is 1.7 GB:

```
1,200,000 extents x 1,500 bytes for each extent = 1.7 GB
```

If other, smaller duplicate-identification processes occur at the same time as the duplicate-identification process for a single large object, the active log might not have enough space. For example, suppose that a storage pool is enabled for deduplication. The storage pool has a mixture of data, including many relatively small files that range from 10 KB to several hundred KB. The storage pool also has few large objects that have a high percentage of duplicate extents.

To take into account not only space requirements but also the timing and duration of concurrent transactions, increase the estimated size of the active log by a factor of two. For example, suppose that your calculations for space requirements are 25 GB (23.3 GB + 1.7 GB for deduplication of a large object). If deduplication processes are running concurrently, the suggested size of the active log is 50 GB. The suggested size of the archive log is 150 GB.

The examples in the following tables show calculations for active and archive logs. The example in the first table uses an average size of 700 KB for extents. The example in the second table uses an average size of 256 KB. As the examples show, the average deduplicate-extent size of 256 KB indicates a larger estimated size for the active log. To minimize or prevent operational problems for the server, use 256 KB to estimate the size of the active log in your production environment.

Table 1. Average duplicate-extent size of 700 KB

Item	**Example values**		**Description**
Size of largest single object to deduplicate	800 GB	4 TB	The granularity of processing for deduplication is at the file level. Therefore, the largest single file to deduplicate represents the largest transaction and a correspondingly large load on the active and archive logs.
Average size of extents	700 KB	700 KB	The deduplication algorithms use a variable block method. Not all deduplicated extents for a given file are the same size, so this calculation assumes an average size for extents.
Extents for a given file	1,198,372 bits	6,135,667 bits	Using the average extent size (700 KB), these calculations represent the total number of extents for a given object. The following calculation was used for an 800 GB object: `(800 GB ÷ 700 KB) = 1,198,372 bits` The following calculation was used for a 4 TB object: `(4 TB ÷ 700 KB) = 6,135,667 bits`
Active log: Suggested size that is required for the deduplication of a single large object during a single duplicate-identification process	1.7 GB	8.6 GB	The estimated active log space that are needed for this transaction.

Item	Example values		Description
Active log: Suggested total size	66 GB [1]	79.8 GB [1]	After considering other aspects of the workload on the server in addition to deduplication, multiply the existing estimate by a factor of two. In these examples, the active log space required to deduplicate a single large object is considered along with previous estimates for the required active log size. The following calculation was used for multiple transactions and an 800 GB object: `(23.3 GB + 1.7 GB) x 2 = 50 GB` Increase that amount by the suggested starting size of 16 GB: `50 + 16 = 66 GB` The following calculation was used for multiple transactions and a 4 TB object: `(23.3 GB + 8.6 GB) x 2 = 63.8 GB` Increase that amount by the suggested starting size of 16 GB: `63.8 + 16 = 79.8 GB`
Archive log: Suggested size	198 GB [1]	239.4 GB [1]	Multiply the estimated size of the active log by a factor of 3. The following calculation was used for multiple transactions and an 800 GB object: `50 GB x 3 = 150 GB` Increase that amount by the suggested starting size of 48 GB: `150 + 48 = 198 GB` The following calculation was used for multiple transactions and a 4 TB object: `63.8 GB x 3 = 191.4 GB` Increase that amount by the suggested starting size of 48 GB: `191.4 + 48 = 239.4 GB`
[1] The example values in this table are used only to illustrate how the sizes for active logs and archive logs are calculated. In a production environment that uses deduplication, 32 GB is the suggested minimum size for an active log. The suggested minimum size for an archive log in a production environment that uses deduplication is 96 GB. If you substitute values from your environment and the results are larger than 32 GB and 96 GB, use your results to size the active log and archive log. Monitor your logs and adjust their size if necessary.			

Table 2. Average duplicate-extent size of 256 KB

Item	Example values		Description
Size of largest single object to deduplicate	800 GB	4 TB	The granularity of processing for deduplication is at the file level. Therefore, the largest single file to deduplicate represents the largest transaction and a correspondingly large load on the active and archive logs.

Item	Example values		Description
Average size of extents	256 KB	256 KB	The deduplication algorithms use a variable block method. Not all deduplicated extents for a given file are the same size, so this calculation assumes an average extent size.
Extents for a given file	3,276,800 bits	16,777,216 bits	Using the average extent size, these calculations represent the total number of extents for a given object. The following calculation was used for multiple transactions and an 800 GB object: `(800 GB ÷ 256 KB) = 3,276,800 bits` The following calculation was used for multiple transactions and a 4 TB object: `(4 TB ÷ 256 KB) = 16,777,216 bits`
Active log: Suggested size that is required for the deduplication of a single large object during a single duplicate-identification process	4.5 GB	23.4 GB	The estimated size of the active log space that is required for this transaction.
Active log: Suggested total size	71.6 GB [1]	109.4 GB [1]	After considering other aspects of the workload on the server in addition to deduplication, multiply the existing estimate by a factor of 2. In these examples, the active log space required to deduplicate a single large object is considered along with previous estimates for the required active log size. The following calculation was used for multiple transactions and an 800 GB object: `(23.3 GB + 4.5 GB) x 2 = 55.6 GB` Increase that amount by the suggested starting size of 16 GB: `55.6 + 16 = 71.6 GB` The following calculation was used for multiple transactions and a 4 TB object: `(23.3 GB + 23.4 GB) x 2 = 93.4 GB` Increase that amount by the suggested starting size of 16 GB: `93.4 + 16 = 109.4 GB`

Item	Example values		Description
Archive log: Suggested size	214.8 GB [1]	328.2 GB [1]	The estimated size of the active log multiplied by a factor of 3. The following calculation was used for an 800 GB object: `55.6 GB x 3 = 166.8 GB` Increase that amount by the suggested starting size of 48 GB: `166.8 + 48 = 214.8 GB` The following calculation was used for a 4 TB object: `93.4 GB x 3 = 280.2 GB` Increase that amount by the suggested starting size of 48 GB: `280.2 + 48 = 328.2 GB`
[1] The example values in this table are used only to illustrate how the sizes for active logs and archive logs are calculated. In a production environment that uses deduplication, 32 GB is the suggested minimum size for an active log. The suggested minimum size for an archive log in a production environment that uses deduplication is 96 GB. If you substitute values from your environment and the results are larger than 32 GB and 96 GB, use your results to size the active log and archive log. Monitor your logs and adjust their size if necessary.			

AIX: Active-log mirror space

The active log can be mirrored so that the mirrored copy can be used if the active log files cannot be read. There can be only one active log mirror.

Creating a log mirror is a suggested option. If you increase the size of the active log, the log mirror size is increased automatically. Mirroring the log can affect performance because of the doubled I/O activity that is required to maintain the mirror. The additional space that the log mirror requires is another factor to consider when deciding whether to create a log mirror.

If the mirror log directory becomes full, the server issues error messages to the activity log and to the db2diag.log. Server activity continues.

AIX: Archive-failover log space

The archive failover log is used by the server if the archive log directory runs out of space.

Specifying an archive failover log directory can prevent problems that occur if the archive log runs out of space. If both the archive log directory and the drive or file system where the archive failover log directory is located become full, the data remains in the active log directory. This condition can cause the active log to fill up, which causes the server to halt.

AIX: Monitoring space utilization for the database and recovery logs

To determine the amount of used and available active log space, you issue the QUERY LOG command. To monitor space utilization in the database and recovery logs, you can also check the activity log for messages.

Active log

If the amount of available active log space is too low, the following messages are displayed in the activity log:

ANR4531I: IC_AUTOBACKUP_LOG_USED_SINCE_LAST_BACKUP_TRIGGER
: This message is displayed when the active log space exceeds the maximum specified size. The IBM Spectrum Protect™ server starts a full database backup.

To change the maximum log size, halt the server. Open the dsmserv.opt file, and specify a new value for the ACTIVELOGSIZE option. When you are finished, restart the server.

ANR0297I: IC_BACKUP_NEEDED_LOG_USED_SINCE_LAST_BACKUP
This message is displayed when the active log space exceeds the maximum specified size. You must back up the database manually.

To change the maximum log size, halt the server. Open the dsmserv.opt file, and specify a new value for the ACTIVELOGSIZE option. When you are finished, restart the server.

ANR4529I: IC_AUTOBACKUP_LOG_UTILIZATION_TRIGGER
The ratio of used active-log space to available active-log space exceeds the log utilization threshold. If at least one full database backup has occurred, the IBM Spectrum Protect server starts an incremental database backup. Otherwise, the server starts a full database backup.

ANR0295I: IC_BACKUP_NEEDED_LOG_UTILIZATION
The ratio of used active-log space to available active-log space exceeds the log utilization threshold. You must back up the database manually.

Archive log

If the amount of available archive log space is too low, the following message is displayed in the activity log:

ANR0299I: IC_BACKUP_NEEDED_ARCHLOG_USED
The ratio of used archive-log space to available archive-log space exceeds the log utilization threshold. The IBM Spectrum Protect server starts a full automatic database backup.

Database

If the amount of space available for database activities is too low, the following messages are displayed in the activity log:

ANR2992W: IC_LOG_FILE_SYSTEM_UTILIZATION_WARNING_2
The used database space exceeds the threshold for database space utilization. To increase the space for the database, use the EXTEND DBSPACE command, the EXTEND DBSPACE command, or the DSMSERV FORMAT utility with the DBDIR parameter.

ANR1546W: FILESYSTEM_DBPATH_LESS_1GB
The available space in the directory where the server database files are located is less than 1 GB.

When an IBM Spectrum Protect server is created with the DSMSERV FORMAT utility or with the configuration wizard, a server database and recovery log are also created. In addition, files are created to hold database information used by the database manager. The path specified in this message indicates the location of the database information used by the database manager. If space is unavailable in the path, the server can no longer function.

You must add space to the file system or make space available on the file system or disk.

AIX: Deleting installation rollback files

You can delete certain installation files that were saved during the installation process to free space in the shared resource directory. For example, files that might have been required for a rollback operation are types of files that you can delete.

About this task

To delete the files that are no longer needed, use either the installation graphical wizard or the command line in console mode.

- AIX: Deleting installation rollback files by using a graphical wizard
  You can delete certain installation files that were saved during installation process by using the IBM® Installation Manager user interface.
- AIX: Deleting installation rollback files by using the command line
  You can delete certain installation files that were saved during the installation process by using the command line.

AIX: Deleting installation rollback files by using a graphical wizard

You can delete certain installation files that were saved during installation process by using the IBM® Installation Manager user interface.

Procedure

1. Open IBM Installation Manager.
   AIX In the directory where IBM Installation Manager is installed, go to the eclipse subdirectory (for example, /opt/IBM/InstallationManager/eclipse), and issue the following command to start IBM Installation Manager:

   ```
   ./IBMIM
   ```

2. Click File > Preferences.
3. Select Files for Rollback.
4. Click Delete Saved Files and click OK.

AIX: Deleting installation rollback files by using the command line

You can delete certain installation files that were saved during the installation process by using the command line.

Procedure

1. In the directory where IBM® Installation Manager is installed, go to the following subdirectory:
   - AIX eclipse/tools

   For example:

   - AIX /opt/IBM/InstallationManager/eclipse/tools
2. From the tools directory, issue the following command to start an IBM Installation Manager command line:
   - AIX `./imcl -c`
3. Enter `P` to select Preferences.
4. Enter `3` to select Files for Rollback.
5. Enter `D` to Delete the Files for Rollback.
6. Enter `A` to Apply Changes and Return to Preferences Menu.
7. Enter `C` to leave the Preference Menu.
8. Enter `X` to Exit Installation Manager.

AIX: Server naming best practices

Use these descriptions as a reference when you install or upgrade an IBM Spectrum Protect™ server.

Instance user ID

The instance user ID is used as the basis for other names related to the server instance. The instance user ID is also called the instance owner.

For example: tsminst1

The instance user ID is the user ID that must have ownership or read/write access authority to all directories that you create for the database and the recovery log. The standard way to run the server is under the instance user ID. That user ID must also have read/write access to the directories that are used for any FILE device classes.

AIX

Home directory for the instance user ID

The home directory can be created when creating the instance user ID, by using the option (-m) to create a home directory if it does not exist already. Depending on local settings, the home directory might have the form: /home/*instance_user_ID*

For example: /home/tsminst1

The home directory is primarily used to contain the profile for the user ID and for security settings.

AIX

Database instance name

The database instance name must be the same as the instance user ID under which you run the server instance.

For example: tsminst1

AIX

Instance directory

The instance directory is a directory that contains files specifically for a server instance (the server options file and other server-specific files). It can have any name that you want. For easier identification, use a name that ties the directory to the instance name.

You can create the instance directory as a subdirectory of the home directory for the instance user ID. For example: /home/*instance_user_ID*/*instance_user_ID*

The following example places the instance directory in the home directory for user ID tsminst1: /home/tsminst1/tsminst1

You can also create the directory in another location, for example: /tsmserver/tsminst1

The instance directory stores the following files for the server instance:

- The server options file, dsmserv.opt
- The server key database file, `cert.kdb`, and the `.arm` files (used by clients and other servers to import the Secure Sockets Layer certificates of the server)
- Device configuration file, if the DEVCONFIG server option does not specify a fully qualified name
- Volume history file, if the VOLUMEHISTORY server option does not specify a fully qualified name
- Volumes for DEVTYPE=FILE storage pools, if the directory for the device class is not fully specified, or not fully qualified
- User exits
- Trace output (if not fully qualified)

Database name

The database name is always TSMDB1, for every server instance. This name cannot be changed.

Server name

The server name is an internal name for IBM Spectrum Protect, and is used for operations that involve communication among multiple IBM Spectrum Protect servers. Examples include server-to-server communication and library sharing.

AIX The server name is also used when you add the server to the Operations Center so that it can be managed using that interface. Use a unique name for each server. For easy identification in the Operations Center (or from a QUERY SERVER command), use a name that reflects the location or purpose of the server. Do not change the name of an IBM Spectrum Protect server after it is configured as a hub or spoke server.

If you use the wizard, the default name that is suggested is the host name of the system that you are using. You can use a different name that is meaningful in your environment. If you have more than one server on the system and you use the wizard, you can use the default name for only one of the servers. You must enter a unique name for each server.

AIX For example:

- `PAYROLL`
- `SALES`

Directories for database space and recovery log

The directories can be named according to local practices. For easier identification, consider using names that tie the directories to the server instance.

For example, for the archive log:

- AIX /tsminst1_archlog

AIX: Installation directories

Installation directories for the IBM Spectrum Protect™ server include the server, DB2®, device, language, and other directories. Each one contains several additional directories.

The (/opt/tivoli/tsm/server/bin) is the default directory that contains server code and licensing.

The DB2 product that is installed as part of the installation of the IBM Spectrum Protect server has the directory structure as documented in DB2 information sources. Protect these directories and files as you do the server directories. The default directory is /opt/tivoli/tsm/db2.

You can use US English, German, French, Italian, Spanish, Brazilian Portuguese, Korean, Japanese, traditional Chinese, simplified Chinese, Chinese GBK, Chinese Big5, and Russian.

AIX: Installing the server components

To install the Version 8.1.2 server components, you can use the installation wizard, the command line in console mode, or silent mode.

About this task

Using the IBM Spectrum Protect™ installation software, you can install the following components:

- server
  Tip: The database (DB2®), the Global Security Kit (GSKit) and IBM® Java™ Runtime Environment (JRE) are automatically installed when you select the server component.
- server languages
- license
- devices
- IBM Spectrum Protect for SAN
- Operations Center

AIX Allow approximately 30 - 45 minutes to install a V8.1.2 server, using this guide.

- AIX: Obtaining the installation package
  You can obtain the IBM Spectrum Protect installation package from an IBM download site such as Passport Advantage® or IBM Fix Central.
- AIX: Installing IBM Spectrum Protect by using the installation wizard
  You can install the server by using the IBM Installation Manager graphical wizard.
- AIX: Installing IBM Spectrum Protect by using console mode
  You can install IBM Spectrum Protect by using the command line in console mode.
- AIX: Installing IBM Spectrum Protect in silent mode
  You can install or upgrade the server in silent mode. In silent mode, the installation does not send messages to a console but instead stores messages and errors in log files.
- AIX: Installing server language packages
  Translations for the server allow the server to display messages and help in languages other than US English. The translations also allow for the use of locale conventions for date, time, and number formatting.

AIX: Obtaining the installation package

You can obtain the IBM Spectrum Protect™ installation package from an IBM® download site such as Passport Advantage® or IBM Fix Central.

AIX

Before you begin

If you plan to download the files, set the system user limit for maximum file size to unlimited to ensure that the files can be downloaded correctly:

1. To query the maximum file size value, issue the following command:

```
ulimit -Hf
```

2. If the system user limit for maximum file size is not set to unlimited, change it to unlimited by following the instructions in the documentation for your operating system.

Procedure

1. Download the appropriate package file from one of the following websites.
   - Download the server package from Passport Advantage or Fix Central.
   - For the latest information, updates, and maintenance fixes, go to the IBM Support Portal.
2. If you downloaded the package from an IBM download site, complete the following steps:
   AIX
   a. Verify that you have enough space to store the installation files when they are extracted from the product package. See the download document for the space requirements:
      - IBM Spectrum Protect technote 4042944
      - IBM Spectrum Protect Extended Edition technote 4042945
      - IBM Spectrum Protect for Data Retention technote 4042946

   b. Download the package file to the directory of your choice. The path must contain no more than 128 characters. Be sure to extract the installation files to an empty directory. Do not extract to a directory that contains previously extracted files, or any other files.
   c. Ensure that executable permission is set for the package. If necessary, change the file permissions by issuing the following command:

      ```
      chmod a+x package_name.bin
      ```

   d. Extract the package by issuing the following command:

      ```
      ./package_name.bin
      ```

      where *package_name* is the name of the downloaded file, for example:

      AIX

      ```
      8.1.x.000-IBM-SPSRV-AIX.bin
      ```

3. AIX Ensure that the following command is enabled so that the IBM Spectrum Protect wizards work properly:
   - AIX `lsuser`

   By default, the command is enabled.
4. Select one of the following methods of installing IBM Spectrum Protect:
   - AIX: Installing IBM Spectrum Protect by using the installation wizard
   - AIX: Installing IBM Spectrum Protect by using console mode
   - AIX: Installing IBM Spectrum Protect in silent mode
5. After you install IBM Spectrum Protect, and before you customize it for your use, go to the IBM Support Portal. Click Support and downloads and apply any applicable fixes.

AIX: Installing IBM Spectrum Protect by using the installation wizard

You can install the server by using the IBM® Installation Manager graphical wizard.

Before you begin

Take the following actions before you start the installation:

- AIX If the following RPM files are not installed on your system, you must install them. For instructions, see Installing RPM files for the graphical wizard.
  - atk-1.12.3-2.aix5.2.ppc.rpm
  - cairo-1.8.8-1.aix5.2.ppc.rpm
  - expat-2.0.1-1.aix5.2.ppc.rpm
  - fontconfig-2.4.2-1.aix5.2.ppc.rpm
  - freetype2-2.3.9-1.aix5.2.ppc.rpm
  - gettext-0.10.40-6.aix5.1.ppc.rpm
  - glib2-2.12.4-2.aix5.2.ppc.rpm
  - gtk2-2.10.6-4.aix5.2.ppc.rpm
  - libjpeg-6b-6.aix5.1.ppc.rpm

    - libpng-1.2.32-2.aix5.2.ppc.rpm
    - libtiff-3.8.2-1.aix5.2.ppc.rpm
    - pango-1.14.5-4.aix5.2.ppc.rpm
    - pixman-0.12.0-3.aix5.2.ppc.rpm
    - xcursor-1.1.7-3.aix5.2.ppc.rpm
    - xft-2.1.6-5.aix5.1.ppc.rpm
    - xrender-0.9.1-3.aix5.2.ppc.rpm
    - zlib-1.2.3-3.aix5.1.ppc.rpm
- Verify that the operating system is set to the language that you require. By default, the language of the operating system is the language of the installation wizard.

Procedure

Install IBM Spectrum Protect™ by using this method:

Option	Description
Installing the software from a downloaded package:	a. Change to the directory where you downloaded the package. b. Start the installation wizard by issuing the following command: AIX `./install.sh`

What to do next

- If errors occur during the installation process, the errors are recorded in log files that are stored in the IBM Installation Manager logs directory.

  You can view installation log files by clicking File > View Log from the Installation Manager tool. To collect these log files, click Help > Export Data for Problem Analysis from the Installation Manager tool.

- After you install the server and components, and before you customize it for your use, go to the IBM Support Portal. Click Downloads (fixes and PTFs) and apply any applicable fixes.

- AIX After you install a new server, review Taking the first steps after you install IBM Spectrum Protect to learn about configuring your server.

- AIX AIX: Installing prerequisite RPM files for the graphical wizard
  Before you can use the graphical wizard of IBM Installation Manager to install IBM Spectrum Protect, you must ensure that the necessary RPM files are installed.

AIX: Installing IBM Spectrum Protect by using console mode

You can install IBM Spectrum Protect™ by using the command line in console mode.

Before you begin

Take the following actions before you start the installation:

- Verify that the operating system is set to the language that you require. By default, the language of the operating system is the language of the installation wizard.

Procedure

Install IBM Spectrum Protect by using this method:

Option	Description

Option	Description
Installing the software from a downloaded package:	a. Change to the directory where you downloaded the package. b. Start the installation wizard in console mode by issuing the following command: AIX `./install.sh -c` Optional: Generate a response file as part of a console mode installation. Complete the console mode installation options, and in the Summary panel, specify `G` to generate the responses.

What to do next

- If errors occur during the installation process, the errors are recorded in log files that are stored in the IBM® Installation Manager logs directory, for example:
  - AIX /var/ibm/InstallationManager/logs
- After you install the server and components, and before you customize it for your use, go to the IBM Support Portal. Click Downloads (fixes and PTFs) and apply any applicable fixes.
- AIX After you install a new server, review Taking the first steps after you install IBM Spectrum Protect to learn about configuring your server.

AIX: Installing IBM Spectrum Protect in silent mode

You can install or upgrade the server in silent mode. In silent mode, the installation does not send messages to a console but instead stores messages and errors in log files.

Before you begin

To provide data input when you use the silent installation method, you can use a response file. The following sample response files are provided in the input directory where the installation package is extracted:

install_response_sample.xml
: Use this file to install the IBM Spectrum Protect™ components.

update_response_sample.xml
: Use this file to upgrade the IBM Spectrum Protect components.

These files contain default values that can help you avoid any unnecessary warnings. To use these files, follow the instructions that are provided in the files.

If you want to customize a response file, you can modify the options that are in the file. For information about response files, see Response files.

Procedure

1. Create a response file. You can modify the sample response file or create your own file.
2. If you install the server and Operations Center in silent mode, create a password for the Operations Center truststore in the response file.
   If you are using the install_response_sample.xml file, add the password in the following line of the file, where *mypassword* represents the password:

   ```
   <variable name='ssl.password' value='mypassword' />
   ```

   For more information about this password, see Installation checklist
   Tip: To upgrade the Operations Center, the truststore password is not required if you are using the update_response_sample.xml file.
3. Start the silent installation by issuing the following command from the directory where the installation package is extracted. The value *response_file* represents the response file path and file name:
   - AIX

   ```
   ./install.sh -s -input response_file -acceptLicense
   ```

What to do next

- If errors occur during the installation process, the errors are recorded in log files that are stored in the IBM® Installation Manager logs directory, for example:
  - AIX /var/ibm/InstallationManager/logs
- After you install the server and components, and before you customize it for your use, go to the IBM Support Portal. Click Downloads (fixes and PTFs) and apply any applicable fixes.
- AIX After you install a new server, review Taking the first steps after you install IBM Spectrum Protect to learn about configuring your server.

AIX

AIX: Installing server language packages

Translations for the server allow the server to display messages and help in languages other than US English. The translations also allow for the use of locale conventions for date, time, and number formatting.

Before you begin

For instructions on installing storage agent language packages, see Language pack configuration for storage agents.

- AIX: Server language locales
  Use either the default language package option or select another language package to display server messages and help.
- AIX: Configuring a language package
  After you configure a language package, messages and help are shown on the server in languages other than US English. Installation packages are provided with IBM Spectrum Protect™.
- AIX: Updating a language package
  You can modify or update a language package by using the IBM® Installation Manager.

AIX: Server language locales

Use either the default language package option or select another language package to display server messages and help.

AIX This language package is automatically installed for the following default language option for IBM Spectrum Protect™ server messages and help:

- AIX LANGUAGE en_US

For languages or locales other than the default, install the language package that your installation requires.
You can use the languages that are shown:
AIX

Table 1. Server languages for AIX®

Language	LANGUAGE option value
Chinese, Simplified	zh_CN
Chinese, Simplified (UTF-8)	ZH_CN
Chinese, Traditional (Big5)	Zh_TW
Chinese, Traditional (UTF-8)	ZH_TW
Chinese, Traditional (euc_tw)	zh_TW
English	en_US
English (UTF-8)	EN_US
French	fr_FR
French (UTF-8)	FR_FR
German	de_DE
German (UTF-8)	DE_DE
Italian	it_IT
Italian (UTF-8)	IT_IT

Language	LANGUAGE option value
Japanese, EUC	ja_JP
Japanese, PC	Ja_JP
Japanese, UTF8	JA_JP
Korean	ko_KR
Korean (UTF-8)	KO_KR
Portuguese, Brazilian	pt_BR
Portuguese, Brazilian (UTF-8)	PT_BR
Russian	ru_RU
Russian (UTF-8)	RU_RU
Spanish	es_ES
Spanish (UTF-8)	ES_ES

AIX Restriction: For Operations Center users, some characters might not be displayed properly if the web browser does not use the same language as the server. If this problem occurs, set the browser to use the same language as the server.

AIX: Configuring a language package

After you configure a language package, messages and help are shown on the server in languages other than US English. Installation packages are provided with IBM Spectrum Protect™.

About this task

AIX To set support for a certain locale, complete one of the following tasks:

- Set the LANGUAGE option in the server options file to the name of the locale that you want to use. For example:
  - AIX To use the `it_IT` locale, set the LANGUAGE option to `it_IT`. See AIX: Server language locales.
- AIX If you are starting the server in the foreground, set the `LC_ALL` environment variable to match the value that is set in the server options file. For example, to set the environment variable for Italian, enter the following value:

  ```
  export LC_ALL=it_IT
  ```

If the locale is successfully initialized, it formats the date, time, and number for the server. If the locale is not successfully initialized, the server uses the US English message files and the date, time, and number format.

AIX: Updating a language package

You can modify or update a language package by using the IBM® Installation Manager.

About this task

You can install another language package within the same IBM Spectrum Protect™ instance.

- Use the Modify function of IBM Installation Manager to install another language package.
- Use the Update function of IBM Installation Manager to update to newer versions of the language packages.

Tip: In IBM Installation Manager, the term *update* means to discover and install updates and fixes to installed software packages. In this context, *update* and *upgrade* are synonymous.

AIX: Taking the first steps after you install IBM Spectrum Protect

After you install Version 8.1.2, prepare for the configuration. Using the configuration wizard is the preferred method of configuring the IBM Spectrum Protect™ instance.

About this task

1. Create the directories and user ID for the server instance. See AIX: Creating the user ID and directories for the server instance.
2. Configure a server instance. Select one of the following options:
    - Use the configuration wizard, the preferred method. See AIX: Configuring IBM Spectrum Protect by using the configuration wizard.
    - Manually configure the new instance. See AIX: Configuring the server instance manually. Complete the following steps during a manual configuration.
        a. Set up your directories and create the IBM Spectrum Protect instance. See AIX: Creating the server instance.
        b. Create a new server options file by copying the sample file to set up communications between the server and clients. See AIX AIX: Configuring server and client communications.
        c. Issue the DSMSERV FORMAT command to format the database. See AIX: Formatting the database and log.
        d. Configure your system for database backup. See AIX: Preparing the database manager for database backup.
3. Configure options to control when database reorganization runs. See AIX: Configuring server options for server database maintenance.
4. Start the server instance if it is not already started.
    - AIX See AIX: Starting the server instance.
5. Register your license. See AIX: Registering licenses.
6. Prepare your system for database backups. See AIX: Specifying a device class in preparation for database backups.
7. Monitor the server. See AIX: Monitoring the server.

- AIX: Creating the user ID and directories for the server instance
  Create the user ID for the IBM Spectrum Protect server instance and create the directories that the server instance needs for database and recovery logs.
- AIX: Configuring the IBM Spectrum Protect server
  After you have installed the server and prepared for the configuration, configure the server instance.
- AIX: Configuring server options for server database maintenance
  To help avoid problems with database growth and server performance, the server automatically monitors its database tables and reorganizes them when needed. Before starting the server for production use, set server options to control when reorganization runs. If you plan to use data deduplication, ensure that the option to run index reorganization is enabled.
- AIX AIX: Starting the server instance
  You can start the server by using the instance user ID, which is the preferred method, or the root user ID.
- AIX: Stopping the server
  You can stop the server when needed to return control to the operating system. To avoid losing administrative and client node connections, stop the server only after current sessions are completed or canceled.
- AIX: Registering licenses
  Immediately register any IBM Spectrum Protect licensed functions that you purchase so you do not lose any data after you start server operations, such as backing up your data.
- AIX: Specifying a device class in preparation for database backups
  To prepare the system for automatic and manual database backups, you must specify the device class to be used.
- AIX: Running multiple server instances on a single system
  You can create more than one server instance on your system. Each server instance has its own instance directory, and database and log directories.
- AIX: Monitoring the server
  When you start to use the server in production, monitor the space that is used by the server to ensure that the amount of space is adequate. Adjust the space if needed.

AIX: Creating the user ID and directories for the server instance

Create the user ID for the IBM Spectrum Protect™ server instance and create the directories that the server instance needs for database and recovery logs.

Before you begin

Review the information about planning space for the server before you complete this task. See AIX: Worksheets for planning details for the server.

Procedure

1. Create the user ID that will own the server instance. You use this user ID when you create the server instance in a later step.

   AIX

AIX Create a user ID and group that will be the owner of the server instance.

a. The following commands can be run from an administrative user ID that will set up the user and group. Create the user ID and group in the home directory of the user.
Restriction: In the user ID, only lowercase letters (a-z), numerals (0-9), and the underscore character (_) can be used. The user ID and group name must comply with the following rules:
   - The length must be 8 characters or less.
   - The user ID and group name cannot start with *ibm*, *sql*, *sys*, or a numeral.
   - The user ID and group name cannot be *user*, *admin*, *guest*, *public*, *local*, or any SQL reserved word.

   For example, create user ID `tsminst1` in group `tsmsrvrs`. The following examples show how to create this user ID and group using operating system commands.

   AIX

   ```
   mkgroup id=1001 tsmsrvrs
   mkuser id=1002 pgrp=tsmsrvrs home=/home/tsminst1 tsminst1
   passwd tsminst1
   ```

   Restriction: DB2® does not support direct operating system user authentication through LDAP.

b. Log off, then log in to your system. Change to the user account that you just created. Use an interactive login program, such as telnet, so that you are prompted for the password and can change it if necessary.

2. Create directories that the server requires.
AIX Create empty directories for each item in the table and ensure that the directories are owned by the new user ID you just created. Mount the associated storage to each directory for the active log, archive log, and database directories.

Item	Example commands for creating the directories	Your directories
The *instance directory* for the server, which is a directory that will contain files specifically for this server instance (the server options file and other server-specific files)	`mkdir /tsminst1`	
The database directories	`mkdir /tsmdb001` `mkdir /tsmdb002` `mkdir /tsmdb003` `mkdir /tsmdb004`	
Active log directory	`mkdir /tsmlog`	
Archive log directory	`mkdir /tsmarchlog`	
Optional: Directory for the log mirror for the active log	`mkdir /tsmlogmirror`	
Optional: Secondary archive log directory (failover location for archive log)	`mkdir /tsmarchlogfailover`	

When a server is initially created by using the DSMSERV FORMAT utility or the configuration wizard, a server database and recovery log are created. In addition, files are created to hold database information that is used by the database manager.

3. Log off the new user ID.

AIX: Configuring the IBM Spectrum Protect server

After you have installed the server and prepared for the configuration, configure the server instance.

About this task

Configure an IBM Spectrum Protect™ server instance by selecting one of the following options:

- AIX: Configuring IBM Spectrum Protect by using the configuration wizard
The wizard offers a guided approach to configuring a server. By using the graphical user interface (GUI), you can avoid some

configuration steps that are complex when done manually. Start the wizard on the system where you installed the IBM Spectrum Protect server program.

- AIX: Configuring the server instance manually
  After installing IBM Spectrum Protect Version 8.1.2, you can configure IBM Spectrum Protect manually instead of using the configuration wizard.

AIX: Configuring IBM Spectrum Protect by using the configuration wizard

The wizard offers a guided approach to configuring a server. By using the graphical user interface (GUI), you can avoid some configuration steps that are complex when done manually. Start the wizard on the system where you installed the IBM Spectrum Protect™ server program.

Before you begin

Before you begin to use the configuration wizard, you must complete all preceding steps to prepare for the configuration. These steps include installing IBM Spectrum Protect, creating the database and log directories, and creating the directories and user ID for the server instance.

Procedure

1. Ensure that the following requirements are met: AIX
   - The system where you installed IBM Spectrum Protect must have the X Window System client. You must also be running an X Window System server on your desktop.
   - The system must have the Secure Shell (SSH) protocol enabled. Ensure that the port is set to the default value, 22, and that the port is not blocked by a firewall. You must enable password authentication in the `sshd_config` file in the /etc/ssh/ directory. Also, ensure that the SSH daemon service has access rights for connecting to the system by using the `localhost` value.
   - You must be able to log in to IBM Spectrum Protect with the user ID that you created for the server instance, by using the SSH protocol. When you use the wizard, you must provide this user ID and password to access that system.
   - Restart the server before you proceed with the Configuration wizard.
2. Start the local version of the wizard:
   - AIX Open the `dsmicfgx` program in the /opt/tivoli/tsm/server/bin directory. This wizard can be only run as a root user.

   Follow the instructions to complete the configuration. The wizard can be stopped and restarted, but the server is not operational until the entire configuration process is complete.

AIX: Configuring the server instance manually

After installing IBM Spectrum Protect™ Version 8.1.2, you can configure IBM Spectrum Protect manually instead of using the configuration wizard.

- AIX: Creating the server instance
  Create an IBM Spectrum Protect instance by issuing the db2icrt command.
- AIX AIX: Configuring server and client communications
  A default sample server options file, dsmserv.opt.smp, is created during IBM Spectrum Protect installation in the /opt/tivoli/tsm/server/bin directory. You must set up communications between the server and clients by creating a new server options file. To do so, copy the sample file to the directory for the server instance.
- AIX: Formatting the database and log
  Use the DSMSERV FORMAT utility to initialize a server instance. No other server activity is allowed while you initialize the database and recovery log.
- AIX: Preparing the database manager for database backup
  To back up the data in the database to IBM Spectrum Protect, you must enable the database manager and configure the IBM Spectrum Protect application programming interface (API).

AIX: Creating the server instance

Create an IBM Spectrum Protect™ instance by issuing the db2icrt command.

About this task

You can have one or more server instances on one workstation.
AIX Important: Before you run the db2icrt command, verify the following items:

- The home directory for the user (/home/tsminst1) exists. If there is no home directory, you must create it.
  The instance directory stores the following core files that are generated by the IBM Spectrum Protect server:
  - The server options file, dsmserv.opt
  - The server key database file, `cert.kdb`, and the `.arm` files (used by clients and other servers to import the Secure Sockets Layer certificates of the server)
  - Device configuration file, if the DEVCONFIG server option does not specify a fully qualified name
  - Volume history file, if the VOLUMEHISTORY server option does not specify a fully qualified name
  - Volumes for DEVTYPE=FILE storage pools, if the directory for the device class is not fully specified, or not fully qualified
  - User exits
  - Trace output (if not fully qualified)
- A shell configuration file (for example, .profile) exists in the home directory. The root user and instance-user ID must have write permission to this file. For more information, see the DB2® product information. Search for Linux and UNIX environment variable settings.

AIX

1. Log in using the root user ID and create an IBM Spectrum Protect instance. The name of the instance must be the same name as the user that owns the instance. Use the db2icrt command and enter the command on one line: AIX

   ```
   /opt/tivoli/tsm/db2/instance/db2icrt -a server -u
   instance_name instance_name
   ```

   For example, if your user ID for this instance is tsminst1, use the following command to create the instance. Enter the command on one line. AIX

   ```
   /opt/tivoli/tsm/db2/instance/db2icrt -a server -u
   tsminst1 tsminst1
   ```

   Remember: From this point on, use this new user ID when you configure your IBM Spectrum Protect server. Log out of the root user ID and log in under the new instance-user ID.
2. Change the default directory for the database to be the same as the instance directory for the server. If you have multiple servers, log in under the instance ID for each server. Issue this command:

   ```
   db2 update dbm cfg using dftdbpath instance_directory
   ```

   For example, where instance_directory is the instance user ID:

   ```
   db2 update dbm cfg using dftdbpath /tsminst1
   ```

3. Modify the library path to use the version of the IBM Global Security Kit (GSKit) that is installed with the server. In the following examples, *server_bin_directory* is a subdirectory of the server installation directory. For example, /opt/tivoli/tsm/server/bin.
   - AIX Issue the following command, on one line:

     ```
     export LIBPATH=server_bin_directory/dbbkapi:
     /usr/opt/ibm/gsk8_64/lib64:$LIBPATH
     ```

   - You must update the following files to set the library path when DB2 or the server are started:

     Bash or Korn shell example:

     ```
     instance_users_home_directory/sqllib/userprofile
     ```

     C shell example:

     ```
     instance_users_home_directory/sqllib/usercshrc
     ```

   - Add the following entry to the *instance_users_home_directory*/sqllib/userprofile (Bash or Korn shell) file. Each entry is on one line. AIX

     ```
     LIBPATH=server_bin_directory/dbbkapi:
     /usr/opt/ibm/gsk8_64/lib64:$LIBPATH

     export LIBPATH
     ```

     Remember: The following entries must be in the library path:

- /usr/local/ibm/gsk8_64/lib64
- /opt/ibm/lib
- /opt/ibm/lib64
- /usr/lib64

- Add the following entry to the *instance_users_home_directory*/sqllib/usercshrc (C shell) file, on one line: AIX

```
setenv LIBPATH server_bin_directory/dbbkapi:
/usr/opt/ibm/gsk8_64/lib64:$LIBPATH
```

- Verify the library path settings and that the GSKit is version 8.0.14.43 or later. Issue the following commands: AIX

```
echo $LIBPATH
gsk8capicmd_64 -version
gsk8ver_64
```

If your GSKit version is not 8.0.14.43 or later, you must reinstall the IBM Spectrum Protect server. The reinstallation ensures that the correct GSKit version is available.

4. Create a new server options file. See AIX: Configuring server and client communications.

AIX

AIX: Configuring server and client communications

A default sample server options file, dsmserv.opt.smp, is created during IBM Spectrum Protect™ installation in the /opt/tivoli/tsm/server/bin directory. You must set up communications between the server and clients by creating a new server options file. To do so, copy the sample file to the directory for the server instance.

About this task

Ensure that you have a server instance directory, for example /tsminst1, and copy the sample file to this directory. Name the new file `dsmserv.opt` and edit the options. Complete this set-up before you initialize the server database. Each sample or default entry in the sample options file is a comment, a line beginning with an asterisk (*). Options are not case-sensitive and one or more blank spaces are allowed between keywords and values.

When editing the options file, follow these guidelines:

- Remove the asterisk at the beginning of the line to activate an option.
- Begin entering the options in any column.
- Enter only one option per line, and the option must be on only one line.
- If you make multiple entries for a keyword, the IBM Spectrum Protect server uses the last entry.

If you change the server options file, you must restart the server for the changes to take effect.

You can specify one or more of the following communication methods:

- TCP/IP Version 4 or Version 6
- Shared memory
- Secure Sockets Layer (SSL)
  Tip: You can authenticate passwords with the LDAP directory server, or authenticate passwords with the IBM Spectrum Protect server. Passwords that are authenticated with the LDAP directory server can provide enhanced system security.

- AIX AIX: Setting TCP/IP options
  Select from a range of TCP/IP options for the IBM Spectrum Protect server or retain the default.
- AIX AIX: Setting shared memory options
  You can use shared memory communications between clients and servers on the same system. To use shared memory, TCP/IP Version 4 must be installed on the system.
- AIX AIX: Setting Secure Sockets Layer options
  You can add more protection for your data and passwords by using Secure Sockets Layer (SSL).

AIX: Setting TCP/IP options

Select from a range of TCP/IP options for the IBM Spectrum Protect™ server or retain the default.

About this task

The following is an example of a list of TCP/IP options that you can use to set up your system.

```
commmethod         tcpip
  tcpport          1500
  tcpwindowsize    0
  tcpnodelay       yes
```

Tip: You can use TCP/IP Version 4, Version 6, or both.

TCPPORT
: The server port address for TCP/IP and SSL communication. The default value is 1500.

AIX TCPWINDOWSIZE
: AIX Specifies the size of the TCP/IP buffer that is used when sending or receiving data. The window size that is used in a session is the smaller of the server and client window sizes. Larger window sizes use additional memory but can improve performance.

  You can specify an integer from 0 to 2048. To use the default window size for the operating system, specify 0.

TCPNODELAY
: Specifies whether or not the server sends small messages or lets TCP/IP buffer the messages. Sending small messages can improve throughput but increases the number of packets sent over the network. Specify YES to send small messages or NO to let TCP/IP buffer them. The default is YES.

TCPADMINPORT
: Specifies the port number on which the server TCP/IP communication driver is to wait for TCP/IP or SSL-enabled communication requests other than client sessions. The default is the value of TCPPORT.

SSLTCPPORT
: (SSL-only) Specifies the Secure Sockets Layer (SSL) port number on which the server TCP/IP communication driver waits for requests for SSL-enabled sessions for the command-line backup-archive client and the command-line administrative client.

SSLTCPADMINPORT
: (SSL-only) Specifies the port address on which the server TCP/IP communication driver waits for requests for SSL-enabled sessions for the command-line administrative client.

AIX: Setting shared memory options

You can use shared memory communications between clients and servers on the same system. To use shared memory, TCP/IP Version 4 must be installed on the system.

About this task

The following example shows a shared memory setting:

```
commmethod      sharedmem
   shmport      1510
```

In this example, SHMPORT specifies the TCP/IP port address of a server when using shared memory. Use the SHMPORT option to specify a different TCP/IP port. The default port address is 1510.
COMMMETHOD can be used multiple times in the IBM Spectrum Protect™ server options file, with a different value each time. For example, the following example is possible:

```
commmethod tcpip
commmethod sharedmem
```

AIX The maximum number of concurrent shared memory sessions is based on available system resources. Each shared memory session uses one shared memory region of up to 4 MB, and four IPCS message queues, depending on the IBM Spectrum Protect client level.

AIX If the server and client are not run under the same user ID, then the server must be root. This prevents shared memory communication errors.

AIX: Setting Secure Sockets Layer options

You can add more protection for your data and passwords by using Secure Sockets Layer (SSL).

Before you begin

SSL is the standard technology for creating encrypted sessions between servers and clients. SSL provides a secure channel for servers and clients to communicate over open communication paths. With SSL, the identity of the server is verified through the use of digital certificates.

To ensure better system performance, use SSL only for sessions when it is needed. Consider adding additional processor resources on the IBM Spectrum Protect™ server to manage the increased requirements.

AIX: Formatting the database and log

Use the DSMSERV FORMAT utility to initialize a server instance. No other server activity is allowed while you initialize the database and recovery log.

After you set up server communications, you are ready to initialize the database. Ensure that you log in by using the instance user ID. Do not place the directories on file systems that might run out of space. If certain directories (for example, the archive log) become unavailable or full, the server stops.

For optimal performance and to facilitate I/O, specify at least two equally sized containers or Logical Unit Numbers (LUNs) for the database. In addition, each active log and archive log needs its own container or LUN.

Setting the exit list handler

Set the DB2NOEXITLIST registry variable to ON for each server instance. Log on to the system as the server instance owner and issue this command:

```
db2set -i server_instance_name DB2NOEXITLIST=ON
```

For example: AIX

```
db2set -i tsminst1 DB2NOEXITLIST=ON
```

Initializing a server instance

Use the DSMSERV FORMAT utility to initialize a server instance. For example, if the server instance directory is */tsminst1*, issue the following commands: AIX

```
cd /tsminst1
dsmserv format dbdir=/tsmdb001 activelogsize=32768
activelogdirectory=/activelog archlogdirectory=/archlog
archfailoverlogdirectory=/archfaillog mirrorlogdirectory=/mirrorlog
```

Tip: If you specify multiple directories, ensure that the underlying file systems are of equal size to ensure a consistent degree of parallelism for database operations. If one or more directories for the database are smaller than the others, they reduce the potential for optimized parallel prefetching and distribution of the database.

AIX Tip: If DB2® does not start after you issue the DSMSERV FORMAT command, you might need to disable the file system mount option NOSUID. If this option is set on the file system that contains the DB2 instance owner directory, or on any file system that contains the DB2 database, active logs, archive logs, failover logs, or mirrored logs, the option must be disabled to start the system.

After you disable the NOSUID option, remount the file system and then start DB2 by issuing the following command:

```
db2start
```

Related information:

DSMSERV FORMAT (Format the database and log)

AIX: Preparing the database manager for database backup

To back up the data in the database to IBM Spectrum Protect™, you must enable the database manager and configure the IBM Spectrum Protect application programming interface (API).

About this task

AIX Starting with IBM Spectrum Protect V7.1, it is no longer necessary to set the API password during a manual configuration of the server. If you set the API password during the manual configuration process, attempts to back up the database might fail.

If you use the configuration wizard to create an IBM Spectrum Protect server instance, you do not have to complete these steps. If you are configuring an instance manually, complete the following steps before you issue either the BACKUP DB or the RESTORE DB commands.

Attention: If the database is unusable, the entire IBM Spectrum Protect server is unavailable. If a database is lost and cannot be recovered, it might be difficult or impossible to recover data that is managed by that server. Therefore, it is critically important to back up the database.

AIX In the following commands, replace the example values with your actual values. The examples use `tsminst1` for the server instance user ID, /tsminst1 for the server instance directory, and /home/tsminst1 as the server instance users home directory.

1. Set the IBM Spectrum Protect API environment-variable configuration for the database instance:
   a. Log in by using the `tsminst1` user ID.
   b. When user `tsminst1` is logged in, ensure that the DB2® environment is properly initialized. The DB2 environment is initialized by running the /home/tsminst1/sqllib/db2profile script, which normally runs automatically from the profile of the user ID. Ensure the `.profile` file exists in the instance users home directory, for example, /home/tsminst1/.profile. If `.profile` does not run the `db2profile` script, add the following lines:

      ```
      if [ -f /home/tsminst1/sqllib/db2profile ]; then
            . /home/tsminst1/sqllib/db2profile
        fi
      ```

   c. In the instance_directory/sqllib/userprofile file, add the following lines:

      ```
      DSMI_CONFIG=server_instance_directory/tsmdbmgr.opt
      DSMI_DIR=server_bin_directory/dbbkapi
      DSMI_LOG=server_instance_directory
      export DSMI_CONFIG DSMI_DIR DSMI_LOG
      ```

      where:
      - *instance_directory* is the home directory of the server instance user.
      - *server_instance_directory* is the server instance directory.
      - *server_bin_directory* is the server bin directory. The default location is /opt/tivoli/tsm/server/bin.

      In the instance_directory/sqllib/usercshrc file, add the following lines:

      ```
      setenv DSMI_CONFIG=server_instance_directory/tsmdbmgr.opt
      setenv DSMI_DIR=server_bin_directory/dbbkapi
      setenv DSMI_LOG=server_instance_directory
      ```

2. Log off and log in again as `tsminst1`, or issue this command:

   ```
   . ~/.profile
   ```

   Tip: Ensure that you enter a space after the initial dot (.) character.
3. Create a file that is named `tsmdbmgr.opt` in the *server_instance* directory, which is in the /tsminst1 directory in this example, and add the following line:

   ```
   SERVERNAME TSMDBMGR_TSMINST1
   ```

   Remember: The value for `SERVERNAME` must be consistent in the `tsmdbmgr.opt` and `dsm.sys` files.
4. As root user, add the following lines to the IBM Spectrum Protect API `dsm.sys` configuration file. By default, the `dsm.sys` configuration file is in the following default location:
   - *server_bin_directory*/dbbkapi/dsm.sys

   ```
   servername TSMDBMGR_TSMINST1
   commmethod tcpip
   tcpserveraddr localhost
   tcpport 1500
   errorlogname /tsminst1/tsmdbmgr.log
   nodename $$_TSMDBMGR_$$
   ```

   where

- *servername* matches the `servername` value in the `tsmdbmgr.opt` file.
- *commethod* specifies the client API that is used to contact the server for database backup. This value can be `tcpip` or `sharedmem`. For more information about shared memory, see step 5.
- *tcpserveraddr* specifies the server address that the client API uses to contact the server for database backup. To ensure that the database can be backed up, this value must be `localhost`.
- *tcpport* specifies the port number that the client API uses to contact the server for database backup. Ensure that you enter the same `tcpport` value that is specified in the dsmserv.opt server options file.
- *errorlogname* specifies the error log where the client API logs errors that are encountered during a database backup. This log is typically in the server instance directory. However, this log can be placed in any location where the instance user ID has write-permission.
- *nodename* specifies the node name that the client API uses to connect to the server during a database backup. To ensure that the database can be backed up, this value must be `$$_TSMDBMGR_$$`.

5. Optional: Configure the server to back up the database by using shared memory. In this way, you might be able to reduce the processor load and improve throughput. Complete the following steps:
   a. Review the dsmserv.opt file. If the following lines are not in the file, add them:

      ```
      commmethod sharedmem
      shmport port_number
      ```

      where *port_number* specifies the port to be used for shared memory.
   b. In the dsm.sys configuration file, locate the following lines:

      ```
      commmethod tcpip
      tcpserveraddr localhost
      tcpport port_number
      ```

      Replace the specified lines with the following lines:

      ```
      commmethod sharedmem
      shmport port_number
      ```

      where *port_number* specifies the port to be used for shared memory.

AIX: Configuring server options for server database maintenance

To help avoid problems with database growth and server performance, the server automatically monitors its database tables and reorganizes them when needed. Before starting the server for production use, set server options to control when reorganization runs. If you plan to use data deduplication, ensure that the option to run index reorganization is enabled.

About this task

Table and index reorganization requires significant processor resources, active log space, and archive log space. Because database backup takes precedence over reorganization, select the time and duration for reorganization to ensure that the processes do not overlap and reorganization can complete.

AIX You can optimize index and table reorganization for the server database. In this way, you can help to avoid unexpected database growth and performance issues. For instructions, see technote 1683633.

If you update these server options while the server is running, you must stop and restart the server before the updated values take effect.

Procedure

1. Modify the server options.
   AIX Edit the server options file, dsmserv.opt, in the server instance directory. Follow these guidelines when you edit the server options file:
   - To enable an option, remove the asterisk at the beginning of the line.
   - Enter an option on any line.
   - Enter only one option per line. The entire option with its value must be on one line.
   - If you have multiple entries for an option in the file, the server uses the last entry.

   To view available server options, see the sample file, dsmserv.opt.smp, in the /opt/tivoli/tsm/server/bin directory.
2. If you plan to use data deduplication, enable the ALLOWREORGINDEX server option. Add the following option and value to the server options file:

```
allowreorgindex yes
```

3. Set the REORGBEGINTIME and REORGDURATION server options to control when reorganization starts and how long it runs. Select a time and duration so that reorganization runs when you expect that the server is least busy. These server options control both table and index reorganization processes.
   a. Set the time for reorganization to start by using the REORGBEGINTIME server option. Specify the time by using the 24-hour system. For example, to set the start time for reorganization as 8:30 p.m., specify the following option and value in the server options file:

      ```
      reorgbegintime 20:30
      ```

   b. Set the interval during which the server can start reorganization. For example, to specify that the server can start reorganization for four hours after the time set by the REORGBEGINTIME server option, specify the following option and value in the server options file:

      ```
      reorgduration 4
      ```

4. If the server was running while you updated the server options file, stop and restart the server.

Related information:
ALLOWREORGINDEX
ALLOWREORGTABLE
REORGBEGINTIME
REORGDURATION
AIX

AIX: Starting the server instance

You can start the server by using the instance user ID, which is the preferred method, or the root user ID.

Before you begin

Ensure that you set access permissions and user limits correctly.

AIX For instructions, see Verifying access rights and user limits.

About this task

When you start the server by using the instance user ID, you simplify the setup process and avoid potential issues. However, in some cases, it might be necessary to start the server with the root user ID. For example, you might want to use the root user ID to ensure that the server can access specific devices. You can set up the server to start automatically by using either the instance user ID or the root user ID.

AIX If you must complete maintenance or reconfiguration tasks, start the server in maintenance mode.

Procedure

To start the server, take one of the following actions:

- Start the server by using the instance user ID.

  AIX For instructions, see Starting the server from the instance user ID.

- Start the server by using the root user ID.

  For instructions about authorizing root user IDs to start the server, see Authorizing root user IDs to start the server (V7.1.1). For instructions about starting the server by using the root user ID, see Starting the server from the root user ID (V7.1.1).

- AIX Start the server automatically.

  AIX For instructions, see AIX: Automatically starting servers.

- AIX Start the server in maintenance mode.

  For instructions, see AIX: Starting the server in maintenance mode.

AIX

AIX: Verifying access rights and user limits

Before you start the server, verify access rights and user limits.

About this task

If you do not verify user limits, also known as *ulimits*, you might experience server instability or a failure of the server to respond. You must also verify the system-wide limit for the maximum number of open files. The system-wide limit must be greater than or equal to the user limit.

Procedure

1. Verify that the server instance user ID has permissions to start the server.
2. For the server instance that you plan to start, ensure that you have authority to read and write files in the server instance directory. Verify that the dsmserv.opt file exists in the server instance directory, and that the file includes parameters for the server instance.
3. If the server is attached to a tape drive, medium changer, or removable media device, and you plan to start the server by using the instance user ID, grant read/write access to the instance user ID for these devices. To set permissions, take one of the following actions:
   - If the system is dedicated to IBM Spectrum Protect™ and only the IBM Spectrum Protect administrator has access, make the device special file world-writable. On the operating system command line, issue the following command:

     ```
     chmod +w /dev/rmtX
     ```

   - If the system has multiple users, you can restrict access by making the IBM Spectrum Protect instance user ID the owner of the special device files. On the operating system command line, issue the following command:

     ```
     chmod u+w /dev/rmtX
     ```

   - If multiple user instances are running on the same system, change the group name, for example TAPEUSERS, and add each IBM Spectrum Protect instance user ID to that group. Then, change the ownership of the device special files to belong to the group TAPEUSERS, and make them group-writable. On the operating system command line, issue the following command:

     ```
     chmod g+w /dev/rmtX
     ```

4. Verify the following user limits based on the guidelines in the table.

   Table 1. User limit (ulimit) values

User limit type	Preferred value	Command to query value
Maximum size of core files created	Unlimited	`ulimit -Hc`
Maximum size of a data segment for a process	Unlimited	`ulimit -Hd`
Maximum file size	Unlimited	`ulimit -Hf`
Maximum number of open files	65536	`ulimit -Hn`
Maximum amount of processor time in seconds	Unlimited	`ulimit -Ht`

   To modify user limits, follow the instructions in the documentation for your operating system.

   Tip: If you plan to start the server automatically by using a script, you can set the user limits in the script.
5. Ensure that the user limit of maximum user processes (the `nproc` setting) is set to the minimum suggested value of 16384.
   a. To verify the current user limit, issue the `ulimit -Hu` command by using the instance user ID. For example:

      ```
      [user@Machine ~]$ ulimit -Hu
      16384
      ```

   b. If the limit of maximum user processes is not set to 16384, set the value to 16384.
      AIX Add the following line to the /etc/security/limits file:

      ```
      instance_user_id        -    nproc          16384
      ```

      where *instance_user_id* specifies the server instance user ID.

AIX

AIX: Starting the server from the instance user ID

To start the server from the instance user ID, log in with the instance user ID and issue the appropriate command from the server instance directory.

Before you begin

Ensure that access rights and user limits are set correctly. For instructions, see AIX: Verifying access rights and user limits.

Procedure

1. Log in to the system where IBM Spectrum Protect™ is installed by using the instance user ID for the server.
2. If you do not have a user profile that runs the `db2profile` script, issue the following command:

   ```
   . /home/tsminst1/sqllib/db2profile
   ```

   Tip: For instructions about updating the user ID login script to run the `db2profile` script automatically, see the DB2® documentation.
3. Start the server by issuing the following command on one line from the server instance directory:

   AIX

   ```
   LDR_CNTRL=TEXTPSIZE=64K@DATAPSIZE=64K@STACKPSIZE=64K@SHMPSIZE=64K
   usr/bin/dsmserv
   ```

   AIX Ensure that you include a space after `SHMPSIZE=64K`. By starting the server with this command, you enable 64 KB memory pages for the server. This setting helps you optimize server performance.

   Tip: The command runs in the foreground so that you can set an administrator ID and connect to the server instance. AIX For example, if the name of the server instance is `tsminst1` and the server instance directory is /tsminst1, you can start the instance by issuing the following commands:

   ```
   cd /tsminst1
    . ~/sqllib/db2profile
   LDR_CNTRL=TEXTPSIZE=64K@DATAPSIZE=64K@STACKPSIZE=64K@SHMPSIZE=64K
   usr/bin/dsmserv
   ```

AIX

AIX: Automatically starting servers

You can configure the server to start automatically at system startup. Use the rc.dsmserv script, which is provided for this purpose.

Before you begin

Ensure that access rights and user limits are set correctly.

AIX For instructions, see Verifying access rights and user limits.

About this task

The rc.dsmserv script is in the server installation directory, for example, in the /opt/tivoli/tsm/server/bin directory.

AIX Tip: If you used the configuration wizard, you might have chosen to start the server automatically when the system is restarted. If you selected that choice, an entry for starting the server was added automatically to the /etc/inittab file.

Procedure

If you did not use a wizard to configure the server, add an entry to the /etc/inittab file for each server that you want to automatically start:

1. Set the run level to the value that corresponds to multiuser mode with networking enabled. Typically, the run level to use is 2, 3, or 5, depending on the operating system and its configuration. Ensure that the run level in the /etc/inittab file matches the run level of the operating system. For more information about multiuser mode and run levels, see the documentation for your operating system.
2. On the rc.dsmserv command in the /etc/inittab file, specify the instance user ID with the -u option, and the location of the server instance directory with the -i option. If you want to start more than one server instance automatically, add an entry for each server instance. To verify the syntax, see the documentation for your operating system.
   Tip: To automatically start a server instance with the root user ID, use the -U option.

Example

For example, if the instance owner is tsminst1 and the server instance directory is /home/tsminst1/tsminst1, add the following entry to /etc/inittab, on one line:

AIX

```
tsm1:2:once:/opt/tivoli/tsm/server/bin/rc.dsmserv -u tsminst1
   -i /home/tsminst1/tsminst1 -q >/dev/console 2>&1
```

In this example, the ID for the process is `tsm1`, and the run level is set to 2.

If you have more than one server instance that you want to run, add an entry for each server instance. For example, if you have instance owner IDs tsminst1 and tsminst2, and instance directories /home/tsminst1/tsminst1 and /home/tsminst2/tsminst2, add the following entries to /etc/inittab. Each entry is on one line.

AIX

```
tsm1:2:once:/opt/tivoli/tsm/server/bin/rc.dsmserv -u tsminst1
   -i /home/tsminst1/tsminst1 -q >/dev/console 2>&1
tsm2:2:once:/opt/tivoli/tsm/server/bin/rc.dsmserv -u tsminst2
   -i /home/tsminst2/tsminst2 -q >/dev/console 2>&1
```

Related reference:
Server startup script: rc.dsmserv
AIX

AIX: Starting the server in maintenance mode

You can start the server in maintenance mode to avoid disruptions during maintenance and reconfiguration tasks.

About this task

Start the server in maintenance mode by running the DSMSERV utility with the MAINTENANCE parameter.

The following operations are disabled in maintenance mode:

- Administrative command schedules
- Client schedules
- Reclamation of storage space on the server
- Inventory expiration
- Migration of storage pools

In addition, clients are prevented from starting sessions with the server.
Tips:

- You do not have to edit the server options file, dsmserv.opt, to start the server in maintenance mode.
- While the server is running in maintenance mode, you can manually start the storage-space reclamation, inventory expiration, and storage-pool migration processes.

Procedure

To start the server in maintenance mode, issue the following command:

```
dsmserv maintenance
```

Tip: To view a video about starting the server in maintenance mode, see Starting a server in maintenance mode.

What to do next

To resume server operations in production mode, complete the following steps:

1. Shut down the server by issuing the HALT command:

   ```
   halt
   ```

2. Start the server by using the method that you use in production mode.

Operations that were disabled during maintenance mode are reenabled.

AIX: Stopping the server

You can stop the server when needed to return control to the operating system. To avoid losing administrative and client node connections, stop the server only after current sessions are completed or canceled.

About this task

To stop the server, issue the following command from the IBM Spectrum Protect™ command line:

```
halt
```

AIX If you cannot connect to the server with an administrative client and you want to stop the server, you must cancel the process by using the kill command with the process ID number (pid). The pid is displayed at initialization.
Important: Before you issue the kill command, ensure that you know the correct process ID for the IBM Spectrum Protect server. The `dsmserv.v6lock` file, in the directory from which the server is running, can be used to identify the process ID of the process to kill. To display the file, enter:

```
cat /instance_dir/dsmserv.v6lock
```

AIX Issue the following command to stop the server:

```
kill -36 dsmserv_pid
```

where *dsmserv_pid* is the process ID number.

AIX: Registering licenses

Immediately register any IBM Spectrum Protect™ licensed functions that you purchase so you do not lose any data after you start server operations, such as backing up your data.

About this task

Use the REGISTER LICENSE command for this task. See REGISTER LICENSE for more details.

Example: Register a license

Register the base IBM Spectrum Protect license.

```
register license file=tsmbasic.lic
```

AIX: Specifying a device class in preparation for database backups

To prepare the system for automatic and manual database backups, you must specify the device class to be used.

Before you begin

Ensure that you have defined a tape or file device class. For details, see DEFINE DEVCLASS, or search for defining a device class.

About this task

Complete the following steps to set up your system for database backups.

Procedure

1. If you did not use the configuration wizard (dsmicfgx) to configure the server, ensure that you have completed the steps to manually configure the system for database backups.
2. Select the device class to be used for backups of the database. Issue the following command from an IBM Spectrum Protect™ administrative command line.

   ```
   set dbrecovery device_class_name
   ```

   The device class that you specify is used by the database manager for database backups. If you do not specify a device class with the SET DBRECOVERY command, the backup fails.

Example

For example, to specify that the DBBACK device class is to be used, issue this command:

```
set dbrecovery dbback
```

AIX: Running multiple server instances on a single system

You can create more than one server instance on your system. Each server instance has its own instance directory, and database and log directories.

Multiply the memory and other system requirements for one server by the number of instances planned for the system.

AIX The set of files for one instance of the server is stored separately from the files used by another server instance on the same system. Use the steps in AIX: Creating the server instance for each new instance, including creation of the new instance user.

To manage the system memory that is used by each server, use the DBMEMPERCENT server option to limit the percentage of system memory. If all servers are equally important, use the same value for each server. If one server is a production server and other servers are test servers, set the value for the production server to a higher value than the test servers.

You can upgrade directly from either V6.3 to V7.1. See the upgrade section (Upgrading to V8.1) for more details. When you upgrade and have multiple servers on your system, you must run the installation wizard only once. The installation wizard collects the database and variables information for all of your original server instances.

If you upgrade from IBM Spectrum Protect V6.3 to V8.1.2 and have multiple servers on your system, all instances that exist in DB2® V9.7 are dropped and recreated in DB2 V11.1. The wizard issues the `db2 upgrade db dbname` command for each database. The database environment variables for each instance on your system are also reconfigured during the upgrade process.

Related tasks:
Running multiple server instances on a single system (V7.1.1)

AIX: Monitoring the server

When you start to use the server in production, monitor the space that is used by the server to ensure that the amount of space is adequate. Adjust the space if needed.

Procedure

1. Monitor the active log to ensure that the size is correct for the workload that is handled by the server instance.

   When the server workload reaches its typical expected level, the space that is used by the active log is 80% - 90% of the space that is available to the active log directory. At that point, you might need to increase the amount of space. Whether you must increase the space depends on the types of transactions in the server workload. Transaction characteristics affect how the active log space is used.

   The following transaction characteristics can affect the space usage in the active log:

- The number and size of files in backup operations
  - Clients such as file servers that back up large numbers of small files can cause large numbers of transactions that are completed quickly. The transactions might use a large amount of space in the active log, but for a short time.
  - Clients such as a mail server or a database server that back up large amounts of data in few transactions can cause small numbers of transactions that take a long time to complete. The transactions might use a small amount of space in the active log, but for a long time.
- Network connection types
  - Backup operations that occur over fast network connections cause transactions that complete more quickly. The transactions use space in the active log for a shorter time.
  - Backup operations that occur over relatively slower connections cause transactions that take a longer time to complete. The transactions use space in the active log for a longer time.

If the server is handling transactions with a wide variety of characteristics, the space that is used for the active log might increase and decrease significantly over time. For such a server, you might need to ensure that the active log typically has a smaller percentage of its space used. The extra space allows the active log to grow for transactions that take a long time to complete.

2. Monitor the archive log to ensure that space is always available.
   Remember: If the archive log becomes full, and the failover archive log becomes full, the active log can become full, and the server stops. The goal is to make enough space available to the archive log so that it never uses all its available space.
   You are likely to notice the following pattern:
   a. Initially, the archive log grows rapidly as typical client-backup operations occur.
   b. Database backups occur regularly, either as scheduled or done manually.
   c. After at least two full database backups occur, log pruning occurs automatically. The space that is used by the archive log decreases when the pruning occurs.
   d. Normal client operations continue, and the archive log grows again.
   e. Database backups occur regularly, and log pruning occurs as often as full database backups occur.

   With this pattern, the archive log grows initially, decreases, and then might grow again. Over time, as normal operations continue, the amount of space that is used by the archive log should reach a relatively constant level.

   If the archive log continues to grow, consider taking one or both of these actions:
   - Add space to the archive log. You might need to move the archive log to a different file system.
   - Increase the frequency of full database backups, so that log pruning occurs more frequently.
3. If you defined a directory for the failover archive log, determine whether any logs get stored in that directory during normal operations. If the failover log space is being used, consider increasing the size of the archive log. The goal is that the failover archive log is used only under unusual conditions, not in normal operation.

AIX: Installing an IBM Spectrum Protect server fix pack

IBM Spectrum Protect™ maintenance updates, which are also referred to as fix packs, bring your server up to the current maintenance level.

Before you begin

To install a fix pack or interim fix to the server, install the server at the level on which you want to run it. You do not have to start the server installation at the base release level. For example, if you currently have V8.1.1 installed, you can go directly to the latest fix pack for V8.1. You do not have to start with the V8.1.0 installation if a maintenance update is available.

You must have the IBM Spectrum Protect license package installed. The license package is provided with the purchase of a base release. When you download a fix pack or interim fix from Fix Central, install the server license that is available on the Passport Advantage® website. To display messages and help in a language other than US English, install the language package of your choice.

If you upgrade the server to V8.1.2 or later, and then revert the server to a level that is earlier than V8.1.2, you must restore the database to a point in time before the upgrade. During the upgrade process, complete the required steps to ensure that the database can be restored: back up the database, the volume history file, the device configuration file, and the server options file. For more information, see AIX: Reverting from Version 8.1.2 to a previous server.

If you are using the client management service, ensure that you upgrade it to the same version as the IBM Spectrum Protect server.

Ensure that you retain the installation media from the base release of the installed server. If you installed IBM Spectrum Protect from a downloaded package, ensure that the downloaded files are available. If the upgrade fails, and the server license module is uninstalled, the installation media from the server base release are required to reinstall the license.

Visit the IBM® Support Portal for the following information:

- A list of the latest maintenance and download fixes. Click **Downloads** and apply any applicable fixes.
- Details about obtaining a base license package. Search for **Downloads > Passport Advantage**.
- Supported platforms and system requirements. Search for **IBM Spectrum Protect supported operating systems**.

Ensure that you upgrade the server before you upgrade backup-archive clients. If you do not upgrade the server first, communication between the server and clients might be interrupted.

Attention: Do not alter the DB2® software that is installed with IBM Spectrum Protect installation packages and fix packs. Do not install or upgrade to a different version, release, or fix pack of DB2 software because doing so can damage the database.

Procedure

To install a fix pack or interim fix, complete the following steps:

1. Back up the database. The preferred method is to use a snapshot backup. A snapshot backup is a full database backup that does not interrupt any scheduled database backups. For example, issue the following IBM Spectrum Protect administrative command:

   ```
   backup db type=dbsnapshot devclass=tapeclass
   ```

2. Back up the device configuration information. Issue the following IBM Spectrum Protect administrative command:

   ```
   backup devconfig filenames=file_name
   ```

   where *file_name* specifies the name of the file in which to store device configuration information.
3. Save the volume history file to another directory or rename the file. Issue the following IBM Spectrum Protect administrative command:

   ```
   backup volhistory filenames=file_name
   ```

   where *file_name* specifies the name of the file in which to store the volume history information.
4. Save a copy of the server options file, typically named dsmserv.opt. The file is in the server instance directory.
5. Halt the server before installing a fix pack or interim fix. Use the HALT command.
6. Ensure that extra space is available in the installation directory. The installation of this fix pack might require additional temporary disk space in the installation directory of the server. The amount of additional disk space can be as much as that required for installing a new database as part of an IBM Spectrum Protect installation. The IBM Spectrum Protect installation wizard displays the amount of space that is required for installing the fix pack and the available amount. If the required amount of space is greater than the available amount, the installation stops. If the installation stops, add the required disk space to the file system and restart the installation.
7. AIX Log in as the root user.
8. Obtain the package file for the fix pack or interim fix that you want to install from the IBM Support Portal, Passport Advantage, or Fix Central.
9. AIX Change to the directory where you placed the executable file and complete the following steps.
   Tip: The files are extracted to the current directory. Ensure that the executable file is in the directory where you want the extracted files to be located.
   a. Change file permissions by entering the following command:

      ```
      chmod a+x 8.x.x.x-IBM-SPSRV-platform.bin
      ```

      where *platform* denotes the architecture that IBM Spectrum Protect is to be installed on.
   b. Issue the following command to extract the installation files:

      ```
      ./8.x.x.x-IBM-SPSRV-platform.bin
      ```

10. Select one of the following ways of installing IBM Spectrum Protect.
    Important: After a fix pack is installed, it is not necessary to go through the configuration again. You can stop after completing the installation, fix any errors, then restart your servers.
    Install the IBM Spectrum Protect software by using one of the following methods:

    Installation wizard
    : Follow the instructions for your operating system:

AIX: Installing IBM Spectrum Protect by using the installation wizard

Tip: After you start the wizard, in the IBM Installation Manager window, click the Update icon; do not click the Install or Modify icon.

Command line in console mode
Follow the instructions for your operating system:
AIX: Installing IBM Spectrum Protect by using console mode

Silent mode
Follow the instructions for your operating system:
AIX: Installing IBM Spectrum Protect in silent mode

Tip: If you have multiple server instances on your system, run the installation wizard only once. The installation wizard upgrades all server instances.

Results

Correct any errors that are detected during the installation process.

If you installed the server by using the installation wizard, you can view installation logs by using the IBM Installation Manager tool. Click File > View Log. To collect log files, from the IBM Installation Manager tool, click Help > Export Data for Problem Analysis.

If you installed the server by using console mode or silent mode, you can view error logs in the IBM Installation Manager log directory, for example:

- AIX /var/ibm/InstallationManager/logs
- AIX AIX: Applying a fix pack to IBM Spectrum Protect V8.1.2 in a clustered environment for AIX
  IBM Spectrum Protect maintenance updates, which are also referred to as fix packs, bring your server up to the current maintenance level. It is possible to apply a fix pack onto a clustered environment for AIX®.

AIX: Reverting from Version 8.1.2 to a previous server

If you must revert to the previous version of the server after an upgrade, you must have a full database backup from your original version. You must also have the server installation media for your original version and key configuration files. Carefully follow the preparation steps before you upgrade the server. By doing so, it might be possible to revert to the previous version of the IBM Spectrum Protect™ server with minimal loss of data.

Before you begin

You must have the following items from the earlier version of the server:

- Server database backup
- Volume history file
- Device configuration file
- Server options file

About this task

Use the same instructions whether you are reverting within releases or to an earlier release, for example, from 8.1.2 to 8.1.1 or from 8.1.2 to 7.1.2. The older version must match the version that you used before the upgrade to V8.1.

Attention: Specify the REUSEDELAY parameter to help prevent backup-archive client data loss when you revert the server to a previous version.

Steps for reverting to the previous server version

About this task

Complete the following steps on the system that has the V8.1 server.

Procedure

1. Halt the server to shut down all server operations by using the HALT command.
2. Remove the database from the database manager, then delete the database and recovery log directories.
   a. Manually remove the database. One way to remove it is by issuing this command: AIX

      ```
      dsmserv removedb tsmdb1
      ```

   b. If you must reuse the space that is occupied by the database and recovery log directories, you can now delete these directories.
3. Use the uninstallation program to uninstall the V8.1 server. Uninstallation removes the server and the database manager, with their directories. For details, see AIX: Uninstalling IBM Spectrum Protect.
4. Stop the cluster service. Reinstall the version of the server program that you were using before the upgrade to V8.1.2. This version must match the version that your server was running when you created the database backup that you restore in a later step. For example, the server was at V7.1.7 before the upgrade, and you intend to use the database backup that was in use on this server. You must install the V7.1.7 fix pack to be able to restore the database backup.
5. Configure the new server database by using the configuration wizard. To start the wizard, issue the following command: AIX

   ```
   . /dsmicfgx
   ```

6. Ensure that no servers are running in the background.
7. Restore the database to a point in time before the upgrade.
8. Copy the following files to the instance directory.
   - Device configuration file
   - Volume history file
   - The server options file (typically dsmserv.opt)
9. If you enabled data deduplication for any FILE-type storage pools that existed before the upgrade, or if you moved data that existed before the upgrade into new storage pools while using the V8.1.2 server, you must complete additional recovery steps. For more details, see Additional recovery steps if you created new storage pools or enabled data deduplication.
10. If the REUSEDELAY parameter setting on storage pools is less than the age of the database that you restored, restore volumes on any sequential-access storage pools that were reclaimed after that database backup. Use the RESTORE VOLUME command.
    If you do not have a backup of a storage pool, audit the reclaimed volumes by using the AUDIT VOLUME command, with the FIX=YES parameter to resolve inconsistencies. For example:

    ```
    audit volume volume_name fix=yes
    ```

11. If client backup or archive operations were completed using the V8.1 server, audit the storage pool volumes on which the data was stored.

Additional recovery steps if you created new storage pools or enabled data deduplication

If you created new storage pools, turned on data deduplication for any FILE-type storage pools, or did both while your server was running as a V8.1.2 server, you must complete more steps to return to the previous server version.

Before you begin

To complete this task, you must have a complete backup of the storage pool that was created before the upgrade to V8.1.2.

About this task

Use this information if you did either or both of the following actions while your server was running as a V8.1.2 server:

- You enabled the data deduplication function for any storage pools that existed before the upgrade to V8.1.2 program. Data deduplication applies only to storage pools that use a FILE device type.
- You created new primary storage pools after the upgrade *and* moved data that was stored in other storage pools into the new storage pools.

Complete these steps after the server is again restored to V7.

Procedure

- For each storage pool for which you enabled the data deduplication function, restore the entire storage pool by using the RESTORE STGPOOL command.
- For storage pools that you created after the upgrade, determine what action to take. Data that was moved from existing V8 storage pools into the new storage pools might be lost because the new storage pools no longer exist in your restored V8 server. Possible recovery depends on the type of storage pool:
    - If data was moved from V8 DISK-type storage pools into a new storage pool, space that was occupied by the data that was moved was probably reused. Therefore, you must restore the original V8 storage pools by using the storage pool backups that were created before the upgrade to V8.1.2.

      If *no* data was moved from V8 DISK-type storage pools into a new storage pool, then audit the storage pool volumes in these DISK-type storage pools.

    - If data was moved from V8 sequential-access storage pools into a new storage pool, that data might still exist and be usable in storage pool volumes on the restored V8 server. The data might be usable if the REUSEDELAY parameter for the storage pool was set to a value that prevented reclamation while the server was running as a V8.1.2 server. If any volumes were reclaimed while the server was running as a V8.1.2 server, restore those volumes from storage pool backups that were created before the upgrade to V8.1.2.

AIX: Reference: DB2 commands for IBM Spectrum Protect server databases

Use this list as reference when you are directed to issue DB2® commands by IBM® support.

Purpose

After using the wizards to install and configure IBM Spectrum Protect™, you seldom need to issue DB2 commands. A limited set of DB2 commands that you might use or be asked to issue are listed in Table 1. This list is supplemental material only and is not a comprehensive list. There is no implication that an IBM Spectrum Protect administrator will use it on a daily or ongoing basis. Samples of some commands are provided. Details of output are not listed.

For a full explanation of the commands described here and of their syntax, see the DB2 product information.

Table 1. DB2 commands

Command	Description	Example
db2icrt	Creates DB2 instances in the home directory of the instance owner. Tip: The IBM Spectrum Protect configuration wizard creates the instance used by the server and database. After a server is installed and configured through the configuration wizard, the db2icrt command is generally not used. AIX This utility is in the DB2DIR/instance directory, where DB2DIR represents the installation location where the current version of the DB2 database system is installed.	Manually create an IBM Spectrum Protect instance. Enter the command on one line: `/opt/tivoli/tsm/db2/instance/db2icrt -a server -u` *`instance_name instance_name`*
db2set	Displays DB2 variables.	List DB2 variables: `db2set`

Command	Description	Example
CATALOG DATABASE	Stores database location information in the system database directory. The database can be located either on the local workstation or on a remote database partition server. The server configuration wizard takes care of any catalog needed for using the server database. Run this command manually, after a server is configured and running, only if something in the environment changes or is damaged.	Catalog the database: `db2 catalog database tsmdb1`
CONNECT TO DATABASE	Connects to a specified database for command-line interface (CLI) use.	Connect to the IBM Spectrum Protect database from a DB2 CLI: `db2 connect to tsmdb1`
GET DATABASE CONFIGURATION	Returns the values of individual entries in a specific database configuration file. Important: This command and parameters are set and managed directly by DB2. They are listed here for informational purposes and a means to view the existing settings. Changing these settings might be advised by IBM support or through service bulletins such as APARs or Technical Guidance documents (technotes). Do not change these settings manually. Change them only at the direction of IBM and only through the use of IBM Spectrum Protect server commands or procedures.	Show the configuration information for a database alias: `db2 get db cfg for tsmdb1` Retrieve information in order to verify settings such as database configuration, log mode, and maintenance. `db2 get db config for tsmdb1 show detail`
GET DATABASE MANAGER CONFIGURATION	Returns the values of individual entries in a specific database configuration file. Important: This command and parameters are set and managed directly by DB2. They are listed here for informational purposes and a means to view the existing settings. Changing these settings might be advised by IBM support or through service bulletins such as APARs or Technical Guidance documents (technotes). Do not change these settings manually. Change them only at the direction of IBM and only through the use of IBM Spectrum Protect server commands or procedures.	Retrieve configuration information for the database manager: `db2 get dbm cfg`
GET HEALTH SNAPSHOT	Retrieves the health status information for the database manager and its databases. The information returned represents a snapshot of the health state at the time the command was issued. IBM Spectrum Protect monitors the state of the database using the health snapshot and other mechanisms that are provided by DB2. There might be cases where the health snapshot or other DB2 documentation indicates that an item or database resource might be in an alert state. Such a case indicates that action must be considered to remedy the situation. IBM Spectrum Protect monitors the condition and responds appropriately. Not all declared alerts by the DB2 database are acted on.	Receive a report on DB2 health monitor indicators: `db2 get health snapshot for database on tsmdb1`

Command	Description	Example
GRANT (Database Authorities)	Grants authorities that apply to the entire database rather than privileges that apply to specific objects within the database.	Grant access to the user ID itmuser: `db2 GRANT CONNECT ON DATABASE TO USER itmuser` `db2 GRANT CREATETAB ON DATABASE TO USER itmuser`
RUNSTATS	Updates statistics about the characteristics of a table and associated indexes or statistical views. These characteristics include number of records, number of pages, and average record length. To see a table, issue this utility after updating or reorganizing the table. A view must be enabled for optimization before its statistics can be used to optimize a query. A view that is enabled for optimization is known as a statistical view. Use the DB2 ALTER VIEW statement to enable a view for optimization. Issue the RUNSTATS utility when changes to underlying tables substantially affect the rows returned by the view. Tip: The server configures DB2 to run the RUNSTATS command as needed.	Update statistics on a single table. `db2 runstats on table SCHEMA_NAME.TABLE_NAME with distribution and sampled detailed indexes all`
SET SCHEMA	Changes the value of the CURRENT SCHEMA special register, in preparation for issuing SQL commands directly through the DB2 CLI. Tip: A special register is a storage area that is defined for an application process by the database manager. It is used to store information that can be referenced in SQL statements.	Set the schema for IBM Spectrum Protect: `db2 set schema tsmdb1`
START DATABASE MANAGER	Starts the current database manager instance background processes. The server starts and stops the instance and database whenever the server starts and halts. Important: Allow the server to manage the starting and stopping of the instance and database unless otherwise directed by IBM support.	Start the database manager: `db2start`
STOP DATABASE MANAGER	Stops the current database manager instance. Unless explicitly stopped, the database manager continues to be active. This command does not stop the database manager instance if any applications are connected to databases. If there are no database connections, but there are instance attachments, the command forces the instance attachments to stop first. Then, it stops the database manager. This command also deactivates any outstanding database activations before stopping the database manager. This command is not valid on a client. The server starts and stops the instance and database whenever the server starts and halts. Important: Allow the server to manage the starting and stopping of the instance and database unless otherwise directed by IBM support.	Stop the database manager: `db2 stop dbm`

AIX: Uninstalling IBM Spectrum Protect

You can use the following procedures to uninstall IBM Spectrum Protect™. Before you remove IBM Spectrum Protect, ensure that you do not lose your backup and archive data.

Before you begin

Complete the following steps before you uninstall IBM Spectrum Protect:

- Complete a full database backup.
- Save a copy of the volume history and device configuration files.
- Store the output volumes in a safe location.

About this task

You can uninstall IBM Spectrum Protect by using any of the following methods: a graphical wizard, the command line in console mode, or silent mode.

- AIX: Uninstalling IBM Spectrum Protect by using a graphical wizard
  You can uninstall IBM Spectrum Protect by using the IBM® Installation Manager installation wizard.
- AIX: Uninstalling IBM Spectrum Protect in console mode
  To uninstall IBM Spectrum Protect by using the command line, you must run the uninstallation program of IBM Installation Manager from the command line with the parameter for console mode.
- AIX: Uninstalling IBM Spectrum Protect in silent mode
  To uninstall IBM Spectrum Protect in silent mode, you must run the uninstallation program of IBM Installation Manager from the command line with the parameters for silent mode.
- AIX: Uninstalling and reinstalling IBM Spectrum Protect
  If you plan to manually reinstall IBM Spectrum Protect instead of using the wizard, there are a number of steps to take to preserve your server instance names and database directories. During an uninstallation, any server instances previously set up are removed, but the database catalogs for those instances still exist.
- AIX: Uninstalling IBM Installation Manager
  You can uninstall IBM Installation Manager if you no longer have any products that were installed by IBM Installation Manager.

What to do next

See AIX: Installing the server components for installation steps to reinstall the IBM Spectrum Protect components.

AIX: Uninstalling IBM Spectrum Protect by using a graphical wizard

You can uninstall IBM Spectrum Protect™ by using the IBM® Installation Manager installation wizard.

Procedure

1. Start the Installation Manager.
   AIX In the directory where the Installation Manager is installed, go to the eclipse subdirectory (for example, /opt/IBM/InstallationManager/eclipse), and issue the following command:

   ```
   ./IBMIM
   ```

2. Click Uninstall.
3. Select IBM Spectrum Protect server, and click Next.
4. Click Uninstall.
5. Click Finish.

AIX: Uninstalling IBM Spectrum Protect in console mode

To uninstall IBM Spectrum Protect™ by using the command line, you must run the uninstallation program of IBM® Installation Manager from the command line with the parameter for console mode.

Procedure

1. In the directory where IBM Installation Manager is installed, go to the following subdirectory:
   - AIX eclipse/tools

   For example:

- AIX /opt/IBM/InstallationManager/eclipse/tools

2. From the tools directory, issue the following command:
   - AIX `./imcl -c`
3. To uninstall, enter `5`.
4. Choose to uninstall from the IBM Spectrum Protect package group.
5. Enter `N` for Next.
6. Choose to uninstall the IBM Spectrum Protect server package.
7. Enter `N` for Next.
8. Enter `U` for Uninstall.
9. Enter `F` for Finish.

AIX: Uninstalling IBM Spectrum Protect in silent mode

To uninstall IBM Spectrum Protect™ in silent mode, you must run the uninstallation program of IBM® Installation Manager from the command line with the parameters for silent mode.

Before you begin

You can use a response file to provide data input to silently uninstall the IBM Spectrum Protect server components. IBM Spectrum Protect includes a sample response file, uninstall_response_sample.xml, in the input directory where the installation package is extracted. This file contains default values to help you avoid any unnecessary warnings.

If you want to uninstall all IBM Spectrum Protect components, leave `modify="false"` set for each component in the response file. If you do not want to uninstall a component, set the value to `modify="true"`.

If you want to customize the response file, you can modify the options that are in the file. For information about response files, see Response files.

Procedure

1. In the directory where IBM Installation Manager is installed, go to the following subdirectory:
   - AIX eclipse/tools

   For example:

   - AIX /opt/IBM/InstallationManager/eclipse/tools
2. From the tools directory, issue the following command, where *response_file* represents the response file path, including the file name:

   AIX

   ```
   ./imcl -input response_file -silent
   ```

   The following command is an example:

   AIX

   ```
   ./imcl -input /tmp/input/uninstall_response.xml -silent
   ```

AIX: Uninstalling and reinstalling IBM Spectrum Protect

If you plan to manually reinstall IBM Spectrum Protect™ instead of using the wizard, there are a number of steps to take to preserve your server instance names and database directories. During an uninstallation, any server instances previously set up are removed, but the database catalogs for those instances still exist.

About this task

To manually uninstall and reinstall IBM Spectrum Protect, complete the following steps:

1. AIX Make a list of your current server instances before proceeding to the uninstallation. Run the following command:

   ```
   /opt/tivoli/tsm/db2/instance/db2ilist
   ```

2. Run the following commands for every server instance:

   AIX

```
db2 attach to instance_name
db2 get dbm cfg show detail
db2 detach
```

Keep a record of the database path for each instance.

3. Uninstall IBM Spectrum Protect. See AIX: Uninstalling IBM Spectrum Protect.
4. When you uninstall any supported version of IBM Spectrum Protect, including a fix pack, an instance file is created. The instance file is created to help reinstall IBM Spectrum Protect. Check this file and use the information when you are prompted for the instance credentials when reinstalling. In silent installation mode, you provide these credentials using the `INSTANCE_CRED` variable.
   You can find the instance file in the following location:
   - AIX /etc/tivoli/tsm/instanceList.obj
5. Reinstall IBM Spectrum Protect. See AIX: Installing the server components.

   If the `instanceList.obj` file does not exist, you need to recreate your server instances using the following steps:

   a. Recreate your server instances. See AIX: Creating the server instance.
   Tip: The installation wizard configures the server instances but you must verify that they exist. If they do not exist, you must manually configure them.
   b. Catalog the database. Log in to each server instance as the instance user, one at a time, and issue the following commands:
   AIX

   ```
   db2 catalog database tsmdb1
   db2 attach to instance_name
   db2 update dbm cfg using dftdbpath instance_directory
   db2 detach
   ```

   c. AIX Verify that the server instance was created successfully. Issue this command:

   ```
   /opt/tivoli/tsm/db2/instance/db2ilist
   ```

   d. Verify that IBM Spectrum Protect recognizes the server instance by listing your directories. Your home directory appears if you did not change it. Your instance directory does appear if you used the configuration wizard. Issue this command:

   ```
   db2 list database directory
   ```

   If you see TSMDB1 listed, you can start the server.

AIX: Uninstalling IBM Installation Manager

You can uninstall IBM® Installation Manager if you no longer have any products that were installed by IBM Installation Manager.

Before you begin

Before you uninstall IBM Installation Manager, you must ensure that all packages that were installed by IBM Installation Manager are uninstalled. Close IBM Installation Manager before you start the uninstall process.

AIX To view installed packages, issue the following command from a command line:

```
cd /opt/IBM/InstallationManager/eclipse/tools
./imcl listInstalledPackages
```

Procedure

To uninstall IBM Installation Manager, complete the following steps:

AIX

1. Open a command line and change directories to /var/ibm/InstallationManager/uninstall.
2. Issue the following command:

   ```
   ./uninstall
   ```

   Restriction: You must be logged in to the system as the `root` user ID.

Linux: Installing the server

Installation of the server includes planning, installation, and initial configuration.

- Linux: Planning to install the server
  Install the server software on the computer that manages storage devices and install the client software on every workstation that transfers data to IBM Spectrum Protect™ server-managed storage.
- Linux: Installing the server components
  To install the Version 8.1.2 server components, you can use the installation wizard, the command line in console mode, or silent mode.
- Linux: Taking the first steps after you install IBM Spectrum Protect
  After you install Version 8.1.2, prepare for the configuration. Using the configuration wizard is the preferred method of configuring the IBM Spectrum Protect instance.
- Linux: Installing an IBM Spectrum Protect server fix pack
  IBM Spectrum Protect maintenance updates, which are also referred to as fix packs, bring your server up to the current maintenance level.
- Linux: Reverting from Version 8.1.2 to a previous server
  If you must revert to the previous version of the server after an upgrade, you must have a full database backup from your original version. You must also have the server installation media for your original version and key configuration files. Carefully follow the preparation steps before you upgrade the server. By doing so, it might be possible to revert to the previous version of the IBM Spectrum Protect server with minimal loss of data.
- Linux: Reference: DB2 commands for IBM Spectrum Protect server databases
  Use this list as reference when you are directed to issue DB2® commands by IBM® support.
- Linux: Uninstalling IBM Spectrum Protect
  You can use the following procedures to uninstall IBM Spectrum Protect. Before you remove IBM Spectrum Protect, ensure that you do not lose your backup and archive data.

Linux: Planning to install the server

Install the server software on the computer that manages storage devices and install the client software on every workstation that transfers data to IBM Spectrum Protect™ server-managed storage.

- Linux: What you should know first
  Before installing IBM Spectrum Protect, be familiar with your operating systems, storage devices, communication protocols, and system configurations.
- Linux: What you should know about security before you install or upgrade the server
  Before you install IBM Spectrum Protect V8.1.2 or later, review information about the enhanced security features and the requirements for updating your environment.
- Linux: Planning for optimal performance
  Before you install the IBM Spectrum Protect server, evaluate the characteristics and configuration of the system to ensure that the server is set up for optimal performance.
- Linux Linux: Minimum system requirements for Linux systems
  To install the IBM Spectrum Protect server on a Linux system, it is necessary to have a minimum level of hardware and software, including a communication method and the most current device driver.
- Linux Linux: Compatibility of the IBM Spectrum Protect server with other DB2 products on the system
  You can install other products that deploy and use DB2® products on the same system as the IBM Spectrum Protect Version 8.1.2 server, with some limitations.
- Linux: IBM Installation Manager
  IBM Spectrum Protect uses IBM® Installation Manager, which is an installation program that can use remote or local software repositories to install or update many IBM products.
- Linux: Worksheets for planning details for the server
  You can use the worksheets to help you plan the amount and location of storage needed for the IBM Spectrum Protect server. You can also use them to keep track of names and user IDs.
- Linux: Capacity planning
  Capacity planning for IBM Spectrum Protect includes managing resources such as the database, the recovery log and the shared resource area. To maximize resources as part of capacity planning, you must estimate space requirements for the database and the recovery log. The shared resource area must have enough space available for each installation or upgrade.
- Linux: Server naming best practices
  Use these descriptions as a reference when you install or upgrade an IBM Spectrum Protect server.

- Linux: Installation directories
  Installation directories for the IBM Spectrum Protect server include the server, DB2, device, language, and other directories. Each one contains several additional directories.

Linux: What you should know first

Before installing IBM Spectrum Protect™, be familiar with your operating systems, storage devices, communication protocols, and system configurations.

Server maintenance releases, client software, and publications are available from the IBM® Support Portal.

Linux Restriction: You can install and run the Version 8.1.2 server on a system that already has DB2® installed on it, whether DB2 was installed independently or as part of some other application, with some restrictions. For details, see the compatibility with other DB2 products topic.

Experienced DB2 administrators can choose to perform advanced SQL queries and use DB2 tools to monitor the database. Do not, however, use DB2 tools to change DB2 configuration settings from those that are preset by IBM Spectrum Protect, or alter the DB2 environment for IBM Spectrum Protect in other ways, such as with other products. The V8.1.2 server has been built and tested extensively using the data definition language (DDL) and database configuration that the server deploys.

Attention: Do not alter the DB2 software that is installed with IBM Spectrum Protect installation packages and fix packs. Do not install or upgrade to a different version, release, or fix pack of DB2 software because doing so can damage the database.

Linux: What you should know about security before you install or upgrade the server

Before you install IBM Spectrum Protect™ V8.1.2 or later, review information about the enhanced security features and the requirements for updating your environment.

About this task

Security enhancements that were introduced in V8.12 and later enforce stricter security settings. To ensure that communication between servers and clients is not interrupted when you install or upgrade IBM Spectrum Protect software to V8.1.2, follow the procedure.

Procedure

1. Install or upgrade the IBM Spectrum Protect servers to 8.1.2 or later.
2. Install or upgrade the backup-archive clients. For more information, see Installing and configuring clients.
   For information about scheduling deployment of client updates from the server, see the following documents:
   - For IBM Spectrum Protect 8.1.2 or later servers, see technote 2004596.
   - For IBM® Tivoli® Storage Manager V7.1 servers and IBM Spectrum Protect V8.1.0 and V8.1.1 servers, see technote 1673299.
3. Configure the options for backup-archive clients. For more information, see Upgrading the IBM Spectrum Protect Server and the IBM Spectrum Protect Client.

Linux: Planning for optimal performance

Before you install the IBM Spectrum Protect™ server, evaluate the characteristics and configuration of the system to ensure that the server is set up for optimal performance.

Procedure

1. Review Linux: What you should know first.
2. Review each of the following sub-sections.

- Linux: Planning for the server hardware and the operating system
  Use the checklist to verify that the system where the server is installed meets requirements for hardware and software configuration.

- Linux: Planning for the server database disks
  Use the checklist to verify that the system where the server is installed meets requirements for hardware and software configuration.
- Linux: Planning for the server recovery log disks
  Use the checklist to verify that the system where the server is installed meets requirements for hardware and software configuration.
- Linux: Planning for directory-container and cloud-container storage pools
  Review how your directory-container and cloud-container storage pools are set up to ensure optimal performance.
- Linux: Planning for storage pools in DISK or FILE device classes
  Use the checklist to review how your disk storage pools are set up. This checklist includes tips for storage pools that use DISK or FILE device classes.
- Linux: Planning for the correct type of storage technology
  Storage devices have different capacity and performance characteristics. These characteristics affect which devices are better for use with IBM Spectrum Protect.
- Linux: Applying best practices to the server installation
  Typically, hardware configuration and selection have the most significant effect on the performance of an IBM Spectrum Protect solution. Other factors that affect performance are the operating system selection and configuration, and the configuration of IBM Spectrum Protect.

Linux: Planning for the server hardware and the operating system

Use the checklist to verify that the system where the server is installed meets requirements for hardware and software configuration.

Question	Tasks, characteristics, options, or settings	More information
Does the operating system and hardware meet or exceed requirements? • Number and speed of processors • System memory • Supported operating system level	If you are using the minimum required amount of memory, you can support a minimal workload. You can experiment by adding more system memory to determine whether the performance is improved. Then, decide whether you want to keep the system memory dedicated to the server. Test the memory variations by using the entire daily cycle of the server workload. If you run multiple servers on the system, add the requirements for each server to get the requirements for the system.	Review operating system requirements at technote 1243309. Additionally, review the guidance in Tuning tasks for operating systems and other applications. For more information about requirements when these features are in use, see the following topics: • Checklist for data deduplication • Checklist for node replication For more information about sizing requirements for the server and storage, see the IBM Spectrum Protect™ Blueprint.
Are disks configured for optimal performance?	The amount of tuning that can be done for different disk systems varies. Ensure that the appropriate queue depths and other disk system options are set.	For more information, see the following topics: • "Planning for server database disks" • "Planning for server recovery log disks" • "Planning for storage pools in DISK or FILE device classes"

Question	Tasks, characteristics, options, or settings	More information
Does the server have enough memory?	Heavier workloads and advanced features such as data deduplication and node replication require more than the minimum system memory that is specified in the system requirements document. For databases that are not enabled for data deduplication, use the following guidelines to specify memory requirements: • For databases less than 500 GB, you need 16 GB of memory. • For databases with a size of 500 GB - 1 TB, you need 24 GB of memory. • For databases with a size of 1 TB - 1.5 TB, you need 32 GB of memory. • For databases greater than 1.5 TB, you need 40 GB of memory. Ensure that you allocate extra space for the active log and the archive log for replication processing.	For more information about requirements when these features are in use, see the following topics: • Checklist for data deduplication • Checklist for node replication • Memory requirements
Does the system have enough host bus adapters (HBAs) to handle the data operations that the IBM Spectrum Protect server must run simultaneously?	Understand what operations require use of HBAs at the same time. For example, a server must store 1 GB/sec of backup data while also doing storage pool migration that requires 0.5 GB/sec capacity to complete. The HBAs must be able to handle all of the data at the speed required.	See Tuning HBA capacity.
Is network bandwidth greater than the planned maximum throughput for backups?	Network bandwidth must allow the system to complete operations such as backups in the time that is allowed or that meets service level commitments. For node replication, network bandwidth must be greater than the planned maximum throughput.	For more information, see the following topics: • Tuning network performance • Checklist for node replication

Question	Tasks, characteristics, options, or settings	More information
Are you using a preferred file system for IBM Spectrum Protect server files?	Use a file system that ensures optimal performance and data availability. The server uses direct I/O with file systems that support the feature. Using direct I/O can improve throughput and reduce processor use. The following list identifies the preferred file system: • Linux Use either the ext3, ext4, or xfs file system for the database, recovery log, and storage pool data. Use the following file system that is appropriate for your operating system and level: ◦ For Red Hat Enterprise Linux x86_64, use the ext3, ext4, or xfs file system. If Red Hat Enterprise Linux 6.4 or later is installed, use the ext4 or xfs file system. ◦ For SUSE Linux Enterprise Server and for Red Hat Enterprise Linux ppc64, use the ext3 or xfs file system. Using xfs on SUSE Linux Enterprise Server 12 requires kernel-default-3.12.32-33.1.x86_64.rpm or later.	For more information, see Configuring the operating system for disk performance.

Question	Tasks, characteristics, options, or settings	More information
Are you planning to configure enough paging space?	Paging space, or swap space, extends the memory that is available for processing. When the amount of free RAM in the system is low, programs or data that is not in use are moved from memory to paging space. This action releases memory for other activities, such as database operations. Linux Use a minimum of 32 GB of paging space or 50% of your RAM, whichever value is larger.	
Linux Are you planning to tune the kernel parameters after installation of the server?	Linux You must tune kernel parameters.	Linux See the information about tuning kernel parameters: Linux: Tuning kernel parameters for Linux systems

Linux: Planning for the server database disks

Use the checklist to verify that the system where the server is installed meets requirements for hardware and software configuration.

Question	Tasks, characteristics, options, or settings	More information
Is the database on fast, low-latency disks?	Do not use the following drives for the IBM Spectrum Protect™ database: • Nearline SAS (NL-SAS) • Serial Advanced Technology Attachment (SATA) • Parallel Advanced Technology Attachment (PATA) Do not use internal disks that are included by default in most server hardware. Enterprise-grade solid-state disks (SSD), with Fibre Channel or SAS interface, offer the best performance. If you plan to use the data deduplication functions of IBM Spectrum Protect, focus on disk performance in terms of I/O operations per second (IOPS).	For more information, see Checklist for data deduplication.

Question	Tasks, characteristics, options, or settings	More information
Is the database stored on disks or LUNs that are separate from disks or LUNs that are used for the active log, archive log, and storage pool volumes?	Separation of the server database from other server components helps reduce contention for the same resources by different operations that must run at the same time. Tip: The database and the archive log can share an array when you use solid-state drive (SSD) technology.	
If you are using RAID, do you know how to select the optimal RAID level for your system? Are you defining all LUNs with the same size and type of RAID?	When a system must do large numbers of writes, RAID 10 outperforms RAID 5. However, RAID 10 requires more disks than RAID 5 for the same amount of usable storage. If your disk system is RAID, define all your LUNs with the same size and type of RAID. For example, do not mix 4+1 RAID 5 with 4+2 RAID 6.	
If an option to set the strip size or segment size is available, are you planning to optimize the size when you configure the disk system?	If you can set the strip size or segment size, use 64 KB or 128 KB sizes on disk systems for the database.	The block size that is used for the database varies depending on the table space. Most table spaces use 8 KB blocks, but some use 32 KB blocks.
Are you planning to create at least four directories, also called storage paths, on four separate LUNs for the database? Create one directory per distinct array on the subsystem. If you have fewer than three arrays, create a separate LUN volume within the array.	Heavier workloads and use of some features require more database storage paths than the minimum requirements. Server operations such as data deduplication drive a high number of input/output operations per second (IOPS) for the database. Such operations perform better when the database has more directories. For server databases that are larger than 2 TB or are expected to grow to that size, use eight directories. Consider planned growth of the system when you determine how many storage paths to create. The server uses the higher number of storage paths more effectively if the storage paths are present when the server is first created. Use the *DB2_PARALLEL_IO* variable to force parallel I/O to occur on table spaces that have one container, or on table spaces that have containers on more than one physical disk. If you do not set the *DB2_PARALLEL_IO* variable, I/O parallelism is equal to the number of containers that are used by the table space. For example, if a table space spans four containers, the level of I/O parallelism that is used is 4.	For more information, see the following topics: • Checklist for data deduplication • Checklist for node replication For help with forecasting growth when the server deduplicates data, see technote 1596944. For the most recent information about database size, database reorganization, and performance considerations for IBM Spectrum Protect servers, see technote 1683633. For information about setting the *DB2_PARALLEL_IO* variable, see Recommended settings for IBM DB2 registry variables.

Question	Tasks, characteristics, options, or settings	More information
Are all directories for the database the same size?	Directories that are all the same size ensure a consistent degree of parallelism for database operations. If one or more directories for the database are smaller than the others, they reduce the potential for optimized parallel prefetching. This guideline also applies if you must add storage paths after the initial configuration of the server.	
Are you planning to raise the queue depth of the database LUNs on AIX® systems?	The default queue depth is often too low.	See Configuring AIX systems for disk performance.

Linux: Planning for the server recovery log disks

Use the checklist to verify that the system where the server is installed meets requirements for hardware and software configuration.

Question	Tasks, characteristics, options, or settings	More information
Are the active log and archive log stored on disks or LUNs that are separate from what is used for the database and storage pool volumes?	Ensure that the disks where you place the active log are not used for other server or system purposes. Do not place the active log on disks that contain the server database, the archive log, or system files such as page or swap space.	Separation of the server database, active log, and archive log helps to reduce contention for the same resources by different operations that must run at the same time.
Are the logs on disks that have nonvolatile write cache?	Nonvolatile write cache allows data to be written to the logs as fast as possible. Faster write operations for the logs can improve performance for server operations.	
Are you setting the logs to a size that adequately supports the workload?	If you are not sure about the workload, use the largest size that you can. Active log The maximum size is 512 GB, set with the ACTIVELOGSIZE server option. Ensure that there is at least 8 GB of free space on the active log file system after the fixed size active logs are created. Archive log The size of the archive log is limited by the size of the file system on which it is located, and not by a server option. Make the archive log at least as large as the active log.	• For log sizing details, see the recovery log information in technote 1421060. • For information about sizing when you use data deduplication, see Checklist for data deduplication.
Are you defining an archive failover log? Are you placing this log on a disk that is separate from the archive log?	The archive failover log is for emergency use by the server when the archive log becomes full. Slower disks can be used for the archive failover log.	Use the ARCHFAILOVERLOGDIRECTORY server option to specify the location of the archive failover log. Monitor the usage of the directory for the archive failover log. If the archive failover log must be used by the server, the space for the archive log might not be large enough.

Question	Tasks, characteristics, options, or settings	More information
If you are mirroring the active log, are you using only one type of mirroring?	You can mirror the log by using one of the following methods. Use only one type of mirroring for the log. • Use the MIRRORLOGDIRECTORY option that is available for the IBM Spectrum Protect™ server to specify a mirror location. • Use software mirroring, such as Logical Volume Manager (LVM) on AIX®. • Use mirroring in the disk system hardware.	If you mirror the active log, ensure that the disks for both the active log and the mirror copy have equal speed and reliability. For more information, see Configuring and tuning the recovery log.

Linux: Planning for directory-container and cloud-container storage pools

Review how your directory-container and cloud-container storage pools are set up to ensure optimal performance.

Question	Tasks, characteristics, options, or settings	More information
Measured in terms of input/output operations per second (IOPS), are you using fast disk storage for the IBM Spectrum Protect™ database?	Use a high-performance disk for the database. Use solid-state drive technology for data deduplication processing. Ensure that the database has a minimum capability of 3000 IOPS. For each TB of data that is backed up daily (before data deduplication), add 1000 IOPS to this minimum. For example, an IBM Spectrum Protect server that is ingesting 3 TB of data per day would need 6000 IOPS for the database disks: `3000 IOPS minimum + 3000 (3 TB x 1000 IOPS) = 6000 IOPS`	For recommendations about disk selection, see "Planning for server database disks". For more information about IOPS, see the IBM Spectrum Protect Blueprints.

Question	Tasks, characteristics, options, or settings	More information
Do you have enough memory for the size of your database?	Use a minimum of 40 GB of system memory for IBM Spectrum Protect servers, with a database size of 100 GB, that are deduplicating data. If the retained capacity of backup data grows, the memory requirement might need to be higher. Monitor memory usage regularly to determine whether more memory is required. Use more system memory to improve caching of database pages. The following memory size guidelines are based on the daily amount of new data that you back up: • 128 GB of system memory for daily backups of data, where the database size is 1 - 2 TB • 192 GB of system memory for daily backups of data, where the database size is 2 - 4 TB	Memory requirements
Have you properly sized the storage capacity for the database active log and archive log?	Configure the server to have a minimum active log size of 128 GB by setting the ACTIVELOGSIZE server option to a value of 131072. The suggested starting size for the archive log is 1 TB. The size of the archive log is limited by the size of the file system on which it is located, and not by a server option. Ensure that there is at least 10% extra disk space for the file system than the size of the archive log. Use a directory for the database archive logs with an initial free capacity of at least 1 TB. Specify the directory by using the ARCHLOGDIRECTORY server option. Define space for the archive failover log by using the ARCHFAILOVERLOGDIRECTORY server option.	For more information about sizing for your system, see the IBM Spectrum Protect Blueprints.
Is compression enabled for the archive log and database backups?	Enable the ARCHLOGCOMPRESS server option to save storage space. This compression option is different from inline compression. Inline compression is enabled by default with IBM Spectrum Protect V7.1.5 and later. Restriction: Do not use this option if the amount of backed up data exceeds 6 TB per day.	For more information about compression for your system, see the IBM Spectrum Protect Blueprints.

Question	Tasks, characteristics, options, or settings	More information
Are the IBM Spectrum Protect database and logs on separate disk volumes (LUNs)? Is the disk that is used for the database configured according to best practices for a transactional database?	The database must not share disk volumes with IBM Spectrum Protect database logs or storage pools, or with any other application or file system.	For more information about server database and recovery log configuration, see Server database and recovery log configuration and tuning.
Are you using a minimum of eight (2.2 GHz or equivalent) processor cores for each IBM Spectrum Protect server that you plan to use with data deduplication?	If you are planning to use client-side data deduplication, verify that client systems have adequate resources available during a backup operation to complete data deduplication processing. Use a processor that is at least the minimum equivalent of one 2.2 GHz processor core per backup process with client-side data deduplication.	• Effective planning and use of deduplication • IBM Spectrum Protect Blueprints
Did you allocate enough storage space for the database?	For a rough estimate, plan for 100 GB of database storage for every 50 TB of data that is to be protected in deduplicated storage pools. *Protected data* is the amount of data before data deduplication, including all versions of objects stored. As a best practice, define a new container storage pool exclusively for data deduplication. Data deduplication occurs at the storage-pool level, and all data within a storage pool, except encrypted data, is deduplicated.	
Have you estimated storage pool capacity to configure enough space for the size of your environment?	You can estimate capacity requirements for a deduplicated storage pool by using the following technique: 1. Estimate the base size of the source data. 2. Estimate the daily backup size by using an estimated change and growth rate. 3. Determine retention requirements. 4. Estimate the total amount of source data by factoring in the base size, daily backup size, and retention requirements. 5. Apply the deduplication ratio factor. 6. Apply the compression ratio factor. 7. Round up the estimate to consider transient storage pool usage.	For an example of using this technique, see Effective planning and use of deduplication.

Question	Tasks, characteristics, options, or settings	More information
Have you distributed disk I/O over many disk devices and controllers?	Use arrays that consist of as many disks as possible, which is sometimes referred to as wide striping. Ensure that you use one database directory per distinct array on the subsystem. Set the *DB2_PARALLEL_IO* registry variable to enable parallel I/O for each table space used if the containers in the table space span multiple physical disks. When I/O bandwidth is available and the files are large, for example 1 MB, the process of finding duplicates can occupy the resources of an entire processor. When files are smaller, other bottlenecks can occur. Specify eight or more file systems for the deduplicated storage pool device class so that I/O is distributed across as many LUNs and physical devices as possible.	For guidelines about setting up storage pools, see "Planning for storage pools in DISK or FILE device classes". For information about setting the *DB2_PARALLEL_IO* variable, see Recommended settings for IBM DB2 registry variables.
Have you scheduled daily operations based on your backup strategy?	The best practice sequence of operations is in the following order: 1. Client backup 2. Storage pool protection 3. Node replication 4. Database backup 5. Expire inventory	• Scheduling data deduplication and node replication processes • Daily operations for directory-container storage pools
Do you have enough storage to manage the DB2® lock list?	If you deduplicate data that includes large files or large numbers of files concurrently, the process can result in insufficient storage space. When the lock list storage is insufficient, backup failures, data management process failures, or server outages can occur. File sizes greater than 500 GB that are processed by data deduplication are most likely to deplete storage space. However, if many backup operations use client-side data deduplication, this problem can also occur with smaller-sized files.	For information about tuning the DB2 LOCKLIST parameter, see Tuning server-side data deduplication.
Is sufficient bandwidth available to transfer data to an IBM Spectrum Protect server?	To transfer data to an IBM Spectrum Protect server, use client-side or server-side data deduplication and compression to reduce the bandwidth that is required. Use a V7.1.5 server or higher to use inline compression and use a V7.1.6 or later client to enable enhanced compression processing.	For more information, see the enablededup client option.

Question	Tasks, characteristics, options, or settings	More information
Have you determined how many storage pool directories to assign to each storage pool?	Assign directories to a storage pool by using the DEFINE STGPOOLDIRECTORY command. Create multiple storage pool directories and ensure that each directory is backed up to a separate disk volume (LUN).	
Did you allocate enough disk space in the cloud-container storage pool?	To prevent backup failures, ensure that the local directory has enough space. Use the following list as a guide for optimal disk space: • For serial-attached SCSI (SAS) and spinning disk, calculate the amount of new data that is expected after daily data reduction (compression and data deduplication). Allocate up to 100 percent of that amount, in terabytes, for disk space. • Provide 3 TB for flash-based storage systems with fast network connections to on-premises, high-performance cloud systems. • Provide 5 TB for solid-state drive (SSD) systems with fast network connections to high-performance cloud systems.	

Question	Tasks, characteristics, options, or settings	More information
Did you select the appropriate type of local storage?	Ensure that data transfers from local storage to cloud finish before the next backup cycle starts. Tip: Data is removed from local storage soon after it moves to the cloud. Use the following guidelines: • Use flash or SSD for large systems that have high-performing cloud systems. Ensure that you have a dedicated 10 GB wide area network (WAN) link with a high-speed connection to the object storage. For example, use flash or SSD if you have a dedicated 10 GB WAN link plus a high-speed connection to either an IBM® Cloud Object Storage location or to an Amazon Simple Storage Service (Amazon S3) data center. • Use larger capacity 15000 rpm SAS disks for these scenarios: ◦ Medium-sized systems ◦ Slower cloud connections, for example, 1 GB ◦ When you use IBM Cloud Object Storage as your service provider across several regions • For SAS or spinning disk, calculate the amount of new data that is expected after daily data reduction (compression and data deduplication). Allocate up to 100 percent of that amount for disk space, in terabytes.	

Linux: Planning for storage pools in DISK or FILE device classes

Use the checklist to review how your disk storage pools are set up. This checklist includes tips for storage pools that use DISK or FILE device classes.

Question	Tasks, characteristics, options, or settings	More information

Question	Tasks, characteristics, options, or settings	More information
Can the storage pool LUNs sustain throughput rates for 256 KB sequential reads and writes to adequately handle the workload within the time constraints?	When you are planning for peak loads, consider all the data that you want the server to read or write to the disk storage pools simultaneously. For example, consider the peak flow of data from client backup operations and server data-movement operations such as migration that run at the same time. The IBM Spectrum Protect™ server reads and writes to storage pools predominantly in 256 KB blocks. If the disk system includes the capability, configure the disk system for optimal performance with sequential read/write operations rather than random read/write operations.	For more information, see Analyzing the basic performance of disk systems.
Is the disk configured to use read and write cache?	Use more cache for better performance.	
For storage pools that use FILE device classes, have you determined a good size to use for the storage pool volumes?	Review the information in Optimal number and size of volumes for storage pools that use disk. If you do not have the information to estimate a size for FILE device class volumes, start with volumes that are 50 GB.	Typically, problems arise more frequently when the volumes are too small. Few problems are reported when volumes are larger than needed. When you determine the volume size to use, as a precaution choose a size that might be larger than necessary.
For storage pools that use FILE device classes, are you using preallocated volumes?	Scratch volumes can cause file fragmentation. To ensure that a storage pool does not run out of volumes, set the MAXSCRATCH parameter to a value greater than zero.	Use the DEFINE VOLUME server command to preallocate volumes in the storage pool. Use the DEFINE STGPOOL or UPDATE STGPOOL server command to set the MAXSCRATCH parameter.
For storage pools that use FILE device classes, have you compared the maximum number of client sessions to the number of volumes that are defined?	Always maintain enough usable volumes in the storage pools to allow for the expected peak number of client sessions that run at one time. The volumes might be scratch volumes, empty volumes, or partly filled volumes.	For storage pools that use FILE device classes, only one session or process can write to a volume at the same time.

Question	Tasks, characteristics, options, or settings	More information
For storage pools that use FILE device classes, have you set the MOUNTLIMIT parameter of the device class to a value that is high enough to account for the number of volumes that might be mounted in parallel?	For storage pools that use data deduplication, the MOUNTLIMIT parameter is typically in the range of 500 - 1000. Set the value for MOUNTLIMIT to the maximum number of mount points that are needed for all active sessions. Consider parameters that affect the maximum number of mount points that are needed: • The MAXSESSIONS server option, which is the maximum number of IBM Spectrum Protect sessions that can run concurrently. • The MAXNUMMP parameter, which sets the maximum number of mount points that each client node can use. For example, if the maximum number of client node backup sessions is typically 100 and each of the nodes has `MAXNUMMP=2`, multiply 100 nodes by the 2 mount points for each node to get the value of 200 for the MOUNTLIMIT parameter.	Use the REGISTER NODE or UPDATE NODE server command to set the MAXNUMMP parameter for client nodes.
For storage pools that use DISK device classes, have you determined how many storage pool volumes to put on each file system?	How you configure the storage for a storage pool that uses a DISK device class depends on whether you are using RAID for the disk system. If you are not using RAID, then configure one file system per physical disk, and define one storage pool volume for each file system. If you are using RAID 5 with *n* + 1 volumes, configure the storage in one of the following ways: • Configure *n* file systems on the LUN and define one storage pool volume per file system. • Configure one file system and *n* storage pool volumes for the LUN.	For an example layout that follows this guideline, see Sample layout of server storage pools.
Did you create your storage pools to distribute I/O across multiple file systems?	Ensure that each file system is on a different LUN on the disk system. Typically, having 10 - 30 file systems is a good goal, but ensure that the file systems are no smaller than approximately 250 GB.	For details, see the following topics: • Tuning disk storage for the server • Tuning and configuring storage pools and volumes

Linux: Planning for the correct type of storage technology

Storage devices have different capacity and performance characteristics. These characteristics affect which devices are better for use with IBM Spectrum Protect™.

Procedure

Review the following table to help you to choose the correct type of storage technology for the storage resources that the server requires.

Table 1. Storage technology types for IBM Spectrum Protect storage requirements

Storage technology type	Database	Active log	Archive log and archive failover log	Storage pools

Storage technology type	Database	Active log	Archive log and archive failover log	Storage pools
Solid-state disk (SSD)	Place the database on SSD in the following circumstances: • You are using IBM Spectrum Protect data deduplication. • You are backing up more than 8 TB of new data daily.	If you place the IBM Spectrum Protect database on an SSD, as a best practice, place the active log on an SSD. If space is not available, use high-performance disk instead.	Save SSDs for use with the database and active log. The archive log and archive failover logs can be placed on slower storage technology types.	Save SSDs for use with the database and active log. Storage pools can be placed on slower storage technology types.
High-performance disk with the following characteristics: • **15k rpm disk** • **Fibre Channel or serial-attached SCSI (SAS) interface**	Use high-performance disks in the following circumstances: • The server does not do data deduplication. • The server does not do node replication. Isolate the server database from its logs and storage pools, and from data for other applications.	Use high-performance disks in the following circumstances: • The server does not do data deduplication. • The server does not do node replication. For performance and availability, isolate the active log from the server database, archive logs, and storage pools.	You can use high-performance disks for the archive log and archive failover logs. For availability, isolate these logs from the database and active log.	Use high-performance disks for storage pools in the following circumstances: • Data is frequently read. • Data is frequently written. For performance and availability, isolate storage pool data from the server database and logs, and from data for other applications.
Medium-performance or high-performance disk with the following characteristics: • **10k rpm disk** • **Fibre Channel or SAS interface**	If the disk system has a mix of disk technologies, use the faster disks for the database and active log. Isolate the server database from its logs and storage pools, and from data for other applications.	If the disk system has a mix of disk technologies, use the faster disks for the database and active log. For performance and availability, isolate the active log from the server database, archive logs, and storage pools.	You can use medium-performance or high-performance disk for the archive log and archive failover logs. For availability, isolate these logs from the database and active log.	Use medium-performance or high-performance disk for storage pools in the following circumstances: • Data is frequently read. • Data is frequently written. For performance and availability, isolate storage pool data from the server database and logs, and from data for other applications.

Storage technology type	Database	Active log	Archive log and archive failover log	Storage pools
SATA, network-attached storage	Do not use this storage for the database. Do not place the database on XIV storage systems.	Do not use this storage for the active log.	Use of this slower storage technology is acceptable because these logs are written once and infrequently read.	Use this slower storage technology in the following circumstances: • Data is infrequently written, for example written once. • Data is infrequently read. .
Tape and virtual tape				Use for long-term retention or if data is infrequently used.

Linux: Applying best practices to the server installation

Typically, hardware configuration and selection have the most significant effect on the performance of an IBM Spectrum Protect™ solution. Other factors that affect performance are the operating system selection and configuration, and the configuration of IBM Spectrum Protect.

Procedure

- The following best practices are the most important for optimal performance and problem prevention.
- Review the table to determine the best practices that apply to your environment.

Best practice	More information
Use fast disks for the server database. Enterprise-grade solid-state disks (SSD), with Fibre Channel or SAS interface, offer the best performance.	Use fast, low-latency disks for the database. Using SSD is essential if you are using data deduplication and node replication. Avoid Serial Advanced Technology Attachment (SATA) and Parallel Advanced Technology Attachment (PATA) disks. For details and more tips, see the following topics: ◦ "Planning for server database disks" ◦ "Planning for the correct type of storage technology"
Ensure that the server system has enough memory.	Review operating system requirements in technote 1243309. Heavier workloads require more than the minimum requirements. Advanced features such as data deduplication and node replication can require more than the minimum memory that is specified in the system requirements document. If you plan to run multiple instances, each instance requires the memory that is listed for one server. Multiply the memory for one server by the number of instances that are planned for the system.

Best practice	More information
Separate the server database, the active log, the archive log, and disk storage pools from each other.	Keep all IBM Spectrum Protect storage resources on separate disks. Keep storage pool disks separate from the disks for the server database and logs. Storage pool operations can interfere with database operations when both are on the same disks. Ideally, the server database and logs are also separated from each other. For details and more tips, see the following topics: ○ "Planning for server database disks" ○ "Planning for server recovery log disks" ○ "Planning for storage pools in DISK or FILE device classes"
Use at least four directories for the server database. For larger servers or servers that use advanced features, use eight directories.	Place each directory on a LUN that is isolated from other LUNs and from other applications. A server is considered to be large if its database is larger than 2 TB or is expected to grow to that size. Use eight directories for such servers. See "Planning for server database disks".
If you are using data deduplication, node replication, or both, follow the guidelines for database configuration and other items.	Configure the server database according to the guidelines, because the database is extremely important to how well the server runs when these features are being used. For details and more tips, see the following topics: ○ Checklist for data deduplication ○ Checklist for node replication
For storage pools that use FILE type device classes, follow the guidelines for the size of storage pool volumes. Typically, 50 GB volumes are best.	Review the information in Optimal number and size of volumes for storage pools that use disk to help you to determine volume size. Configure storage pool devices and file systems based on throughput requirements, not only on capacity requirements. Isolate the storage devices that are used by IBM Spectrum Protect from other applications that have high I/O, and ensure that there is enough throughput to that storage. For more details, see Checklist for storage pools on DISK or FILE.
Schedule IBM Spectrum Protect client operations and server maintenance activities to avoid or minimize overlap of operations.	For more details, see the following topics: ○ Tuning the schedule for daily operations ○ Checklist for server configuration
Monitor operations constantly.	By monitoring, you can find problems early and more easily identify causes. Keep records of monitoring reports for up to a year to help you identify trends and plan for growth. See Monitoring and maintaining the environment for performance.

Linux: Minimum system requirements for Linux systems

To install the IBM Spectrum Protect™ server on a Linux system, it is necessary to have a minimum level of hardware and software, including a communication method and the most current device driver.

These tables list the minimum hardware and software requirements for the installation of an IBM Spectrum Protect server. Use these requirements as a starting point for systems without data deduplication. The optimal IBM Spectrum Protect environment is set up with data deduplication by using the IBM Spectrum Protect Blueprints. For the most current information about system requirements, see technote 1243309.

The IBM Spectrum Protect device driver package does not contain a device driver for this operating system because a SCSI generic device driver is used. Configure the device driver before using the IBM Spectrum Protect server with tape devices. The IBM Spectrum Protect driver package contains driver tools and ACSLS daemons. You can locate IBM® driver packages at the Fix Central website.

Requirements, supported devices, client installation packages, and fixes are available in the IBM Support Portal for IBM Spectrum Protect. After you install IBM Spectrum Protect and before you customize it for your use, go to the website and download and apply any applicable fixes.

- Linux Linux: Minimum Linux X86_64 server requirements
  Before you install an IBM Spectrum Protect server on a Linux X86_64 operating system, review the hardware and software requirements.
- Linux Linux: Minimum Linux on System z server requirements
  Before you install an IBM Spectrum Protect server on a Linux on System z® operating system, review the hardware and software requirements.
- Linux Linux: Minimum Linux on Power Systems (little endian) server requirements
  Before you install an IBM Spectrum Protect server on a Linux on Power Systems (little endian) operating system, review the hardware and software requirements.

Linux: Minimum Linux X86_64 server requirements

Before you install an IBM Spectrum Protect™ server on a Linux X86_64 operating system, review the hardware and software requirements.

Hardware requirements

Table 1 describes the minimum hardware requirements for the server. If the server does not meet the minimum requirements, the installation fails. For more details about planning disk space, see Linux: Capacity planning.

Table 1. Hardware requirements

Type of hardware	Hardware requirements
Server	An AMD64 or Intel EMT-64 processor
Disk space	The following minimum values for disk space: • 5 GB for the installation directory • 512 MB for the /var directory • 2 GB for the /tmp directory • 128 MB in the home directory for the root user. • 2 GB for the shared resources area In case a problem arises and any diagnosis is needed, it is optimal to have temporary or other space available on the system for a first failure data capture (FFDC) log or for other temporary uses such as for collecting trace logs. Significant additional disk space is required for database and log files. The size of the database depends on the number of client files to be stored and the method by which the server manages them. The default active log space is 16 GB, the minimum that is needed for most workloads and configurations. When you create the active log, you need at least 64 GB to run replication. If replication and data deduplication are both being used, create an active log of 128 GB. Allocate at least three times the default active log space for the archive log (48 GB). Ensure that you have sufficient resources if you are using data deduplication or expect a heavy client workload. For optimal performance and to facilitate I/O, specify at least two equally sized containers or Logical Unit Numbers (LUNs) for the database. In addition, each active log and archive log needs its own container or LUN. Ensure that you see Linux: Capacity planning for more details about disk space.

Type of hardware	Hardware requirements
Memory	The following minimum values for memory: • 16 GB for standard server operations without data deduplication and node replication • 24 GB for data deduplication or node replication • 32 GB for node replication with data deduplication For more specific memory requirements for larger databases and higher ingestion capability, see the IBM Spectrum Protect server memory tuning table. For more specific memory requirements when you are using data deduplication, see the IBM Spectrum Protect Blueprint for your operating system.

Software requirements

Table 2 describes the minimum software requirements that are needed for a server on a Linux X86_64 system.

Table 2. Software requirements

Type of software	Minimum software requirements
Operating system	The IBM Spectrum Protect server on Linux X86_64 requires one of the following operating systems: • Red Hat Enterprise Linux 6.7 • Red Hat Enterprise Linux 7, including updates • SUSE Linux Enterprise Server 11, Service Pack 4 or later • SUSE Linux Enterprise Server 12
Libraries	GNU C libraries, Version 2.3.3-98.38 or later, which are installed on the IBM Spectrum Protect system. For SUSE Linux Enterprise Servers: • libaio • libstdc++.so.6 at version 4.3 or later (32-bit and 64-bit packages are required) For Red Hat Enterprise Linux Servers: • libaio • libstdc++.so.6 (32 and 64 bit packages are required) • numactl.x86_64 To determine if SELinux is installed and in enforcing mode, take one of the following actions: • Check the /etc/sysconfig/selinux file. • Run the sestatus operating system command. • Check the /var/log/messages file for SELinux notices. To disable SELinux, complete one of the following tasks: • Set permissive mode by issuing the `setenforce 0` command as a superuser. • Modify the /etc/sysconfig/selinux file and restart the machine.
Communication protocol	• TCP/IP Version 4 or Version 6, which is standard with Linux • Shared memory protocol (with IBM Spectrum Protect Linux X86_64 client)
Processing	Asynchronous I/O must be enabled. On Linux kernels at 2.6 or later, install the libaio library to enable asynchronous I/O.

Type of software	Minimum software requirements
Device drivers	The IBM Spectrum Protect passthru device driver is used for non-IBM® devices. It uses the SCSI passthru interface to communicate with tape devices and tape libraries. The Linux SCSI Generic (sg) device driver is required for tape drives and tape libraries. The IBM Spectrum Protect device driver package contains device driver tools and ACSLS daemons. For the IBM 3590, 3592, or the Ultrium tape library or drives, the IBM device drivers are required. Install the most current device drivers. You can locate IBM driver packages at Fix Central. Configure the device drivers before you use the server with tape devices.
Other software	Korn Shell (ksh) is required. Configure the I/O completion ports (IOCP) on the operating system. To authenticate IBM Spectrum Protect users with a Lightweight Directory Access Protocol (LDAP) server, you must use one of the following directory servers: • Microsoft Active Directory (Windows Server 2012, Windows Server 2012 R2) • IBM Security Directory Server V6.3 • IBM Security Directory Server V6.4

Linux: Minimum Linux on System z server requirements

Before you install an IBM Spectrum Protect™ server on a Linux on System z® operating system, review the hardware and software requirements.

Hardware requirements

Table 1 describes the minimum hardware requirements that are needed for your IBM Spectrum Protect Linux on System z system. For more details about planning disk space, see Linux: Capacity planning.

Table 1. Hardware requirements

Type of hardware	Hardware requirements
Server	An IBM® zSeries, IBM System z9®, IBM System z10®, or IBM zEnterprise® System (z114 and z196) 64-bit native logical partition (LPAR) or z/VM® guest.
Disk space	The following minimum values for disk space: • 5 GB for the installation directory • 512 MB for the /var directory • 2 GB for the /tmp directory • 128 MB in the home directory for the root user. • 2 GB for the shared resources area In case a problem arises and any diagnosis is needed, it is optimal to have temporary or other space available on the system for a first failure data capture (FFDC) log or for other temporary uses such as for collecting trace logs. Significant additional disk space is required for database and log files. The size of the database depends on the number of client files to be stored and the method by which the server manages them. The default active log space is 16 GB, the minimum that is needed for most workloads and configurations. When you create the active log, you need at least 64 GB to run replication. If replication and data deduplication are both being used, create an active log of 128 GB. Allocate at least three times the default active log space for the archive log (48 GB). Ensure that you have sufficient resources if you are using data deduplication or expect a heavy client workload. For optimal performance and to facilitate I/O, specify at least two equally sized containers or Logical Unit Numbers (LUNs) for the database. In addition, each active log and archive log needs its own container or LUN. Ensure that you see Linux: Capacity planning for more details about disk space.

Type of hardware	Hardware requirements
Memory	The following minimum values for memory: • 16 GB for standard server operations without data deduplication and node replication • 24 GB for data deduplication or node replication • 32 GB for node replication with data deduplication For more specific memory requirements for larger databases and higher ingestion capability, see the IBM Spectrum Protect server memory tuning table. For more specific memory requirements when you are using data deduplication, see the IBM Spectrum Protect Blueprint for your operating system.

Software requirements

Table 2 describes the minimum software requirements that are needed for your IBM Spectrum Protect Linux on System z system.

Table 2. Software requirements

Type of software	Minimum software requirements
Server	The IBM Spectrum Protect server on Linux on System z (s390x 64-bit architecture) requires one of the following operating systems: • Red Hat Enterprise Linux 7.1 • SUSE Linux Enterprise Server 12
Libraries	A GNU C library, Version 2.4-31.43.6, is installed on the IBM Spectrum Protect system. For SUSE Linux Enterprise Servers: • libaio • libstdc++.so.6 at version 4.3 or later (32-bit and 64-bit packages are required) • libxlc-1.2.0.0.151119a.s390x or later For Red Hat Enterprise Linux Servers: • libaio • libstdc++.so.6 (32-bit and 64-bit packages are required) • numactl.x86_64 • libxlc-1.2.0.0.151119a.s390x or later
Communication protocol	• TCP/IP Version 4 or Version 6, which is standard with Linux • Shared memory protocol (with IBM Spectrum Protect Version 8.1.2 Linux on System z client)
Processing	Asynchronous I/O must be enabled. On Linux kernels at 2.6 or later, install the libaio library to enable asynchronous I/O.
Other software	Korn Shell (ksh) is required. Configure the I/O completion ports (IOCP) on the operating system. To authenticate IBM Spectrum Protect users with a Lightweight Directory Access Protocol (LDAP) server, you must use one of the following directory servers: • Microsoft Active Directory (Windows Server 2012, Windows Server 2012 R2) • IBM Security Directory Server V6.3 • IBM Security Directory Server V6.4

Linux: Minimum Linux on Power Systems™ (little endian) server requirements

Before you install an IBM Spectrum Protect™ server on a Linux on Power Systems (little endian) operating system, review the hardware and software requirements.

Hardware requirements

Table 1 describes the minimum hardware requirements for the server. If the server does not meet the minimum requirements, the installation fails. For more details about planning disk space, see Linux: Capacity planning.

Table 1. Hardware requirements

Type of hardware	Hardware requirements
Server	A Linux on Power Systems (little endian) server on an IBM® system, such as one listed on the Linux on IBM Power Systems website.
Disk space	The following minimum disk space: • 5 GB for the installation directory • 128 MB in the home directory for the root user. • 2 GB for the shared resources area In case a problem arises and any diagnosis is needed, it is optimal to have temporary or other space available on the system for a first failure data capture (FFDC) log or for other temporary uses such as for collecting trace logs. Significant additional disk space is required for database and log files. The size of the database depends on the number of client files to be stored and the method by which the server manages them. The default active log space is 16 GB, the minimum that is needed for most workloads and configurations. When you create the active log, you need at least 64 GB to run replication. If replication and data deduplication are both being used, create an active log of 128 GB. Allocate at least three times the default active log space for the archive log (48 GB). Ensure that you have sufficient resources if you are using data deduplication or expect a heavy client workload. For optimal performance and to facilitate I/O, specify at least two equally sized containers or Logical Unit Numbers (LUNs) for the database. In addition, each active log and archive log needs its own container or LUN. Ensure that you see Linux: Capacity planning for more details about disk space.
Memory	• 16 GB for standard server operations without data deduplication and node replication • 24 GB for data deduplication or node replication • 32 GB for node replication with data deduplication For more specific memory requirements for larger databases and higher ingestion capability, see the IBM Spectrum Protect server memory tuning table. For more specific memory requirements when you are using data deduplication, see the IBM Spectrum Protect Blueprint for your operating system.

Software requirements

Table 2 describes the minimum software requirements that are needed for your system.

Table 2. Software requirements

Type of software	Minimum software requirements
Operating system	The Red Hat Enterprise Linux (RHEL) 7.3 operating system with the PPC64LE architecture.
Libraries	GNU C libraries, Version 2.4-31.30 and later. libaio.so.1 (32-bit and 64-bit packages).
Communication protocol	• TCP/IP Version 4 or Version 6, which is standard with Linux • Shared memory protocol (with a Version 8.1.2 client)
Processing	Asynchronous I/O must be enabled. On Linux kernels at 2.6 or later, install the libaio library to enable asynchronous I/O.

Type of software	Minimum software requirements
Other software	Korn Shell (ksh) is required. Configure the I/O completion ports (IOCP) on the operating system. To authenticate IBM Spectrum Protect users with a Lightweight Directory Access Protocol (LDAP) server, you must use one of the following directory servers: • Microsoft Active Directory (Windows Server 2012, Windows Server 2012 R2) • IBM Security Directory Server V6.3 • IBM Security Directory Server V6.4

Restriction: Raw logical volumes are not supported.

Linux

Linux: Compatibility of the IBM Spectrum Protect server with other DB2 products on the system

You can install other products that deploy and use DB2® products on the same system as the IBM Spectrum Protect™ Version 8.1.2 server, with some limitations.

To install and use other products that use a DB2 product on the same system as the IBM Spectrum Protect server, ensure that the following criteria are met:

Table 1. Compatibility of the IBM Spectrum Protect server with other DB2 products on the system

Criterion	Instructions
Version level	The other products that use a DB2 product must use DB2 version 9 or later. DB2 products include product encapsulation and segregation support beginning with Version 9. Starting with this version, you can run multiple copies of DB2 products, at different code levels, on the same system. For details, see the information about multiple DB2 copies in the DB2 product information.
User IDs and directories	Ensure that the user IDs, fence user IDs, installation location, other directories, and related information are not shared across DB2 installations. Your specifications must be different from the IDs and locations that you used for the IBM Spectrum Protect server installation and configuration. If you used the dsmicfgx wizard to configure the server, these are values that you entered when running the wizard. If you used the manual configuration method, review the procedures that you used if necessary to recall the values that were used for the server.
Resource allocation	Consider the resources and capability of the system compared to the requirements for both the IBM Spectrum Protect server and the other applications that use the DB2 product. To provide sufficient resources for the other DB2 applications, you might have to change the IBM Spectrum Protect server settings so that the server uses less system memory and resources. Similarly, if the workloads for the other DB2 applications compete with the IBM Spectrum Protect server for processor or memory resources, the performance of the server in handling the expected client workload or other server operations might be adversely affected. To segregate resources and provide more capability for the tuning and allocation of processor, memory, and other system resources for multiple applications, consider using logical partition (LPAR), workload partition (WPAR), or other virtual workstation support. For example, run a DB2 application on its own virtualized system.

Linux: IBM Installation Manager

IBM Spectrum Protect™ uses IBM® Installation Manager, which is an installation program that can use remote or local software repositories to install or update many IBM products.

If the required version of IBM Installation Manager is not already installed, it is automatically installed or upgraded when you install IBM Spectrum Protect. It must remain installed on the system so that IBM Spectrum Protect can be updated or uninstalled

later as needed.

The following list contains explanations of some terms that are used in IBM Installation Manager:

Offering
: An installable unit of a software product.

  The IBM Spectrum Protect offering contains all of the media that IBM Installation Manager requires to install IBM Spectrum Protect.

Package
: The group of software components that are required to install an offering.
  The IBM Spectrum Protect package contains the following components:

  - IBM Installation Manager installation program
  - IBM Spectrum Protect offering

Package group
: A set of packages that share a common parent directory.

  The default package group for the IBM Spectrum Protect package is `IBM Installation Manager`.

Repository
: A remote or local storage area for data and other application resources.

  The IBM Spectrum Protect package is stored in a repository on IBM Fix Central.

Shared resources directory
: A directory that contains software files or plug-ins that are shared by packages.

  IBM Installation Manager stores installation-related files in the shared resources directory, including files that are used for rolling back to a previous version of IBM Spectrum Protect.

Linux: Worksheets for planning details for the server

You can use the worksheets to help you plan the amount and location of storage needed for the IBM Spectrum Protect™ server. You can also use them to keep track of names and user IDs.

Item	Space required	Number of directories	Location of directories
The database			
Active log			
Archive log			
Optional: Log mirror for the active log			
Optional: Secondary archive log (failover location for archive log)			

Item	Names and user IDs	Location
The *instance user ID* for the server, which is the ID you use to start and run the IBM Spectrum Protect server		
The *home directory* for the server, which is the directory that contains the instance user ID		
The database instance name		

Item	Names and user IDs	Location
The *instance directory* for the server, which is a directory that contains files specifically for this server instance (the server options file and other server-specific files)		
The server name, use a unique name for each server		

Linux: Capacity planning

Capacity planning for IBM Spectrum Protect™ includes managing resources such as the database, the recovery log and the shared resource area. To maximize resources as part of capacity planning, you must estimate space requirements for the database and the recovery log. The shared resource area must have enough space available for each installation or upgrade.

- Linux: Estimating space requirements for the database
  To estimate space requirements for the database, you can use the maximum number of files that can be in server storage at one time or you can use storage pool capacity.
- Linux: Recovery log space requirements
  In IBM Spectrum Protect, the term *recovery log* comprises the active log, the archive log, the active log mirror, and the archive failover log. The amount of space that you require for the recovery log depends on various factors, including, for example, the amount of client activity with the server.
- Linux: Monitoring space utilization for the database and recovery logs
  To determine the amount of used and available active log space, you issue the QUERY LOG command. To monitor space utilization in the database and recovery logs, you can also check the activity log for messages.
- Linux: Deleting installation rollback files
  You can delete certain installation files that were saved during the installation process to free space in the shared resource directory. For example, files that might have been required for a rollback operation are types of files that you can delete.

Linux: Estimating space requirements for the database

To estimate space requirements for the database, you can use the maximum number of files that can be in server storage at one time or you can use storage pool capacity.

About this task

Consider using at least 25 GB for the initial database space. Provision file system space appropriately. A database size of 25 GB is adequate for a test environment or a library-manager-only environment. For a production server supporting client workloads, the database size is expected to be larger. If you use random-access disk (DISK) storage pools, more database and log storage space is needed than for sequential-access storage pools.

The maximum size of the IBM Spectrum Protect™ database is 6 TB.

For information about sizing the database in a production environment that is based on the number of files and on storage pool size, see the following topics.

- Linux: Estimating database space requirements based on the number of files
  If you can estimate the maximum number of files that might be in server storage at a time, you can use that number to estimate space requirements for the database.
- Linux: Estimating database space requirements based on storage pool capacity
  To estimate database space requirements based on storage pool capacity, use a ratio of 1 - 5%. For example, if you require 200 TB of storage pool capacity, the size of your database is expected to be 2 - 10 TB. As a general rule, make your database as large as possible to prevent running out of space. If you run out of database space, server operations and client-store operations can fail.
- Linux: The database manager and temporary space
  The IBM Spectrum Protect server database manager manages and allocates system memory and disk space for the database. The amount of database space you require depends on the amount of system memory available and the server workload.

Linux: Estimating database space requirements based on the number of files

If you can estimate the maximum number of files that might be in server storage at a time, you can use that number to estimate space requirements for the database.

About this task

To estimate space requirements that is based on the maximum number of files in server storage, use the following guidelines:

- 600 - 1000 bytes for each stored version of a file, including image backups.
  Restriction: The guideline does not include space that is used during data deduplication.
- 100 - 200 bytes for each cached file, copy storage pool file, active-data pool file, and deduplicated file.
- Additional space is required for database optimization to support varying data-access patterns and to support server back-end processing of the data. The amount of extra space is equal to 50% of the estimate for the total number of bytes for file objects.

In the following example for a single client, the calculations are based on the maximum values in the preceding guidelines. The examples do not take into account that you might use file aggregation. In general, when you aggregate small files, it reduces the amount of required database space. File aggregation does not affect space-managed files.

Procedure

1. Calculate the number of file versions. Add each of the following values to obtain the number of file versions:
   a. Calculate the number of backed-up files. For example, as many as 500,000 client files might be backed up at a time. In this example, storage policies are set to keep up to three copies of backed up files:

      ```
      500,000 files * 3 copies = 1,500,000 files
      ```

   b. Calculate the number of archive files. For example, as many as 100,000 client files might be archived copies.
   c. Calculate the number of space-managed files. For example, as many as 200,000 client files might be migrated from client workstations.

   Using 1000 bytes per file, the total amount of database space that is required for the files that belong to the client is 1.8 GB:

   ```
   (1,500,000 + 100,000 + 200,000) * 1000 = 1.8 GB
   ```

2. Calculate the number of cached files, copy storage-pool files, active-data pool files, and deduplicated files:
   a. Calculate the number of cached copies. For example, caching is enabled in a 5 GB disk storage pool. The high migration threshold of the pool is 90% and the low migration threshold of the pool is 70%. Thus, 20% of the disk pool, or 1 GB, is occupied by cached files.
   If the average file size is about 10 KB, approximately 100,000 files are in cache at any one time:

      ```
      100,000 files * 200 bytes = 19 MB
      ```

   b. Calculate the number of copy storage-pool files. All primary storage pools are backed up to the copy storage pool:

      ```
      (1,500,000 + 100,000 + 200,000) * 200 bytes = 343 MB
      ```

   c. Calculate the number of active storage-pool files. All the active client-backup data in primary storage pools is copied to the active-data storage pool. Assume that 500,000 versions of the 1,500,000 backup files in the primary storage pool are active:

      ```
      500,000 * 200 bytes = 95 MB
      ```

   d. Calculate the number of deduplicated files. Assume that a deduplicated storage pool contains 50,000 files:

      ```
      50,000 * 200 bytes = 10 MB
      ```

   Based on the preceding calculations, about 0.5 GB of extra database space is required for the client's cached files, copy storage-pool files, active-data pool files, and deduplicated files.
3. Calculate the amount of extra space that is required for database optimization. To provide optimal data access and management by the server, extra database space is required. The amount of extra database space is equal to 50% of the total space requirements for file objects.

```
(1.8 + 0.5) * 50% = 1.2 GB
```

4. Calculate the total amount of database space that is required for the client. The total is approximately 3.5 GB:

   ```
   1.8 + 0.5 + 1.2 = 3.5 GB
   ```

5. Calculate the total amount of database space that is required for all clients. If the client that was used in the preceding calculations is typical and you have 500 clients, for example, you can use the following calculation to estimate the total amount of database space that is required for all clients:

   ```
   500 * 3.5 = 1.7 TB
   ```

Results

Tip: In the preceding examples, the results are estimates. The actual size of the database might differ from the estimate because of factors such as the number of directories and the length of the path and file names. Periodically monitor your database and adjust its size as necessary.

What to do next

During normal operations, the IBM Spectrum Protect™ server might require temporary database space. This space is needed for the following reasons:

- To hold the results of sorting or ordering that are not already being kept and optimized in the database directly. The results are temporarily held in the database for processing.
- To give administrative access to the database through one of the following methods:
  - A DB2® open database connectivity (ODBC) client
  - An Oracle Java™ database connectivity (JDBC) client
  - Structured Query Language (SQL) to the server from an administrative-client command line

Consider using an extra 50 GB of temporary space for every 500 GB of space for file objects and optimization. See the guidelines in the following table. In the example that is used in the preceding step, a total of 1.7 TB of database space is required for file objects and optimization for 500 clients. Based on that calculation, 200 GB is required for temporary space. The total amount of required database space is 1.9 TB.

Database size	Minimum temporary-space requirement
< 500 GB	50 GB
≥ 500 GB and < 1 TB	100 GB
≥ 1 TB and < 1.5 TB	150 GB
≥ 1.5 and < 2 TB	200 GB
≥ 2 and < 3 TB	250 - 300 GB
≥ 3 and < 4 TB	350 - 400 GB

Linux: Estimating database space requirements based on storage pool capacity

To estimate database space requirements based on storage pool capacity, use a ratio of 1 - 5%. For example, if you require 200 TB of storage pool capacity, the size of your database is expected to be 2 - 10 TB. As a general rule, make your database as large as possible to prevent running out of space. If you run out of database space, server operations and client-store operations can fail.

Linux: The database manager and temporary space

The IBM Spectrum Protect™ server database manager manages and allocates system memory and disk space for the database. The amount of database space you require depends on the amount of system memory available and the server workload.

The database manager sorts data in a specific sequence, according to the SQL statement that you issue to request the data. Depending on the workload on the server, and if there is more data than the database manager can manage, the data (that is

ordered in sequence) is allocated to temporary disk space. Data is allocated to temporary disk space when there is a large result set. The database manager dynamically manages the memory that is used when data is allocated to temporary disk space.

For example, expiration processing can produce a large result set. If there is not enough system memory on the database to store the result set, some of the data is allocated to temporary disk space. During expiration processing, if a node or file space are selected that are too large to process, the database manager cannot sort the data in memory. The database manager must use temporary space to sort data.

To run database operations, consider adding more database space for the following scenarios:

- The database has a small amount of space and the server operation that requires temporary space uses the remaining free space.
- The file spaces are large, or the file spaces have an assigned policy that creates many file versions.
- The IBM Spectrum Protect server must run with limited memory. The database uses the IBM Spectrum Protect server main memory to run database operations. However, if there is insufficient memory available, the IBM Spectrum Protect server allocates temporary space on disk to the database. For example, if 10G of memory is available and database operations require 12G of memory, the database uses temporary space.
- An `out of database space` error is displayed when you deploy an IBM Spectrum Protect server. Monitor the server activity log for messages that are related to database space.

Important: Do not change the DB2 software that is installed with the IBM Spectrum Protect installation packages and fix packs. Do not install or upgrade to a different version, release, or fix pack, of DB2 software to avoid damage to the database.

Linux: Recovery log space requirements

In IBM Spectrum Protect™, the term *recovery log* comprises the active log, the archive log, the active log mirror, and the archive failover log. The amount of space that you require for the recovery log depends on various factors, including, for example, the amount of client activity with the server.

- Linux: Active and archive log space
  When you estimate space requirements for active and archive logs, include some extra space for contingencies such as occasional heavy workloads and failovers.
- Linux: Active-log mirror space
  The active log can be mirrored so that the mirrored copy can be used if the active log files cannot be read. There can be only one active log mirror.
- Linux: Archive-failover log space
  The archive failover log is used by the server if the archive log directory runs out of space.

Linux: Active and archive log space

When you estimate space requirements for active and archive logs, include some extra space for contingencies such as occasional heavy workloads and failovers.

In IBM Spectrum Protect™ servers V7.1 and later, the active log can be a maximum size of 512 GB. The archive log size is limited to the size of the file system that it is installed on.

Use the following general guidelines when you estimate the size of the active log:

- The suggested starting size for the active log is 16 GB.
- Ensure that the active log is at least large enough for the amount of concurrent activity that the server typically handles. As a precaution, try to anticipate the largest amount of work that the server manages at one time. Provision the active log with extra space that can be used if needed. Consider using 20% of extra space.
- Monitor used and available active log space. Adjust the size of the active log as needed, depending upon factors such as client activity and the level of server operations.
- Ensure that the directory that holds the active log is as large as, or larger than, the size of the active log. A directory that is larger than the active log can accommodate failovers, if they occur.
- Ensure that the file system that contains the active log directory has at least 8 GB of free space for temporary log movement requirements.

The suggested starting size for the archive log is 48 GB.

The archive log directory must be large enough to contain the log files that are generated since the previous full backup. For example, if you perform a full backup of the database every day, the archive log directory must be large enough to hold the log

files for all the client activity that occurs during 24 hours. To recover space, the server deletes obsolete archive log files after a full backup of the database. If the archive log directory becomes full and a directory for archive failover logs does not exist, log files remain in the active log directory. This condition can cause the active log directory to fill up and stop the server. When the server restarts, some of the existing active-log space is released.

After the server is installed, you can monitor archive log utilization and the space in the archive log directory. If the space in the archive log directory fills up, it can cause the following problems:

- The server is unable to perform full database backups. Investigate and resolve this problem.
- Other applications write to the archive log directory, exhausting the space that is required by the archive log. Do not share archive log space with other applications including other IBM Spectrum Protect servers. Ensure that each server has a separate storage location that is owned and managed by that specific server.

- Linux: Example: Estimating active and archive log sizes for basic client-store operations
  Basic client-store operations include backup, archive, and space management. Log space must be sufficient to handle all store transactions that are in progress at one time.
- Linux: Example: Estimating active and archive log sizes for clients that use multiple sessions
  If the client option RESOURCEUTILIZATION is set to a value that is greater than the default, the concurrent workload for the server increases.
- Linux: Example: Estimating active and archive log sizes for simultaneous write operations
  If client backup operations use storage pools that are configured for simultaneous write, the amount of log space that is required for each file increases.
- Linux: Example: Estimating active and archive log sizes for basic client store operations and server operations
  Migration of data in server storage, identification processes for data deduplication, reclamation, and expiration might run concurrently with client store operations. Administrative tasks such as administrative commands or SQL queries from administrative clients can also run concurrently with client store operations. Server operations and administrative tasks that run concurrently can increase the active log space that is required.
- Linux: Example: Estimating active and archive log sizes under conditions of extreme variation
  Problems with running out of active log space can occur if you have many transactions that complete quickly and some transactions that take much longer to complete. A typical case occurs when many workstation or file-server backup sessions are active and a few very large database server-backup sessions are active. If this situation applies to your environment, you might need to increase the size of the active log so that the work completes successfully.
- Linux: Example: Estimating archive log sizes with full database backups
  The IBM Spectrum Protect server deletes unnecessary files from the archive log only when a full database backup occurs. Consequently, when you estimate the space that is required for the archive log, you must also consider the frequency of full database backups.
- Linux: Example: Estimating active and archive log sizes for data deduplication operations
  If you deduplicate data, you must consider its effects on space requirements for active and archive logs.

Linux: Example: Estimating active and archive log sizes for basic client-store operations

Basic client-store operations include backup, archive, and space management. Log space must be sufficient to handle all store transactions that are in progress at one time.

To determine the sizes of the active and archive logs for basic client-store operations, use the following calculation:

```
number of clients  x  files stored during each transaction
  x  log space needed for each file
```

This calculation is used in the example in the following table.

Table 1. Basic client-store operations

Item	Example values	Description
Maximum number of client nodes that back up, archive, or migrate files concurrently at any time	300	The number of client nodes that back up, archive, or migrate files every night.
Files stored during each transaction	4096	The default value of the server option TXNGROUPMAX is 4096.

Item	Example values	Description
Log space that is required for each file	3053 bytes	The value of 3053 bytes for each file in a transaction represents the log bytes that are needed when backing up files from a Windows client where the file names are 12 - 120 bytes. This value is based on the results of tests performed under laboratory conditions. The tests consisted of backup-archive clients performing backup operations to a random-access disk (DISK) storage pool. DISK pools result in more log use than sequential-access storage pools. Consider a value larger than 3053 bytes if the data being stored has file names that are longer than 12 - 120 bytes.
Active log: Suggested size	19.5 GB [1]	Use the following calculation to determine the size of the active log. One GB equals 1,073,741,824 bytes. `(300 clients x 4096 files stored during each transaction x 3053 bytes for each file) ÷ 1,073,741,824 bytes = 3.5 GB` Increase that amount by the suggested starting size of 16 GB: `3.5 + 16 = 19.5 GB`
Archive log: Suggested size	58.5 GB [1]	Because of the requirement to be able to store archive logs across three server database-backup cycles, multiply the estimate for the active log by 3 to estimate the total archive log requirement. `3.5 x 3 = 10.5 GB` Increase that amount by the suggested starting size of 48 GB: `10.5 + 48 = 58.5 GB`
[1] The example values in this table are used only to illustrate how the sizes for active logs and archive logs are calculated. In a production environment that does not use deduplication, 16 GB is the suggested minimum size for an active log. The suggested minimum size for an archive log in a production environment that does not use deduplication is 48 GB. If you substitute values from your environment and the results are larger than 16 GB and 48 GB, use your results to size the active log and archive log. Monitor your logs and adjust their size if necessary.		

Linux: Example: Estimating active and archive log sizes for clients that use multiple sessions

If the client option RESOURCEUTILIZATION is set to a value that is greater than the default, the concurrent workload for the server increases.

To determine the sizes of the active and archive logs when clients use multiple sessions, use the following calculation:

```
number of clients  x  sessions for each client  x  files stored
  during each transaction  x  log space needed for each file
```

This calculation is used in the example in the following table.

Table 1. Multiple client sessions

Item	Example values		Description
Maximum number of client nodes that back up, archive, or migrate files concurrently at any time	300	1000	The number of client nodes that back up, archive, or migrate files every night.

Item	Example values		Description
Possible sessions for each client	3	3	The setting of the client option RESOURCEUTILIZATION is larger than the default. Each client session runs a maximum of three sessions in parallel.
Files stored during each transaction	4096	4096	The default value of the server option TXNGROUPMAX is 4096.
Log space that is required for each file	3053	3053	The value of 3053 bytes for each file in a transaction represents the log bytes needed when backing up files from a Windows client where the file names are 12 - 120 bytes. This value is based on the results of tests performed under laboratory conditions. Tests consisted of clients performing backup operations to a random-access disk (DISK) storage pool. DISK pools result in more log use than sequential-access storage pools. Consider a value larger than 3053 bytes if the data being stored has file names that are longer than 12 - 120 bytes.
Active log: Suggested size	26.5 GB [1]	51 GB [1]	The following calculation was used for 300 clients. One GB equals 1,073,741,824 bytes. `(300 clients x 3 sessions for each client x 4096 files stored during each transaction x 3053 bytes for each file) ÷ 1,073,741,824 = 10.5 GB` Increase that amount by the suggested starting size of 16 GB: `10.5 + 16 = 26.5 GB` The following calculation was used for 1000 clients. One GB equals 1,073,741,824 bytes. `(1000 clients x 3 sessions for each client x 4096 files store during each transaction x 3053 bytes for each file) ÷ 1,073,741,824 = 35 GB` Increase that amount by the suggested starting size of 16 GB: `35 + 16 = 51 GB`
Archive log: Suggested size	79.5 GB [1]	153 GB [1]	Because of the requirement to be able to store archive logs across three server-database backup cycles, the estimate for the active log is multiplied by 3: `10.5 x 3 = 31.5 GB` `35 x 3 = 105 GB` Increase those amounts by the suggested starting size of 48 GB: `31.5 + 48 = 79.5 GB` `105 + 48 = 153 GB`

[1] The example values in this table are used only to illustrate how the sizes for active logs and archive logs are calculated. In a production environment that does not use deduplication, 16 GB is the suggested minimum size for an active log. The suggested minimum size for an archive log in a production environment that does not use deduplication is 48 GB. If you substitute values from your environment and the results are larger than 16 GB and 48 GB, use your results to size the active log and archive log.

Monitor your active log and adjust its size if necessary.

Linux: Example: Estimating active and archive log sizes for simultaneous write operations

If client backup operations use storage pools that are configured for simultaneous write, the amount of log space that is required for each file increases.

The log space that is required for each file increases by about 200 bytes for each copy storage pool that is used for a simultaneous write operation. In the example in the following table, data is stored to two copy storage pools in addition to a primary storage pool. The estimated log size increases by 400 bytes for each file. If you use the suggested value of 3053 bytes of log space for each file, the total number of required bytes is 3453.

This calculation is used in the example in the following table.

Table 1. Simultaneous write operations

Item	Example values	Description
Maximum number of client nodes that back up, archive, or migrate files concurrently at any time	300	The number of client nodes that back up, archive, or migrate files every night.
Files stored during each transaction	4096	The default value of the server option TXNGROUPMAX is 4096.
Log space that is required for each file	3453 bytes	3053 bytes plus 200 bytes for each copy storage pool. The value of 3053 bytes for each file in a transaction represents the log bytes that are needed when backing up files from a Windows client where the file names are 12 - 120 bytes. This value is based on the results of tests performed under laboratory conditions. The tests consisted of backup-archive clients performing backup operations to a random-access disk (DISK) storage pool. DISK pools result in more log use than sequential-access storage pools. Consider a value larger than 3053 bytes if the data being stored has file names that are longer than 12 - 120 bytes.
Active log: Suggested size	20 GB [1]	Use the following calculation to determine the size of the active log. One GB equals 1,073,741,824 bytes. `(300 clients x 4096 files stored during each transaction x 3453 bytes for each file) ÷ 1,073,741,824 bytes = 4.0 GB` Increase that amount by the suggested starting size of 16 GB: `4 + 16 = 20 GB`
Archive log: Suggested size	60 GB [1]	Because of the requirement to be able to store archive logs across three server database-backup cycles, multiply the estimate for the active log by 3 to estimate the archive log requirement: `4 GB x 3 = 12 GB` Increase that amount by the suggested starting size of 48 GB: `12 + 48 = 60 GB`

[1] The example values in this table are used only to illustrate how the sizes for active logs and archive logs are calculated. In a production environment that does not use deduplication, 16 GB is the suggested minimum size for an active log. The suggested minimum size for an archive log in a production environment that does not use deduplication is 48 GB. If you substitute values from your environment and the results are larger than 16 GB and 48 GB, use your results to size the active log and archive log.

Monitor your logs and adjust their size if necessary.

Linux: Example: Estimating active and archive log sizes for basic client store operations and server operations

Migration of data in server storage, identification processes for data deduplication, reclamation, and expiration might run concurrently with client store operations. Administrative tasks such as administrative commands or SQL queries from administrative clients can also run concurrently with client store operations. Server operations and administrative tasks that run concurrently can increase the active log space that is required.

For example, migration of files from the random-access (DISK) storage pool to a sequential-access disk (FILE) storage pool uses approximately 110 bytes of log space for each file that is migrated. For example, suppose that you have 300 backup-archive clients and each one of them backs up 100,000 files every night. The files are initially stored on DISK and then migrated to a FILE storage pool. To estimate the amount of active log space that is required for the data migration, use the following calculation. The number of clients in the calculation represents the maximum number of client nodes that back up, archive, or migrate files concurrently at any time.

```
300 clients  x 100,000 files for each client   x  110 bytes =  3.1 GB
```

Add this value to the estimate for the size of the active log that calculated for basic client store operations.

Linux: Example: Estimating active and archive log sizes under conditions of extreme variation

Problems with running out of active log space can occur if you have many transactions that complete quickly and some transactions that take much longer to complete. A typical case occurs when many workstation or file-server backup sessions are active and a few very large database server-backup sessions are active. If this situation applies to your environment, you might need to increase the size of the active log so that the work completes successfully.

Linux: Example: Estimating archive log sizes with full database backups

The IBM Spectrum Protect™ server deletes unnecessary files from the archive log only when a full database backup occurs. Consequently, when you estimate the space that is required for the archive log, you must also consider the frequency of full database backups.

For example, if a full database backup occurs once a week, the archive log space must be able to contain the information in the archive log for a full week.

The difference in archive log size for daily and full database backups is shown in the example in the following table.

Table 1. Full database backups

Item	Example values	Description
Maximum number of client nodes that back up, archive, or migrate files concurrently at any time	300	The number of client nodes that back up, archive, or migrate files every night.
Files stored during each transaction	4096	The default value of the server option TXNGROUPMAX is 4096.
Log space that is required for each file	3453 bytes	3053 bytes for each file plus 200 bytes for each copy storage pool. The value of 3053 bytes for each file in a transaction represents the log bytes needed when backing up files from a Windows client where the file names are 12 - 120 bytes. This value is based on the results of tests performed under laboratory conditions. Tests consisted of clients performing backup operations to a random-access disk (DISK) storage pool. DISK pools result in more log use than sequential-access storage pools. Consider a value larger than 3053 bytes if the data being stored has file names that are longer than 12 - 120 bytes.
Active log: Suggested size	20 GB [1]	Use the following calculation to determine the size of the active log. One GB equals 1,073,741,824 bytes. `(300 clients x 4096 files per transaction x 3453 bytes per file) ÷ 1,073,741,824 bytes = 4.0 GB` Increase that amount by the suggested starting size of 16 GB: `4 + 16 = 20 GB`

Item	Example values	Description
Archive log: Suggested size with a full database backup every day	60 GB [1]	Because of the requirement to be able to store archive logs across three backup cycles, multiply the estimate for the active log by 3 to estimate the total archive log requirement: `4 GB x 3 = 12 GB` Increase that amount by the suggested starting size of 48 GB: `12 + 48 = 60 GB`
Archive log: Suggested size with a full database every week	132 GB [1]	Because of the requirement to be able to store archive logs across three server database-backup cycles, multiply the estimate for the active log by 3 to estimate the total archive log requirement. Multiply the result by the number of days between full database backups: `(4 GB x 3 ) x 7 = 84 GB` Increase that amount by the suggested starting size of 48 GB: `84 + 48 = 132 GB`
[1] The example values in this table are used only to illustrate how the sizes for active logs and archive logs are calculated. In a production environment that does not use deduplication, 16 GB is the suggested minimum size for an active log. The suggested starting size for an archive log in a production environment that does not use deduplication is 48 GB. If you substitute values from your environment and the results are larger than 16 GB and 48 GB, use your results to size the active log and archive log. Monitor your logs and adjust their size if necessary.		

Linux: Example: Estimating active and archive log sizes for data deduplication operations

If you deduplicate data, you must consider its effects on space requirements for active and archive logs.

The following factors affect requirements for active and archive log space:

The amount of deduplicated data

The effect of data deduplication on the active log and archive log space depends on the percentage of data that is eligible for deduplication. If the percentage of data that can be deduplicated is relatively high, more log space is required.

The size and number of extents

Approximately 1,500 bytes of active log space are required for each extent that is identified by a duplicate-identification process. For example, if 250,000 extents are identified by a duplicate-identification process, the estimated size of the active log is 358 MB:

```
250,000 extents identified during each process x 1,500 bytes
 for each extent = 358 MB
```

Consider the following scenario. Three hundred backup-archive clients back up 100,000 files each night. This activity creates a workload of 30,000,000 files. The average number of extents for each file is two. Therefore, the total number of extents is 60,000,000, and the space requirement for the archive log is 84 GB:

```
60,000,000 extents x 1,500 bytes for each extent = 84 GB
```

A duplicate-identification process operates on aggregates of files. An aggregate consists of files that are stored in a given transaction, as specified by the TXNGROUPMAX server option. Suppose that the TXNGROUPMAX server option is set to the default of 4096. If the average number of extents for each file is two, the total number of extents in each aggregate is 8192, and the space required for the active log is 12 MB:

```
8192 extents in each aggregate x 1500 bytes for each extent =
   12 MB
```

The timing and number of the duplicate-identification processes

The timing and number of duplicate-identification processes also affects the size of the active log. Using the 12 MB active-log size that was calculated in the preceding example, the concurrent load on the active log is 120 MB if 10 duplicate-identification processes are running in parallel:

```
12 MB for each process x 10 processes = 120 MB
```

File size

Large files that are processed for duplicate identification can also affect the size of the active log. For example, suppose that a backup-archive client backs up an 80 GB, file-system image. This object can have a high number of duplicate extents if, for example, the files included in the file system image were backed up incrementally. For example, assume that a file system image has 1.2 million duplicate extents. The 1.2 million extents in this large file represent a single transaction for a duplicate-identification process. The total space in the active log that is required for this single object is 1.7 GB:

```
1,200,000 extents x 1,500 bytes for each extent = 1.7 GB
```

If other, smaller duplicate-identification processes occur at the same time as the duplicate-identification process for a single large object, the active log might not have enough space. For example, suppose that a storage pool is enabled for deduplication. The storage pool has a mixture of data, including many relatively small files that range from 10 KB to several hundred KB. The storage pool also has few large objects that have a high percentage of duplicate extents.

To take into account not only space requirements but also the timing and duration of concurrent transactions, increase the estimated size of the active log by a factor of two. For example, suppose that your calculations for space requirements are 25 GB (23.3 GB + 1.7 GB for deduplication of a large object). If deduplication processes are running concurrently, the suggested size of the active log is 50 GB. The suggested size of the archive log is 150 GB.

The examples in the following tables show calculations for active and archive logs. The example in the first table uses an average size of 700 KB for extents. The example in the second table uses an average size of 256 KB. As the examples show, the average deduplicate-extent size of 256 KB indicates a larger estimated size for the active log. To minimize or prevent operational problems for the server, use 256 KB to estimate the size of the active log in your production environment.

Table 1. Average duplicate-extent size of 700 KB

Item	Example values		Description
Size of largest single object to deduplicate	800 GB	4 TB	The granularity of processing for deduplication is at the file level. Therefore, the largest single file to deduplicate represents the largest transaction and a correspondingly large load on the active and archive logs.
Average size of extents	700 KB	700 KB	The deduplication algorithms use a variable block method. Not all deduplicated extents for a given file are the same size, so this calculation assumes an average size for extents.
Extents for a given file	1,198,372 bits	6,135,667 bits	Using the average extent size (700 KB), these calculations represent the total number of extents for a given object. The following calculation was used for an 800 GB object: `(800 GB ÷ 700 KB) = 1,198,372 bits` The following calculation was used for a 4 TB object: `(4 TB ÷ 700 KB) = 6,135,667 bits`
Active log: Suggested size that is required for the deduplication of a single large object during a single duplicate-identification process	1.7 GB	8.6 GB	The estimated active log space that are needed for this transaction.

Item	Example values		Description
Active log: Suggested total size	66 GB [1]	79.8 GB [1]	After considering other aspects of the workload on the server in addition to deduplication, multiply the existing estimate by a factor of two. In these examples, the active log space required to deduplicate a single large object is considered along with previous estimates for the required active log size. The following calculation was used for multiple transactions and an 800 GB object: `(23.3 GB + 1.7 GB) x 2 = 50 GB` Increase that amount by the suggested starting size of 16 GB: `50 + 16 = 66 GB` The following calculation was used for multiple transactions and a 4 TB object: `(23.3 GB + 8.6 GB) x 2 = 63.8 GB` Increase that amount by the suggested starting size of 16 GB: `63.8 + 16 = 79.8 GB`
Archive log: Suggested size	198 GB [1]	239.4 GB [1]	Multiply the estimated size of the active log by a factor of 3. The following calculation was used for multiple transactions and an 800 GB object: `50 GB x 3 = 150 GB` Increase that amount by the suggested starting size of 48 GB: `150 + 48 = 198 GB` The following calculation was used for multiple transactions and a 4 TB object: `63.8 GB x 3 = 191.4 GB` Increase that amount by the suggested starting size of 48 GB: `191.4 + 48 = 239.4 GB`
[1] The example values in this table are used only to illustrate how the sizes for active logs and archive logs are calculated. In a production environment that uses deduplication, 32 GB is the suggested minimum size for an active log. The suggested minimum size for an archive log in a production environment that uses deduplication is 96 GB. If you substitute values from your environment and the results are larger than 32 GB and 96 GB, use your results to size the active log and archive log. Monitor your logs and adjust their size if necessary.			

Table 2. Average duplicate-extent size of 256 KB

Item	Example values		Description
Size of largest single object to deduplicate	800 GB	4 TB	The granularity of processing for deduplication is at the file level. Therefore, the largest single file to deduplicate represents the largest transaction and a correspondingly large load on the active and archive logs.

Item	Example values		Description
Average size of extents	256 KB	256 KB	The deduplication algorithms use a variable block method. Not all deduplicated extents for a given file are the same size, so this calculation assumes an average extent size.
Extents for a given file	3,276,800 bits	16,777,216 bits	Using the average extent size, these calculations represent the total number of extents for a given object. The following calculation was used for multiple transactions and an 800 GB object: `(800 GB ÷ 256 KB) = 3,276,800 bits` The following calculation was used for multiple transactions and a 4 TB object: `(4 TB ÷ 256 KB) = 16,777,216 bits`
Active log: Suggested size that is required for the deduplication of a single large object during a single duplicate-identification process	4.5 GB	23.4 GB	The estimated size of the active log space that is required for this transaction.
Active log: Suggested total size	71.6 GB [1]	109.4 GB [1]	After considering other aspects of the workload on the server in addition to deduplication, multiply the existing estimate by a factor of 2. In these examples, the active log space required to deduplicate a single large object is considered along with previous estimates for the required active log size. The following calculation was used for multiple transactions and an 800 GB object: `(23.3 GB + 4.5 GB) x 2 = 55.6 GB` Increase that amount by the suggested starting size of 16 GB: `55.6 + 16 = 71.6 GB` The following calculation was used for multiple transactions and a 4 TB object: `(23.3 GB + 23.4 GB) x 2 = 93.4 GB` Increase that amount by the suggested starting size of 16 GB: `93.4 + 16 = 109.4 GB`

Item	Example values		Description
Archive log: Suggested size	214.8 GB [1]	328.2 GB [1]	The estimated size of the active log multiplied by a factor of 3. The following calculation was used for an 800 GB object: `55.6 GB x 3 = 166.8 GB` Increase that amount by the suggested starting size of 48 GB: `166.8 + 48 = 214.8 GB` The following calculation was used for a 4 TB object: `93.4 GB x 3 = 280.2 GB` Increase that amount by the suggested starting size of 48 GB: `280.2 + 48 = 328.2 GB`
[1] The example values in this table are used only to illustrate how the sizes for active logs and archive logs are calculated. In a production environment that uses deduplication, 32 GB is the suggested minimum size for an active log. The suggested minimum size for an archive log in a production environment that uses deduplication is 96 GB. If you substitute values from your environment and the results are larger than 32 GB and 96 GB, use your results to size the active log and archive log. Monitor your logs and adjust their size if necessary.			

Linux: Active-log mirror space

The active log can be mirrored so that the mirrored copy can be used if the active log files cannot be read. There can be only one active log mirror.

Creating a log mirror is a suggested option. If you increase the size of the active log, the log mirror size is increased automatically. Mirroring the log can affect performance because of the doubled I/O activity that is required to maintain the mirror. The additional space that the log mirror requires is another factor to consider when deciding whether to create a log mirror.

If the mirror log directory becomes full, the server issues error messages to the activity log and to the db2diag.log. Server activity continues.

Linux: Archive-failover log space

The archive failover log is used by the server if the archive log directory runs out of space.

Specifying an archive failover log directory can prevent problems that occur if the archive log runs out of space. If both the archive log directory and the drive or file system where the archive failover log directory is located become full, the data remains in the active log directory. This condition can cause the active log to fill up, which causes the server to halt.

Linux: Monitoring space utilization for the database and recovery logs

To determine the amount of used and available active log space, you issue the QUERY LOG command. To monitor space utilization in the database and recovery logs, you can also check the activity log for messages.

Active log

If the amount of available active log space is too low, the following messages are displayed in the activity log:

ANR4531I: IC_AUTOBACKUP_LOG_USED_SINCE_LAST_BACKUP_TRIGGER
: This message is displayed when the active log space exceeds the maximum specified size. The IBM Spectrum Protect™ server starts a full database backup.

To change the maximum log size, halt the server. Open the dsmserv.opt file, and specify a new value for the ACTIVELOGSIZE option. When you are finished, restart the server.

ANR0297I: IC_BACKUP_NEEDED_LOG_USED_SINCE_LAST_BACKUP
This message is displayed when the active log space exceeds the maximum specified size. You must back up the database manually.

To change the maximum log size, halt the server. Open the dsmserv.opt file, and specify a new value for the ACTIVELOGSIZE option. When you are finished, restart the server.

ANR4529I: IC_AUTOBACKUP_LOG_UTILIZATION_TRIGGER
The ratio of used active-log space to available active-log space exceeds the log utilization threshold. If at least one full database backup has occurred, the IBM Spectrum Protect server starts an incremental database backup. Otherwise, the server starts a full database backup.

ANR0295I: IC_BACKUP_NEEDED_LOG_UTILIZATION
The ratio of used active-log space to available active-log space exceeds the log utilization threshold. You must back up the database manually.

Archive log

If the amount of available archive log space is too low, the following message is displayed in the activity log:

ANR0299I: IC_BACKUP_NEEDED_ARCHLOG_USED
The ratio of used archive-log space to available archive-log space exceeds the log utilization threshold. The IBM Spectrum Protect server starts a full automatic database backup.

Database

If the amount of space available for database activities is too low, the following messages are displayed in the activity log:

ANR2992W: IC_LOG_FILE_SYSTEM_UTILIZATION_WARNING_2
The used database space exceeds the threshold for database space utilization. To increase the space for the database, use the EXTEND DBSPACE command, the EXTEND DBSPACE command, or the DSMSERV FORMAT utility with the DBDIR parameter.

ANR1546W: FILESYSTEM_DBPATH_LESS_1GB
The available space in the directory where the server database files are located is less than 1 GB.

When an IBM Spectrum Protect server is created with the DSMSERV FORMAT utility or with the configuration wizard, a server database and recovery log are also created. In addition, files are created to hold database information used by the database manager. The path specified in this message indicates the location of the database information used by the database manager. If space is unavailable in the path, the server can no longer function.

You must add space to the file system or make space available on the file system or disk.

Linux: Deleting installation rollback files

You can delete certain installation files that were saved during the installation process to free space in the shared resource directory. For example, files that might have been required for a rollback operation are types of files that you can delete.

About this task

To delete the files that are no longer needed, use either the installation graphical wizard or the command line in console mode.

- Linux: Deleting installation rollback files by using a graphical wizard
  You can delete certain installation files that were saved during installation process by using the IBM® Installation Manager user interface.
- Linux: Deleting installation rollback files by using the command line
  You can delete certain installation files that were saved during the installation process by using the command line.

Linux: Deleting installation rollback files by using a graphical wizard

You can delete certain installation files that were saved during installation process by using the IBM® Installation Manager user interface.

Procedure

1. Open IBM Installation Manager.
   Linux In the directory where IBM Installation Manager is installed, go to the eclipse subdirectory (for example, /opt/IBM/InstallationManager/eclipse), and issue the following command to start IBM Installation Manager:

   ```
   ./IBMIM
   ```

2. Click File > Preferences.
3. Select Files for Rollback.
4. Click Delete Saved Files and click OK.

Linux: Deleting installation rollback files by using the command line

You can delete certain installation files that were saved during the installation process by using the command line.

Procedure

1. In the directory where IBM® Installation Manager is installed, go to the following subdirectory:
   - Linux eclipse/tools

   For example:

   - Linux /opt/IBM/InstallationManager/eclipse/tools
2. From the tools directory, issue the following command to start an IBM Installation Manager command line:
   - Linux `./imcl -c`
3. Enter `P` to select Preferences.
4. Enter `3` to select Files for Rollback.
5. Enter `D` to Delete the Files for Rollback.
6. Enter `A` to Apply Changes and Return to Preferences Menu.
7. Enter `C` to leave the Preference Menu.
8. Enter `X` to Exit Installation Manager.

Linux: Server naming best practices

Use these descriptions as a reference when you install or upgrade an IBM Spectrum Protect™ server.

Instance user ID

The instance user ID is used as the basis for other names related to the server instance. The instance user ID is also called the instance owner.

For example: tsminst1

The instance user ID is the user ID that must have ownership or read/write access authority to all directories that you create for the database and the recovery log. The standard way to run the server is under the instance user ID. That user ID must also have read/write access to the directories that are used for any FILE device classes.

Linux

Home directory for the instance user ID

The home directory can be created when creating the instance user ID, by using the option (-m) to create a home directory if it does not exist already. Depending on local settings, the home directory might have the form: /home/*instance_user_ID*

For example: /home/tsminst1

The home directory is primarily used to contain the profile for the user ID and for security settings.

Linux

Database instance name

The database instance name must be the same as the instance user ID under which you run the server instance.

For example: tsminst1

Linux

Instance directory

The instance directory is a directory that contains files specifically for a server instance (the server options file and other server-specific files). It can have any name that you want. For easier identification, use a name that ties the directory to the instance name.

You can create the instance directory as a subdirectory of the home directory for the instance user ID. For example: /home/*instance_user_ID*/*instance_user_ID*

The following example places the instance directory in the home directory for user ID tsminst1: /home/tsminst1/tsminst1

You can also create the directory in another location, for example: /tsmserver/tsminst1

The instance directory stores the following files for the server instance:

- The server options file, dsmserv.opt
- The server key database file, `cert.kdb`, and the `.arm` files (used by clients and other servers to import the Secure Sockets Layer certificates of the server)
- Device configuration file, if the DEVCONFIG server option does not specify a fully qualified name
- Volume history file, if the VOLUMEHISTORY server option does not specify a fully qualified name
- Volumes for DEVTYPE=FILE storage pools, if the directory for the device class is not fully specified, or not fully qualified
- User exits
- Trace output (if not fully qualified)

Database name

The database name is always TSMDB1, for every server instance. This name cannot be changed.

Server name

The server name is an internal name for IBM Spectrum Protect, and is used for operations that involve communication among multiple IBM Spectrum Protect servers. Examples include server-to-server communication and library sharing.

Linux The server name is also used when you add the server to the Operations Center so that it can be managed using that interface. Use a unique name for each server. For easy identification in the Operations Center (or from a QUERY SERVER command), use a name that reflects the location or purpose of the server. Do not change the name of an IBM Spectrum Protect server after it is configured as a hub or spoke server.

If you use the wizard, the default name that is suggested is the host name of the system that you are using. You can use a different name that is meaningful in your environment. If you have more than one server on the system and you use the wizard, you can use the default name for only one of the servers. You must enter a unique name for each server.

Linux For example:

- `PAYROLL`
- `SALES`

Directories for database space and recovery log

The directories can be named according to local practices. For easier identification, consider using names that tie the directories to the server instance.

For example, for the archive log:

- Linux /tsminst1_archlog

Linux: Installation directories

Installation directories for the IBM Spectrum Protect™ server include the server, DB2®, device, language, and other directories. Each one contains several additional directories.

The (/opt/tivoli/tsm/server/bin) is the default directory that contains server code and licensing.

The DB2 product that is installed as part of the installation of the IBM Spectrum Protect server has the directory structure as documented in DB2 information sources. Protect these directories and files as you do the server directories. The default directory is /opt/tivoli/tsm/db2.

You can use US English, German, French, Italian, Spanish, Brazilian Portuguese, Korean, Japanese, traditional Chinese, simplified Chinese, Chinese GBK, Chinese Big5, and Russian.

Linux: Installing the server components

To install the Version 8.1.2 server components, you can use the installation wizard, the command line in console mode, or silent mode.

About this task

Using the IBM Spectrum Protect™ installation software, you can install the following components:

- server
  Tip: The database (DB2®), the Global Security Kit (GSKit) and IBM® Java™ Runtime Environment (JRE) are automatically installed when you select the server component.
- server languages
- license
- devices
- IBM Spectrum Protect for SAN
- Operations Center

Linux Allow approximately 30 - 45 minutes to install a V8.1.2 server, using this guide.

- Linux: Obtaining the installation package
  You can obtain the IBM Spectrum Protect installation package from an IBM download site such as Passport Advantage® or IBM Fix Central.
- Linux: Installing IBM Spectrum Protect by using the installation wizard
  You can install the server by using the IBM Installation Manager graphical wizard.
- Linux: Installing IBM Spectrum Protect by using console mode
  You can install IBM Spectrum Protect by using the command line in console mode.
- Linux: Installing IBM Spectrum Protect in silent mode
  You can install or upgrade the server in silent mode. In silent mode, the installation does not send messages to a console but instead stores messages and errors in log files.
- Linux: Installing server language packages
  Translations for the server allow the server to display messages and help in languages other than US English. The translations also allow for the use of locale conventions for date, time, and number formatting.

Linux: Obtaining the installation package

You can obtain the IBM Spectrum Protect™ installation package from an IBM® download site such as Passport Advantage® or IBM Fix Central.

Linux

Before you begin

If you plan to download the files, set the system user limit for maximum file size to unlimited to ensure that the files can be downloaded correctly:

1. To query the maximum file size value, issue the following command:

```
ulimit -Hf
```

2. If the system user limit for maximum file size is not set to unlimited, change it to unlimited by following the instructions in the documentation for your operating system.

Procedure

1. Download the appropriate package file from one of the following websites.
   - Download the server package from Passport Advantage or Fix Central.
   - For the latest information, updates, and maintenance fixes, go to the IBM Support Portal.
2. If you downloaded the package from an IBM download site, complete the following steps:
   Linux
   a. Verify that you have enough space to store the installation files when they are extracted from the product package. See the download document for the space requirements:
      - IBM Spectrum Protect technote 4042944
      - IBM Spectrum Protect Extended Edition technote 4042945
      - IBM Spectrum Protect for Data Retention technote 4042946

   b. Download the package file to the directory of your choice. The path must contain no more than 128 characters. Be sure to extract the installation files to an empty directory. Do not extract to a directory that contains previously extracted files, or any other files.
   c. Ensure that executable permission is set for the package. If necessary, change the file permissions by issuing the following command:

      ```
      chmod a+x package_name.bin
      ```

   d. Extract the package by issuing the following command:

      ```
      ./package_name.bin
      ```

      where *package_name* is the name of the downloaded file, for example:

      Linux

      ```
      8.1.x.000-IBM-SPSRV-Linuxx86_64.bin
      8.1.x.000-IBM-SPSRV-Linuxs390x.bin
      8.1.x.000-IBM-SPSRV-Linuxppc64le.bin
      ```

3. Select one of the following methods of installing IBM Spectrum Protect:
   - Linux: Installing IBM Spectrum Protect by using the installation wizard
   - Linux: Installing IBM Spectrum Protect by using console mode
   - Linux: Installing IBM Spectrum Protect in silent mode
4. After you install IBM Spectrum Protect, and before you customize it for your use, go to the IBM Support Portal. Click Support and downloads and apply any applicable fixes.

Linux: Installing IBM Spectrum Protect by using the installation wizard

You can install the server by using the IBM® Installation Manager graphical wizard.

Before you begin

Take the following actions before you start the installation:

- Verify that the operating system is set to the language that you require. By default, the language of the operating system is the language of the installation wizard.

Procedure

Install IBM Spectrum Protect™ by using this method:

Option	Description

Option	Description
Installing the software from a downloaded package:	a. Change to the directory where you downloaded the package. b. Start the installation wizard by issuing the following command: Linux `./install.sh`

What to do next

- If errors occur during the installation process, the errors are recorded in log files that are stored in the IBM Installation Manager logs directory.

  You can view installation log files by clicking File > View Log from the Installation Manager tool. To collect these log files, click Help > Export Data for Problem Analysis from the Installation Manager tool.

- After you install the server and components, and before you customize it for your use, go to the IBM Support Portal. Click Downloads (fixes and PTFs) and apply any applicable fixes.

- Linux After you install a new server, review Taking the first steps after you install IBM Spectrum Protect to learn about configuring your server.

Linux: Installing IBM Spectrum Protect by using console mode

You can install IBM Spectrum Protect™ by using the command line in console mode.

Before you begin

Take the following actions before you start the installation:

- Verify that the operating system is set to the language that you require. By default, the language of the operating system is the language of the installation wizard.

Procedure

Install IBM Spectrum Protect by using this method:

Option	Description
Installing the software from a downloaded package:	a. Change to the directory where you downloaded the package. b. Start the installation wizard in console mode by issuing the following command: Linux `./install.sh -c` Optional: Generate a response file as part of a console mode installation. Complete the console mode installation options, and in the Summary panel, specify `G` to generate the responses.

What to do next

- If errors occur during the installation process, the errors are recorded in log files that are stored in the IBM® Installation Manager logs directory, for example:
  - Linux /var/ibm/InstallationManager/logs
- After you install the server and components, and before you customize it for your use, go to the IBM Support Portal. Click Downloads (fixes and PTFs) and apply any applicable fixes.
- Linux After you install a new server, review Taking the first steps after you install IBM Spectrum Protect to learn about configuring your server.

Linux: Installing IBM Spectrum Protect in silent mode

You can install or upgrade the server in silent mode. In silent mode, the installation does not send messages to a console but instead stores messages and errors in log files.

Before you begin

To provide data input when you use the silent installation method, you can use a response file. The following sample response files are provided in the input directory where the installation package is extracted:

install_response_sample.xml
: Use this file to install the IBM Spectrum Protect™ components.

update_response_sample.xml
: Use this file to upgrade the IBM Spectrum Protect components.

These files contain default values that can help you avoid any unnecessary warnings. To use these files, follow the instructions that are provided in the files.

If you want to customize a response file, you can modify the options that are in the file. For information about response files, see Response files.

Procedure

1. Create a response file. You can modify the sample response file or create your own file.
2. If you install the server and Operations Center in silent mode, create a password for the Operations Center truststore in the response file.
   If you are using the install_response_sample.xml file, add the password in the following line of the file, where *mypassword* represents the password:

   ```
   <variable name='ssl.password' value='mypassword' />
   ```

   For more information about this password, see Installation checklist
   Tip: To upgrade the Operations Center, the truststore password is not required if you are using the update_response_sample.xml file.
3. Start the silent installation by issuing the following command from the directory where the installation package is extracted. The value *response_file* represents the response file path and file name:
   - Linux

     ```
     ./install.sh -s -input response_file -acceptLicense
     ```

What to do next

- If errors occur during the installation process, the errors are recorded in log files that are stored in the IBM® Installation Manager logs directory, for example:
  - Linux /var/ibm/InstallationManager/logs
- After you install the server and components, and before you customize it for your use, go to the IBM Support Portal. Click Downloads (fixes and PTFs) and apply any applicable fixes.
- Linux After you install a new server, review Taking the first steps after you install IBM Spectrum Protect to learn about configuring your server.

Linux

Linux: Installing server language packages

Translations for the server allow the server to display messages and help in languages other than US English. The translations also allow for the use of locale conventions for date, time, and number formatting.

Before you begin

For instructions on installing storage agent language packages, see Language pack configuration for storage agents.

- Linux: Server language locales
  Use either the default language package option or select another language package to display server messages and help.
- Linux: Configuring a language package
  After you configure a language package, messages and help are shown on the server in languages other than US English. Installation packages are provided with IBM Spectrum Protect™.
- Linux: Updating a language package
  You can modify or update a language package by using the IBM® Installation Manager.

Linux: Server language locales

Use either the default language package option or select another language package to display server messages and help.

Linux This language package is automatically installed for the following default language option for IBM Spectrum Protect™ server messages and help:

- Linux LANGUAGE en_US

For languages or locales other than the default, install the language package that your installation requires.
You can use the languages that are shown:
Linux

Table 1. Server languages for Linux

LANGUAGE	LANGUAGE option value
Chinese, Simplified	zh_CN
	zh_CN.gb18030
	zh_CN.utf8
Chinese, Traditional	Big5 / Zh_TW
	zh_TW
	zh_TW.utf8
English, United States	en_US
	en_US.utf8
French	fr_FR
	fr_FR.utf8
German	de_DE
	de_DE.utf8
Italian	it_IT
	it_IT.utf8
Japanese	ja_JP
	ja_JP.utf8
Korean	ko_KR
	ko_KR.utf8
Portuguese, Brazilian	pt_BR
	pt_BR.utf8
Russian	ru_RU
	ru_RU.utf8
Spanish	es_ES
	es_ES.utf8

Linux Restriction: For Operations Center users, some characters might not be displayed properly if the web browser does not use the same language as the server. If this problem occurs, set the browser to use the same language as the server.

Linux: Configuring a language package

After you configure a language package, messages and help are shown on the server in languages other than US English. Installation packages are provided with IBM Spectrum Protect™.

About this task

Linux To set support for a certain locale, complete one of the following tasks:

- Set the LANGUAGE option in the server options file to the name of the locale that you want to use. For example:
  - Linux To use the `it_IT` locale, set the LANGUAGE option to `it_IT`. See Linux: Server language locales.
- Linux If you are starting the server in the foreground, set the `LC_ALL` environment variable to match the value that is set in the server options file. For example, to set the environment variable for Italian, enter the following value:

  ```
  export LC_ALL=it_IT
  ```

If the locale is successfully initialized, it formats the date, time, and number for the server. If the locale is not successfully initialized, the server uses the US English message files and the date, time, and number format.

Linux: Updating a language package

You can modify or update a language package by using the IBM® Installation Manager.

About this task

You can install another language package within the same IBM Spectrum Protect™ instance.

- Use the Modify function of IBM Installation Manager to install another language package.
- Use the Update function of IBM Installation Manager to update to newer versions of the language packages.

Tip: In IBM Installation Manager, the term *update* means to discover and install updates and fixes to installed software packages. In this context, *update* and *upgrade* are synonymous.

Linux: Taking the first steps after you install IBM Spectrum Protect

After you install Version 8.1.2, prepare for the configuration. Using the configuration wizard is the preferred method of configuring the IBM Spectrum Protect™ instance.

About this task

1. Linux Update the kernel parameter values.

   Linux See Linux: Tuning kernel parameters for Linux systems.

2. Create the directories and user ID for the server instance. See Linux: Creating the user ID and directories for the server instance.
3. Configure a server instance. Select one of the following options:
   - Use the configuration wizard, the preferred method. See Linux: Configuring IBM Spectrum Protect by using the configuration wizard.
   - Manually configure the new instance. See Linux: Configuring the server instance manually. Complete the following steps during a manual configuration.
     a. Set up your directories and create the IBM Spectrum Protect instance. See Linux: Creating the server instance.
     b. Create a new server options file by copying the sample file to set up communications between the server and clients. See Linux Linux: Configuring server and client communications.
     c. Issue the DSMSERV FORMAT command to format the database. See Linux: Formatting the database and log.
     d. Configure your system for database backup. See Linux: Preparing the database manager for database backup.
4. Configure options to control when database reorganization runs. See Linux: Configuring server options for server database maintenance.
5. Start the server instance if it is not already started.
   - Linux See Linux: Starting the server instance.
6. Register your license. See Linux: Registering licenses.
7. Prepare your system for database backups. See Linux: Specifying a device class in preparation for database backups.
8. Monitor the server. See Linux: Monitoring the server.

- Linux Linux: Tuning kernel parameters for Linux systems
  For IBM Spectrum Protect and DB2 to install and operate correctly on Linux, you must update the kernel configuration parameters.

- Linux: Creating the user ID and directories for the server instance
  Create the user ID for the IBM Spectrum Protect server instance and create the directories that the server instance needs for database and recovery logs.
- Linux: Configuring the IBM Spectrum Protect server
  After you have installed the server and prepared for the configuration, configure the server instance.
- Linux: Configuring server options for server database maintenance
  To help avoid problems with database growth and server performance, the server automatically monitors its database tables and reorganizes them when needed. Before starting the server for production use, set server options to control when reorganization runs. If you plan to use data deduplication, ensure that the option to run index reorganization is enabled.
- Linux: Starting the server instance
  You can start the server by using the instance user ID, which is the preferred method, or the root user ID.
- Linux: Stopping the server
  You can stop the server when needed to return control to the operating system. To avoid losing administrative and client node connections, stop the server only after current sessions are completed or canceled.
- Linux: Registering licenses
  Immediately register any IBM Spectrum Protect licensed functions that you purchase so you do not lose any data after you start server operations, such as backing up your data.
- Linux: Specifying a device class in preparation for database backups
  To prepare the system for automatic and manual database backups, you must specify the device class to be used.
- Linux: Running multiple server instances on a single system
  You can create more than one server instance on your system. Each server instance has its own instance directory, and database and log directories.
- Linux: Monitoring the server
  When you start to use the server in production, monitor the space that is used by the server to ensure that the amount of space is adequate. Adjust the space if needed.

Linux

Linux: Tuning kernel parameters for Linux systems

For IBM Spectrum Protect™ and DB2® to install and operate correctly on Linux, you must update the kernel configuration parameters.

About this task

If you do not update these parameters, the installation of DB2 and IBM Spectrum Protect might fail. Even if installation is successful, operational problems might occur if you do not set parameter values.

- Linux: Updating kernel parameters on Linux
  DB2 automatically increases interprocess communication (IPC) kernel parameter values to the preferred settings.
- Linux: Suggested values for kernel parameters on Linux
  Ensure that the values for kernel parameters are sufficient to prevent operational problems from occurring when you run the IBM Spectrum Protect server.

Linux

Linux: Updating kernel parameters on Linux

DB2® automatically increases interprocess communication (IPC) kernel parameter values to the preferred settings.

About this task

To update the kernel parameters on Linux servers, complete the following steps:

Procedure

1. Issue the ipcs -l command to list the parameter values.
2. Analyze the results to determine whether any changes are required for your system. If changes are required, you can set the parameter in the /etc/sysctl.conf file. The parameter value is applied when the system starts.

What to do next

For Red Hat Enterprise Linux 6 (RHEL6), you must set the `kernel.shmmax` parameter in the /etc/sysctl.conf file before automatically starting the IBM Spectrum Protect™ server on system startup.

For details about the DB2 database for Linux, see the DB2 product information.

Linux

Linux: Suggested values for kernel parameters on Linux

Ensure that the values for kernel parameters are sufficient to prevent operational problems from occurring when you run the IBM Spectrum Protect™ server.

About this task

The following table contains the suggested kernel parameter settings to run both IBM Spectrum Protect and DB2®.

Parameter	Description	Preferred value
kernel.randomize_va_space	The kernel.randomize_va_space parameter configures the kernels use of memory ASLR. When you set the value to 0, `kernel.randomize_va_space=0`, it disables ASLR. DB2 data servers rely on fixed addresses for certain shared memory objects, and the ASLR can cause errors for some activities. To learn more details about the Linux ASLR and DB2, see the technote at: http://www.ibm.com/support/docview.wss?uid=swg21365583.	0
vm.swappiness	The vm.swappiness parameter defines whether the kernel can swap application memory out of physical random access memory (RAM). For more information about kernel parameters, see the DB2 product information.	0
vm.overcommit_memory	The vm.overcommit_memory parameter influences how much virtual memory the kernel can permit be allocated. For more information about kernel parameters, see the DB2 product information.	0

Linux: Creating the user ID and directories for the server instance

Create the user ID for the IBM Spectrum Protect™ server instance and create the directories that the server instance needs for database and recovery logs.

Before you begin

Review the information about planning space for the server before you complete this task. See Linux: Worksheets for planning details for the server.

Procedure

1. Create the user ID that will own the server instance. You use this user ID when you create the server instance in a later step.

   Linux

   Linux Create a user ID and group that will be the owner of the server instance.

   a. The following commands can be run from an administrative user ID that will set up the user and group. Create the user ID and group in the home directory of the user.
   Restriction: In the user ID, only lowercase letters (a-z), numerals (0-9), and the underscore character (_) can be used. The user ID and group name must comply with the following rules:
      - The length must be 8 characters or less.

- The user ID and group name cannot start with *ibm*, *sql*, *sys*, or a numeral.
- The user ID and group name cannot be *user*, *admin*, *guest*, *public*, *local*, or any SQL reserved word.

For example, create user ID `tsminst1` in group `tsmsrvrs`. The following examples show how to create this user ID and group using operating system commands.

Linux

```
groupadd tsmsrvrs -g 1111
useradd -d /home/tsminst1 -u 2222 -g 1111 -s /bin/bash tsminst1
passwd tsminst1
```

Restriction: DB2® does not support direct operating system user authentication through LDAP.

b. Log off, then log in to your system. Change to the user account that you just created. Use an interactive login program, such as telnet, so that you are prompted for the password and can change it if necessary.

2. Create directories that the server requires.
Linux Create empty directories for each item in the table and ensure that the directories are owned by the new user ID you just created. Mount the associated storage to each directory for the active log, archive log, and database directories.

Item	Example commands for creating the directories	Your directories
The *instance directory* for the server, which is a directory that will contain files specifically for this server instance (the server options file and other server-specific files)	`mkdir /tsminst1`	
The database directories	`mkdir /tsmdb001` `mkdir /tsmdb002` `mkdir /tsmdb003` `mkdir /tsmdb004`	
Active log directory	`mkdir /tsmlog`	
Archive log directory	`mkdir /tsmarchlog`	
Optional: Directory for the log mirror for the active log	`mkdir /tsmlogmirror`	
Optional: Secondary archive log directory (failover location for archive log)	`mkdir /tsmarchlogfailover`	

When a server is initially created by using the DSMSERV FORMAT utility or the configuration wizard, a server database and recovery log are created. In addition, files are created to hold database information that is used by the database manager.

3. Log off the new user ID.

Linux: Configuring the IBM Spectrum Protect server

After you have installed the server and prepared for the configuration, configure the server instance.

About this task

Configure an IBM Spectrum Protect™ server instance by selecting one of the following options:

- Linux: Configuring IBM Spectrum Protect by using the configuration wizard
  The wizard offers a guided approach to configuring a server. By using the graphical user interface (GUI), you can avoid some configuration steps that are complex when done manually. Start the wizard on the system where you installed the IBM Spectrum Protect server program.
- Linux: Configuring the server instance manually
  After installing IBM Spectrum Protect Version 8.1.2, you can configure IBM Spectrum Protect manually instead of using the configuration wizard.

Linux: Configuring IBM Spectrum Protect by using the configuration wizard

The wizard offers a guided approach to configuring a server. By using the graphical user interface (GUI), you can avoid some configuration steps that are complex when done manually. Start the wizard on the system where you installed the IBM Spectrum Protect™ server program.

Before you begin

Before you begin to use the configuration wizard, you must complete all preceding steps to prepare for the configuration. These steps include installing IBM Spectrum Protect, creating the database and log directories, and creating the directories and user ID for the server instance.

Procedure

1. Ensure that the following requirements are met: Linux
   - The system where you installed IBM Spectrum Protect must have the X Window System client. You must also be running an X Window System server on your desktop.
   - The system must have the Secure Shell (SSH) protocol enabled. Ensure that the port is set to the default value, 22, and that the port is not blocked by a firewall. You must enable password authentication in the `sshd_config` file in the /etc/ssh/ directory. Also, ensure that the SSH daemon service has access rights for connecting to the system by using the `localhost` value.
   - You must be able to log in to IBM Spectrum Protect with the user ID that you created for the server instance, by using the SSH protocol. When you use the wizard, you must provide this user ID and password to access that system.
   - Restart the server before you proceed with the Configuration wizard.
2. Start the local version of the wizard:
   - Linux Open the `dsmicfgx` program in the /opt/tivoli/tsm/server/bin directory. This wizard can be only run as a root user.

   Follow the instructions to complete the configuration. The wizard can be stopped and restarted, but the server is not operational until the entire configuration process is complete.

Linux: Configuring the server instance manually

After installing IBM Spectrum Protect™ Version 8.1.2, you can configure IBM Spectrum Protect manually instead of using the configuration wizard.

- Linux: Creating the server instance
  Create an IBM Spectrum Protect instance by issuing the db2icrt command.
- Linux Linux: Configuring server and client communications
  A default sample server options file, dsmserv.opt.smp, is created during IBM Spectrum Protect installation in the /opt/tivoli/tsm/server/bin directory. You must set up communications between the server and clients by creating a new server options file. To do so, copy the sample file to the directory for the server instance.
- Linux: Formatting the database and log
  Use the DSMSERV FORMAT utility to initialize a server instance. No other server activity is allowed while you initialize the database and recovery log.
- Linux: Preparing the database manager for database backup
  To back up the data in the database to IBM Spectrum Protect, you must enable the database manager and configure the IBM Spectrum Protect application programming interface (API).

Linux: Creating the server instance

Create an IBM Spectrum Protect™ instance by issuing the db2icrt command.

About this task

You can have one or more server instances on one workstation.
Linux Important: Before you run the db2icrt command, verify the following items:

- The home directory for the user (/home/tsminst1) exists. If there is no home directory, you must create it.
  The instance directory stores the following core files that are generated by the IBM Spectrum Protect server:
  - The server options file, dsmserv.opt
  - The server key database file, `cert.kdb`, and the `.arm` files (used by clients and other servers to import the Secure Sockets Layer certificates of the server)
  - Device configuration file, if the DEVCONFIG server option does not specify a fully qualified name
  - Volume history file, if the VOLUMEHISTORY server option does not specify a fully qualified name
  - Volumes for DEVTYPE=FILE storage pools, if the directory for the device class is not fully specified, or not fully qualified
  - User exits
  - Trace output (if not fully qualified)
- A shell configuration file (for example, .profile) exists in the home directory. The root user and instance-user ID must have write permission to this file. For more information, see the DB2® product information. Search for Linux and UNIX environment variable settings.

Linux

1. Log in using the root user ID and create an IBM Spectrum Protect instance. The name of the instance must be the same name as the user that owns the instance. Use the db2icrt command and enter the command on one line: Linux

   ```
   /opt/tivoli/tsm/db2/instance/db2icrt -a server -u
   instance_name instance_name
   ```

   For example, if your user ID for this instance is tsminst1, use the following command to create the instance. Enter the command on one line. Linux

   ```
   /opt/tivoli/tsm/db2/instance/db2icrt -a server -u
   tsminst1 tsminst1
   ```

   Remember: From this point on, use this new user ID when you configure your IBM Spectrum Protect server. Log out of the root user ID and log in under the new instance-user ID.
2. Change the default directory for the database to be the same as the instance directory for the server. If you have multiple servers, log in under the instance ID for each server. Issue this command:

   ```
   db2 update dbm cfg using dftdbpath instance_directory
   ```

   For example, where instance_directory is the instance user ID:

   ```
   db2 update dbm cfg using dftdbpath /tsminst1
   ```

3. Modify the library path to use the version of the IBM Global Security Kit (GSKit) that is installed with the server. In the following examples, *server_bin_directory* is a subdirectory of the server installation directory. For example, /opt/tivoli/tsm/server/bin.
   - You must update the following files to set the library path when DB2 or the server are started:

     Bash or Korn shell example:

     ```
     instance_users_home_directory/sqllib/userprofile
     ```

     C shell example:

     ```
     instance_users_home_directory/sqllib/usercshrc
     ```

   - Add the following entry to the *instance_users_home_directory*/sqllib/userprofile (Bash or Korn shell) file. Each entry is on one line. Linux

     ```
     LD_LIBRARY_PATH=server_bin_directory/dbbkapi:
     /opt/ibm/lib:/opt/ibm/lib64:/usr/lib64:$LD_LIBRARY_PATH

     export LD_LIBRARY_PATH
     ```

     Remember: The following entries must be in the library path:
     - /usr/local/ibm/gsk8_64/lib64
     - /opt/ibm/lib
     - /opt/ibm/lib64
     - /usr/lib64
   - Add the following entry to the *instance_users_home_directory*/sqllib/usercshrc (C shell) file, on one line: Linux

```
setenv LD_LIBRARY_PATH server_bin_directory/dbbkapi:
/opt/ibm/lib:/opt/ibm/lib64:/usr/lib64:$LD_LIBRARY_PATH
```

- Verify the library path settings and that the GSKit is version 8.0.14.43 or later. Issue the following commands:
  Linux

  ```
  echo $LD_LIBRARY_PATH
  gsk8capicmd_64 -version
  gsk8ver_64
  ```

  If your GSKit version is not 8.0.14.43 or later, you must reinstall the IBM Spectrum Protect server. The reinstallation ensures that the correct GSKit version is available.

4. Create a new server options file. See Linux: Configuring server and client communications.

Linux

Linux: Configuring server and client communications

A default sample server options file, dsmserv.opt.smp, is created during IBM Spectrum Protect™ installation in the /opt/tivoli/tsm/server/bin directory. You must set up communications between the server and clients by creating a new server options file. To do so, copy the sample file to the directory for the server instance.

About this task

Ensure that you have a server instance directory, for example /tsminst1, and copy the sample file to this directory. Name the new file `dsmserv.opt` and edit the options. Complete this set-up before you initialize the server database. Each sample or default entry in the sample options file is a comment, a line beginning with an asterisk (*). Options are not case-sensitive and one or more blank spaces are allowed between keywords and values.

When editing the options file, follow these guidelines:

- Remove the asterisk at the beginning of the line to activate an option.
- Begin entering the options in any column.
- Enter only one option per line, and the option must be on only one line.
- If you make multiple entries for a keyword, the IBM Spectrum Protect server uses the last entry.

If you change the server options file, you must restart the server for the changes to take effect.

You can specify one or more of the following communication methods:

- TCP/IP Version 4 or Version 6
- Shared memory
- Secure Sockets Layer (SSL)
  Tip: You can authenticate passwords with the LDAP directory server, or authenticate passwords with the IBM Spectrum Protect server. Passwords that are authenticated with the LDAP directory server can provide enhanced system security.

- Linux Linux: Setting TCP/IP options
  Select from a range of TCP/IP options for the IBM Spectrum Protect server or retain the default.
- Linux Linux: Setting shared memory options
  You can use shared memory communications between clients and servers on the same system. To use shared memory, TCP/IP Version 4 must be installed on the system.
- Linux Linux: Setting Secure Sockets Layer options
  You can add more protection for your data and passwords by using Secure Sockets Layer (SSL).

Linux: Setting TCP/IP options

Select from a range of TCP/IP options for the IBM Spectrum Protect™ server or retain the default.

About this task

The following is an example of a list of TCP/IP options that you can use to set up your system.

```
commmethod         tcpip
  tcpport          1500
```

```
  tcpwindowsize    0
  tcpnodelay       yes
```

Tip: You can use TCP/IP Version 4, Version 6, or both.

TCPPORT
: The server port address for TCP/IP and SSL communication. The default value is 1500.

Linux TCPWINDOWSIZE
: Linux Specifies the size of the TCP/IP buffer that is used when sending or receiving data. The window size that is used in a session is the smaller of the server and client window sizes. Larger window sizes use additional memory but can improve performance.

  You can specify an integer from 0 to 2048. To use the default window size for the operating system, specify 0.

TCPNODELAY
: Specifies whether or not the server sends small messages or lets TCP/IP buffer the messages. Sending small messages can improve throughput but increases the number of packets sent over the network. Specify YES to send small messages or NO to let TCP/IP buffer them. The default is YES.

TCPADMINPORT
: Specifies the port number on which the server TCP/IP communication driver is to wait for TCP/IP or SSL-enabled communication requests other than client sessions. The default is the value of TCPPORT.

SSLTCPPORT
: (SSL-only) Specifies the Secure Sockets Layer (SSL) port number on which the server TCP/IP communication driver waits for requests for SSL-enabled sessions for the command-line backup-archive client and the command-line administrative client.

SSLTCPADMINPORT
: (SSL-only) Specifies the port address on which the server TCP/IP communication driver waits for requests for SSL-enabled sessions for the command-line administrative client.

Linux: Setting shared memory options

You can use shared memory communications between clients and servers on the same system. To use shared memory, TCP/IP Version 4 must be installed on the system.

About this task

The following example shows a shared memory setting:

```
commmethod      sharedmem
   shmport      1510
```

In this example, SHMPORT specifies the TCP/IP port address of a server when using shared memory. Use the SHMPORT option to specify a different TCP/IP port. The default port address is 1510.
COMMMETHOD can be used multiple times in the IBM Spectrum Protect™ server options file, with a different value each time. For example, the following example is possible:

```
commmethod tcpip
commmethod sharedmem
```

Linux You might receive the following message from the server when using shared memory:

```
ANR9999D shmcomm.c(1598): ThreadId<39>
Error from msgget (2), errno = 28
```

The message means that a message queue must be created but the system limit for the maximum number of message queues (MSGMNI) would be exceeded.
Linux To find out the maximum number of message queues (MSGMNI) on your system, issue the following command:

```
cat /proc/sys/kernel/msgmni
```

To increase the MSGMNI value on your system, issue the following command:

```
sysctl -w kernel.msgmni=n
```

where **n** is the maximum number of message queues that you want the system to allow.

Linux: Setting Secure Sockets Layer options

You can add more protection for your data and passwords by using Secure Sockets Layer (SSL).

Before you begin

SSL is the standard technology for creating encrypted sessions between servers and clients. SSL provides a secure channel for servers and clients to communicate over open communication paths. With SSL, the identity of the server is verified through the use of digital certificates.

To ensure better system performance, use SSL only for sessions when it is needed. Consider adding additional processor resources on the IBM Spectrum Protect™ server to manage the increased requirements.

Linux: Formatting the database and log

Use the DSMSERV FORMAT utility to initialize a server instance. No other server activity is allowed while you initialize the database and recovery log.

After you set up server communications, you are ready to initialize the database. Ensure that you log in by using the instance user ID. Do not place the directories on file systems that might run out of space. If certain directories (for example, the archive log) become unavailable or full, the server stops.

For optimal performance and to facilitate I/O, specify at least two equally sized containers or Logical Unit Numbers (LUNs) for the database. In addition, each active log and archive log needs its own container or LUN.

Setting the exit list handler

Set the DB2NOEXITLIST registry variable to ON for each server instance. Log on to the system as the server instance owner and issue this command:

```
db2set -i server_instance_name DB2NOEXITLIST=ON
```

For example: Linux

```
db2set -i tsminst1 DB2NOEXITLIST=ON
```

Initializing a server instance

Use the DSMSERV FORMAT utility to initialize a server instance. For example, if the server instance directory is */tsminst1*, issue the following commands: Linux

```
cd /tsminst1
dsmserv format dbdir=/tsmdb001 activelogsize=32768
activelogdirectory=/activelog archlogdirectory=/archlog
archfailoverlogdirectory=/archfaillog mirrorlogdirectory=/mirrorlog
```

Tip: If you specify multiple directories, ensure that the underlying file systems are of equal size to ensure a consistent degree of parallelism for database operations. If one or more directories for the database are smaller than the others, they reduce the potential for optimized parallel prefetching and distribution of the database.

Linux Tip: If DB2® does not start after you issue the DSMSERV FORMAT command, you might need to disable the file system mount option NOSUID. If this option is set on the file system that contains the DB2 instance owner directory, or on any file system that contains the DB2 database, active logs, archive logs, failover logs, or mirrored logs, the option must be disabled to start the system.

After you disable the NOSUID option, remount the file system and then start DB2 by issuing the following command:

```
db2start
```

DSMSERV FORMAT (Format the database and log)

Linux: Preparing the database manager for database backup

To back up the data in the database to IBM Spectrum Protect™, you must enable the database manager and configure the IBM Spectrum Protect application programming interface (API).

About this task

Linux Starting with IBM Spectrum Protect V7.1, it is no longer necessary to set the API password during a manual configuration of the server. If you set the API password during the manual configuration process, attempts to back up the database might fail.

If you use the configuration wizard to create an IBM Spectrum Protect server instance, you do not have to complete these steps. If you are configuring an instance manually, complete the following steps before you issue either the BACKUP DB or the RESTORE DB commands.

Attention: If the database is unusable, the entire IBM Spectrum Protect server is unavailable. If a database is lost and cannot be recovered, it might be difficult or impossible to recover data that is managed by that server. Therefore, it is critically important to back up the database.

Linux In the following commands, replace the example values with your actual values. The examples use `tsminst1` for the server instance user ID, /tsminst1 for the server instance directory, and /home/tsminst1 as the server instance users home directory.

1. Set the IBM Spectrum Protect API environment-variable configuration for the database instance:
   a. Log in by using the `tsminst1` user ID.
   b. When user `tsminst1` is logged in, ensure that the DB2® environment is properly initialized. The DB2 environment is initialized by running the /home/tsminst1/sqllib/db2profile script, which normally runs automatically from the profile of the user ID. Ensure the `.profile` file exists in the instance users home directory, for example, /home/tsminst1/.profile. If `.profile` does not run the `db2profile` script, add the following lines:

      ```
      if [ -f /home/tsminst1/sqllib/db2profile ]; then
            . /home/tsminst1/sqllib/db2profile
        fi
      ```

   c. In the instance_directory/sqllib/userprofile file, add the following lines:

      ```
      DSMI_CONFIG=server_instance_directory/tsmdbmgr.opt
      DSMI_DIR=server_bin_directory/dbbkapi
      DSMI_LOG=server_instance_directory
      export DSMI_CONFIG DSMI_DIR DSMI_LOG
      ```

      where:
      - *instance_directory* is the home directory of the server instance user.
      - *server_instance_directory* is the server instance directory.
      - *server_bin_directory* is the server bin directory. The default location is /opt/tivoli/tsm/server/bin.

      In the instance_directory/sqllib/usercshrc file, add the following lines:

      ```
      setenv DSMI_CONFIG=server_instance_directory/tsmdbmgr.opt
      setenv DSMI_DIR=server_bin_directory/dbbkapi
      setenv DSMI_LOG=server_instance_directory
      ```

2. Log off and log in again as `tsminst1`, or issue this command:

   ```
   . ~/.profile
   ```

   Tip: Ensure that you enter a space after the initial dot (.) character.
3. Create a file that is named `tsmdbmgr.opt` in the *server_instance* directory, which is in the /tsminst1 directory in this example, and add the following line:

   ```
   SERVERNAME TSMDBMGR_TSMINST1
   ```

   Remember: The value for `SERVERNAME` must be consistent in the `tsmdbmgr.opt` and `dsm.sys` files.
4. As root user, add the following lines to the IBM Spectrum Protect API `dsm.sys` configuration file. By default, the `dsm.sys` configuration file is in the following default location:
   - *server_bin_directory*/dbbkapi/dsm.sys

   ```
   servername TSMDBMGR_TSMINST1
   commmethod tcpip
   tcpserveraddr localhost
   tcpport 1500
   ```

```
errorlogname /tsminst1/tsmdbmgr.log
nodename $$_TSMDBMGR_$$
```

where

- *servername* matches the `servername` value in the `tsmdbmgr.opt` file.
- *commethod* specifies the client API that is used to contact the server for database backup. This value can be `tcpip` or `sharedmem`. For more information about shared memory, see step 5.
- *tcpserveraddr* specifies the server address that the client API uses to contact the server for database backup. To ensure that the database can be backed up, this value must be `localhost`.
- *tcpport* specifies the port number that the client API uses to contact the server for database backup. Ensure that you enter the same `tcpport` value that is specified in the dsmserv.opt server options file.
- *errorlogname* specifies the error log where the client API logs errors that are encountered during a database backup. This log is typically in the server instance directory. However, this log can be placed in any location where the instance user ID has write-permission.
- *nodename* specifies the node name that the client API uses to connect to the server during a database backup. To ensure that the database can be backed up, this value must be `$$_TSMDBMGR_$$`.

Linux Attention: Do not add the PASSWORDACCESS generate option to the dsm.sys configuration file. This option can cause the database backup to fail.

5. Optional: Configure the server to back up the database by using shared memory. In this way, you might be able to reduce the processor load and improve throughput. Complete the following steps:
   a. Review the dsmserv.opt file. If the following lines are not in the file, add them:

      ```
      commmethod sharedmem
      shmport port_number
      ```

      where *port_number* specifies the port to be used for shared memory.
   b. In the dsm.sys configuration file, locate the following lines:

      ```
      commmethod tcpip
      tcpserveraddr localhost
      tcpport port_number
      ```

      Replace the specified lines with the following lines:

      ```
      commmethod sharedmem
      shmport port_number
      ```

      where *port_number* specifies the port to be used for shared memory.

Linux: Configuring server options for server database maintenance

To help avoid problems with database growth and server performance, the server automatically monitors its database tables and reorganizes them when needed. Before starting the server for production use, set server options to control when reorganization runs. If you plan to use data deduplication, ensure that the option to run index reorganization is enabled.

About this task

Table and index reorganization requires significant processor resources, active log space, and archive log space. Because database backup takes precedence over reorganization, select the time and duration for reorganization to ensure that the processes do not overlap and reorganization can complete.

Linux You can optimize index and table reorganization for the server database. In this way, you can help to avoid unexpected database growth and performance issues. For instructions, see technote 1683633.

If you update these server options while the server is running, you must stop and restart the server before the updated values take effect.

Procedure

1. Modify the server options.
   Linux Edit the server options file, dsmserv.opt, in the server instance directory. Follow these guidelines when you edit the server options file:
   - To enable an option, remove the asterisk at the beginning of the line.
   - Enter an option on any line.
   - Enter only one option per line. The entire option with its value must be on one line.

- If you have multiple entries for an option in the file, the server uses the last entry.

To view available server options, see the sample file, dsmserv.opt.smp, in the /opt/tivoli/tsm/server/bin directory.

2. If you plan to use data deduplication, enable the ALLOWREORGINDEX server option. Add the following option and value to the server options file:

   ```
   allowreorgindex yes
   ```

3. Set the REORGBEGINTIME and REORGDURATION server options to control when reorganization starts and how long it runs. Select a time and duration so that reorganization runs when you expect that the server is least busy. These server options control both table and index reorganization processes.
   a. Set the time for reorganization to start by using the REORGBEGINTIME server option. Specify the time by using the 24-hour system. For example, to set the start time for reorganization as 8:30 p.m., specify the following option and value in the server options file:

      ```
      reorgbegintime 20:30
      ```

   b. Set the interval during which the server can start reorganization. For example, to specify that the server can start reorganization for four hours after the time set by the REORGBEGINTIME server option, specify the following option and value in the server options file:

      ```
      reorgduration 4
      ```

4. If the server was running while you updated the server options file, stop and restart the server.

REORGDURATION
Linux

Linux: Starting the server instance

You can start the server by using the instance user ID, which is the preferred method, or the root user ID.

Before you begin

Ensure that you set access permissions and user limits correctly.

Linux For instructions, see Verifying access rights and user limits.

About this task

When you start the server by using the instance user ID, you simplify the setup process and avoid potential issues. However, in some cases, it might be necessary to start the server with the root user ID. For example, you might want to use the root user ID to ensure that the server can access specific devices. You can set up the server to start automatically by using either the instance user ID or the root user ID.

Linux If you must complete maintenance or reconfiguration tasks, start the server in maintenance mode.

Procedure

To start the server, take one of the following actions:

- Start the server by using the instance user ID.

  Linux For instructions, see Starting the server from the instance user ID.

- Start the server by using the root user ID.

  For instructions about authorizing root user IDs to start the server, see Authorizing root user IDs to start the server (V7.1.1). For instructions about starting the server by using the root user ID, see Starting the server from the root user ID (V7.1.1).

- Linux Start the server automatically.

Linux For instructions, see Linux: Automatically starting servers on Linux systems.

- Linux Start the server in maintenance mode.

  For instructions, see Linux: Starting the server in maintenance mode.

Linux

Linux: Verifying access rights and user limits

Before you start the server, verify access rights and user limits.

About this task

If you do not verify user limits, also known as *ulimits*, you might experience server instability or a failure of the server to respond. You must also verify the system-wide limit for the maximum number of open files. The system-wide limit must be greater than or equal to the user limit.

Procedure

1. Verify that the server instance user ID has permissions to start the server.
2. For the server instance that you plan to start, ensure that you have authority to read and write files in the server instance directory. Verify that the dsmserv.opt file exists in the server instance directory, and that the file includes parameters for the server instance.
3. If the server is attached to a tape drive, medium changer, or removable media device, and you plan to start the server by using the instance user ID, grant read/write access to the instance user ID for these devices. To set permissions, take one of the following actions:
   - If the system is dedicated to IBM Spectrum Protect™ and only the IBM Spectrum Protect administrator has access, make the device special file world-writable. On the operating system command line, issue the following command:

     ```
     chmod +w /dev/rmtX
     ```

   - If the system has multiple users, you can restrict access by making the IBM Spectrum Protect instance user ID the owner of the special device files. On the operating system command line, issue the following command:

     ```
     chmod u+w /dev/rmtX
     ```

   - If multiple user instances are running on the same system, change the group name, for example TAPEUSERS, and add each IBM Spectrum Protect instance user ID to that group. Then, change the ownership of the device special files to belong to the group TAPEUSERS, and make them group-writable. On the operating system command line, issue the following command:

     ```
     chmod g+w /dev/rmtX
     ```

4. Linux If you are using the IBM Spectrum Protect device driver and the autoconf utility, use the -a option to grant read/write access to the instance user ID.
5. Linux To prevent server failures during interaction with DB2®, tune the kernel parameters.

   Linux For instructions about tuning kernel parameters, see Linux: Tuning kernel parameters for Linux systems.

6. Verify the following user limits based on the guidelines in the table.

Table 1. User limit (ulimit) values

User limit type	Preferred value	Command to query value
Maximum size of core files created	Unlimited	`ulimit -Hc`
Maximum size of a data segment for a process	Unlimited	`ulimit -Hd`
Maximum file size	Unlimited	`ulimit -Hf`
Maximum number of open files	65536	`ulimit -Hn`
Maximum amount of processor time in seconds	Unlimited	`ulimit -Ht`

To modify user limits, follow the instructions in the documentation for your operating system.

Tip: If you plan to start the server automatically by using a script, you can set the user limits in the script.

7. Ensure that the user limit of maximum user processes (the `nproc` setting) is set to the minimum suggested value of 16384.
   a. To verify the current user limit, issue the `ulimit -Hu` command by using the instance user ID. For example:

      ```
      [user@Machine ~]$ ulimit -Hu
      16384
      ```

   b. If the limit of maximum user processes is not set to 16384, set the value to 16384.
      Linux Add the following line to the /etc/security/limits.conf file:

      ```
      instance_user_id        -     nproc           16384
      ```

      where *instance_user_id* specifies the server instance user ID.
      Linux If the server is installed on the Red Hat Enterprise Linux 6 operating system, set the user limit by editing the /etc/security/limits.d/90-nproc.conf file in the /etc/security/limits.d directory. This file overrides the settings in the /etc/security/limits.conf file.
      Tip: The default value for the user limit of maximum user processes has changed on some distributions and versions of the Linux operating system. The default value is 1024. If you do not change the value to the minimum suggested value of 16384, the server might fail or hang.

Linux

Linux: Starting the server from the instance user ID

To start the server from the instance user ID, log in with the instance user ID and issue the appropriate command from the server instance directory.

Before you begin

Ensure that access rights and user limits are set correctly. For instructions, see Linux: Verifying access rights and user limits.

Procedure

1. Log in to the system where IBM Spectrum Protect™ is installed by using the instance user ID for the server.
2. If you do not have a user profile that runs the `db2profile` script, issue the following command:

   ```
   . /home/tsminst1/sqllib/db2profile
   ```

   Tip: For instructions about updating the user ID login script to run the `db2profile` script automatically, see the DB2® documentation.
3. Start the server by issuing the following command on one line from the server instance directory:

   Linux

   ```
   usr/bin/dsmserv
   ```

   Tip: The command runs in the foreground so that you can set an administrator ID and connect to the server instance.
   Linux For example, if the name of the server instance is `tsminst1` and the server instance directory is /tsminst1, you can start the instance by issuing the following commands:

   ```
   cd /tsminst1
    . ~/sqllib/db2profile
   /usr/bin/dsmserv
   ```

Linux

Linux: Automatically starting servers on Linux systems

To automatically start a server on a Linux operating system, use the dsmserv.rc script.

Before you begin

Ensure that kernel parameters are set correctly. For instructions, see Tuning kernel parameters for Linux systems.

Ensure that the server instance runs under the instance owner user ID.

Ensure that access rights and user limits are set correctly. For instructions, see Verifying access rights and user limits.

About this task

The dsmserv.rc script is in the server installation directory, for example, /opt/tivoli/tsm/server/bin.

The dsmserv.rc script can be used either to start the server manually or to start the server automatically by adding entries to the /etc/rc.d/init.d directory. The script works with Linux utilities such as CHKCONFIG and SERVICE.

Procedure

For each server instance that you want to automatically start, complete the following steps:

1. Place a copy of the dsmserv.rc script in the /init.d directory, for example, /etc/rc.d/init.d.

   Ensure that you change only the copy of the script. Do not change the original script.

2. Rename the script copy so that it matches the name of the server instance owner, for example, `tsminst1`.

   The script was created under the assumption that the server instance directory is *home_directory*/tsminst1, for example: /home/tsminst1/tsminst1.

3. If the server instance directory is not *home_directory*/tsminst1, locate the following line in the script copy:

   ```
   instance_dir="${instance_home}/tsminst1"
   ```

   Change the line so that it points to your server instance directory, for example:

   ```
   instance_dir="/tsminst1"
   ```

4. In the script copy, locate the following line:

   ```
   # pidfile: /var/run/dsmserv_instancename.pid
   ```

   Change the instance name value to the name of the server instance owner. For example, if the server instance owner is tsminst1, update the line as shown:

   ```
   # pidfile: /var/run/dsmserv_tsminst1.pid
   ```

5. Configure the run level in which the server automatically starts. By using tools such as the CHKCONFIG utility, specify a value that corresponds to a multiuser mode, with networking turned on. Typically, the run level to use is 3 or 5, depending on the operating system and its configuration. For more information about multiuser mode and run levels, see the documentation for your operating system.
6. To start or stop the server, issue one of the following commands:
   - To start the server:

     ```
     service tsminst1 start
     ```

   - To stop the server:

     ```
     service tsminst1 stop
     ```

Example

This example uses the following values:

- The instance owner is tsminst1.
- The server instance directory is /home/tsminst1/tsminst1.
- The dsmserv.rc script copy is named `tsminst1`.
- The CHKCONFIG utility is used to configure the script to start at run levels 3, 4, and 5.

```
cp /opt/tivoli/tsm/server/bin/dsmserv.rc /etc/rc.d/init.d/tsminst1
sed -i 's/dsmserv_instancename.pid/dsmserv_tsminst1.pid/' /etc/rc.d/init.d/tsminst1
chkconfig --list tsminst1
service tsminst1 supports chkconfig, but is not referenced in
any runlevel (run 'chkconfig --add tsminst1')
chkconfig --add tsminst1
chkconfig --list tsminst1
tsminst1 0:off 1:off 2:off 3:off 4:off 5:off 6:off
chkconfig --level 345 tsminst1 on
```

```
chkconfig --list tsminst1
tsminst1 0:off 1:off 2:off 3:on 4:on 5:on 6:off
```

Related reference:
Server startup script: dsmserv.rc
Linux

Linux: Starting the server in maintenance mode

You can start the server in maintenance mode to avoid disruptions during maintenance and reconfiguration tasks.

About this task

Start the server in maintenance mode by running the DSMSERV utility with the MAINTENANCE parameter.

The following operations are disabled in maintenance mode:

- Administrative command schedules
- Client schedules
- Reclamation of storage space on the server
- Inventory expiration
- Migration of storage pools

In addition, clients are prevented from starting sessions with the server.
Tips:

- You do not have to edit the server options file, dsmserv.opt, to start the server in maintenance mode.
- While the server is running in maintenance mode, you can manually start the storage-space reclamation, inventory expiration, and storage-pool migration processes.

Procedure

To start the server in maintenance mode, issue the following command:

```
dsmserv maintenance
```

Tip: To view a video about starting the server in maintenance mode, see Starting a server in maintenance mode.

What to do next

To resume server operations in production mode, complete the following steps:

1. Shut down the server by issuing the HALT command:

   ```
   halt
   ```

2. Start the server by using the method that you use in production mode.

Operations that were disabled during maintenance mode are reenabled.

Linux: Stopping the server

You can stop the server when needed to return control to the operating system. To avoid losing administrative and client node connections, stop the server only after current sessions are completed or canceled.

About this task

To stop the server, issue the following command from the IBM Spectrum Protect™ command line:

```
halt
```

Linux If you cannot connect to the server with an administrative client and you want to stop the server, you must cancel the process by using the kill command with the process ID number (pid). The pid is displayed at initialization.
Important: Before you issue the kill command, ensure that you know the correct process ID for the IBM Spectrum Protect server.

The `dsmserv.v6lock` file, in the directory from which the server is running, can be used to identify the process ID of the process to kill. To display the file, enter:

```
cat /instance_dir/dsmserv.v6lock
```

Linux Issue the following command to stop the server:

```
kill -23 dsmserv_pid
```

where *dsmserv_pid* is the process ID number.

Linux: Registering licenses

Immediately register any IBM Spectrum Protect™ licensed functions that you purchase so you do not lose any data after you start server operations, such as backing up your data.

About this task

Use the REGISTER LICENSE command for this task. See REGISTER LICENSE for more details.

Example: Register a license

Register the base IBM Spectrum Protect license.

```
register license file=tsmbasic.lic
```

Linux: Specifying a device class in preparation for database backups

To prepare the system for automatic and manual database backups, you must specify the device class to be used.

Before you begin

Ensure that you have defined a tape or file device class. For details, see DEFINE DEVCLASS, or search for defining a device class.

About this task

Complete the following steps to set up your system for database backups.

Procedure

1. If you did not use the configuration wizard (dsmicfgx) to configure the server, ensure that you have completed the steps to manually configure the system for database backups.
2. Select the device class to be used for backups of the database. Issue the following command from an IBM Spectrum Protect™ administrative command line.

   ```
   set dbrecovery device_class_name
   ```

   The device class that you specify is used by the database manager for database backups. If you do not specify a device class with the SET DBRECOVERY command, the backup fails.

Example

For example, to specify that the DBBACK device class is to be used, issue this command:

```
set dbrecovery dbback
```

Linux: Running multiple server instances on a single system

You can create more than one server instance on your system. Each server instance has its own instance directory, and database and log directories.

Multiply the memory and other system requirements for one server by the number of instances planned for the system.

Linux The set of files for one instance of the server is stored separately from the files used by another server instance on the same system. Use the steps in Linux: Creating the server instance for each new instance, including creation of the new instance user.

To manage the system memory that is used by each server, use the DBMEMPERCENT server option to limit the percentage of system memory. If all servers are equally important, use the same value for each server. If one server is a production server and other servers are test servers, set the value for the production server to a higher value than the test servers.

You can upgrade directly from either V6.3 to V7.1. See the upgrade section (Upgrading to V8.1) for more details. When you upgrade and have multiple servers on your system, you must run the installation wizard only once. The installation wizard collects the database and variables information for all of your original server instances.

If you upgrade from IBM Spectrum Protect V6.3 to V8.1.2 and have multiple servers on your system, all instances that exist in DB2® V9.7 are dropped and recreated in DB2 V11.1. The wizard issues the `db2 upgrade db dbname` command for each database. The database environment variables for each instance on your system are also reconfigured during the upgrade process.

Related tasks:
Running multiple server instances on a single system (V7.1.1)

Linux: Monitoring the server

When you start to use the server in production, monitor the space that is used by the server to ensure that the amount of space is adequate. Adjust the space if needed.

Procedure

1. Monitor the active log to ensure that the size is correct for the workload that is handled by the server instance.

   When the server workload reaches its typical expected level, the space that is used by the active log is 80% - 90% of the space that is available to the active log directory. At that point, you might need to increase the amount of space. Whether you must increase the space depends on the types of transactions in the server workload. Transaction characteristics affect how the active log space is used.

   The following transaction characteristics can affect the space usage in the active log:

   - The number and size of files in backup operations
     - Clients such as file servers that back up large numbers of small files can cause large numbers of transactions that are completed quickly. The transactions might use a large amount of space in the active log, but for a short time.
     - Clients such as a mail server or a database server that back up large amounts of data in few transactions can cause small numbers of transactions that take a long time to complete. The transactions might use a small amount of space in the active log, but for a long time.
   - Network connection types
     - Backup operations that occur over fast network connections cause transactions that complete more quickly. The transactions use space in the active log for a shorter time.
     - Backup operations that occur over relatively slower connections cause transactions that take a longer time to complete. The transactions use space in the active log for a longer time.

   If the server is handling transactions with a wide variety of characteristics, the space that is used for the active log might increase and decrease significantly over time. For such a server, you might need to ensure that the active log typically has a smaller percentage of its space used. The extra space allows the active log to grow for transactions that take a long time to complete.

2. Monitor the archive log to ensure that space is always available.
   Remember: If the archive log becomes full, and the failover archive log becomes full, the active log can become full, and the server stops. The goal is to make enough space available to the archive log so that it never uses all its available space. You are likely to notice the following pattern:
   a. Initially, the archive log grows rapidly as typical client-backup operations occur.
   b. Database backups occur regularly, either as scheduled or done manually.
   c. After at least two full database backups occur, log pruning occurs automatically. The space that is used by the archive log decreases when the pruning occurs.
   d. Normal client operations continue, and the archive log grows again.

e. Database backups occur regularly, and log pruning occurs as often as full database backups occur.

With this pattern, the archive log grows initially, decreases, and then might grow again. Over time, as normal operations continue, the amount of space that is used by the archive log should reach a relatively constant level.

If the archive log continues to grow, consider taking one or both of these actions:
- Add space to the archive log. You might need to move the archive log to a different file system.
- Increase the frequency of full database backups, so that log pruning occurs more frequently.

3. If you defined a directory for the failover archive log, determine whether any logs get stored in that directory during normal operations. If the failover log space is being used, consider increasing the size of the archive log. The goal is that the failover archive log is used only under unusual conditions, not in normal operation.

Linux: Installing an IBM Spectrum Protect server fix pack

IBM Spectrum Protect™ maintenance updates, which are also referred to as fix packs, bring your server up to the current maintenance level.

Before you begin

To install a fix pack or interim fix to the server, install the server at the level on which you want to run it. You do not have to start the server installation at the base release level. For example, if you currently have V8.1.1 installed, you can go directly to the latest fix pack for V8.1. You do not have to start with the V8.1.0 installation if a maintenance update is available.

You must have the IBM Spectrum Protect license package installed. The license package is provided with the purchase of a base release. When you download a fix pack or interim fix from Fix Central, install the server license that is available on the Passport Advantage® website. To display messages and help in a language other than US English, install the language package of your choice.

If you upgrade the server to V8.1.2 or later, and then revert the server to a level that is earlier than V8.1.2, you must restore the database to a point in time before the upgrade. During the upgrade process, complete the required steps to ensure that the database can be restored: back up the database, the volume history file, the device configuration file, and the server options file. For more information, see Linux: Reverting from Version 8.1.2 to a previous server.

If you are using the client management service, ensure that you upgrade it to the same version as the IBM Spectrum Protect server.

Ensure that you retain the installation media from the base release of the installed server. If you installed IBM Spectrum Protect from a downloaded package, ensure that the downloaded files are available. If the upgrade fails, and the server license module is uninstalled, the installation media from the server base release are required to reinstall the license.

Visit the IBM® Support Portal for the following information:

- A list of the latest maintenance and download fixes. Click **Downloads** and apply any applicable fixes.
- Details about obtaining a base license package. Search for **Downloads > Passport Advantage**.
- Supported platforms and system requirements. Search for **IBM Spectrum Protect supported operating systems**.

Ensure that you upgrade the server before you upgrade backup-archive clients. If you do not upgrade the server first, communication between the server and clients might be interrupted.

Attention: Do not alter the DB2® software that is installed with IBM Spectrum Protect installation packages and fix packs. Do not install or upgrade to a different version, release, or fix pack of DB2 software because doing so can damage the database.

Procedure

To install a fix pack or interim fix, complete the following steps:

1. Back up the database. The preferred method is to use a snapshot backup. A snapshot backup is a full database backup that does not interrupt any scheduled database backups. For example, issue the following IBM Spectrum Protect administrative command:

```
backup db type=dbsnapshot devclass=tapeclass
```

2. Back up the device configuration information. Issue the following IBM Spectrum Protect administrative command:

```
backup devconfig filenames=file_name
```

where *file_name* specifies the name of the file in which to store device configuration information.

3. Save the volume history file to another directory or rename the file. Issue the following IBM Spectrum Protect administrative command:

   ```
   backup volhistory filenames=file_name
   ```

   where *file_name* specifies the name of the file in which to store the volume history information.
4. Save a copy of the server options file, typically named dsmserv.opt. The file is in the server instance directory.
5. Halt the server before installing a fix pack or interim fix. Use the HALT command.
6. Ensure that extra space is available in the installation directory. The installation of this fix pack might require additional temporary disk space in the installation directory of the server. The amount of additional disk space can be as much as that required for installing a new database as part of an IBM Spectrum Protect installation. The IBM Spectrum Protect installation wizard displays the amount of space that is required for installing the fix pack and the available amount. If the required amount of space is greater than the available amount, the installation stops. If the installation stops, add the required disk space to the file system and restart the installation.
7. Linux Log in as the root user.
8. Obtain the package file for the fix pack or interim fix that you want to install from the IBM Support Portal, Passport Advantage, or Fix Central.
9. Linux Change to the directory where you placed the executable file and complete the following steps.
   Tip: The files are extracted to the current directory. Ensure that the executable file is in the directory where you want the extracted files to be located.
   a. Change file permissions by entering the following command:

      ```
      chmod a+x 8.x.x.x-IBM-SPSRV-platform.bin
      ```

      where *platform* denotes the architecture that IBM Spectrum Protect is to be installed on.
   b. Issue the following command to extract the installation files:

      ```
      ./8.x.x.x-IBM-SPSRV-platform.bin
      ```

10. Select one of the following ways of installing IBM Spectrum Protect.
    Important: After a fix pack is installed, it is not necessary to go through the configuration again. You can stop after completing the installation, fix any errors, then restart your servers.
    Install the IBM Spectrum Protect software by using one of the following methods:

    Installation wizard
    : Follow the instructions for your operating system:
      Linux: Installing IBM Spectrum Protect by using the installation wizard

    Tip: After you start the wizard, in the IBM Installation Manager window, click the Update icon; do not click the Install or Modify icon.

    Command line in console mode
    : Follow the instructions for your operating system:
      Linux: Installing IBM Spectrum Protect by using console mode

    Silent mode
    : Follow the instructions for your operating system:
      Linux: Installing IBM Spectrum Protect in silent mode

    Tip: If you have multiple server instances on your system, run the installation wizard only once. The installation wizard upgrades all server instances.

Results

Correct any errors that are detected during the installation process.

If you installed the server by using the installation wizard, you can view installation logs by using the IBM Installation Manager tool. Click File > View Log. To collect log files, from the IBM Installation Manager tool, click Help > Export Data for Problem Analysis.

If you installed the server by using console mode or silent mode, you can view error logs in the IBM Installation Manager log directory, for example:

- Linux /var/ibm/InstallationManager/logs

Linux: Reverting from Version 8.1.2 to a previous server

If you must revert to the previous version of the server after an upgrade, you must have a full database backup from your original version. You must also have the server installation media for your original version and key configuration files. Carefully follow the preparation steps before you upgrade the server. By doing so, it might be possible to revert to the previous version of the IBM Spectrum Protect™ server with minimal loss of data.

Before you begin

You must have the following items from the earlier version of the server:

- Server database backup
- Volume history file
- Device configuration file
- Server options file

About this task

Use the same instructions whether you are reverting within releases or to an earlier release, for example, from 8.1.2 to 8.1.1 or from 8.1.2 to 7.1.2. The older version must match the version that you used before the upgrade to V8.1.

Attention: Specify the REUSEDELAY parameter to help prevent backup-archive client data loss when you revert the server to a previous version.

Steps for reverting to the previous server version

About this task

Complete the following steps on the system that has the V8.1 server.

Procedure

1. Halt the server to shut down all server operations by using the HALT command.
2. Remove the database from the database manager, then delete the database and recovery log directories.
   a. Manually remove the database. One way to remove it is by issuing this command: Linux

      ```
      dsmserv removedb tsmdb1
      ```

   b. If you must reuse the space that is occupied by the database and recovery log directories, you can now delete these directories.
3. Use the uninstallation program to uninstall the V8.1 server. Uninstallation removes the server and the database manager, with their directories. For details, see Linux: Uninstalling IBM Spectrum Protect.
4. Stop the cluster service. Reinstall the version of the server program that you were using before the upgrade to V8.1.2. This version must match the version that your server was running when you created the database backup that you restore in a later step. For example, the server was at V7.1.7 before the upgrade, and you intend to use the database backup that was in use on this server. You must install the V7.1.7 fix pack to be able to restore the database backup.
5. Configure the new server database by using the configuration wizard. To start the wizard, issue the following command: Linux

   ```
   . /dsmicfgx
   ```

6. Ensure that no servers are running in the background.
7. Restore the database to a point in time before the upgrade.
8. Copy the following files to the instance directory.
   - Device configuration file
   - Volume history file
   - The server options file (typically dsmserv.opt)
9. If you enabled data deduplication for any FILE-type storage pools that existed before the upgrade, or if you moved data that existed before the upgrade into new storage pools while using the V8.1.2 server, you must complete additional recovery steps. For more details, see Additional recovery steps if you created new storage pools or enabled data deduplication.
10. If the REUSEDELAY parameter setting on storage pools is less than the age of the database that you restored, restore volumes on any sequential-access storage pools that were reclaimed after that database backup. Use the RESTORE

VOLUME command.
If you do not have a backup of a storage pool, audit the reclaimed volumes by using the AUDIT VOLUME command, with the FIX=YES parameter to resolve inconsistencies. For example:

```
audit volume volume_name fix=yes
```

11. If client backup or archive operations were completed using the V8.1 server, audit the storage pool volumes on which the data was stored.

Additional recovery steps if you created new storage pools or enabled data deduplication

If you created new storage pools, turned on data deduplication for any FILE-type storage pools, or did both while your server was running as a V8.1.2 server, you must complete more steps to return to the previous server version.

Before you begin

To complete this task, you must have a complete backup of the storage pool that was created before the upgrade to V8.1.2.

About this task

Use this information if you did either or both of the following actions while your server was running as a V8.1.2 server:

- You enabled the data deduplication function for any storage pools that existed before the upgrade to V8.1.2 program. Data deduplication applies only to storage pools that use a FILE device type.
- You created new primary storage pools after the upgrade *and* moved data that was stored in other storage pools into the new storage pools.

Complete these steps after the server is again restored to V7.

Procedure

- For each storage pool for which you enabled the data deduplication function, restore the entire storage pool by using the RESTORE STGPOOL command.
- For storage pools that you created after the upgrade, determine what action to take. Data that was moved from existing V8 storage pools into the new storage pools might be lost because the new storage pools no longer exist in your restored V8 server. Possible recovery depends on the type of storage pool:
  - If data was moved from V8 DISK-type storage pools into a new storage pool, space that was occupied by the data that was moved was probably reused. Therefore, you must restore the original V8 storage pools by using the storage pool backups that were created before the upgrade to V8.1.2.

    If *no* data was moved from V8 DISK-type storage pools into a new storage pool, then audit the storage pool volumes in these DISK-type storage pools.

  - If data was moved from V8 sequential-access storage pools into a new storage pool, that data might still exist and be usable in storage pool volumes on the restored V8 server. The data might be usable if the REUSEDELAY parameter for the storage pool was set to a value that prevented reclamation while the server was running as a V8.1.2 server. If any volumes were reclaimed while the server was running as a V8.1.2 server, restore those volumes from storage pool backups that were created before the upgrade to V8.1.2.

Linux: Reference: DB2 commands for IBM Spectrum Protect server databases

Use this list as reference when you are directed to issue DB2® commands by IBM® support.

Purpose

After using the wizards to install and configure IBM Spectrum Protect™, you seldom need to issue DB2 commands. A limited set of DB2 commands that you might use or be asked to issue are listed in Table 1. This list is supplemental material only and is not a comprehensive list. There is no implication that an IBM Spectrum Protect administrator will use it on a daily or ongoing basis. Samples of some commands are provided. Details of output are not listed.

For a full explanation of the commands described here and of their syntax, see the DB2 product information.

Table 1. DB2 commands

Command	Description	Example
db2icrt	Creates DB2 instances in the home directory of the instance owner. Tip: The IBM Spectrum Protect configuration wizard creates the instance used by the server and database. After a server is installed and configured through the configuration wizard, the db2icrt command is generally not used. Linux This utility is in the DB2DIR/instance directory, where DB2DIR represents the installation location where the current version of the DB2 database system is installed.	Manually create an IBM Spectrum Protect instance. Enter the command on one line: `/opt/tivoli/tsm/db2/instance/db2icrt -a server -u` *`instance_name instance_name`*
db2set	Displays DB2 variables.	List DB2 variables: `db2set`
CATALOG DATABASE	Stores database location information in the system database directory. The database can be located either on the local workstation or on a remote database partition server. The server configuration wizard takes care of any catalog needed for using the server database. Run this command manually, after a server is configured and running, only if something in the environment changes or is damaged.	Catalog the database: `db2 catalog database tsmdb1`
CONNECT TO DATABASE	Connects to a specified database for command-line interface (CLI) use.	Connect to the IBM Spectrum Protect database from a DB2 CLI: `db2 connect to tsmdb1`
GET DATABASE CONFIGURATION	Returns the values of individual entries in a specific database configuration file. Important: This command and parameters are set and managed directly by DB2. They are listed here for informational purposes and a means to view the existing settings. Changing these settings might be advised by IBM support or through service bulletins such as APARs or Technical Guidance documents (technotes). Do not change these settings manually. Change them only at the direction of IBM and only through the use of IBM Spectrum Protect server commands or procedures.	Show the configuration information for a database alias: `db2 get db cfg for tsmdb1` Retrieve information in order to verify settings such as database configuration, log mode, and maintenance. `db2 get db config for tsmdb1 show detail`

Command	Description	Example
GET DATABASE MANAGER CONFIGURATION	Returns the values of individual entries in a specific database configuration file. Important: This command and parameters are set and managed directly by DB2. They are listed here for informational purposes and a means to view the existing settings. Changing these settings might be advised by IBM support or through service bulletins such as APARs or Technical Guidance documents (technotes). Do not change these settings manually. Change them only at the direction of IBM and only through the use of IBM Spectrum Protect server commands or procedures.	Retrieve configuration information for the database manager: `db2 get dbm cfg`
GET HEALTH SNAPSHOT	Retrieves the health status information for the database manager and its databases. The information returned represents a snapshot of the health state at the time the command was issued. IBM Spectrum Protect monitors the state of the database using the health snapshot and other mechanisms that are provided by DB2. There might be cases where the health snapshot or other DB2 documentation indicates that an item or database resource might be in an alert state. Such a case indicates that action must be considered to remedy the situation. IBM Spectrum Protect monitors the condition and responds appropriately. Not all declared alerts by the DB2 database are acted on.	Receive a report on DB2 health monitor indicators: `db2 get health snapshot for database on tsmdb1`
GRANT (Database Authorities)	Grants authorities that apply to the entire database rather than privileges that apply to specific objects within the database.	Grant access to the user ID itmuser: `db2 GRANT CONNECT ON DATABASE TO USER itmuser` `db2 GRANT CREATETAB ON DATABASE TO USER itmuser`
RUNSTATS	Updates statistics about the characteristics of a table and associated indexes or statistical views. These characteristics include number of records, number of pages, and average record length. To see a table, issue this utility after updating or reorganizing the table. A view must be enabled for optimization before its statistics can be used to optimize a query. A view that is enabled for optimization is known as a statistical view. Use the DB2 ALTER VIEW statement to enable a view for optimization. Issue the RUNSTATS utility when changes to underlying tables substantially affect the rows returned by the view. Tip: The server configures DB2 to run the RUNSTATS command as needed.	Update statistics on a single table. `db2 runstats on table SCHEMA_NAME.TABLE_NAME with distribution and sampled detailed indexes all`
SET SCHEMA	Changes the value of the CURRENT SCHEMA special register, in preparation for issuing SQL commands directly through the DB2 CLI. Tip: A special register is a storage area that is defined for an application process by the database manager. It is used to store information that can be referenced in SQL statements.	Set the schema for IBM Spectrum Protect: `db2 set schema tsmdb1`

Command	Description	Example
START DATABASE MANAGER	Starts the current database manager instance background processes. The server starts and stops the instance and database whenever the server starts and halts. Important: Allow the server to manage the starting and stopping of the instance and database unless otherwise directed by IBM support.	Start the database manager: `db2start`
STOP DATABASE MANAGER	Stops the current database manager instance. Unless explicitly stopped, the database manager continues to be active. This command does not stop the database manager instance if any applications are connected to databases. If there are no database connections, but there are instance attachments, the command forces the instance attachments to stop first. Then, it stops the database manager. This command also deactivates any outstanding database activations before stopping the database manager. This command is not valid on a client. The server starts and stops the instance and database whenever the server starts and halts. Important: Allow the server to manage the starting and stopping of the instance and database unless otherwise directed by IBM support.	Stop the database manager: `db2 stop dbm`

Linux: Uninstalling IBM Spectrum Protect

You can use the following procedures to uninstall IBM Spectrum Protect™. Before you remove IBM Spectrum Protect, ensure that you do not lose your backup and archive data.

Before you begin

Complete the following steps before you uninstall IBM Spectrum Protect:

- Complete a full database backup.
- Save a copy of the volume history and device configuration files.
- Store the output volumes in a safe location.

About this task

You can uninstall IBM Spectrum Protect by using any of the following methods: a graphical wizard, the command line in console mode, or silent mode.

- Linux: Uninstalling IBM Spectrum Protect by using a graphical wizard
  You can uninstall IBM Spectrum Protect by using the IBM® Installation Manager installation wizard.
- Linux: Uninstalling IBM Spectrum Protect in console mode
  To uninstall IBM Spectrum Protect by using the command line, you must run the uninstallation program of IBM Installation Manager from the command line with the parameter for console mode.
- Linux: Uninstalling IBM Spectrum Protect in silent mode
  To uninstall IBM Spectrum Protect in silent mode, you must run the uninstallation program of IBM Installation Manager from the command line with the parameters for silent mode.
- Linux: Uninstalling and reinstalling IBM Spectrum Protect
  If you plan to manually reinstall IBM Spectrum Protect instead of using the wizard, there are a number of steps to take to preserve your server instance names and database directories. During an uninstallation, any server instances previously set up are removed, but the database catalogs for those instances still exist.
- Linux: Uninstalling IBM Installation Manager
  You can uninstall IBM Installation Manager if you no longer have any products that were installed by IBM Installation Manager.

What to do next

See Linux: Installing the server components for installation steps to reinstall the IBM Spectrum Protect components.

Linux: Uninstalling IBM Spectrum Protect by using a graphical wizard

You can uninstall IBM Spectrum Protect™ by using the IBM® Installation Manager installation wizard.

Procedure

1. Start the Installation Manager.
   Linux In the directory where the Installation Manager is installed, go to the eclipse subdirectory (for example, /opt/IBM/InstallationManager/eclipse), and issue the following command:

   ```
   ./IBMIM
   ```

2. Click Uninstall.
3. Select IBM Spectrum Protect server, and click Next.
4. Click Uninstall.
5. Click Finish.

Linux: Uninstalling IBM Spectrum Protect in console mode

To uninstall IBM Spectrum Protect™ by using the command line, you must run the uninstallation program of IBM® Installation Manager from the command line with the parameter for console mode.

Procedure

1. In the directory where IBM Installation Manager is installed, go to the following subdirectory:
   - Linux eclipse/tools

   For example:

   - Linux /opt/IBM/InstallationManager/eclipse/tools
2. From the tools directory, issue the following command:
   - Linux `./imcl -c`
3. To uninstall, enter `5`.
4. Choose to uninstall from the IBM Spectrum Protect package group.
5. Enter `N` for Next.
6. Choose to uninstall the IBM Spectrum Protect server package.
7. Enter `N` for Next.
8. Enter `U` for Uninstall.
9. Enter `F` for Finish.

Linux: Uninstalling IBM Spectrum Protect in silent mode

To uninstall IBM Spectrum Protect™ in silent mode, you must run the uninstallation program of IBM® Installation Manager from the command line with the parameters for silent mode.

Before you begin

You can use a response file to provide data input to silently uninstall the IBM Spectrum Protect server components. IBM Spectrum Protect includes a sample response file, uninstall_response_sample.xml, in the input directory where the installation package is extracted. This file contains default values to help you avoid any unnecessary warnings.

If you want to uninstall all IBM Spectrum Protect components, leave `modify="false"` set for each component in the response file. If you do not want to uninstall a component, set the value to `modify="true"`.

If you want to customize the response file, you can modify the options that are in the file. For information about response files, see Response files.

Procedure

1. In the directory where IBM Installation Manager is installed, go to the following subdirectory:
   - Linux eclipse/tools

For example:

- Linux /opt/IBM/InstallationManager/eclipse/tools

2. From the tools directory, issue the following command, where *response_file* represents the response file path, including the file name:
   Linux

   ```
   ./imcl -input response_file -silent
   ```

   The following command is an example:

   Linux

   ```
   ./imcl -input /tmp/input/uninstall_response.xml -silent
   ```

Linux: Uninstalling and reinstalling IBM Spectrum Protect

If you plan to manually reinstall IBM Spectrum Protect™ instead of using the wizard, there are a number of steps to take to preserve your server instance names and database directories. During an uninstallation, any server instances previously set up are removed, but the database catalogs for those instances still exist.

About this task

To manually uninstall and reinstall IBM Spectrum Protect, complete the following steps:

1. Linux Make a list of your current server instances before proceeding to the uninstallation. Run the following command:

   ```
   /opt/tivoli/tsm/db2/instance/db2ilist
   ```

2. Run the following commands for every server instance:
   Linux

   ```
   db2 attach to instance_name
   db2 get dbm cfg show detail
   db2 detach
   ```

   Keep a record of the database path for each instance.
3. Uninstall IBM Spectrum Protect. See Linux: Uninstalling IBM Spectrum Protect.
4. When you uninstall any supported version of IBM Spectrum Protect, including a fix pack, an instance file is created. The instance file is created to help reinstall IBM Spectrum Protect. Check this file and use the information when you are prompted for the instance credentials when reinstalling. In silent installation mode, you provide these credentials using the `INSTANCE_CRED` variable.
   You can find the instance file in the following location:
   - Linux /etc/tivoli/tsm/instanceList.obj
5. Reinstall IBM Spectrum Protect. See Linux: Installing the server components.

   If the `instanceList.obj` file does not exist, you need to recreate your server instances using the following steps:

   a. Recreate your server instances. See Linux: Creating the server instance.
      Tip: The installation wizard configures the server instances but you must verify that they exist. If they do not exist, you must manually configure them.
   b. Catalog the database. Log in to each server instance as the instance user, one at a time, and issue the following commands:
      Linux

      ```
      db2 catalog database tsmdb1
      db2 attach to instance_name
      db2 update dbm cfg using dftdbpath instance_directory
      db2 detach
      ```

   c. Linux Verify that the server instance was created successfully. Issue this command:

      ```
      /opt/tivoli/tsm/db2/instance/db2ilist
      ```

   d. Verify that IBM Spectrum Protect recognizes the server instance by listing your directories. Your home directory appears if you did not change it. Your instance directory does appear if you used the configuration wizard. Issue this command:

```
db2 list database directory
```

If you see TSMDB1 listed, you can start the server.

Linux: Uninstalling IBM Installation Manager

You can uninstall IBM® Installation Manager if you no longer have any products that were installed by IBM Installation Manager.

Before you begin

Before you uninstall IBM Installation Manager, you must ensure that all packages that were installed by IBM Installation Manager are uninstalled. Close IBM Installation Manager before you start the uninstall process.

Linux To view installed packages, issue the following command from a command line:

```
cd /opt/IBM/InstallationManager/eclipse/tools
./imcl listInstalledPackages
```

Procedure

To uninstall IBM Installation Manager, complete the following steps:

Linux

1. Open a command line and change directories to /var/ibm/InstallationManager/uninstall.
2. Issue the following command:

   ```
   ./uninstall
   ```

   Restriction: You must be logged in to the system as the `root` user ID.

Windows: Installing the server

Installation of the server includes planning, installation, and initial configuration.

- Windows: Planning to install the server
  Install the server software on the computer that manages storage devices and install the client software on every workstation that transfers data to IBM Spectrum Protect™ server-managed storage.
- Windows: Installing the server components
  To install the Version 8.1.2 server components, you can use the installation wizard, the command line in console mode, or silent mode.
- Windows: Taking the first steps after you install IBM Spectrum Protect
  After you install Version 8.1.2, prepare for the configuration. Using the configuration wizard is the preferred method of configuring the IBM Spectrum Protect instance.
- Windows: Installing an IBM Spectrum Protect server fix pack
  IBM Spectrum Protect maintenance updates, which are also referred to as fix packs, bring your server up to the current maintenance level.
- Windows: Reverting from Version 8.1.2 to a previous server
  If you must revert to the previous version of the server after an upgrade, you must have a full database backup from your original version. You must also have the server installation media for your original version and key configuration files. Carefully follow the preparation steps before you upgrade the server. By doing so, it might be possible to revert to the previous version of the IBM Spectrum Protect server with minimal loss of data.
- Windows: Reference: DB2 commands for IBM Spectrum Protect server databases
  Use this list as reference when you are directed to issue DB2® commands by IBM® support.
- Windows: Uninstalling IBM Spectrum Protect
  You can use the following procedures to uninstall IBM Spectrum Protect. Before you remove IBM Spectrum Protect, ensure that you do not lose your backup and archive data.

Windows: Planning to install the server

Install the server software on the computer that manages storage devices and install the client software on every workstation that transfers data to IBM Spectrum Protect™ server-managed storage.

- Windows: What you should know first
  Before installing IBM Spectrum Protect, be familiar with your operating systems, storage devices, communication protocols, and system configurations.
- Windows: What you should know about security before you install or upgrade the server
  Before you install IBM Spectrum Protect V8.1.2 or later, review information about the enhanced security features and the requirements for updating your environment.
- Windows: Planning for optimal performance
  Before you install the IBM Spectrum Protect server, evaluate the characteristics and configuration of the system to ensure that the server is set up for optimal performance.
- Windows: Windows: Minimum system requirements for Windows systems
  The server can require a large amount of memory, network bandwidth, and processor resources. In many cases, the server performs best when other applications are not installed on the same system.
- Windows: IBM Installation Manager
  IBM Spectrum Protect uses IBM® Installation Manager, which is an installation program that can use remote or local software repositories to install or update many IBM products.
- Windows: Worksheets for planning details for the server
  You can use the worksheets to help you plan the amount and location of storage needed for the IBM Spectrum Protect server. You can also use them to keep track of names and user IDs.
- Windows: Capacity planning
  Capacity planning for IBM Spectrum Protect includes managing resources such as the database, the recovery log and the shared resource area. To maximize resources as part of capacity planning, you must estimate space requirements for the database and the recovery log. The shared resource area must have enough space available for each installation or upgrade.
- Windows: Server naming best practices
  Use these descriptions as a reference when you install or upgrade an IBM Spectrum Protect server.
- Windows: Installation directories
  Installation directories for the IBM Spectrum Protect server include the server, DB2®, device, language, and other directories. Each one contains several additional directories.

Windows: What you should know first

Before installing IBM Spectrum Protect™, be familiar with your operating systems, storage devices, communication protocols, and system configurations.

Server maintenance releases, client software, and publications are available from the IBM® Support Portal.

Windows Restriction: You cannot install and run the Version 8.1.2 server on a system that already has DB2® installed on it, whether DB2 was installed by itself or as part of some other application. The V8.1.2 server requires the installation and use of the DB2 version that is packaged with the V8.1.2 server. No other version of DB2 can exist on the system.

Windows You can install the IBM Spectrum Protect server on a domain controller. The server can have heavy processor usage, however, and that might affect and stall other applications.

Experienced DB2 administrators can choose to perform advanced SQL queries and use DB2 tools to monitor the database. Do not, however, use DB2 tools to change DB2 configuration settings from those that are preset by IBM Spectrum Protect, or alter the DB2 environment for IBM Spectrum Protect in other ways, such as with other products. The V8.1.2 server has been built and tested extensively using the data definition language (DDL) and database configuration that the server deploys.

Attention: Do not alter the DB2 software that is installed with IBM Spectrum Protect installation packages and fix packs. Do not install or upgrade to a different version, release, or fix pack of DB2 software because doing so can damage the database.

Windows: What you should know about security before you install or upgrade the server

Before you install IBM Spectrum Protect™ V8.1.2 or later, review information about the enhanced security features and the requirements for updating your environment.

About this task

Security enhancements that were introduced in V8.12 and later enforce stricter security settings. To ensure that communication between servers and clients is not interrupted when you install or upgrade IBM Spectrum Protect software to V8.1.2, follow the

procedure.

Procedure

1. Install or upgrade the IBM Spectrum Protect servers to 8.1.2 or later.
2. Install or upgrade the backup-archive clients. For more information, see Installing and configuring clients.
   For information about scheduling deployment of client updates from the server, see the following documents:
   - For IBM Spectrum Protect 8.1.2 or later servers, see technote 2004596.
   - For IBM® Tivoli® Storage Manager V7.1 servers and IBM Spectrum Protect V8.1.0 and V8.1.1 servers, see technote 1673299.
3. Configure the options for backup-archive clients. For more information, see Upgrading the IBM Spectrum Protect Server and the IBM Spectrum Protect Client.

Windows: Planning for optimal performance

Before you install the IBM Spectrum Protect™ server, evaluate the characteristics and configuration of the system to ensure that the server is set up for optimal performance.

Procedure

1. Review Windows: What you should know first.
2. Review each of the following sub-sections.

- Windows: Planning for the server hardware and the operating system
  Use the checklist to verify that the system where the server is installed meets requirements for hardware and software configuration.
- Windows: Planning for the server database disks
  Use the checklist to verify that the system where the server is installed meets requirements for hardware and software configuration.
- Windows: Planning for the server recovery log disks
  Use the checklist to verify that the system where the server is installed meets requirements for hardware and software configuration.
- Windows: Planning for directory-container and cloud-container storage pools
  Review how your directory-container and cloud-container storage pools are set up to ensure optimal performance.
- Windows: Planning for storage pools in DISK or FILE device classes
  Use the checklist to review how your disk storage pools are set up. This checklist includes tips for storage pools that use DISK or FILE device classes.
- Windows: Planning for the correct type of storage technology
  Storage devices have different capacity and performance characteristics. These characteristics affect which devices are better for use with IBM Spectrum Protect.
- Windows: Applying best practices to the server installation
  Typically, hardware configuration and selection have the most significant effect on the performance of an IBM Spectrum Protect solution. Other factors that affect performance are the operating system selection and configuration, and the configuration of IBM Spectrum Protect.

Windows: Planning for the server hardware and the operating system

Use the checklist to verify that the system where the server is installed meets requirements for hardware and software configuration.

Question	Tasks, characteristics, options, or settings	More information

Question	Tasks, characteristics, options, or settings	More information
Does the operating system and hardware meet or exceed requirements? • Number and speed of processors • System memory • Supported operating system level	If you are using the minimum required amount of memory, you can support a minimal workload. You can experiment by adding more system memory to determine whether the performance is improved. Then, decide whether you want to keep the system memory dedicated to the server. Test the memory variations by using the entire daily cycle of the server workload. If you run multiple servers on the system, add the requirements for each server to get the requirements for the system.	Review operating system requirements at technote 1243309. Additionally, review the guidance in Tuning tasks for operating systems and other applications. For more information about requirements when these features are in use, see the following topics: • Checklist for data deduplication • Checklist for node replication For more information about sizing requirements for the server and storage, see the IBM Spectrum Protect™ Blueprint.
Are disks configured for optimal performance?	The amount of tuning that can be done for different disk systems varies. Ensure that the appropriate queue depths and other disk system options are set.	For more information, see the following topics: • "Planning for server database disks" • "Planning for server recovery log disks" • "Planning for storage pools in DISK or FILE device classes"

Question	Tasks, characteristics, options, or settings	More information
Does the server have enough memory?	Heavier workloads and advanced features such as data deduplication and node replication require more than the minimum system memory that is specified in the system requirements document. For databases that are not enabled for data deduplication, use the following guidelines to specify memory requirements: • For databases less than 500 GB, you need 16 GB of memory. • For databases with a size of 500 GB - 1 TB, you need 24 GB of memory. • For databases with a size of 1 TB - 1.5 TB, you need 32 GB of memory. • For databases greater than 1.5 TB, you need 40 GB of memory. Ensure that you allocate extra space for the active log and the archive log for replication processing.	For more information about requirements when these features are in use, see the following topics: • Checklist for data deduplication • Checklist for node replication • Memory requirements
Does the system have enough host bus adapters (HBAs) to handle the data operations that the IBM Spectrum Protect server must run simultaneously?	Understand what operations require use of HBAs at the same time. For example, a server must store 1 GB/sec of backup data while also doing storage pool migration that requires 0.5 GB/sec capacity to complete. The HBAs must be able to handle all of the data at the speed required.	See Tuning HBA capacity.

Question	Tasks, characteristics, options, or settings	More information
Is network bandwidth greater than the planned maximum throughput for backups?	Network bandwidth must allow the system to complete operations such as backups in the time that is allowed or that meets service level commitments. For node replication, network bandwidth must be greater than the planned maximum throughput.	For more information, see the following topics: • Tuning network performance • Checklist for node replication
Are you using a preferred file system for IBM Spectrum Protect server files?	Use a file system that ensures optimal performance and data availability. The server uses direct I/O with file systems that support the feature. Using direct I/O can improve throughput and reduce processor use. The following list identifies the preferred file system: • Windows Use New Technology File System (NTFS) without compression.	For more information, see Configuring the operating system for disk performance.
Are you planning to configure enough paging space?	Paging space, or swap space, extends the memory that is available for processing. When the amount of free RAM in the system is low, programs or data that is not in use are moved from memory to paging space. This action releases memory for other activities, such as database operations. Windows Paging space is automatically configured.	

Windows: Planning for the server database disks

Use the checklist to verify that the system where the server is installed meets requirements for hardware and software configuration.

Question	Tasks, characteristics, options, or settings	More information

Question	Tasks, characteristics, options, or settings	More information
Is the database on fast, low-latency disks?	Do not use the following drives for the IBM Spectrum Protect™ database: • Nearline SAS (NL-SAS) • Serial Advanced Technology Attachment (SATA) • Parallel Advanced Technology Attachment (PATA) Do not use internal disks that are included by default in most server hardware. Enterprise-grade solid-state disks (SSD), with Fibre Channel or SAS interface, offer the best performance. If you plan to use the data deduplication functions of IBM Spectrum Protect, focus on disk performance in terms of I/O operations per second (IOPS).	For more information, see Checklist for data deduplication.
Is the database stored on disks or LUNs that are separate from disks or LUNs that are used for the active log, archive log, and storage pool volumes?	Separation of the server database from other server components helps reduce contention for the same resources by different operations that must run at the same time. Tip: The database and the archive log can share an array when you use solid-state drive (SSD) technology.	
If you are using RAID, do you know how to select the optimal RAID level for your system? Are you defining all LUNs with the same size and type of RAID?	When a system must do large numbers of writes, RAID 10 outperforms RAID 5. However, RAID 10 requires more disks than RAID 5 for the same amount of usable storage. If your disk system is RAID, define all your LUNs with the same size and type of RAID. For example, do not mix 4+1 RAID 5 with 4+2 RAID 6.	
If an option to set the strip size or segment size is available, are you planning to optimize the size when you configure the disk system?	If you can set the strip size or segment size, use 64 KB or 128 KB sizes on disk systems for the database.	The block size that is used for the database varies depending on the table space. Most table spaces use 8 KB blocks, but some use 32 KB blocks.

Question	Tasks, characteristics, options, or settings	More information
Are you planning to create at least four directories, also called storage paths, on four separate LUNs for the database? Create one directory per distinct array on the subsystem. If you have fewer than three arrays, create a separate LUN volume within the array.	Heavier workloads and use of some features require more database storage paths than the minimum requirements. Server operations such as data deduplication drive a high number of input/output operations per second (IOPS) for the database. Such operations perform better when the database has more directories. For server databases that are larger than 2 TB or are expected to grow to that size, use eight directories. Consider planned growth of the system when you determine how many storage paths to create. The server uses the higher number of storage paths more effectively if the storage paths are present when the server is first created. Use the *DB2_PARALLEL_IO* variable to force parallel I/O to occur on table spaces that have one container, or on table spaces that have containers on more than one physical disk. If you do not set the *DB2_PARALLEL_IO* variable, I/O parallelism is equal to the number of containers that are used by the table space. For example, if a table space spans four containers, the level of I/O parallelism that is used is 4.	For more information, see the following topics: • Checklist for data deduplication • Checklist for node replication For help with forecasting growth when the server deduplicates data, see technote 1596944. For the most recent information about database size, database reorganization, and performance considerations for IBM Spectrum Protect servers, see technote 1683633. For information about setting the *DB2_PARALLEL_IO* variable, see Recommended settings for IBM DB2 registry variables.
Are all directories for the database the same size?	Directories that are all the same size ensure a consistent degree of parallelism for database operations. If one or more directories for the database are smaller than the others, they reduce the potential for optimized parallel prefetching. This guideline also applies if you must add storage paths after the initial configuration of the server.	
Are you planning to raise the queue depth of the database LUNs on AIX® systems?	The default queue depth is often too low.	See Configuring AIX systems for disk performance.

Windows: Planning for the server recovery log disks

Use the checklist to verify that the system where the server is installed meets requirements for hardware and software configuration.

Question	Tasks, characteristics, options, or settings	More information
Are the active log and archive log stored on disks or LUNs that are separate from what is used for the database and storage pool volumes?	Ensure that the disks where you place the active log are not used for other server or system purposes. Do not place the active log on disks that contain the server database, the archive log, or system files such as page or swap space.	Separation of the server database, active log, and archive log helps to reduce contention for the same resources by different operations that must run at the same time.

Question	Tasks, characteristics, options, or settings	More information
Are the logs on disks that have nonvolatile write cache?	Nonvolatile write cache allows data to be written to the logs as fast as possible. Faster write operations for the logs can improve performance for server operations.	
Are you setting the logs to a size that adequately supports the workload?	If you are not sure about the workload, use the largest size that you can. Active log The maximum size is 512 GB, set with the ACTIVELOGSIZE server option. Ensure that there is at least 8 GB of free space on the active log file system after the fixed size active logs are created. Archive log The size of the archive log is limited by the size of the file system on which it is located, and not by a server option. Make the archive log at least as large as the active log.	• For log sizing details, see the recovery log information in technote 1421060. • For information about sizing when you use data deduplication, see Checklist for data deduplication.
Are you defining an archive failover log? Are you placing this log on a disk that is separate from the archive log?	The archive failover log is for emergency use by the server when the archive log becomes full. Slower disks can be used for the archive failover log.	Use the ARCHFAILOVERLOGDIRECTORY server option to specify the location of the archive failover log. Monitor the usage of the directory for the archive failover log. If the archive failover log must be used by the server, the space for the archive log might not be large enough.
If you are mirroring the active log, are you using only one type of mirroring?	You can mirror the log by using one of the following methods. Use only one type of mirroring for the log. • Use the MIRRORLOGDIRECTORY option that is available for the IBM Spectrum Protect™ server to specify a mirror location. • Use software mirroring, such as Logical Volume Manager (LVM) on AIX®. • Use mirroring in the disk system hardware.	If you mirror the active log, ensure that the disks for both the active log and the mirror copy have equal speed and reliability. For more information, see Configuring and tuning the recovery log.

Windows: Planning for directory-container and cloud-container storage pools

Review how your directory-container and cloud-container storage pools are set up to ensure optimal performance.

Question	Tasks, characteristics, options, or settings	More information

Question	Tasks, characteristics, options, or settings	More information
Measured in terms of input/output operations per second (IOPS), are you using fast disk storage for the IBM Spectrum Protect™ database?	Use a high-performance disk for the database. Use solid-state drive technology for data deduplication processing. Ensure that the database has a minimum capability of 3000 IOPS. For each TB of data that is backed up daily (before data deduplication), add 1000 IOPS to this minimum. For example, an IBM Spectrum Protect server that is ingesting 3 TB of data per day would need 6000 IOPS for the database disks: `3000 IOPS minimum + 3000 (3 TB x 1000 IOPS) = 6000 IOPS`	For recommendations about disk selection, see "Planning for server database disks". For more information about IOPS, see the IBM Spectrum Protect Blueprints.
Do you have enough memory for the size of your database?	Use a minimum of 40 GB of system memory for IBM Spectrum Protect servers, with a database size of 100 GB, that are deduplicating data. If the retained capacity of backup data grows, the memory requirement might need to be higher. Monitor memory usage regularly to determine whether more memory is required. Use more system memory to improve caching of database pages. The following memory size guidelines are based on the daily amount of new data that you back up: • 128 GB of system memory for daily backups of data, where the database size is 1 - 2 TB • 192 GB of system memory for daily backups of data, where the database size is 2 - 4 TB	Memory requirements

Question	Tasks, characteristics, options, or settings	More information
Have you properly sized the storage capacity for the database active log and archive log?	Configure the server to have a minimum active log size of 128 GB by setting the ACTIVELOGSIZE server option to a value of 131072. The suggested starting size for the archive log is 1 TB. The size of the archive log is limited by the size of the file system on which it is located, and not by a server option. Ensure that there is at least 10% extra disk space for the file system than the size of the archive log. Use a directory for the database archive logs with an initial free capacity of at least 1 TB. Specify the directory by using the ARCHLOGDIRECTORY server option. Define space for the archive failover log by using the ARCHFAILOVERLOGDIRECTORY server option.	For more information about sizing for your system, see the IBM Spectrum Protect Blueprints.
Is compression enabled for the archive log and database backups?	Enable the ARCHLOGCOMPRESS server option to save storage space. This compression option is different from inline compression. Inline compression is enabled by default with IBM Spectrum Protect V7.1.5 and later. Restriction: Do not use this option if the amount of backed up data exceeds 6 TB per day.	For more information about compression for your system, see the IBM Spectrum Protect Blueprints.
Are the IBM Spectrum Protect database and logs on separate disk volumes (LUNs)? Is the disk that is used for the database configured according to best practices for a transactional database?	The database must not share disk volumes with IBM Spectrum Protect database logs or storage pools, or with any other application or file system.	For more information about server database and recovery log configuration, see Server database and recovery log configuration and tuning.
Are you using a minimum of eight (2.2 GHz or equivalent) processor cores for each IBM Spectrum Protect server that you plan to use with data deduplication?	If you are planning to use client-side data deduplication, verify that client systems have adequate resources available during a backup operation to complete data deduplication processing. Use a processor that is at least the minimum equivalent of one 2.2 GHz processor core per backup process with client-side data deduplication.	• Effective planning and use of deduplication • IBM Spectrum Protect Blueprints

Question	Tasks, characteristics, options, or settings	More information
Did you allocate enough storage space for the database?	For a rough estimate, plan for 100 GB of database storage for every 50 TB of data that is to be protected in deduplicated storage pools. *Protected data* is the amount of data before data deduplication, including all versions of objects stored. As a best practice, define a new container storage pool exclusively for data deduplication. Data deduplication occurs at the storage-pool level, and all data within a storage pool, except encrypted data, is deduplicated.	
Have you estimated storage pool capacity to configure enough space for the size of your environment?	You can estimate capacity requirements for a deduplicated storage pool by using the following technique: 1. Estimate the base size of the source data. 2. Estimate the daily backup size by using an estimated change and growth rate. 3. Determine retention requirements. 4. Estimate the total amount of source data by factoring in the base size, daily backup size, and retention requirements. 5. Apply the deduplication ratio factor. 6. Apply the compression ratio factor. 7. Round up the estimate to consider transient storage pool usage.	For an example of using this technique, see Effective planning and use of deduplication.
Have you distributed disk I/O over many disk devices and controllers?	Use arrays that consist of as many disks as possible, which is sometimes referred to as wide striping. Ensure that you use one database directory per distinct array on the subsystem. Set the *DB2_PARALLEL_IO* registry variable to enable parallel I/O for each table space used if the containers in the table space span multiple physical disks. When I/O bandwidth is available and the files are large, for example 1 MB, the process of finding duplicates can occupy the resources of an entire processor. When files are smaller, other bottlenecks can occur. Specify eight or more file systems for the deduplicated storage pool device class so that I/O is distributed across as many LUNs and physical devices as possible.	For guidelines about setting up storage pools, see "Planning for storage pools in DISK or FILE device classes". For information about setting the *DB2_PARALLEL_IO* variable, see Recommended settings for IBM DB2 registry variables.

Question	Tasks, characteristics, options, or settings	More information
Have you scheduled daily operations based on your backup strategy?	The best practice sequence of operations is in the following order: 1. Client backup 2. Storage pool protection 3. Node replication 4. Database backup 5. Expire inventory	• Scheduling data deduplication and node replication processes • Daily operations for directory-container storage pools
Do you have enough storage to manage the DB2® lock list?	If you deduplicate data that includes large files or large numbers of files concurrently, the process can result in insufficient storage space. When the lock list storage is insufficient, backup failures, data management process failures, or server outages can occur. File sizes greater than 500 GB that are processed by data deduplication are most likely to deplete storage space. However, if many backup operations use client-side data deduplication, this problem can also occur with smaller-sized files.	For information about tuning the DB2 LOCKLIST parameter, see Tuning server-side data deduplication.
Is sufficient bandwidth available to transfer data to an IBM Spectrum Protect server?	To transfer data to an IBM Spectrum Protect server, use client-side or server-side data deduplication and compression to reduce the bandwidth that is required. Use a V7.1.5 server or higher to use inline compression and use a V7.1.6 or later client to enable enhanced compression processing.	For more information, see the enablededup client option.
Have you determined how many storage pool directories to assign to each storage pool?	Assign directories to a storage pool by using the DEFINE STGPOOLDIRECTORY command. Create multiple storage pool directories and ensure that each directory is backed up to a separate disk volume (LUN).	

Question	Tasks, characteristics, options, or settings	More information
Did you allocate enough disk space in the cloud-container storage pool?	To prevent backup failures, ensure that the local directory has enough space. Use the following list as a guide for optimal disk space: • For serial-attached SCSI (SAS) and spinning disk, calculate the amount of new data that is expected after daily data reduction (compression and data deduplication). Allocate up to 100 percent of that amount, in terabytes, for disk space. • Provide 3 TB for flash-based storage systems with fast network connections to on-premises, high-performance cloud systems. • Provide 5 TB for solid-state drive (SSD) systems with fast network connections to high-performance cloud systems.	
Did you select the appropriate type of local storage?	Ensure that data transfers from local storage to cloud finish before the next backup cycle starts. Tip: Data is removed from local storage soon after it moves to the cloud. Use the following guidelines: • Use flash or SSD for large systems that have high-performing cloud systems. Ensure that you have a dedicated 10 GB wide area network (WAN) link with a high-speed connection to the object storage. For example, use flash or SSD if you have a dedicated 10 GB WAN link plus a high-speed connection to either an IBM® Cloud Object Storage location or to an Amazon Simple Storage Service (Amazon S3) data center. • Use larger capacity 15000 rpm SAS disks for these scenarios: ◦ Medium-sized systems ◦ Slower cloud connections, for example, 1 GB ◦ When you use IBM Cloud Object Storage as your service provider across several regions • For SAS or spinning disk, calculate the amount of new data that is expected after daily data reduction (compression and data deduplication). Allocate up to 100 percent of that amount for disk space, in terabytes.	

Windows: Planning for storage pools in DISK or FILE device classes

Use the checklist to review how your disk storage pools are set up. This checklist includes tips for storage pools that use DISK or FILE device classes.

Question	Tasks, characteristics, options, or settings	More information
Can the storage pool LUNs sustain throughput rates for 256 KB sequential reads and writes to adequately handle the workload within the time constraints?	When you are planning for peak loads, consider all the data that you want the server to read or write to the disk storage pools simultaneously. For example, consider the peak flow of data from client backup operations and server data-movement operations such as migration that run at the same time. The IBM Spectrum Protect™ server reads and writes to storage pools predominantly in 256 KB blocks. If the disk system includes the capability, configure the disk system for optimal performance with sequential read/write operations rather than random read/write operations.	For more information, see Analyzing the basic performance of disk systems.
Is the disk configured to use read and write cache?	Use more cache for better performance.	
For storage pools that use FILE device classes, have you determined a good size to use for the storage pool volumes?	Review the information in Optimal number and size of volumes for storage pools that use disk. If you do not have the information to estimate a size for FILE device class volumes, start with volumes that are 50 GB.	Typically, problems arise more frequently when the volumes are too small. Few problems are reported when volumes are larger than needed. When you determine the volume size to use, as a precaution choose a size that might be larger than necessary.
For storage pools that use FILE device classes, are you using preallocated volumes?	Scratch volumes can cause file fragmentation. To ensure that a storage pool does not run out of volumes, set the MAXSCRATCH parameter to a value greater than zero.	Use the DEFINE VOLUME server command to preallocate volumes in the storage pool. Use the DEFINE STGPOOL or UPDATE STGPOOL server command to set the MAXSCRATCH parameter.
For storage pools that use FILE device classes, have you compared the maximum number of client sessions to the number of volumes that are defined?	Always maintain enough usable volumes in the storage pools to allow for the expected peak number of client sessions that run at one time. The volumes might be scratch volumes, empty volumes, or partly filled volumes.	For storage pools that use FILE device classes, only one session or process can write to a volume at the same time.

Question	Tasks, characteristics, options, or settings	More information
For storage pools that use FILE device classes, have you set the MOUNTLIMIT parameter of the device class to a value that is high enough to account for the number of volumes that might be mounted in parallel?	For storage pools that use data deduplication, the MOUNTLIMIT parameter is typically in the range of 500 - 1000. Set the value for MOUNTLIMIT to the maximum number of mount points that are needed for all active sessions. Consider parameters that affect the maximum number of mount points that are needed: • The MAXSESSIONS server option, which is the maximum number of IBM Spectrum Protect sessions that can run concurrently. • The MAXNUMMP parameter, which sets the maximum number of mount points that each client node can use. For example, if the maximum number of client node backup sessions is typically 100 and each of the nodes has `MAXNUMMP=2`, multiply 100 nodes by the 2 mount points for each node to get the value of 200 for the MOUNTLIMIT parameter.	Use the REGISTER NODE or UPDATE NODE server command to set the MAXNUMMP parameter for client nodes.
For storage pools that use DISK device classes, have you determined how many storage pool volumes to put on each file system?	How you configure the storage for a storage pool that uses a DISK device class depends on whether you are using RAID for the disk system. If you are not using RAID, then configure one file system per physical disk, and define one storage pool volume for each file system. If you are using RAID 5 with *n* + 1 volumes, configure the storage in one of the following ways: • Configure *n* file systems on the LUN and define one storage pool volume per file system. • Configure one file system and *n* storage pool volumes for the LUN.	For an example layout that follows this guideline, see Sample layout of server storage pools.
Did you create your storage pools to distribute I/O across multiple file systems?	Ensure that each file system is on a different LUN on the disk system. Typically, having 10 - 30 file systems is a good goal, but ensure that the file systems are no smaller than approximately 250 GB.	For details, see the following topics: • Tuning disk storage for the server • Tuning and configuring storage pools and volumes

Windows: Planning for the correct type of storage technology

Storage devices have different capacity and performance characteristics. These characteristics affect which devices are better for use with IBM Spectrum Protect™.

Procedure

Review the following table to help you to choose the correct type of storage technology for the storage resources that the server requires.

Table 1. Storage technology types for IBM Spectrum Protect storage requirements

Storage technology type	Database	Active log	Archive log and archive failover log	Storage pools
Solid-state disk (SSD)	Place the database on SSD in the following circumstances: • You are using IBM Spectrum Protect data deduplication. • You are backing up more than 8 TB of new data daily.	If you place the IBM Spectrum Protect database on an SSD, as a best practice, place the active log on an SSD. If space is not available, use high-performance disk instead.	Save SSDs for use with the database and active log. The archive log and archive failover logs can be placed on slower storage technology types.	Save SSDs for use with the database and active log. Storage pools can be placed on slower storage technology types.
High-performance disk with the following characteristics: • **15k rpm disk** • **Fibre Channel or serial-attached SCSI (SAS) interface**	Use high-performance disks in the following circumstances: • The server does not do data deduplication. • The server does not do node replication. Isolate the server database from its logs and storage pools, and from data for other applications.	Use high-performance disks in the following circumstances: • The server does not do data deduplication. • The server does not do node replication. For performance and availability, isolate the active log from the server database, archive logs, and storage pools.	You can use high-performance disks for the archive log and archive failover logs. For availability, isolate these logs from the database and active log.	Use high-performance disks for storage pools in the following circumstances: • Data is frequently read. • Data is frequently written. For performance and availability, isolate storage pool data from the server database and logs, and from data for other applications.
Medium-performance or high-performance disk with the following characteristics: • **10k rpm disk** • **Fibre Channel or SAS interface**	If the disk system has a mix of disk technologies, use the faster disks for the database and active log. Isolate the server database from its logs and storage pools, and from data for other applications.	If the disk system has a mix of disk technologies, use the faster disks for the database and active log. For performance and availability, isolate the active log from the server database, archive logs, and storage pools.	You can use medium-performance or high-performance disk for the archive log and archive failover logs. For availability, isolate these logs from the database and active log.	Use medium-performance or high-performance disk for storage pools in the following circumstances: • Data is frequently read. • Data is frequently written. For performance and availability, isolate storage pool data from the server database and logs, and from data for other applications.

Storage technology type	Database	Active log	Archive log and archive failover log	Storage pools
SATA, network-attached storage	Do not use this storage for the database. Do not place the database on XIV storage systems.	Do not use this storage for the active log.	Use of this slower storage technology is acceptable because these logs are written once and infrequently read.	Use this slower storage technology in the following circumstances: • Data is infrequently written, for example written once. • Data is infrequently read. .
Tape and virtual tape				Use for long-term retention or if data is infrequently used.

Windows: Applying best practices to the server installation

Typically, hardware configuration and selection have the most significant effect on the performance of an IBM Spectrum Protect™ solution. Other factors that affect performance are the operating system selection and configuration, and the configuration of IBM Spectrum Protect.

Procedure

- The following best practices are the most important for optimal performance and problem prevention.
- Review the table to determine the best practices that apply to your environment.

Best practice	More information
Use fast disks for the server database. Enterprise-grade solid-state disks (SSD), with Fibre Channel or SAS interface, offer the best performance.	Use fast, low-latency disks for the database. Using SSD is essential if you are using data deduplication and node replication. Avoid Serial Advanced Technology Attachment (SATA) and Parallel Advanced Technology Attachment (PATA) disks. For details and more tips, see the following topics: ◦ "Planning for server database disks" ◦ "Planning for the correct type of storage technology"
Ensure that the server system has enough memory.	Review operating system requirements in technote 1243309. Heavier workloads require more than the minimum requirements. Advanced features such as data deduplication and node replication can require more than the minimum memory that is specified in the system requirements document. If you plan to run multiple instances, each instance requires the memory that is listed for one server. Multiply the memory for one server by the number of instances that are planned for the system.

Best practice	More information
Separate the server database, the active log, the archive log, and disk storage pools from each other.	Keep all IBM Spectrum Protect storage resources on separate disks. Keep storage pool disks separate from the disks for the server database and logs. Storage pool operations can interfere with database operations when both are on the same disks. Ideally, the server database and logs are also separated from each other. For details and more tips, see the following topics: ○ "Planning for server database disks" ○ "Planning for server recovery log disks" ○ "Planning for storage pools in DISK or FILE device classes"
Use at least four directories for the server database. For larger servers or servers that use advanced features, use eight directories.	Place each directory on a LUN that is isolated from other LUNs and from other applications. A server is considered to be large if its database is larger than 2 TB or is expected to grow to that size. Use eight directories for such servers. See "Planning for server database disks".
If you are using data deduplication, node replication, or both, follow the guidelines for database configuration and other items.	Configure the server database according to the guidelines, because the database is extremely important to how well the server runs when these features are being used. For details and more tips, see the following topics: ○ Checklist for data deduplication ○ Checklist for node replication
For storage pools that use FILE type device classes, follow the guidelines for the size of storage pool volumes. Typically, 50 GB volumes are best.	Review the information in Optimal number and size of volumes for storage pools that use disk to help you to determine volume size. Configure storage pool devices and file systems based on throughput requirements, not only on capacity requirements. Isolate the storage devices that are used by IBM Spectrum Protect from other applications that have high I/O, and ensure that there is enough throughput to that storage. For more details, see Checklist for storage pools on DISK or FILE.
Schedule IBM Spectrum Protect client operations and server maintenance activities to avoid or minimize overlap of operations.	For more details, see the following topics: ○ Tuning the schedule for daily operations ○ Checklist for server configuration
Monitor operations constantly.	By monitoring, you can find problems early and more easily identify causes. Keep records of monitoring reports for up to a year to help you identify trends and plan for growth. See Monitoring and maintaining the environment for performance.

Windows: Minimum system requirements for Windows systems

The server can require a large amount of memory, network bandwidth, and processor resources. In many cases, the server performs best when other applications are not installed on the same system.

Hardware and software requirements for the IBM Spectrum Protect server installation

These tables list the minimum hardware and software requirements for the installation of an IBM Spectrum Protect™ server. Use these requirements as a starting point for systems without data deduplication. The optimal IBM Spectrum Protect environment is set up with data deduplication by using the IBM Spectrum Protect Blueprints. For the most current information about system requirements, see technote 1243309.

Hardware requirements

Table 1 describes the minimum hardware requirements for the server. If the server does not meet the minimum requirements, the installation fails. For more details about planning disk space, see Windows: Capacity planning.

Table 1. Hardware requirements

Type of hardware	Hardware requirements
Hardware	An AMD64 or Intel EMT-64 processor
Disk Space	The following minimum values for disk space: • At least 7.5 GB of free disk storage for a typical installation • 60 MB in the temporary directory space • 2 GB partition size in the C:\ drive • 300 MB in the instance directory • 2 GB for the shared resources area In case a problem arises and any diagnosis is needed, it is optimal to have temporary or other space available on the system for a first failure data capture (FFDC) log or for other temporary uses such as for collecting trace logs. Significant additional disk space is required for database and log files. The size of the database depends on the number of client files to be stored and the method by which the server manages them. The default active log space is 16 GB, the minimum that is needed for most workloads and configurations. When you create the active log, you need at least 64 GB to run replication. If replication and data deduplication are both being used, create an active log of 128 GB. Allocate at least three times the default active log space for the archive log (48 GB). Ensure that you have sufficient resources if you are using data deduplication or expect a heavy client workload. For optimal performance and to facilitate I/O, specify at least two equally sized containers or Logical Unit Numbers (LUNs) for the database. In addition, each active log and archive log needs its own container or LUN. Ensure that you see Windows: Capacity planning for more details about disk space.
Memory	The following minimum values for memory: • 16 GB for standard server operations without data deduplication and node replication • 24 GB for data deduplication or node replication • 32 GB for node replication with data deduplication For more specific memory requirements for larger databases and higher ingestion capability, see the IBM Spectrum Protect server memory tuning table. For more specific memory requirements when you are using data deduplication, see the IBM Spectrum Protect Blueprint for your operating system.

Software requirements

Table 2 describes the minimum software requirements that are needed for a server on a Windows system.

Table 2. Software requirements

Type of software	Minimum software requirements
Operating system	One of the following operating systems: • Microsoft Windows Server 2012: Standard, Enterprise, or Datacenter Edition (64-bit) • Microsoft Windows Server 2012 R2 (64-bit) • Microsoft Windows Server 2016

Type of software	Minimum software requirements
Communication protocol	At least one of the following communication protocols (installed by default with the current Windows operating systems): • Named Pipes • TCP/IP Version 4 or Version 6
Device drivers	The IBM Spectrum Protect passthru device driver that is required for non-IBM® drives and tape libraries. The Windows native device driver is recommended for tape drives and tape libraries. Otherwise, the IBM Spectrum Protect kernel device driver can be used. For the IBM 3590, 3592, or the Ultrium tape library or drives, the IBM device drivers are required. Install the most current device drivers. You can locate IBM driver packages at Fix Central. Configure the device drivers before you use the server with tape devices.
Other software	Windows 2012, Windows 2012 R2, and Windows 2016 require that .NET Framework 3.5 is installed and enabled. The following User Account Control policies must be disabled: • User Account Control: Admin Approval Mode for the Built-in Administrator account • User Account Control: Run all administrators in Admin Approval Mode To authenticate IBM Spectrum Protect users with a Lightweight Directory Access Protocol (LDAP) server, you must use one of the following directory servers: • Microsoft Active Directory (Windows Server 2012, Windows Server 2012 R2) • IBM Security Directory Server V6.3 • IBM Security Directory Server V6.4

Windows: IBM Installation Manager

IBM Spectrum Protect™ uses IBM® Installation Manager, which is an installation program that can use remote or local software repositories to install or update many IBM products.

If the required version of IBM Installation Manager is not already installed, it is automatically installed or upgraded when you install IBM Spectrum Protect. It must remain installed on the system so that IBM Spectrum Protect can be updated or uninstalled later as needed.

The following list contains explanations of some terms that are used in IBM Installation Manager:

Offering
: An installable unit of a software product.

  The IBM Spectrum Protect offering contains all of the media that IBM Installation Manager requires to install IBM Spectrum Protect.

Package
: The group of software components that are required to install an offering.
  The IBM Spectrum Protect package contains the following components:

  - IBM Installation Manager installation program
  - IBM Spectrum Protect offering

Package group
: A set of packages that share a common parent directory.

  The default package group for the IBM Spectrum Protect package is `IBM Installation Manager`.

Repository
: A remote or local storage area for data and other application resources.

  The IBM Spectrum Protect package is stored in a repository on IBM Fix Central.

Shared resources directory
: A directory that contains software files or plug-ins that are shared by packages.

  IBM Installation Manager stores installation-related files in the shared resources directory, including files that are used for rolling back to a previous version of IBM Spectrum Protect.

Windows: Worksheets for planning details for the server

You can use the worksheets to help you plan the amount and location of storage needed for the IBM Spectrum Protect™ server. You can also use them to keep track of names and user IDs.

Windows Restriction: If you are using a File Allocation Table (FAT or FAT32) or a New Technology File System (NTFS) format, you cannot specify the root directory of that system as the location of a database directory or log directory. Instead, you must create one or more subdirectories within the root directory. Then, create the database directories and log directories within the subdirectories.

Item	Space required	Number of directories	Location of directories
The database			
Active log			
Archive log			
Optional: Log mirror for the active log			
Optional: Secondary archive log (failover location for archive log)			

Item	Names and user IDs	Location
The *instance user ID* for the server, which is the ID you use to start and run the IBM Spectrum Protect server		
The *home directory* for the server, which is the directory that contains the instance user ID		
The database instance name		
The *instance directory* for the server, which is a directory that contains files specifically for this server instance (the server options file and other server-specific files)		
The server name, use a unique name for each server		

Windows: Capacity planning

Capacity planning for IBM Spectrum Protect™ includes managing resources such as the database, the recovery log and the shared resource area. To maximize resources as part of capacity planning, you must estimate space requirements for the database and the recovery log. The shared resource area must have enough space available for each installation or upgrade.

- Windows: Estimating space requirements for the database
  To estimate space requirements for the database, you can use the maximum number of files that can be in server storage at one time or you can use storage pool capacity.
- Windows: Recovery log space requirements
  In IBM Spectrum Protect, the term *recovery log* comprises the active log, the archive log, the active log mirror, and the archive failover log. The amount of space that you require for the recovery log depends on various factors, including, for example, the amount of client activity with the server.

- Windows: Monitoring space utilization for the database and recovery logs
  To determine the amount of used and available active log space, you issue the QUERY LOG command. To monitor space utilization in the database and recovery logs, you can also check the activity log for messages.
- Windows: Deleting installation rollback files
  You can delete certain installation files that were saved during the installation process to free space in the shared resource directory. For example, files that might have been required for a rollback operation are types of files that you can delete.

Windows: Estimating space requirements for the database

To estimate space requirements for the database, you can use the maximum number of files that can be in server storage at one time or you can use storage pool capacity.

About this task

Consider using at least 25 GB for the initial database space. Provision file system space appropriately. A database size of 25 GB is adequate for a test environment or a library-manager-only environment. For a production server supporting client workloads, the database size is expected to be larger. If you use random-access disk (DISK) storage pools, more database and log storage space is needed than for sequential-access storage pools.

The maximum size of the IBM Spectrum Protect™ database is 6 TB.

For information about sizing the database in a production environment that is based on the number of files and on storage pool size, see the following topics.

- Windows: Estimating database space requirements based on the number of files
  If you can estimate the maximum number of files that might be in server storage at a time, you can use that number to estimate space requirements for the database.
- Windows: Estimating database space requirements based on storage pool capacity
  To estimate database space requirements based on storage pool capacity, use a ratio of 1 - 5%. For example, if you require 200 TB of storage pool capacity, the size of your database is expected to be 2 - 10 TB. As a general rule, make your database as large as possible to prevent running out of space. If you run out of database space, server operations and client-store operations can fail.
- Windows: The database manager and temporary space
  The IBM Spectrum Protect server database manager manages and allocates system memory and disk space for the database. The amount of database space you require depends on the amount of system memory available and the server workload.

Windows: Estimating database space requirements based on the number of files

If you can estimate the maximum number of files that might be in server storage at a time, you can use that number to estimate space requirements for the database.

About this task

To estimate space requirements that is based on the maximum number of files in server storage, use the following guidelines:

- 600 - 1000 bytes for each stored version of a file, including image backups.
  Restriction: The guideline does not include space that is used during data deduplication.
- 100 - 200 bytes for each cached file, copy storage pool file, active-data pool file, and deduplicated file.
- Additional space is required for database optimization to support varying data-access patterns and to support server back-end processing of the data. The amount of extra space is equal to 50% of the estimate for the total number of bytes for file objects.

In the following example for a single client, the calculations are based on the maximum values in the preceding guidelines. The examples do not take into account that you might use file aggregation. In general, when you aggregate small files, it reduces the amount of required database space. File aggregation does not affect space-managed files.

Procedure

1. Calculate the number of file versions. Add each of the following values to obtain the number of file versions:
   a. Calculate the number of backed-up files. For example, as many as 500,000 client files might be backed up at a time. In this example, storage policies are set to keep up to three copies of backed up files:

      ```
      500,000 files * 3 copies = 1,500,000 files
      ```

   b. Calculate the number of archive files. For example, as many as 100,000 client files might be archived copies.
   c. Calculate the number of space-managed files. For example, as many as 200,000 client files might be migrated from client workstations.

   Using 1000 bytes per file, the total amount of database space that is required for the files that belong to the client is 1.8 GB:

   ```
   (1,500,000 + 100,000 + 200,000) * 1000 = 1.8 GB
   ```

2. Calculate the number of cached files, copy storage-pool files, active-data pool files, and deduplicated files:
   a. Calculate the number of cached copies. For example, caching is enabled in a 5 GB disk storage pool. The high migration threshold of the pool is 90% and the low migration threshold of the pool is 70%. Thus, 20% of the disk pool, or 1 GB, is occupied by cached files.
   If the average file size is about 10 KB, approximately 100,000 files are in cache at any one time:

      ```
      100,000 files * 200 bytes = 19 MB
      ```

   b. Calculate the number of copy storage-pool files. All primary storage pools are backed up to the copy storage pool:

      ```
      (1,500,000 + 100,000 + 200,000) * 200 bytes = 343 MB
      ```

   c. Calculate the number of active storage-pool files. All the active client-backup data in primary storage pools is copied to the active-data storage pool. Assume that 500,000 versions of the 1,500,000 backup files in the primary storage pool are active:

      ```
      500,000 * 200 bytes = 95 MB
      ```

   d. Calculate the number of deduplicated files. Assume that a deduplicated storage pool contains 50,000 files:

      ```
      50,000 * 200 bytes = 10 MB
      ```

   Based on the preceding calculations, about 0.5 GB of extra database space is required for the client's cached files, copy storage-pool files, active-data pool files, and deduplicated files.
3. Calculate the amount of extra space that is required for database optimization. To provide optimal data access and management by the server, extra database space is required. The amount of extra database space is equal to 50% of the total space requirements for file objects.

   ```
   (1.8 + 0.5) * 50% = 1.2 GB
   ```

4. Calculate the total amount of database space that is required for the client. The total is approximately 3.5 GB:

   ```
   1.8 + 0.5 + 1.2 = 3.5 GB
   ```

5. Calculate the total amount of database space that is required for all clients. If the client that was used in the preceding calculations is typical and you have 500 clients, for example, you can use the following calculation to estimate the total amount of database space that is required for all clients:

   ```
   500 * 3.5 = 1.7 TB
   ```

Results

Tip: In the preceding examples, the results are estimates. The actual size of the database might differ from the estimate because of factors such as the number of directories and the length of the path and file names. Periodically monitor your database and adjust its size as necessary.

What to do next

During normal operations, the IBM Spectrum Protect™ server might require temporary database space. This space is needed for the following reasons:

- To hold the results of sorting or ordering that are not already being kept and optimized in the database directly. The results are temporarily held in the database for processing.
- To give administrative access to the database through one of the following methods:

- A DB2® open database connectivity (ODBC) client
- An Oracle Java™ database connectivity (JDBC) client
- Structured Query Language (SQL) to the server from an administrative-client command line

Consider using an extra 50 GB of temporary space for every 500 GB of space for file objects and optimization. See the guidelines in the following table. In the example that is used in the preceding step, a total of 1.7 TB of database space is required for file objects and optimization for 500 clients. Based on that calculation, 200 GB is required for temporary space. The total amount of required database space is 1.9 TB.

Database size	Minimum temporary-space requirement
< 500 GB	50 GB
≥ 500 GB and < 1 TB	100 GB
≥ 1 TB and < 1.5 TB	150 GB
≥ 1.5 and < 2 TB	200 GB
≥ 2 and < 3 TB	250 - 300 GB
≥ 3 and < 4 TB	350 - 400 GB

Windows: Estimating database space requirements based on storage pool capacity

To estimate database space requirements based on storage pool capacity, use a ratio of 1 - 5%. For example, if you require 200 TB of storage pool capacity, the size of your database is expected to be 2 - 10 TB. As a general rule, make your database as large as possible to prevent running out of space. If you run out of database space, server operations and client-store operations can fail.

Windows: The database manager and temporary space

The IBM Spectrum Protect™ server database manager manages and allocates system memory and disk space for the database. The amount of database space you require depends on the amount of system memory available and the server workload.

The database manager sorts data in a specific sequence, according to the SQL statement that you issue to request the data. Depending on the workload on the server, and if there is more data than the database manager can manage, the data (that is ordered in sequence) is allocated to temporary disk space. Data is allocated to temporary disk space when there is a large result set. The database manager dynamically manages the memory that is used when data is allocated to temporary disk space.

For example, expiration processing can produce a large result set. If there is not enough system memory on the database to store the result set, some of the data is allocated to temporary disk space. During expiration processing, if a node or file space are selected that are too large to process, the database manager cannot sort the data in memory. The database manager must use temporary space to sort data.

To run database operations, consider adding more database space for the following scenarios:

- The database has a small amount of space and the server operation that requires temporary space uses the remaining free space.
- The file spaces are large, or the file spaces have an assigned policy that creates many file versions.
- The IBM Spectrum Protect server must run with limited memory. The database uses the IBM Spectrum Protect server main memory to run database operations. However, if there is insufficient memory available, the IBM Spectrum Protect server allocates temporary space on disk to the database. For example, if 10G of memory is available and database operations require 12G of memory, the database uses temporary space.
- An `out of database space` error is displayed when you deploy an IBM Spectrum Protect server. Monitor the server activity log for messages that are related to database space.

Important: Do not change the DB2 software that is installed with the IBM Spectrum Protect installation packages and fix packs. Do not install or upgrade to a different version, release, or fix pack, of DB2 software to avoid damage to the database.

Windows: Recovery log space requirements

In IBM Spectrum Protect™, the term *recovery log* comprises the active log, the archive log, the active log mirror, and the archive failover log. The amount of space that you require for the recovery log depends on various factors, including, for example, the amount of client activity with the server.

- Windows: Active and archive log space
  When you estimate space requirements for active and archive logs, include some extra space for contingencies such as occasional heavy workloads and failovers.
- Windows: Active-log mirror space
  The active log can be mirrored so that the mirrored copy can be used if the active log files cannot be read. There can be only one active log mirror.
- Windows: Archive-failover log space
  The archive failover log is used by the server if the archive log directory runs out of space.

Windows: Active and archive log space

When you estimate space requirements for active and archive logs, include some extra space for contingencies such as occasional heavy workloads and failovers.

In IBM Spectrum Protect™ servers V7.1 and later, the active log can be a maximum size of 512 GB. The archive log size is limited to the size of the file system that it is installed on.

Use the following general guidelines when you estimate the size of the active log:

- The suggested starting size for the active log is 16 GB.
- Ensure that the active log is at least large enough for the amount of concurrent activity that the server typically handles. As a precaution, try to anticipate the largest amount of work that the server manages at one time. Provision the active log with extra space that can be used if needed. Consider using 20% of extra space.
- Monitor used and available active log space. Adjust the size of the active log as needed, depending upon factors such as client activity and the level of server operations.
- Ensure that the directory that holds the active log is as large as, or larger than, the size of the active log. A directory that is larger than the active log can accommodate failovers, if they occur.
- Ensure that the file system that contains the active log directory has at least 8 GB of free space for temporary log movement requirements.

The suggested starting size for the archive log is 48 GB.

The archive log directory must be large enough to contain the log files that are generated since the previous full backup. For example, if you perform a full backup of the database every day, the archive log directory must be large enough to hold the log files for all the client activity that occurs during 24 hours. To recover space, the server deletes obsolete archive log files after a full backup of the database. If the archive log directory becomes full and a directory for archive failover logs does not exist, log files remain in the active log directory. This condition can cause the active log directory to fill up and stop the server. When the server restarts, some of the existing active-log space is released.

After the server is installed, you can monitor archive log utilization and the space in the archive log directory. If the space in the archive log directory fills up, it can cause the following problems:

- The server is unable to perform full database backups. Investigate and resolve this problem.
- Other applications write to the archive log directory, exhausting the space that is required by the archive log. Do not share archive log space with other applications including other IBM Spectrum Protect servers. Ensure that each server has a separate storage location that is owned and managed by that specific server.

- Windows: Example: Estimating active and archive log sizes for basic client-store operations
  Basic client-store operations include backup, archive, and space management. Log space must be sufficient to handle all store transactions that are in progress at one time.
- Windows: Example: Estimating active and archive log sizes for clients that use multiple sessions
  If the client option RESOURCEUTILIZATION is set to a value that is greater than the default, the concurrent workload for the server increases.
- Windows: Example: Estimating active and archive log sizes for simultaneous write operations
  If client backup operations use storage pools that are configured for simultaneous write, the amount of log space that is required for each file increases.
- Windows: Example: Estimating active and archive log sizes for basic client store operations and server operations
  Migration of data in server storage, identification processes for data deduplication, reclamation, and expiration might run concurrently with client store operations. Administrative tasks such as administrative commands or SQL queries from

administrative clients can also run concurrently with client store operations. Server operations and administrative tasks that run concurrently can increase the active log space that is required.

- Windows: Example: Estimating active and archive log sizes under conditions of extreme variation
  Problems with running out of active log space can occur if you have many transactions that complete quickly and some transactions that take much longer to complete. A typical case occurs when many workstation or file-server backup sessions are active and a few very large database server-backup sessions are active. If this situation applies to your environment, you might need to increase the size of the active log so that the work completes successfully.
- Windows: Example: Estimating archive log sizes with full database backups
  The IBM Spectrum Protect server deletes unnecessary files from the archive log only when a full database backup occurs. Consequently, when you estimate the space that is required for the archive log, you must also consider the frequency of full database backups.
- Windows: Example: Estimating active and archive log sizes for data deduplication operations
  If you deduplicate data, you must consider its effects on space requirements for active and archive logs.

Windows: Example: Estimating active and archive log sizes for basic client-store operations

Basic client-store operations include backup, archive, and space management. Log space must be sufficient to handle all store transactions that are in progress at one time.

To determine the sizes of the active and archive logs for basic client-store operations, use the following calculation:

```
number of clients  x  files stored during each transaction
  x  log space needed for each file
```

This calculation is used in the example in the following table.

Table 1. Basic client-store operations

Item	Example values	Description
Maximum number of client nodes that back up, archive, or migrate files concurrently at any time	300	The number of client nodes that back up, archive, or migrate files every night.
Files stored during each transaction	4096	The default value of the server option TXNGROUPMAX is 4096.
Log space that is required for each file	3053 bytes	The value of 3053 bytes for each file in a transaction represents the log bytes that are needed when backing up files from a Windows client where the file names are 12 - 120 bytes. This value is based on the results of tests performed under laboratory conditions. The tests consisted of backup-archive clients performing backup operations to a random-access disk (DISK) storage pool. DISK pools result in more log use than sequential-access storage pools. Consider a value larger than 3053 bytes if the data being stored has file names that are longer than 12 - 120 bytes.
Active log: Suggested size	19.5 GB [1]	Use the following calculation to determine the size of the active log. One GB equals 1,073,741,824 bytes. `(300 clients x 4096 files stored during each transaction x 3053 bytes for each file) ÷ 1,073,741,824 bytes = 3.5 GB` Increase that amount by the suggested starting size of 16 GB: `3.5 + 16 = 19.5 GB`

Item	Example values	Description
Archive log: Suggested size	58.5 GB [1]	Because of the requirement to be able to store archive logs across three server database-backup cycles, multiply the estimate for the active log by 3 to estimate the total archive log requirement. `3.5 x 3 = 10.5 GB` Increase that amount by the suggested starting size of 48 GB: `10.5 + 48 = 58.5 GB`

[1] The example values in this table are used only to illustrate how the sizes for active logs and archive logs are calculated. In a production environment that does not use deduplication, 16 GB is the suggested minimum size for an active log. The suggested minimum size for an archive log in a production environment that does not use deduplication is 48 GB. If you substitute values from your environment and the results are larger than 16 GB and 48 GB, use your results to size the active log and archive log.

Monitor your logs and adjust their size if necessary.

Windows: Example: Estimating active and archive log sizes for clients that use multiple sessions

If the client option RESOURCEUTILIZATION is set to a value that is greater than the default, the concurrent workload for the server increases.

To determine the sizes of the active and archive logs when clients use multiple sessions, use the following calculation:

```
number of clients  x  sessions for each client  x  files stored
  during each transaction  x  log space needed for each file
```

This calculation is used in the example in the following table.

Table 1. Multiple client sessions

Item	Example values		Description
Maximum number of client nodes that back up, archive, or migrate files concurrently at any time	300	1000	The number of client nodes that back up, archive, or migrate files every night.
Possible sessions for each client	3	3	The setting of the client option RESOURCEUTILIZATION is larger than the default. Each client session runs a maximum of three sessions in parallel.
Files stored during each transaction	4096	4096	The default value of the server option TXNGROUPMAX is 4096.
Log space that is required for each file	3053	3053	The value of 3053 bytes for each file in a transaction represents the log bytes needed when backing up files from a Windows client where the file names are 12 - 120 bytes. This value is based on the results of tests performed under laboratory conditions. Tests consisted of clients performing backup operations to a random-access disk (DISK) storage pool. DISK pools result in more log use than sequential-access storage pools. Consider a value larger than 3053 bytes if the data being stored has file names that are longer than 12 - 120 bytes.

Item	Example values		Description
Active log: Suggested size	26.5 GB [1]	51 GB [1]	The following calculation was used for 300 clients. One GB equals 1,073,741,824 bytes. `(300 clients x 3 sessions for each client x 4096 files stored during each transaction x 3053 bytes for each file) ÷ 1,073,741,824 = 10.5 GB` Increase that amount by the suggested starting size of 16 GB: `10.5 + 16 = 26.5 GB` The following calculation was used for 1000 clients. One GB equals 1,073,741,824 bytes. `(1000 clients x 3 sessions for each client x 4096 files store during each transaction x 3053 bytes for each file) ÷ 1,073,741,824 = 35 GB` Increase that amount by the suggested starting size of 16 GB: `35 + 16 = 51 GB`
Archive log: Suggested size	79.5 GB [1]	153 GB [1]	Because of the requirement to be able to store archive logs across three server-database backup cycles, the estimate for the active log is multiplied by 3: `10.5 x 3 = 31.5 GB` `35 x 3 = 105 GB` Increase those amounts by the suggested starting size of 48 GB: `31.5 + 48 = 79.5 GB` `105 + 48 = 153 GB`

[1] The example values in this table are used only to illustrate how the sizes for active logs and archive logs are calculated. In a production environment that does not use deduplication, 16 GB is the suggested minimum size for an active log. The suggested minimum size for an archive log in a production environment that does not use deduplication is 48 GB. If you substitute values from your environment and the results are larger than 16 GB and 48 GB, use your results to size the active log and archive log.

Monitor your active log and adjust its size if necessary.

Windows: Example: Estimating active and archive log sizes for simultaneous write operations

If client backup operations use storage pools that are configured for simultaneous write, the amount of log space that is required for each file increases.

The log space that is required for each file increases by about 200 bytes for each copy storage pool that is used for a simultaneous write operation. In the example in the following table, data is stored to two copy storage pools in addition to a primary storage pool. The estimated log size increases by 400 bytes for each file. If you use the suggested value of 3053 bytes of log space for each file, the total number of required bytes is 3453.

This calculation is used in the example in the following table.

Table 1. Simultaneous write operations

Item	Example values	Description
Maximum number of client nodes that back up, archive, or migrate files concurrently at any time	300	The number of client nodes that back up, archive, or migrate files every night.

Item	Example values	Description
Files stored during each transaction	4096	The default value of the server option TXNGROUPMAX is 4096.
Log space that is required for each file	3453 bytes	3053 bytes plus 200 bytes for each copy storage pool. The value of 3053 bytes for each file in a transaction represents the log bytes that are needed when backing up files from a Windows client where the file names are 12 - 120 bytes. This value is based on the results of tests performed under laboratory conditions. The tests consisted of backup-archive clients performing backup operations to a random-access disk (DISK) storage pool. DISK pools result in more log use than sequential-access storage pools. Consider a value larger than 3053 bytes if the data being stored has file names that are longer than 12 - 120 bytes.
Active log: Suggested size	20 GB [1]	Use the following calculation to determine the size of the active log. One GB equals 1,073,741,824 bytes. `(300 clients x 4096 files stored during each transaction x 3453 bytes for each file) ÷ 1,073,741,824 bytes = 4.0 GB` Increase that amount by the suggested starting size of 16 GB: `4 + 16 = 20 GB`
Archive log: Suggested size	60 GB [1]	Because of the requirement to be able to store archive logs across three server database-backup cycles, multiply the estimate for the active log by 3 to estimate the archive log requirement: `4 GB x 3 = 12 GB` Increase that amount by the suggested starting size of 48 GB: `12 + 48 = 60 GB`

[1] The example values in this table are used only to illustrate how the sizes for active logs and archive logs are calculated. In a production environment that does not use deduplication, 16 GB is the suggested minimum size for an active log. The suggested minimum size for an archive log in a production environment that does not use deduplication is 48 GB. If you substitute values from your environment and the results are larger than 16 GB and 48 GB, use your results to size the active log and archive log.

Monitor your logs and adjust their size if necessary.

Windows: Example: Estimating active and archive log sizes for basic client store operations and server operations

Migration of data in server storage, identification processes for data deduplication, reclamation, and expiration might run concurrently with client store operations. Administrative tasks such as administrative commands or SQL queries from administrative clients can also run concurrently with client store operations. Server operations and administrative tasks that run concurrently can increase the active log space that is required.

For example, migration of files from the random-access (DISK) storage pool to a sequential-access disk (FILE) storage pool uses approximately 110 bytes of log space for each file that is migrated. For example, suppose that you have 300 backup-archive clients and each one of them backs up 100,000 files every night. The files are initially stored on DISK and then migrated to a FILE storage pool. To estimate the amount of active log space that is required for the data migration, use the following calculation. The number of clients in the calculation represents the maximum number of client nodes that back up, archive, or migrate files concurrently at any time.

```
300 clients  x 100,000 files for each client   x  110 bytes =  3.1 GB
```

Add this value to the estimate for the size of the active log that calculated for basic client store operations.

Windows: Example: Estimating active and archive log sizes under conditions of extreme variation

Problems with running out of active log space can occur if you have many transactions that complete quickly and some transactions that take much longer to complete. A typical case occurs when many workstation or file-server backup sessions are active and a few very large database server-backup sessions are active. If this situation applies to your environment, you might need to increase the size of the active log so that the work completes successfully.

Windows: Example: Estimating archive log sizes with full database backups

The IBM Spectrum Protect™ server deletes unnecessary files from the archive log only when a full database backup occurs. Consequently, when you estimate the space that is required for the archive log, you must also consider the frequency of full database backups.

For example, if a full database backup occurs once a week, the archive log space must be able to contain the information in the archive log for a full week.

The difference in archive log size for daily and full database backups is shown in the example in the following table.

Table 1. Full database backups

Item	Example values	Description
Maximum number of client nodes that back up, archive, or migrate files concurrently at any time	300	The number of client nodes that back up, archive, or migrate files every night.
Files stored during each transaction	4096	The default value of the server option TXNGROUPMAX is 4096.
Log space that is required for each file	3453 bytes	3053 bytes for each file plus 200 bytes for each copy storage pool. The value of 3053 bytes for each file in a transaction represents the log bytes needed when backing up files from a Windows client where the file names are 12 - 120 bytes. This value is based on the results of tests performed under laboratory conditions. Tests consisted of clients performing backup operations to a random-access disk (DISK) storage pool. DISK pools result in more log use than sequential-access storage pools. Consider a value larger than 3053 bytes if the data being stored has file names that are longer than 12 - 120 bytes.
Active log: Suggested size	20 GB [1]	Use the following calculation to determine the size of the active log. One GB equals 1,073,741,824 bytes. `(300 clients x 4096 files per transaction x 3453 bytes per file) ÷ 1,073,741,824 bytes = 4.0 GB` Increase that amount by the suggested starting size of 16 GB: `4 + 16 = 20 GB`
Archive log: Suggested size with a full database backup every day	60 GB [1]	Because of the requirement to be able to store archive logs across three backup cycles, multiply the estimate for the active log by 3 to estimate the total archive log requirement: `4 GB x 3 = 12 GB` Increase that amount by the suggested starting size of 48 GB: `12 + 48 = 60 GB`

Item	Example values	Description
Archive log: Suggested size with a full database every week	132 GB [1]	Because of the requirement to be able to store archive logs across three server database-backup cycles, multiply the estimate for the active log by 3 to estimate the total archive log requirement. Multiply the result by the number of days between full database backups: `(4 GB x 3 ) x 7 = 84 GB` Increase that amount by the suggested starting size of 48 GB: `84 + 48 = 132 GB`

[1] The example values in this table are used only to illustrate how the sizes for active logs and archive logs are calculated. In a production environment that does not use deduplication, 16 GB is the suggested minimum size for an active log. The suggested starting size for an archive log in a production environment that does not use deduplication is 48 GB. If you substitute values from your environment and the results are larger than 16 GB and 48 GB, use your results to size the active log and archive log.

Monitor your logs and adjust their size if necessary.

Windows: Example: Estimating active and archive log sizes for data deduplication operations

If you deduplicate data, you must consider its effects on space requirements for active and archive logs.

The following factors affect requirements for active and archive log space:

The amount of deduplicated data
: The effect of data deduplication on the active log and archive log space depends on the percentage of data that is eligible for deduplication. If the percentage of data that can be deduplicated is relatively high, more log space is required.

The size and number of extents
: Approximately 1,500 bytes of active log space are required for each extent that is identified by a duplicate-identification process. For example, if 250,000 extents are identified by a duplicate-identification process, the estimated size of the active log is 358 MB:

```
250,000 extents identified during each process x 1,500 bytes
 for each extent = 358 MB
```

Consider the following scenario. Three hundred backup-archive clients back up 100,000 files each night. This activity creates a workload of 30,000,000 files. The average number of extents for each file is two. Therefore, the total number of extents is 60,000,000, and the space requirement for the archive log is 84 GB:

```
60,000,000 extents x 1,500 bytes for each extent = 84 GB
```

A duplicate-identification process operates on aggregates of files. An aggregate consists of files that are stored in a given transaction, as specified by the TXNGROUPMAX server option. Suppose that the TXNGROUPMAX server option is set to the default of 4096. If the average number of extents for each file is two, the total number of extents in each aggregate is 8192, and the space required for the active log is 12 MB:

```
8192 extents in each aggregate x 1500 bytes for each extent =
   12 MB
```

The timing and number of the duplicate-identification processes
: The timing and number of duplicate-identification processes also affects the size of the active log. Using the 12 MB active-log size that was calculated in the preceding example, the concurrent load on the active log is 120 MB if 10 duplicate-identification processes are running in parallel:

```
12 MB for each process x 10 processes = 120 MB
```

File size
: Large files that are processed for duplicate identification can also affect the size of the active log. For example, suppose that a backup-archive client backs up an 80 GB, file-system image. This object can have a high number of duplicate extents if, for example, the files included in the file system image were backed up incrementally. For example, assume that a file

system image has 1.2 million duplicate extents. The 1.2 million extents in this large file represent a single transaction for a duplicate-identification process. The total space in the active log that is required for this single object is 1.7 GB:

```
1,200,000 extents x 1,500 bytes for each extent = 1.7 GB
```

If other, smaller duplicate-identification processes occur at the same time as the duplicate-identification process for a single large object, the active log might not have enough space. For example, suppose that a storage pool is enabled for deduplication. The storage pool has a mixture of data, including many relatively small files that range from 10 KB to several hundred KB. The storage pool also has few large objects that have a high percentage of duplicate extents.

To take into account not only space requirements but also the timing and duration of concurrent transactions, increase the estimated size of the active log by a factor of two. For example, suppose that your calculations for space requirements are 25 GB (23.3 GB + 1.7 GB for deduplication of a large object). If deduplication processes are running concurrently, the suggested size of the active log is 50 GB. The suggested size of the archive log is 150 GB.

The examples in the following tables show calculations for active and archive logs. The example in the first table uses an average size of 700 KB for extents. The example in the second table uses an average size of 256 KB. As the examples show, the average deduplicate-extent size of 256 KB indicates a larger estimated size for the active log. To minimize or prevent operational problems for the server, use 256 KB to estimate the size of the active log in your production environment.

Table 1. Average duplicate-extent size of 700 KB

Item	**Example values**		**Description**
Size of largest single object to deduplicate	800 GB	4 TB	The granularity of processing for deduplication is at the file level. Therefore, the largest single file to deduplicate represents the largest transaction and a correspondingly large load on the active and archive logs.
Average size of extents	700 KB	700 KB	The deduplication algorithms use a variable block method. Not all deduplicated extents for a given file are the same size, so this calculation assumes an average size for extents.
Extents for a given file	1,198,372 bits	6,135,667 bits	Using the average extent size (700 KB), these calculations represent the total number of extents for a given object. The following calculation was used for an 800 GB object: `(800 GB ÷ 700 KB) = 1,198,372 bits` The following calculation was used for a 4 TB object: `(4 TB ÷ 700 KB) = 6,135,667 bits`
Active log: Suggested size that is required for the deduplication of a single large object during a single duplicate-identification process	1.7 GB	8.6 GB	The estimated active log space that are needed for this transaction.

Item	Example values		Description
Active log: Suggested total size	66 GB [1]	79.8 GB [1]	After considering other aspects of the workload on the server in addition to deduplication, multiply the existing estimate by a factor of two. In these examples, the active log space required to deduplicate a single large object is considered along with previous estimates for the required active log size. The following calculation was used for multiple transactions and an 800 GB object: `(23.3 GB + 1.7 GB) x 2 = 50 GB` Increase that amount by the suggested starting size of 16 GB: `50 + 16 = 66 GB` The following calculation was used for multiple transactions and a 4 TB object: `(23.3 GB + 8.6 GB) x 2 = 63.8 GB` Increase that amount by the suggested starting size of 16 GB: `63.8 + 16 = 79.8 GB`
Archive log: Suggested size	198 GB [1]	239.4 GB [1]	Multiply the estimated size of the active log by a factor of 3. The following calculation was used for multiple transactions and an 800 GB object: `50 GB x 3 = 150 GB` Increase that amount by the suggested starting size of 48 GB: `150 + 48 = 198 GB` The following calculation was used for multiple transactions and a 4 TB object: `63.8 GB x 3 = 191.4 GB` Increase that amount by the suggested starting size of 48 GB: `191.4 + 48 = 239.4 GB`
[1] The example values in this table are used only to illustrate how the sizes for active logs and archive logs are calculated. In a production environment that uses deduplication, 32 GB is the suggested minimum size for an active log. The suggested minimum size for an archive log in a production environment that uses deduplication is 96 GB. If you substitute values from your environment and the results are larger than 32 GB and 96 GB, use your results to size the active log and archive log. Monitor your logs and adjust their size if necessary.			

Table 2. Average duplicate-extent size of 256 KB

Item	Example values		Description
Size of largest single object to deduplicate	800 GB	4 TB	The granularity of processing for deduplication is at the file level. Therefore, the largest single file to deduplicate represents the largest transaction and a correspondingly large load on the active and archive logs.

Item	Example values		Description
Average size of extents	256 KB	256 KB	The deduplication algorithms use a variable block method. Not all deduplicated extents for a given file are the same size, so this calculation assumes an average extent size.
Extents for a given file	3,276,800 bits	16,777,216 bits	Using the average extent size, these calculations represent the total number of extents for a given object. The following calculation was used for multiple transactions and an 800 GB object: `(800 GB ÷ 256 KB) = 3,276,800 bits` The following calculation was used for multiple transactions and a 4 TB object: `(4 TB ÷ 256 KB) = 16,777,216 bits`
Active log: Suggested size that is required for the deduplication of a single large object during a single duplicate-identification process	4.5 GB	23.4 GB	The estimated size of the active log space that is required for this transaction.
Active log: Suggested total size	71.6 GB [1]	109.4 GB [1]	After considering other aspects of the workload on the server in addition to deduplication, multiply the existing estimate by a factor of 2. In these examples, the active log space required to deduplicate a single large object is considered along with previous estimates for the required active log size. The following calculation was used for multiple transactions and an 800 GB object: `(23.3 GB + 4.5 GB) x 2 = 55.6 GB` Increase that amount by the suggested starting size of 16 GB: `55.6 + 16 = 71.6 GB` The following calculation was used for multiple transactions and a 4 TB object: `(23.3 GB + 23.4 GB) x 2 = 93.4 GB` Increase that amount by the suggested starting size of 16 GB: `93.4 + 16 = 109.4 GB`

Item	Example values		Description
Archive log: Suggested size	214.8 GB [1]	328.2 GB [1]	The estimated size of the active log multiplied by a factor of 3. The following calculation was used for an 800 GB object: `55.6 GB x 3 = 166.8 GB` Increase that amount by the suggested starting size of 48 GB: `166.8 + 48 = 214.8 GB` The following calculation was used for a 4 TB object: `93.4 GB x 3 = 280.2 GB` Increase that amount by the suggested starting size of 48 GB: `280.2 + 48 = 328.2 GB`
[1] The example values in this table are used only to illustrate how the sizes for active logs and archive logs are calculated. In a production environment that uses deduplication, 32 GB is the suggested minimum size for an active log. The suggested minimum size for an archive log in a production environment that uses deduplication is 96 GB. If you substitute values from your environment and the results are larger than 32 GB and 96 GB, use your results to size the active log and archive log. Monitor your logs and adjust their size if necessary.			

Windows: Active-log mirror space

The active log can be mirrored so that the mirrored copy can be used if the active log files cannot be read. There can be only one active log mirror.

Creating a log mirror is a suggested option. If you increase the size of the active log, the log mirror size is increased automatically. Mirroring the log can affect performance because of the doubled I/O activity that is required to maintain the mirror. The additional space that the log mirror requires is another factor to consider when deciding whether to create a log mirror.

If the mirror log directory becomes full, the server issues error messages to the activity log and to the db2diag.log. Server activity continues.

Windows: Archive-failover log space

The archive failover log is used by the server if the archive log directory runs out of space.

Specifying an archive failover log directory can prevent problems that occur if the archive log runs out of space. If both the archive log directory and the drive or file system where the archive failover log directory is located become full, the data remains in the active log directory. This condition can cause the active log to fill up, which causes the server to halt.

Windows: Monitoring space utilization for the database and recovery logs

To determine the amount of used and available active log space, you issue the QUERY LOG command. To monitor space utilization in the database and recovery logs, you can also check the activity log for messages.

Active log

If the amount of available active log space is too low, the following messages are displayed in the activity log:

ANR4531I: IC_AUTOBACKUP_LOG_USED_SINCE_LAST_BACKUP_TRIGGER

This message is displayed when the active log space exceeds the maximum specified size. The IBM Spectrum Protect™ server starts a full database backup.

To change the maximum log size, halt the server. Open the dsmserv.opt file, and specify a new value for the ACTIVELOGSIZE option. When you are finished, restart the server.

ANR0297I: IC_BACKUP_NEEDED_LOG_USED_SINCE_LAST_BACKUP
This message is displayed when the active log space exceeds the maximum specified size. You must back up the database manually.

To change the maximum log size, halt the server. Open the dsmserv.opt file, and specify a new value for the ACTIVELOGSIZE option. When you are finished, restart the server.

ANR4529I: IC_AUTOBACKUP_LOG_UTILIZATION_TRIGGER
The ratio of used active-log space to available active-log space exceeds the log utilization threshold. If at least one full database backup has occurred, the IBM Spectrum Protect server starts an incremental database backup. Otherwise, the server starts a full database backup.

ANR0295I: IC_BACKUP_NEEDED_LOG_UTILIZATION
The ratio of used active-log space to available active-log space exceeds the log utilization threshold. You must back up the database manually.

Archive log

If the amount of available archive log space is too low, the following message is displayed in the activity log:

ANR0299I: IC_BACKUP_NEEDED_ARCHLOG_USED
The ratio of used archive-log space to available archive-log space exceeds the log utilization threshold. The IBM Spectrum Protect server starts a full automatic database backup.

Database

If the amount of space available for database activities is too low, the following messages are displayed in the activity log:

ANR2992W: IC_LOG_FILE_SYSTEM_UTILIZATION_WARNING_2
The used database space exceeds the threshold for database space utilization. To increase the space for the database, use the EXTEND DBSPACE command, the EXTEND DBSPACE command, or the DSMSERV FORMAT utility with the DBDIR parameter.

ANR1546W: FILESYSTEM_DBPATH_LESS_1GB
The available space in the directory where the server database files are located is less than 1 GB.

When an IBM Spectrum Protect server is created with the DSMSERV FORMAT utility or with the configuration wizard, a server database and recovery log are also created. In addition, files are created to hold database information used by the database manager. The path specified in this message indicates the location of the database information used by the database manager. If space is unavailable in the path, the server can no longer function.

You must add space to the file system or make space available on the file system or disk.

Windows: Deleting installation rollback files

You can delete certain installation files that were saved during the installation process to free space in the shared resource directory. For example, files that might have been required for a rollback operation are types of files that you can delete.

About this task

To delete the files that are no longer needed, use either the installation graphical wizard or the command line in console mode.

- Windows: Deleting installation rollback files by using a graphical wizard
  You can delete certain installation files that were saved during installation process by using the IBM® Installation Manager user interface.
- Windows: Deleting installation rollback files by using the command line
  You can delete certain installation files that were saved during the installation process by using the command line.

Windows: Deleting installation rollback files by using a graphical wizard

You can delete certain installation files that were saved during installation process by using the IBM® Installation Manager user interface.

Procedure

1. Open IBM Installation Manager.
2. Click File > Preferences.
3. Select Files for Rollback.
4. Click Delete Saved Files and click OK.

Windows: Deleting installation rollback files by using the command line

You can delete certain installation files that were saved during the installation process by using the command line.

Procedure

1. In the directory where IBM® Installation Manager is installed, go to the following subdirectory:
   - Windows eclipse\tools

   For example:

   - Windows C:\Program Files\IBM\Installation Manager\eclipse\tools
2. From the tools directory, issue the following command to start an IBM Installation Manager command line:
   - Windows `imcl.exe -c`
3. Enter `P` to select Preferences.
4. Enter `3` to select Files for Rollback.
5. Enter `D` to Delete the Files for Rollback.
6. Enter `A` to Apply Changes and Return to Preferences Menu.
7. Enter `C` to leave the Preference Menu.
8. Enter `X` to Exit Installation Manager.

Windows: Server naming best practices

Use these descriptions as a reference when you install or upgrade an IBM Spectrum Protect™ server.

Instance user ID

The instance user ID is used as the basis for other names related to the server instance. The instance user ID is also called the instance owner.

For example: tsminst1

The instance user ID is the user ID that must have ownership or read/write access authority to all directories that you create for the database and the recovery log. The standard way to run the server is under the instance user ID. That user ID must also have read/write access to the directories that are used for any FILE device classes.

Windows

Database instance name

The database instance name is the name of the server instance as it appears in the registry.

For example: Server1

Windows

Instance directory

The instance directory is a directory that contains files specifically for a server instance (the server options file and other server-specific files). It can have any name that you want. For easier identification, use a name that ties the directory to the instance name.

You can use a name that includes the name of the server instance as it appears (or will appear) in the registry. Default server instance names have the form Server*x*.

For example: C:\tsm\server1

The instance directory stores the following files for the server instance:

- The server options file, dsmserv.opt
- The server key database file, `cert.kdb`, and the `.arm` files (used by clients and other servers to import the Secure Sockets Layer certificates of the server)
- Device configuration file, if the DEVCONFIG server option does not specify a fully qualified name
- Volume history file, if the VOLUMEHISTORY server option does not specify a fully qualified name
- Volumes for DEVTYPE=FILE storage pools, if the directory for the device class is not fully specified, or not fully qualified
- User exits
- Trace output (if not fully qualified)

Database name

The database name is always TSMDB1, for every server instance. This name cannot be changed.

Server name

The server name is an internal name for IBM Spectrum Protect, and is used for operations that involve communication among multiple IBM Spectrum Protect servers. Examples include server-to-server communication and library sharing.

Windows The server name is also used when you add the server to the Operations Center so that it can be managed using that interface. Use a unique name for each server. For easy identification in the Operations Center (or from a QUERY SERVER command), use a name that reflects the location or purpose of the server. Do not change the name of an IBM Spectrum Protect server after it is configured as a hub or spoke server.

If you use the wizard, the default name that is suggested is the host name of the system that you are using. You can use a different name that is meaningful in your environment. If you have more than one server on the system and you use the wizard, you can use the default name for only one of the servers. You must enter a unique name for each server.

Windows For example,

- `TUCSON_SERVER1`
- `TUCSON_SERVER2`

Directories for database space and recovery log

The directories can be named according to local practices. For easier identification, consider using names that tie the directories to the server instance.

For example, for the archive log:

- Windows f:\server1\archlog

Windows: Installation directories

Installation directories for the IBM Spectrum Protect™ server include the server, DB2®, device, language, and other directories. Each one contains several additional directories.

The (/opt/tivoli/tsm/server/bin) is the default directory that contains server code and licensing.

The DB2 product that is installed as part of the installation of the IBM Spectrum Protect server has the directory structure as documented in DB2 information sources. Protect these directories and files as you do the server directories. The default directory is /opt/tivoli/tsm/db2.

You can use US English, German, French, Italian, Spanish, Brazilian Portuguese, Korean, Japanese, traditional Chinese, simplified Chinese, Chinese GBK, Chinese Big5, and Russian.

Windows: Installing the server components

To install the Version 8.1.2 server components, you can use the installation wizard, the command line in console mode, or silent mode.

About this task

Using the IBM Spectrum Protect™ installation software, you can install the following components:

- server
  Tip: The database (DB2®), the Global Security Kit (GSKit) and IBM® Java™ Runtime Environment (JRE) are automatically installed when you select the server component.
- server languages
- license
- devices
- IBM Spectrum Protect for SAN
- Operations Center

Windows Allow approximately 15 - 30 minutes to install a V8.1.2 server, using this guide.

- Windows: Obtaining the installation package
  You can obtain the IBM Spectrum Protect installation package from an IBM download site such as Passport Advantage® or IBM Fix Central.
- Windows: Installing IBM Spectrum Protect by using the installation wizard
  You can install the server by using the IBM Installation Manager graphical wizard.
- Windows: Installing IBM Spectrum Protect by using console mode
  You can install IBM Spectrum Protect by using the command line in console mode.
- Windows: Installing IBM Spectrum Protect in silent mode
  You can install or upgrade the server in silent mode. In silent mode, the installation does not send messages to a console but instead stores messages and errors in log files.
- Windows: Installing server language packages
  Translations for the server allow the server to display messages and help in languages other than US English. The translations also allow for the use of locale conventions for date, time, and number formatting.

Windows: Obtaining the installation package

You can obtain the IBM Spectrum Protect™ installation package from an IBM® download site such as Passport Advantage® or IBM Fix Central.

Procedure

1. Download the appropriate package file from one of the following websites.
   - Download the server package from Passport Advantage or Fix Central.
   - For the latest information, updates, and maintenance fixes, go to the IBM Support Portal.
2. If you downloaded the package from an IBM download site, complete the following steps:
   Windows
   a. Verify that you have enough space to store the installation files when they are extracted from the product package. See the download document for the space requirements:
      - IBM Spectrum Protect technote 4042944
      - IBM Spectrum Protect Extended Edition technote 4042945
      - IBM Spectrum Protect for Data Retention technote 4042946

   b. Change to the directory where you placed the executable file.
   Important: In the next step, the files are extracted to the current directory. The path must contain no more than 128 characters. Be sure to extract the installation files to an empty directory. Do not extract to a directory that contains previously extracted files, or any other files.
   c. Either double-click the executable file, or enter the following command on the command line to extract the installation files. The files are extracted to the current directory.

   ```
   package_name.exe
   ```

where *package_name* is like this example: *8.1.x.000*-IBM-SPSRV-WindowsX64.exe

3. Select one of the following methods of installing IBM Spectrum Protect:
   - Windows: Installing IBM Spectrum Protect by using the installation wizard
   - Windows: Installing IBM Spectrum Protect by using console mode
   - Windows: Installing IBM Spectrum Protect in silent mode
4. After you install IBM Spectrum Protect, and before you customize it for your use, go to the IBM Support Portal. Click Support and downloads and apply any applicable fixes.

Windows: Installing IBM Spectrum Protect by using the installation wizard

You can install the server by using the IBM® Installation Manager graphical wizard.

Before you begin

Take the following actions before you start the installation:

- Verify that the operating system is set to the language that you require. By default, the language of the operating system is the language of the installation wizard.
- Windows Ensure that the user ID that you plan to use during the installation is a user with local Administrator authority.

Procedure

Install IBM Spectrum Protect™ by using this method:

Option	Description
Installing the software from a downloaded package:	a. Change to the directory where you downloaded the package. b. Start the installation wizard by issuing the following command: Windows `install.bat` Windows Or, in the directory where the installation files were extracted, double-click the install.bat file.

What to do next

- If errors occur during the installation process, the errors are recorded in log files that are stored in the IBM Installation Manager logs directory.

  You can view installation log files by clicking File > View Log from the Installation Manager tool. To collect these log files, click Help > Export Data for Problem Analysis from the Installation Manager tool.

- After you install the server and components, and before you customize it for your use, go to the IBM Support Portal. Click Downloads (fixes and PTFs) and apply any applicable fixes.

- Windows After you install a new server, review Taking the first steps after you install IBM Spectrum Protect to learn about configuring your server.
- Windows If a native device driver is available on Windows for the tape drives or medium changers that you plan to use, use the native device driver. If a native device driver is not available on Windows for the tape drives or medium changers that you plan to use, install the IBM Spectrum Protect device driver by issuing the `dpinst.exe /a` command. The `dpinst.exe` file is in the device driver directory. The default directory is C:\Program Files\Tivoli\TSM\device\drivers.

Windows: Installing IBM Spectrum Protect by using console mode

You can install IBM Spectrum Protect™ by using the command line in console mode.

Before you begin

Take the following actions before you start the installation:

- Verify that the operating system is set to the language that you require. By default, the language of the operating system is the language of the installation wizard.
- Windows Ensure that the user ID that you plan to use during the installation is a user with local Administrator authority.

Procedure

Install IBM Spectrum Protect by using this method:

Option	Description
Installing the software from a downloaded package:	a. Change to the directory where you downloaded the package. b. Start the installation wizard in console mode by issuing the following command: Windows `install.bat -c` Optional: Generate a response file as part of a console mode installation. Complete the console mode installation options, and in the Summary panel, specify `G` to generate the responses.

What to do next

- If errors occur during the installation process, the errors are recorded in log files that are stored in the IBM® Installation Manager logs directory, for example:
  - Windows C:\ProgramData\IBM\Installation Manager\logs
- After you install the server and components, and before you customize it for your use, go to the IBM Support Portal. Click Downloads (fixes and PTFs) and apply any applicable fixes.
- Windows After you install a new server, review Taking the first steps after you install IBM Spectrum Protect to learn about configuring your server.
- Windows If a native device driver is available on Windows for the tape drives or medium changers that you plan to use, use the native device driver. If a native device driver is not available on Windows for the tape drives or medium changers that you plan to use, install the IBM Spectrum Protect device driver by issuing the `dpinst.exe /a` command. The `dpinst.exe` file is in the device driver directory. The default directory is C:\Program Files\Tivoli\TSM\device\drivers.

Windows: Installing IBM Spectrum Protect in silent mode

You can install or upgrade the server in silent mode. In silent mode, the installation does not send messages to a console but instead stores messages and errors in log files.

Before you begin

To provide data input when you use the silent installation method, you can use a response file. The following sample response files are provided in the input directory where the installation package is extracted:

install_response_sample.xml
: Use this file to install the IBM Spectrum Protect™ components.

update_response_sample.xml
: Use this file to upgrade the IBM Spectrum Protect components.

These files contain default values that can help you avoid any unnecessary warnings. To use these files, follow the instructions that are provided in the files.

If you want to customize a response file, you can modify the options that are in the file. For information about response files, see Response files.

Procedure

1. Create a response file. You can modify the sample response file or create your own file.
2. If you install the server and Operations Center in silent mode, create a password for the Operations Center truststore in the response file.
   If you are using the install_response_sample.xml file, add the password in the following line of the file, where *mypassword* represents the password:

   ```
   <variable name='ssl.password' value='mypassword' />
   ```

For more information about this password, see Installation checklist
Tip: To upgrade the Operations Center, the truststore password is not required if you are using the update_response_sample.xml file.

3. Start the silent installation by issuing the following command from the directory where the installation package is extracted. The value *response_file* represents the response file path and file name:
   - Windows

     ```
     install.bat -s -input response_file -acceptLicense
     ```

What to do next

- If errors occur during the installation process, the errors are recorded in log files that are stored in the IBM® Installation Manager logs directory, for example:
  - Windows C:\ProgramData\IBM\Installation Manager\logs
- After you install the server and components, and before you customize it for your use, go to the IBM Support Portal. Click Downloads (fixes and PTFs) and apply any applicable fixes.
- Windows After you install a new server, review Taking the first steps after you install IBM Spectrum Protect to learn about configuring your server.
- Windows If a native device driver is available on Windows for the tape drives or medium changers that you plan to use, use the native device driver. If a native device driver is not available on Windows for the tape drives or medium changers that you plan to use, install the IBM Spectrum Protect device driver by issuing the `dpinst.exe /a` command. The `dpinst.exe` file is in the device driver directory. The default directory is C:\Program Files\Tivoli\TSM\device\drivers.

Windows

Windows: Installing server language packages

Translations for the server allow the server to display messages and help in languages other than US English. The translations also allow for the use of locale conventions for date, time, and number formatting.

Before you begin

For instructions on installing storage agent language packages, see Language pack configuration for storage agents.

- Windows: Server language locales
  Use either the default language package option or select another language package to display server messages and help.
- Windows: Configuring a language package
  After you configure a language package, messages and help are shown on the server in languages other than US English. Installation packages are provided with IBM Spectrum Protect™.
- Windows: Updating a language package
  You can modify or update a language package by using the IBM® Installation Manager.

Windows: Server language locales

Use either the default language package option or select another language package to display server messages and help.

Windows This language package is automatically installed for the following default language option for server messages and help: LANGUAGE AMENG.

For languages or locales other than the default, install the language package that your installation requires.
You can use the languages that are shown:
Windows

Table 1. Server languages for Windows

Language	LANGUAGE option value
Chinese, Simplified	chs
Chinese, Traditional	cht
English	ameng
French	fra
German	deu

Language	LANGUAGE option value
Italian	ita
Japanese (Shift-JIS)	jpn
Korean	kor
Portuguese, Brazilian	ptb
Russian	rus
Spanish	esp

Windows Restriction: For Operations Center users, some characters might not be displayed properly if the web browser does not use the same language as the server. If this problem occurs, set the browser to use the same language as the server.

Windows: Configuring a language package

After you configure a language package, messages and help are shown on the server in languages other than US English. Installation packages are provided with IBM Spectrum Protect™.

About this task

Windows Set the LANGUAGE option in the server options file to the name of the locale that you want to use. For example: to use the `ita` locale, set the LANGUAGE option to `ita`. See Windows: Server language locales.

If the locale is successfully initialized, it formats the date, time, and number for the server. If the locale is not successfully initialized, the server uses the US English message files and the date, time, and number format.

Windows: Updating a language package

You can modify or update a language package by using the IBM® Installation Manager.

About this task

You can install another language package within the same IBM Spectrum Protect™ instance.

- Use the Modify function of IBM Installation Manager to install another language package.
- Use the Update function of IBM Installation Manager to update to newer versions of the language packages.

Tip: In IBM Installation Manager, the term *update* means to discover and install updates and fixes to installed software packages. In this context, *update* and *upgrade* are synonymous.

Windows: Taking the first steps after you install IBM Spectrum Protect

After you install Version 8.1.2, prepare for the configuration. Using the configuration wizard is the preferred method of configuring the IBM Spectrum Protect™ instance.

About this task

1. Create the directories and user ID for the server instance. See Windows: Creating the user ID and directories for the server instance.
2. Configure a server instance. Select one of the following options:
    - Use the configuration wizard, the preferred method. See Windows: Configuring IBM Spectrum Protect by using the configuration wizard.
    - Manually configure the new instance. See Windows: Configuring the server instance manually. Complete the following steps during a manual configuration.
        a. Set up your directories and create the IBM Spectrum Protect instance. See Windows: Creating the server instance.
        b. Create a new server options file by copying the sample file to set up communications between the server and clients. See Windows Windows: Configuring server and client communications.

c. Issue the DSMSERV FORMAT command to format the database. See Windows: Formatting the database and log.
d. Configure your system for database backup. See Windows: Preparing the database manager for database backup.

3. Configure options to control when database reorganization runs. See Windows: Configuring server options for server database maintenance.
4. Start the server instance if it is not already started.
   - Windows See Windows: Starting the server instance on Windows systems.
5. Register your license. See Windows: Registering licenses.
6. Prepare your system for database backups. See Windows: Specifying a device class in preparation for database backups.
7. Monitor the server. See Windows: Monitoring the server.

- Windows: Creating the user ID and directories for the server instance
  Create the user ID for the IBM Spectrum Protect server instance and create the directories that the server instance needs for database and recovery logs.
- Windows: Configuring the IBM Spectrum Protect server
  After you have installed the server and prepared for the configuration, configure the server instance.
- Windows: Configuring server options for server database maintenance
  To help avoid problems with database growth and server performance, the server automatically monitors its database tables and reorganizes them when needed. Before starting the server for production use, set server options to control when reorganization runs. If you plan to use data deduplication, ensure that the option to run index reorganization is enabled.
- Windows Windows: Starting the server instance on Windows systems
  In a production environment, the preferred method for starting the server is as a Windows service. In an environment where you are reconfiguring, testing, or completing maintenance tasks, start the server in the foreground or use maintenance mode.
- Windows: Stopping the server
  You can stop the server when needed to return control to the operating system. To avoid losing administrative and client node connections, stop the server only after current sessions are completed or canceled.
- Windows: Registering licenses
  Immediately register any IBM Spectrum Protect licensed functions that you purchase so you do not lose any data after you start server operations, such as backing up your data.
- Windows: Specifying a device class in preparation for database backups
  To prepare the system for automatic and manual database backups, you must specify the device class to be used.
- Windows: Running multiple server instances on a single system
  You can create more than one server instance on your system. Each server instance has its own instance directory, and database and log directories.
- Windows: Monitoring the server
  When you start to use the server in production, monitor the space that is used by the server to ensure that the amount of space is adequate. Adjust the space if needed.

Windows: Creating the user ID and directories for the server instance

Create the user ID for the IBM Spectrum Protect™ server instance and create the directories that the server instance needs for database and recovery logs.

Before you begin

Review the information about planning space for the server before you complete this task. See Windows: Worksheets for planning details for the server.

Procedure

1. Create the user ID that will own the server instance. You use this user ID when you create the server instance in a later step.

   Windows

   Windows Create a user ID that will be the owner of the IBM Spectrum Protect server instance. A user ID can own more than one IBM Spectrum Protect server instance. Identify the user account that will own the server instance.

   When the server is started as a Windows service, this account is the one that the service will log on to. The user account must have administrative authority on the system. One user account can own more than one server instance.

If you have multiple servers on one system and want to run each server with a different user account, create a new user account in this step.

Create the user ID.
Restriction: The user ID must comply with the following rule:

In the user ID, only lowercase letters (a-z), numerals (0-9), and the underscore character (_) can be used. The user ID must be 30 characters or less, and cannot start with *ibm*, *sql*, *sys*, or a numeral. The user ID and group name cannot be *user*, *admin*, *guest*, *public*, *local*, or any SQL reserved word.

a. Use the following operating system command to create the user ID:

```
net user user_ID * /add
```

You are prompted to create and verify a password for the new user ID.

b. Issue the following operating system commands to add the new user ID to the Administrators groups:

```
net localgroup Administrators user_ID /add
net localgroup DB2ADMNS user_ID /add
```

2. Create directories that the server requires.
Windows Create empty directories for each item in the table and ensure that the new user ID you just created has read/write permission to the directories. The database, archive log, and active log must reside on different physical volumes.

Item	Example commands for creating the directories	Your directories
The *instance directory* for the server, which is a directory that will contain files specifically for this server instance (the server options file and other server-specific files)	`mkdir d:\tsm\server1`	
The database directories	`mkdir d:\tsm\db001` `mkdir e:\tsm\db002` `mkdir f:\tsm\db003` `mkdir g:\tsm\db004`	
Active log directory	`mkdir h:\tsm\log`	
Archive log directory	`mkdir i:\tsm\archlog`	
Optional: Directory for the log mirror for the active log	`mkdir j:\tsm\logmirror`	
Optional: Secondary archive log directory (failover location for archive log)	`mkdir k:\tsm\archlogfailover`	

When a server is initially created by using the DSMSERV FORMAT utility or the configuration wizard, a server database and recovery log are created. In addition, files are created to hold database information that is used by the database manager.

3. Log off the new user ID.

Windows: Configuring the IBM Spectrum Protect server

After you have installed the server and prepared for the configuration, configure the server instance.

About this task

Windows Tip: The IBM Spectrum Protect™ Management Console, which is a Microsoft Management Console (MMC) snap-in, is no longer delivered with IBM Spectrum Protect. The preferred method for configuring the server is to use the configuration wizard. You can use the wizard to complete several server configuration tasks. However, you cannot use the wizard to extend the Active Directory schema so that clients can automatically discover servers.
Configure an IBM Spectrum Protect server instance by selecting one of the following options:

- Windows: Configuring IBM Spectrum Protect by using the configuration wizard
  The wizard offers a guided approach to configuring a server. By using the graphical user interface (GUI), you can avoid some configuration steps that are complex when done manually. Start the wizard on the system where you installed the IBM Spectrum Protect server program.
- Windows: Configuring the server instance manually
  After installing IBM Spectrum Protect Version 8.1.2, you can configure IBM Spectrum Protect manually instead of using the configuration wizard.

Windows: Configuring IBM Spectrum Protect by using the configuration wizard

The wizard offers a guided approach to configuring a server. By using the graphical user interface (GUI), you can avoid some configuration steps that are complex when done manually. Start the wizard on the system where you installed the IBM Spectrum Protect™ server program.

Before you begin

Before you begin to use the configuration wizard, you must complete all preceding steps to prepare for the configuration. These steps include installing IBM Spectrum Protect, creating the database and log directories, and creating the directories and user ID for the server instance.
Windows

About this task

Windows Tip: The IBM Spectrum Protect Console, which is an MMC snap-in, is no longer delivered with IBM Spectrum Protect. The preferred method for configuring the server instance is to use the configuration wizard. You can use the wizard to complete several configuration tasks.

Procedure

1. Ensure that the following requirements are met: Windows
   - Ensure that the following requirements are met:
     a. Click Start > Administrative Tools > Services.
     b. In the Services window, select the Remote Registry service if it is not started, and click Start.
   - Ensure ports 137, 139 and 445 are not blocked by a firewall:
     a. Click Start > Control Panel > Windows Firewall.
     b. Select Advanced Settings.
     c. Select Inbound Rules in the left pane.
     d. Select New Rule in the right pane.
     e. Create a port rule for TCP ports 137, 139 and 445 to allow connections for domain and private networks.
   - Configure User Account Control:

     Access all three of the user account control configuration settings by first accessing Local Security Policy Security options, by using the following steps:

     a. Enable the built-in Administrator account:
        - Select the Accounts: Administrator account status.
        - Select Enable and click OK.
     b. Disable User Account Control for all Windows administrators:
        - Select the User Account Control: Run all administrators in Admin Approval Mode.
        - Select Disable and click OK.
     c. Disable User Account Controll for the built-in Administrator account:
        - Select the User Account Control: Admin Approval Mode for the Built-in Administrator Account.
        - Select Disable and click OK.
   - Restart the server before you proceed with the Configuration wizard.
2. Start the local version of the wizard:
   - Windows Either click Start > All Programs > IBM Spectrum Protect > Configuration Wizard. Or, double-click the `dsmicfgx.exe` program in *installation_directory*\server. The default directory is C:\Program Files\Tivoli\TSM.

Follow the instructions to complete the configuration. The wizard can be stopped and restarted, but the server is not operational until the entire configuration process is complete.

- Windows: Windows: Configuring Remote Execution Protocol on Windows
  Configure remote access settings by using these procedures.

Windows: Configuring the server instance manually

After installing IBM Spectrum Protect™ Version 8.1.2, you can configure IBM Spectrum Protect manually instead of using the configuration wizard.

- Windows: Creating the server instance
  Create an IBM Spectrum Protect instance by issuing the db2icrt command.
- Windows: Windows: Configuring server and client communications
  After installing the server, you can set up client and server communications by specifying options in the server and client options files.
- Windows: Formatting the database and log
  Use the DSMSERV FORMAT utility to initialize a server instance. No other server activity is allowed while you initialize the database and recovery log.
- Windows: Preparing the database manager for database backup
  To back up the data in the database to IBM Spectrum Protect, you must enable the database manager and configure the IBM Spectrum Protect application programming interface (API).

Windows: Creating the server instance

Create an IBM Spectrum Protect™ instance by issuing the db2icrt command.

About this task

You can have one or more server instances on one workstation.
Windows Important: Before you run the db2icrt command, ensure that the user and the instance directory of the user exists. If there is no instance directory, you must create it.
The instance directory stores the following files for the server instance:

- The server options file, dsmserv.opt
- The server key database file, `cert.kdb`, and the `.arm` files (used by clients and other servers to import the Secure Sockets Layer certificates of the server)
- Device configuration file, if the DEVCONFIG server option does not specify a fully qualified name
- Volume history file, if the VOLUMEHISTORY server option does not specify a fully qualified name
- Volumes for DEVTYPE=FILE storage pools, if the directory for the device class is not fully specified, or not fully qualified
- User exits
- Trace output (if not fully qualified)

Windows

1. Log in as an administrator and create an IBM Spectrum Protect instance, by using the db2icrt command. Enter the following command on one line. The user account that you specify becomes the user ID that owns the Version 8.1.2 server (the instance user ID).

   ```
   db2icrt -u user_account instance_name
   ```

   For example, if the user account is *tsminst1* and the server instance is *Server1*, enter the following command:

   ```
   db2icrt -u tsminst1 server1
   ```

   You are prompted for the password for user ID *tsminst1*. Later, when you create and format the database, you use the instance name that you specified with this command, with the -k option.
2. Change the default path for the database to be the drive where the instance directory for the server is located. Complete the following steps:
   a. Click Start > Programs > IBM DB2 > DB2TSM1 > Command Line Tools > Command Line Processor.
   b. Enter `quit` to exit the command line processor.

      A window with a command prompt should now be open, with the environment properly set up to successfully issue the commands in the next steps.

c. From the command prompt in that window, issue the following command to set the environment variable for the server instance that you are working with:

```
set db2instance=instance_name
```

The *instance_name* is the same as the instance name that you specified when you issued the db2icrt command. For example, to set the environment variable for the *Server1* server instance, issue the following command:

```
set db2instance=server1
```

d. Issue the command to set the default drive:

```
db2 update dbm cfg using dftdbpath instance_location
```

For example, the instance directory is d:\tsm\server1 and the instance location is drive d:. Enter the command:

```
db2 update dbm cfg using dftdbpath d:
```

3. Create a new server options file. See Windows: Configuring server and client communications.

Windows

Windows: Configuring server and client communications

After installing the server, you can set up client and server communications by specifying options in the server and client options files.

About this task

Set these server options before you start the server. When you start the server, the new options go into effect. If you modify any server options after starting the server, you must stop and restart the server to activate the updated options.

Review the server options file (`dsmserv.opt.smp`) that is located in the server instance directory to view and specify server communications options. By default, the server uses the TCP/IP and Named Pipes communication methods.

Tip: If you start the server console and see warning messages that a protocol could not be used by the server, either the protocol is not installed or the settings do not match the Windows protocol settings.

For a client to use a protocol that is enabled on the server, the client options file must contain corresponding values for communication options. In the server options file, you can view the values for each protocol.

You can specify one or more of the following communication methods:

- TCP/IP Version 4 or Version 6
- Named Pipes
- Shared memory
- Secure Sockets Layer (SSL)
  Tip: You can authenticate passwords with the LDAP directory server, or authenticate passwords with the server. Passwords that are authenticated with the LDAP directory server can provide enhanced system security.

- Windows Windows: Setting TCP/IP options
  Select from a range of TCP/IP options for the IBM Spectrum Protect server or retain the default.
- Windows Windows: Setting Named Pipes options
  The Named Pipes communication method is ideal when running the server and client on the same Windows machine. Named Pipes require no special configuration.
- Windows Windows: Setting Secure Sockets Layer options
  You can add more protection for your data and passwords by using Secure Sockets Layer (SSL).

Windows: Setting TCP/IP options

Select from a range of TCP/IP options for the IBM Spectrum Protect™ server or retain the default.

About this task

The following is an example of a list of TCP/IP options that you can use to set up your system.

```
commmethod         tcpip
  tcpport          1500
  tcpwindowsize    0
  tcpnodelay       yes
```

Tip: You can use TCP/IP Version 4, Version 6, or both.

TCPPORT
: The server port address for TCP/IP and SSL communication. The default value is 1500.

Windows TCPWINDOWSIZE
: Windows Specifies the size of the TCP/IP buffer that is used when sending or receiving data. The window size that is used in a session is the smaller of the server and client window sizes. Larger window sizes use additional memory but can improve performance.

  To use the default window size for the operating system, specify 0.

TCPNODELAY
: Specifies whether or not the server sends small messages or lets TCP/IP buffer the messages. Sending small messages can improve throughput but increases the number of packets sent over the network. Specify YES to send small messages or NO to let TCP/IP buffer them. The default is YES.

TCPADMINPORT
: Specifies the port number on which the server TCP/IP communication driver is to wait for TCP/IP or SSL-enabled communication requests other than client sessions. The default is the value of TCPPORT.

SSLTCPPORT
: (SSL-only) Specifies the Secure Sockets Layer (SSL) port number on which the server TCP/IP communication driver waits for requests for SSL-enabled sessions for the command-line backup-archive client and the command-line administrative client.

SSLTCPADMINPORT
: (SSL-only) Specifies the port address on which the server TCP/IP communication driver waits for requests for SSL-enabled sessions for the command-line administrative client.

Windows: Setting Named Pipes options

The Named Pipes communication method is ideal when running the server and client on the same Windows machine. Named Pipes require no special configuration.

About this task

Here is an example of a Named Pipes setting:

```
commmethod                      namedpipe
     namedpipename              \\.\pipe\adsmpipe
```

COMMMETHOD can be used multiple times in the IBM Spectrum Protect™ server options file, with a different value each time. For example, the following example is possible:

```
commmethod tcpip
commmethod namedpipe
```

Windows: Setting Secure Sockets Layer options

You can add more protection for your data and passwords by using Secure Sockets Layer (SSL).

Before you begin

SSL is the standard technology for creating encrypted sessions between servers and clients. SSL provides a secure channel for servers and clients to communicate over open communication paths. With SSL, the identity of the server is verified through the use of digital certificates.

To ensure better system performance, use SSL only for sessions when it is needed. Consider adding additional processor resources on the IBM Spectrum Protect™ server to manage the increased requirements.

Windows: Formatting the database and log

Use the DSMSERV FORMAT utility to initialize a server instance. No other server activity is allowed while you initialize the database and recovery log.

After you set up server communications, you are ready to initialize the database. Ensure that you log in by using the instance user ID. Do not place the directories on file systems that might run out of space. If certain directories (for example, the archive log) become unavailable or full, the server stops.

For optimal performance and to facilitate I/O, specify at least two equally sized containers or Logical Unit Numbers (LUNs) for the database. In addition, each active log and archive log needs its own container or LUN.

Windows Important: The installation program creates a set of registry keys. One of these keys points to the directory where a default server, named SERVER1, is created. To install an additional server, create a directory and use the DSMSERV FORMAT utility, with the -k parameter, from that directory. That directory becomes the location of the server. The registry tracks the installed servers.

Setting the exit list handler

Set the DB2NOEXITLIST registry variable to ON for each server instance. Log on to the system as the server instance owner and issue this command:

```
db2set -i server_instance_name DB2NOEXITLIST=ON
```

For example: Windows

```
db2set -i server1 DB2NOEXITLIST=ON
```

Initializing a server instance

Use the DSMSERV FORMAT utility to initialize a server instance. For example, if the server instance directory is */tsminst1*, issue the following commands: Windows

```
cd \tsminst1
dsmserv -k server2 format dbdir=d:\tsm\db001 activelogsize=32768
activelogdirectory=e:\tsm\activelog archlogdirectory=f:\tsm\archlog
archfailoverlogdirectory=g:\tsm\archfaillog mirrorlogdirectory=h:\tsm\mirrorlog
```

Tip: If you specify multiple directories, ensure that the underlying file systems are of equal size to ensure a consistent degree of parallelism for database operations. If one or more directories for the database are smaller than the others, they reduce the potential for optimized parallel prefetching and distribution of the database.

Related information:

DSMSERV FORMAT (Format the database and log)

Windows: Preparing the database manager for database backup

To back up the data in the database to IBM Spectrum Protect™, you must enable the database manager and configure the IBM Spectrum Protect application programming interface (API).

About this task

If you use the configuration wizard to create an IBM Spectrum Protect server instance, you do not have to complete these steps. If you are configuring an instance manually, complete the following steps before you issue either the BACKUP DB or the RESTORE DB commands.

Attention: If the database is unusable, the entire IBM Spectrum Protect server is unavailable. If a database is lost and cannot be recovered, it might be difficult or impossible to recover data that is managed by that server. Therefore, it is critically important to back up the database.

Windows Restriction: Database backup and restore over shared memory are not available on Windows systems.

Windows In the following commands, the examples use `server1` for the database instance and d:\tsmserver1 for the IBM Spectrum Protect server directory. Replace these values with your actual values in the commands.

1. Create a file that is called `tsmdbmgr.env` in the d:\tsmserver1 directory with the following contents:

   ```
   DSMI_CONFIG=server_instance_directory\tsmdbmgr.opt
   DSMI_LOG=server_instance_directory
   ```

2. Set the DSMI_ api environment-variable configuration for the database instance:
   a. Open a DB2® command window. One method is to go to the C:\Program Files\Tivoli\TSM\db2\bin directory, or if you installed IBM Spectrum Protect in a different location, go to the db2\bin subdirectory in your main installation directory. Then, issue this command:

      ```
      db2cmd
      ```

   b. Issue this command:

      ```
      db2set -i server1 DB2_VENDOR_INI=d:\tsmserver1\tsmdbmgr.env
      ```

3. Create a file that is called `tsmdbmgr.opt` in the d:\tsmserver1 directory with the following contents:

   ```
   ************************************************
   nodename $$_TSMDBMGR_$$
   commmethod tcpip
   tcpserveraddr localhost
   tcpport 1500
   passwordaccess generate
   errorlogname d:\tsmserver1\tsmdbmgr.log
   ```

   where
   - *nodename* specifies the node name the client API uses to connect to the server during a database backup. This value must be `$$_TSMDBMGR_$$` for database backup to work.
   - *commethod* specifies the client API used to contact the server for database backup.
   - *tcpserveraddr* specifies the server address that the client API uses to contact the server for database backup. To ensure that the database can be backed up, this value must be `localhost`.
   - *tcpport* specifies the port number that the client API uses to contact the server for database backup. Ensure that you enter the same `tcpport` value that is specified in the dsmserv.opt server options file.
   - *passwordaccess* is required for the backup node to connect to the server on windows systems.
   - *errorlogname* specifies the error log where the client API logs errors that are encountered during a database backup. This log is typically in the server instance directory. However, this log can be placed in any location where the instance user ID has write-permission.

Windows: Configuring server options for server database maintenance

To help avoid problems with database growth and server performance, the server automatically monitors its database tables and reorganizes them when needed. Before starting the server for production use, set server options to control when reorganization runs. If you plan to use data deduplication, ensure that the option to run index reorganization is enabled.

About this task

Table and index reorganization requires significant processor resources, active log space, and archive log space. Because database backup takes precedence over reorganization, select the time and duration for reorganization to ensure that the processes do not overlap and reorganization can complete.

Windows You can optimize index and table reorganization for the server database. In this way, you can help to avoid unexpected database growth and performance issues. For instructions, see technote 1683633.

If you update these server options while the server is running, you must stop and restart the server before the updated values take effect.

Procedure

1. Modify the server options.
   Windows Edit the server options file, dsmserv.opt, in the server instance directory by using a text editor. Follow these guidelines when you edit the server options file:
   - To enable an option, remove the asterisk at the beginning of the line.
   - Enter an option on any line.
   - Enter only one option per line. The entire option with its value must be on one line.
   - If you have multiple entries for an option in the file, the server uses the last entry.

   To view available server options, see the sample file, dsmserv.opt.smp, in the c:\Program Files\Tivoli\TSM directory.
2. If you plan to use data deduplication, enable the ALLOWREORGINDEX server option. Add the following option and value to the server options file:

```
allowreorgindex yes
```

3. Set the REORGBEGINTIME and REORGDURATION server options to control when reorganization starts and how long it runs. Select a time and duration so that reorganization runs when you expect that the server is least busy. These server options control both table and index reorganization processes.
   a. Set the time for reorganization to start by using the REORGBEGINTIME server option. Specify the time by using the 24-hour system. For example, to set the start time for reorganization as 8:30 p.m., specify the following option and value in the server options file:

      ```
      reorgbegintime 20:30
      ```

   b. Set the interval during which the server can start reorganization. For example, to specify that the server can start reorganization for four hours after the time set by the REORGBEGINTIME server option, specify the following option and value in the server options file:

      ```
      reorgduration 4
      ```

4. If the server was running while you updated the server options file, stop and restart the server.

Windows

Windows: Starting the server instance on Windows systems

In a production environment, the preferred method for starting the server is as a Windows service. In an environment where you are reconfiguring, testing, or completing maintenance tasks, start the server in the foreground or use maintenance mode.

Before you begin

Select one of the following methods for starting the server:

As a Windows service
: This method is useful in a production environment. When you configure the server to run as a service, you can specify that the server starts automatically whenever the system is started.

In the foreground
: This method is useful when you are configuring or testing the server. When you start the server in the foreground, IBM Spectrum Protect™ provides a special administrator user ID that is named SERVER_CONSOLE. All server messages are displayed in the foreground. The messages can be useful if you must debug startup problems.

In maintenance mode
: This method is useful when you are completing maintenance or reconfiguration tasks. When you start the server in maintenance mode, you disable operations that might disrupt your maintenance or reconfiguration tasks.

Procedure

Follow the instructions for your selected option:

Option	Description
Starting the server as a Windows service	To start the server as a Windows service, take one of the following actions: • If you configured the server by using the configuration wizard, complete the following steps: a. Configure the server to start as a Windows service by following the instructions in Windows: Configuring the server to start as a Windows service. b. Start the server by following the instructions in Windows: Starting the server as a Windows service. • If you did not use the configuration wizard, create and configure the Windows service by following the instructions in Windows: Manually creating and configuring a Windows service.
Starting the server in the foreground	To start the server in the foreground, follow the instructions in Windows: Starting the server in the foreground.

Option	Description
Starting the server in maintenance mode	To start the server in maintenance mode, follow the instructions in Windows: Starting the server in maintenance mode.

Windows

Windows: Configuring the server to start as a Windows service

Before you can start the server as a Windows service, you must ensure that options and access rights are set correctly.

Before you begin

A Windows service must be created. If you configured the server by using the configuration wizard, a Windows service was created automatically. In that case, use this procedure to configure the server to start as a Windows service.

If you did not use a wizard, you must create and configure the Windows service manually by following the steps in Windows: Manually creating and configuring a Windows service.

Procedure

1. From the Windows Start menu, click Run, type `services.msc`, and click OK.
2. In the Services window, select the server instance that you want to start as a service, and click Properties. For example, select TSM INST1, and click Properties.
3. To ensure that the server service starts automatically, click the General tab. From the Startup type list, select Automatic.
4. To set the user for starting the server service, click the Log On tab, and take one of the following actions:
   - If you plan to run the server service under the Local System account, select Local System account and click OK.
   - If you plan to run the server service under the instance user ID, take the following actions:
     a. Select This account, and browse for the user ID that owns the server DB2® instance and has permissions for starting the server.
     b. In the Select User window, in the Enter the object name to select field, enter the user ID.
     c. Click Check Names.
     d. Click OK twice.
5. If you configured the server service to run under the Local System account, grant database access to the Local System account:
   a. Log on with the user ID that was used to create the server database. This user ID is the user ID that was used to run the DSMSERV FORMAT utility to initialize the server database. Alternatively, if you configured the server with the dsmicfgx configuration wizard, this user ID is the user ID that was used to create the instance.
   b. Open a DB2 command window. If the server is installed on Windows Server 2012, open the Start window, and click DB2 Command Window - Administrator.
   c. In the DB2 command window, enter the following commands:

```
set DB2INSTANCE=server1
db2 connect to TSMDB1
db2 grant dbadm with dataaccess with accessctrl on database to user system
db2 grant secadm on database to user system
```

   Tip: When the server service is configured to run under the Local System account, the database can be accessed by any administrator on the system. In addition, any administrator who can log on to the system can run the server.

What to do next

To start the service, follow the instructions in Windows: Starting the server as a Windows service.

Windows

Windows: Starting the server as a Windows service

If you are running IBM Spectrum Protect™ on a Windows operating system, you can start the server as a service.

Before you begin

A Windows service must be created. The service was created automatically if you configured the server by using the configuration wizard. If the service was created automatically, you must configure the server to start as a service by following the steps in

Windows: Configuring the server to start as a Windows service. Then, use this procedure to start the server as a service.

If you did not use the configuration wizard to create the service, you must create and configure the service manually. Follow the steps in Windows: Manually creating and configuring a Windows service.

Procedure

To start the server as a Windows service, complete the following steps:

1. Log on to the server with a user ID that is in the Administrators group.
2. From the Windows Start menu, click Run, type `services.msc`, and click OK.
3. In the Services window, select the server instance that you want to start, and click Start.

What to do next

Because the server service can issue requests that require action, it is important to monitor server activity with the Operations Center or the administrative client.

To view start and stop completion messages that are logged in the Windows application log, use the Event Viewer tool in the Administrative Tools folder.

Windows

Windows: Manually creating and configuring a Windows service

If you configured the server by using the configuration wizard, a Windows service was created automatically. If a service was not created automatically, you must create it.

Before you begin

To complete this procedure, you must log on with a user ID that is in the Administrators group.

Procedure

To create a Windows service and configure the startup options for the service, complete the following step:

Open a command window and enter the sc.exe create command:

```
sc.exe create server_name binPath= "path_to_server -k instance_name"
start= start_type obj= account_name password= password
```

where:

server_name
: Specifies the name of the server service.

path_to_server
: Specifies the path to the dsmsvc.exe executable file, including the file name. This path is the default path:

  C:\Program Files\Tivoli\TSM\server

instance_name
: Specifies the name of the DB2® instance, which is also the name of the server instance, for example, Server1.

start_type
: Specifies the method for starting the service. To automatically start the service, enter `auto`. If you specify the `auto` option, the service starts automatically at system startup and restarts automatically whenever the system is restarted. To manually start the service, enter `demand`.

account_name
: Specifies the user ID for the account under which the service runs. For example, the account name might be Administrator. This parameter is optional. If it is not specified, the Local System account is used.

password
: Specifies the password for the *account_name* user account.

Tip: When you enter the command, ensure that you enter a space after each equal sign (=).

Results

The server starts as a Windows service.

Windows

Windows: Starting the server in the foreground

To directly interact with an IBM Spectrum Protect™ server, start the server in the foreground. For example, if you want to enter commands, start the server in the foreground.

Procedure

1. Change to the directory where the server is installed. For example, change to the c:\program files\tivoli\tsm\server directory.
2. Enter the following command:

   ```
   dsmserv -k instance_name
   ```

   where *instance_name* specifies the server instance.

Windows

Windows: Services associated with the server on Windows systems

When you start the IBM Spectrum Protect™ server as a service, other services start automatically. These services are associated with the database manager, DB2®.

The following services are associated with the server.

Service name	Purpose	Comments
TSM *Server_instance*	The service for the server instance that is named *Server_instance*. For example: `TSM Server1`	Set the start and stop options for this service to start and stop the server instance automatically. Each server instance runs as a separate service.
DB2 - DB2TSM1 - *SERVER_INSTANCE*	The DB2 service for the server instance that is named *Server_instance*. For example: `DB2 - DB2TSM1 - SERVER1`	This service is automatically started when the service for the server instance is started. The DB2 service is not stopped automatically when you stop the service for the server. The system has one of these services for each server-instance service that is started on the system.
DB2 Governor (DB2TSM1)	A DB2 service that is created at installation time, and is required for all server instances.	Do not change the options for this service.
DB2 License Server (DB2TSM1)	A DB2 service that is created at installation time, and is required for all server instances.	Do not change the options for this service.
DB2 Management Server (DB2TSM1)	A DB2 service that is created at installation time, and is required for all server instances.	Do not change the options for this service.
DB2 Remote Command Server (DB2TSM1)	A DB2 service that is created at installation time, and is required for all server instances.	Do not change the options for this service.

Windows

Windows: Starting the server in maintenance mode

You can start the server in maintenance mode to avoid disruptions during maintenance and reconfiguration tasks.

About this task

Start the server in maintenance mode by running the DSMSERV utility with the MAINTENANCE parameter.

The following operations are disabled in maintenance mode:

- Administrative command schedules
- Client schedules
- Reclamation of storage space on the server
- Inventory expiration
- Migration of storage pools

In addition, clients are prevented from starting sessions with the server.
Tips:

- You do not have to edit the server options file, dsmserv.opt, to start the server in maintenance mode.
- While the server is running in maintenance mode, you can manually start the storage-space reclamation, inventory expiration, and storage-pool migration processes.

Procedure

To start the server in maintenance mode, issue the following command:

```
dsmserv maintenance
```

Tip: To view a video about starting the server in maintenance mode, see Starting a server in maintenance mode.

What to do next

To resume server operations in production mode, complete the following steps:

1. Shut down the server by issuing the HALT command:

   ```
   halt
   ```

2. Start the server by using the method that you use in production mode.

Operations that were disabled during maintenance mode are reenabled.

Windows: Stopping the server

You can stop the server when needed to return control to the operating system. To avoid losing administrative and client node connections, stop the server only after current sessions are completed or canceled.

About this task

To stop the server, issue the following command from the IBM Spectrum Protect™ command line:

```
halt
```

Windows: Registering licenses

Immediately register any IBM Spectrum Protect™ licensed functions that you purchase so you do not lose any data after you start server operations, such as backing up your data.

About this task

Use the REGISTER LICENSE command for this task. See REGISTER LICENSE for more details.

Example: Register a license

Register the base IBM Spectrum Protect license.

```
register license file=tsmbasic.lic
```

Windows: Specifying a device class in preparation for database backups

To prepare the system for automatic and manual database backups, you must specify the device class to be used.

Before you begin

Ensure that you have defined a tape or file device class. For details, see DEFINE DEVCLASS, or search for defining a device class.

About this task

Complete the following steps to set up your system for database backups.

Procedure

1. If you did not use the configuration wizard (dsmicfgx) to configure the server, ensure that you have completed the steps to manually configure the system for database backups.
2. Select the device class to be used for backups of the database. Issue the following command from an IBM Spectrum Protect™ administrative command line.

   ```
   set dbrecovery device_class_name
   ```

   The device class that you specify is used by the database manager for database backups. If you do not specify a device class with the SET DBRECOVERY command, the backup fails.

Example

For example, to specify that the DBBACK device class is to be used, issue this command:

```
set dbrecovery dbback
```

Windows: Running multiple server instances on a single system

You can create more than one server instance on your system. Each server instance has its own instance directory, and database and log directories.

Multiply the memory and other system requirements for one server by the number of instances planned for the system.

Windows The set of files for one instance of the server is stored separately from the files used by another server instance on the same system. Use the steps in Windows: Creating the server instance for each new instance, optionally creating the new instance user.

To manage the system memory that is used by each server, use the DBMEMPERCENT server option to limit the percentage of system memory. If all servers are equally important, use the same value for each server. If one server is a production server and other servers are test servers, set the value for the production server to a higher value than the test servers.

You can upgrade directly from either V6.3 to V7.1. See the upgrade section (Upgrading to V8.1) for more details. When you upgrade and have multiple servers on your system, you must run the installation wizard only once. The installation wizard collects the database and variables information for all of your original server instances.

If you upgrade from IBM Spectrum Protect V6.3 to V8.1.2 and have multiple servers on your system, all instances that exist in DB2® V9.7 are dropped and recreated in DB2 V11.1. The wizard issues the `db2 upgrade db dbname` command for each database. The database environment variables for each instance on your system are also reconfigured during the upgrade process.

Windows A typical IBM Spectrum Protect installation involves one server instance on the IBM Spectrum Protect server computer. You might want to install a second instance if you are configuring in a clustered environment. You might also want to run more than one server on a large computer if you have multiple tape libraries or a disk-only configuration. After you install and configure the first IBM Spectrum Protect server, use the Server Initialization wizard to create additional IBM Spectrum Protect server instances on the same computer.

Windows By using the Server Initialization wizard, you can install up to four IBM Spectrum Protect server instances on a single system or cluster.

Related tasks:
Running multiple server instances on a single system (V7.1.1)

Windows: Monitoring the server

When you start to use the server in production, monitor the space that is used by the server to ensure that the amount of space is adequate. Adjust the space if needed.

Procedure

1. Monitor the active log to ensure that the size is correct for the workload that is handled by the server instance.

   When the server workload reaches its typical expected level, the space that is used by the active log is 80% - 90% of the space that is available to the active log directory. At that point, you might need to increase the amount of space. Whether you must increase the space depends on the types of transactions in the server workload. Transaction characteristics affect how the active log space is used.

   The following transaction characteristics can affect the space usage in the active log:

   - The number and size of files in backup operations
     - Clients such as file servers that back up large numbers of small files can cause large numbers of transactions that are completed quickly. The transactions might use a large amount of space in the active log, but for a short time.
     - Clients such as a mail server or a database server that back up large amounts of data in few transactions can cause small numbers of transactions that take a long time to complete. The transactions might use a small amount of space in the active log, but for a long time.
   - Network connection types
     - Backup operations that occur over fast network connections cause transactions that complete more quickly. The transactions use space in the active log for a shorter time.
     - Backup operations that occur over relatively slower connections cause transactions that take a longer time to complete. The transactions use space in the active log for a longer time.

   If the server is handling transactions with a wide variety of characteristics, the space that is used for the active log might increase and decrease significantly over time. For such a server, you might need to ensure that the active log typically has a smaller percentage of its space used. The extra space allows the active log to grow for transactions that take a long time to complete.

2. Monitor the archive log to ensure that space is always available.
   Remember: If the archive log becomes full, and the failover archive log becomes full, the active log can become full, and the server stops. The goal is to make enough space available to the archive log so that it never uses all its available space.
   You are likely to notice the following pattern:
   a. Initially, the archive log grows rapidly as typical client-backup operations occur.
   b. Database backups occur regularly, either as scheduled or done manually.
   c. After at least two full database backups occur, log pruning occurs automatically. The space that is used by the archive log decreases when the pruning occurs.
   d. Normal client operations continue, and the archive log grows again.
   e. Database backups occur regularly, and log pruning occurs as often as full database backups occur.

   With this pattern, the archive log grows initially, decreases, and then might grow again. Over time, as normal operations continue, the amount of space that is used by the archive log should reach a relatively constant level.

   If the archive log continues to grow, consider taking one or both of these actions:
   - Add space to the archive log. You might need to move the archive log to a different file system.
   - Increase the frequency of full database backups, so that log pruning occurs more frequently.
3. If you defined a directory for the failover archive log, determine whether any logs get stored in that directory during normal operations. If the failover log space is being used, consider increasing the size of the archive log. The goal is that the failover archive log is used only under unusual conditions, not in normal operation.

Windows: Installing an IBM Spectrum Protect server fix pack

IBM Spectrum Protect™ maintenance updates, which are also referred to as fix packs, bring your server up to the current maintenance level.

Before you begin

To install a fix pack or interim fix to the server, install the server at the level on which you want to run it. You do not have to start the server installation at the base release level. For example, if you currently have V8.1.1 installed, you can go directly to the latest fix pack for V8.1. You do not have to start with the V8.1.0 installation if a maintenance update is available.

You must have the IBM Spectrum Protect license package installed. The license package is provided with the purchase of a base release. When you download a fix pack or interim fix from Fix Central, install the server license that is available on the Passport Advantage® website. To display messages and help in a language other than US English, install the language package of your choice.

If you upgrade the server to V8.1.2 or later, and then revert the server to a level that is earlier than V8.1.2, you must restore the database to a point in time before the upgrade. During the upgrade process, complete the required steps to ensure that the database can be restored: back up the database, the volume history file, the device configuration file, and the server options file. For more information, see Windows: Reverting from Version 8.1.2 to a previous server.

If you are using the client management service, ensure that you upgrade it to the same version as the IBM Spectrum Protect server.

Ensure that you retain the installation media from the base release of the installed server. If you installed IBM Spectrum Protect from a downloaded package, ensure that the downloaded files are available. If the upgrade fails, and the server license module is uninstalled, the installation media from the server base release are required to reinstall the license.

Visit the IBM® Support Portal for the following information:

- A list of the latest maintenance and download fixes. Click **Downloads** and apply any applicable fixes.
- Details about obtaining a base license package. Search for **Downloads > Passport Advantage**.
- Supported platforms and system requirements. Search for **IBM Spectrum Protect supported operating systems**.

Ensure that you upgrade the server before you upgrade backup-archive clients. If you do not upgrade the server first, communication between the server and clients might be interrupted.

Attention: Do not alter the DB2® software that is installed with IBM Spectrum Protect installation packages and fix packs. Do not install or upgrade to a different version, release, or fix pack of DB2 software because doing so can damage the database.

Procedure

To install a fix pack or interim fix, complete the following steps:

1. Back up the database. The preferred method is to use a snapshot backup. A snapshot backup is a full database backup that does not interrupt any scheduled database backups. For example, issue the following IBM Spectrum Protect administrative command:

   ```
   backup db type=dbsnapshot devclass=tapeclass
   ```

2. Back up the device configuration information. Issue the following IBM Spectrum Protect administrative command:

   ```
   backup devconfig filenames=file_name
   ```

   where *file_name* specifies the name of the file in which to store device configuration information.
3. Save the volume history file to another directory or rename the file. Issue the following IBM Spectrum Protect administrative command:

   ```
   backup volhistory filenames=file_name
   ```

   where *file_name* specifies the name of the file in which to store the volume history information.
4. Save a copy of the server options file, typically named dsmserv.opt. The file is in the server instance directory.
5. Halt the server before installing a fix pack or interim fix. Use the HALT command.
6. Ensure that extra space is available in the installation directory. The installation of this fix pack might require additional temporary disk space in the installation directory of the server. The amount of additional disk space can be as much as that required for installing a new database as part of an IBM Spectrum Protect installation. The IBM Spectrum Protect installation wizard displays the amount of space that is required for installing the fix pack and the available amount. If the

required amount of space is greater than the available amount, the installation stops. If the installation stops, add the required disk space to the file system and restart the installation.

7. Obtain the package file for the fix pack or interim fix that you want to install from the IBM Support Portal, Passport Advantage, or Fix Central.
8. Windows Change to the directory where you placed the executable file. Then, either double-click the following executable file or enter the following command on the command line to extract the installation files.
   Tip: The files are extracted to the current directory. Ensure that the executable file is in the directory where you want the extracted files to be located.

   ```
   8.x.x.x-IBM-SPSRV-platform.exe
   ```

   where: *platform* denotes the operating system that IBM Spectrum Protect is to be installed on.
9. Select one of the following ways of installing IBM Spectrum Protect.
   Important: After a fix pack is installed, it is not necessary to go through the configuration again. You can stop after completing the installation, fix any errors, then restart your servers.
   Install the IBM Spectrum Protect software by using one of the following methods:

   Installation wizard
   : Follow the instructions for your operating system:
     Windows: Installing IBM Spectrum Protect by using the installation wizard

   Tip: After you start the wizard, in the IBM Installation Manager window, click the Update icon; do not click the Install or Modify icon.

   Command line in console mode
   : Follow the instructions for your operating system:
     Windows: Installing IBM Spectrum Protect by using console mode

   Silent mode
   : Follow the instructions for your operating system:
     Windows: Installing IBM Spectrum Protect in silent mode

   Tip: If you have multiple server instances on your system, run the installation wizard only once. The installation wizard upgrades all server instances.

Results

Correct any errors that are detected during the installation process.

If you installed the server by using the installation wizard, you can view installation logs by using the IBM Installation Manager tool. Click File > View Log. To collect log files, from the IBM Installation Manager tool, click Help > Export Data for Problem Analysis.

If you installed the server by using console mode or silent mode, you can view error logs in the IBM Installation Manager log directory, for example:

- Windows C:\ProgramData\IBM\Installation Manager\logs
- Windows Windows: Applying a fix pack to IBM Spectrum Protect 8.1.2 in a clustered environment for Windows
  To take advantage of new product features, you can upgrade a server that is installed on a Windows operating system in a clustered environment from V6.3 or V7.1 to IBM Spectrum Protect V8.1.2.

Windows: Reverting from Version 8.1.2 to a previous server

If you must revert to the previous version of the server after an upgrade, you must have a full database backup from your original version. You must also have the server installation media for your original version and key configuration files. Carefully follow the preparation steps before you upgrade the server. By doing so, it might be possible to revert to the previous version of the IBM Spectrum Protect™ server with minimal loss of data.

Before you begin

You must have the following items from the earlier version of the server:

- Server database backup

- Volume history file
- Device configuration file
- Server options file

About this task

Use the same instructions whether you are reverting within releases or to an earlier release, for example, from 8.1.2 to 8.1.1 or from 8.1.2 to 7.1.2. The older version must match the version that you used before the upgrade to V8.1.

Attention: Specify the REUSEDELAY parameter to help prevent backup-archive client data loss when you revert the server to a previous version.

- Windows Windows: Reverting to the previous server version in a cluster configuration
  If you must revert to the previous version of the server after an upgrade, you must have a full database backup from your original version. You must also have the server installation media for your original version and key configuration files. Carefully follow the preparation steps before you upgrade the server. By doing so, it might be possible to revert to the previous version of the IBM Spectrum Protect server with minimal loss of data.

Steps for reverting to the previous server version

About this task

Complete the following steps on the system that has the V8.1 server.

Procedure

1. Halt the server to shut down all server operations by using the HALT command.
2. Remove the database from the database manager, then delete the database and recovery log directories.
   a. Manually remove the database. One way to remove it is by issuing this command: Windows

      ```
      dsmserv -k instance_name removedb tsmdb1
      ```

   b. If you must reuse the space that is occupied by the database and recovery log directories, you can now delete these directories.
3. Use the uninstallation program to uninstall the V8.1 server. Uninstallation removes the server and the database manager, with their directories. For details, see Windows: Uninstalling IBM Spectrum Protect.
4. Stop the cluster service. Reinstall the version of the server program that you were using before the upgrade to V8.1.2. This version must match the version that your server was running when you created the database backup that you restore in a later step. For example, the server was at V7.1.7 before the upgrade, and you intend to use the database backup that was in use on this server. You must install the V7.1.7 fix pack to be able to restore the database backup.
5. Configure the new server database by using the configuration wizard. To start the wizard, issue the following command: Windows

   ```
   /dsmicfgx
   ```

6. Ensure that no servers are running in the background.
7. Restore the database to a point in time before the upgrade.
8. Copy the following files to the instance directory.
   - Device configuration file
   - Volume history file
   - The server options file (typically dsmserv.opt)
9. If you enabled data deduplication for any FILE-type storage pools that existed before the upgrade, or if you moved data that existed before the upgrade into new storage pools while using the V8.1.2 server, you must complete additional recovery steps. For more details, see Additional recovery steps if you created new storage pools or enabled data deduplication.
10. If the REUSEDELAY parameter setting on storage pools is less than the age of the database that you restored, restore volumes on any sequential-access storage pools that were reclaimed after that database backup. Use the RESTORE VOLUME command.
    If you do not have a backup of a storage pool, audit the reclaimed volumes by using the AUDIT VOLUME command, with the FIX=YES parameter to resolve inconsistencies. For example:

    ```
    audit volume volume_name fix=yes
    ```

11. If client backup or archive operations were completed using the V8.1 server, audit the storage pool volumes on which the data was stored.

Additional recovery steps if you created new storage pools or enabled data deduplication

If you created new storage pools, turned on data deduplication for any FILE-type storage pools, or did both while your server was running as a V8.1.2 server, you must complete more steps to return to the previous server version.

Before you begin

To complete this task, you must have a complete backup of the storage pool that was created before the upgrade to V8.1.2.

About this task

Use this information if you did either or both of the following actions while your server was running as a V8.1.2 server:

- You enabled the data deduplication function for any storage pools that existed before the upgrade to V8.1.2 program. Data deduplication applies only to storage pools that use a FILE device type.
- You created new primary storage pools after the upgrade *and* moved data that was stored in other storage pools into the new storage pools.

Complete these steps after the server is again restored to V7.

Procedure

- For each storage pool for which you enabled the data deduplication function, restore the entire storage pool by using the RESTORE STGPOOL command.
- For storage pools that you created after the upgrade, determine what action to take. Data that was moved from existing V8 storage pools into the new storage pools might be lost because the new storage pools no longer exist in your restored V8 server. Possible recovery depends on the type of storage pool:
    - If data was moved from V8 DISK-type storage pools into a new storage pool, space that was occupied by the data that was moved was probably reused. Therefore, you must restore the original V8 storage pools by using the storage pool backups that were created before the upgrade to V8.1.2.

      If *no* data was moved from V8 DISK-type storage pools into a new storage pool, then audit the storage pool volumes in these DISK-type storage pools.

    - If data was moved from V8 sequential-access storage pools into a new storage pool, that data might still exist and be usable in storage pool volumes on the restored V8 server. The data might be usable if the REUSEDELAY parameter for the storage pool was set to a value that prevented reclamation while the server was running as a V8.1.2 server. If any volumes were reclaimed while the server was running as a V8.1.2 server, restore those volumes from storage pool backups that were created before the upgrade to V8.1.2.

Windows: Reference: DB2 commands for IBM Spectrum Protect server databases

Use this list as reference when you are directed to issue DB2® commands by IBM® support.

Purpose

After using the wizards to install and configure IBM Spectrum Protect™, you seldom need to issue DB2 commands. A limited set of DB2 commands that you might use or be asked to issue are listed in Table 1. This list is supplemental material only and is not a comprehensive list. There is no implication that an IBM Spectrum Protect administrator will use it on a daily or ongoing basis. Samples of some commands are provided. Details of output are not listed.

For a full explanation of the commands described here and of their syntax, see the DB2 product information.

Table 1. DB2 commands

Command	Description	Example

Command	Description	Example
Windows db2cmd	Windows Opens the command line processor DB2 window, and initializes the DB2 command-line environment.	Windows Open the DB2 command window: `db2cmd`
db2icrt	Creates DB2 instances in the home directory of the instance owner. Tip: The IBM Spectrum Protect configuration wizard creates the instance used by the server and database. After a server is installed and configured through the configuration wizard, the db2icrt command is generally not used. Windows This utility is located in the DB2PATH\bin directory where DB2PATH is the location where the DB2 copy is installed.	Manually create an IBM Spectrum Protect instance. Enter the command on one line: `/opt/tivoli/tsm/db2/instance/db2icrt -a server -u` *`instance_name`* *`instance_name`*
db2set	Displays DB2 variables.	List DB2 variables: `db2set`
CATALOG DATABASE	Stores database location information in the system database directory. The database can be located either on the local workstation or on a remote database partition server. The server configuration wizard takes care of any catalog needed for using the server database. Run this command manually, after a server is configured and running, only if something in the environment changes or is damaged.	Catalog the database: `db2 catalog database tsmdb1`
CONNECT TO DATABASE	Connects to a specified database for command-line interface (CLI) use.	Connect to the IBM Spectrum Protect database from a DB2 CLI: `db2 connect to tsmdb1`

Command	Description	Example
GET DATABASE CONFIGURATION	Returns the values of individual entries in a specific database configuration file. Important: This command and parameters are set and managed directly by DB2. They are listed here for informational purposes and a means to view the existing settings. Changing these settings might be advised by IBM support or through service bulletins such as APARs or Technical Guidance documents (technotes). Do not change these settings manually. Change them only at the direction of IBM and only through the use of IBM Spectrum Protect server commands or procedures.	Show the configuration information for a database alias: `db2 get db cfg for tsmdb1` Retrieve information in order to verify settings such as database configuration, log mode, and maintenance. `db2 get db config for tsmdb1 show detail`
GET DATABASE MANAGER CONFIGURATION	Returns the values of individual entries in a specific database configuration file. Important: This command and parameters are set and managed directly by DB2. They are listed here for informational purposes and a means to view the existing settings. Changing these settings might be advised by IBM support or through service bulletins such as APARs or Technical Guidance documents (technotes). Do not change these settings manually. Change them only at the direction of IBM and only through the use of IBM Spectrum Protect server commands or procedures.	Retrieve configuration information for the database manager: `db2 get dbm cfg`
GET HEALTH SNAPSHOT	Retrieves the health status information for the database manager and its databases. The information returned represents a snapshot of the health state at the time the command was issued. IBM Spectrum Protect monitors the state of the database using the health snapshot and other mechanisms that are provided by DB2. There might be cases where the health snapshot or other DB2 documentation indicates that an item or database resource might be in an alert state. Such a case indicates that action must be considered to remedy the situation. IBM Spectrum Protect monitors the condition and responds appropriately. Not all declared alerts by the DB2 database are acted on.	Receive a report on DB2 health monitor indicators: `db2 get health snapshot for database on tsmdb1`
GRANT (Database Authorities)	Grants authorities that apply to the entire database rather than privileges that apply to specific objects within the database.	Grant access to the user ID itmuser: `db2 GRANT CONNECT ON DATABASE TO USER itmuser` `db2 GRANT CREATETAB ON DATABASE TO USER itmuser`

Command	Description	Example
RUNSTATS	Updates statistics about the characteristics of a table and associated indexes or statistical views. These characteristics include number of records, number of pages, and average record length. To see a table, issue this utility after updating or reorganizing the table. A view must be enabled for optimization before its statistics can be used to optimize a query. A view that is enabled for optimization is known as a statistical view. Use the DB2 ALTER VIEW statement to enable a view for optimization. Issue the RUNSTATS utility when changes to underlying tables substantially affect the rows returned by the view. Tip: The server configures DB2 to run the RUNSTATS command as needed.	Update statistics on a single table. `db2 runstats on table SCHEMA_NAME.TABLE_NAME with distribution and sampled detailed indexes all`
Windows set db2instance	Windows Determines which instance applies to the current session.	Windows Determine which instance is applicable: `set db2instance=tsminst1`
SET SCHEMA	Changes the value of the CURRENT SCHEMA special register, in preparation for issuing SQL commands directly through the DB2 CLI. Tip: A special register is a storage area that is defined for an application process by the database manager. It is used to store information that can be referenced in SQL statements.	Set the schema for IBM Spectrum Protect: `db2 set schema tsmdb1`
START DATABASE MANAGER	Starts the current database manager instance background processes. The server starts and stops the instance and database whenever the server starts and halts. Important: Allow the server to manage the starting and stopping of the instance and database unless otherwise directed by IBM support.	Start the database manager: `db2start`
STOP DATABASE MANAGER	Stops the current database manager instance. Unless explicitly stopped, the database manager continues to be active. This command does not stop the database manager instance if any applications are connected to databases. If there are no database connections, but there are instance attachments, the command forces the instance attachments to stop first. Then, it stops the database manager. This command also deactivates any outstanding database activations before stopping the database manager. This command is not valid on a client. The server starts and stops the instance and database whenever the server starts and halts. Important: Allow the server to manage the starting and stopping of the instance and database unless otherwise directed by IBM support.	Stop the database manager: `db2 stop dbm`

Windows: Uninstalling IBM Spectrum Protect

You can use the following procedures to uninstall IBM Spectrum Protect™. Before you remove IBM Spectrum Protect, ensure that you do not lose your backup and archive data.

Before you begin

Complete the following steps before you uninstall IBM Spectrum Protect:

- Complete a full database backup.
- Save a copy of the volume history and device configuration files.
- Store the output volumes in a safe location.

Windows Attention: Do not use the Add/Remove Programs tool in the Windows Control Panel to uninstall IBM Spectrum Protect. Use only the uninstallation procedure that is described in this section.

About this task

You can uninstall IBM Spectrum Protect by using any of the following methods: a graphical wizard, the command line in console mode, or silent mode.

- Windows: Uninstalling IBM Spectrum Protect by using a graphical wizard
  You can uninstall IBM Spectrum Protect by using the IBM® Installation Manager installation wizard.
- Windows: Uninstalling IBM Spectrum Protect in console mode
  To uninstall IBM Spectrum Protect by using the command line, you must run the uninstallation program of IBM Installation Manager from the command line with the parameter for console mode.
- Windows: Uninstalling IBM Spectrum Protect in silent mode
  To uninstall IBM Spectrum Protect in silent mode, you must run the uninstallation program of IBM Installation Manager from the command line with the parameters for silent mode.
- Windows: Uninstalling and reinstalling IBM Spectrum Protect
  If you plan to manually reinstall IBM Spectrum Protect instead of using the wizard, there are a number of steps to take to preserve your server instance names and database directories. During an uninstallation, any server instances previously set up are removed, but the database catalogs for those instances still exist.
- Windows: Uninstalling IBM Installation Manager
  You can uninstall IBM Installation Manager if you no longer have any products that were installed by IBM Installation Manager.

What to do next

See Windows: Installing the server components for installation steps to reinstall the IBM Spectrum Protect components.

Windows: Uninstalling IBM Spectrum Protect by using a graphical wizard

You can uninstall IBM Spectrum Protect™ by using the IBM® Installation Manager installation wizard.

Procedure

1. Start the Installation Manager.

   Windows Open the Installation Manager from the Start menu.

2. Click Uninstall.
3. Select IBM Spectrum Protect server, and click Next.
4. Click Uninstall.
5. Click Finish.

Windows: Uninstalling IBM Spectrum Protect in console mode

To uninstall IBM Spectrum Protect™ by using the command line, you must run the uninstallation program of IBM® Installation Manager from the command line with the parameter for console mode.

Procedure

1. In the directory where IBM Installation Manager is installed, go to the following subdirectory:
   - Windows eclipse\tools

For example:

- Windows C:\Program Files\IBM\Installation Manager\eclipse\tools

2. From the tools directory, issue the following command:
   - Windows `imcl.exe -c`
3. To uninstall, enter `5`.
4. Choose to uninstall from the IBM Spectrum Protect package group.
5. Enter `N` for Next.
6. Choose to uninstall the IBM Spectrum Protect server package.
7. Enter `N` for Next.
8. Enter `U` for Uninstall.
9. Enter `F` for Finish.

Windows: Uninstalling IBM Spectrum Protect in silent mode

To uninstall IBM Spectrum Protect™ in silent mode, you must run the uninstallation program of IBM® Installation Manager from the command line with the parameters for silent mode.

Before you begin

You can use a response file to provide data input to silently uninstall the IBM Spectrum Protect server components. IBM Spectrum Protect includes a sample response file, uninstall_response_sample.xml, in the input directory where the installation package is extracted. This file contains default values to help you avoid any unnecessary warnings.

If you want to uninstall all IBM Spectrum Protect components, leave `modify="false"` set for each component in the response file. If you do not want to uninstall a component, set the value to `modify="true"`.

If you want to customize the response file, you can modify the options that are in the file. For information about response files, see Response files.

Procedure

1. In the directory where IBM Installation Manager is installed, go to the following subdirectory:
   - Windows eclipse\tools

   For example:

   - Windows C:\Program Files\IBM\Installation Manager\eclipse\tools
2. From the tools directory, issue the following command, where *response_file* represents the response file path, including the file name:

   Windows

   ```
   imcl.exe -input response_file -silent
   ```

   The following command is an example:

   Windows

   ```
   imcl.exe -input C:\tmp\input\uninstall_response.xml -silent
   ```

Windows: Uninstalling and reinstalling IBM Spectrum Protect

If you plan to manually reinstall IBM Spectrum Protect™ instead of using the wizard, there are a number of steps to take to preserve your server instance names and database directories. During an uninstallation, any server instances previously set up are removed, but the database catalogs for those instances still exist.

About this task

To manually uninstall and reinstall IBM Spectrum Protect, complete the following steps:

1. Windows Make a list of your current server instances before proceeding to the uninstallation. Run the following command:

   ```
   db2ilist
   ```

2. Run the following commands for every server instance:
   Windows

   ```
   db2 attach to server1
   db2 get dbm cfg show detail
   db2 detach
   ```

   Keep a record of the database path for each instance.
3. Uninstall IBM Spectrum Protect. See Windows: Uninstalling IBM Spectrum Protect.

   Windows After uninstalling IBM Spectrum Protect, check the Control Panel > Add or Remove Programs to verify that IBM Spectrum Protect DB2® is uninstalled.

4. When you uninstall any supported version of IBM Spectrum Protect, including a fix pack, an instance file is created. The instance file is created to help reinstall IBM Spectrum Protect. Check this file and use the information when you are prompted for the instance credentials when reinstalling. In silent installation mode, you provide these credentials using the `INSTANCE_CRED` variable.
   You can find the instance file in the following location:
   - Windows `C:\ProgramData\IBM\Tivoli\TSM\instanceList.obj` in the IBM Spectrum Protect server installation directory
5. Reinstall IBM Spectrum Protect. See Windows: Installing the server components.

   If the `instanceList.obj` file does not exist, you need to recreate your server instances using the following steps:

   a. Recreate your server instances. See Windows: Creating the server instance.
      Tip: The installation wizard configures the server instances but you must verify that they exist. If they do not exist, you must manually configure them.
   b. Catalog the database. Log in to each server instance as the instance user, one at a time, and issue the following commands:
      Windows

      ```
      set db2instance=server1
      db2 catalog database tsmdb1
      db2 attach to server1
      db2 update dbm cfg using dftdbpath instance_drive
      db2 detach
      ```

   c. Verify that IBM Spectrum Protect recognizes the server instance by listing your directories. Your home directory appears if you did not change it. Your instance directory does appear if you used the configuration wizard. Issue this command:

      ```
      db2 list database directory
      ```

      If you see TSMDB1 listed, you can start the server.

Windows: Uninstalling IBM Installation Manager

You can uninstall IBM® Installation Manager if you no longer have any products that were installed by IBM Installation Manager.

Before you begin

Before you uninstall IBM Installation Manager, you must ensure that all packages that were installed by IBM Installation Manager are uninstalled. Close IBM Installation Manager before you start the uninstall process.

Windows To view installed packages, click Start > All Programs > IBM Installation Manager > View Installed Packages.

Procedure

To uninstall IBM Installation Manager, complete the following steps:

Windows

1. From the Start menu, click Control Panel > Programs and Features.
2. Select IBM Installation Manager and click Uninstall.

Upgrading to V8.1

To take advantage of new product features and updates, upgrade the IBM Spectrum Protect™ server to Version 8.1.2.

Before you begin

Upgrade the IBM Spectrum Protect server before you update clients. For more information, see:

AIX What you should know about security before you install or upgrade the server

Linux What you should know about security before you install or upgrade the server

Windows What you should know about security before you install or upgrade the server

About this task

To upgrade the server on the same operating system, see the upgrade instructions. For instructions about migrating the server to a different operating system, see IBM Spectrum Protect Upgrade and Migration Process - Frequently Asked Questions.

Table 1. Upgrade instructions

To upgrade from this version	To this version	See this information
V8.1	V8.1 fix pack or interim fix	AIX Installing an IBM Spectrum Protect server fix pack Linux Installing an IBM Spectrum Protect server fix pack Windows Installing an IBM Spectrum Protect server fix pack
V7.1	V8.1	Installing the server and verifying the upgrade
V7.1	V8.1 fix pack or interim fix	AIX Installing an IBM Spectrum Protect server fix pack Linux Installing an IBM Spectrum Protect server fix pack Windows Installing an IBM Spectrum Protect server fix pack
V5.5, V6.2, or V6.3	V8.1	IBM Spectrum Protect Upgrade and Migration Process - Frequently Asked Questions

An upgrade from V7 to V8.1 takes approximately 20 - 50 minutes. Your environment might produce different results from the results that were obtained in the labs.

For information about upgrades in a clustered environment, see Upgrading the server in a clustered environment.

To revert to an earlier version of the server after an upgrade or migration, you must have a full database backup and the installation software for the original server. You must also have the following key configuration files:

- Volume history file
- Device configuration file
- Server options file

- Upgrading to V8.1
  You can upgrade the server directly from V7.1 to V8.1. You do not have to uninstall V7.1.
- Upgrading the server in a clustered environment
  To upgrade a server to V8.1.2 in a clustered environment, you must complete preparation and installation tasks. The procedures vary, depending on the operating system and release.
- Windows Removing GSKit Version 7 after upgrading to IBM Spectrum Protect Version 8.1.2
  The IBM Spectrum Protect installation wizard upgrades GSKit Version 8 and later. GSKit Version 7 is not removed or upgraded when you upgrade to IBM Spectrum Protect Version 8.1.2, even if GSKit was installed with an earlier version of IBM Spectrum Protect.

Related information:
IBM Spectrum Protect Upgrade and Migration Process - Frequently Asked Questions

Upgrading to V8.1

You can upgrade the server directly from V7.1 to V8.1. You do not have to uninstall V7.1.

Before you begin

Ensure that you retain the installation media from the server base release that you are upgrading. If you installed the server components from a DVD, ensure that the DVD is available. If you installed the server components from a downloaded package, ensure that the downloaded files are available. If the upgrade fails, and the server license module is uninstalled, the installation media from the server base release are required to reinstall the license.
Tip: DVDs are no longer available with V8.1 and later.

Procedure

To upgrade the server to V8.1, complete the following tasks:

- Planning the upgrade
  Before you upgrade the server from V7.1 to V8.1, you must review the relevant planning information, such as system requirements and release notes. Then, select an appropriate day and time to upgrade the system so that you can minimize the impact on production operations.
- Preparing the system
  To prepare the system for the upgrade from V7.1 to V8.1, you must gather information about each DB2® instance. Then, back up the server database, save key configuration files, cancel sessions, and stop the server.
- Installing the server and verifying the upgrade
  To complete the process of upgrading the server to V8.1, you must install the V8.1 server. Then, verify that the upgrade was successful by starting the server instance.

Planning the upgrade

Before you upgrade the server from V7.1 to V8.1, you must review the relevant planning information, such as system requirements and release notes. Then, select an appropriate day and time to upgrade the system so that you can minimize the impact on production operations.

About this task

In lab tests, the process of upgrading the server from V7.1 to V8.1 took 14 - 45 minutes. The results that you achieve might differ, depending on your hardware and software environment, and the size of the server database.

Procedure

1. Review the hardware and software requirements:

   AIX System requirements for AIX® systems

   Linux System requirements for Linux systems

   Windows System requirements for Windows systems

   For the latest updates related to system requirements, see the IBM Spectrum Protect™ support website at technote 1243309.

2. For special instructions or specific information for your operating system, review the Release notes for Version 8.1 server components and IBM Spectrum Protect server Version 8.1 fix pack readme files.
3. Select an appropriate day and time to upgrade your system to minimize the impact on production operations. The amount of time that is required to update the system depends on the database size and many other factors. When you start the upgrade process, clients cannot connect to the server until the new software is installed and any required licenses are registered again.
4. If you are upgrading the server from V6 or V7 to V8.1, verify that you have the system ID and password for the DB2 instance of the IBM Spectrum Protect server. These credentials are required to upgrade the system.

Preparing the system

To prepare the system for the upgrade from V7.1 to V8.1, you must gather information about each DB2® instance. Then, back up the server database, save key configuration files, cancel sessions, and stop the server.

Procedure

1. Log on to the computer where the server is installed.

   AIX Linux Ensure that you are logged on with the instance user ID.

   Windows Ensure that you are logged on with the administrative user ID that was used to install the V7.1 server.

2. Obtain a list of DB2 instances. Issue the following system command:

   AIX Linux

   ```
   /opt/tivoli/tsm/db2/instance/db2ilist
   ```

   Windows

   ```
   db2ilist
   ```

   The output might be similar to the following example:

   AIX Linux

   ```
   tsminst1
   ```

   Windows

   ```
   SERVER1
   ```

   Ensure that each instance corresponds to a server that is running on the system.
3. AIX Linux For each DB2 instance, note the default database path, actual database path, database name, database alias, and any DB2 variables that are configured for the instance. Keep the record for future reference. This information is required to restore the V7.1 database.
4. Windows Gather information about each DB2 instance. Note the default database path, actual database path, database name, database alias, and any DB2 variables that are configured for the instance. Keep the record for future reference. This information is required to restore the V7.1 database.
   a. Open the DB2 command window by issuing the following system command:

      ```
      db2cmd
      ```

   b. To change the instance, issue the following system command:

      ```
      set DB2INSTANCE=instance
      ```

      where *instance* specifies the DB2 instance.
   c. Obtain the default database path for the DB2 instance by issuing the following system command:

      ```
      db2 get dbm cfg | findstr DFTDBPATH
      ```

      The output might be similar to the following example:

      ```
      Default database path                       (DFTDBPATH) = D:
      ```

   d. Obtain information about the DB2 instance databases by issuing the following system command:

      ```
      db2 list database directory
      ```

      The output might be similar to the following example:

      ```
      System Database Directory

                     Number of entries in the directory = 2

                    Database 1 entry:

                     Database alias                     = TSMAL001
                     Database name                      = TSMDB1
                     Node name                          = TSMNODE1
                     Database release level             = d.00
                     Comment                            = TSM SERVER DATABASE VIA TCPIP
                     Directory entry type               = Remote
                     Catalog database partition number  = -1
                     Alternate server hostname          =
                     Alternate server port number       =
      ```

```
Database 2 entry:

 Database alias                       = TSMDB1
 Database name                        = TSMDB1
 Local database directory             = D:
 Database release level               = d.00
 Comment                              =
 Directory entry type                 = Indirect
 Catalog database partition number    = 0
 Alternate server hostname            =
 Alternate server port number         =
```

e. Obtain the DB2 instance variables by issuing the following system command:

```
db2set -all
```

The output might be similar to the following example:

```
[e] DB2CODEPAGE=1208
[e] DB2PATH=D:\TSM\db2
[i] DB2_PMODEL_SETTINGS=MAX_BACKGROUND_SYSAPPS:500
[i] DB2_SKIPINSERTED=ON
[i] DB2_KEEPTABLELOCK=OFF
[i] DB2_EVALUNCOMMITTED=ON
[i] DB2_VENDOR_INI=D:\Server1\tsmdbmgr.env
[i] DB2_SKIPDELETED=ON
[i] DB2INSTPROF=C:\ProgramData\IBM\DB2\DB2TSM1
[i] DB2COMM=TCPIP
[i] DB2CODEPAGE=819
[i] DB2_PARALLEL_IO=*
[g] DB2_EXTSECURITY=YES
[g] DB2_COMMON_APP_DATA_PATH=C:\ProgramData

[g] DB2PATH=D:\TSM\db2
[g] DB2INSTDEF=SERVER1
```

5. Connect to the server by using an administrative user ID.
6. Back up the database by using the BACKUP DB command. The preferred method is to create a snapshot backup, which is a full database backup that does not interrupt scheduled database backups. For example, you can create a snapshot backup by issuing the following command:

   ```
   backup db type=dbsnapshot devclass=tapeclass
   ```

7. Back up the device configuration information to another directory by issuing the following administrative command:

   ```
   backup devconfig filenames=file_name
   ```

   where *file_name* specifies the name of the file in which to store device configuration information.
   Tip: If you decide to restore the V7.1 database, this file is required.
8. Back up the volume history file to another directory. Issue the following administrative command:

   ```
   backup volhistory filenames=file_name
   ```

   where *file_name* specifies the name of the file in which to store the volume history information.
   Tip: If you decide to restore the V7.1 database, this file is required.
9. Save a copy of the server options file, which is typically named dsmserv.opt. The file is in the server instance directory.
10. Prevent activity on the server by disabling new sessions. Issue the following administrative commands:

    ```
    disable sessions client
    disable sessions server
    ```

11. Verify whether any sessions exist, and notify the users that the server will be stopped. To check for existing sessions, issue the following administrative command:

    ```
    query session
    ```

12. Cancel sessions by issuing the following administrative command:

    ```
    cancel session all
    ```

    This command cancels all sessions except for your current session.

13. Stop the server by issuing the following administrative command:

    ```
    halt
    ```

14. Verify that the server is shut down and no processes are running.
    AIX Linux Issue the following command:

    ```
    ps -ef | grep dsmserv
    ```

    Windows Open the Windows Task Manager application and review the list of active processes.

15. In the server instance directory of your installation, locate the NODELOCK file and move it to another directory, where you are saving configuration files. The NODELOCK file contains the previous licensing information for your installation. This licensing information is replaced when the upgrade is complete.

Related reference:
BACKUP DB (Back up the database)
BACKUP DEVCONFIG (Create backup copies of device configuration information)
BACKUP VOLHISTORY (Save sequential volume history information)
DISABLE SESSIONS (Prevent new sessions from accessing Tivoli Storage Manager)
QUERY SESSION (Query client sessions)
CANCEL SESSION (Cancel one or more client sessions)
HALT (Shut down the server)

Installing the server and verifying the upgrade

To complete the process of upgrading the server to V8.1, you must install the V8.1 server. Then, verify that the upgrade was successful by starting the server instance.

Before you begin

AIX Linux You must be logged on to the system by using the root user ID.

Windows You must be logged on to the system with the administrative user ID that was used to install the previous server.

You can obtain the installation package from an IBM® download site.

AIX Linux Set the system user limit for maximum file size to unlimited to ensure that the files can be downloaded correctly.

1. To query the maximum file size value, run the following command:

   ```
   ulimit -Hf
   ```

2. If the system user limit for maximum file size is not set to unlimited, change the setting to unlimited by completing the instructions in the documentation for your operating system.

About this task

By using the IBM Spectrum Protect™ installation software, you can install the following components:

- Server
  Tip: The database (DB2®), the Global Security Kit (GSKit), and IBM Java™ Runtime Environment (JRE) are automatically installed when you select the server component.
- Server languages
- License
- Devices
- IBM Spectrum Protect for SAN
- Operations Center

Procedure

1. Download the appropriate package file from one of the following websites:
   - Download the server package from Passport Advantage® or Fix Central.
   - For the most recent information, updates, and maintenance fixes, go to the IBM Support Portal.

2. Complete the following steps:

AIX Linux

AIX Linux

a. Verify that you have enough space to store the installation files when they are extracted from the product package. For space requirements, see the download document for your product.
   - IBM Spectrum Protect technote 4042944
   - IBM Spectrum Protect Extended Edition technote 4042945
   - IBM Spectrum Protect for Data Retention technote 4042946

b. Download the package file to the directory of your choice. The path must contain no more than 128 characters. Be sure to extract the installation files to an empty directory. Do not extract to a directory that contains previously extracted files, or any other files.

   Also, ensure that you have executable permission for the package file.

c. If necessary, run the following command to change the file permissions:

   ```
   chmod a+x package_name.bin
   ```

   where *package_name* is like the following example:

   AIX

   ```
   8.1.x.000-IBM-SPSRV-AIX.bin
   ```

   Linux

   ```
   8.1.x.000-IBM-SPSRV-Linuxs390x.bin
   8.1.x.000-IBM-SPSRV-Linuxx86_64.bin
   8.1.x.000-IBM-SPSRV-Linuxppc64le.bin
   ```

   In the examples, *8.1.x.000* represents the product release level.

d. Extract the installation files by running the following command:

   ```
   ./package_name.bin
   ```

   The package is large. Therefore, the extraction takes some time.

Windows

Windows

a. Verify that you have enough space to store the installation files when they are extracted from the product package. For space requirements, see the download document for your product.
   - IBM Spectrum Protect technote 4042944
   - IBM Spectrum Protect Extended Edition technote 4042945
   - IBM Spectrum Protect for Data Retention technote 4042946

b. Change to the directory where you placed the executable file.
   Tip: In the next step, the files are extracted to the current directory. The path must contain no more than 128 characters. Be sure to extract the installation files to an empty directory. Do not extract to a directory that contains previously extracted files, or any other files.

c. To extract the installation files, double-click the executable file:

   ```
   package_name.exe
   ```

   Where *package_name* is similar to the following example:

   ```
   8.1.x.000-SPSRV-WindowsX64.exe
   ```

   The package is large. Therefore, the extraction takes some time.

3. AIX To ensure that the IBM Spectrum Protect wizards work correctly, verify that the following command is enabled:
   - AIX `lsuser`

   By default, the command is enabled.
4. Install the IBM Spectrum Protect software by using one of the following methods. Install the IBM Spectrum Protect license during the installation process.
   Tip: If you have multiple server instances on your system, install the IBM Spectrum Protect software only one time to upgrade all server instances.

   Installation wizard

   AIX To install the server by using the graphical wizard of IBM Installation Manager, follow the instructions in Installing IBM Spectrum Protect by using the installation wizard.

Linux To install the server by using the graphical wizard of IBM Installation Manager, follow the instructions in Installing IBM Spectrum Protect by using the installation wizard.

Windows To install the server by using the graphical wizard of IBM Installation Manager, follow the instructions in Installing IBM Spectrum Protect by using the installation wizard.

Ensure that your system meets the prerequisites for using the installation wizard. Then, complete the installation procedure. In the IBM Installation Manager window, click the Update or Modify icon.

Installing the server by using the console mode

AIX To install the server by using the console mode, follow the instructions in Installing Tivoli® Storage Manager by using console mode.

Linux To install the server by using the console mode, follow the instructions in Installing Tivoli Storage Manager by using console mode.

Windows To install the server by using the console mode, follow the instructions in Installing Tivoli Storage Manager by using console mode.

Review the information about installing the server in console mode and then complete the installation procedure.

Silent mode

AIX To install the server by using silent mode, follow the instructions in Installing Tivoli Storage Manager in silent mode.

Linux To install the server by using silent mode, follow the instructions in Installing Tivoli Storage Manager in silent mode.

Windows To install the server by using silent mode, follow the instructions in Installing Tivoli Storage Manager in silent mode.

Review the information about installing the server in silent mode and then complete the installation procedure.

After you install the software, you do not have to reconfigure the system.

5. Correct any errors that are detected during the installation process.

   If you installed the server by using the installation wizard, you can view installation logs by using the IBM Installation Manager tool. Click File > View Log. To collect log files, from the IBM Installation Manager tool, click Help > Export Data for Problem Analysis.

   If you installed the server by using console mode or silent mode, you can view error logs in the IBM Installation Manager log directory, for example:
   - AIX Linux /var/ibm/InstallationManager/logs
   - Windows C:\ProgramData\IBM\Installation Manager\logs
6. Go to the IBM Support Portal to obtain fixes. Click Fixes, updates, and drivers and apply any applicable fixes.
7. AIX Linux Verify that the upgrade was successful:
   a. Start the server instance.

      AIX For instructions, see Starting the server instance.

      Linux For instructions, see Starting the server instance.

   b. Monitor the messages that the server issues as it starts. Watch for error and warning messages, and resolve any issues.
   c. Verify that you can connect to the server by using the administrative client. To start an administrative client session, run the following IBM Spectrum Protect administrative command:

      ```
      dsmadmc
      ```

   d. To obtain information about the upgraded system, run QUERY commands. For example, to obtain consolidated information about the system, run the following IBM Spectrum Protect administrative command:

      ```
      query system
      ```

      To obtain information about the database, run the following IBM Spectrum Protect administrative command:

```
query db format=detailed
```

8. Windows Verify that the upgrade was successful:
   a. Start the server instance. To start the server from the default directory, C:\Program Files\Tivoli\TSM, run the following IBM Spectrum Protect administrative command:

      ```
      dsmserv -k server_instance
      ```

      server_instance is the name of your server instance. Server1 is the default name for the first instance of the IBM Spectrum Protect server.

      If you plan to run the server as a service under the Local System account, the Local System account must be explicitly granted access to the server database. For instructions, see Starting the server by using Windows services.

   b. Monitor the messages that the server issues as it starts. Watch for error and warning messages, and resolve any issues.
   c. Verify that you can connect to the server by using the administrative client. To start an administrative client session, run the following IBM Spectrum Protect administrative command:

      ```
      dsmadmc
      ```

   d. To obtain information about the upgraded system, run QUERY commands. For example, to obtain consolidated information about the system, run the following IBM Spectrum Protect administrative command:

      ```
      query system
      ```

      To obtain information about the database, run the following IBM Spectrum Protect administrative command:

      ```
      query db format=detailed
      ```

9. AIX Linux Register the licenses for the IBM Spectrum Protect server components that are installed on your system by running the REGISTER LICENSE command:

   ```
   register license file=installation_directory/server/bin/component_name.lic
   ```

   where *installation_directory* specifies the directory in which you installed the component, and *component_name* specifies the abbreviation for the component.

   For example, if you installed the server in the default directory, /opt/tivoli/tsm, run the following command to register the license:

   ```
   register license file=/opt/tivoli/tsm/server/bin/tsmbasic.lic
   ```

   For example, if you installed IBM Spectrum Protect Extended Edition in the /opt/tivoli/tsm directory, run the following command:

   ```
   register license file=/opt/tivoli/tsm/server/bin/tsmee.lic
   ```

   For example, if you installed IBM Spectrum Protect for Data Retention in the /opt/tivoli/tsm directory, run the following command:

   ```
   register license file=/opt/tivoli/tsm/server/bin/dataret.lic
   ```

   Restriction:
   You cannot use the IBM Spectrum Protect server to register licenses for the following products:
   - IBM Spectrum Protect for Mail
   - IBM Spectrum Protect for Databases
   - IBM Spectrum Protect for ERP
   - IBM Spectrum Protect for Space Management

   The REGISTER LICENSE command does not apply to these licenses. The licensing for these products is done by IBM Spectrum Protect clients.
10. Windows Register the licenses for the server components that are installed on your system by running the REGISTER LICENSE command:

    ```
    register license file=installation_directory\server\component_name.lic
    ```

    Where *installation_directory* specifies the directory in which you installed the component, and *component_name* specifies the abbreviation for the component.

For example, if you installed the server in the default directory, c:\Program Files\Tivoli\TSM, run the following command to register the license:

```
register license file=c:\Program Files\Tivoli\TSM\server\tsmbasic.lic
```

For example, if you installed IBM Spectrum Protect Extended Edition in the c:\Program Files\Tivoli\TSM directory, run the following command:

```
register license file=c:\Program Files\Tivoli\TSM\server\tsmee.lic
```

For example, if you installed IBM Spectrum Protect for Data Retention in the c:\Program Files\Tivoli\TSM directory, run the following command:

```
register license file=c:\Program Files\Tivoli\TSM\server\dataret.lic
```

Restriction:
You cannot use the IBM Spectrum Protect server to register licenses for the following products:

- IBM Spectrum Protect for Mail
- IBM Spectrum Protect for Databases
- IBM Spectrum Protect for ERP
- IBM Spectrum Protect for Space Management

The REGISTER LICENSE command does not apply to these licenses. The licensing for these products is done by IBM Spectrum Protect clients.

11. Optional: To install an extra language package, use the modify function of the IBM Installation Manager.
12. Optional: To upgrade to a newer version of a language package, use the update function of the IBM Installation Manager.

What to do next

You can authenticate passwords with the LDAP directory server, or authenticate passwords with the IBM Spectrum Protect server. Passwords that are authenticated with the LDAP directory server can provide enhanced system security.

Windows If a device driver is available on Windows for the tape drives or medium changers that you plan to use, use the device driver. If a device driver is not available on Windows for the tape drives or medium changers that you plan to use, install the IBM Spectrum Protect device driver by running the `dpinst.exe /a` command. The `dpinst.exe` file is in the device driver directory. The default directory is C:\Program Files\Tivoli\TSM\device\drivers.

AIX Linux Windows

Upgrading the server in a clustered environment

To upgrade a server to V8.1.2 in a clustered environment, you must complete preparation and installation tasks. The procedures vary, depending on the operating system and release.

Procedure

Follow the procedure for your operating system, source release, and target release:

AIX

Table 1. Procedures for upgrading the server in a clustered environment on an AIX operating system

Source release	Target release	Procedure
V8.1.2	V8.1.2 fix pack	Applying a fix pack to V8 in a clustered environment for AIX
V6.3 or V7.1	V8.1.2	Upgrading IBM Spectrum Protect from V6.3 or V7.1 to V8.1.2 in a clustered environment for AIX with a shared database instance Upgrading from V6.3 to V8.1.2 in a clustered environment for AIX with separate database instances
V6.1	V8.1.2	Upgrading IBM Spectrum Protect from V6.1 to V8.1.2 in a clustered environment for AIX

Source release	Target release	Procedure
V5	V7.1.1 or later	Upgrading the server to V7.1.1 in an AIX clustered environment

Linux

Table 2. Procedures for upgrading the server in a clustered environment on a Linux operating system

Source release	Target release	Procedure
V6 or V7	V8.1.2	Upgrading a server that is configured with Tivoli System Automation

Windows

Table 3. Procedures for upgrading the server in a clustered environment on a Windows operating system

Source release	Target release	Procedure
V8.1.2	V8.1.2 fix pack	Applying a fix pack to V8 in a clustered environment for Windows
V6.3 or V7.1	V8.1.2	Upgrading V6.3 or V7.1 to V8.1 in a clustered environment on Windows
V6.1	V8.1.2	Upgrading V6.1 to V8.1 in a clustered environment on Windows
V5	V7.1 or later	Upgrading the server to V7.1 or later in a Windows clustered environment

- Upgrading IBM Spectrum Protect from V6.3 or V7.1 to V8.1.2 in a clustered environment for AIX with a shared database instance
  You can upgrade an IBM Spectrum Protect server from or V6.3 or V7.1 to V8.1.2 in a clustered environment on AIX with a shared database instance. In this way, you can take advantage of the new features in IBM Spectrum Protect V8.1.2.
- Upgrading from V6.3 to V8.1.2 in a clustered environment for AIX with separate database instances
  You can upgrade a server from V6.3 to V8.1.2 in a clustered environment on AIX with separate database instances. In this way, you can take advantage of the new features in V8.1.2.
- Upgrading IBM Spectrum Protect from V6.1 to V8.1.2 in a clustered environment for AIX
  You can upgrade an IBM Spectrum Protect server on AIX from V6.1 to V8.1.2 in a clustered environment. Complete the upgrade to take advantage of the new features in V8.1.2.
- Upgrading IBM Spectrum Protect to V8.1.2 in a clustered environment for Linux
  To take advantage of new features in IBM Spectrum Protect, you can upgrade the IBM Spectrum Protect server that is installed on a Linux operating system in a clustered environment.
- Upgrading a V6.3 or V7.1 server to V8.1.2 in a clustered environment for Windows
  To take advantage of new product features, you can upgrade a server that is installed on a Windows operating system in a clustered environment from V6.3 or V7.1 to IBM Spectrum Protect V8.1.2.
- Upgrading IBM Tivoli Storage Manager V6.1 to IBM Spectrum Protect V8.1.2 in a clustered environment for Windows
  To take advantage of new features, you can upgrade a server that is installed on a Windows operating system in a clustered environment from V6.1 to V8.1.2.

AIX

Upgrading IBM Spectrum Protect from V6.3 or V7.1 to V8.1.2 in a clustered environment for AIX with a shared database instance

You can upgrade an IBM Spectrum Protect™ server from or V6.3 or V7.1 to V8.1.2 in a clustered environment on AIX® with a shared database instance. In this way, you can take advantage of the new features in IBM Spectrum Protect V8.1.2.

Before you begin

Ensure that you retain the installation media from the V6.3 or V7.1 server base release that you are upgrading. If you installed IBM Spectrum Protect from a DVD, ensure that the DVD is available. If you installed IBM Spectrum Protect from a downloaded package, ensure that the downloaded files are available. If the upgrade fails, and the server license module is uninstalled, you must reinstall the license from the installation media of the server base release.

About this task

Use the following procedure when the DB2® instance directory is shared between the nodes in the cluster. The DB2 instance directory is in the following location:

```
/home/tsminst1/sqllib
```

If the DB2 instance directory is not shared between nodes, follow the instructions in Upgrading from V6.3 to V8.1.2 in a clustered environment for AIX with separate database instances.

Procedure

1. Back up the database by using the BACKUP DB command. The preferred method is to use a snapshot backup, which creates a full database backup without interrupting any scheduled backups. For example, you can create a snapshot backup by running the following command:

   ```
   backup db type=dbsnapshot devclass=tapeclass
   ```

2. Back up the device configuration information to another directory, by running the following command:

   ```
   backup devconfig filenames=file_name
   ```

   Where *file_name* specifies the name of the file in which to store device configuration information.
3. Back up the volume history file to another directory, by running the following command:

   ```
   backup volhistory filenames=file_name
   ```

   Where *file_name* specifies the name of the file in which to store the volume history information.
4. Save a copy of the server options file, typically named dsmserv.opt, which is in the server instance directory.
5. Stop all instances of the server. Verify that no server processes are running. If you are using application-level monitoring of the IBM Spectrum Protect server, use your clustering tool to suspend monitoring of the dsmserv application resource.
6. Verify that the database manager is not running for any instance. Determine whether any db2sysc processes are running. The owner of running processes indicates which instances are active. For each server instance owner, run the following command to stop DB2:

   ```
   db2stop
   ```

7. On the primary node, install the IBM Spectrum Protect V8.1.2 server by running the ./install.sh command. For instructions, see Installing the server components. After you start the wizard, in the IBM Installation Manager window, click the Install icon; do not click the Update or Modify icon.
8. Start each V8.1.2 server in the foreground:
   a. Verify that you are logged in with the instance owner ID.
   b. Navigate to the instance directory and run the following command:

      ```
      /opt/tivoli/tsm/server/bin/dsmserv
      ```

      Wait until you see the server prompt, which indicates that the server is started.

9. Stop the server for each IBM Spectrum Protect instance that is being upgraded. Issue the following command:

   ```
   halt
   ```

   Tip: Because the DB2 instance directory is shared between the nodes in the cluster, you do not have to move the shared resources to the secondary node in the cluster.
10. On each secondary node in the cluster, complete the following steps:
    a. Install the IBM Spectrum Protect V8.1.2 server by running the ./install.sh command. For instructions, see Installing the server components.
       i. If you are running the installation wizard, in the IBM Installation Manager window, click the Install icon; do not click the Update or Modify icon.
       ii. If you are running the installation wizard, in the Instance Credentials panel, clear the Update this instance check box for each instance.
       iii. If you are installing the server in console mode, at the prompt `Do you want update this instance?`, enter `NO` for each instance.
       iv. If you are installing the server in silent mode, specify `FALSE` for the value of the `user.`*`instance_name`*`_update` variable for each instance.
    b. Ensure that each IBM Spectrum Protect V8.1.2 server starts. If you are using application-level monitoring, use the clustering tool to start the server.

       For instructions about starting the server, see Starting the server instance.

11. Register the licenses for the server components that are installed on your system by running the REGISTER LICENSE command:

    ```
    register license file=installation_directory/server/bin/component_name.lic
    ```

    Where *installation_directory* specifies the directory in which you installed the component and *component_name* specifies the abbreviation for the component.

    For example, if you installed the server in the default directory, /opt/tivoli/tsm, run the following command to register the license:

    ```
    register license file=/opt/tivoli/tsm/server/bin/tsmbasic.lic
    ```

    For example, if you installed IBM Spectrum Protect Extended Edition in the /opt/tivoli/tsm directory, run the following command:

    ```
    register license file=/opt/tivoli/tsm/server/bin/tsmee.lic
    ```

    For example, if you installed IBM Spectrum Protect for Data Retention in the /opt/tivoli/tsm directory, run the following command:

    ```
    register license file=/opt/tivoli/tsm/server/bin/dataret.lic
    ```

    Restriction:
    You cannot use the IBM Spectrum Protect server to register licenses for the following products:
    - IBM Spectrum Protect for Mail
    - IBM Spectrum Protect for Databases
    - IBM Spectrum Protect for ERP
    - IBM Spectrum Protect for Space Management

    The REGISTER LICENSE command does not apply to these licenses. The licensing for these products is done by IBM Spectrum Protect clients.

AIX

Upgrading from V6.3 to V8.1.2 in a clustered environment for AIX with separate database instances

You can upgrade a server from V6.3 to V8.1.2 in a clustered environment on AIX® with separate database instances. In this way, you can take advantage of the new features in V8.1.2.

Before you begin

Ensure that you retain the installation media from the V6.3 or V7.1 server base release that you are upgrading. If you installed IBM Spectrum Protect™ from a DVD, ensure that the DVD is available. If you installed IBM Spectrum Protect from a downloaded package, ensure that the downloaded files are available. If the upgrade fails, and the server license module is uninstalled, you must reinstall the license from the installation media of the server base release.

About this task

Use the following procedure when the DB2® instance directory is not shared between the nodes in the cluster. The DB2 instance directory is at the following location:

```
/home/tsminst1/sqllib
```

If the DB2 instance directory is shared between the nodes in the cluster, follow the instructions in Upgrading IBM Spectrum Protect from V6.3 or V7.1 to V8.1.2 in a clustered environment for AIX with a shared database instance.

Procedure

1. Back up the database by using the BACKUP DB command. The preferred method is to use a snapshot backup, which creates a full database backup without interrupting any scheduled backups. For example, you can create a snapshot backup by running the following command:

   ```
   backup db type=dbsnapshot devclass=tapeclass
   ```

2. Back up the device configuration information to another directory, by running the following command:

   ```
   backup devconfig filenames=file_name
   ```

   Where *file_name* specifies the name of the file in which to store device configuration information.
3. Back up the volume history file to another directory, by running the following command:

   ```
   backup volhistory filenames=file_name
   ```

   Where *file_name* specifies the name of the file in which to store the volume history information.
4. Save a copy of the server options file, typically named dsmserv.opt, which is in the server instance directory.
5. Stop all instances of the server. Verify that no server processes are running. If you are using application-level monitoring of the IBM Spectrum Protect server, use your clustering tool to suspend monitoring of the dsmserv application resource.
6. Verify that the database manager is not running for any instance. Determine whether any db2sysc processes are running. The owner of running processes indicates which instances are active. For each server instance owner, run the following command to stop DB2:

   ```
   db2stop
   ```

7. Ensure that the shared resources for all IBM Spectrum Protect instances are on the primary node. Verify that no other nodes have write access to these resources during the upgrade. If the environment includes multiple instances of the server, shared resources for all instances must be accessible to the primary node.
8. On the primary node, install the V8.1.2 server by running the ./install.sh command. For instructions, see Installing the server components. After you start the wizard, in the IBM Installation Manager window, click the Install icon; do not click the Update or Modify icon. To complete the upgrade from V6.3 to V8.1.2, you must install the V8.1.2 server.
9. Start each V8.1.2 server in the foreground:
   a. Verify that you are logged in with the instance owner ID.
   b. Navigate to the instance directory and run the following command:

      ```
      /opt/tivoli/tsm/server/bin/dsmserv
      ```

      Wait until you see the server prompt, which indicates that the server is started.

10. Stop the server for each IBM Spectrum Protect instance that is being upgraded. Run the following command:

    ```
    halt
    ```

11. On each secondary node in the cluster, complete the following steps:
    a. Move all shared resources to the secondary node. If the environment includes multiple instances of the server, shared resources for all instances must be accessible to the secondary nodes during the upgrade.
    b. Stop all instances of the server. Verify that no server processes are running.
    c. Verify that the database manager is not running for any instance. Determine whether any db2sysc processes are running. The owner of running processes indicates which instances are active. For each server instance owner, run the following command to stop DB2:

       ```
       db2stop
       ```

    d. Install the V8.1.2 server by running the ./install.sh command. For instructions, see Installing the server components.
       i. If you are using the installation wizard, in the IBM Installation Manager window, click the Install icon; do not click the Update or Modify icon.
       ii. If you are using the installation wizard, on the Instance Credentials page, select the Configure this instance on a secondary node of the cluster check box for each instance that you are configuring.
       iii. If you are installing the server in console mode, at the prompt `Configure this instance on a secondary node of the cluster?`, enter `YES` for each instance.
       iv. If you are installing the server in silent mode, specify `TRUE` for the value of the `user.`*`instance_name`*`_secondaryNode` variable for each instance.
    e. Ensure that each V8.1.2 server starts. If you are using application-level monitoring, use the clustering tool to start the server.

       For instructions about starting the server, see Starting the server instance.

12. Register the licenses for the server components that are installed on your system by running the REGISTER LICENSE command:

    ```
    register license file=installation_directory/server/bin/component_name.lic
    ```

    Where *installation_directory* specifies the directory in which you installed the component and *component_name* specifies the abbreviation for the component.

    For example, if you installed the server in the default directory, /opt/tivoli/tsm, run the following command to register the license:

    ```
    register license file=/opt/tivoli/tsm/server/bin/tsmbasic.lic
    ```

    For example, if you installed IBM Spectrum Protect Extended Edition in the /opt/tivoli/tsm directory, run the following command:

    ```
    register license file=/opt/tivoli/tsm/server/bin/tsmee.lic
    ```

    For example, if you installed IBM Spectrum Protect for Data Retention in the /opt/tivoli/tsm directory, run the following command:

    ```
    register license file=/opt/tivoli/tsm/server/bin/dataret.lic
    ```

    Restriction:
    You cannot use the IBM Spectrum Protect server to register licenses for the following products:
    - IBM Spectrum Protect for Mail
    - IBM Spectrum Protect for Databases
    - IBM Spectrum Protect for ERP
    - IBM Spectrum Protect for Space Management

    The REGISTER LICENSE command does not apply to these licenses. The licensing for these products is done by IBM Spectrum Protect clients.

AIX

Upgrading IBM Spectrum Protect from V6.1 to V8.1.2 in a clustered environment for AIX

You can upgrade an IBM Spectrum Protect™ server on AIX® from V6.1 to V8.1.2 in a clustered environment. Complete the upgrade to take advantage of the new features in V8.1.2.

Before you begin

Ensure that you retain the installation media from the base release of the V6.1 and V6.3 servers. If you obtained the server software from a DVD, ensure that the DVD is available. If you obtained the server software from a downloaded package, ensure that the downloaded files are available. If the upgrade fails, and the server license module is uninstalled, the installation media from the server base release are required to reinstall the license.

About this task

If the clustered environment contains multiple server instances, move all resources that are required for the instances onto a single cluster node, which is the primary node, during the upgrade process.

Procedure

1. Back up the database by using the BACKUP DB command. The preferred method is to use a snapshot backup, which creates a full database backup without interrupting any scheduled backups. For example, you can create a snapshot backup by running the following command:

```
backup db type=dbsnapshot devclass=tapeclass
```

2. Back up the device configuration information to another directory, by running the following command:

   ```
   backup devconfig filenames=file_name
   ```

   Where *file_name* specifies the name of the file in which to store device configuration information.
3. Back up the volume history file to another directory, by running the following command:

   ```
   backup volhistory filenames=file_name
   ```

   Where *file_name* specifies the name of the file in which to store the volume history information.
4. Save a copy of the server options file, which is typically named dsmserv.opt. The file is in the server instance directory.
5. Stop all instances of the IBM Spectrum Protect server. Verify that no IBM Spectrum Protect server processes are running. If you are using application-level monitoring of the IBM Spectrum Protect server, use your clustering tool to suspend monitoring of the dsmserv application resource.
6. Verify that the database manager is not running for any instance. Determine whether any db2sysc processes are running. The owner of running processes indicates which instances are active. For each server instance owner, run the following command to stop DB2®:

   ```
   db2stop
   ```

7. Ensure that the shared resources for all IBM Spectrum Protect instances are on the primary node. Verify that no other nodes have write access to these resources during the upgrade.
8. On the primary node, install the V6.3 server by using the ./install.bin command. For detailed instructions about installing the V6.3 server, see Installing the server components.
9. On the primary node, install the IBM Spectrum Protect V8.1.2 server by running the ./install.sh command. For instructions, see Installing the server components. After you start the wizard, in the IBM Installation Manager window, click the Install icon; do not click the Update or Modify icon.
10. Start each IBM Spectrum Protect V8.1.2 server in the foreground. Using the instance owner ID, navigate to the instance directory and issue the following command:

    ```
    /opt/tivoli/tsm/server/bin/dsmserv
    ```

    Wait until you see the server prompt, which indicates that the server is started.

11. Stop the server for each IBM Spectrum Protect instance that is being upgraded.
12. On each secondary node in the cluster, complete the following steps:
    a. Move all shared resources to the secondary node. If your environment includes multiple instances of IBM Spectrum Protect, shared resources for all instances must be accessible to the secondary nodes during the upgrade.
    b. Stop all instances of the IBM Spectrum Protect server. Verify that no IBM Spectrum Protect server processes are running.
    c. Verify that the database manager is not running for any instance. Determine whether any db2sysc processes are running. The owner of running processes indicates which instances are active. For each server instance owner, run the following command to stop DB2:

       ```
       db2stop
       ```

    d. Uninstall the V6.1 server:
       i. In the /opt/tivoli/tsm/_uninst directory, issue the following command:

          ```
          cd _uninst
          ```

       ii. Issue the following command:

          ```
          ./Uninstall_Tivoli_Storage_Manager
          ```

          For detailed instructions about uninstalling the server, see the Tivoli Storage Manager V6.1 documentation.
    e. Install the IBM Spectrum Protect V8.1.2 server by running the ./install.sh command. In the IBM Installation Manager window, click the Install icon; do not click the Update or Modify icon. For instructions about installing the server, see Installing the server components.
    f. Ensure that each IBM Spectrum Protect V8.1.2 server starts.
13. Register the licenses for the server components that are installed on your system by running the REGISTER LICENSE command:

    ```
    register license file=installation_directory/server/bin/component_name.lic
    ```

Where *installation_directory* specifies the directory in which you installed the component and *component_name* specifies the abbreviation for the component.

For example, if you installed the server in the default directory, /opt/tivoli/tsm, run the following command to register the license:

```
register license file=/opt/tivoli/tsm/server/bin/tsmbasic.lic
```

For example, if you installed IBM Spectrum Protect Extended Edition in the /opt/tivoli/tsm directory, run the following command:

```
register license file=/opt/tivoli/tsm/server/bin/tsmee.lic
```

For example, if you installed IBM Spectrum Protect for Data Retention in the /opt/tivoli/tsm directory, run the following command:

```
register license file=/opt/tivoli/tsm/server/bin/dataret.lic
```

Restriction:
You cannot use the IBM Spectrum Protect server to register licenses for the following products:

- IBM Spectrum Protect for Mail
- IBM Spectrum Protect for Databases
- IBM Spectrum Protect for ERP
- IBM Spectrum Protect for Space Management

The REGISTER LICENSE command does not apply to these licenses. The licensing for these products is done by IBM Spectrum Protect clients.

Linux

Upgrading IBM Spectrum Protect to V8.1.2 in a clustered environment for Linux

To take advantage of new features in IBM Spectrum Protect™, you can upgrade the IBM Spectrum Protect server that is installed on a Linux operating system in a clustered environment.

Procedure

Follow the instructions in Configuring a Linux environment for clustering.

Windows

Upgrading a V6.3 or V7.1 server to V8.1.2 in a clustered environment for Windows

To take advantage of new product features, you can upgrade a server that is installed on a Windows operating system in a clustered environment from V6.3 or V7.1 to IBM Spectrum Protect™ V8.1.2.

Before you begin

Ensure that you retain the installation media from the V6.3 or V7.1 server base release that you are upgrading. If you installed the server from a downloaded package, ensure that the downloaded files are available. If the upgrade fails, and the server license module is uninstalled, you must reinstall the license from the installation media of the server base release.

Procedure

1. If you plan to install the IBM Spectrum Protect V8.1.2 server on the Windows Server 2012 operating system, install the failover cluster automation server and the failover cluster command interface first. To install these components, issue the

following commands from Windows 2.0 PowerShell:

```
Install-WindowsFeature -Name RSAT-Clustering-AutomationServer
Install-WindowsFeature -Name RSAT-Clustering-CmdInterface
```

2. Back up the database by using the BACKUP DB command. The preferred method is to use a snapshot backup, which provides a full database backup without interrupting scheduled backups. For example, you can run the following command to create a snapshot backup:

   ```
   backup db type=dbsnapshot devclass=tapeclass
   ```

3. Back up the device configuration information to another directory. Run the following command:

   ```
   backup devconfig filenames=file_name
   ```

   Where *file_name* specifies the name of the file in which to store device configuration information.
4. Back up the volume history file to another directory. Run the following command:

   ```
   backup volhistory filenames=file_name
   ```

   Where *file_name* specifies the name of the file in which to store the volume history information.
5. Save a copy of the server options file, typically named dsmserv.opt, which is in the server instance directory.
6. Ensure that the resource group is on the primary node, and that all nodes in the cluster are running. Take the following actions on the primary node:
   a. In the Failover Cluster Manager window, take the server resource offline and delete it:
      i. Select Services and applications, and then select the cluster group. The server resource is displayed in the Other Resources section.
      ii. Select the server resource, and click Take this resource offline.
      iii. To delete the server resource, select it, and click Delete.
   b. In the Failover Cluster Manager window, delete the network name and IP address:
      i. In the Server name section, expand the network name to view the IP address. Note the network name and IP address.
      ii. Select the network name and the IP address, and click Remove.
   c. In the Failover Cluster Manager window, take the DB2® server resource offline:
      i. Select Services and applications, and then select the cluster group. The IBM Spectrum Protect server resource is displayed in the Other Resources section.
      ii. Select a DB2 server resource, for example, SERVER1, and click Take this resource offline.
7. On the primary node, run the following command to remove DB2 clustering from each IBM Spectrum Protect instance in the cluster:

   ```
   db2mscs -u:instancename
   ```

   For example, run the following command to remove DB2 clustering from the SERVER1 instance:

   ```
   db2mscs -u:server1
   ```

   Tip: You might see an error message about a missing cluster resource. Ignore this message.
8. On the primary node, in the Failover Cluster Manager window, review the resource group Summary section. Verify that only the shared disks and any tape resources remain in the resource group.
9. Stop the cluster service on each node in the cluster and delete the server cluster DLL files. Then, restart the cluster service.
10. Install the IBM Spectrum Protect V8.1.2 server on each node in the cluster. For instructions, see Installing the IBM Spectrum Protect server components. If you use the installation wizard to install the server, in the IBM Installation Manager window, click the Update icon. Do not click the Install or Modify icon.
11. On the primary node, start the server in the foreground to allow the database schema reconciliation and configuration to be completed. When the server starts, halt it by running the HALT command. If your environment has multiple server instances, complete this step for each instance.
12. On the primary node, start the configuration wizard by clicking Start > All Programs > IBM Spectrum Protect server > Configuration Wizard. Complete the following steps in the configuration wizard:
    a. When you are prompted to enter the user ID, enter the name of the domain account that is associated with the cluster.
    b. When you are prompted to enter the instance name, enter the name of the instance that you are reclustering.
    c. Click Yes when you are prompted to indicate whether you want to recluster.
    d. Continue stepping through the wizard until you see a message that the configuration was successful.
13. Register the licenses for the IBM Spectrum Protect server components that are installed on your system by running the REGISTER LICENSE command:

```
register license file=installation_directory\server\component_name.lic
```

Where *installation_directory* specifies the directory in which you installed the component and *component_name* specifies the abbreviation for the component.

For example, if you installed the server in the default directory, c:\Program Files\Tivoli\TSM, run the following command to register the license:

```
register license file=c:\Program Files\Tivoli\TSM\server\tsmbasic.lic
```

For example, if you installed IBM Spectrum Protect Extended Edition in the c:\Program Files\Tivoli\TSM directory, run the following command:

```
register license file=c:\Program Files\Tivoli\TSM\server\tsmee.lic
```

For example, if you installed IBM Spectrum Protect for Data Retention in the c:\Program Files\Tivoli\TSM directory, run the following command:

```
register license file=c:\Program Files\Tivoli\TSM\server\dataret.lic
```

Restriction:
You cannot use the IBM Spectrum Protect server to register licenses for the following products:

- IBM Spectrum Protect for Mail
- IBM Spectrum Protect for Databases
- IBM Spectrum Protect for ERP
- IBM Spectrum Protect for Space Management

The REGISTER LICENSE command does not apply to these licenses. The licensing for these products is done by IBM Spectrum Protect clients.

What to do next

If a device driver is available on Windows for the tape drives or medium changers that you plan to use, use the device driver. If a device driver is not available, install the IBM Spectrum Protect device driver by running the dpinst.exe /a command. The dpinst.exe file is in the device driver directory, and the default location is C:\Program Files\Tivoli\TSM\device\drivers.

Windows

Upgrading IBM® Tivoli® Storage Manager V6.1 to IBM Spectrum Protect V8.1.2 in a clustered environment for Windows

To take advantage of new features, you can upgrade a server that is installed on a Windows operating system in a clustered environment from V6.1 to V8.1.2.

Before you begin

Ensure that you retain the installation media from the V6.1 and V6.3 server base releases. If you obtained the server software from a downloaded package, ensure that the downloaded files are available. If the upgrade fails, and the server license module is uninstalled, the installation media from the server base release are required to reinstall the license.

Procedure

1. If you plan to install the IBM Spectrum Protect™ V8.1.2 server on the Windows Server 2012 operating system, install the failover cluster automation server and the failover cluster command interface first. To install these components, issue the following commands from Windows 2.0 PowerShell:

   ```
   Install-WindowsFeature -Name RSAT-Clustering-AutomationServer
   Install-WindowsFeature -Name RSAT-Clustering-CmdInterface
   ```

2. Back up the database by using the BACKUP DB command. The preferred method is to use a snapshot backup, which provides a full database backup without interrupting scheduled backups. For example, you can run the following command

to create a snapshot backup:

```
backup db type=dbsnapshot devclass=tapeclass
```

3. Back up the device configuration information to another directory. Run the following command:

   ```
   backup devconfig filenames=file_name
   ```

   Where *file_name* specifies the name of the file in which to store device configuration information.
4. Back up the volume history file to another directory. Run the following command:

   ```
   backup volhistory filenames=file_name
   ```

   Where *file_name* specifies the name of the file in which to store the volume history information.
5. Save a copy of the server options file, typically named dsmserv.opt, which is in the server instance directory.
6. Ensure that the resource group is on the primary node, and that all nodes in the cluster are running. Take the following actions on the primary node:
   a. In the Failover Cluster Manager window, take the server resource offline and delete it:
      i. Select Services and applications, and then select the cluster group. The server resource is displayed in the Other Resources section.
      ii. Select the server resource, and click Take this resource offline.
      iii. To delete the server resource, select it, and click Delete.
   b. In the Failover Cluster Manager window, delete the network name and IP address:
      i. In the Server name section, expand the network name to view the IP address. Note the network name and IP address.
      ii. Select the network name and the IP address, and click Remove.
   c. In the Failover Cluster Manager window, take the DB2® server resource offline:
      i. Select Services and applications, and then select the cluster group. The IBM Spectrum Protect server resource is displayed in the Other Resources section.
      ii. Select a DB2 server resource, for example, SERVER1, and click Take this resource offline.
7. On the primary node, to remove DB2 clustering from the instance, for each IBM Spectrum Protect instance in the cluster, issue the following command:

   ```
   db2mscs -u:instancename
   ```

   For example:

   ```
   db2mscs -u:server1
   ```

   Tip: You might see an error message about a missing cluster resource. Ignore this message.
8. On the primary node, in the Failover Cluster Manager window, in the resource group Summary section, verify that only the shared disks and any tape resources remain in the resource group.
9. On the primary node, install the V6.3 server by using the install.exe command. For detailed instructions about installing the V6.3 server, see Installing the server components.
10. On the primary node, install the IBM Spectrum Protect V8.1.2 server. For instructions, see Installing the server components. If you use the installation wizard to install the server, in the IBM Installation Manager window, click the Install icon. Do not click the Update or Modify icon.
11. On each secondary node, uninstall V6.1:
    a. Change to the following directory:

       ```
       C:\Program Files\Tivoli\TSM\_uninst
       ```

    b. Issue the following command:

       ```
       Uninstall Tivoli Storage Manager.exe
       ```

12. On the primary node, start the configuration wizard by clicking Start > All Programs > IBM Spectrum Protect server > Configuration Wizard. Step through the configuration wizard:
    a. When you are prompted to enter the instance name, enter the name of the instance that you are reclustering.
    b. When you are prompted to enter the user ID, enter the name of the domain account that is associated with the cluster.
    c. When you are prompted to indicate whether you want to recluster, click Yes.
    d. Continue stepping through the wizard until you see a message that the configuration was successful.
13. Register the licenses for the IBM Spectrum Protect server components that are installed on your system by running the REGISTER LICENSE command:

    ```
    register license file=installation_directory\server\component_name.lic
    ```

Where *installation_directory* specifies the directory in which you installed the component and *component_name* specifies the abbreviation for the component.

For example, if you installed the server in the default directory, c:\Program Files\Tivoli\TSM, run the following command to register the license:

```
register license file=c:\Program Files\Tivoli\TSM\server\tsmbasic.lic
```

For example, if you installed IBM Spectrum Protect Extended Edition in the c:\Program Files\Tivoli\TSM directory, run the following command:

```
register license file=c:\Program Files\Tivoli\TSM\server\tsmee.lic
```

For example, if you installed IBM Spectrum Protect for Data Retention in the c:\Program Files\Tivoli\TSM directory, run the following command:

```
register license file=c:\Program Files\Tivoli\TSM\server\dataret.lic
```

Restriction:
You cannot use the IBM Spectrum Protect server to register licenses for the following products:

- IBM Spectrum Protect for Mail
- IBM Spectrum Protect for Databases
- IBM Spectrum Protect for ERP
- IBM Spectrum Protect for Space Management

The REGISTER LICENSE command does not apply to these licenses. The licensing for these products is done by IBM Spectrum Protect clients.

What to do next

If a device driver is available on Windows for the tape drives or medium changers that you plan to use, use the device driver. If a device driver is not available, install the IBM Spectrum Protect device driver by running the dpinst.exe /a command. The dpinst.exe file is in the device driver directory, and the default location is C:\Program Files\Tivoli\TSM\device\drivers.

Removing GSKit Version 7 after upgrading to IBM Spectrum Protect Version 8.1.2

The IBM Spectrum Protect™ installation wizard upgrades GSKit Version 8 and later. GSKit Version 7 is not removed or upgraded when you upgrade to IBM Spectrum Protect Version 8.1.2, even if GSKit was installed with an earlier version of IBM Spectrum Protect.

About this task

If you no longer need GSKit V7 and want to free up space on your system, you can remove it after the upgrade to IBM Spectrum Protect V8.1.2.
Important: Removing GSKit V7 might affect other programs on your system that rely on it.

Procedure

To remove GSKit V7, complete the following steps:

1. Back up your registry.
   a. Click Start, and then click Run.
   b. Type `Regedit`. Click OK.
   c. To save a copy of your registry, select File > Export.
   d. If you must later restore the registry, select File > Import.
   For more information, see the Windows documentation.
2. Locate the directory where the GSKit is installed. The default directory is C:\Program Files\IBM\gsk7\.

3. Remove the GSKit installation directory, gsk7, and all subfiles and directories. Right-click the folder and click Delete.
4. Remove the GSKit 7 registry key and all subkeys and values.
   Important: Removing the wrong key can cause system problems such as not being able to restart the workstation.
   a. Click Start, and then click Run.
   b. Type `Regedit`. Click OK.
   c. The GSKit registry key is in this directory: HKEY_LOCAL_MACHINE\SOFTWARE\IBM. Right-click the registry key, HKEY_LOCAL_MACHINE\SOFTWARE\IBM\GSK7, and click Delete.

AIX | Linux | Windows

Installing and upgrading the Operations Center

The IBM Spectrum Protect™ Operations Center is the web-based interface for managing your storage environment.

Before you begin

Before you install and configure the Operations Center, review the following information:

- System requirements for the Operations Center
  - Operations Center computer requirements
  - Hub and spoke server requirements
  - Operating system requirements
  - Web browser requirements
  - Language requirements
  - Requirements and limitations for IBM Spectrum Protect client management services
- Administrator IDs that the Operations Center requires
- IBM Installation Manager
- Installation checklist
- Obtaining the Operations Center installation package

About this task

Table 1 lists the methods for installing or uninstalling the Operations Center and indicates where to find the associated instructions.

For information about upgrading the Operations Center, see Upgrading the Operations Center.

Table 1. Methods for installing or uninstalling the Operations Center

Method	Instructions
Graphical wizard	• Installing the Operations Center by using a graphical wizard • Uninstalling the Operations Center by using a graphical wizard
Console mode	• Installing the Operations Center in console mode • Uninstalling the Operations Center in console mode
Silent mode	• Installing the Operations Center in silent mode • Uninstalling the Operations Center in silent mode

- Planning to install the Operations Center
  Before you install the Operations Center, you must understand the system requirements, the administrator IDs that the Operations Center requires, and the information that you must provide to the installation program.
- Installing the Operations Center
  You can install the Operations Center by using any of the following methods: a graphical wizard, the command line in console mode, or silent mode.
- Upgrading the Operations Center
  You can upgrade the Operations Center by using any of the following methods: a graphical wizard, the command line in console mode, or silent mode.
- Getting started with the Operations Center
  Before you can use the Operations Center to manage your storage environment, you must configure it.

- AIX | Linux Troubleshooting the Operations Center installation
  If a problem occurs with the Operations Center installation and you cannot solve it, you can consult the descriptions of known problems for a possible solution.
- Uninstalling the Operations Center
  You can uninstall the Operations Center by using any of the following methods: a graphical wizard, the command line in console mode, or silent mode.
- Rolling back to a previous version of the Operations Center
  By default, IBM Installation Manager saves earlier versions of a package to roll back to if you experience a problem with later versions of updates, fixes, or packages.

AIX | Linux | Windows

Planning to install the Operations Center

Before you install the Operations Center, you must understand the system requirements, the administrator IDs that the Operations Center requires, and the information that you must provide to the installation program.

About this task

From the Operations Center, you can manage the following primary aspects of the storage environment:

- IBM Spectrum Protect™ servers and clients
- Services such as backup and restore, archive and retrieve, and migrate and recall
- Storage pools and storage devices

The Operations Center includes the following features:

User interface for multiple servers
: You can use the Operations Center to manage one or more IBM Spectrum Protect servers.

  In an environment with multiple servers, you can designate one server as a *hub server* and the others as *spoke servers*. The hub server can receive alerts and status information from the spoke servers and present the information in a consolidated view in the Operations Center.

Alert monitoring
: An *alert* is a notification of a relevant problem on the server and is triggered by a server message. You can define which server messages trigger alerts, and only those messages are reported as alerts in the Operations Center or in an email.

  This alert monitoring can help you identify and track relevant problems on the server.

Convenient command-line interface
: The Operations Center includes a command-line interface for advanced features and configuration.

- System requirements for the Operations Center
  Before you install the Operations Center, ensure that your system meets the minimum requirements.
- Administrator IDs that the Operations Center requires
  An administrator must have a valid ID and password on the hub server to log in to the Operations Center. An administrator ID is also assigned to the Operations Center so that the Operations Center can monitor servers.
- IBM Installation Manager
  The Operations Center uses IBM® Installation Manager, which is an installation program that can use remote or local software repositories to install or update many IBM products.
- Installation checklist
  Before you install the Operations Center, you must verify certain information, such as the installation credentials, and you must determine the input to provide to IBM Installation Manager for the installation.

AIX | Linux | Windows

System requirements for the Operations Center

Before you install the Operations Center, ensure that your system meets the minimum requirements.

Use the Operations Center System Requirements Calculator to estimate the system requirements for running the Operations Center and the hub and spoke servers that are monitored by the Operations Center.

Requirements that are verified during the installation

Table 1 lists the prerequisite requirements that are verified during the installation and indicates where to find more information about these requirements.

Table 1. Requirements that are verified during the installation

Requirement	Details
Minimum memory requirement	Operations Center computer requirements
Operating system requirement	Operating system requirements
Host name for the computer where the Operations Center will be installed	Installation checklist
Requirements for the Operations Center installation directory	Installation checklist

- Operations Center computer requirements
  You can install the Operations Center on a computer that is also running IBM Spectrum Protect server or on a different computer. If you install the Operations Center on the same computer as a server, that computer must meet the system requirements for both the Operations Center and the server.
- Hub and spoke server requirements
  When you open the Operations Center for the first time, you must associate the Operations Center with one IBM Spectrum Protect server that is designated as the *hub server*. In a multiple-server environment, you can connect the other servers, called *spoke servers*, to the hub server.
- Operating system requirements
  The Operations Center is available for AIX, Linux, and Windows systems.
- Web browser requirements
  The Operations Center can run in Apple, Google, Microsoft, and Mozilla web browsers.
- Language requirements
  By default, the Operations Center uses the language that the web browser uses. However, the installation process uses the language that the operating system uses. Verify that the web browser and the operating system are set to the language that you require.
- Requirements and limitations for IBM Spectrum Protect client management services
  IBM Spectrum Protect client management services is a component that you install on backup-archive clients to collect diagnostic information such as client log files. Before you install the client management service on your system, you must understand the requirements and limitations.

AIX | Linux | Windows

Operations Center computer requirements

You can install the Operations Center on a computer that is also running IBM Spectrum Protect™ server or on a different computer. If you install the Operations Center on the same computer as a server, that computer must meet the system requirements for both the Operations Center and the server.

Resource requirements

The following resources are required to run the Operations Center:

- One processor core
- 4 GB of memory
- 1 GB of disk space

The hub and spoke servers that are monitored by the Operations Center require additional resources, as described in Hub and spoke server requirements.

AIX | Linux | Windows

Hub and spoke server requirements

When you open the Operations Center for the first time, you must associate the Operations Center with one IBM Spectrum Protect™ server that is designated as the *hub server*. In a multiple-server environment, you can connect the other servers, called *spoke servers*, to the hub server.

The spoke servers send alerts and status information to the hub server. The Operations Center shows you a consolidated view of alerts and status information for the hub server and any spoke servers.

If only one server is monitored by the Operations Center, that server is still called a hub server, even though no spoke servers are connected to it.

Table 1 indicates the version of IBM Spectrum Protect server that must be installed on the hub server and on each spoke server that is managed by the Operations Center.

Table 1. IBM Spectrum Protect server version requirements for hub and spoke servers

Operations Center	Version on the hub server	Version on each spoke server
V8.1.2	V8.1.2	V6.3.4 or later Restriction: Some Operations Center functions are not available for servers that use a version earlier than V8.1.2.

Number of spoke servers that a hub server can support

The number of spoke servers that a hub server can support depends on the configuration and on the version of IBM Spectrum Protect on each spoke server. However, a general guideline is that a hub server can support 10 - 20 V6.3.4 spoke servers but can support more V7.1 or later spoke servers.

- Tips for designing the hub and spoke server configuration
  In designing the hub and spoke configuration, especially consider the resource requirements for status monitoring. Also, consider how you want to group hub and spoke servers and whether you want to use multiple hub servers.
- Tips for choosing a hub server
  For the hub server, you must choose a server that has adequate resources and is located for minimal roundtrip network latency.

AIX | Linux | Windows

Tips for designing the hub and spoke server configuration

In designing the hub and spoke configuration, especially consider the resource requirements for status monitoring. Also, consider how you want to group hub and spoke servers and whether you want to use multiple hub servers.

Use the Operations Center System Requirements Calculator to estimate the system requirements for running the Operations Center and the hub and spoke servers that are monitored by the Operations Center.

Primary factors that affect performance

The following factors have the most significant impact on the performance of the Operations Center:

- The processor and memory on the computer where the Operations Center is installed
- The system resources of the hub and spoke servers, including the disk system that is in use for the hub server database
- The number of client nodes and virtual machine file spaces that are managed by the hub and spoke servers
- The frequency at which data is refreshed in the Operations Center

How to group hub and spoke servers

Consider grouping hub and spoke servers by geographic location. For example, managing the servers within the same data center can help prevent issues that are caused by firewalls or by inadequate network bandwidth between different locations. If necessary, you can further divide servers according to one or more of the following characteristics:

- The administrator who manages the servers
- The organizational entity that funds the servers
- Server operating system
- The language in which the servers run
  Tip: If the hub and spoke servers are not running in the same language, you might see corrupted text in the Operations Center.

How to group hub and spoke servers in an enterprise configuration

In an enterprise configuration, a network of IBM Spectrum Protect™ servers are managed as a group. Changes that are made on the *configuration manager* can be distributed automatically to one or more *managed servers* in the network.

The Operations Center normally registers and maintains a dedicated administrator ID on the hub and spoke servers. This *monitoring administrator* must always have the same password on all the servers.

If you use an enterprise configuration, you can improve the process by which the administrator credentials are synchronized on spoke servers. To improve the performance and efficiency of maintaining the monitoring administrator ID, complete the following steps:

1. Designate the configuration manager server as the Operations Center hub server. During the hub server configuration, a monitoring administrator ID named IBM-OC-*hub_server_name* is registered.
2. On the hub server, add the monitoring administrator ID to a new or existing enterprise configuration profile. Issue the NOTIFY SUBSCRIBERS command to distribute the profile to the managed servers.
3. Add one or more of the managed servers as Operations Center spoke servers.

The Operations Center detects this configuration and allows the configuration manager to distribute and update the monitoring administrator ID on the spoke servers.

When to use multiple hub servers

If you have more than 10 - 20 V6.3.4 spoke servers, or if resource limitations require the environment to be partitioned, you can configure multiple hub servers, and connect a subset of the spoke servers to each hub server.
Restrictions:

- A single server cannot be both a hub server and a spoke server.
- Each spoke server can be assigned to only one hub server.
- Each hub server requires a separate instance of the Operations Center, each of which has a separate web address.

AIX | Linux | Windows

Tips for choosing a hub server

For the hub server, you must choose a server that has adequate resources and is located for minimal roundtrip network latency.

Attention: Do not use the same server as the hub server for multiple Operations Centers.
Use the following guidelines in deciding which server to designate as the hub server:

Choose a lightly loaded server
: Consider a server that has a light load for operations such as client backup and archive. A lightly loaded server is also a good choice as the host system for the Operations Center.

  Ensure that the server has the resources to handle both its typical server workload and the estimated workload for acting as the hub server.

Locate the server for minimal roundtrip network latency
: Locate the hub server so that the network connection between the hub server and the spoke servers has a roundtrip latency that is no greater than 5 ms. This latency can typically be achieved when the servers are on the same local area network (LAN).

  Networks that are poorly tuned, are heavily used by other applications, or have roundtrip latency much higher than 5 ms can degrade communications between the hub and spoke servers. For example, roundtrip latencies of 50 ms or higher can result in communication timeouts that cause spoke servers to disconnect or reconnect to the Operations Center. Such high latencies might be experienced in long-distance, wide area network (WAN) communications.

  If spoke servers are a long distance from the hub server and experience frequent disconnects in the Operations Center, you can increase the value of the ADMINCOMMTIMEOUT option on each server to reduce the problem.

Verify that the hub server meets the resource requirements for status monitoring
: Status monitoring requires extra resources on each server on which it is enabled. The resources that are required depend primarily on the number of clients that are managed by the hub and spoke servers. Fewer resources are used on a hub server with a V7.1 or later spoke server than on a hub server with a V6.3.4 spoke server.

  Verify that the hub server meets the resource requirements for processor usage, database space, archive log space, and I/O operations per second (IOPS) capacity.

A hub server with high IOPS capacity can handle a larger amount of incoming status data from spoke servers. Use of the following storage devices for the hub server database can help meet this capacity:

- An enterprise-level solid-state drive (SSD)
- An external SAN disk storage device with multiple volumes or multiple spindles under each volume

In an environment with fewer than 1000 clients, consider establishing a baseline capacity of 1000 IOPS for the hub server database if the hub server manages any spoke servers.

Determine whether your environment requires multiple hub servers

If more than 10,000 - 20,000 client nodes and virtual machine file spaces are managed by one set of hub and spoke servers, the resource requirements might exceed what the hub server has available, especially if the spoke servers are V6.3.4 servers. Consider designating a second server as a hub server and moving spoke servers to the new hub server to balance the load.

AIX Linux Windows

Operating system requirements

The Operations Center is available for AIX®, Linux, and Windows systems.

You can run the Operations Center on the following systems:

- AIX AIX systems:
  - IBM® AIX V7.1 (64 bit) TL 4 and SP 2
  - IBM AIX V7.2 (64 bit) TL 0 and SP 2
- Linux Linux on x86_64 systems:
  - Red Hat Enterprise Linux 6.7
  - Red Hat Enterprise Linux 7.1
  - SUSE Linux Enterprise Server 11, Service Pack 4 or later
  - SUSE Linux Enterprise Server 12
- Linux Linux on System z (s390x 64-bit architecture) systems:
  - Red Hat Enterprise Linux 7.1
  - SUSE Linux Enterprise Server 12
- Linux Linux on Power Systems (little endian) systems:
  - Red Hat Enterprise Linux 7 with the PPC64LE architecture
- Windows Windows systems:
  - Microsoft Windows Server 2012: Standard, Enterprise, or Datacenter Edition (64-bit)
  - Microsoft Windows Server 2012 R2 (64-bit)
  - Microsoft Windows Server 2016

For the most up-to-date requirements information, see Software and Hardware Requirements.

AIX Linux Windows

Web browser requirements

The Operations Center can run in Apple, Google, Microsoft, and Mozilla web browsers.

For optimal viewing of the Operations Center in the web browser, ensure that the screen resolution for the system is set to a minimum of 1024 X 768 pixels.

For optimal performance, use a web browser that has good JavaScript performance, and enable browser caching.

The Operations Center can run in the following web browsers:

- Apple Safari on the iPad
  Restriction: If Apple Safari is running on iOS 8.x or iOS 9.x, you cannot use a self-signed certificate for secure communication with the Operations Center without extra configuration of the certificate. Use a certificate authority (CA) certificate, or configure the self-signed certificate as needed. For instructions, see Technote http://www.ibm.com/support/docview.wss?uid=swg21963153.
- Google Chrome 40 or later
- Microsoft Internet Explorer 11 or later
- Mozilla Firefox ESR 31 or later

To run the Operations Center in compliance with the National Institute of Standards and Technology (NIST) Special Publications (SP) 800-131A recommendation, communication between the Operations Center and the web browser must be secured by using the Transport Layer Security (TLS) 1.2 protocol. During installation, you specify whether SP 800-131A compliance is required and the level of compliance. If strict SP 800-131A compliance is specified during installation, the web browser must support TLS 1.2, and TLS 1.2 must be enabled.

The web browser displays an SSL error if strict SP 800-131A compliance is specified during installation, and the web browser does not meet the preceding requirements.

AIX Linux Windows

Language requirements

By default, the Operations Center uses the language that the web browser uses. However, the installation process uses the language that the operating system uses. Verify that the web browser and the operating system are set to the language that you require.

AIX

AIX Linux Windows

Requirements and limitations for IBM Spectrum Protect client management services

IBM Spectrum Protect™ client management services is a component that you install on backup-archive clients to collect diagnostic information such as client log files. Before you install the client management service on your system, you must understand the requirements and limitations.

In the documentation for the client management service, *client system* is the system where the backup-archive client is installed.

Diagnostic information can be collected only from Linux and Windows clients, but administrators can view the diagnostic information in the Operations Center on AIX®, Linux, or Windows operating systems.

Requirements for the client management service

Verify the following requirements before you install the client management service:

- To remotely access the client, the Operations Center administrator must have system authority or one of the following client authority levels:
  - Policy authority
  - Client owner authority
  - Client node access authority
- Ensure that the client system meets the following requirements:
  - The client management service can be installed only on client systems that run on Linux or Windows operating systems:
    - Linux x86 64-bit operating systems that are supported for the backup-archive client.
    - Windows 32-bit and 64-bit operating systems that are supported for the backup-archive client.
  - Transport Layer Security (TLS) 1.2 must be installed for transmission of data between the client management service and Operations Center. Basic authentication is provided and data and authentication information are encrypted through the SSL channel. TLS 1.2 is automatically installed along with the necessary SSL certificates when you install the client management service.
- On Linux client systems, you must have root user authority to install the client management service.
- For client systems that can have multiple client nodes, such as Linux client systems, ensure that each node name is unique on the client system.
  Tip: After you install the client management service, you do not have to install it again because the service can discover multiple client options files.

Limitations of the client management service

The client management service provides basic services for collecting diagnostic information from backup-archive clients. The following limitations exist for the client management service:

- You can install the client management service only on systems with backup-archive clients, including backup-archive clients that are installed on data mover nodes for IBM Spectrum Protect for Virtual Environments: Data Protection for VMware.
- You cannot install the client management service on other IBM Spectrum Protect client components or products that do not have backup-archive clients.
- If the backup-archive clients are protected by a firewall, ensure that the Operations Center can connect to the backup-archive clients through the firewall by using the configured port for the client management service. The default port is 9028, but it can be changed.
- The client management service scans all client log files to locate entries for the previous 72-hour period.
- The Diagnosis page in the Operations Center provides basic troubleshooting information for backup-archive clients. However, for some backup issues, you might have to access the client system and obtain further diagnostic information.
- If the combined size of the client error log files and schedule log files on a client system is more than 500 MB, delays can occur in sending log records to the Operations Center. You can control the size of the log files by enabling log file pruning or wrapping by specifying the errorlogretention or errorlogmax client option.
- If you use the same client node name to connect to multiple IBM Spectrum Protect servers that are installed on the same server, you can view log files for only one of the client nodes.

For updates about the client management service, including requirements, limitations, and documentation updates, see technote 1963610.

Collecting diagnostic information with IBM Spectrum Protect client management services
AIX Linux Windows

Administrator IDs that the Operations Center requires

An administrator must have a valid ID and password on the hub server to log in to the Operations Center. An administrator ID is also assigned to the Operations Center so that the Operations Center can monitor servers.

The Operations Center requires the following IBM Spectrum Protect™ administrator IDs:

Administrator IDs that are registered on the hub server
: Any administrator ID that is registered on the hub server can be used to log in to the Operations Center. The authority level of the ID determines which tasks can be completed. You can create new administrator IDs by using the REGISTER ADMIN command.
Restriction: To use an administrator ID in a multiple-server configuration, the ID must be registered on the hub and spoke servers with the same password and authority level.
To manage authentication for these servers, consider using one of the following methods:

- A Lightweight Directory Access Protocol (LDAP) server
- The enterprise configuration functions to automatically distribute changes to the administrator definitions.

Monitoring administrator ID
: When you initially configure the hub server, an administrator ID named IBM-OC-*server_name* is registered with system authority on the hub server and is associated with the initial password that you specify. This ID, which is sometimes called the *monitoring administrator*, is intended for use only by the Operations Center.

  Do not delete, lock, or modify this ID. The same administrator ID with the same password is registered on the spoke servers that you add. The password is automatically changed on the hub and spoke servers every 90 days. You do not need to use or manage this password.

  Restriction: The Operations Center maintains the monitoring administrator ID and password on spoke servers unless you use an enterprise configuration to manage these credentials. For more information about using an enterprise configuration to manage the credentials, see Tips for designing the hub and spoke server configuration.

Related reference:
REGISTER ADMIN (Register an administrator ID)
AIX Linux Windows

IBM Installation Manager

The Operations Center uses IBM® Installation Manager, which is an installation program that can use remote or local software repositories to install or update many IBM products.

If the required version of IBM Installation Manager is not already installed, it is automatically installed or upgraded when you install the Operations Center. It must remain installed on the system so that the Operations Center can be updated or uninstalled later as needed.

The following list contains explanations of some terms that are used in IBM Installation Manager:

Offering
: An installable unit of a software product.

  The Operations Center offering contains all of the media that IBM Installation Manager requires to install the Operations Center.

Package
: The group of software components that are required to install an offering.
  The Operations Center package contains the following components:

  - IBM Installation Manager installation program
  - Operations Center offering

Package group

A set of packages that share a common parent directory.

Repository
: A remote or local storage area for data and other application resources.

  The Operations Center package is stored in a repository on IBM Fix Central.

Shared resources directory
: A directory that contains software files or plug-ins that are shared by packages.

  IBM Installation Manager stores installation-related files in the shared resources directory, including files that are used for rolling back to a previous version of the Operations Center.

AIX Linux Windows

Installation checklist

Before you install the Operations Center, you must verify certain information, such as the installation credentials, and you must determine the input to provide to IBM® Installation Manager for the installation.

The following checklist highlights the information that you must verify or determine before you install the Operations Center, and Table 1 describes the details of this information:

- ☐ Verify the host name for the computer where the Operations Center is to be installed.
- ☐ Verify the installation credentials.
- ☐ Determine the Operations Center installation directory, if you do not want to accept the default path.
- ☐ Determine the IBM Installation Manager installation directory, if you do not want to accept the default path.
- ☐ Determine the port number to be used by the Operations Center web server, if you do not want to accept the default port number.
- ☐ Determine the password for secure communications.
- ☐ Determine whether secure communications must comply with the National Institute of Standards and Technology (NIST) Special Publications (SP) 800-131A recommendation.

Table 1. Information to verify or determine before you install the Operations Center

Information	Details
Host name for the computer where the Operations Center is to be installed.	The host name must meet the following criteria: • It must not contain double-byte character set (DBCS) characters or the underscore character (_). • Although the host name can contain the hyphen character (–), it cannot have a hyphen as the last character in the name.
Installation credentials	To install the Operations Center, you must use the following user account: • AIX Linux The root user • Windows Administrator

Information	Details
Operations Center installation directory	The Operations Center is installed in the ui subdirectory of the installation directory. The following path is the default path for the Operations Center installation directory: • AIX Linux /opt/tivoli/tsm For example, if you use this default path, the Operations Center is installed in the following directory: `/opt/tivoli/tsm/ui` • Windows c:\Program Files\Tivoli\TSM For example, if you use this default path, the Operations Center is installed in the following directory: `c:\Program Files\Tivoli\TSM\ui` The installation directory path must meet the following criteria: • The path must contain no more than 128 characters. • The path must include only ASCII characters. • The path cannot include non-displayable control characters. • The path cannot include any of the following characters: `% | < > ' " $ & ; *`
IBM Installation Manager installation directory	The following path is the default path for the IBM Installation Manager installation directory: • AIX Linux /opt/IBM/InstallationManager • Windows C:\Program Files\IBM\Installation Manager
Port number that is used by the Operations Center web server.	The value for the secure (https) port number must meet the following criteria: • The number must be an integer in the range 1024 - 65535. • The number cannot be in use or allocated to other programs. If you do not specify a port number, the default value is `11090`. Tip: If you later do not remember the port number that you specified, refer to the following file, where *installation_dir* represents the directory where the Operations Center is installed: • AIX Linux *installation_dir*/ui/Liberty/usr/servers/guiServer/bootstrap.properties • Windows *installation_dir*\ui\Liberty\usr\servers\guiServer\bootstrap.properties The bootstrap.properties file contains the IBM Spectrum Protect™ server connection information.

Information	Details
Password for secure communications	The Operations Center uses Hypertext Transfer Protocol Secure (HTTPS) to communicate with web browsers. The Operations Center requires secure communication between the server and the Operations Center. To secure communication, you must add the Transport Layer Security (TLS) certificate of the hub server to the truststore file of the Operations Center. The truststore file of the Operations Center contains the certificate that the Operations Center uses for HTTPS communication with web browsers. During installation of the Operations Center, you create a password for the truststore file. When you set up secure communication between the Operations Center and the hub server, you must use the same password to add the certificate of the hub server to the truststore file. The password for the truststore file must meet the following criteria: • The password must contain a minimum of 6 characters and a maximum of 64 characters. • The password must contain at least the following characters: ◦ One uppercase letter (A – Z) ◦ One lowercase letter (a – z) ◦ One digit (0 – 9) ◦ Two of the non-alphanumeric characters that are listed in the following series: ~ ! @ # $ % ^ & * _ - + = ` | ( ) { } [ ] : ; < > , . ? /

Resetting the password for the Operations Center truststore file

AIX | Linux | Windows

Installing the Operations Center

You can install the Operations Center by using any of the following methods: a graphical wizard, the command line in console mode, or silent mode.

Before you begin

You cannot configure the Operations Center until you install, configure, and start the IBM Spectrum Protect™ server. Therefore, before you install the Operations Center, install the appropriate server package, according to the server version requirements in Hub and spoke server requirements.

You can install the Operations Center on a computer with the IBM Spectrum Protect server or on a separate computer.

- Obtaining the Operations Center installation package
  You can obtain the installation package from an IBM® download site such as IBM Passport Advantage® or IBM Fix Central.
- Installing the Operations Center by using a graphical wizard
  You can install or update the Operations Center by using the graphical wizard of IBM Installation Manager.
- Installing the Operations Center in console mode
  You can install or update the Operations Center by using the command line in console mode.
- Installing the Operations Center in silent mode
  You can install or upgrade the Operations Center in silent mode. In silent mode, the installation does not send messages to a console but instead stores messages and errors in log files.

AIX | Linux | Windows

Obtaining the Operations Center installation package

You can obtain the installation package from an IBM® download site such as IBM Passport Advantage® or IBM Fix Central.

About this task

After you obtain the package from an IBM download site, you must extract the installation files.

Procedure

Complete the following steps to extract the Operations Center installation files. In the following steps, replace *version_number* with the version of Operations Center that you are installing.

AIX On AIX® systems:

a. Download the following package file to the directory of your choice:

```
version_number.000
-IBM-SPOC-AIX.bin
```

b. Ensure that you have executable permission for the package file.
If necessary, change the file permissions by issuing the following command:

```
chmod a+x version_number.000-IBM-SPOC-AIX.bin
```

c. Issue the following command to extract the installation files:

```
./version_number.000-IBM-SPOC-AIX.bin
```

The self-extracting package file is extracted to the directory.

Linux On Linux systems:

a. Download one of the following package files to the directory of your choice:
   - *version_number*.000-IBM-SPOC-LinuxS390.bin
   - *version_number*.000-IBM-SPOC-Linuxx86_64.bin

b. Ensure that you have executable permission for the package file.
If necessary, change the file permissions by issuing the following command:

```
chmod a+x package_name.bin
```

c. Issue the following command to extract the installation files:

```
./package_name.bin
```

The self-extracting package file is extracted to the directory.

Windows On Windows systems:

a. Download the following package file to the directory of your choice:

```
version_number.000-IBM-SPOC-WindowsX64.exe
```

b. In Windows Explorer, double-click the file name to extract the installation files.

The self-extracting package file is extracted to the directory.

AIX | Linux | Windows

Installing the Operations Center by using a graphical wizard

You can install or update the Operations Center by using the graphical wizard of IBM® Installation Manager.

AIX

Before you begin

If the following RPM files are not installed on the computer, install them. For instructions, see Installing RPM files for the graphical wizard.

- atk-1.12.3-2.aix5.2.ppc.rpm
- cairo-1.8.8-1.aix5.2.ppc.rpm
- expat-2.0.1-1.aix5.2.ppc.rpm

- fontconfig-2.4.2-1.aix5.2.ppc.rpm
- freetype2-2.3.9-1.aix5.2.ppc.rpm
- gettext-0.10.40-6.aix5.1.ppc.rpm
- glib2-2.12.4-2.aix5.2.ppc.rpm
- gtk2-2.10.6-4.aix5.2.ppc.rpm
- libjpeg-6b-6.aix5.1.ppc.rpm
- libpng-1.2.32-2.aix5.2.ppc.rpm
- libtiff-3.8.2-1.aix5.2.ppc.rpm
- pango-1.14.5-4.aix5.2.ppc.rpm
- pixman-0.12.0-3.aix5.2.ppc.rpm
- xcursor-1.1.7-3.aix5.2.ppc.rpm
- xft-2.1.6-5.aix5.1.ppc.rpm
- xrender-0.9.1-3.aix5.2.ppc.rpm
- zlib-1.2.3-3.aix5.1.ppc.rpm

Procedure

1. From the directory where the Operations Center installation package file is extracted, issue the following command:
   - AIX Linux `./install.sh`
   - Windows `install.bat`
2. Follow the wizard instructions to install the IBM Installation Manager and Operations Center packages.
   AIX The following message might be displayed, and the installation wizard might be slow, if your locale uses UTF-8 encoding:

   ```
   Cannot create font set
   ```

   If the message is displayed, take one of the following actions:
   - Change to a locale that does not use UTF-8 encoding. For language-option values that do not use UTF-8 encoding, see Language requirements.
   - Install the Operations Center by using the command line in console mode.
   - Install the Operations Center in silent mode.

What to do next

See Configuring the Operations Center.

- AIX Installing RPM files for the graphical wizard
  Before you can use the graphical wizard of IBM Installation Manager to install the Operations Center, certain RPM files must be installed.

AIX Linux Windows

Installing the Operations Center in console mode

You can install or update the Operations Center by using the command line in console mode.

Procedure

1. From the directory where the installation package file is extracted, run the following program:
   AIX Linux

   ```
   ./install.sh -c
   ```

   Windows

   ```
   install.bat -c
   ```

2. Follow the console instructions to install the Installation Manager and Operations Center packages.

What to do next

See Configuring the Operations Center.

AIX Linux Windows

Installing the Operations Center in silent mode

You can install or upgrade the Operations Center in silent mode. In silent mode, the installation does not send messages to a console but instead stores messages and errors in log files.

Before you begin

To provide data input when you use the silent installation method, you can use a response file. The following sample response files are provided in the input directory where the installation package is extracted:

install_response_sample.xml
: Use this file to install the Operations Center.

update_response_sample.xml
: Use this file to upgrade the Operations Center.

These files contain default values that can help you avoid any unnecessary warnings. To use these files, follow the instructions that are provided in the files.

If you want to customize a response file, you can modify the options that are in the file. For information about response files, see Response files.

Procedure

1. Create a response file. You can modify the sample response file or create your own file.
   Tip: To generate a response file as part of a console-mode installation, complete the selection of the console-mode installation options. Then, in the Summary panel, enter `G` to generate the response file according to the previously selected options.
2. Create a password for the Operations Center truststore in the response file.
   If you are using the install_response_sample.xml file, add the password in the following line of the file, where *mypassword* represents the password:

   ```
   <variable name='ssl.password' value='mypassword' />
   ```

   For more information about this password, see Installation checklist.
   Tip: To upgrade the Operations Center, the truststore password is not required if you are using the update_response_sample.xml file.
3. Start the silent installation by issuing the following command from the directory where the installation package is extracted. The value *response_file* represents the response file path and file name:
   - AIX Linux

     ```
     ./install.sh -s -input response_file -acceptLicense
     ```

   - Windows

     ```
     install.bat -s -input response_file -acceptLicense
     ```

What to do next

See Configuring the Operations Center.

AIX Linux Windows

Upgrading the Operations Center

You can upgrade the Operations Center by using any of the following methods: a graphical wizard, the command line in console mode, or silent mode.

Before you begin

Before you upgrade the Operations Center, review the system requirements and the installation checklist. The new version of the Operations Center might have more or different requirements and considerations than the version you are currently using.

About this task

The instructions for upgrading the Operations Center are the same as the instructions for installing the Operations Center, with the following exceptions:

- You use the Update function of IBM® Installation Manager rather than the Install function.
  Tip: In IBM Installation Manager, the term *update* means to discover and install updates and fixes to installed software packages. In this context, *update* and *upgrade* are synonymous.
- If you are upgrading the Operations Center in silent mode, you can skip the step of creating a password for the truststore file.

AIX | Linux | Windows

Getting started with the Operations Center

Before you can use the Operations Center to manage your storage environment, you must configure it.

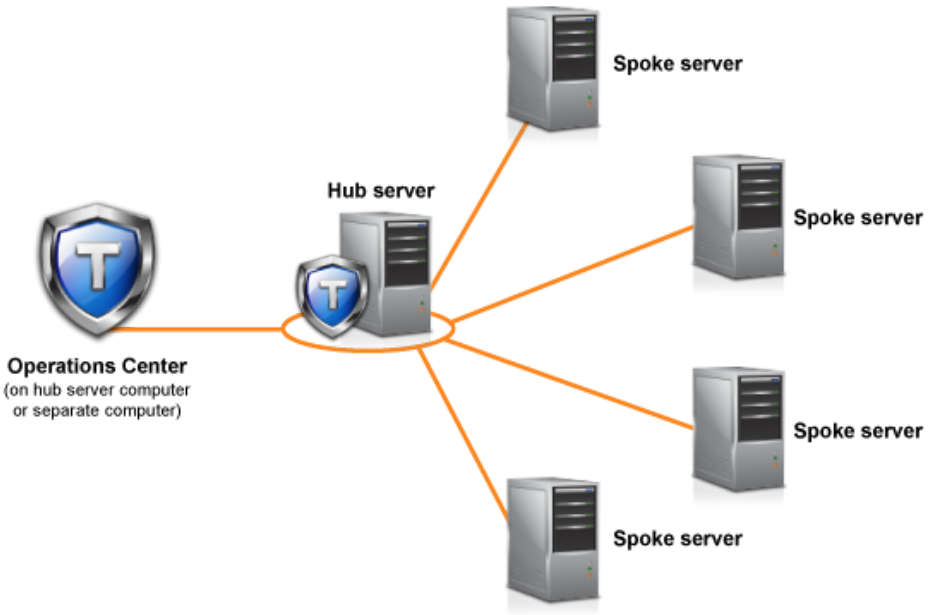
About this task

After you install the Operations Center, complete the following basic configuration steps:

1. Designate the hub server.
2. Add any spoke servers.
3. Optionally, configure email alerts on the hub and spoke servers.

Figure 1 illustrates an Operations Center configuration.

Figure 1. Example of an Operations Center configuration with the hub and spoke servers



- Configuring the Operations Center
  When you open the Operations Center for the first time, you must configure it to manage your storage environment. You must associate the Operations Center with the IBM Spectrum Protect server that is designated as the hub server. You can then connect additional IBM Spectrum Protect servers as spoke servers.
- Configuring for secure communication
  The Operations Center uses Hypertext Transfer Protocol Secure (HTTPS) to communicate with web browsers. The Transport Layer Security (TLS) protocol secures communications between the Operations Center and the hub server, and between the hub server and associated spoke servers.
- Starting and stopping the web server
  The web server of the Operations Center runs as a service and starts automatically. You might need to stop and start the web server, for example, to make configuration changes.
- Opening the Operations Center
  The Overview page is the default initial view in the Operations Center. However, in your web browser, you can bookmark the page that you want to open when you log in to the Operations Center.
- Collecting diagnostic information with IBM Spectrum Protect client management services
  The client management service collects diagnostic information about backup-archive clients and makes the information

available to the Operations Center for basic monitoring capability.

AIX | Linux | Windows

Configuring the Operations Center

When you open the Operations Center for the first time, you must configure it to manage your storage environment. You must associate the Operations Center with the IBM Spectrum Protect™ server that is designated as the hub server. You can then connect additional IBM Spectrum Protect servers as spoke servers.

- Designating the hub server
  When you connect to the Operations Center for the first time, you must designate which IBM Spectrum Protect server is the hub server.
- Adding a spoke server
  After you configure the hub server for the Operations Center, you can add one or more spoke servers to the hub server.
- Sending email alerts to administrators
  An alert is a notification of a relevant problem on the IBM Spectrum Protect server and is triggered by a server message. Alerts can be shown in the Operations Center and can be sent from the server to administrators by email.
- Adding customized text to the login screen
  You can add customized text, such as your organization's Terms of Use of the software, to the login screen of the Operations Center so that users of the Operations Center see the text before they enter their user name and password.
- Enabling REST services
  Applications that use Representational State Transfer (REST) services can query and manage the storage environment by connecting to the Operations Center.

AIX | Linux | Windows

Designating the hub server

When you connect to the Operations Center for the first time, you must designate which IBM Spectrum Protect™ server is the hub server.

Before you begin

The Operations Center requires secure communication between the hub server and the Operations Center. To secure communication, you must add the Transport Layer Security (TLS) certificate of the hub server to the truststore file of the Operations Center. For more information, see Securing communication between the Operations Center and the hub server.

Procedure

In a web browser, enter the following address, where *hostname* represents the name of the computer where the Operations Center is installed, and *secure_port* represents the port number that the Operations Center uses for HTTPS communication on that computer:

`https://hostname:secure_port/oc`

Tips:

- The URL is case-sensitive. For example, ensure that you type "oc" in lowercase as indicated.
- For more information about the port number, see the Installation checklist.
- If you are connecting to the Operations Center for the first time, you must provide the following information:
  - Connection information for the server that you want to designate as a hub server
  - Login credentials for an administrator ID that is defined for that server
- If the event-record retention period of the server is less than 14 days, the period is automatically reset to 14 days if you configure the server as a hub server.

What to do next

If you have multiple IBM Spectrum Protect servers in your environment, add the other servers as spoke servers to the hub server.

Attention: Do not change the name of a server after it is configured as a hub or spoke server.
Related concepts:

Hub and spoke server requirements
Administrator IDs that the Operations Center requires
AIX Linux Windows

Adding a spoke server

After you configure the hub server for the Operations Center, you can add one or more spoke servers to the hub server.

Before you begin

Communication between the spoke server and the hub server must be secured by using the Transport Layer Security (TLS) protocol. To secure communication, add the certificate of the spoke server to the truststore file of the hub server.

Procedure

1. In the Operations Center menu bar, click Servers. The Servers page opens.

   In the table on the Servers page, a server might have a status of "Unmonitored." This status means that although an administrator defined this server to the hub server by using the DEFINE SERVER command, the server is not yet configured as a spoke server.

2. Complete one of the following steps:
   - Click the server to highlight it, and in the table menu bar, click Monitor Spoke.
   - If the server that you want to add is not shown in the table, and secure SSL/TLS communication is not required, click + Spoke in the table menu bar.
3. Provide the necessary information, and complete the steps in the spoke configuration wizard.
   Tip: If the event-record retention period of the server is less than 14 days, the period is automatically reset to 14 days if you configure the server as a spoke server.

AIX Linux Windows

Sending email alerts to administrators

An alert is a notification of a relevant problem on the IBM Spectrum Protect™ server and is triggered by a server message. Alerts can be shown in the Operations Center and can be sent from the server to administrators by email.

Before you begin

Before you configure email notification for administrators about alerts, ensure that the following requirements are met:

- An SMTP server is required to send and receive alerts by email, and the server that sends the alerts by email must have access to the SMTP server.
  Tip: If the Operations Center is installed on a separate computer, that computer does not need access to the SMTP server.
- An administrator must have system privilege to configure email notification.

About this task

An email notification is sent only for the first occurrence of an alert. Also, if an alert is generated before you configure email notification, no email notification is sent for that alert.

You can configure email notification in the following ways:

- Send notification for individual alerts
- Send alert summaries

An alert summary contains information about current alerts. The summary includes the total number of alerts, the total number of active and inactive alerts, the oldest alert, the newest alert, and the most frequently occurring alert.

You can specify a maximum of three administrators to receive alert summaries by email. Alert summaries are sent approximately every hour.

Procedure

To configure email notification for administrators about alerts, complete the following steps on each hub and spoke server from which you want to receive email alerts:

1. To verify that alert monitoring is turned on, issue the following command:

   ```
   QUERY MONITORSETTINGS
   ```

2. If the command output indicates that alert monitoring is turned off, issue the following command. Otherwise, proceed to the next step.

   ```
   SET ALERTMONITOR ON
   ```

3. To enable the sending of email notification, issue the following command:

   ```
   SET ALERTEMAIL ON
   ```

4. To define the SMTP server that is used to send email notification, issue the following command:

   ```
   SET ALERTEMAILSMTPHOST host_name
   ```

5. To specify the port number for the SMTP server, issue the following command:

   ```
   SET ALERTEMAILSMTPPORT port_number
   ```

   The default port number is 25.

6. To specify the email address of the sender of the alerts, issue the following command:

   ```
   SET ALERTEMAILFROMADDR email_address
   ```

7. For each administrator ID that must receive email notification, issue one of the following commands to activate email notification and to specify the email address:

   ```
   REGISTER ADMIN admin_name ALERT=YES EMAILADDRESS=email_address

   UPDATE ADMIN admin_name ALERT=YES EMAILADDRESS=email_address
   ```

8. Choose either, or both, of the following options, and specify the administrator IDs to receive email notification:
   - Send notification for individual alerts
     To specify or update the administrator IDs to receive email notification for an individual alert, issue one of the following commands:

     ```
     DEFINE ALERTTRIGGER message_number ADmin=admin_name1,admin_name2

     UPDATE ALERTTRIGGER message_number ADDadmin=admin_name3 DELadmin=admin_name1
     ```

     Tip: From the Configure Alerts page of the Operations Center, you can select the administrators who will receive email notification.
   - Send alert summaries
     To specify or update the administrator IDs to receive alert summaries by email, issue the following command:

     ```
     SET ALERTSUMMARYTOADMINS admin_name1,admin_name2,admin_name3
     ```

   If you want to receive alert summaries but do not want to receive notification about individual alerts, complete the following steps:
   a. Suspend notification about individual alerts, as described in Suspending email alerts temporarily.
   b. Ensure that the respective administrator ID is listed in the following command:

      ```
      SET ALERTSUMMARYTOADMINS admin_name1,admin_name2,admin_name3
      ```

Sending email alerts to multiple administrators

The following example illustrates the commands that cause any alerts for message ANR1075E to be sent in an email to the administrators `myadmin`, `djadmin`, and `csadmin`:

```
SET ALERTMONITOR ON
SET ALERTEMAIL ON
SET ALERTEMAILSMTPHOST mymailserver.domain.com
```

```
SET ALERTEMAILSMTPPORT 450
SET ALERTEMAILFROMADDR srvadmin@mydomain.com
UPDATE ADMIN myadmin ALERT=YES EMAILADDRESS=myaddr@anycompany.com
UPDATE ADMIN djadmin ALERT=YES EMAILADDRESS=djaddr@anycompany.com
UPDATE ADMIN csadmin ALERT=YES EMAILADDRESS=csaddr@anycompany.com
DEFINE ALERTTRIGGER anr0175e ADMIN=myadmin,djadmin,csadmin
```

- Suspending email alerts temporarily
  In certain situations, you might want to suspend email alerts temporarily. For example, you might want to receive alert summaries but suspend notification about individual alerts, or you might want to suspend email alerts when an administrator is on vacation.

SET ALERTEMAILSMTPHOST (Set the SMTP mail server host name)
SET ALERTEMAILSMTPPORT (Set the SMTP mail server host port)
SET ALERTMONITOR (Set the alert monitor to on or off)
SET ALERTSUMMARYTOADMINS (Set the list of administrators to receive alert summaries by email)
UPDATE ADMIN (Update an administrator)
UPDATE ALERTTRIGGER (Update a defined alert trigger)
AIX Linux Windows

Adding customized text to the login screen

You can add customized text, such as your organization's Terms of Use of the software, to the login screen of the Operations Center so that users of the Operations Center see the text before they enter their user name and password.

Procedure

To add customized text to the login screen, complete the following steps:

1. On the computer where the Operations Center is installed, go to the following directory, where *installation_dir* represents the directory in which the Operations Center is installed:

   AIX Linux *installation_dir*/ui/Liberty/usr/servers/guiServer

   Windows *installation_dir*\ui\Liberty\usr\servers\guiServer

2. In the directory, create a file that is named loginText.html that contains the text that you want to add to the login screen. Any special, non-ASCII text must be UTF-8 encoded.
   Tip: You can format the text by adding HTML tags.
3. Review the added text on the login screen of the Operations Center.
   To open the Operations Center, enter the following address in a web browser, where *hostname* represents the name of the computer where the Operations Center is installed, and *secure_port* represents the port number that the Operations Center uses for HTTPS communication on that computer:

   `https://hostname:secure_port/oc`

Enabling REST services

Applications that use Representational State Transfer (REST) services can query and manage the storage environment by connecting to the Operations Center.

About this task

Enable this feature to allow REST services to interact with hub and spoke servers by sending calls to the following address:

`https://oc_host_name:port/oc/api`

where *oc_host_name* is the network name or IP address of the Operations Center host system and *port* is the Operations Center port number. The default port number is 11090.
For information about the REST services that are available for the Operations Center, see Technote http://www.ibm.com/support/docview.wss?uid=swg21973011, or issue the following REST call:

```
https://oc_host_name:port/oc/api/help
```

Procedure

1. On the Operations Center menu bar, hover over the settings icon  and click Settings.
2. On the General page, select the Enable administrative REST API check box.
3. Click Save.

AIX | Linux | Windows

Configuring for secure communication

The Operations Center uses Hypertext Transfer Protocol Secure (HTTPS) to communicate with web browsers. The Transport Layer Security (TLS) protocol secures communications between the Operations Center and the hub server, and between the hub server and associated spoke servers.

About this task

TLS 1.2 is required for secure communication between the IBM Spectrum Protect™ server and the Operations Center, and between the hub server and spoke servers.

- Securing communication between the Operations Center and the hub server
  To secure communications between the Operations Center and the hub server, you must add the Transport Layer Security (TLS) certificate of the hub server to the truststore file of the Operations Center.
- Securing communication between the hub server and a spoke server
  To secure communications between the hub server and a spoke server by using the Transport Layer Security (TLS) protocol, you must define the certificate of the spoke server to the hub server. You must also configure the Operations Center to monitor the spoke server.
- Resetting the password for the Operations Center truststore file
  To set up secure communication between the Operations Center and the hub server, you must know the password for the truststore file of the Operations Center. You create this password during the installation of the Operations Center. If you do not know the password, you can reset it.

AIX | Linux | Windows

Securing communication between the Operations Center and the hub server

To secure communications between the Operations Center and the hub server, you must add the Transport Layer Security (TLS) certificate of the hub server to the truststore file of the Operations Center.

Before you begin

The truststore file of the Operations Center is a container for certificates that the Operations Center can access. The truststore file contains the certificate that the Operations Center uses for HTTPS communication with web browsers.

During the installation of the Operations Center, you create a password for the truststore file. To secure communication between the Operations Center and the hub server, you must use the same password to add the certificate of the hub server to the truststore file. If you do not remember this password, you can reset it. See Resetting the password for the Operations Center truststore file.

Procedure

1. Specify the cert256.arm certificate as the default certificate in the key database file of the hub server.

   To specify cert256.arm as the default certificate, complete the following steps:

a. Issue the following command from the hub server instance directory:

```
gsk8capicmd_64 -cert -setdefault -db cert.kdb -stashed
 -label "TSM Server SelfSigned SHA Key"
```

b. Restart the hub server so that it can receive the changes to the key database file.

2. To verify that the cert256.arm certificate is set as the default certificate in the key database file of the hub server, issue the following command:

```
gsk8capicmd_64 -cert -list -db cert.kdb -stashed
```

3. Stop the Operations Center web server.
4. Go to the command line of the operating system on which the Operations Center is installed.
5. Add the certificate to the truststore file of the Operations Center by using the iKeycmd command or the iKeyman command. The iKeyman command opens the IBM® Key Management graphical user interface, and iKeycmd is a command line interface.
   To add the SSL certificate by using the command line interface, issue the iKeycmd command to add the cert256.arm certificate as the default certificate in the key database file of the hub server:

```
ikeycmd -cert -add
-db /installation_dir/Liberty/usr/servers/guiServer/gui-truststore.jks
-file /fvt/comfrey/srv/cert256.arm
-label 'label description'
-pw 'password' -type jks -format ascii -trust enable
```

   where:

   installation_dir
   : The directory in which the Operations Center is installed.

   label description
   : The description that you assign to the label.

   password
   : The password that you created when you installed the Operations Center. To reset the password, uninstall the Operations Center, delete the .jks file, and reinstall the Operations Center.

   To add the certificate by using the IBM Key Management window, complete the following steps:

   a. Go to the following directory, where *installation_dir* represents the directory in which the Operations Center is installed:
      - AIX Linux *installation_dir*/ui/jre/bin
      - Windows *installation_dir*\ui\jre\bin

   b. Open the IBM Key Management window by issuing the following command:

```
ikeyman
```

   c. Click Key Database File > Open.
   d. In the Open window, click Browse, and go to the following directory, where *installation_dir* represents the directory in which the Operations Center is installed:
      - AIX Linux *installation_dir*/ui/Liberty/usr/servers/guiServer
      - Windows *installation_dir*\ui\Liberty\usr\servers\guiServer

   e. In the guiServer directory, select the gui-truststore.jks file.
   f. Click Open, and click OK.
   g. Enter the password for the truststore file, and click OK.
   h. In the Key database content area of the IBM Key Management window, click the arrow, and select Signer Certificates from the list.
   i. Click Add.
   j. In the Open window, click Browse, and go to the hub server instance directory, as shown in the following example:
      - AIX Linux /opt/tivoli/tsm/server/bin
      - Windows c:\Program Files\Tivoli\TSM\server1

      The directory contains the cert256.arm certificate.

      If you cannot access the hub server instance directory from the Open window, complete the following steps:
      i. Use FTP or another file-transfer method to copy the cert256.arm files from the hub server to the following directory on the computer where the Operations Center is installed:
         - AIX Linux *installation_dir*/ui/Liberty/usr/servers/guiServer
         - Windows *installation_dir*\ui\Liberty\usr\servers\guiServer

ii. In the Open window, go to the guiServer directory.

k. Select the cert256.arm certificate as the certificate.
Tip: The certificate that you choose must be set as the default certificate in the key database file of the hub server. For more information, see step 1 and 2.

l. Click Open, and click OK.

m. Enter a label for the certificate. For example, enter the name of the hub server.

n. Click OK. The SSL certificate of the hub server is added to the truststore file, and the label is displayed in the Key database content area of the IBM Key Management window.

o. Close the IBM Key Management window.

6. Start the Operations Center web server.
7. When you connect to the Operations Center for the first time, you are prompted to identify the IP address or network name of the hub server, and the port number for communicating with the hub server. If the ADMINONCLIENTPORT server option is enabled for the IBM Spectrum Protect™ server, enter the port number that is specified by the TCPADMINPORT server option. If the ADMINONCLIENTPORT server option is not enabled, enter the port number that is specified by the TCPPORT server option.
If the Operations Center was previously configured, you can review the contents of the serverConnection.properties file to verify the connection information. The serverConnection.properties file is in the following directory on the computer where the Operations Center is installed:
   - AIX Linux *installation_dir*/ui/Liberty/usr/servers/guiServer
   - Windows *installation_dir*\ui\Liberty\usr\servers\guiServer

What to do next

To set up SSL communication between the hub server and a spoke server, see Securing communication between the hub server and a spoke server.

Related reference:
QUERY OPTION (Query server options)
AIX Linux Windows

Securing communication between the hub server and a spoke server

To secure communications between the hub server and a spoke server by using the Transport Layer Security (TLS) protocol, you must define the certificate of the spoke server to the hub server. You must also configure the Operations Center to monitor the spoke server.

Procedure

1. On the spoke server, change to the directory of the spoke server instance.
2. Specify the required cert256.arm certificate as the default certificate in the key database file of the spoke server. Issue the following command:

```
gsk8capicmd_64 -cert -setdefault -db cert.kdb -stashed
 -label "TSM Server SelfSigned SHA Key"
```

3. Verify the certificates in the key database file of the spoke server. Issue the following command:

```
gsk8capicmd_64 -cert -list -db cert.kdb -stashed
```

4. Securely transfer the cert256.arm file of the spoke server to the hub server.
5. On the hub server, change to the directory of the hub server instance.
6. Define the spoke server certificate to the hub server. Issue the following command from the hub server instance directory, where *spoke_servername* is the name of the spoke server, and *spoke_cert256.arm* is the file name of the spoke server certificate:

```
gsk8capicmd_64 -cert -add -db cert.kdb -stashed -format ascii
 -label spoke_servername -file spoke_cert256.arm
```

   The spoke server does not require the hub server certificate for hub-to-spoke communication. However, other server configurations that require cross-defined servers do require the spoke server to have the hub server certificate.
7. Restart the hub server and the spoke server.
8. For the hub server, issue the DEFINE SERVER command, according to the following example:

```
DEFINE SERVER spoke_servername HLA=spoke_address
 LLA=spoke_SSLTCPADMINPort SERVERPA=spoke_serverpassword
```

Tip: By default, server communication is encrypted except when the server is sending or receiving object data. Object data is sent and received by using TCP/IP. By choosing not to encrypt the object data, server performance is similar to communication over a TCP/IP session and the session is secure. To encrypt all communication with the specified server, even when the server is sending and receiving object data, specify the SSL=YES parameter on the DEFINE SERVER command.

9. On the Operations Center menu bar, click Servers.

   In the table on the Servers page, the spoke server that you defined in step 8 typically has a status of "Unmonitored." Depending on the setting for the status refresh interval, you might not see the spoke server immediately.

10. Click the spoke server to highlight the item, and in the table menu bar, click Monitor Spoke.

Related reference:
DEFINE SERVER (Define a server for server-to-server communications)
QUERY OPTION (Query server options)
AIX Linux Windows

Resetting the password for the Operations Center truststore file

To set up secure communication between the Operations Center and the hub server, you must know the password for the truststore file of the Operations Center. You create this password during the installation of the Operations Center. If you do not know the password, you can reset it.

About this task

To reset the password, you must create a new password, delete the truststore file of the Operations Center, and restart the Operations Center web server.

Procedure

1. Stop the Operations Center web server.
2. Go to the following directory, where *installation_dir* represents the directory in which the Operations Center is installed:
   - AIX Linux *installation_dir*/ui/Liberty/usr/servers/guiServer
   - Windows *installation_dir*\ui\Liberty\usr\servers\guiServer
3. Open the bootstrap.properties file, which contains the password for the truststore file. If the password is unencrypted, you can use it to open the truststore file without having to reset it.
   The following examples indicate the difference between an encrypted and an unencrypted password:

   Encrypted password example

   Encrypted passwords begin with the text string `{xor}`.
   The following example shows the encrypted password as the value of the tsm.truststore.pswd parameter:

   ```
   tsm.truststore.pswd={xor}MiYPPiwsKDAtOw==
   ```

   Unencrypted password example

   The following example shows the unencrypted password as the value of the tsm.truststore.pswd parameter:

   ```
   tsm.truststore.pswd=J8b%^B
   ```

4. Reset the password by replacing the password in the bootstrap.properties file with a new password. You can replace the password with an encrypted or unencrypted password. Remember the unencrypted password for future use.
   To create an encrypted password, complete the following steps:
   a. Create an unencrypted password.
      The password for the truststore file must meet the following criteria:
      - The password must contain a minimum of 6 characters and a maximum of 64 characters.
      - The password must contain at least the following characters:
        - One uppercase letter (A – Z)
        - One lowercase letter (a – z)
        - One digit (0 – 9)
        - Two of the non-alphanumeric characters that are listed in the following series:

```
~ ! @ # $ % ^ & * _ - + = ` |
( ) { } [ ] : ; < > , . ? /
```

b. From the command line of the operating system, go to the following directory:
   - AIX Linux *installation_dir*/ui/Liberty/bin
   - Windows *installation_dir*\ui\Liberty\bin

c. To encrypt the password, issue the following command, where *myPassword* represents the unencrypted password:
   - AIX Linux `securityUtility encode myPassword`
   - Windows `securityUtility.bat encode myPassword`

Windows The following message might be shown:

```
! "java"' is not recognized as an internal or external command,
operable program or batch file.
```

If this message is shown, complete the following steps:

i. Issue the following command, where *installation_dir* represents the directory where the Operations Center is installed:

```
set JAVA_HOME="installation_dir\ui\jre"
```

ii. Reissue the following command to encrypt the password:

```
securityUtility.bat encode myPassword
```

5. Close the bootstrap.properties file.
6. Go to the following directory:
   - AIX Linux *installation_dir*/ui/Liberty/usr/servers/guiServer
   - Windows *installation_dir*\ui\Liberty\usr\servers\guiServer
7. Delete the gui-truststore.jks file, which is the truststore file of the Operations Center.
8. Start the Operations Center web server.

Results

A new truststore file is automatically created for the Operations Center, and the TLS certificate of the Operations Center is automatically included in the truststore file.

AIX Linux Windows

Starting and stopping the web server

The web server of the Operations Center runs as a service and starts automatically. You might need to stop and start the web server, for example, to make configuration changes.

Procedure

Stop and start the web server.

- AIX From the /*installation_dir*/ui/utils directory, where *installation_dir* represents the directory where the Operations Center is installed, issue the following commands:
  - To stop the server:

    ```
    ./stopserver.sh
    ```

  - To start the server:

    ```
    ./startserver.sh
    ```

- Linux Issue the following commands:
  - To stop the server:

    ```
    service opscenter.rc stop
    ```

  - To start the server:

    ```
    service opscenter.rc start
    ```

  - To restart the server:

```
service opscenter.rc restart
```

To determine whether the server is running, issue the following command:

```
service opscenter.rc status
```

- Windows From the Services window, stop or start the Operations Center service.

Opening the Operations Center

The Overview page is the default initial view in the Operations Center. However, in your web browser, you can bookmark the page that you want to open when you log in to the Operations Center.

Procedure

1. In a web browser, enter the following address, where *hostname* represents the name of the computer where the Operations Center is installed, and *secure_port* represents the port number that the Operations Center uses for HTTPS communication on that computer:

   `https://hostname:secure_port/oc`

   Tips:
   - The URL is case-sensitive. For example, ensure that you type "oc" in lowercase as indicated.
   - The default port number for HTTPS communication is 11090, but a different port number can be specified during Operations Center installation.
2. Log in, using an administrator ID that is registered on the hub server.

   In the Overview page, you can view summary information for clients, services, servers, storage pools, and storage devices. You can view more details by clicking items or by using the Operations Center menu bar.

   Monitoring from a mobile device: To remotely monitor the storage environment, you can view the Overview page of the Operations Center in the web browser of a mobile device. The Operations Center supports the Apple Safari web browser on the iPad. Other mobile devices can also be used.

AIX Linux Windows

Collecting diagnostic information with IBM Spectrum Protect client management services

The client management service collects diagnostic information about backup-archive clients and makes the information available to the Operations Center for basic monitoring capability.

About this task

After you install the client management service, you can view the Diagnosis page in the Operations Center to obtain troubleshooting information for backup-archive clients.

Diagnostic information can be collected only from Linux and Windows clients, but administrators can view the diagnostic information in the Operations Center on AIX®, Linux, or Windows operating systems.

You can also install the client management service on data mover nodes for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware to collect diagnostic information about the data movers.

Tip: In the documentation for the client management service, *client system* is the system where the backup-archive client is installed.

- Installing the client management service by using a graphical wizard
  To collect diagnostic information about backup-archive clients such as client log files, you must install the client management service on the client systems that you manage.
- Installing the client management service in silent mode
  You can install the client management service in silent mode. When you use silent mode, you provide the installation values in a response file and then run an installation command.

- Verifying that the client management service is installed correctly
  Before you use the client management service to collect diagnostic information about a backup-archive client, you can verify that the client management service is correctly installed and configured.
- Configuring the Operations Center to use the client management service
  If you did not use the default configuration for the client management service, you must configure the Operations Center to access the client management service.
- Starting and stopping the client management service
  The client management service is automatically started after it is installed on the client system. You might need to stop and start the service in certain situations.
- Uninstalling the client management service
  If you no longer have to collect client diagnostic information, you can uninstall the client management service from the client system.
- Configuring the client management service for custom client installations
  The client management service uses information in the client configuration file (client-configuration.xml) to discover diagnostic information. If the client management service is unable to discover the location of log files, you must run the CmsConfig utility to add the location of the log files to the client-configuration.xml file.

Installing the client management service by using a graphical wizard

To collect diagnostic information about backup-archive clients such as client log files, you must install the client management service on the client systems that you manage.

Before you begin

Review Requirements and limitations for IBM Spectrum Protect client management services.

About this task

You must install the client management service on the same computer as the backup-archive client.

Procedure

1. Download the installation package for the client management service from an IBM® download site such as IBM Passport Advantage® or IBM Fix Central. Look for a file name that is similar to `<version>-IBM-SPCMS-<operating system>.bin`.

   The following table shows the names of the installation packages.

Client operating system	Installation package name
Linux x86 64-bit	8.1.x.000-IBM-SPCMS-Linuxx64.bin
Windows 32-bit	8.1.x.000-IBM-SPCMS-Windows32.exe
Windows 64-bit	8.1.x.000-IBM-SPCMS-Windows64.exe

2. Create a directory on the client system that you want to manage, and copy the installation package there.
3. Extract the contents of the installation package file.
   - On Linux client systems, complete the following steps:
     a. Change the file to an executable file by issuing the following command:

     ```
     chmod +x 8.1.x.000-IBM-SPCMS-Linuxx64.bin
     ```

     b. Issue the following command:

     ```
     ./8.1.x.000-IBM-SPCMS-Linuxx64.bin
     ```

   - On Windows client systems, double-click the installation package name in Windows Explorer.

   Tip: If you previously installed and uninstalled the package, select All when prompted to replace the existing installation files.
4. Run the installation batch file from the directory where you extracted the installation files and associated files. This is the directory that you created in step 2.
   - On Linux client systems, issue the following command:

```
./install.sh
```

- On Windows client systems, double-click install.bat.

5. To install the client management service, follow the instructions in the IBM Installation Manager wizard.

   If IBM Installation Manager is not already installed on the client system, you must select both IBM Installation Manager and IBM Spectrum Protect Client Management Services.

   Tip: You can accept the default locations for the shared resources directory and the installation directory for IBM Installation Manager.

What to do next

Follow the instructions in Verifying that the client management service is installed correctly.

AIX | Linux | Windows

Installing the client management service in silent mode

You can install the client management service in silent mode. When you use silent mode, you provide the installation values in a response file and then run an installation command.

Before you begin

Review Requirements and limitations for IBM Spectrum Protect client management services.

Extract the installation package by following the instructions in Installing the client management service by using a graphical wizard.

About this task

You must install the client management service on the same computer as the backup-archive client.

The input directory, which is in the directory where the installation package is extracted, contains the following sample response file:

install_response_sample.xml

You can use the sample file with the default values, or you can customize it.

Tip: If you want to customize the sample file, create a copy of the sample file, rename it, and edit the copy.

Procedure

1. Create a response file based on the sample file, or use the sample file, install_response_sample.xml.
   In either case, ensure that the response file specifies the port number for the client management service. The default port is 9028. For example:

   ```
   <variable name='port' value='9028'/>
   ```

2. Run the command to install the client management service and accept the license. From the directory where the installation package file is extracted, issue the following command, where *response_file* represents the response file path, including the file name:
   On a Linux client system:

   ```
   ./install.sh -s -input response_file -acceptLicense
   ```

   For example:

   ```
   ./install.sh -s -input /cms_install/input/install_response.xml -acceptLicense
   ```

   On a Windows client system:

   ```
   install.bat -s -input response_file -acceptLicense
   ```

   For example:

```
install.bat -s -input c:\cms_install\input\install_response.xml -acceptLicense
```

What to do next

Follow the instructions in Verifying that the client management service is installed correctly.

AIX | Linux | Windows

Verifying that the client management service is installed correctly

Before you use the client management service to collect diagnostic information about a backup-archive client, you can verify that the client management service is correctly installed and configured.

Procedure

On the client system, at the command line, run the following commands to view the configuration of the client management service:

- On Linux client systems, issue the following command:

  ```
  client_install_dir/cms/bin/CmsConfig.sh list
  ```

  where *client_install_dir* is the directory where the backup-archive client is installed. For example, with the default client installation, issue the following command:

  ```
  /opt/tivoli/tsm/cms/bin/CmsConfig.sh list
  ```

  The output is similar to the following text:

  ```
  Listing CMS configuration

  server1.example.com:1500 NO_SSL HOSTNAME
  Capabilities: [LOG_QUERY]
      Opt Path: /opt/tivoli/tsm/client/ba/bin/dsm.sys

      Log File: /opt/tivoli/tsm/client/ba/bin/dsmerror.log
          en_US MM/dd/yyyy HH:mm:ss Windows-1252

      Log File: /opt/tivoli/tsm/client/ba/bin/dsmsched.log
          en_US MM/dd/yyyy HH:mm:ss Windows-1252
  ```

- On Windows client systems, issue the following command:

  ```
  client_install_dir\cms\bin\CmsConfig.bat list
  ```

  where *client_install_dir* is the directory where the backup-archive client is installed. For example, with the default client installation, issue the following command:

  ```
  C:\"Program Files"\Tivoli\TSM\cms\bin\CmsConfig.bat list
  ```

  The output is similar to the following text:

  ```
  Listing CMS configuration

  server1.example.com:1500 NO_SSL HOSTNAME
  Capabilities: [LOG_QUERY]
      Opt Path: C:\Program Files\Tivoli\TSM\baclient\dsm.opt

      Log File: C:\Program Files\Tivoli\TSM\baclient\dsmerror.log
          en_US MM/dd/yyyy HH:mm:ss Windows-1252

      Log File: C:\Program Files\Tivoli\TSM\baclient\dsmsched.log
          en_US MM/dd/yyyy HH:mm:ss Windows-1252
  ```

If the client management service is correctly installed and configured, the output displays the location of the error log file. The output text is extracted from the following configuration file:

- On Linux client systems:

  ```
  client_install_dir/cms/Liberty/usr/servers/cmsServer/client-configuration.xml
  ```

- On Windows client systems:

  client_install_dir\cms\Liberty\usr\servers\cmsServer\client-configuration.xml

If the output does not contain any entries, you must configure the client-configuration.xml file. For instructions about how to configure this file, see Configuring the client management service for custom client installations. You can use the CmsConfig verify command to verify that a node definition is correctly created in the client-configuration.xml file.

AIX | Linux | Windows

Configuring the Operations Center to use the client management service

If you did not use the default configuration for the client management service, you must configure the Operations Center to access the client management service.

Before you begin

Ensure that the client management service is installed and started on the client system.

Verify whether the default configuration is used. The default configuration is not used if either of the following conditions is met:

- The client management service does not use the default port number, 9028.
- The backup-archive client is not accessed by the same IP address as the client system where the backup-archive client is installed. For example, a different IP address might be used in the following situations:
  - The computer system has two network cards. The backup-archive client is configured to communicate on one network, while the client management service communicates on the other network.
  - The client system is configured with the Dynamic Host Configuration Protocol (DHCP). As a result, the client system is dynamically assigned an IP address, which is saved on the IBM Spectrum Protect™ server during the previous backup-archive client operation. When the client system is restarted, the client system might be assigned a different IP address. To ensure that the Operations Center can always find the client system, you specify a fully qualified domain name.

Procedure

To configure the Operations Center to use the client management service, complete the following steps:

1. On the Clients page of the Operations Center, select the client.
2. Click Details.
3. Click the Properties tab.
4. In the Remote diagnostics URL field in the General section, specify the URL for the client management service on the client system.

   The address must start with `https`. The following table shows examples of the remote diagnostics URL.

Type of URL	Example
With DNS host name and default port, 9028	`https://server.example.com`
With DNS host name and non-default port	`https://server.example.com:1599`
With IP address and non-default port	`https://192.0.2.0:1599`

5. Click Save.

What to do next

You can access client diagnostic information such as client log files from the Diagnosis tab in the Operations Center.

AIX | Linux | Windows

Starting and stopping the client management service

The client management service is automatically started after it is installed on the client system. You might need to stop and start the service in certain situations.

Procedure

- To stop, start, or restart the client management service on Linux client systems, issue the following commands:
  - To stop the service:

    ```
    service cms.rc stop
    ```

  - To start the service:

    ```
    service cms.rc start
    ```

  - To restart the service:

    ```
    service cms.rc restart
    ```

- On Windows client systems, open the Services window, and stop, start, or restart the IBM Spectrum Protect™ Client Management Services service.

AIX | Linux | Windows

Uninstalling the client management service

If you no longer have to collect client diagnostic information, you can uninstall the client management service from the client system.

About this task

You must use IBM® Installation Manager to uninstall the client management service. If you no longer plan to use IBM Installation Manager, you can also uninstall it.

Procedure

1. Uninstall the client management service from the client system:
   a. Open IBM Installation Manager:
      - On the Linux client system, in the directory where IBM Installation Manager is installed, go to the eclipse subdirectory (for example, /opt/IBM/InstallationManager/eclipse), and issue the following command:

        ```
        ./IBMIM
        ```

      - On the Windows client system, open IBM Installation Manager from the Start menu.

   b. Click Uninstall.
   c. Select IBM Spectrum Protect Client Management Services, and click Next.
   d. Click Uninstall, and then click Finish.
   e. Close the IBM Installation Manager window.
2. If you no longer require IBM Installation Manager, uninstall it from the client system:
   a. Open the IBM Installation Manager uninstall wizard:
      - On the Linux client system, change to the IBM Installation Manager uninstallation directory (for example, /var/ibm/InstallationManager/uninstall), and issue the following command:

        ```
        ./uninstall
        ```

      - On the Windows client system, click Start > Control Panel. Then, click Uninstall a program > IBM Installation Manager > Uninstall.

   b. In the IBM Installation Manager window, select IBM Installation Manager if it is not already selected, and click Next.
   c. Click Uninstall, and click Finish.

AIX | Linux | Windows

Configuring the client management service for custom client installations

The client management service uses information in the client configuration file (client-configuration.xml) to discover diagnostic information. If the client management service is unable to discover the location of log files, you must run the CmsConfig utility to add the location of the log files to the client-configuration.xml file.

- CmsConfig utility
  If you are not using the default client configuration, you can run the CmsConfig utility on the client system to discover and add the location of the client log files to the client-configuration.xml file. After you complete the configuration, the client management service can access the client log files and make them available for basic diagnostic functions in the Operations Center.

AIX Linux

Troubleshooting the Operations Center installation

If a problem occurs with the Operations Center installation and you cannot solve it, you can consult the descriptions of known problems for a possible solution.

- AIX Graphical installation wizard cannot be started on an AIX system
  You are installing the Operations Center on an AIX® system by using the graphical wizard, and the installation program does not start.
- Linux Chinese, Japanese, or Korean fonts are displayed incorrectly
  Chinese, Japanese, or Korean fonts are displayed incorrectly in the Operations Center on Red Hat Enterprise Linux 5.

AIX

Graphical installation wizard cannot be started on an AIX system

You are installing the Operations Center on an AIX® system by using the graphical wizard, and the installation program does not start.

Solution

The RPM files that are listed in Installing the Operations Center by using a graphical wizard must be installed on the computer. Verify that the RPM files are installed.

Linux

Chinese, Japanese, or Korean fonts are displayed incorrectly

Chinese, Japanese, or Korean fonts are displayed incorrectly in the Operations Center on Red Hat Enterprise Linux 5.

Solution

Install the following font packages, which are available from Red Hat:

- fonts-chinese
- fonts-japanese
- fonts-korean

AIX Linux Windows

Uninstalling the Operations Center

You can uninstall the Operations Center by using any of the following methods: a graphical wizard, the command line in console mode, or silent mode.

- Uninstalling the Operations Center by using a graphical wizard
  You can uninstall the Operations Center by using the graphical wizard of IBM® Installation Manager.
- Uninstalling the Operations Center in console mode
  To uninstall the Operations Center by using the command line, you must run the uninstallation program of IBM Installation Manager from the command line with the parameter for console mode.
- Uninstalling the Operations Center in silent mode
  To uninstall the Operations Center in silent mode, you must run the uninstallation program of IBM Installation Manager from the command line with the parameters for silent mode.

AIX Linux Windows

Uninstalling the Operations Center by using a graphical wizard

You can uninstall the Operations Center by using the graphical wizard of IBM® Installation Manager.

Procedure

1. Open IBM Installation Manager.
   AIX Linux In the directory where IBM Installation Manager is installed, go to the eclipse subdirectory (for example, /opt/IBM/InstallationManager/eclipse), and issue the following command:

   ```
   ./IBMIM
   ```

   Windows You can open IBM Installation Manager from the Start menu.
2. Click Uninstall.
3. Select the option for the Operations Center, and click Next.
4. Click Uninstall.
5. Click Finish.

AIX Linux Windows

Uninstalling the Operations Center in console mode

To uninstall the Operations Center by using the command line, you must run the uninstallation program of IBM® Installation Manager from the command line with the parameter for console mode.

Procedure

1. In the directory where IBM Installation Manager is installed, go to the following subdirectory:
   - AIX Linux eclipse/tools
   - Windows eclipse\tools

   For example:

   - AIX Linux /opt/IBM/InstallationManager/eclipse/tools
   - Windows C:\Program Files\IBM\Installation Manager\eclipse\tools
2. From the tools directory, issue the following command:
   - AIX Linux `./imcl -c`
   - Windows `imcl.exe -c`
3. To uninstall, enter `5`.
4. Choose to uninstall from the IBM Spectrum Protect™ package group.
5. Enter `N` for Next.
6. Choose to uninstall the Operations Center package.
7. Enter `N` for Next.
8. Enter `U` for Uninstall.
9. Enter `F` for Finish.

AIX Linux Windows

Uninstalling the Operations Center in silent mode

To uninstall the Operations Center in silent mode, you must run the uninstallation program of IBM® Installation Manager from the command line with the parameters for silent mode.

Before you begin

You can use a response file to provide data input to silently uninstall the Operations Center server. IBM Spectrum Protect™ includes a sample response file, uninstall_response_sample.xml, in the input directory where the installation package is extracted. This file contains default values to help you avoid any unnecessary warnings.

To uninstall the Operations Center, leave `modify="false"` set for the Operations Center entry in the response file.

If you want to customize the response file, you can modify the options that are in the file. For information about response files, see Response files.

Procedure

1. In the directory where IBM Installation Manager is installed, go to the following subdirectory:
   - AIX Linux eclipse/tools
   - Windows eclipse\tools

   For example:

   - AIX Linux /opt/IBM/InstallationManager/eclipse/tools
   - Windows C:\Program Files\IBM\Installation Manager\eclipse\tools
2. From the tools directory, issue the following command, where *response_file* represents the response file path, including the file name:
   - AIX Linux `./imcl -input response_file -silent`
   - Windows `imcl.exe -input response_file -silent`

   The following command is an example:
   - AIX Linux `./imcl -input /tmp/input/uninstall_response.xml -silent`
   - Windows `imcl.exe -input C:\tmp\input\uninstall_response.xml -silent`

AIX Linux Windows

Rolling back to a previous version of the Operations Center

By default, IBM® Installation Manager saves earlier versions of a package to roll back to if you experience a problem with later versions of updates, fixes, or packages.

Before you begin

The rollback function is available only after the Operations Center is updated.

About this task

When IBM Installation Manager rolls back a package to a previous version, the current version of the package files is uninstalled, and an earlier version is reinstalled.

To roll back to a previous version, IBM Installation Manager must access files for that version. By default, these files are saved during each successive installation. Because the number of saved files increases with each installed version, you might want to delete these files from your system on a regular schedule. However, if you delete the files, you cannot roll back to a previous version.

To delete saved files or to update your preference for saving these files in future installations, complete the following steps:

1. In IBM Installation Manager, click File > Preferences.
2. On the Preferences page, click Files for Rollback, and specify your preference.

Procedure

To roll back to a previous version of the Operations Center, use the Roll Back function of IBM Installation Manager.

Configuring servers

To complete configuration tasks for the IBM Spectrum Protect™ server, review available documentation.

About this task

For an existing solution, review the following actions.

To plan, implement, monitor, and operate a new solution, follow the instructions in IBM Spectrum Protect data protection solutions.

Tip: Beginning with IBM Spectrum Protect V7.1.3, the *Administrator's Guide* is obsoleted.

Action	Details	Documentation
Monitor a storage solution	Monitor the storage solution to identify existing and potential issues. In this way, you can troubleshoot problems and optimize system performance.	Monitoring storage solutions
Select and configure storage	Select storage based on your business needs and then complete the tasks for configuration.	Configuring storage
Eliminate duplicate data	Use data deduplication to eliminate redundant data in storage pools. Data deduplication reduces the storage that is required to retain the data. Only one instance of the data is retained in a deduplicated storage pool. With IBM Spectrum Protect V7.1.3 and later, you can use inline data deduplication.	To learn more about the differences between inline and post-process data deduplication and to configure the best practice solution for data deduplication, see Data deduplication options.
Replicate data	You can replicate client node data from a source replication server to a target replication server. If a disaster occurs and the source server is temporarily unavailable, client nodes can recover their data from the target replication server.	To implement a best practice solution that uses IBM Spectrum Protect replication and automatic failover, see Multisite disk solution. For general information about replication, including configuration steps, see Replicating client data to another server.
Manage the database and recovery log	The database and recovery log, or server inventory, store information about client data and are critical to the operation of the server.	• For general information about the database and recovery log, see: Managing the database and recovery log (V7.1.1). • To optimize index and table reorganization for the server database, and prevent and resolve issues that are related to database growth and performance issues, see technote 1683633.
Secure the server	Secure the IBM Spectrum Protect server and data by controlling access to servers and client nodes, encrypting data, and maintaining secure access levels and passwords.	Securing the IBM Spectrum Protect server
Configure SSL for Lightweight Directory Access Protocol (LDAP)	You can configure SSL for LDAP directory servers and manage passwords and logon procedures.	For information about LDAP, see: • Authenticating users by using an LDAP server • Configuring SSL or TLS for LDAP directory servers (V7.1.1)

Action	Details	Documentation
Learn about and configure policies for data retention	IBM Spectrum Protect policies define the rules for managing your data.	To update policies, use the Operations Center. To learn more about policies and create policies, see Customizing policies.
Protect the server and recover in a disaster	Protect your system infrastructure and data so that you can recover from a disaster. Use the tools and procedures that IBM Spectrum Protect provides to help you create a disaster plan.	For information about protecting and recovering the server, see: • Protecting the database and infrastructure setup files (V7.1.1) • Using disaster recovery manager for tape environments (V7.1.1)
Protect NAS file servers	You can plan, configure, and manage a backup environment that protects your network-attached storage (NAS) file server.	Protecting NAS file servers
Configure a clustered environment	Configure a clustered environment on AIX®, Linux, or Windows to ensure higher server availability and minimized downtime.	Configuring clustered environments
Verify license compliance	Verify that your IBM Spectrum Protect solution complies with the provisions of your licensing agreement. By verifying compliance regularly, you can track trends in data growth or processor value unit (PVU) usage.	Verifying license compliance

- Securing the IBM Spectrum Protect server
  Secure the IBM Spectrum Protect server and data by controlling access to servers and client nodes, encrypting data, and maintaining secure access levels and passwords.
- Replicating client data to another server
  Replicating client data from a source server to another server helps to ensure that backed-up client data is available for recovery if the source server is damaged. Replication incrementally copies data from the source server to the target server to provide failover and failback capability.
- Configuring clustered environments
  You can configure the IBM Spectrum Protect server for clustering on AIX, Linux, or Windows systems.

Securing the IBM Spectrum Protect server

Secure the IBM Spectrum Protect™ server and data by controlling access to servers and client nodes, encrypting data, and maintaining secure access levels and passwords.

- Security concepts
  You can protect IBM Spectrum Protect from security risks by using communication protocols, securing passwords, and providing different access levels for administrators.
- Managing administrators
  An administrator who has system authority can complete any task with the IBM Spectrum Protect server, including assigning authority levels to other administrators. To complete some tasks, you must be granted authority by being assigned one or more authority levels.
- Changing password requirements
  You can change the minimum password limit, password length, password expiration, and enable or disable authentication for IBM Spectrum Protect.
- Securing IBM Spectrum Protect on the system
  Protect the system where the IBM Spectrum Protect server runs to prevent unauthorized access.

- Securing communications
  Your data and passwords are more secure when you protect them by using Secure Sockets Layer (SSL) or Transport Layer Security (TLS), a form of SSL.
- Authenticating IBM Spectrum Protect users by using an LDAP server
  Within an IBM Spectrum Protect system, users must authenticate to the server by providing a user ID and password. If your organization uses a Lightweight Directory Access Protocol (LDAP) server to manage user IDs, you can use the LDAP server to authenticate IBM Spectrum Protect user IDs.

Security concepts

You can protect IBM Spectrum Protect™ from security risks by using communication protocols, securing passwords, and providing different access levels for administrators.

Transport Layer Security

You can use the Secure Sockets Layer (SSL) or the Transport Layer Security (TLS) protocol to provide transport layer security for a secure connection between servers, clients, and storage agents. If you send data between the server, client, and storage agent, use SSL or TLS to encrypt the data.

Tip: Any IBM Spectrum Protect documentation that indicates "SSL" or to "select SSL" applies to TLS.

SSL is provided by the Global Security Kit (GSKit) that is installed with the IBM Spectrum Protect server that the server, client, and storage agent use.

Restriction: Do not use the SSL or TLS protocols for communications with a DB2® database instance that is used by any IBM Spectrum Protect servers.

Each server, client, or storage agent that enables SSL must use a trusted self-signed certificate or obtain a unique certificate that is signed by a certificate authority (CA). You can use your own certificates or purchase certificates from a CA. Either certificate must be installed and added to the key database on the IBM Spectrum Protect server, client, or storage agent. The certificate is verified by the SSL client or server that requests or initiates the SSL communication. Some CA certificates are preinstalled in the key databases, by default.

SSL is set up independently on the IBM Spectrum Protect server, client, and storage agent.

Authority levels

With each IBM Spectrum Protect server, different administrative authority levels are available that determine the tasks that an administrator can complete.

After registration, an administrator must be granted authority by being assigned one or more administrative authority levels. An administrator with system authority can complete any task with the server and assign authority levels to other administrators by using the GRANT AUTHORITY command. Administrators with policy, storage, or operator authority can complete subsets of tasks.

An administrator can register other administrator IDs, grant levels of authority to them, rename IDs, remove IDs, and lock and unlock them from the server.

An administrator can control access to specific client nodes for root user IDs and non-root user IDs. By default, a non-root user ID cannot back up data on the node. Use the UPDATE NODE command to change the node settings to enable backup.

Passwords

By default, the server automatically uses password authentication. With password authentication, all users must enter a password when they access the server.

Use Lightweight Directory Access Protocol (LDAP) to apply stricter requirements for passwords. For more information, see Authenticating users by using an LDAP server.

Table 1. Password authentication characteristics

Characteristic	More information
Case-sensitivity	Not case-sensitive.

Characteristic	More information
Default password expiration	90 days. The expiration period begins when an administrator ID or client node is first registered to the server. If the password is not changed within this period, the password must be changed the next time that the user accesses the server.
Invalid password attempts	You can set a limit on consecutive invalid password attempts for all client nodes. When the limit is exceeded, the server locks the node.
Password length	The administrator can specify a minimum length.

Session security

Session security is the level of security that is used for communication among IBM Spectrum Protect client nodes, administrative clients, and servers and is set by using the SESSIONSECURITY parameter.

The SESSIONSECURITY parameter can be set to one of the following values:

- The STRICT value enforces the highest level of security for communication between IBM Spectrum Protect servers, nodes, and administrators.
- The TRANSITIONAL value specifies that the existing communication protocol is used while you update your IBM Spectrum Protect software to V8.1.2 or later. This is the default. When SESSIONSECURITY=TRANSITIONAL, stricter security settings are automatically enforced as higher versions of the TLS protocol are used and as the software is updated to V8.1.2 or later. After a node, administrator, or server meets the requirements for the STRICT value, session security is automatically updated to the STRICT value, and the entity can no longer authenticate by using a previous version of the client or earlier TLS protocols.

For more information about the SESSIONSECURITY parameter values, see the following commands.

Table 2. Commands used to set the SESSIONSECURITY parameter

Entity	Command
Client nodes	• REGISTER NODE • UPDATE NODE
Administrators	• REGISTER ADMIN • UPDATE ADMIN
Servers	• DEFINE SERVER • UPDATE SERVER

Administrators that authenticate by using the DSMADMC command, DSMC command, or dsm program cannot authenticate by using an earlier version after authenticating by using V8.1.2 or later. To resolve authentication issues for administrators, see the following tips:
Tips:

- Ensure that all IBM Spectrum Protect software that the administrator account uses to log on is upgraded to V8.1.2 or later. If an administrator account logs on from multiple systems, ensure that the server's certificate is installed on each system.
- After an administrator authenticates to a V8.1.2 or later server by using a V8.1.2 or later client, the administrator can authenticate only on clients or servers that are using V8.1.2 or later. An administrator command can be issued from any system.
- If necessary, create a separate administrator account to use only with clients and servers that are using V8.1.1 or earlier software.

Enforce the highest level of security for communication with the IBM Spectrum Protect server by ensuring that all nodes, administrators, and servers use STRICT session security. You can use the SELECT command to determine which servers, nodes, and administrators are using TRANSITIONAL session security and should be updated to use STRICT session security.

Related reference:
Securing communications
SELECT (Perform an SQL query of the database)

Managing administrators

An administrator who has system authority can complete any task with the IBM Spectrum Protect™ server, including assigning authority levels to other administrators. To complete some tasks, you must be granted authority by being assigned one or more authority levels.

Procedure

Complete the following tasks to modify administrator settings.

Task	Procedure
Add an administrator.	To add an administrator, ADMIN1, with system authority and specify a password, complete the following steps: a. Register the administrator and specify Pa$#$twO as the password by issuing the following command: `register admin admin1 Pa$#$twO` b. Grant system authority to the administrator by issuing the following command: `grant authority admin1 classes=system`
Change administrative authority.	Change the authority level for an administrator, ADMIN1. • Grant system authority to the administrator by issuing the following command: `grant authority admin1 classes=system` • Revoke system authority for the administrator by issuing the following command: `revoke authority admin1 classes=system`
Remove administrators.	Remove an administrator, ADMIN1, from accessing the IBM Spectrum Protect server by issuing the following command: `remove admin admin1`
Temporarily prevent access to the server.	Lock or unlock an administrator by using the LOCK ADMIN or UNLOCK ADMIN command.

Changing password requirements

You can change the minimum password limit, password length, password expiration, and enable or disable authentication for IBM Spectrum Protect™.

About this task

By enforcing password authentication and managing password restrictions, you protect your data and your servers from potential security risks.

Procedure

Complete the following tasks to change password requirements for IBM Spectrum Protect servers.

Table 1. Authentication tasks for IBM Spectrum Protect servers

Task	Procedure
Set a limit for invalid password attempts.	a. On the Servers page in the Operations Center, select the server. b. Click Details, and then click the Properties tab. c. Set the number of invalid attempts in the Invalid sign-on attempt limit field. The default value at installation is 0.
Set a minimum length for passwords.	a. On the Servers page in the Operations Center, select the server. b. Click Details and then click the Properties tab. c. Set the number of characters in the Minimum password length field.
Set the expiration period for passwords.	a. On the Servers page in the Operations Center, select the server. b. Click Details and then click the Properties tab. c. Set the number of days in the Password common expiration field.
Disable password authentication.	By default, the server automatically uses password authentication. With password authentication, all users must enter a password to access the server. You can disable password authentication only for passwords that authenticate with the server (LOCAL). By disabling password authentication, you increase the security risk for the server.
Set a default authentication method.	Issue the SET DEFAULTAUTHENTICATION command. For example, to use the server as the default authentication method, issue the following command: `set defaultauthentication local` To update one client node to authenticate with the server, include `AUTHENTICATION=LOCAL` in the UPDATE NODE command: `update node authentication=local`

Securing IBM Spectrum Protect on the system

Protect the system where the IBM Spectrum Protect™ server runs to prevent unauthorized access.

Procedure

Ensure that unauthorized users cannot access the directories for the server database and the server instance. Keep the access settings for these directories that you configured during implementation.

- Restricting user access to the server
  Authority levels determine what an administrator can do with the IBM Spectrum Protect server. An administrator with system authority can complete any task with the server. Administrators with policy, storage, or operator authority can complete subsets of tasks.
- Limiting access through port restrictions
  Limit access to the server by applying port restrictions.

Restricting user access to the server

Authority levels determine what an administrator can do with the IBM Spectrum Protect™ server. An administrator with system authority can complete any task with the server. Administrators with policy, storage, or operator authority can complete subsets of tasks.

Procedure

1. After you register an administrator by using the REGISTER ADMIN command, use the GRANT AUTHORITY command to set the administrator's authority level. For details about setting and changing authority, see Managing administrators.
2. To control the authority of an administrator to complete some tasks, use the following two server options:
   a. You can select the authority level that an administrator must have to issue QUERY and SELECT commands with the QUERYAUTH server option. By default, no authority level is required. You can change the requirement to one of the authority levels, including system.
   b. You can specify that system authority is required for commands that cause the server to write to an external file with the REQSYSAUTHOUTFILE server option. By default, system authority is required for such commands.
3. You can restrict data backup on a client node to only root user IDs or authorized users. For example, to limit backups to the root user ID, issue the REGISTER NODE or UPDATE NODE command and specify the BACKUPINITIATION=root parameter:

```
update node backupinitiation=root
```

Limiting access through port restrictions

Limit access to the server by applying port restrictions.

About this task

You might have to restrict access to specific servers, based on your security requirements. The IBM Spectrum Protect™ server can be configured to listen on four TCP/IP ports: two that can be used for either regular TCP/IP protocols or Secure Sockets Layer (SSL)/Transport Layer Security (TLS) protocols and two that can be used only for the SSL/TLS protocol.

Procedure

You can set the server options to specify the port that you require, as listed in Table 1.

Table 1. Server options and port access

Server option	Port access
TCPPORT	Specifies the port number on which the server TCP/IP communication driver is to wait for requests for client sessions. This port listens for both TCP/IP and SSL-enabled sessions. The default value is 1500.
TCPADMINPORT	Specifies the port number on which the server TCP/IP communication driver is to wait for requests for sessions other than client sessions. This port listens for both TCP/IP and SSL-enabled sessions. The default is the value of TCPPORT. Use this option to separate administrative client traffic from regular client traffic that uses the TCPPORT and SSLTCPPORT options.
SSLTCPPORT	Specifies the SSL TCP/IP port address for a server. This port listens for SSL-enabled sessions only. A default port value is not available.
SSLTCPADMINPORT	Specifies the port address on which the server TCP/IP communication driver waits for requests for SSL-enabled sessions. A default port value is not available. Use this option to separate administrative client traffic from regular client traffic that uses the TCPPORT and SSLTCPPORT options.

Securing communications

Your data and passwords are more secure when you protect them by using Secure Sockets Layer (SSL) or Transport Layer Security (TLS), a form of SSL.

SSL and TLS are the standard technology for creating encrypted sessions between servers and clients. SSL and TLS provide a secure channel for servers and clients to communicate over open communication paths. With SSL and TLS, the identity of the

server is verified by using digital certificates. Clients, servers, and storage agents that are using IBM Spectrum Protect™ V8.1.2 or later software to communicate are automatically configured to use TLS 1.2.

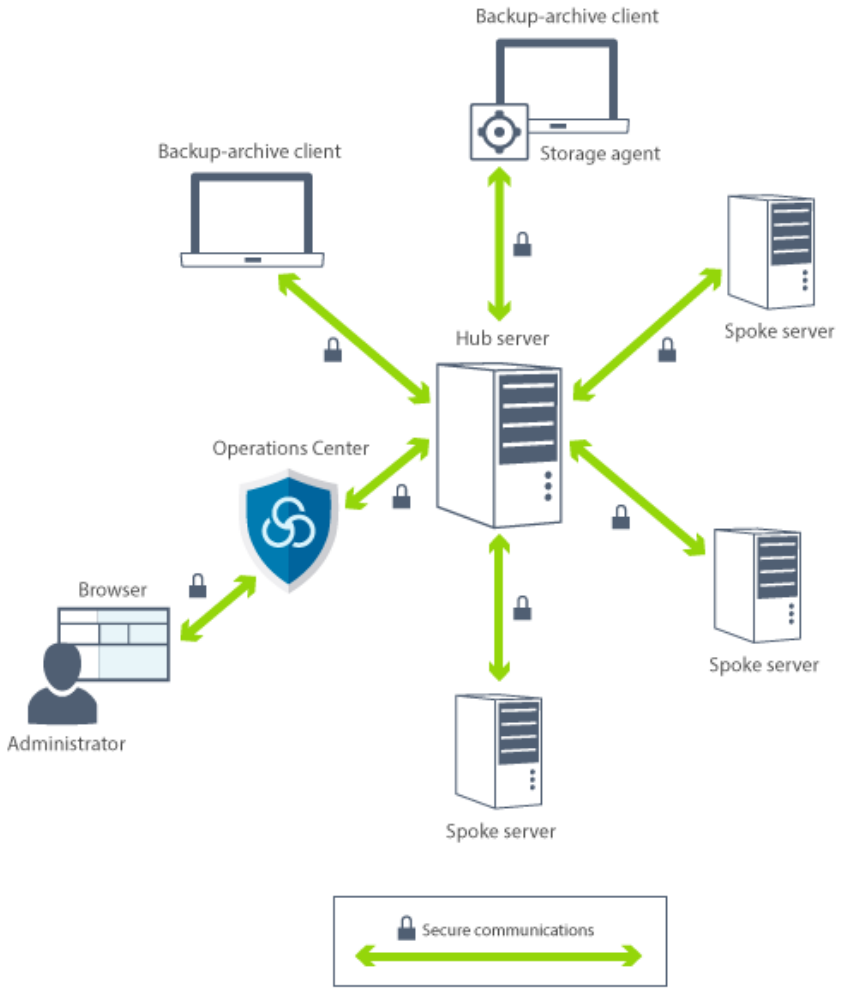
To improve system performance, use TLS for authentication without encrypting object data. To specify whether the server uses TLS 1.2 for the entire session or only for authentication, see the SSL client option for client-to-server communication, and the SSL parameter in the UPDATE SERVER command for server-to-server communication. If you choose to use TLS to encrypt object data, consider adding more processor resources on the IBM Spectrum Protect server to manage the increased network traffic.

If you authenticate passwords with an LDAP directory server, TLS protects passwords between the IBM Spectrum Protect server and the LDAP server. TLS is required for all LDAP password communications.

- Secure Sockets Layer and Transport Layer Security communication
  The Secure Sockets Layer (SSL) or the Transport Layer Security (TLS) protocol is used to provide transport layer security for a secure connection between IBM Spectrum Protect servers, clients, storage agents, and the Operations Center. If you send data between the server, client, and storage agent, SSL or TLS is used to encrypt the data.
- Configuring storage agents, servers, clients, and the Operations Center to connect to the server by using SSL
  Configure Secure Sockets Layer (SSL) on the IBM Spectrum Protect server, backup-archive client, storage agent, and the Operations Center to ensure that data is encrypted during communication.

Secure Sockets Layer and Transport Layer Security communication

The Secure Sockets Layer (SSL) or the Transport Layer Security (TLS) protocol is used to provide transport layer security for a secure connection between IBM Spectrum Protect™ servers, clients, storage agents, and the Operations Center. If you send data between the server, client, and storage agent, SSL or TLS is used to encrypt the data.



Restriction: Do not use the SSL or TLS protocols for communications with an IBM DB2 database instance that is used by the IBM Spectrum Protect server.

Each server or storage agent has a unique private key and a unique signed certificate that is used to allow SSL connections. If you use self-signed certificates, you must distribute the self-signed certificate for each server or storage agent to all the clients, storage agents, and servers that use TLS to communicate with it. If you use certificates that are signed by a certificate authority (CA), you must distribute only the CA certificates to all the clients, storage agents, and servers that use TLS to communicate.

If you use a root certificate from a CA, you must install it on each key database for the client, server, and storage agent that initiates SSL communication. A *root certificate* is a certificate that identifies the Root Certificate Authority. The certificate is verified by the SSL client or server that requests or initiates the SSL communication.

Beginning with IBM Spectrum Protect Version 8.1.2, SSL is enabled by default for communications among V8.1.2 servers, clients, and storage agents.

The IBM Spectrum Protect server, client, or storage agent can serve as SSL clients during communication. An SSL client is the component that initiates communication and verifies the certificate for an SSL server. For example, if the IBM Spectrum Protect client initiates the SSL communication with the IBM Spectrum Protect server, the IBM Spectrum Protect client is the SSL client and the server is the SSL server.

Table 1 lists the components that can be an SSL client or SSL server.

Table 1. SSL clients and servers in the IBM Spectrum Protect environment

SSL client	SSL server	Scenario
Client	Server	The IBM Spectrum Protect client initiates a communication request with the IBM Spectrum Protect server. The client verifies the certificate. The server provides the certificate.
Server (such as a source server)	Server (such as a target server)	The IBM Spectrum Protect source server initiates a communication request with the IBM Spectrum Protect target server. The source server acts as an SSL client and verifies the certificate that the target server provides. This type of communication is common during replication processing.
Client through a storage agent	Server	The client verifies each certificate when it initiates SSL communication separately with the IBM Spectrum Protect server and the storage agent. When the storage agent communicates with the server by using the SSL communication protocol, the storage agent acts as an SSL client and verifies the certificate that the server provides. The storage agent can be the SSL client and the SSL provider at the same time.
Server	LDAP server	The IBM Spectrum Protect server initiates a communication request with the LDAP server. The IBM Spectrum Protect server acts as the SSL client and verifies the certificate that the LDAP server provides.
Operations Center	Server	The Operations Center initiates a communication request with the IBM Spectrum Protect server. The Operations Center acts as the SSL client and verifies the certificate that the IBM Spectrum Protect server provides.
Reporting	Server	The reporting agent initiates a communication request with the IBM Spectrum Protect server. The Reporting feature acts as the SSL client and verifies the certificate that the IBM Spectrum Protect server provides.

Configuring storage agents, servers, clients, and the Operations Center to connect to the server by using SSL

Configure Secure Sockets Layer (SSL) on the IBM Spectrum Protect™ server, backup-archive client, storage agent, and the Operations Center to ensure that data is encrypted during communication.

You can use a self-signed SSL certificate or a signed certificate from a third-party certificate authority (CA) to verify an SSL communication request between the server, client, and storage agent. Each IBM Spectrum Protect server, client, or storage agent that enables SSL must use a trusted self-signed certificate or obtain a unique certificate that is signed by a CA.

The benefit of CA-signed certificates is that a single CA-signed certificate can be used for all servers, which allows you to distribute a single certificate to clients. If you use a self-signed certificate, the certificate is automatically created for each server and storage agent. If you use a root certificate from a CA, it must be installed on each key database for the client, server, and

storage agent that initiates SSL communication. The certificate is verified by the SSL client or server that requests or initiates the SSL communication.

Restriction: Some CAs use certificates in a format that is not recognized by IBM Spectrum Protect. You might have to contact your CA to convert the certificate to a format that you can use with IBM Spectrum Protect.

- Configuring the server to accept SSL connections
  Configure the server to accept SSL connections before you enable SSL communication from the server to a client, a storage agent, or another server.
- Configuring a storage agent to use SSL
  To ensure that data is encrypted for communication between the storage agent and the server and the storage agent and the client, configure the storage agents to communicate by using the SSL protocol.
- Configuring the client to connect to a storage agent by using SSL
  To protect the data that is transmitted between a client and storage agent, configure the client to connect to the storage agent by using the SSL protocol.

Configuring the server to accept SSL connections

Configure the server to accept SSL connections before you enable SSL communication from the server to a client, a storage agent, or another server.

Procedure

1. Specify the port on which the server waits for client communications that are enabled for SSL or accept the default port number. Optionally, update the dsmserv.opt file in the server instance directory by specifying the TCPPORT or TCPADMINPORT options, or both. The SSLTCPPORT and SSLTCPADMINPORT options can be used for SSL-only connections.
2. Create the server key database by starting the server. The server key database file, cert.kdb, is stored in the server instance directory, and the default certificate label is automatically set as "TSM Server SelfSigned SHA Key". The certificate is exported to the cert256.arm file.
3. If you are using the default self-signed certificate, the default self-signed certificate (cert256.arm) file is needed when you connect to the server by using TLS.
4. If you are importing a CA signed certificate, complete the following steps:
   a. Import a unique certificate that is signed by a CA on each server that enables SSL. You can import both a root and intermediate CA signed certificate. The same CA-signed certificate is used for each server. Log on to the IBM Spectrum Protect™ server system with the instance user ID and issue the following example command from the instance directory:

      ```
      gsk8capicmd_64 -cert -add -db cert.kdb -stashed -label "CA cert" -file ca.crt
      ```

   b. To import an intermediate CA signed certificate, issue the following example command:

      ```
      gsk8capicmd_64 -cert -add -db cert.kdb -stashed
      -label "Intermediate CA cert" -file intca.crt
      ```

   c. The root and intermediate certificates (ca.crt and intca.crt) are needed when you connect the server by using TLS.
   d. On the server, create a certificate request for the CA to sign by issuing a command that is similar to the following example:

      ```
      gsk8capicmd_64 -certreq -create -db cert.kdb -stashed -label "CA cert"
      -sigalg sha256 -size 2048 -ku "digitalSignature,keyEncipherment,keyAgreement"
      -eku "clientAuth,serverAuth" -dn "CN=tucson.example.com,OU=Spectrum Protect,O=IBM"
      -san_dnsname tucson.example.com -san_ipaddr 9.11.0.0 -file cert_request.csr
      ```

   e. To receive the signed certificate and make it the default for communicating with clients, issue the following example command:

      ```
      gsk8capicmd_64 -cert -receive -db cert.kdb -stashed -file cert_signed.crt
      -default_cert yes
      ```

5. If you made any changes, restart the server.

What to do next

Enable SSL communication from a client, a storage agent, or another server to this server. To complete the following tasks, you must have the server's certificate and the port number that is defined for the server.

1. To enable SSL communication from a client to this server, see Configuring IBM Spectrum Protect client/server communication with Secure Sockets Layer.
2. To enable SSL communication from another server to this server, see Configuring the server to connect to another server by using SSL.
3. To enable SSL communication from a storage agent to this server, see Configuring a storage agent to use SSL.
4. To enable SSL communication from the Operations Center to this server, see Configuring the Operations Center to connect to the hub server by using SSL.

- Configuring clients to communicate with the server by using SSL
  To ensure that data is encrypted during client/server communication, configure clients to communicate with the server by using the SSL protocol.
- Configuring the server to connect to another server by using SSL
  To ensure that data is encrypted for server-to-server communication, configure servers to communicate with servers by using the SSL protocol.
- Configuring the Operations Center to connect to the hub server by using SSL
  To ensure that data is encrypted for communication between the Operations Center and the hub server, configure the Operations Center to communicate with the hub server by using the SSL protocol.

QUERY SESSION (Query client sessions)

Configuring clients to communicate with the server by using SSL

To ensure that data is encrypted during client/server communication, configure clients to communicate with the server by using the SSL protocol.

Before you begin

You must have the server's certificate and the port number that the server is using. For more information, see Configuring the server to accept SSL connections.

Procedure

To enable SSL communication between the server and clients, see Configuring IBM Spectrum Protect client/server communication with Secure Sockets Layer.

Configuring the server to connect to another server by using SSL

To ensure that data is encrypted for server-to-server communication, configure servers to communicate with servers by using the SSL protocol.

Before you begin

You must have the certificate and the port number for the server that you are connecting to. For more information, see Configuring the server to accept SSL connections.

About this task

Tip: If both servers are using IBM Spectrum Protect™ V8.1.2 or later software, SSL is automatically configured. Manual configuration is recommended but not required. If either the server or the storage agent is using IBM Spectrum Protect software earlier than V8.1.2, you must manually configure SSL.
In the procedure, the following server addresses are used as examples:

- ServerA (the server you are connecting to) is at `bfa.tucson.example.com`
- ServerB is at `bfb.tucson.example.com`

Procedure

1. Create the server key database by starting the server. The server key database file, cert.kdb, is stored in the server instance directory.
2. For each server, import the other server's cert256.arm or CA-certificate files:

   ```
   gsk8capicmd_64 -cert -add -label server_ip_address -db cert.kdb -stashed
   -file cert256.arm
   ```

   Tip: Use the IP address of the server as the label name.
3. From each server, you can view the certificates in the key database by issuing the following command:

   ```
   gsk8capicmd_64 -cert -list -db cert.kdb -stashed
   ```

4. Restart the servers.
5. Issue the DEFINE SERVER command.
   a. For ServerA, issue the following command:

      ```
      DEFINE SERVER BFB hla=bfb.tucson.example.com lla=1542
      serverpa=passwordforbfb SSL=YES
      ```

   b. For ServerB, issue the following command:

      ```
      DEFINE SERVER BFA hla=bfa.tucson.example.com lla=1542
      serverpa=passwordforbfa SSL=YES
      ```

DEFINE SERVER (Define a server for server-to-server communications)

Configuring the Operations Center to connect to the hub server by using SSL

To ensure that data is encrypted for communication between the Operations Center and the hub server, configure the Operations Center to communicate with the hub server by using the SSL protocol.

Before you begin

You must have the hub server's certificate and the port number that the server is using. For more information, see Configuring the server to accept SSL connections.

Procedure

To configure SSL communications with the Operations Center, see Securing communications between the Operations Center and the hub server.

Configuring a storage agent to use SSL

To ensure that data is encrypted for communication between the storage agent and the server and the storage agent and the client, configure the storage agents to communicate by using the SSL protocol.

Before you begin

You must have the server's certificate and the port number that the server is using. For more information, see Configuring the server to accept SSL connections.

Procedure

1. Initialize the storage agent and add communication information to the device configuration file and the storage agent options file dsmsta.opt by issuing the DSMSTA SETSTORAGESERVER command. You must specify the SSL=YES and STAKEYDBPW=password parameters to create the key database file in dsmsta.opt. All passwords are encrypted in dsmsta.opt.

```
dsmsta setstorageserver myname=storage_agent_name mypa=sta_password
myhla=ip_address servername=server_name serverpa=server_password hla=ip_address lla=ssl_port
STAKEYDBPW=password ssl=yes
```

2. Create the key database certificate and default certificates by starting the storage agent.
3. For the storage agent and the server, import the other's cert256.arm or CA-certificate files:

```
gsk8capicmd_64 -cert -add -label ip_address -db cert.kdb -stashed
-file cert256.arm
```

   Tip: Use the IP address as the label name.
4. You can view the certificates in the key database by issuing the following command:

```
gsk8capicmd_64 -cert -list -db cert.kdb -stashed
```

5. Restart the storage agent and the server.
6. Establish communication between the server and the storage agent by issuing the following command:

```
define server sta hla=ip_address lla=port serverpa=password ssl=yes
```

Authenticating IBM Spectrum Protect users by using an LDAP server

Within an IBM Spectrum Protect™ system, users must authenticate to the server by providing a user ID and password. If your organization uses a Lightweight Directory Access Protocol (LDAP) server to manage user IDs, you can use the LDAP server to authenticate IBM Spectrum Protect user IDs.

You can use one of the following methods to authenticate users with an LDAP server:

Method that is preferred for IBM Spectrum Protect V7.1.7 and later servers
: To use this method, sometimes known as *integrated mode*, user IDs must be registered in an Active Directory database on an LDAP server. Then, you register the same users with the IBM Spectrum Protect server. When a registered user ID accesses the IBM Spectrum Protect server, the credentials are authenticated against the Active Directory database.
To use this method, follow the instructions in Authenticating users by using an Active Directory database.

Method that is used for servers earlier than V7.1.7, and by IBM® Security Directory Server users
: To use this method, user IDs must be registered in an Active Directory database on an LDAP server. Alternatively, user IDs can be registered in an IBM Security Directory Server (formerly IBM Tivoli® Directory Server) database on an LDAP server.

With this method, you cannot use the standard user accounts that are registered with the LDAP server. You must create separate user accounts that are associated with a specific organizational unit. To use this method, follow the instructions in Managing passwords and logon procedures (V7.1.1).

- Authenticating users by using an Active Directory database
  You can authenticate IBM Spectrum Protect users by using an Active Directory database on a Lightweight Directory Access Protocol (LDAP) server. With this method, you use the standard user accounts that are registered with the LDAP server. The same user ID can be used to authenticate to the IBM Spectrum Protect server and to the LDAP server.

Replicating client data to another server

Replicating client data from a source server to another server helps to ensure that backed-up client data is available for recovery if the source server is damaged. Replication incrementally copies data from the source server to the target server to provide failover and failback capability.

About this task

If a disaster occurs and the source server is temporarily unavailable, client nodes can recover their data from the target server. If the source server cannot be recovered, you can change client node configurations to store data on the target server. When an outage occurs, the source server can automatically fail over to a target server for data recovery.
Restriction: A server can replicate data to only one target server.
You can replicate data that is stored in any type of storage pool. The storage pool type can be different at the source replication server and the target replication server. You can control replication by type of client node data:

- Active and inactive backup data together, or only active backup data
- Archive data
- Data that was migrated to a source server by IBM Spectrum Protect™ for Space Management clients

When you replicate data in directory-container storage pools, use storage pool protection to improve the efficiency of the replication process, and to enable repair of data. When you use the Operations Center to set up your storage pools, schedules for protection are automatically defined to coordinate with the replication schedule.

Procedure

1. Verify that servers are compatible and have the system resources for successful use of replication.

   Increased amounts of memory and processor cores are required. The database and its logs must be sized to ensure that transactions can complete. A dedicated network, with enough bandwidth to handle the amount of data you intend to replicate, is required.

   a. Verify that the source and target servers are compatible for replication. See Replication compatibility.
   b. Verify that the server has appropriate resources for good performance. For details, see Checklist for node replication.
2. Enable replication. See Enabling node replication.
3. Schedule replication for the source server. For information about how to integrate this schedule in regular server maintenance schedules, see Defining schedules for server maintenance activities.
4. Schedule storage pool protection for all directory-container storage pools on the source server. See Protecting data in directory-container storage pools.
5. Monitor replication by using the Operations Center. For more information, see Daily monitoring checklist.

- Replication compatibility
  Before you set up replication operations with IBM Spectrum Protect, you must ensure that the source and target replication servers are compatible for replication.
- Enabling node replication
  You can enable node replication to protect your data.
- Protecting data in directory-container storage pools
  Protect data in directory-container storage pools to reduce node replication time and to enable repair of data in directory-container storage pools.
- Modifying replication settings
  Modify replication settings in the Operations Center. Change settings such as the number of replication sessions, replication rules, the data that you want to replicate, the replication schedule, and the replication workload.
- Setting different retention policies for the source server and target server
  You can set policies on the target replication server that manage the replicated client-node data differently than on the

source server. For example, you can maintain a different number of versions of files on the source and the target servers.

Replication compatibility

Before you set up replication operations with IBM Spectrum Protect™, you must ensure that the source and target replication servers are compatible for replication.

Table 1. Replication compatibility of server versions

Source replication server version	Compatible versions for the target replication server
V6.3.0 - V6.3.2	V6.3.0 - V6.3.2
V6.3.3	V6.3.3 or later V6.3 levels
V6.3.4 or later V6.3 levels	V6.3.4 or later
V7.1	V7.1 or later
V7.1.1	V7.1 or later
V7.1.3	V7.1.3 or later
V7.1.4	V7.1.3 or later
V7.1.5	V7.1.3 or later
V7.1.6	V7.1.3 or later
V7.1.7	V7.1.3 or later
V8.1	V7.1.3 or later
V8.1.1	V7.1.3 or later
V8.1.2	V7.1.3 or later

Enabling node replication

You can enable node replication to protect your data.

Before you begin

Ensure that the source and target servers are compatible for replication.

About this task

Replicate the client node to replicate all client data, including metadata. By default, node replication is disabled when you start the server for the first time.
Tips:

- To reduce replication processing time, protect the storage pool before you replicate client nodes. When node replication is started, the data extents that are already replicated through storage pool protection are skipped.
- Replication requires increased amounts of memory and sufficient bandwidth to complete processing. Size the database and its logs to ensure that transactions can complete.

Procedure

To enable node replication, complete the following steps in the Operations Center:

a. On the Servers page, click Details.
b. On the Details page, click Properties.
c. In the Replication section, select Enabled in the Outbound replication field.
d. Click Save.

What to do next

Complete the following actions:

1. To verify that replication was successful, review the Daily monitoring checklist.
2. Linux If the IBM Spectrum Protect™ server replicates nodes to a remote server, determine whether Aspera® Fast Adaptive Secure Protocol (FASP®) technology can improve data throughput to the remote server. Follow the instructions in Determining whether Aspera FASP technology can optimize data transfer in your system environment.

Protecting data in directory-container storage pools

Protect data in directory-container storage pools to reduce node replication time and to enable repair of data in directory-container storage pools.

Before you begin

Ensure that at least one directory-container storage pool exists on the target replication server. When you enable replication in the Operations Center, you can schedule storage pool protection. To configure replication and enable storage pool protection, complete the following steps:

1. On the Operations Center menu bar, hover over Storage and click Replication.
2. On the Replication page, click Server Pair.
3. Complete the steps in the Add Server Pair wizard.

About this task

Protecting a directory-container storage pool backs up data extents to another storage pool, and can improve performance for node replication. When node replication is started, the data extents that are already backed up through storage pool protection are skipped, which reduces the replication processing time. You can schedule the protection of storage pools several times a day to keep up with changes to data.

By protecting a storage pool, you do not use resources that replicate existing data and metadata, which improves server performance. You must use directory-container storage pools if you want to protect and back up the storage pool only.

Alternative protection strategy: As an alternative to using replication, you can protect data in directory-container storage pools by copying the data to container-copy storage pools. Data in container-copy storage pools is stored on tape volumes. Tape copies that are stored offsite provide additional disaster recovery protection in a replicated environment.

Procedure

1. Alternatively, to enable storage pool protection, you can use the PROTECT STGPOOL command from the source server to back up data extents in a directory-container storage pool. For example, to protect a directory-container storage pool that is named POOL1 issue the following command:

   ```
   protect stgpool pool1
   ```

   As part of the operation of the PROTECT STGPOOL command, damaged extents in the target storage pool are repaired. To be repaired, extents must already be marked as damaged on the target server. For example, an AUDIT CONTAINER command might identify damage in the target storage pool before the PROTECT STGPOOL command is issued.
2. Optional: If damaged extents were repaired in the target storage pool and you protect multiple source storage pools in one target storage pool, complete the following steps to ensure a complete repair:
   a. Issue the PROTECT STGPOOL command for all source storage pools to repair as much of the damage as possible.
   b. Issue the PROTECT STGPOOL command again for all source storage pools. For this second operation, use the FORCERECONCILE=YES parameter. This step ensures that any repairs from other source pools are properly recognized for all source storage pools.

Results

If a directory-container storage pool is protected, you can repair the storage pool if damage occurs, by using the REPAIR STGPOOL command.
Restriction: If you replicate client nodes but do not protect the directory-container storage pool, you cannot repair the storage pool.

What to do next

Complete the following actions:

1. To view replication workload status, follow the instructions in the Daily monitoring checklist.
2. Linux If the IBM Spectrum Protect™ server replicates nodes to a remote server, determine whether Aspera® Fast Adaptive Secure Protocol (FASP®) technology can improve data throughput to the remote server. Follow the instructions in Determining whether Aspera FASP technology can optimize data transfer in your system environment.

Modifying replication settings

Modify replication settings in the Operations Center. Change settings such as the number of replication sessions, replication rules, the data that you want to replicate, the replication schedule, and the replication workload.

About this task

You might need to customize your replication settings in the following scenarios:

- Changes to data priorities
- Changes to replication rules
- Requirement for a different server to be the target server
- Scheduled processes that negatively affect server performance

Procedure

Use the Operations Center to modify replication settings.

Task	Procedure
Change a replication rule.	a. On the Servers page, click Details. b. On the Details page, click Properties. c. In the Replication section, choose the replication rule that you want to apply: Default archive rule, Default backup rule, or Default space-management rule. d. Click Save.
Specify the duration that replication records are retained.	a. On the Servers page, click Details. b. On the Details page, click Properties. c. In the Replication section, enter the number of days that replication records must be retained in the Retain replication history field. Alternatively, select the Do not retain check box if you do not require replication records. d. Click Save.
Specify a target replication server.	a. On the Servers page, click Details. b. On the Details page, click Properties. c. In the Replication section, specify the target server. d. Click Save.
Cancel a replication process.	a. On the Servers page, click Active tasks. b. Select the process or session that you want to cancel. c. Click Cancel.

Setting different retention policies for the source server and target server

You can set policies on the target replication server that manage the replicated client-node data differently than on the source server. For example, you can maintain a different number of versions of files on the source and the target servers.

Procedure

1. From the source replication server, validate the replication configuration and verify that the source replication server can communicate with the target replication server by issuing the VALIDATE REPLICATION command. For example, validate the configuration by using the name of one client node that is being replicated:

   ```
   validate replication node1 verifyconnection=yes
   ```

2. From the source replication server, issue the VALIDATE REPLPOLICY command to review the differences between the policies on the source and target replication servers. For example, to display the differences between the policies on the source server and the target server, CVT_SRV2, issue the following command from the source server:

   ```
   validate replpolicy cvt_srv2
   ```

3. Update the policies on the target server if necessary.
   Tip: You can use the Operations Center to modify the policies on the target server. Follow the instructions in Editing policies.
   For example, to maintain inactive versions of files for a shorter time on the target server than on the source server, reduce the Backups setting in the management classes that apply to replicated client data.
4. Enable the target replication server to use its policies to manage the replicated client-node data by issuing the SET DISSIMILARPOLICIES command on the source server. For example, to enable the policies on the target replication server, CVT_SRV2, issue the following command on the source server:

   ```
   set dissimilarpolicies cvt_srv2 on
   ```

   The next time that the replication process runs, the policies on the target replication server are used to manage the replicated client-node data.
   Tip: If you configure replication by using the Operations Center and the policies on the source and target replication servers do not match, the policy that is specified for the source replication server is used. If you enabled the policies on the target replication server by using the SET DISSIMILARPOLICIES command, the policy that is specified for the target replication server is used. If the target replication server does not have the policy that is used by the node on the source replication server, the STANDARD policy is used.

AIX | Linux | Windows

Configuring clustered environments

You can configure the IBM Spectrum Protect™ server for clustering on AIX®, Linux, or Windows systems.

You can use a clustered environment for the following operating systems:

- IBM® PowerHA® SystemMirror for AIX
- IBM Tivoli® System Automation for Multiplatforms for AIX and Linux
- Microsoft Failover Cluster for Windows

You can use other cluster products with IBM Spectrum Protect, however, documentation is not available and support is limited. For the latest information about support for clustered environments, see http://www.ibm.com/support/docview.wss?uid=swg21609772.

Before you use another cluster product, verify that DB2® supports the required file systems. For more information about the level of DB2 that you are using, see the DB2 product information, and search for recommended file systems.

- Clustered environment overview
  Clusters consist of many components such as IBM Spectrum Protect servers, hardware, and software. You can use clustering to join two or more servers or nodes by using a shared disk system.

- AIX Configuring an AIX environment for clustering
  You can configure the IBM Spectrum Protect server for AIX clustered environments by using IBM PowerHA SystemMirror for AIX or IBM Tivoli System Automation for Multiplatforms.
- Linux Configuring a Linux environment for clustering
  You can configure the IBM Spectrum Protect Linux server in a clustered environment by using IBM Tivoli System Automation for Multiplatforms Version 3.2.2.
- Windows Configuring a Windows clustered environment
  You can configure an IBM Spectrum Protect server for Windows in a Microsoft failover cluster environment. Windows cluster environments consist of components such as IBM Spectrum Protect servers, hardware, and software. When these components are connected to the same disk system, downtime is minimized.

Related information:
Upgrading the server in a clustered environment
AIX Linux Windows

Clustered environment overview

Clusters consist of many components such as IBM Spectrum Protect™ servers, hardware, and software. You can use clustering to join two or more servers or nodes by using a shared disk system.

This configuration provides the nodes with the ability to share data, which allows higher server availability and minimized downtime. For example:

- You can configure, monitor, and control applications and hardware components that are deployed on a cluster.
- You can use an administrative cluster interface and IBM Spectrum Protect to designate cluster arrangements and define a failover pattern. The server is part of the cluster that provides an extra level of security by ensuring that no transactions are missed because a server failed. The failover pattern that you establish prevents future failures.
- You can apply clustering to the node replication process. In this way, server availability is higher than it would be if node replication is used as a process on its own. Server availability is higher because a client is less likely to fail over to another server in a clustered environment. If you replicate data from several source replication servers to one target replication server, there is a high dependency on the target replication server. A clustered environment eases the dependency on the target replication server.

Components in a server cluster are known as *cluster objects*. Cluster objects are associated with a set of properties that have data values that describe the identity and behavior of an object in the cluster. Cluster objects can include the following components:

- Nodes
- Storage
- Services and applications
- Networks

You manage cluster objects by manipulating their properties, typically through a cluster management application.

- Cluster nodes
  Nodes in a cluster all have similar characteristics, which allows them to work together.

AIX

Configuring an AIX environment for clustering

You can configure the IBM Spectrum Protect™ server for AIX® clustered environments by using IBM® PowerHA® SystemMirror for AIX or IBM Tivoli® System Automation for Multiplatforms.

PowerHA SystemMirror for AIX and Tivoli System Automation detect system failures and manage failover to a recovery processor with a minimal loss of user time. You can set up the IBM Spectrum Protect server on a system in a PowerHA or a Tivoli System Automation cluster. Then, if the system fails, the IBM Spectrum Protect server can be started on another system in the cluster.

In both failover and failback, it seems that the IBM Spectrum Protect server halted and is then restarted. Any transactions that were in progress at the time of the failover or failback are rolled back, and all completed transactions are still complete. IBM Spectrum Protect clients see failover or failback as a communications failure and try to reestablish their connections.

See the following information for details about these clustering options.

- Configure IBM Spectrum Protect for AIX to use IBM PowerHA SystemMirror for AIX in a clustered environment by reviewing the following topics.
- Configure IBM Spectrum Protect for AIX to use Tivoli System Automation in a clustered environment by reviewing the information in http://www.ibm.com/support/docview.wss?uid=swg27039780.
- Learn more about PowerHA SystemMirror® product information.

- AIX Requirements for a PowerHA cluster
  IBM PowerHA SystemMirror for AIX detects system failures and manages failover to a recovery processor with a minimal loss of user time.
- AIX PowerHA failover and failback
  If a node fails, the server cluster transfers the groups that were being hosted by the node to other nodes in the cluster. This transfer process is called *failover*. The reverse process, *failback*, occurs when the failed node becomes active again and the groups that were failed over to the other nodes are transferred back to the original node.

  For PowerHA, ensure that the IBM Spectrum Protect server is not running on the production node before you set up the standby node.
- AIX Defining the removable media storage devices to AIX for PowerHA
  For an AIX operating system, you must define the removable-media storage devices that are used by IBM Spectrum Protect on the production and standby nodes. The library manager validates that the cartridge that contains the removable-media storage device is in the correct drive.
- AIX Completing the cluster manager and IBM Spectrum Protect configurations
  Update the cluster manager configuration to define the IBM Spectrum Protect server as an application and a failover resource of the standby node. This application is owned by the production node.
- AIX Troubleshooting the PowerHA clustered environment
  Review the following list for information about troubleshooting common problems. The information that is provided for IBM PowerHA SystemMirror for AIX does not represent all possible scenarios.

AIX

Requirements for a PowerHA cluster

IBM PowerHA® SystemMirror for AIX® detects system failures and manages failover to a recovery processor with a minimal loss of user time.

The following hardware requirements are for configuring the IBM Spectrum Protect™ server:

- A hardware configuration that is suitable for PowerHA. The removable media storage devices for the IBM Spectrum Protect server must be physically connected to at least two nodes of the PowerHA cluster on a shared bus (including a SAN).
- Sufficient shared disk space to hold the IBM Spectrum Protect database, recovery logs, instance directory, and disk storage pools to be used. See Managing inventory capacity to determine how much space is required for the database and recovery log and to ensure the availability of the database and recovery log.
- A TCP/IP network.

Tip: If an IBM Spectrum Protect server manages removable media storage devices, you can configure two IBM Spectrum Protect servers to run on different systems in an PowerHA cluster. Either system can run both servers if the other system fails. To configure two IBM Spectrum Protect servers to run on different systems in an PowerHA cluster, use another file system that is accessible to both servers.

AIX

PowerHA failover and failback

If a node fails, the server cluster transfers the groups that were being hosted by the node to other nodes in the cluster. This transfer process is called *failover*. The reverse process, *failback*, occurs when the failed node becomes active again and the groups that were failed over to the other nodes are transferred back to the original node.

The terms *production node* and *standby node* refer to the two PowerHA® nodes on which the IBM Spectrum Protect™ server runs.

PowerHA manages taking over the TCP/IP address and mounting the shared file system on the standby node or production node, as appropriate.

When a *failover* or *failback* occurs, any transactions that were being processed at the time are rolled back. To IBM Spectrum Protect clients, *failover* or *failback* represents a communications failure. Therefore, you must reestablish a connection that is based on their COMMRESTARTDURATION and COMMRESTARTINTERVAL option settings.

Typically, you can restart the backup-archive client from the last committed transaction. If a client schedule is running when a *failover* occurs, the client operation is likely to fail. If you can restart client operations, then you must restart them from the beginning of the processing. The clients and agent operations complete as they normally do if the server was halted and restarted while they were connected. The only difference is that the server is physically restarted on different hardware.

If you do not want automatic *failback* to occur, you can configure the resource as a cascading resource group without *failback*.

PowerHA SystemMirror product information

Installing and configuring PowerHA SystemMirror for AIX

You can configure the IBM Spectrum Protect™ server for AIX® clustered environments by using IBM® PowerHA® SystemMirror® for AIX.

- AIX Installing and configuring the PowerHA cluster
  You might experience processing errors if your IBM PowerHA SystemMirror for AIX installation and configuration are not done correctly.
- AIX Configuring IBM Spectrum Protect server on the primary node for PowerHA
  You can configure an IBM Spectrum Protect server instance on the primary node.
- AIX Configuring IBM Spectrum Protect server on a secondary node for PowerHA with a shared DB2 instance
  If the DB2® instance directory is shared between the nodes in the PowerHA cluster, you do not need to create a DB2 instance on the secondary node. You do not run the dsmicfgx wizard.
- AIX Configuring IBM Spectrum Protect server on a secondary node for PowerHA with a separate DB2 instance
  You must create a DB2 instance on each secondary node if the DB2 instance directory, /home/tsminst1/sqllib, is not shared between the nodes in the PowerHA cluster.

AIX

Installing and configuring the PowerHA cluster

You might experience processing errors if your IBM PowerHA® SystemMirror for AIX® installation and configuration are not done correctly.

Procedure

Complete the following steps to install and configure the PowerHA cluster:

1. Define the shared file systems and logical volumes when they are needed. You might want to put files in separate file systems or on separate physical disks for integrity or performance reasons. Do not put the home directory of the user instance on a shared disk. Mirror the logical volumes to provide maximum availability (including the underlying file systems). The file systems that must be defined include the IBM Spectrum Protect™ server instance directory, the database and log directories, all disk storage pool directories, and FILE device type storage pool directories.
2. Configure PowerHA so that the production node owns the shared volume groups and the standby node takes over the shared volume groups if the production node fails.
3. Configure PowerHA so that the file systems also fail over.
4. Set up a Service IP address for the IBM Spectrum Protect server. The Service IP address must be different from each host IP address. The Service IP is moved from host to host, not the actual host IP address.
5. Failover the shared database and the log and instance directories to the standby node of the PowerHA cluster.

Results

You must configure the removable media storage devices for failover and define the IBM Spectrum Protect server as an application to PowerHA.

AIX

Configuring IBM Spectrum Protect server on the primary node for PowerHA

You can configure an IBM Spectrum Protect™ server instance on the primary node.

Procedure

1. Review the topics in the configuring the IBM Spectrum Protect server information.
2. After you configure the IBM Spectrum Protect server instance on the primary node, you can configure the IBM Spectrum Protect server on a secondary node.

Related tasks:
Configuring the IBM Spectrum Protect server instance
AIX

Configuring IBM Spectrum Protect server on a secondary node for PowerHA with a shared DB2 instance

If the DB2® instance directory is shared between the nodes in the PowerHA® cluster, you do not need to create a DB2 instance on the secondary node. You do not run the dsmicfgx wizard.

Procedure

To configure a server instance on the secondary node with a shared DB2 instance, complete the following steps:

1. On each node in the cluster, add the following text to the /opt/tivoli/tsm/server/bin/rc.dsmserv script:

```
DB2NODES_TEMP='/tmp/db2nodes.tmp'
DB2NODES=${homeDir}/sqllib/db2nodes.cfg
# Current hostname
HOSTNAME=$(/bin/hostname)
# hostname saved in db2nodes.cfg
DB2_HOST=$(cat $DB2NODES | cut -d ' ' -f 2)
# if they are different update the file
if [[ "$HOSTNAME" != "$DB2_HOST" ]]
then
  echo "Updating hostname in db2nodes.cfg"
  sed -e s_${DB2_HOST}_${HOSTNAME}_g $DB2NODES > $DB2NODES_TEMP
  cp $DB2NODES_TEMP $DB2NODES
fi
```

   Tip: If the text is not included in the script, you can include it before you issue /opt/tivoli/tsm/server/bin/rc.dsmserv script.
2. Move all the shared resources to the secondary node.
3. Update the following variables in the /opt/tivoli/tsm/server/bin/startserver script, by using the following values:

Table 1. Variables in the /opt/tivoli/tsm/server/bin/startserver script

Description	Variable	Example
Set the INST_USER to the instance user ID.	INST_USER	INST_USER='tsmuser1'
Set the INST_DIR to the location of the IBM Spectrum Protect™ instance directory. This directory contains dsmserv.dbid and dsmserv.opt.	INST_DIR	INST_DIR='/home/tsmuser1/tsminst1'

Description	Variable	Example
Select one of the following startup options: Option 1 - use instance: $INST_USER but run the server as root (-U) Option 2 - use instance: $INST_USER and run the server as $INST_USER (-u)	INST_OPTION	Option 1: INST_OPTION='-U $INST_USER' Option 2: INST_OPTION='-u $INST_USER'

4. Start the server by issuing the following script:

```
/opt/tivoli/tsm/server/bin/startserver
```

5. When the server is started, issue the BACKUP DB command to verify that the data is successfully backed up.

AIX

Configuring IBM Spectrum Protect server on a secondary node for PowerHA with a separate DB2 instance

You must create a DB2® instance on each secondary node if the DB2 instance directory, /home/tsminst1/sqllib, is not shared between the nodes in the PowerHA® cluster.

About this task

You can configure the IBM Spectrum Protect™ server on a secondary node by using the dsmicfgx wizard or manually.

Procedure

- To create a DB2 instance on a secondary node by using the dsmicfgx wizard, complete the following steps:
  1. Run the dsmicfgx wizard.
  2. From the Instance Directory panel, select the Check this if you are configuring the server instance on a secondary node of a high availability cluster check box.
- To create a DB2 instance on a secondary node manually, complete the following steps:
  1. Move all the shared resources to the secondary node.
  2. Create a DB2 instance by issuing the following db2icrt command:

     ```
     /opt/tivoli/tsm/db2/instance/db2icrt -s ese -u instance_user instance_user
     ```

     where *instance_user* is the same user that owns the DB2 instance on the primary node.
  3. When the DB2 instance is created, log in as the instance user or by issuing the su command:

     ```
     su - <instance_user>
     ```

  4. As the instance user, issue the following commands:

     ```
     db2start
     db2 update dbm cfg using DFTDBPATH  shared_db_path
     db2 catalog db TSMDB1
     db2stop
     ```

     where *shared_db_path* is the shared database directory. The shared database directory is typically the server instance directory.
     Tip: To determine the *shared_db_path* value, issue the following command on the primary node:

     ```
     db2 get dbm cfg | grep DFTDBPATH
     ```

  5. Update the following variables in the /opt/tivoli/tsm/server/bin/startserver script, by using the following values:

Table 1. Variables in the /opt/tivoli/tsm/server/bin/startserver script

Description	Variable	Example
Set the INST_USER to the instance user ID.	INST_USER	INST_USER='tsmuser1'
Set the INST_DIR to the location of the IBM Spectrum Protect instance directory. This directory contains dsmserv.dbid and dsmserv.opt.	INST_DIR	INST_DIR='/home/tsmuser1/tsminst1'
Select one of the following startup options: Option 1 - use instance: $INST_USER but run the server as root (-U) Option 2 - use instance: $INST_USER and run the server as $INST_USER (-u)	INST_OPTION	Option 1: INST_OPTION='-U $INST_USER' Option 2: INST_OPTION='-u $INST_USER'

6. Start the server by issuing the following script:

   ```
   /opt/tivoli/tsm/server/bin/startserver
   ```

7. When the server is started, issue the BACKUP DB command to verify that the data is successfully backed up.

AIX

Installing the IBM Spectrum Protect server on a production node for PowerHA

Install the IBM Spectrum Protect™ server on a production node for PowerHA® to be able to configure the server for clustering.

Procedure

Complete the following steps to install the IBM Spectrum Protect server on the production node:

1. Install IBM Spectrum Protect. Select one of the following components:
   - The IBM Spectrum Protect server
   - The IBM Spectrum Protect device driver, if needed
   - The IBM Spectrum Protect license

   The executable files are typically installed on the internal disks of the production node, not on the shared IBM Spectrum Protect disk space. IBM Spectrum Protect server executable files are installed in the /opt/tivoli/tsm/server/bin directory.

2. Configure IBM Spectrum Protect to use the TCP/IP communication method. For instructions, see the information about configuring a server instance in AIX: Taking the first steps after you install IBM Spectrum Protect.
3. Define a new user ID that owns the IBM Spectrum Protect server instance or use an existing user ID that does not already own an IBM Spectrum Protect instance. While logged in to the instance user ID, complete the following steps:
   a. Create an instance directory by using the mkdir command on a shared file system that can fail over to the standby system. This disk must be defined to PowerHA.
   b. Create the database and log directories by using the mkdir command on shared file systems that can fail over to the standby system. These disks must also be defined to PowerHA to fail over.
   c. Complete the configuration by using the dsmicfgx wizard.

AIX

Installing the IBM Spectrum Protect client on a production node for PowerHA

You need to install only the backup-archive client file set, which contains the backup-archive client files and the administrative command-line client.

Procedure

For detailed instructions on installing the IBM Spectrum Protect™ client, see Installing the IBM Spectrum Protect backup-archive clients.

Complete the following steps to install the IBM Spectrum Protect client on the production node.

1. Install the IBM Spectrum Protect client executable files in the /usr/tivoli/tsm/client/ba/bin directory. These files are typically installed on the internal disks of the production node.
2. For the client to find the server, ensure that the client options file, dsm.sys, points to the IBM Spectrum Protect server. The server name in dsm.sys is used only on the -servername parameter of the dsmadmc command to specify the server to be contacted.

AIX

Verifying the configuration of the IBM Spectrum Protect server for PowerHA

When you configure the IBM Spectrum Protect™ server to use PowerHA®, you must verify the configuration.

About this task

When you use PowerHA, all database, log, storage, and instance directories must be on shared disks that are configured to fail over by PowerHA.

Procedure

To identify the directories that are on shared disk, complete the following steps:

1. Log on as the instance user.
2. Run the /opt/tivoli/tsm/server/bin/dsmclustfs script.
3. Examine the file systems that are reported by the script and verify that they are on shared disks. The following example script shows the type of information that you must review:

```
> su - tsminst1
$ /opt/tivoli/tsm/server/bin/dsmclustfs
SQL1026N  The database manager is already active.
```

The following database connection information is displayed when the IBM Spectrum Protect server connects to the DB2® database:

```
DB20000I  The START DATABASE MANAGER command completed successfully.

   Database Connection Information

 Database server        = DB2/AIX64 11.1.0
 SQL authorization ID   = TSMINST1
 Local database alias   = TSMDB1

File systems for the DB2 database: /TSMdbspace2 /TSMdbspace1
File system for Active Log: /TSMalog
File system for Archive Log: /TSMarchlog
Active log mirror not defined for this database
```

The following mandatory DB2 file systems are in the script:

```
 /TSMdb-1 /TSMalog-1 /TSMarchlog-1

Checking existing TSM disk-based volumes...
TSM Data is stored in the following file systems: /TSMdisk-1 /TSMfile-1
```

AIX

Setting up the standby node for PowerHA

For PowerHA®, ensure that the IBM Spectrum Protect™ server is not running on the production node before you set up the standby node.

Procedure

Complete the following steps to set up the standby node:

1. On the standby node, open the shared volume group and any IBM Spectrum Protect file systems.
2. On the standby node, install the IBM Spectrum Protect product code. For more information, see Installing the IBM Spectrum Protect server on a production node for PowerHA. If the executable files are installed on shared disk space, you might need to install them on the standby node. IBM Spectrum Protect device drivers, SMIT panels, and other files must be installed in AIX® system directories.
3. Open the dsmicfgx wizard. Follow the instructions to complete the configuration. Select the check box to indicate that this item is a secondary node in the cluster.
4. Start the server on the standby node. Query the database, recovery log, and storage pool volumes to verify that they are the same as when the server was started on the production node.
5. Install the client on the standby node. If the executable files are installed on shared disk space, you might need to install them on the standby node. IBM Spectrum Protect SMIT panels and other files must be installed in AIX system directories. Use the AIX RCP command with the -p option to copy the dsm.sys file from the production node to the standby node. If the dsm.sys file is changed on one node, it must be copied to the other node.

Results

Tip: If the dsm.sys file is changed on one node, you must copy it to the other node.
AIX

Defining the removable media storage devices to AIX for PowerHA

For an AIX® operating system, you must define the removable-media storage devices that are used by IBM Spectrum Protect™ on the production and standby nodes. The library manager validates that the cartridge that contains the removable-media storage device is in the correct drive.

About this task

Prerequisite:

- If you define a library manager server that is not shared with the IBM Spectrum Protect server, ensure that the RESETDRIVES parameter for the DEFINE LIBRARY command or the UPDATE LIBRARY command is specified as YES. If you define a library manager server that is shared with the IBM Spectrum Protect server, the SANDISCOVERY option must be set to ON in the IBM Spectrum Protect server option file dsmserv.opt. By default, this option is set to OFF.
- You can issue the PERFORM LIBACTION command from SCSI and VTL library types. Use this command to define the drives and paths for a library in one step.

If your SAN device mapping is accurate, continue to the Completing the cluster manager and IBM Spectrum Protect configurations section. If the device names on the primary and secondary systems are not the same, you must use SAN discovery so that the IBM Spectrum Protect server can access the devices.

Related tasks:
Configuring library sharing (V7.1.1)

Completing the cluster manager and IBM Spectrum Protect configurations

Update the cluster manager configuration to define the IBM Spectrum Protect™ server as an application and a failover resource of the standby node. This application is owned by the production node.

About this task

You can issue IBM® PowerHA® SystemMirror for AIX® or Tivoli® System Automation commands to set up the cluster. Continue with configuring the IBM Spectrum Protect server.

Related information:

PowerHA SystemMirror product information

IBM Tivoli System Automation for Multiplatforms Version 3.2.2 product information

AIX

Troubleshooting the PowerHA clustered environment

Review the following list for information about troubleshooting common problems. The information that is provided for IBM® PowerHA® SystemMirror for AIX® does not represent all possible scenarios.

Warning messages that are issued after you run the clverify utility

You can run the PowerHA cluster verification utility, clverify, on one node to verify the cluster configuration and the assignment on the PowerHA resources. If you run the clverify utility after you define the IBM Spectrum Protect™ server as a PowerHA application, warning messages are issued.

Warning messages display because the shell scripts that start and stop the IBM Spectrum Protect servers are in a shared file system. The shell scripts can be run only on one node at a time. Therefore, the shell scripts can be available on only one node at a time. You can ignore the clverify utility warning messages. If a shared file system cannot be mounted, the IBM Spectrum Protect server cannot be started.

IBM Spectrum Protect server fails to start after you issue the startserver script

If you use the startserver shell script and PowerHA fails to start the IBM Spectrum Protect server, start it manually on a terminal without the quiet option. If you want to run the server with the quiet option, issue the dsmserv -q command.

Messages that are associated with the tctl command

If you issue the tctl -f/dev/rmt2 rewind command, the following message might be displayed:

```
/dev/rmt2: A device is already mounted or cannot be unmounted
```

This message means that the I/O device is locked with a SCSI RESERVE by a system other than the one on which the tctl command was run. If you are using persistent reservation, the IBM Spectrum Protect server preempts a drive reservation by default. If the device driver does not use persistent reservation, the server completes a target reset.

`ANS4329S Server out of data storage space` message

If the `ANS4329S Server out of data storage space` message is displayed on an IBM Spectrum Protect client, the license for the IBM Spectrum Protect server might be non-compliant. Issue the QUERY LICENSE command to display the compliance information for the license. If the compliance state is valid, use the QUERY ACTLOG command on the server and review the messages that are displayed to identify the problem.

Linux

Configuring a Linux environment for clustering

You can configure the IBM Spectrum Protect™ Linux server in a clustered environment by using IBM® Tivoli® System Automation for Multiplatforms Version 3.2.2.

- Linux Overview of a two-node IBM Spectrum Protect cluster using Tivoli System Automation
  Use the Tivoli System Automation cluster for higher server and database availability during a failure. By using the Tivoli System Automation failover function, server components such as the database can automatically recover from a failure.
- Linux Setting up an IBM Spectrum Protect cluster with Tivoli System Automation
  You must set up the IBM Spectrum Protect cluster to use Tivoli System Automation.
- Linux Prerequisites to configuring a Linux clustered environment with Tivoli System Automation
  Before you install and configure IBM Spectrum Protect in a clustered environment with Tivoli System Automation, you must check the prerequisites.
- Linux Installing and configuring IBM Spectrum Protect components on the primary and secondary nodes
  You must install the IBM Spectrum Protect server and database components on the primary and secondary nodes in the cluster. Then, configure the primary node first followed by the secondary node.

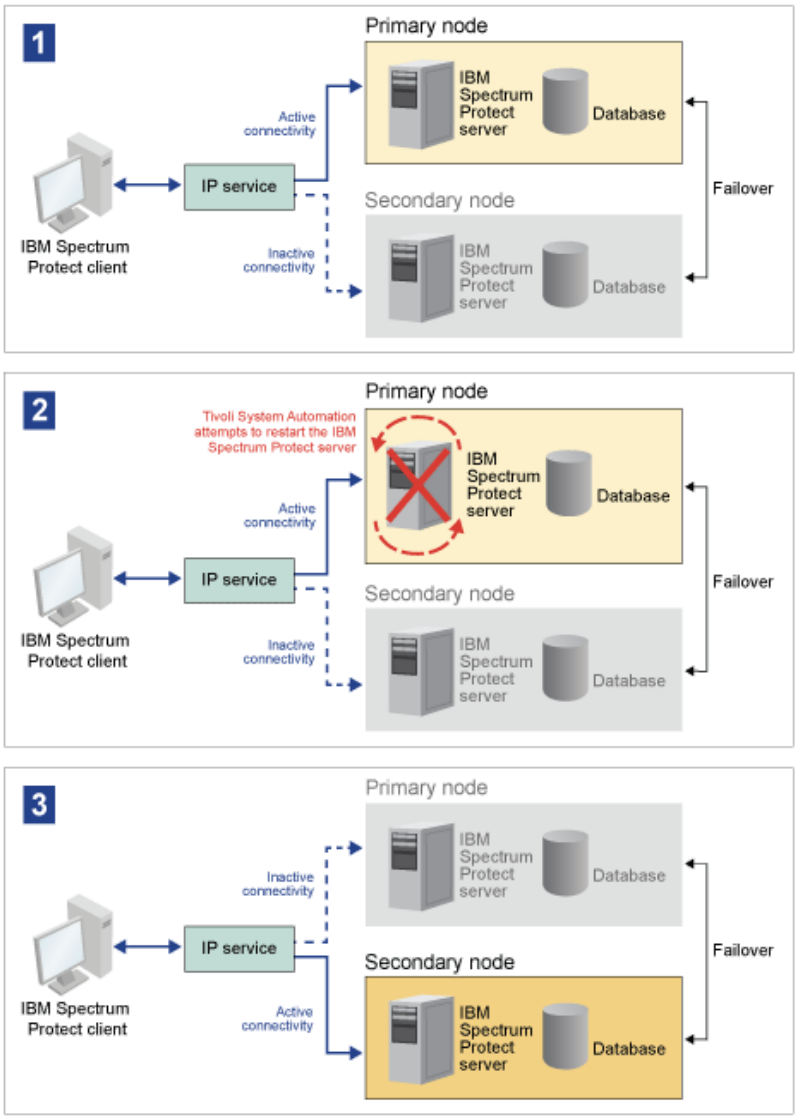
- Linux Installing Tivoli System Automation on the primary and secondary nodes
  After you install and configure IBM Spectrum Protect on the primary and secondary nodes in the cluster, you must install and configure Tivoli System Automation on these nodes. Then, you must activate these nodes for the domain, configure the resources, and activate the base policy. Finally, you must add the mount points to the IBM Spectrum Protect directories.
- Linux Configuring storage resources
  Use the Tivoli System Automation user interface or command line to add or delete storage resources and to delete mount points that are no longer required. If you add a storage pool to the cluster, you must add it to the resource group. If you remove a storage pool from the cluster, you must also delete it from the resource group.
- Linux Upgrading a server that is configured with Tivoli System Automation
  You can upgrade a server that is configured with Tivoli System Automation from Version 6.3 or Version 7.1.

Linux

Overview of a two-node IBM Spectrum Protect cluster using Tivoli System Automation

Use the Tivoli® System Automation cluster for higher server and database availability during a failure. By using the Tivoli System Automation failover function, server components such as the database can automatically recover from a failure.

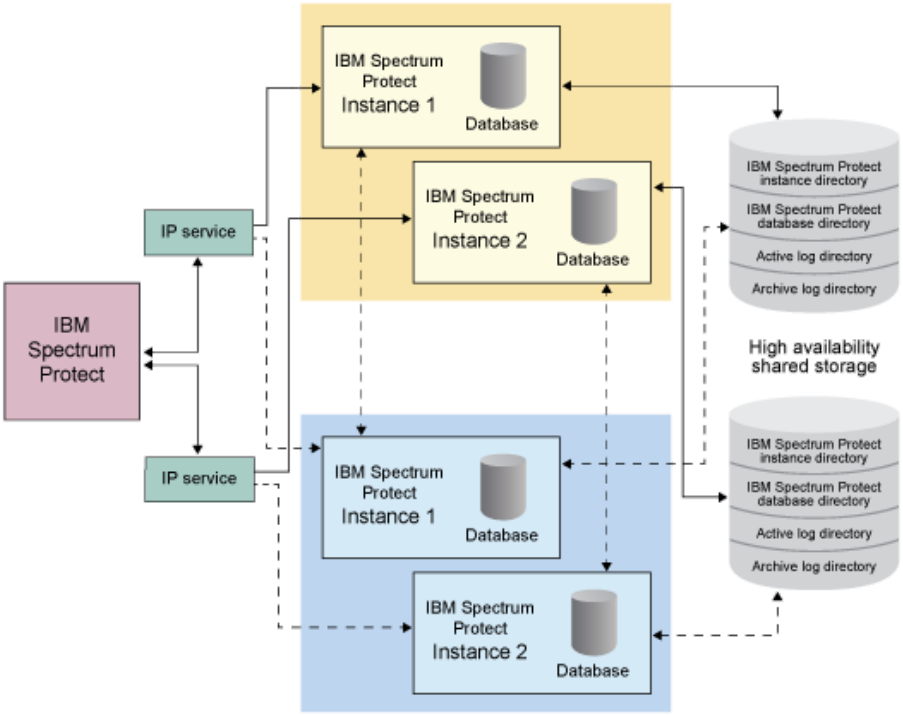
The IBM Spectrum Protect™ server and the DB2® database are the underlying server components for this two-node cluster. The server is the core component. It is responsible for client and server activity. The DB2 database is an internal component, which is installed as part of the server. The server controls all database activity such as startup and shutdown. When the server detects a server or database component failure, it tries to restart the database. If the restart fails, the server and database are automatically shut down on the primary node and Tivoli System Automation automatically starts these components on the secondary node. Because the IBM Spectrum Protect functions are restored immediately, server and database availability is higher.
Figure 1. The failover function. The server and database components fail on the primary node. Tivoli System Automation starts these components on the secondary node.



The server and the database include the following log directories, which are used for storage:

- IBM Spectrum Protect instance directory
- Active log directory
- Archive log directory
- Database directory

The two nodes in this Tivoli System Automation cluster are configured to access highly available shared storage that protects the data. For example, a two-node topology includes a primary node and a secondary node. These nodes are on separate physical systems but they can access the same data by using the shared storage array.
Figure 2. Multiple IBM Spectrum Protect server instances on separate nodes. These server instances are on separate physical systems. These instances can access the highly available shared storage.



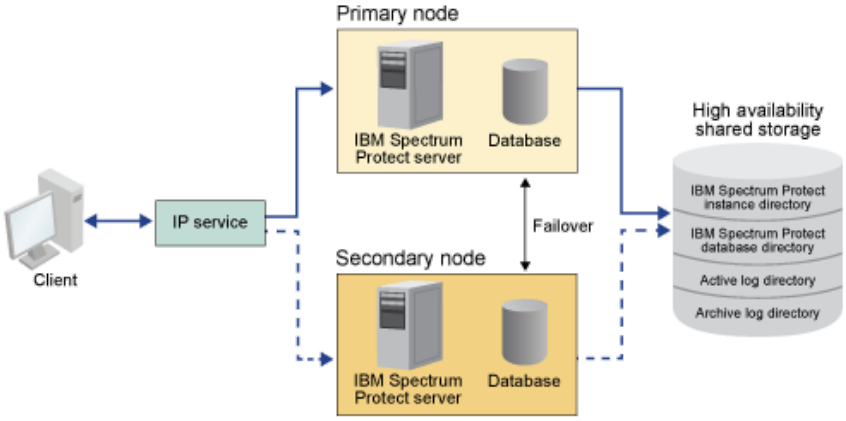
- Linux Two-node shared disk topology
  This cluster uses a two-node shared disk topology. It includes a primary and secondary node. The primary node hosts the IBM Spectrum Protect server, database, IBM Spectrum Protect instance, and the data. The secondary node is where the IBM Spectrum Protect resources are moved to if a failure occurs.
- Linux Tivoli System Automation resource groups
  Use Tivoli System Automation resources groups with defined automation policies to manage the IBM Spectrum Protect components for this cluster. The only exception is the database server instance resource that is managed by the IBM Spectrum Protect server.

Linux

Two-node shared disk topology

This cluster uses a two-node shared disk topology. It includes a primary and secondary node. The primary node hosts the IBM Spectrum Protect™ server, database, IBM Spectrum Protect instance, and the data. The secondary node is where the IBM Spectrum Protect resources are moved to if a failure occurs.

The two nodes in this cluster are connected to each other over a single public network and wired to a *shared disk storage* system, which is always available. *Shared disk storage* is where one or more disks are available to both the primary and secondary nodes. These disks are only mounted to one node, the primary node, at any one time. One node can input and output data to the shared storage disks. The following illustration shows a two-node shared topology where automatic failover to the secondary node occurs in the instance of a failure.



Linux

Tivoli System Automation resource groups

Use Tivoli® System Automation resources groups with defined automation policies to manage the IBM Spectrum Protect™ components for this cluster. The only exception is the database server instance resource that is managed by the IBM Spectrum Protect server.

The shared file systems and IBM Spectrum Protect components are defined as resources. Multiple resources make up a resource group. Each resource in a resource group has a resource type. Each IBM Spectrum Protect instance in a cluster includes one resource group. During planned outages, resource groups can be manually moved from the primary node to the secondary node.

The IBM Spectrum Protect resource group includes the following resources. The name of the IBM Spectrum Protect resource group is SA-tsm-inst1-rg, where inst1 is the instance name. The following resources are used for different but mandatory functions in this cluster.

Service IP
: The Service IP resource is used for communication. It is called tsm-inst1-ip-rs, where inst1 is the instance name. Service IP is managed by Tivoli System Automation. This IP is available on the node where the IBM Spectrum Protect server is running. You must create the Service IP logical interface on the same physical interface as the public network interface.

Shared disk storage resource
: A *shared disk storage* resource is a physical storage device on the IBM Spectrum Protect server where IBM Spectrum Protect and DB2® application data is stored. You must create the following disk storage resources:

  - Instance directory - tsm-inst1-instdir-ag
  - DB2 directory - tsm-inst1-db2dir-ag
  - Active log directory - tsm-inst1-actlog-ag
  - Archive log directory - tsm-inst1-archlog-ag

Shared disk storage for storage pools
: The storage pool resource includes physical storage devices on the IBM Spectrum Protect server where client data is stored.

Volume group resources
: If you decide to configure your storage by using volume groups, a volume group resource is available for the preceding *shared disk storage* resources. Volume group resources are automatically created by Tivoli System Automation.

Application resources for the IBM Spectrum Protect server instance

The IBM Spectrum Protect server instance resource is the server resource that manages the IBM Spectrum Protect application. This resource is managed by Tivoli System Automation control scripts.

Table 1. Tasks that are completed by the Tivoli System Automation control scripts

Tasks	Description	Sample commands
Start	Starts the IBM Spectrum Protect server instance.	The /opt/tivoli/tsm/server/bin/rc.dsmserv -u db2inst1 –i /tsminst1 command starts the server instance with the db2inst1 user in the /tsminst1 directory.
Stop	Stops the IBM Spectrum Protect server instance.	kill –s SIGURG 345 where `345` is the *PID*. The *PID* can be found in the /tsminst1/dsmserv.v6lock file.
Monitor	Checks whether the /tsminst1/dsmserv.v6lock file exists. It uses the *PID* to check whether the process is running.	ps -ef | grep 345 where `345` is the *PID*.

- Linux Resource group dependencies
  Resource group dependencies are automatically created to control the order in which resources are started. These dependencies also control which resources must be restarted or shut down when the specific resource that these resources depend on fails.

Linux

Setting up an IBM Spectrum Protect cluster with Tivoli System Automation

You must set up the IBM Spectrum Protect™ cluster to use Tivoli® System Automation.

Procedure

1. Install and configure the IBM Spectrum Protect components on the primary and secondary nodes.
2. Install Tivoli System Automation on the primary and secondary nodes.
3. Configure the storage resources.
4. Depending on the IBM Spectrum Protect version that is installed on the server, you might have to upgrade the IBM Spectrum Protect server for the Tivoli System Automation cluster.
5. Optional: You can set the *FILE_EXIT* variable in the tsmserverctrl cluster script to route the Tivoli System Automation event data to the IBM Spectrum Protect server FILEEXIT file.
   For example, edit the tsmserverctrl cluster script in the *<server_install_directory>*/tsam/controls directory and add the following line:

   ```
   FILE_EXIT="fileexittmp"
   ```

Linux

Prerequisites to configuring a Linux clustered environment with Tivoli System Automation

Before you install and configure IBM Spectrum Protect™ in a clustered environment with Tivoli® System Automation, you must check the prerequisites.

Check that the following prerequisites are met.

- Plan the installation of the IBM Spectrum Protect server.
- After you install IBM Spectrum Protect, verify the following items:
  - Ensure that the DB2® database is installed on the same node as the server.
  - Check that the server can control database recovery.
  - Verify that shared storage devices are available. IBM Spectrum Protect requires highly available shared storage devices to protect data integrity.
  - Verify that each node in the cluster can contain multiple instances of the server.

- Prepare for the Tivoli System Automation installation. For instructions, go to the Tivoli System Automation product documentation. In the *Installation and Configuration Guide*, search for *Preparing for installation*.
- After you install Tivoli System Automation, check that Tivoli System Automation can process failover such as IP failover and data failover for the database, instance data, active and archive logs, and storage pools.

Planning to install the IBM Spectrum Protect server
Linux

Installing and configuring IBM Spectrum Protect components on the primary and secondary nodes

You must install the IBM Spectrum Protect™ server and database components on the primary and secondary nodes in the cluster. Then, configure the primary node first followed by the secondary node.

- Linux Installing IBM Spectrum Protect server components
  After you check and verify the prerequisites, you must install the required components on the primary and secondary nodes on the system.
- Linux Configuring the primary node
  To set up the two-node topology, configure the IBM Spectrum Protect components on both nodes. First, you must configure the IBM Spectrum Protect instance on the primary node.
- Linux Configuring the secondary node
  After you configure the primary node, you must configure the secondary node so that Tivoli System Automation can move the IBM Spectrum Protect server components to the secondary node if the server fails on the primary node.

Linux

Installing IBM Spectrum Protect server components

After you check and verify the prerequisites, you must install the required components on the primary and secondary nodes on the system.

Procedure

Review the topics in the installing the IBM Spectrum Protect™ server components information.
Related tasks:
Installing the IBM Spectrum Protect server components
Linux

Configuring the primary node

To set up the two-node topology, configure the IBM Spectrum Protect™ components on both nodes. First, you must configure the IBM Spectrum Protect instance on the primary node.

Before you begin

- Install the IBM Spectrum Protect server components.
- Verify that the IBM Spectrum Protect instance owner has the same user and group ID for all of the nodes in the cluster domain.
- Verify that the IBM Spectrum Protect instance owner has the same password for all of the cluster nodes.

Procedure

1. For detailed instructions about creating the directories and the user ID for the server instance, see Linux: Creating the user ID and directories for the server instance.
2. Verify that the IBM Spectrum Protect server, DB2® instance, and the active and archive log directories are shared.
3. Define the mount points by adding entries to the /etc/fstab file.

   When you add mount points on the cluster nodes, use the noauto option to prevent the mount points from being automatically mounted on more than one node in the cluster.

4. Set the following permissions on each of the mount points:
   - 755. For example, the following command sets the 755 permission on the `/tsminst1` mount point.

     ```
     chmod -R 755 /tsminst1
     ```

   - IBM Spectrum Protect server instance owner. For example, the following command sets the permissions for the instance owner.

     ```
     chown -R  tsminst1  /tsminst1
     ```

   - IBM Spectrum Protect server group that the instance owner belongs to. For example, the following command sets the permissions for the instance owner's group.

     ```
     chgrp tsmsrv_1_group /tsminst1
     ```

5. For detailed instructions on configuring the IBM Spectrum Protect server by using the configuration wizard, see Linux: Configuring IBM Spectrum Protect by using the configuration wizard. Check that all of the shared directories are mounted on the primary node.
6. Start the IBM Spectrum Protect server instance on the primary node by using the DSMSERV utility. For example, the following command starts the server for normal operation.

   ```
   /opt/tivoli/tsm/server/bin/dsmserv
   ```

7. Verify that the IBM Spectrum Protect components are started without any errors.
8. Shut down the IBM Spectrum Protect server.
9. As root user, unmount the shared drives.

Linux

Configuring the secondary node

After you configure the primary node, you must configure the secondary node so that Tivoli® System Automation can move the IBM Spectrum Protect™ server components to the secondary node if the server fails on the primary node.

Procedure

1. To create the directories and the user ID for the server instance manually, follow the instructions in Creating the user ID and directories for the server instance.
2. Verify that the IBM Spectrum Protect server, DB2® instance, and the active and archive log directories are shared.
3. Define the mount points by adding entries in the /etc/fstab file.

   When you add mount points on the cluster nodes, use the noauto option. This option prevents the mount points from being automatically mounted on more than one node in the cluster.

   Check that all of the shared directories are mounted on the secondary node.
4. Set the following permissions on each of the mount points:
   - 755. For example, the following command sets the 755 permission on the `/tsminst1` mount point.

     ```
     chmod -R 755 /tsminst1
     ```

   - IBM Spectrum Protect server instance owner. For example, the following command sets the permissions for the instance owner.

     ```
     chown -R  tsminst1  /tsminst1
     ```

   - IBM Spectrum Protect server group that the instance owner belongs to. For example, the following command sets the permissions for the instance owner's group.

     ```
     chgrp tsmsrv_1_group /tsminst1
     ```

5. Create the IBM Spectrum Protect server instance by issuing the db2icrt command. For instructions, see Creating the server instance.
   Remember: You do not need to create a new server options file because the secondary node uses the dsmserv.opt file from the primary node.
   Check that all of the shared directories are mounted on the secondary node.
6. Catalog the database by issuing the catalog db command. For example, the following command catalogs the `tsmdb1` database.

```
db2 catalog db tsmdb1
```

7. Prepare the database for backup. For instructions, see Preparing the database manager for database backup.
8. Start the IBM Spectrum Protect server by using the DSMSERV utility. For example, the following command starts the server for normal operation.

   ```
   /opt/tivoli/tsm/server/bin/dsmserv
   ```

9. Verify that the IBM Spectrum Protect components are starting without any errors.
10. On the secondary nodes, shut down the IBM Spectrum Protect server and unmount the shared directories.

Linux

Installing Tivoli System Automation on the primary and secondary nodes

After you install and configure IBM Spectrum Protect™ on the primary and secondary nodes in the cluster, you must install and configure Tivoli® System Automation on these nodes. Then, you must activate these nodes for the domain, configure the resources, and activate the base policy. Finally, you must add the mount points to the IBM Spectrum Protect directories.

- Linux Creating the label for the mount points
  Create a label for each mount point on the primary and secondary nodes in the cluster.
- Linux Installing and configuring Tivoli System Automation
  You must install IBM Tivoli System Automation for Multiplatforms on the primary and secondary nodes in the system.
- Linux Preparing to activate the cluster nodes for the domain
  After you install Tivoli System Automation on the primary and secondary nodes in the cluster, you must prepare these nodes so that you can activate the cluster and start the cluster domain.
- Linux Configuring volume group resources
  If you created volume groups for your cluster, you must configure these resources. Tivoli System Automation automatically finds and defines the shared disk volume resources.
- Linux Configuring resources that are not in a volume group
  If you created your *shared disk storage* resources by using ext2, ext3, or reiserfs resource types in one of the nodes in the cluster, then you must configure these resources.
- Linux Activating the base policy
  After you configure the resources, you must activate the policy on the primary and secondary nodes to create any remaining resources and the resource group.
- Linux Adding mount points to the IBM Spectrum Protect directories
  Before you can start the cluster, you must add the mount points that you created for the IBM Spectrum Protect components.

Linux

Creating the label for the mount points

Create a label for each mount point on the primary and secondary nodes in the cluster.

Procedure

1. Create a label for each of the volumes that you created previously for the shared directory mount points by issuing the e2label command. For example, the following command creates the /tsminst1 label that has a /dev/tsmvg1/tsminst1LV partition.

   ```
   e2label /dev/tsmvg1/tsminst1LV /tsminst1
   ```

2. For each node in the cluster, replace the entries for the mount points that you created previously in the /etc/fstab file. For example, for the previous sample label, issue the following command:

   ```
   LABEL=/tsminst1 /tsminst1 ext3 defaults 0 0
   ```

Linux

Installing and configuring Tivoli System Automation

You must install IBM® Tivoli® System Automation for Multiplatforms on the primary and secondary nodes in the system.

Procedure

1. To install and configure Tivoli System Automation, detailed information is available in the Tivoli System Automation Installation and Configuration Guide.
2. Download the TSM-25072011-1015.zip file from the Integrated Service Management Library. Extract the compressed file on each cluster node.
3. After you extract the compressed file, verify that the new Tivoli System Automation directory that was created during the installation includes the /TSM/HA directory and subdirectories.

Related information:

IBM Tivoli System Automation for Multiplatforms Version 3.2.2 product information

Linux

Preparing to activate the cluster nodes for the domain

After you install Tivoli® System Automation on the primary and secondary nodes in the cluster, you must prepare these nodes so that you can activate the cluster and start the cluster domain.

Procedure

1. Prepare each node for the domain by issuing the preprpnode command. Issue this command for all the cluster nodes in the domain. For example, the following command prepares the HOST1.ibm.com and HOST2.ibm.com nodes.

   ```
   preprpnode HOST1.ibm.com HOST2.ibm.com
   ```

2. Create a domain for each node by issuing the mkrpdomain command. For example, the following command creates the tsm_domain for the HOST1.ibm.com and HOST2.ibm.com nodes.

   ```
   mkrpdomain tsm_domain HOST1.ibm.com HOST2.ibm.com
   ```

3. Start the domain for each node by issuing startrpdomain command. For example, the following command starts the tsm_domain.

   ```
   startrpdomain tsm_domain
   ```

Linux

Configuring volume group resources

If you created volume groups for your cluster, you must configure these resources. Tivoli® System Automation automatically finds and defines the shared disk volume resources.

Procedure

To configure the volume group resources for the shared IBM Spectrum Protect™ directories and mount points that you created previously, complete the following steps on the primary node.

1. Import the volume groups. For example, use the vgimport X command to import the X volume groups.
2. Activate the volume groups. For example, use the vgchange -ay X command to activate the X volume groups.
3. Mount the file system by issuing the mount command. The following example mounts the X file system.

   ```
   mount X
   ```

4. Restart the domain by issuing the stoprpdomain and startrpdomain commands. For example, the following commands restart the tsm_domain.

   ```
   stoprpdomain tsm_domain
   startrpdomain tsm_domain
   ```

5. Unmount the file system by issuing the umount command. For example, use the umount X command to unmount the X file system.
6. Deactivate the volume groups. For example, use the vgchange -an X command to deactivate the X volume groups.
7. Verify that all of the IBM®.AgfileSystem storage resources are harvested by Tivoli System Automation by issuing the following command:

```
lsrsrc -s "Name=='Resource_Name' && ResourceType=1" IBM.AgFileSystem
```

Linux

Configuring resources that are not in a volume group

If you created your *shared disk storage* resources by using ext2, ext3, or reiserfs resource types in one of the nodes in the cluster, then you must configure these resources.

Procedure

Complete the following steps on the primary node.

1. Mount the file system by issuing the mount command. For example, the following command mounts the `X` file system.

   ```
   mount X
   ```

2. Restart the domain by issuing the stoprpdomain and startrpdomain commands. For example, the following command restarts the tsm_domain.

   ```
   stoprpdomain tsm_domain
   startrpdomain tsm_domain
   ```

3. Unmount the file system by issuing the umount command. For example, the following command unmounts the `X` file system.

   ```
   umount X
   ```

4. Verify that all of the IBM®.AgfileSystem storage resources are harvested by Tivoli® System Automation by issuing the following command:

   ```
   lsrsc -s "Name=='Resource_Name' && ResourceType=1" IBM.AgFileSystem
   ```

   For example, to verify the *tsmalog* resource, issue the following command:

   ```
   lsrsrc -s "Name=='tsmalog' && ResourceType=1" IBM.AgFileSystem
         Resource Persistent Attributes for IBM.AgFileSystem resource 1:
         ResourceHandle= "0x2038 0xffff 0x6ad47197 0x256fc23d 0x9338a9950x263fa510"
         Name                = "tsmalog"
         ResourceType        = 1   <------------------------------
         MountPoint          = ""
         DeviceName          = ""
         Vfs                 = "ext3"
         AggregateResource   = "0x3fff 0xffff 0x00000000 0x00000000 0x00000000 0x00000000"
         ContainerResource   = "0x2036 0xffff 0x6ad47197 0x256fc23d 0x9338a995 0x25ffaa28"
         GhostDevice         = 0
         ResourceId          = "360050768019c021d30000000000005da"
         ProtectionMode      = 1
         UserControl         = 0
         SysMountPoint       = "/tsmalog"
         Label               = "/tsmalog"
         FSID                = "5792f887-8547-4c33-a519-9d0c50ab6882"
         PreOnlineMethod     = 0
         ContainerResourceId = "360050768019c021d30000000000005da"
         AutoMonitor         = 1
         Options             = "defaults,noauto"
         PreOfflineMethod    = 0
         ActivePeerDomain    = "TSM_Domain"
         NodeNameList        =
   {"tsmlnode01.storage.tucson.ibm.com","tsmlnode02.storage.tucson.ibm.com"}
   ```

Linux

Activating the base policy

After you configure the resources, you must activate the policy on the primary and secondary nodes to create any remaining resources and the resource group.

About this task

To activate the base policy, you must create the Service IP resource and IBM Spectrum Protect™ application resources for the IBM Spectrum Protect server instance. Then, you must create the resource group and the policies to manage the cluster.

Procedure

Complete the following steps first on the primary node and then on the secondary node.

1. Go to the directory where you extracted the contents of the TSM-25072011-1015.zip file.
2. Set the file permissions on the scripts in the bin directory by issuing the chmod command. For example, the following command sets the file permissions for all of the scripts in the bin directory. XXX is the name of the extracted folder.

   ```
   chmod 755 /XXX/TSM/HA/bin/*
   ```

3. Go to the bin directory by issuing the cd command.
4. Update the following variables in the base_cluster_variables.sh script:
   - *NODE1* specifies the host name for node 1 (primary node) in the cluster.
   - *NODE2* specifies the host name for node 2 (secondary node) in the cluster.
   - *IP_GATEWAY* specifies the gateway of the Service IP.
   - *SUBNET_MASK* specifies the subnet mask of the Service IP.
   - *NET_INT* specifies the network interface name of a specific node in the cluster. This name must be the same for all the nodes in the cluster.
5. Run the configureHA.sh configuration script by issuing the ./configureHA.sh command on all of the nodes in the cluster. If the configureHA.sh script fails with the `-bash: ./configureHA.sh: /bin/bash^M: bad interpreter: No such file or directory` error, issue the dos2unix command on all of the scripts in the bin directory. For example, for each script run the following command:

   ```
   dos2unix -o <filename>
   ```

6. Verify that the configuration is a success by verifying that the configuration script runs successfully.
7. Attention: Complete this step on the primary node only.
   Run the setup script by issuing the ./setup.sh command. For example, the following command runs the setup script on the `inst1` IBM Spectrum Protect server instance for the `dbinst1` instance user in the `/tsminst1` IBM Spectrum Protect server instance directory with `9.11.142.129` as the service IP.

   ```
   ./setup.sh inst1 dbinst1 /tsminst1 9.11.142.129
   ```

8. Verify that you are using the correct IP by running the following command:

   ```
   lssam -V
   ```

9. Repeat step 5 for all of the IBM Spectrum Protect instances that you have in your IBM Spectrum Protect server environment.
10. Complete all of the previous steps on the secondary node.

Linux

Adding mount points to the IBM Spectrum Protect directories

Before you can start the cluster, you must add the mount points that you created for the IBM Spectrum Protect™ components.

Procedure

To add the shared disk mount points to the cluster resource group and bring the cluster online, complete the following steps:

1. Identify mount points for the following directories:
   - Instance
   - Database
   - Active log
   - Archive log
   - Storage pool
2. Add resources to each mount point:
   a. Check whether the tsm-$INST_NAME-rg resource group is online by issuing the lssam command.
   b. If the tsm-$INST_NAME-rg resource group is online, take it offline by issuing the following command:

      ```
      chrg -o offline tsm-$INST_NAME-rg
      ```

c. Go to the directory where you extracted the contents of the TSM-25072011-1015.zip file.
d. Move to the bin directory by issuing the cd command.
e. To add shared disk resources to each mount point, run the ./update_setup.sh script. For example, the following command adds the `/tsminst1` mount point to the `inst1` IBM Spectrum Protect server instance.

```
./update_setup.sh inst1 /tsminst1
```

3. Bring the tsm-$INST_NAME-rg resource group online by issuing the following command:

```
chrg -o online tsm-$INST_NAME-rg
```

4. Connect to the server using the service gateway IP to verify that the configuration is correct.

Linux

Configuring storage resources

Use the Tivoli® System Automation user interface or command line to add or delete storage resources and to delete mount points that are no longer required. If you add a storage pool to the cluster, you must add it to the resource group. If you remove a storage pool from the cluster, you must also delete it from the resource group.

- Linux Adding a storage pool to a resource group
  If your IBM Spectrum Protect configuration stores data on disks, then you must add the shared disk mount point for the storage pool to the resource group.
- Linux Deleting a storage pool from a resource group
  You can delete a storage pool that is no longer required. If a storage pool is removed from the IBM Spectrum Protect server instance, it must be deleted from the resource group.
- Linux Deleting a mount point from a resource group
  You might want to delete a mount point that is no longer required.

Linux

Adding a storage pool to a resource group

If your IBM Spectrum Protect™ configuration stores data on disks, then you must add the shared disk mount point for the storage pool to the resource group.

Procedure

To add the shared disk mount point for the storage pool to the resource group, complete the following steps:

1. Lock the resource group by issuing the rgreq -o lock command. For example, the following command locks the `Sample_Resourcegroup_X` resource group.

```
rgreq -o lock Sample_Resourcegroup_X
```

2. Move to the bin directory by issuing the cd command:
3. To add a storage pool resource to a resource group, run the update_setup.sh script by issuing the ./update_setup.sh command. For example, the following command adds the `/inst1stg1` storage pool mount point to the `inst1` IBM Spectrum Protect server instance.

```
./update_setup.sh inst1 /inst1stg1
```

4. Unlock the resource group by issuing the rgreq -o unlock command. For example, the following command unlocks the `Sample_Resourcegroup_X` resource group.

```
rgreq -o unlock Sample_Resourcegroup_X
```

Linux

Deleting a storage pool from a resource group

You can delete a storage pool that is no longer required. If a storage pool is removed from the IBM Spectrum Protect™ server instance, it must be deleted from the resource group.

Procedure

To delete a storage pool, complete the following steps:

1. Lock the resource group by issuing the rgreq -o lock command. For example, the following command locks the `Sample_Resourcegroup_X` resource group.

   ```
   rgreq -o lock Sample_Resourcegroup_X
   ```

2. Move to the bin directory by issuing the cd command.
